Thirty RA patients fulfilling the 2010 ACR/EULAR criteria were recruited. ACPA positive patients were compared to ACPA negative patients. Imaging was performed with a 3 T whole body scanner (VERIO; SIEMENS Healthcare) of the 2<sup>nd</sup> and 3<sup>rd</sup> MCP joint, using two surface coils to perform high-resolution imaging and to enable parallel imaging techniques.(2)T2 maps were obtained using a pixel-wise, mono-exponential, non-negative least-squares-fit analysis. Region-of-interest (ROI) analysis was performed dividing the cartilage into medial, central and lateral phalangeal (med, cent, lat P ) and metacarpal (MC) area. All results are provided as mean±standard deviation (SD). Statistical evaluation was performed by means of univariate ANOVA testing with random factors. A p-value <0.05 was considered statistically significant. The study protocol was approved by the local ethics commission and written informed consent was obtained from all patients.

## Results:

Fourteen ACPA positive (3 male/11 female) and 16 ACPA negative patients (6 male/10 female) were included. Mean age, sex distribution and disease duration were comparable (age:  $49.0 \pm 15.1$  years (ACPA+) vs.  $56.1 \pm 10.9$  years (ACPA-),  $t=1.494$ ,  $p=0.146$ ; sex distribution:  $\chi^2(1)=0.918$ ,  $p=0.338$ , disease duration:  $7.9 \pm 7.3$  years (ACPA+) vs.  $3.9 \pm 3.8$  years (ACPA-),  $U=69.0$ ,  $Z=-1.799$ ,  $p=0.072$ ).

T2 values were significantly higher in the majority of the ROIs in ACPA-positive RA patients compared to ACPA negative patients with a statistical significance in most of the ROIs. Details are provided in Table 1.

## Conclusion:

In our study we were able to demonstrate the feasibility of T2 mapping in MRI as a non-invasive tool for cartilage evaluation in MC joints in RA patients in a clinical setting. Interestingly, ACPA positive RA patients showed significantly increased T2 values compared to ACPA negative patients reflecting a more severe cartilage alteration despite comparable disease duration.

	ACPA pos.	ACPA neg.	p-value
<b>Demographic characteristics</b>			
N	14	16	
Male/Female N	3/11	6/10	0.338

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pulmonary hypertension (PH) is a disease entity characterized by elevated pulmonary artery pressure, which often results in right ventricular failure. As part of PH evaluation, anti-cyclic citrullinated protein antibody (ACPA) titers are intermittently checked. However, data regarding presence and clinical significance of elevated ACPA titers is unavailable.

**Methods:** A retrospective analysis of patients from 12/1/2006 to 12/31/2016 was completed at a single tertiary center. Patients with a diagnosis of PH, based on right heart catheterization and/or evaluation by a pulmonologist and consistent echocardiogram, in whom ACPA levels were obtained were included. Patients with RA and connective tissue disease (CTD), including SSc, SLE, MCTD, UCTD, PM, DM, Sjogren's disease, Overlap and antisynthetase syndrome were identified based on a clinical diagnosis by a rheumatologist. P values were computed using Fishers exact test.

**Results:** A total of 263 charts were reviewed; 106 patients were confirmed to have PH and had ACPA measured. Of these patients, 21 (19.8%) were ACPA positive and 85 (80.2%) were ACPA negative.

Of the 21 patients who were ACPA positive, 15 (71%) had a concomitant diagnosis of RA and PH; the diagnosis of RA preceded the diagnosis of PH in 7 patients (46.7%); followed by PH preceding the diagnosis of RA in 5 (33.3%); and a

concurrent diagnosis was made in 3 (20%).

Similarly, of 85 ACPA negative patients, a concomitant diagnosis of RA and PH was made in 7 (8.2%); the diagnosis of RA preceded the diagnosis of PH in 3 (42.8%); a concurrent diagnosis of PH and RA was seen in 3 (42.8%), followed by a diagnosis of PH preceding the diagnosis of RA in 1 (14.4%).

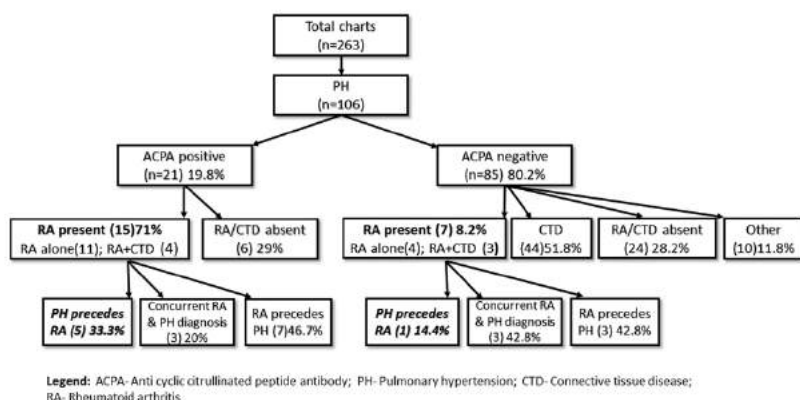

In the 15 patients who were ACPA positive and had RA, 5 (33%) also had a diagnosis of interstitial lung disease (ILD). Of those who were ACPA negative and had RA, 3 of 7 (42.9%) had ILD ( $p=1$ ).

Among ACPA positive patients (21) only 4 had a diagnosis of CTD along with RA as compared to the ACPA negative group of 85 patients of whom 44 (51.8%) had CTD alone and 3 had CTD with RA (47, 55.2%) ( $p=0.003$ ).

The ACPA positive patients (7/21, 33.3%) had similar mortality compared to the ACPA negative patients (26/85, 30%) and ACPA positivity was not associated with an increased risk of death ( $p=0.79$ ).

**Conclusion:** In a cohort of patients with PH who had ACPA levels obtained, 20% were positive. In majority of both ACPA positive and ACPA negative patients, the diagnosis of RA preceded or was made concurrently with the diagnosis of PH. However, the diagnosis of PH preceded that of RA in a relatively higher percentage of ACPA positive patients compared to ACPA negative patients. Interestingly, about 30% of ACPA positive patients with PH did not develop RA over the course of the follow-up. The link between positive ACPA and PH is not explained by ILD in isolation. Further data is required to understand the prognostic implications of the presence of ACPA in patients with PH.

Figure 1 : Flow chart of the cohort of patients with PH and their ACPA status

## Early Frailty Syndrome in Rheumatoid Arthritis: Screening Using the Frail Scale

**Elisa Trujillo**<sup>1,2</sup> and Maria del Mar Trujillo<sup>3</sup>, <sup>1</sup>Rheumatology, Hospital Universitario de Canarias, La Laguna.Tenerife, Spain, <sup>2</sup>Hospital Universitario de Canarias, Servicio de Reumatología, Tenerife, Spain, <sup>3</sup>Servicio de Evaluación y Planificación, Fundación Canaria de Investigación Sanitaria (FUNCANIS) Red de Investigación en Servicios de Salud en Enfermedades Crónicas (REDISSEC), Santa cruz de Tenerife, Spain

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Frailty is defined as a syndrome of physiological decline in late life, characterized by marked vulnerability to adverse health outcomes. Frail adults are less able to adapt to stressors such as acute illness or trauma than non-frail adults. This increased vulnerability contributes to increased risk for multiple adverse outcomes, including procedural complications, falls, institutionalization, disability, and death.

The frailty syndrome requires at least three of the following five characteristics: Unintentional weight loss, as evidenced by a loss of at least 10 lbs or greater than 5% of body weight in the prior year, muscle weakness, as measured by reduced grip strength in the lowest 20% at baseline, adjusted for gender and BMI, physical slowness, based on measured time to walk a distance of 15 ft, poor endurance, as indicated by self-reported exhaustion and low physical activity, as scored using a standardized assessment questionnaire.

Rheumatoid arthritis (RA) is a chronic disabling disease, which leads to functional limitations and diminishes health-related quality of life. The presence of comorbidity and polypharmacy are both related to RA severity.

The aim of this study was to assess the prevalence of frailty in patients with RA using de Frail Scale.

**Methods:** We studied patients with RA (ACR criteria) that were seen at the outpatient clinic of the Rheumatology Service of a third level hospital. We applied the Frail Scale and registered data (demographic and diseased related data) using a cross-sectional, observational, and descriptive study design.

Frail scale: Based on five items, reflecting performance, selfreports and common co-morbidities (*Morley JE et al., J Nutr Health Aging. 2012;16(7):601-8*).

### FRAIL SCALE

Did you feel worn out? or Did you feel tired?

Ability to climb one flight of stairs

Ability to walk 100 m

Self-report of >5% weight loss

≤5 of: dementia; heart Disease; depression; arthritis; asthma;bronchitis/ emphysema; diabetes; hypertension; osteoporosis; stroke.

**Results:** 231 consecutive RA patients were included, 83.2 %) were female. Mean age was 55.4 years and mean disease duration was 11.4 years.

Mean number of comorbidities was 1.48, with systemic hypertension and obesity as the most frequent ones (33.8 % and 26.4 %, respectively). Polypharmacy was found in 96.8 % and 64.7 % received more than five drugs simultaneously.

21.5 % met frailty criteria.

**Conclusion:** Prevalence of frailty in this study was high. Rheumatologists should make an early detection of signs of frailty.

Early detection of frailty can spur reforms to make routine care less hazardous, can focus on outcomes most relevant to patients and can aid in understanding effectiveness of health care interventions, including at the population level

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

TNF- $\alpha$  inhibitors increase the risk of emergence of active tuberculosis (TB). Screening rheumatic patients for latent TB is a necessity before initiation of biological treatment. Population is vaccinated with BCG in Turkey and BCG vaccination decreases the specificity of tuberculin skin test (TST). QuantiFERON-TB Gold In-Tube Assay (QFT-GIT) is an option for latent TB screening in a BCG-vaccinated population. The aim of this study was to assess the factors affecting QFT-GIT test results before biological treatment.

### **Methods:**

Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a single center biological registry since 2005. The study group is composed of patients registered in HUR-BIO. Only QFT-GIT is performed for latent TB screening before biological treatment since May 2011. Patients, who were screened with QFT-GIT for latent TB between May 2011 and August 2015, were included in the study. Demographical and clinical characteristics, QFT-GIT results of the patients were collected. Potential factors affecting QFT positivity were analyzed. Indeterminate results and diagnoses other than SpA and RA were excluded during the analysis.

### **Results:**

1335 (58.2% female) patients were recruited. The mean age was  $44.2 \pm 12.9$ . Diagnoses were followed, 62.6 % SpA, 32.4 % RA, 5.0 % others. 94.2 % of patients declared that they had had BCG vaccination. QFT-GIT results were followed; 79.0 % negative, 19.3 % positive, 1.7 % indeterminate. On univariate analyses male gender (53.9% vs. 38.8%,  $p < 0.001$ ), mean age ( $50.6 \pm 12.4$  vs.  $42.8 \pm 12.5$ ,  $p < 0.001$ ), ever-smoked (60.3% vs. 51.0%,  $p = 0.008$ ), diabetes mellitus (10.1% vs. 6.5%,  $p = 0.05$ ), educational level (high school, 47.3% vs. 57.5%,  $p = 0.003$ ), married patients (85.1%

vs. 77.1%,  $p=0.005$ ) and RA diagnosis (39.5% vs. 32.4%,  $p=0.032$ ) were significantly higher in QFT-GIT positive group compared to the negative group. There was no difference between positive and negative groups in terms of BCG vaccination, neither steroid nor other immunosuppressant use. On multivariate logistic analysis for QFT-GIT positivity, age  $\geq 45$  years and male gender were identified as independent factors with adjusted odd ratios of respectively 3.91 (95% CI 2.71-5.63,  $p<0.001$ ) and 2.62 (95% CI 1.83-3.75,  $p<0.001$ ).

### Conclusion:

The risk of QFT-GIT positivity increases with male gender and older age among rheumatic patients. The fact that males participate social life more actively in Turkey and the increased possibility of encountering tuberculosis bacillus with age can explain this situation. The use of steroids, other immunosuppressive drugs and BCG status in the rheumatic patient group does not affect QFT-GIT results.

## Serious Infection Risk in Patients with Rheumatoid Arthritis Compared to Patients with Non-Inflammatory Rheumatic Diseases: A US National Cohort Study

**Bella Y. Mehta**<sup>1</sup>, Sofia Pedro<sup>2</sup>, Gulsen Ozen<sup>3</sup> and Kaleb Michaud<sup>4</sup>, <sup>1</sup>Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, <sup>2</sup>National Data Bank for Rheumatic Diseases, Wichita, KS, <sup>3</sup>Rheumatology, Marmara University, School of Medicine, Rheumatology, Istanbul, Turkey, <sup>4</sup>University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Serious infections (SI) in patients with rheumatoid arthritis (RA) are a perpetual concern. We compared the risk by first and recurrent SIs in patients with RA compared to those with non-inflammatory rheumatic diseases (NIRD) in a real-world setting.

**Methods:** Participants had RA or NIRD from 1998 through 2016 in the National Data Bank for Rheumatic Diseases (NDB). NIRD included diagnoses such as osteoarthritis, back pain syndromes, tendonitis, etc; this comparator group helps minimize selection and reporting bias. SIs were defined as those requiring hospitalization or intravenous antibiotics, or leading to death. All SIs were described by etiology and location and were additionally categorized as opportunistic or herpes zoster when they occur. Survival analysis methods (Cox regression, time to first infection using time-varying covariates and Andersen-Gill multiple failures model) were applied, both in a univariate and multivariable manner. Confounders included demographics, comorbidities, disease severity measures and glucocorticoid (GC) use.

**Results:** There were 20,361 RA and 6,176 NIRD patients who contributed to 81,499 and 20,665 patient-years of exposure, having had 1,643 (7.9%) and 281 (4.5%) SIs, respectively. A higher proportion of RA patients with SI were younger, had worse HAQ scores, lower BMI, and a higher frequency of GC use and smoking compared to NIRD patients (*Table 1*). The most frequent SIs by etiology were bacterial and by location was respiratory in both groups. The incidence rate ratios (IRR) of the first and recurrent SIs for RA vs. NIRD were similar (1.5 [1.3 -1.7]). The IRRs for opportunistic infections and herpes zoster ranged between 2.2 - 3.3. The multivariable analysis showed a significant SI risk increase in RA patients compared to NIRD (HR 1.32 [1.15-1.52]). By etiology, the risk of bacterial infections was significantly higher in patients with RA than NIRD. Respiratory, bloodstream infections with sepsis, skin, bone and joint infections were also significantly increased in RA (*Table 2*).

**Conclusion:** The risk of SIs, particularly bacterial, respiratory, blood stream, skin and joint infections is increased in RA patients compared to NIRD patients. The increased risk could be explained by immune dysregulation caused by the disease itself, comorbid conditions or medications. A limitation of this study is that there was a significant proportion of SIs that were not categorized by type or location in medical records. Further studies collecting detailed SI information and the impact of medications would be needed to accurately describe the risk of SIs in RA.

**Table 1. Mean (SD) baseline characteristics of all RA and NIRD patients and by serious infections**

## In-Hospital Risk of Asthma in Patients with Rheumatoid Arthritis: A Cross-Sectional Nationwide Analysis

**Yiming Luo**<sup>1</sup>, Jiehui Xu<sup>2</sup>, Yumeng Wen<sup>1</sup>, Alvaro Ramos-Rodriguez<sup>3</sup>, Changchuan Jiang<sup>1</sup>, Shuyang Fang<sup>1</sup>, Mustafa Kagalwalla<sup>1</sup> and Neha Ohri<sup>4</sup>, <sup>1</sup>Department of Medicine, Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY, <sup>2</sup>Department of Biostatistics, Mailman School of Public Health, Columbia University Medical Center, New York, NY, <sup>3</sup>Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY, <sup>4</sup>Division of Rheumatology, Department of Medicine, Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis (RA) and asthma are both chronic inflammatory disorders. Lung pathology is a well-known extra-articular manifestation of RA and previous studies have shown an increased risk of asthma in patients with RA. Few studies have addressed the effects of RA on asthma exacerbations. We sought to explore the association of different asthma subtypes and asthma exacerbations in hospitalized adult patients with RA.

### **Methods:**

We conducted a cross-sectional study using data from National Inpatient Sample (NIS) for the year of 2014. Diagnosis for asthma, subtypes of asthma (i.e. allergic asthma, non-allergic asthma, exercise-induced bronchospasm and cough variant asthma) and rheumatoid arthritis were identified using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. STATA software package was used for statistical analyses. Multivariate logistic regression models were created to adjust for potential confounders such as age, gender, race, insurance type, current tobacco abuse and obesity. Patients younger than 18 years old were excluded from the study. For asthma exacerbations, we also studied exacerbations related to acute respiratory infections (ARI) and status asthmaticus.

### **Results:**

A total of 102,805 hospitalizations with a diagnosis of RA and 2,331,616 hospitalizations with a diagnosis of asthma were included in our study. Compared those without RA, asthma patients with RA are more likely to be older (mean age 63.1 vs 55.0), more female (85.8% vs 69.6%), more Caucasian and less African American (68.4% and 17.8% vs 62.8% and 21.6%). The adjusted OR for all types of asthma and RA was 1.52 (95% CI 1.49 - 1.56,  $p < 0.001$ ). For asthma subtypes, the adjusted OR was statistically significant only for allergic asthma (OR 1.43, 95% CI 1.23 - 1.66,  $p < 0.001$ ). There was no difference for non-allergic asthma (OR 1.42, 95% CI 0.84 - 2.42,  $p=0.190$ ), exercise-induced bronchospasm (OR 0.91, 95% CI 0.51 - 1.60,  $p = 0.732$ ), and cough-variant asthma (OR 0.89, 95% CI 0.43 - 1.86,  $p=0.766$ ) in hospitalized patients with RA. For asthma exacerbations, RA was associated with a higher risk of overall exacerbations (OR 1.26, 95% CI 1.21 - 1.33  $p < 0.001$ ), including both ARI-related exacerbations (OR 1.36, 95% CI 1.17 - 1.57,  $p < 0.001$ ) and non-ARI related exacerbations (OR 1.21 95% CI 1.11 - 1.31,  $p < 0.001$ ). There was no difference for status asthmaticus (OR 1.17, 95% CI 0.92 - 1.48,  $p=0.191$ ) in patients with RA.

### **Conclusion:**

Our study is consistent with previous studies that RA is associated with a higher risk of asthma in hospitalized adult population. However, our subgroup analysis showed that RA is only associated with allergic subtype of asthma, which may imply complex cross-link between Th1 and Th2 type autoimmunity. Furthermore, RA is associated with higher risk of both ARI and non-ARI related asthma exacerbations, despite that RA patients are more likely to take oral steroid, which is also a Global Initiative for Asthma (GINA) guideline recommended Step 5 asthma control medication. It suggests that increased infection risk secondary to immunosuppressive medications and systemic inflammation due to RA may both play a role in the pathophysiology of asthma exacerbation.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung disease (ILD) is the most common extra-articular manifestation in Rheumatoid Arthritis (RA) generating higher mortality in these patients. The objective is to describe the mortality rate in a cohort of Rheumatoid Arthritis patients (RA) with Interstitial lung disease (ILD) over time, and to assess the influence of the ILD types on mortality risk.

**Methods:** The design was a longitudinal prospective study. A cohort of RA patients diagnosed of ILD since February 2007 until June 2017 were recruited and followed up in a multidisciplinary ILD, carried by a pneumologist and a rheumatologist in a Tertiary Hospital in Madrid, Spain. The main variable was death. Covariables: a) sociodemographic (age, sex), b) clinical (basal comorbidities, duration of RA disease, smoke, ILD type (non specific interstitial pneumonia [NSIP]; usual interstitial pneumonia [UIP]); c) pulmonary function tests (PTF ); d) laboratory tests (ESR, CRP, Rheumatoid factor) and therapy (concomitant corticoids, DMARDs and BA). Survival techniques were used to estimate the mortality rate (MR) in our cohort, expressed per 100 patient-years with their respective confidence interval [95 % CI]. They were follow-up until lost of follow-up, death or end of the study. Multivariable Cox proportional hazards model were run to evaluate the influence of ILD types on mortality.

**Results:** We included 37 patients, 67% were women with a mean lag time from RA diagnosis to ILD of 7.3±8 years and a mean age at diagnosis of ILD 69±9.6 years. 40% never smoked and the BMI was 27±4. Concomitant diseases were as follows: 62% hypertension, 13% cerebrovascular disease, 8% ischemic heart disease, 13% peripheral vascular disease 10% cancer, and 11% sleep apnea syndrome (SAS). Rheumatoid factor was positive in 92% of the patients, and the baseline ESR was 42± 22. Regarding the ILD type, 32% had NSIP and 65.6% had UIP. The mean values of PTF parameters were 102%±16.8 for FVC and 68%±16.2 for DLCO. There were 7 deaths per 123.96 person-years at risk in the total cohort. The prevalence of deaths was 19%, and the most of them were due to respiratory cause (72%). The mean survival was 7.6 years and the MR was estimated in 5.6 [2.7-11.8] per 100 patient-years. MR for men 9.6 [3.1-29.9] and for women was 4.3[1.6-11.5]. Concerning the ILD types, MR for UIP was 10.2 [4.5-22.6] and for NSIP 2.0 [0.2-14]. All death people were RF positive and 72% smokers. Controlling for age, gender and smoking habit, the HR of mortality in IUP compared to NSIP was 5.4 [1.3-24.3].

**Conclusion:** 19% of the patients died, up to 72% were smokers and all of them positive to RF. The mortality rate in RA patients with ILD was 5.6% patient-years, with a mean survival time from diagnosis of ILD of 7.6 years. It seems that the type of ILD influence on mortality, showing that UIP patients have a poorer prognosis independently of the age and the sex.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although it is generally accepted that peripheral neuropathy can occur in patients with rheumatoid arthritis (RA), most previous studies were conducted in RA patients with neurologic symptoms. We first evaluated the nerve conduction study (NCS) parameters of most distal sensory nerves of the lower extremities-namely the medial dorsal cutaneous (MDC), dorsal sural (DS), and medial plantar (MP) nerves as well as conventional nerves in RA patient, irrespective of neurologic symptoms.

**Methods:** Standard NCSs were performed on healthy controls (HC, n = 68), and RA group (n = 31). The bilateral NCS parameters of the MDC, DS, and MP nerves were investigated. The Toronto Clinical Scoring System (TCSS) was assessed.

**Results:** Age and BMI did not differ between the control and RA group. The mean TCSS scores of the RA and control groups were  $5.8 \pm 3.0$  and  $1.3 \pm 0.9$  respectively ( $p < 0.001$ ). Although there were differences in NCS values of conventionally studied nerves (sural, superficial peroneal, median, and tibial nerves) between the two groups, the mean values of RA patients were within normal ranges. Interestingly, the RA group showed significant NCS differences in MDC, DS and MP nerves compared with the control group ( $p < 0.001$ ). The NCS parameters of most distal sensory nerves in RA group were not within normal values (mean  $\pm$  2 standard deviation). TCSS of RA patients showed significant associations with NCS values of most distal sensory nerves (onset amplitude of MP, sensory nerve action potential [SNAP] of MDC, peak amplitude of DS) ( $p < 0.05$ ).

**Conclusion:** RA patients, despite of absence of evident neuropathic pain in most cases, showed axonal damage predominantly in most distal sensory large fiber. In patients with vague or equivocal neuropathic pain who showed normal findings on their routine NCS should be considered to evaluate whether they have early NCS changes in the most distal sensory large fiber such as MDC, DS and MP nerves.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Patients with RA have a two to four-fold increased risk of developing infections than the general population. This is due to both, the disease itself and the therapy used to treat it. For this reason, the use of influenza and pneumococcal vaccines is recommended in all patients with AR, as well as shingles vaccine in patients older than 50 years. However, several studies have demonstrated a low prevalence of immunization and adherence to current recommendations by rheumatologists.

Our objective was to determine the knowledge and adherence to the current immunization recommendations in patients with RA by members of the Mexican College of Rheumatology (MCR) and to identify barriers in the application of this recommendations in patients with RA.

## Methods:

A cross-sectional study was conducted through a survey sent by email to 577 rheumatologists from Mexico through the MCR database in January 2017.

The questions of this survey were aimed at evaluating the knowledge and adherence to current recommendations on vaccination in RA and to the clinical practice of rheumatologists in relation to these.

## Results:

We obtained 122 responses, representing 21.14% of the 577 rheumatologists, of which 38.2% (n=47) were private practitioners, 19.67% (n=24) public practitioners and 41.8% (n=51) were both private and public practitioners.

Of those surveyed, 14.05% considered the responsibility for the update of vaccination schedules belonged to the family or general practitioner, 4.96% to the internist and 80.99% to the rheumatologist.

Moreover, 43.44% reported they did not collect the immunization history in the clinical record.

Also, 75.86% answered they did not recommend vaccines if the patient had contraindications for it, 20.69% did not recommend them because they gave priority to other aspects of the office visit and 3.45% responded they did not recommend it because of lack of time.

In terms of influenza vaccine, 9.84% reported recommending it to 0-25% of their patients, 12.3% to 26-50%, 27.05% to 51-75% and 50.82% to 76-100%. For pneumococcal vaccine, 19.67% reported recommending it to 0-25% of their patients, 20.49% to 26-50%, 23.77% to 51-75% and 36.07% to 76-100%.

Regarding the time of administration for influenza and pneumococcal vaccine, 13.11% administered it before starting treatment with DMARD. 22.13% administered it only before starting treatment with a biologic or tofacitinib, and 54.1% administered it indistinctly, before or during treatment with DMARD, tofacitinib or biologics and 10.66% responded they did not administer it routinely.

For Herpes Zoster vaccine, 69.67% answered they did not routinely recommend it to their patients. Only 6.56% recommended it before or during treatment with conventional DMARD and 23.77% recommended it before starting treatment with tofacitinib or biologics.

### **Conclusion:**

According to the data obtained in this study, we conclude there is not yet adequate information on the importance of vaccination in patients with RA. It also shows us that the degree of adherence to the vaccine recommendations as well as the safety knowledge and optimal timing of vaccine administration are low in Mexico, this is most notable in Herpes Zoster immunization.

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Patients with rheumatoid arthritis (RA) are at an increased risk of some serious vaccine-preventable infections, like Pneumococcal infections. Since 2013, French vaccine recommendations committee considered as the best strategy for immune-suppressed patients, previously vaccinated by one dose of 23-valent pneumococcal polysaccharide vaccine (PPV23), a prime-boost revaccination strategy three years later. We evaluated in a pilot study the immunogenicity of the prime-boost revaccination strategy using PCV13 vaccination followed by PPV23 vaccination 8 weeks later in 24

patients with Rheumatoid Arthritis (RA) treated by Methotrexate (MTX) and anti-TNF. The persistence of a protective immunity for two years after revaccination was also evaluated in our population.

### Methods:

Twenty-four patients with RA treated by MTX + anti-TNF were included after having received one dose of PCV13 (Prevenar13; Pfizer) followed two months later by one dose of PPV23 (Pneumovax®, Merck) during routine-visits according to recommendations. All patients received a previous vaccination by the PPV23, at least three years before enrolment. Blood samples were obtained at baseline, 4 months, 12 months and 24 months following PCV13 immunization. Concentrations of IgG specific for 10 serotypes (7 common to both vaccines: 4, 6B, 9V, 14, 18C, 19F and 23F, and 3 uncommon, included only in the PPV23: 10A, 12F and 15B) were measured by standardized ELISA. Responders were defined as at least an IgG-concentration two fold increased from baseline by ELISA. An IgG-concentration  $\geq 1.3\mu\text{g/ml}$  was used to define long-term protection and Protected patients were those who fulfilled this criteria for at least 70% of the serotypes. Primary endpoint was the proportion of responders in ELISA for 70% of serotypes at four months.

### Results:

Long term follow-up of antibody response to the vaccine shows a more severe decrease in the percentage of responders one and two years post immunization for the 7 common serotypes (from 33% responders at four months to 4% at 12 months and 3% at 24 months post immunization) compared to the 3 uncommon (from 47% responders at 4 months to 24% at 12 months and 23% at 24 months post immunization). As all patients received at least 3 years before enrolment one dose of PPV23, we found 33% (7 common serotypes) and 24% (3 uncommon serotypes) of patients considered protected at baseline. Similar percentages of protection were found at 4 months (63% vs. 65%), 12 months (54% vs. 59%) and 24 months (50% vs. 77%) for the 7 common and 3 uncommon serotypes.

### Conclusion:

If the percentage of protection is quite equivalent for the seven common and the three uncommon serotypes, the more intense drop in antibody response for the seven common serotype compared to the three uncommon may suggest a negative impact of the PPV23 vaccine on the PCV13 response. The prime-boost strategy is recommended because of the poor immunogenicity of both type of pneumococcal vaccine in this case. Our results clearly question the advantage of the prime-boost strategy versus PPV23 or PCV13 alone as it highlights the possible hyporesponse induced by PPV23 against the immune response elicited by the primo-injection of the PCV13 vaccine.

## Histopathological Change Caused By Biological Treatment in Rheumatoid Arthritis Synovial Tissue

**Ayako Kubota**, Toru Suguro, Masayuki Sekiguchi and Kazuaki Tsuchiya, Toho University Omori Medical Center, Tokyo, Japan

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Multiple studies addressing the effects of biologics on the synovial tissue in rheumatoid arthritis (RA) patients have been reported. There are, however, few studies comparing histopathological changes in the synovial tissue in the same RA patients between before and after biologics treatment. We examined biologics impacts on RA synovial tissues based on pathological findings in them collected during surgeries for the same patient before and after biological drug usage.

### **Methods:**

Synovial tissues were collected from 28 RA joints before and after biologics. The average age and disease duration of the study subjects were 63.8 and 20.9, respectively. Histopathological changes in the synovial tissues were compared based on Rooney's score, and presence or absence of fibrinoid degeneration, proliferation of villi and plasma cell infiltration in the subsynovial tissue. We examined correlation between pathological findings in RA synovium and disease activity under biologics. Disease activity was assessed by CDAI. Etanercept, Infliximab, Tocilizumab, Adalimumab and Abatacept was used as biological drug for 16, 5, 3, 2 and 2 joints respectively.

### **Results:**

Rooney score between before and after biological drug usage improved from 28.4 to 12.3 showing significant difference. Significant improvement in Rooney score was observed in all items. Fibrinoid degeneration was observed in 25 cases (89.3%) and 5 cases (17.9%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. Proliferation of villi was observed in 27 cases (96.4%) and 10 (35.7%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. Plasma cell was observed in 24 cases (85.7%) and 15 (53.6%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. After biologics treatment, Rooney's scores in the remission, low disease activity and moderate disease activity were 9.0, 10.2 and 15.6, respectively, showing a statistically significant difference. In addition, the moderate disease activity had significantly higher scores in perivascular lymphocytic infiltration, lymphoid follicle and lymphocyte infiltration compared to the remission and low disease activity.

### **Conclusion:**

The study results demonstrated that biologics treatment significantly ameliorated inflammatory changes in the synovial lining layers and sublining layers. In addition, the results suggested that histopathological findings in the subsynovial tissue reflected disease activity.

## **Occult Coronary Plaque Presence and Burden Predict Cardiovascular Events in Patients with Rheumatoid Arthritis**

**George Karpouzas**<sup>1</sup>, Joel Estis<sup>2</sup>, John Todd<sup>2</sup> and Matthew Budoff<sup>3</sup>, <sup>1</sup>Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, <sup>2</sup>Singulex, Alameda, California, Alameda, CA, <sup>3</sup>Cardiology, Harbor-UCLA Medical Center, Torrance, CA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

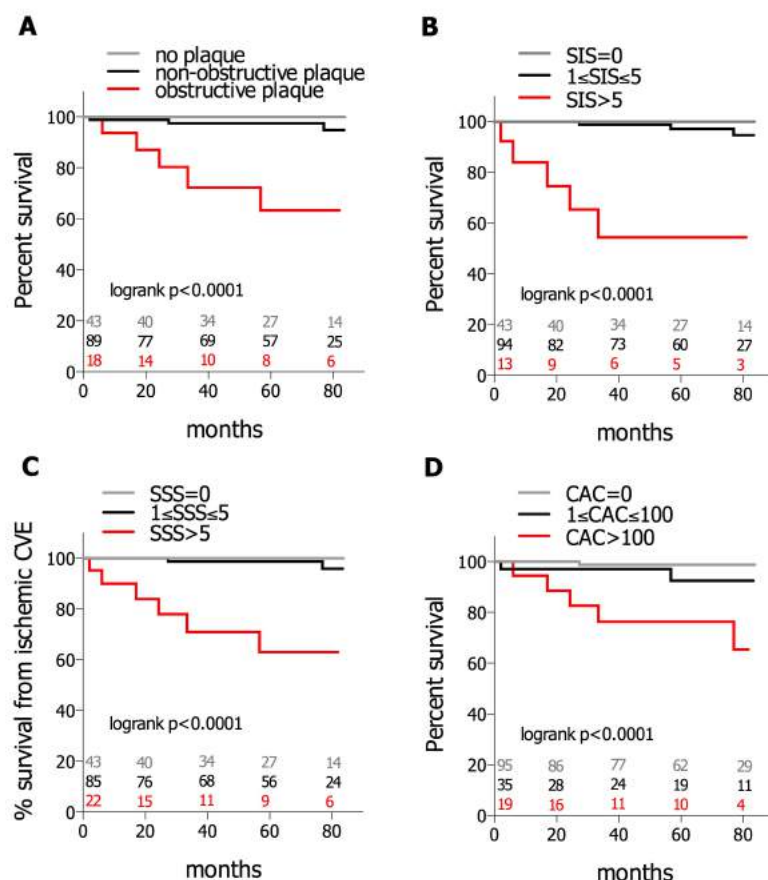

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with Rheumatoid Arthritis (RA) experience higher cardiovascular (CV) morbidity compared to controls. Coronary computed tomography angiography (CCTA) accurately detects plaque presence, burden and composition and independently predicts short and long-term incident cardiac events in general patients with unknown coronary artery disease (CAD). We evaluated, for the first time, the long-term prognostic role of CCTA in a cohort of established RA patients without symptoms or known cardiovascular disease.

**Methods:** One hundred and fifty participants from a single center underwent a baseline 64-slice CCTA for plaque evaluation between 3/2010- 3/2011 and followed for a mean of  $60 \pm 26$  months. Patients were classified based on presence of normal coronaries, non-obstructive ( $<50\%$ ) and obstructive ( $>50\%$ ) lesions. Atherosclerosis burden was further evaluated with coronary plaque scores: SIS or segment involvement score, reflected number of segments with at least 1 plaque; SSS or segment stenosis score represented the overall plaque extent. The composite rates of ischemic CV events [cardiac death, non-fatal myocardial infarction (MI), ischemic stroke, peripheral arterial ischemia] were the study end-points. Cox regression analysis evaluated associations between CCTA parameters and outcomes; hazards ratios were generated in both raw and adjusted models. Event-free survival was assessed with Kaplan-Meier analysis and curves were compared using the log-rank test.

**Results:** Eleven patients suffered incident CV events (1.54/100PY): 8 were ischemic, including 1 cardiac death, 3 MI, 2 strokes, and 2 peripheral arterial ischemic events requiring emergent revascularizations; the 3 non-ischemic events were new onset, hospitalized, systolic heart failure. No ischemic events occurred in patients with normal coronaries (Figure 1); by contrast event-free survival was 97.5% and 63.3% in patients with non-obstructive and obstructive CAD respectively at 60 months ( $p < 0.0001$ ). Obstructive CAD was an independent predictor of ischemic events ( $HR = 16.4$ ,  $p = 0.003$ , Table 1). Plaque burden was equally predictive; event-free survival was 97.1% vs. 54.4% in those with  $SIS = <5$  vs.  $SIS > 5$  and 98.6% vs. 63% in patients with  $SSS = <5$  vs.  $SSS > 5$ , (both  $p < 0.0001$ ); 95% with  $CAC = <100$  vs. 76% with  $CAC > 100$  experienced no events at 60 months ( $p < 0.0001$ , Figure 1).

**Conclusion:** CCTA provided prognostic information in RA patients without symptoms or known CV disease; it showed excellent long-term prognosis when there was no evidence of atherosclerosis, and allowed risk stratification when CAD was present.

**Figure 1.** Kaplan-Meier survival curves for ischemic cardiovascular events based on presence and burden of atherosclerotic disease. **A:** classification based on normal coronary arteries, non-obstructive (<50%), and obstructive (>50%) atherosclerotic lesions. **B:** Classification based on segment involvement score (SIS). **C:** Classification based on SSS (segment stenosis score). **D:** Classification based on CAC (coronary artery calcium score).

**Table 1.** Prediction of long-term ischemic CV Event risk by CCTA

# Tissue-Engineered Human Skeletal Muscle Model of Rheumatoid Arthritis

Catherine E. Oliver<sup>1</sup>, Brittany N. Davis<sup>1</sup>, James Hong<sup>1</sup>, Kim M. Huffman<sup>2</sup> and George A. Truskey<sup>3</sup>, <sup>1</sup>Duke University, Durham, NC, <sup>2</sup>School of Medicine, Division of Rheumatology, Immunology and Molecular Physiology and Durham VA Medical Center, Duke University, Durham, NC, <sup>3</sup>BME, Duke University, Durham, NC

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In rheumatoid arthritis (RA) reduced muscle function clearly contributes to disability. Due to a lack of accurate *in vitro* RA models, the underlying mechanisms are not well understood. Moreover, current animal and cell culture systems are imperfect models of human disease, including RA, and do not recapitulate biologic and physiologic features of human skeletal muscle. Using engineered electrically responsive, contractile human skeletal muscle constructs (myobundles), we have established an *in vitro* 3D disease model of RA muscle to test the hypothesis that (1) myobundles derived from cells of RA patients show reduced capacity for repair and differentiation and reduced force production and (2) the overall decrement in function is due to select myokine (e.g. myostatin) and cytokine production.

**Methods:** Myobundles were fabricated using *vastus lateralis* skeletal muscle cells from RA patients and healthy controls. To block myostatin and subsequent downstream signaling events, LDN-193189 was added at the transition from myoblasts to myotubes, after myobundle fabrication. After a 1- to 2-week differentiation period, tissue function was assessed by measuring myobundle twitch and tetanic contraction using a custom force measurement system. Muscle maturation was assessed by immunostaining myobundles for maturation markers, myosin heavy chain (MHC) or sarcomeric  $\alpha$ -actinin (SAA). 2D studies were also performed with RA cells and healthy controls to quantify myoblast purity and percent nuclei per SAA-positive fiber. Unpaired t-tests were used to compare differences.

**Results:** Compared to healthy controls (n=4 donors) at 2-weeks differentiation, myobundles generated from RA *vastus lateralis* cells (n=3 donors) exhibited reduced twitch and tetanus forces and myosin heavy chain staining. Treatment with 0.05  $\mu$ M LDN-19318979 in 2D culture improved maturation (RA <sub>$\Delta$</sub> =47.5 $\pm$ 1.5% % nuclei/SAA+ fiber versus Control <sub>$\Delta$</sub> =20.3 $\pm$ 2.0%; Figure 1). Ten-day treatment of myobundles with 0.05  $\mu$ M LDN-19318979 increased force production in RA myobundles (n=3 donors), but not in controls (n=3 donors).

**Conclusion:** Compared to healthy controls, RA myobundles exhibit reduced force production and MHC or SAA staining, indicative of reduced maturity and fiber formation. Treatment with LDN-19318979 increased RA myoblast fusion and myofiber formation in 2D and force production in 3D. RA muscle dysfunction may result from myostatin-mediated alterations in muscle remodeling.

**Figure 1.** Percent nuclei per SAA+ fiber in a healthy (n=3) versus RA donor (n=4). \*\*p<0.01 statistically different than control. Mean±SEM.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

To analyze the effect of demographic and clinical related characteristics of rheumatoid arthritis (RA) patients in the immunomodulatory effects of mesenchymal stem cells (MSCs). The proportion of CD69+, CD25+, and regulatory T cells (Treg) among CD4+ peripheral blood mononuclear cells (PBMCs) was used as surrogate markers of immunomodulation.

## Methods:

**RA patients:** Consecutive patients diagnosed with RA according to the 2010 ACR/EULAR criteria attending from the *Hospital Clinico San Carlos* Rheumatology Outpatient Clinic. Demographic and clinical data was collected, including a Disease Activity Score of 28 joints (DAS28). PBMCs were isolated from fasting venous blood using density gradient centrifugation.

**MSCs donors:** MSCs were obtained from bone marrow aspirates from the iliac crests of 6 healthy donors. Cells in the fourth passage were used in the experiments.

**Co-cultures:** PBMCs were cultured alone or with MSCs (1 MSC:10 PBMCs) for 24h, 72h and 6 days. PBMCs were stimulated using CD3/CD28 coated beads (1 bead:4 PBMCs).

**T cell cytometry:** PBMCs were stained with anti CD4, anti CD25, anti CD69, and anti CD127 antibodies. The lymphocyte population was identified by side scatter/forward scatter. Treg cells were gated on the basis of CD4 expression, in combination with higher (bright) expression of CD25 and low/negative expression of CD127.

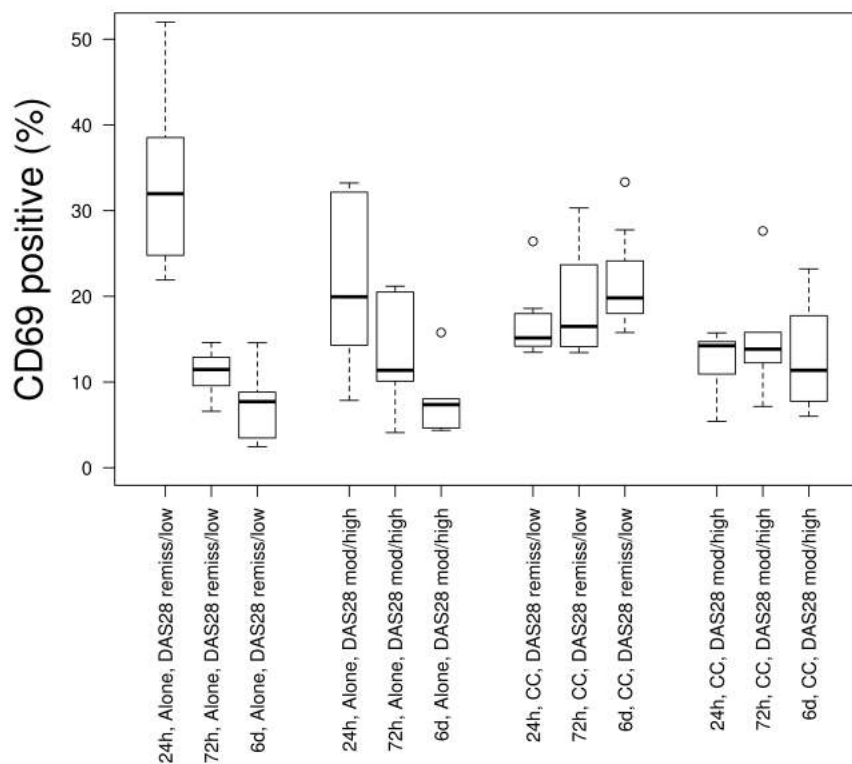

**Statistical analysis:** Influence of co-culture with MSCs and duration of culture in surface markers expression and Treg proportion was analyzed using repeated measures ANOVA (nested by RA patient) with the “*lmerTest*” R package. Coculture with BM-MSCs (yes/no) and time of culture (24h, 72h, 6 days) were the within-subject variables. An interaction between both was introduced in the analysis. Gender, age at inclusion, presence of RF, presence of ACPA, disease activity (DAS28-CRP: remission/low vs. moderate/high disease activity), current use of methotrexate, and current use of biological therapies were between subject variables. Triple interactions (adjusted by the BM-MSCs donor) among the within-subject variables and each between-subject variables were performed. P-values were adjusted using the FDR correction.

## Results:

15 RA patients were collected. Interactions between co-culture and time were significant for CD69+, CD25+ and Treg proportion ( $p < 0.0001$  for each term). Only disease activity showed a significant interaction with time and co-culture in their influence in the proportion of CD69+ cells ( $p = 0.003$ ; Figure 1). In the post-hoc comparisons, patients in remission/low disease activity showed a higher expression of CD69 after 6 days of co-culture ( $p = 0.017$ ).

## Conclusion:

The degree of disease activity could influence the effect of MSCs. In patients with lower disease activity could exert a greater immunomodulatory effect.

## Mass Cytometry Analysis of CD4+ T Cells in Patients with Rheumatoid Arthritis

**Laura Su**<sup>1</sup>, **Daniel del Alcazar**<sup>2</sup> and **Adam Marc**<sup>2</sup>, <sup>1</sup>University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Medicine, University of Pennsylvania, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CD4+ T cells play a key role in the initiation and progression of RA. Past studies have identified impaired function and regulation of several CD4+ T cell lineages in RA patients. However, how diverse cellular subsets are maintained has not been comprehensively analyzed. Here, we utilized mass cytometry to

simultaneously assay expression of 36 markers to examine high-dimensional complexity of CD4<sup>+</sup> T cells in RA patients.

**Methods:** Cryopreserved cells from 10 RA patients and 7 healthy controls were thawed, washed, and stimulated with 5ng/ml of PMA and 50ng/ml ionomycin in the presence of 2mM Monensin and 5ug/ml Brefeldin A at 37°C for 5 hours. After stimulation, cells were washed and incubated in 1uM cisplatin for 5 min, followed by staining with surface antibody cocktail for 30 min at room temperature. A panel of 36 metal conjugated antibodies was generated using the X8 Maxpar kit. For intracellular staining, cells were permeabilized and fixed using Foxp3 staining buffer set and incubated with the intracellular antibody cocktail for 1 hr at room temperature. After staining, cells were washed then resuspended in 2% paraformaldehyde with 125nM iridium intercalator for an overnight incubation at 4°C. The next day, cells were washed and resuspended in PBS containing normalization beads before acquisition on CyTOF 2.

**Results:** Our data show a prominent expansion of CD57<sup>+</sup> CD4<sup>+</sup> T cells in RA patients. CD57<sup>+</sup> T cells express cytotoxic granules, perforin, granzymes A and B, and have been previously associated with more active and erosive disease in RA. Interestingly, we identified three distinct subsets of CD57<sup>+</sup> CD4<sup>+</sup> T cells and only those that co-express high levels of IFN- $\gamma$  and TNF- $\alpha$  are increased in RA patients. In addition, patient derived samples showed a decrease in several populations of cytokine negative CD45RA<sup>+</sup> naïve T cells.

**Conclusion:** Pilot analysis on a small numbers of samples from RA patients and healthy controls revealed cellular complexity in CD4<sup>+</sup> T cells and suggested unique changes in RA patients. Extension of this analysis to a large cohort of RA patients with well annotated disease characteristics may uncover novel biomarkers for detection of early disease and provide new insights into the pathogenesis of RA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease arising from a breakdown of peripheral tolerance, which leads to aberrant Th1- or Th17-driven immune reaction. Although aberrant Calcium/calmodulin-dependent protein kinase IV (CaMK4) activation has been implicated in the development of Th17 driven autoimmune diseases, the roles of CaMK4 activation in CD4<sup>+</sup> T cells in the development and the pathogenesis of RA remain to be elucidated.

## Objectives:

We sought to determine the significance of CaMK4 in the pathological condition of RA and to clarify whether the expression of CaMK4 can be a prognostic predictor for the progression of RA in daily practice.

## Methods:

We treated collagen-induced arthritis (CIA) mice with KN-93, an inhibitor of CaMK4 and evaluated the clinical score, in vivo micro-computed tomography (*f*Ê-CT), and histological assessment. We examined the gene expression of *Camk4* in CD4<sup>+</sup> T cells from healthy controls (HC: n=20) and patients with active RA (n=21; median of DAS-ESR:5.14). We performed a multiple logistic regression analysis to explore the factors to predict poor response to treatment at 6 months.

## Results:

Treatment of CIA mice with KN-93 results in a significant reduction of the clinical score of CIA severity and this is accompanied by decreased joint destruction evaluated by *f*Ê-CT and histology analysis. The expression of *Camk4* mRNA in CD4<sup>+</sup> T cells displayed significantly higher in RA patients than HC. Of note, the multiple logistic regression analysis revealed that the independent variables to predict poor response to treatment were the expression level of *Camk4* mRNA in CD4 positive T cells from RA patients at baseline (OR= 24.7, 95%CI 2.76-634) and DAS-ESR at baseline (1-unit increase OR=4.40, 95%CI 1.67-18.5).

## Conclusion:

Our results indicate that CaMK4 expression associates with RA development and its inhibition represents a novel therapeutic strategy for the treatment of RA.

## Rheumatoid Arthritis (RA) Synovial Fluid Treg Cells Secrete IL-17 and at the Same Time Are Potent Suppressors of Tresp Cell Proliferation, TNF- $\alpha$ and Interferon $\gamma$ Production

Lorena Valdeolivas-De Opazo<sup>1</sup>, Paula Fortea-Gordo<sup>1</sup>, Marta Benito-Miguel<sup>1,2</sup>, Alejandro Villalba<sup>1</sup>, Gema Bonilla<sup>1</sup>, Diana Peiteado<sup>1</sup>, Alejandro Balsa<sup>1</sup>, Pilar Aguado<sup>1</sup>, Paloma Sanchez-Mateos<sup>3</sup>, Amaya Puig-Kröger<sup>4</sup>, Emilio Martín-Mola<sup>1</sup> and Maria Eugenia Miranda-Carus<sup>1</sup>, <sup>1</sup>Rheumatology, Hospital La Paz-IdiPAZ, Madrid, Spain, <sup>2</sup>Biochemistry, Centro de Ciencias de la Salud San Rafael. ### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IL-17-expressing FoxP3 regulatory T cells have been described, and their suppressive capacity has been questioned. An inflammatory environment seems to favor IL-17 secretion by regulatory CD4+CD25+FoxP3+ T cells. Therefore, our objective was to assess the suppressive function and IL-17 producing capacity of CD4+CD25+CD127-FoxP3+ T cells in the synovial fluid of RA patients (RASFd).

### Methods:

Synovial fluid was drawn from 35 patients with established RA who were receiving methotrexate and low-dose oral prednisone. The frequency of CD4+CD25+CD127-FoxP3+ T cells was assessed by flow cytometry. Total CD4+ T cells, CD4+CD25+CD127- T reg cells and CD4+CD25- Tresp cells were isolated by Ficoll-Hypaque gradient, followed by sorting. After isolation, cells were cultured for 5 days in flat-bottom 96-well plates coated with an anti-CD3 monoclonal antibody. Treg cell function was assessed using two different approaches: A. The regulatory function of natural proportions of Tregs was inferred by comparing the proliferative and cytokine responses of total CD4+ T cells (TCD4T) versus CD25+ depleted CD4+ T cells (CD4+CD25-T cells or Tresp cells); B. The per cell suppressor potency of Tregs was assessed in cocultures of isolated Tregs with Tresp, established at different Treg/Tresp ratios. Proliferation was determined by <sup>3</sup>Hthymidine incorporation and CFSE dilution; cytokine secretion was measured by ELISA of culture supernatants.

### Results:

A high proportion of CD4+CD25+CD127- T cells was present in RASFd (mean  $\pm$  SD, 21.1% $\pm$ 6.2), which is significantly higher than reported frequencies of this cell population in the peripheral blood of both RA and healthy subjects. These RASFd CD4+CD25+CD127- T cells expressed FoxP3 but did not express CD69. The proliferation rate, TNF $\alpha$  and IFN $\gamma$  secretion were significantly higher for isolated Tresp as compared with TCD4T cells, indicating that natural proportions of Treg cells present in the synovial fluid of RA are functionally suppressive. Surprisingly, TCD4T cells secreted higher amounts of IL-17 as compared with Tresp cells, although the difference did not reach statistical significance. On a per cell basis, RAPB Tregs were potent suppressors of Tresp proliferation, TNF $\alpha$  and IFN $\gamma$  but not of

IL-17 secretion; in fact IL-17 secretion did not decrease but was enhanced in the presence of increasing proportions of Treg cells. Isolated Treg cells did not proliferate or produce cytokines when cultured alone in anti-CD3 coated plates. However, in the presence of plate-bound anti-CD3 plus anti-CD28 and recombinant human IL-2, isolated Treg cells secreted significant amounts of IL-17 whereas no TNF $\alpha$  or IFN $\gamma$  could be detected in supernatants.

**Conclusion:** CD4+CD27+CD127- FoxP3+ Treg cells present in the synovial fluid of RA patients are potent suppressors of Tresp cell proliferation, TNF $\alpha$  and IFN $\gamma$  secretion, and at the same time produce significant amounts of IL-17.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

An atypical subgroup of patients with seropositive rheumatoid arthritis (RA) was identified with active disease (confirmed by Power Doppler ultrasound (PDUS)) but normal levels of the acute phase protein C-reactive protein (CRP). We questioned whether this presentation was associated with altered response to treatment, risking worse disease outcome. Our objective was to investigate whether we could exploit the immunological and clinical phenotype of this patient subgroup to propose a more appropriate treatment algorithm.

### **Methods:**

48 RA patients with active synovitis were recruited, defined by  $\geq 1$  joint with positive PDUS, 30 had normal (n)CRP ( $\leq 5$ mg/L) and 18 had high (h)CRP ( $> 5$ mg/L) levels. Peripheral blood mononuclear cells (PBMC), serum and detailed clinical data were collected. 20 age- and sex-matched healthy donors were also analyzed. Multiparameter flow cytometry was used to perform in-depth PBMC immunophenotyping.

## Results:

Pro-inflammatory cytokines IL-6, IL-1 $\beta$ , and TNF- $\alpha$  contribute to RA pathogenesis and are key in triggering CRP production. Despite normal measured CRP levels, all these cytokines were significantly elevated in both patient groups compared to HC ( $p < 0.001$ ). CRP, SAA and IL-6 all correlated positively with pro-inflammatory cytokines in hCRP patients but not nCRP patients. Conversely, pro-inflammatory cytokine levels positively correlated with markers of disease severity in nCRP patients only. Interestingly, nCRP patients were able to mount a CRP response to infection. Thus the results point to an altered disease mechanism in nCRP compared to hCRP patients. In-depth phenotyping identified unique immune signatures in both patient groups compared to HCs and when compared to each other.

Notably, nCRP patients had a significant increase in naïve regulatory T cells (Tregs) and in CD161<sup>+</sup> Tregs (known to correlate negatively with CRP levels and have increased suppressive capacity) compared to hCRP patients. Furthermore, Treg frequencies correlated significantly with markers of disease progression and serum lipids in the nCRP but not the hCRP patients suggesting that defects in Treg function and potentially lipid metabolism could play a role in disease pathogenesis in nCRP patients.

The immunological differences between the two groups were associated with an altered response to treatment. Disease activity was assessed  $\geq 1$  year post recruitment. In nCRP patients 50% still had active disease compared to only 10% in hCRP patients. Also, 50% of nCRP patients had treatment escalated to a biological (b)DMARD compared to only 10% of hCRP patients.

## Conclusion:

This study stratifies distinct patient subgroups using detailed, clinical, immunophenotyping and proteomic signatures. We have identified altered immunopathological mechanisms in nCRP patients which could translate to improved patient-specific therapies. Provisional analysis suggested that nCRP patients were less responsive to treatment with conventional DMARDS, needing escalation to biologics earlier in their disease.

## CD8-Positive Lymphocytes in Biopsy Specimens Predict Spontaneous Regression of Lymphoproliferative Disorders in Patients with Rheumatoid Arthritis Treated with Methotrexate

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) have a high risk of developing lymphoproliferative disorders (LPDs). LPDs that develop in patients treated with methotrexate (MTX) are known as MTX-associated LPDs (MTX-LPDs). We previously reported that MTX is an independent risk factor for LPD onset in Japanese patients with RA. The main characteristic of MTX-LPDs is that MTX withdrawal possibly results in spontaneous regression of the LPD. However, the predictive factors of spontaneous regression of MTX-LPDs remain unclear. Some reports have suggested that Epstein-Barr virus infection and increased peripheral lymphocytes after MTX discontinuation are related to spontaneous regression of MTX-LPDs. However, evidence of the relationships between these factors and spontaneous regression of MTX-LPDs is lacking. We investigated the predictive factors for spontaneous regression of MTX-LPDs in patients with RA.

**Methods:** We enrolled RA patients who developed MTX-LPDs in Kagawa Prefecture, Japan from June 2010 to March 2017. Patients were diagnosed according to the American College of Rheumatology 1987 classification criteria and treated with MTX. We divided the patients into those who were followed up after discontinuation of MTX alone (MTX withdrawal group) and those who underwent chemotherapy (CTx)  $\geq 1$  month after MTX discontinuation (CTx group). The following differences between the two groups were examined: 1) change in the peripheral lymphocyte count after MTX discontinuation, 2) subset of lymphocytes in a biopsy specimen from a lesion, and 3) histological findings of biopsied lesions using immunohistochemistry (IHC).

**Results:** We enrolled 45 patients with MTX-LPDs. The withdrawal group comprised 30 patients, and the CTx group comprised 15 patients. Between these two groups, 32 patients underwent analysis of the change in the peripheral lymphocyte count. Additionally, 22 patients (11 in the withdrawal group and 11 in the CTx group) underwent analysis of the subset of lymphocytes, and 12 (8 in the withdrawal group and 4 in the CTx group) underwent analysis of the IHC findings with a specimen from a lesion. In the withdrawal group, the peripheral lymphocyte count was significantly elevated after MTX discontinuation. With respect to the subset of lymphocytes and IHC findings, the number of CD8-positive lymphocytes increased by more in the CTx group than withdrawal group.

**Conclusion:** This study showed that the change in lymphocytes before and after MTX discontinuation and low levels of CD8-positive lymphocytes in biopsy lesions are associated with spontaneous regression of MTX-LPDs. We suggest that these factors may become predictive markers for MTX-LPD treatment strategies.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CD8 T cells comprise 40 % of all T cells in the synovial compartment and are detectable in the preclinical stages as well. They have been shown to play an important role in rheumatoid arthritis pathogenesis. They can be divided by cytokine production into CD8+IFN $\gamma$ +, CD8+IL4+ and CD8+IL17+. Methotrexate is the gold standard benchmark DMARD used in therapy of RA. The effect of methotrexate on these circulating CD8 T cell subsets has not been well described.

**Methods:** Patients who were 18 to 65 years of age and having active rheumatoid arthritis (fulfilling the ACR 1987 criteria) were treated with methotrexate for 24 weeks. Methotrexate was started at 15 mg per week, and escalated at 5 mg per month to a maximum of 25 mg per week. Disease activity was measured using the disease activity score and response to treatment assessed by EULAR criteria. At 0 (baseline) and 24 weeks (post methotrexate), PBMCs were isolated using density gradient centrifugation and stimulated with PMA /Ionomycin (with Brefeldin) for 5.5 hours. Surface staining was done using anti CD3/ anti CD8 and intracellular cytokine staining with tagged antibodies to IFN $\gamma$ , IL17 and IL4. 30,000 events were acquired and in CD3+ gate, frequencies of CD8+IFN $\gamma$ + cells, CD8+IL17+ and CD8+IL4+ were determined. Cytokine bead array was used to determine levels of IFN $\gamma$ , IL-12, IL-10, IL-4 and IL-17 in plasma at 0 and 24 weeks. Cell frequencies and cytokine levels at baseline and 24 weeks were described by using median (IQR=interquartile range, 25th- 75th percentile) and compared using non-parametric paired test (Wilcoxon signed rank).

**Results:** This study included 67 patients (F:M=4:1) with rheumatoid arthritis, 57 (85%) being RF positive and 20 receiving prednisolone at baseline. The mean dose of methotrexate at 24 weeks was 22.9 $\pm$ 3.0 mg per week. DAS28 declined from 5.9 $\pm$ 1.1 to 4.8 $\pm$ 1.0 ( $p$ <0.001). CD8+IFN $\gamma$ + cells declined from 37.2 (IQR 19.4-60.2) to 22.7% (IQR 8.5-49.7),  $p$ =0.04 and there was marginal increase in CD8+IL17+ cells from 0.3 (IQR 0.1-0.6) to 0.4 (IQR 0.2-1.2),  $p$ =0.006. In non-responders, there was a significant increase in CD8+IL17+ ( $p$ =0.01) that was not seen in responders. There was a significant decline in the circulating levels of IL-12 [519(IQR 40.4-2336.1), 124.7(IQR 23.5-771.9) pg/ml,  $p$ <0.001) and IL-17 but increase in IL-4 with treatment.

**Conclusion:** Methotrexate leads to changes in circulating CD8 subsets, predominantly decline of the CD8+IFN $\gamma$ + subset, that may be explained due to reduction in the polarising cytokine IL-12 and increase in IL-4. This may be one of the mechanisms responsible for the effect of methotrexate in RA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Follicular T helper (Tfh) cells are typically located in lymphoid organs where they promote B cell differentiation and function. Circulating CD4 T cells expressing CXCR5 together with ICOS and/or PD-1 are considered as counterparts of Tfh and have B cell helper capacity (Simpson N et al, Arthritis Rheum 2010; Craft J, Nat Rev Rheumatol 2012). In addition, three subpopulations of circulating Tfh counterparts have been described: CXCR5+CXCR3+CCR6- (Tfh-Th1), CXCR5+CXCR3-CCR6+ (Tfh-Th17) and CXCR5+CXCR3-CCR6- (Tfh-Th2). Only Tfh-Th17 and Tfh-Th2, but not Tfh-Th1, display functional properties of Tfh cells (Morita et al., Immunity 2011). Altered numbers of these circulating Tfh counterparts (cTfh) and subpopulations have been associated with established RA but there are no reported studies on early RA (eRA). Furthermore, it has recently been published that CD4+CXCR5-PD-1<sup>hi</sup> cells ("peripheral helper T cells" or Tph) also have a Tfh-like function, and are increased in the peripheral blood of RA patients (Rao DA et al, Nature 2017). Therefore, our objective was to study the frequency of cTfh, cTfh cell subsets, Tph cells and circulating plasmablasts (CD19+CD20-CD27+CD38<sup>hi</sup> B cells), in patients with eRA.

### Methods:

Peripheral blood was drawn from DMARD-naïve early RA patients (2010 ACR criteria) with a disease duration < 24 months (n=32), and healthy controls matched for age and gender (n=32). After isolation by Ficoll-Hypaque gradient, PBMCs were stained with antibodies to CD3, CD4, CXCR5, ICOS, PD-1, CCR6, CXCR3, CD19, CD20, CD27, and CD38, and examined by flow cytometry.

### Results:

The frequency of circulating CXCR5+ cells gated for CD4+ T cells was not different among the studied groups. In contrast, eRA patients demonstrated an increased frequency of CD4+CXCR5+ICOS<sup>hi</sup>, CD4+CXCR5+PD-1<sup>hi</sup> and CD4+CXCR5+ ICOS<sup>hi</sup>PD-1<sup>hi</sup> cells. Furthermore, in eRA patients, the frequency of Tfh-Th1 cells was significantly decreased and the frequency of Tfh-Th17 and Tfh-Th2 cells was significantly increased as compared with controls. Subsequently, the ratio (Tfh-Th17+Tfh-Th2)/Tfh-Th1 was increased in eRA. That is, eRA patients demonstrate a higher proportion of Tfh cell subsets bearing a phenotype associated with B cell helping capacity. When examining seropositive (RF+ and/or ACPA+, n=17) and seronegative eRA patients (RF- and ACPA-, n=15) separately, it was evident that the above described alterations were only apparent in seropositive eRA. At the same time, the frequency of circulating plasmablasts was increased in seropositive but not in seronegative eRA. However, the frequency of Tph cells in seropositive or seronegative eRA was not different from controls.

### Conclusion:

Seropositive, but not seronegative eRA patients, demonstrate an increased frequency of circulating Tfh counterparts and altered proportions of circulating Tfh subpopulations, with overrepresentation of subsets bearing a phenotype associated with B cell helping capacity. At the same time, an increased proportion of circulating plasmablasts is apparent in seropositive eRA patients. However, the frequency of Tph cells in eRA is not different from controls.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Exosomes have been recognized to have a function in cell-to-cell communication by transporting various factors including proteins and nucleic acids. These factors impact cell viability and cell differentiation, and are likely to play a prominent role in the pathophysiology of rheumatoid arthritis (RA); however, it is still not reveal that the roles of exosomes as inflammatory mediator in pathogenesis of RA. The purpose of this study is to investigate the role of T lymphocytes derived exosomes in the pathogenesis of RA.

**Methods:** Exosomes were isolated and purified from cultured medium of T lymphocytes cell line (JK). RA synovial fibroblasts (RASFs) were cultured with exosomes derived from JK with or without IFN- $\gamma$  for 24hours. Total RNA was extracted using TRIZOL methods. The expression of RIG-I, TLR3, IL-6 and CXCL10 mRNA in RASFs was measured using real-time quantitative PCR. The protein levels of RIG-I and TLR3 were determined by immune blotting. Silencing of RIG-I and TLR3 in RASF was performed by transfection of siRNA against these proteins.

**Results:** Treatment with PMA/Ionomycin increased the release of exosomes from JK. Large amount of RNA was detectable in exosomes derived from JK. Exosomes derived from JK increased the expression of IL-6 and CXCL10 mRNA in RASFs. When IFN- $\gamma$  is added to the culture medium of RASFs, increased expression of both RIG-I and TLR3 protein in RASF was observed in a dose dependent manner. IFN- $\gamma$  also induced the expression of CXCL10 mRNA, but not IL-6 mRNA, in RASF. Exosomes derived from JK significantly enhances the expression of CXCL10 mRNA, but not IL-6 mRNA, in RASF treated with IFN- $\gamma$ . Finally, silencing of RIG-I, but not TLR3, suppressed the expression of CXCL10 in RASF induced by co-stimulation of both exosomes and IFN- $\gamma$ .

**Conclusion:** The present study demonstrates that exosomes derived from JK enhance IFN- $\gamma$  induced expression of CXCL10 in RASF via pattern recognition receptor, RIG-I. The interaction between exosomes derived from T-cells and RIG-I can be a therapeutic target for RA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Epstein-Barr virus (EBV) infection causes various malignant tumors such as B cell lymphoma and epithelial cell cancer. Previous reports showed several variants in carboxyl-terminal region of EBV nuclear antigen 1 (EBNA-1), and the mutation was frequently detected in patients with nasopharyngeal carcinoma. The mutation of EBV gene may trigger development of the malignant cells. It was reported that titer of anti-EBV antibody was higher in rheumatoid arthritis (RA) compared to controls. Interestingly, the protein sequence of EBV gp110 glycoprotein resembles HLA DRB1 shared epitope (SE). These data suggest EBV infection may play a role of RA, however, underlying mechanisms remains unknown. Moreover, mutation of EBV in RA patients has not been examined. We then investigated EBNA-1 carboxy-terminal region in the synovial tissue of RA.

**Methods:** One hundred twenty-eight RA and 98 osteoarthritis (OA) patients undergoing joint surgery of the knee at the Toho University Omori Medical Center were enrolled in this study. Synovial tissues were collected during surgery under sterile condition. Informed consent was obtained from all the patients. DNA was extracted from the synovial tissues. The EBV gene was determined by nested PCR for amplifying EBNA-1 carboxy-terminal region, and then, the amplicons were detected by performing electrophoresis. Nucleotide sequence of the PCR product was determined. HLA DRB1 genotyping was also performed.

**Results:** EBV DNA was more frequently detected in synovial tissue from RA patients (32.8%; 42 of 128) than OA patient (15.3%; 15 of 98) ( $p < 0.01$ , chi-squared test). The sequence of EBNA-1 carboxy-terminal revealed Japanese prototype (V-Val subtype) in 35 of the 42 RA (83.3%) and 13 of the 15 OA (86.7%) patients. Although four other subtypes were also detected in small number of patients, there were no significant differences between RA and OA. Frequency of HLA-DRB1\*0405, \*0410, \*1001 (SE) was significantly higher in RA (55.5%) than OA (30.6%). Proportion of EBV-positive tended to be higher in SE-positive (39.4%; 28 of 71) than SE-negative (24.6%; 14 of 57), although it is not statistically significant.

## Conclusion:

EBV infection might be an environmental risk factor for development or chronic synovitis of RA. However, nucleotide mutations of EBNA-1 may not contribute it.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Genetic variants in *AFF3* have been associated with RA, including in our GWAS and ImmunoChip analyses of African-Americans (610 RA; 1543 controls). Likewise, an *AFF3* SNP (rs10865035) has been associated with response of RA to TNF inhibitors (TNFi) (Ann Rheum Dis. 2010 69:1029). *AFF3* encodes LAF4, a tissue-restricted nuclear transcriptional activator expressed in cells such as monocytes and lymphocytes. Variants most strongly associated with RA are in the 5' UTR; several are expression quantitative trait loci (eQTLs) for *AFF3*. We examined trans-ethnic associations of *AFF3* with RA, prioritized candidate pathogenic variants using established algorithms, and compared this list to variants reported to influence the likelihood of response to TNFi in RA.

**Methods:** We aggregated our African American RA genetic data with publicly available GWAS data from >100,000 European and Asian RA patients and controls, using METASOFT meta-analysis software to assess overall trans-ethnic association strength ( $p_{TE}$ ) and concordance of effects in each ethnicity ( $m$ -value).  $m > 0.8$  indicates high likelihood of existence of effect for a given population. We then used the PAINTOR3 algorithm (which incorporates multiple types of data) on data from all 3 ancestries to prioritize SNPs according to likelihood of being pathogenic. We compared this list to variants implicated in TNFi response.

**Results:** We found strong evidence ( $m > 0.9$ ) of trans-ethnic effect on RA for 91 *AFF3* variants, mostly in the 5' UTR. We confirmed the association of the *AFF3* locus and the previously reported index variant (rs9653442) with RA in African-Americans ( $p_{AFR} = 7.4 \times 10^{-3}$ ,  $m_{AFR} = 0.975$ ). rs9653442 has a robust trans-ethnic association with RA ( $m_{EUR} = 1.000$ ;  $m_{ASIAN} = 0.999$ ;  $m_{AFR} = 0.975$ ;  $p_{TE} = 1.14 \times 10^{-15}$ ). We identified a set of 12 variants that together are >90% likely to include the pathogenic variant (the 90% ancestry informed credible set, see Table). rs10865035, which was previously associated with TNFi response in RA, was outside our 90% ancestry informed credible set.

**Conclusion:** We defined a set of 12 leading candidate pathogenic *AFF3* variants, which may act to increase *AFF3* expression in T cells or monocytes and influence RA susceptibility. Our study did not identify a likely pathogenic role for rs10865035 in RA susceptibility, but further studies are needed to establish whether rs10865035 underlies differences in TNFi response in RA. Our findings will guide selection of SNPs for future functional studies of susceptibility to RA.

## For Each HLA-DRB1 Genotype, the Likelihood to Develop RA Correlates with the Probability of Binding at Least a Peptide from PAD4

Isabelle Auger<sup>1</sup>, Nathalie Balandraud<sup>2</sup> and **Jean Roudier**<sup>3</sup>, <sup>1</sup>INSERM UMRs 1097, Marseille, France, <sup>2</sup>Rheumatology, APHM, Marseilles, France, <sup>3</sup>Arthrites auto-immunes, INSERM UMRs 1097, Marseille, France

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

HLA-DRB1 genotypic risk to develop ACPA positive RA correlates with capability of encoded HLA-DRB1 chains to bind Peptidyl Arginyl Deiminase (PAD4) peptides, not citrullinated Fibrinogen peptides.

**Background/Purpose:** The risk to develop ACPA positive RA is controlled by HLA-DRB1 genotypes. This may be due to the binding of citrullinated peptides by HLA-DRB1 chains encoded by each genotype. Alternatively, we propose that binding of peptides from PAD4 by HLA-DRB1 allows to help the production of antibodies to citrullinated epitopes on any protein bound by PAD4.

**Methods:** We studied the binding of 65 overlapping peptides from PAD4 and 96 overlapping peptides from the Fibrinogen alpha and beta chains under their native or citrullinated form to purified HLA-DRB1\*0401, \*0404, \*0101, \*0402, \*0701 by ELISA. We calculated a likelihood of binding at least one peptide from PAD4, native Fibrinogen or

citrullinated Fibrinogen by the two HLA-DRB1 chains encoded by each possible genotype and compared it with the risk carried by the same genotype to develop ACPA positive RA.

**Results:** HLA-DRB1 genotypic risks to develop RA correlate with likelihood to bind PAD4 peptides ( $P=0.06$ , Pearson's), not citrullinated Fibrinogen peptides ( $p>0.6$  and  $p>0.9$ ) (Figure 1).

**Conclusion:** Comparison of binding properties of HLA-DRB1 molecules in each of 12 genotypes to PAD4 or native or citrullinated Fibrinogen peptides suggests restriction of PAD4 presentation may explain the association of HLA-DRB1 alleles with ACPA positive RA

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** As in many autoimmune diseases, rheumatoid arthritis (RA) has a female predominance and strong genetic susceptibility from the HLA region. The shared epitope (SE), motif of five amino-acids <sup>70</sup>Q(or R)-K(or R)-R-A-A-<sup>74</sup> on the third hypervariable region of DRβ1, accounts for the highest genetic risk. In contrast, *HLA-DRB1* alleles that express <sup>70</sup>D-E-R-A-A-<sup>74</sup> in the same positions are associated with protection from RA. Many RA patients do not carry the SE and, in women with RA, disease risk can be influenced by SE-positive alleles carried by their children (1). Two previous studies showed that, compared to healthy women, women with RA who are SE-negative more frequently harbor SE-positive microchimerism (Mc), a long-term legacy derived from fetomaternal exchange of cells during pregnancy (2, 3). In this study, we asked whether RA women who are DERA-negative have less DERA-positive Mc compared to healthy controls.

**Methods:** To detect and quantify Mc with DERA-encoding alleles, a quantitative polymerase chain reaction (qPCR) assay was developed with primers and fluorogenic probes specific for the DERA sequence and validated for specificity and sensitivity against an extensive panel of HLA well-characterized cell lines. We tested 53 female subjects who were genotypically negative for DERA-encoding alleles, 26 RA patients and 27 healthy controls, similar for age, parity and gravidity. DERA-Mc qPCR was conducted on DNA extracted from peripheral blood mononuclear cells (PBMC). Logistic regression modeled DERA-Mc prevalence, and negative binomial regression modeled DERA-Mc quantitative levels.

**Results:** DERA-Mc was identified in 42.3% (11/26) of women with RA and in 7.4% (2/27) of healthy women ( $P = 0.0041$ ). The odds ratio for DERA-negative RA patients of being DERA-Mc positive was 9.2 [1.8–47.9] (95% confidence interval {CI}). Quantitatively, DERA-positive Mc was 313.8 [38.3–2573.3]<sub>95%CI</sub> times more abundant in PBMC of RA patients compared to controls ( $P < 0.0001$ ). Among RA patients, DERA-Mc levels increased 28.1 [4.0–195.8]<sub>95%CI</sub> fold if genotype was SE+/+ compared to SE+/- or -/- ( $P = 0.0008$ ) and increased 3.3 [1.6–6.8]<sub>95%CI</sub> fold with increasing parity ( $P = 0.0014$ ).

**Conclusion:** Unexpectedly, the presence of Mc carrying HLA alleles that encode RA-protective alleles was significantly increased in women with RA. This result aligns with a recent report that found increased RA risk in women who had a DERA-positive child born prior to disease onset (also unexpectedly) (1). Furthermore, DERA-Mc levels were especially high among RA women with a SE+/+ genotype. While the explanation for these observations is unknown, results support the concept that RA in women can be influenced by “reverse inheritance” from her children and suggest complexity in immunological interactions across generations (4).

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many women with rheumatoid arthritis (RA) experience an improvement in disease activity during pregnancy, and a predictable flare in the months after they give birth. The cause of these changes is unknown. We hypothesized that understanding biological changes (through gene expression) that occur from pre-pregnancy through the pregnancy and post-partum periods will contribute important evidence to our knowledge of the drivers of disease activity in RA during and after pregnancy.

**Methods:** We have established a prospective RA pregnancy cohort, with clinical data and blood samples collected at pre-pregnancy (T0), each trimester of pregnancy and every 3 months up to a year post-partum (up to 8 time points). Disease activity at each time point was assessed using disease activity scores (DAS28CRP4); women who showed an improvement during pregnancy were selected for analysis (n=9). Global gene expression profiles for each sample were generated using RNA-sequencing (RNA-seq). Raw reads were pseudo-aligned and quantified using kallisto. Random effects regression models were used to estimate the effects of changes in gene expression on disease activity (a) from T0 through the pregnancy period (P1), and (b) in the post-partum period (P2). The models were adjusted for age, medication status at baseline and batch effects. Significance was assessed using a threshold of  $q < 0.05$  (FDR-adjusted). Functional enrichment analysis was performed using WebGestalt.

**Results:** During pregnancy, 1,174 genes had expression patterns significantly associated with disease activity. While these were not significantly enriched in specific pathways, the genes whose increased expression was associated with the largest decrease (improvement) in disease activity during pregnancy were immune-related, and included ERAP1, CSNK2A1 and FAM175B. ERAP1 is involved in trimming peptides for presentation on MHC class I molecules; CSNK2A1 regulates cellular processes including cellular response to viral infection; FAM175B is involved in interferon-signaling. In the post-partum period, 4,693 genes had expression patterns significantly associated with disease activity. These were enriched ( $p < 1 \times 10^{-6}$ ) in numerous immune-related pathways including MAPK signaling, T cell receptor signaling, osteoclast differentiation, hematopoietic cell lineage, B cell receptor signaling, Toll-like receptor signaling and leukocyte trans-endothelial migration, in addition to several pathways related to cancer. The genes whose increased expression were associated with larger increases in disease activity included EI24, CMTM7, PPP2CB and BFAR which are related to tumor suppression and/or regulation of apoptosis.

**Conclusion:** In this pilot RA pregnancy cohort study with longitudinal RNA-seq data, several candidate genes were identified as significantly associated with improvement in disease activity during pregnancy, and others were associated with post-partum flares. These results warrant further investigations into possible roles of these genes in modulating RA disease activity in a larger cohort.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gene expression changes induced by pregnancy in women with rheumatoid arthritis (RA) and healthy women have not been examined. The few studies previously conducted did not have pre-pregnancy samples available as baseline. We have established a cohort of RA and healthy women followed prospectively from pre-pregnancy. In this study, we aimed to identify pregnancy-induced changes in gene expression among women with RA and healthy women, and to assess how those changes may differ between RA women who improve or worsen during pregnancy.

**Methods:** Clinical data and samples collected from a subset of 11 women with RA and 5 healthy women from our cohort before pregnancy (T0) and at the third trimester (T3) were analyzed. Disease activity scores were used to determine whether the RA women improved or worsened during pregnancy. Global gene expression profiles were generated by RNA sequencing (RNA-seq). The raw RNA-seq reads were pseudo-aligned to the reference transcriptome and expression levels were estimated with kallisto. Differential expression analysis of normalized expression levels was performed using edgeR to identify genes differentially expressed within each group of women (T3 vs T0), using a fold-change cut-off of 2 and a significance threshold of  $q < 0.05$  (FDR-adjusted). Functional enrichment analysis was performed using WebGestalt.

**Results:** Of the 11 women with RA, 8 showed an improvement in disease activity by T3 (RA<sub>improved</sub>), while 3 worsened (RA<sub>worsened</sub>). In the RA<sub>improved</sub> group, a total of 161 genes were differentially expressed (DE) between T3 and T0. These included several genes whose expression have previously been associated with RA (e.g. S100A12, SLC14A1) as well as genes involved in the innate immune system (e.g. type I interferon-inducible genes). The majority of these genes (108 of 161) were also DE among healthy women. Of interest, most genes (30 of 31) that were significantly DE in both of the RA groups were also DE among healthy women (e.g.  $\alpha$ -defensin genes). There were also differences between the RA<sub>improved</sub> and RA<sub>worsened</sub> groups. A set of IFN-inducible genes was over-expressed at T3 (vs T0) in the RA<sub>improved</sub> but not the RA<sub>worsened</sub> women. Additionally, some interesting candidate genes whose expression

have previously been associated with RA (e.g. MMP9, PADI4 and PGLYRP1) were over-expressed at T3 (vs. T0) among RA<sub>worsened</sub> but not among RA<sub>improved</sub> women.

**Conclusion:** Pregnancy-induced gene expression changes common between RA women who improved and those who worsened appeared to be normal pregnancy-related changes that were also observed among healthy women. Other genes that demonstrated different patterns of expression between the two RA groups are potential candidates that could be involved in the natural pregnancy-induced amelioration of RA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** MicroRNAs (miRNAs) post-transcriptionally regulate gene expression by targeting messenger RNAs. The expression of miRNAs was demonstrated to differ between patients with rheumatoid arthritis (RA) and healthy subjects. The aim of this study was to analyse cellular miRNAs from peripheral mononuclear cells (PBMCs) in order to determine their predictive value for achieving remission or low disease activity in patients with early RA.

**Methods:** At first, miRNAs were screened by TaqMan MicroRNA Array Cards in 4 treatment naïve patients with early RA (disease duration < 6 months) who achieved long-term remission (3 females; mean age 59 years; DAS28 < 2.6) and 4 treatment naïve patients with early RA (disease duration < 6 months) with persistently high disease activity (3 females; mean age 63 years; DAS28 > 5.1). Thirteen miRNAs with at least 2-fold difference between both groups were validated in a cohort of 60 patients (44 females; mean age 54 years) with early RA (baseline DAS28 = 5.64, CRP = 22.72; DAS28 after 6 months = 2.80, CRP = 5.17); and 54 healthy controls (HC) (41 females; mean age 51 years). Total RNA was isolated from PBMCs in treatment naïve early RA patients at baseline and after the first and third month of conventional therapy. The expression of miRNAs was determined by quantitative PCR. Small nucleolar RNA RNU44 was used for normalization. Disease activity of RA patients was assessed according to the 28-Joint Count Disease Activity Score (DAS28) and the Simplified Disease Activity Index (SDAI). Area under the curve analysis was used to determine the predictive value of miRNAs to achieve remission or low disease activity.

**Results:** Cellular miRNA-31 expression was significantly lower in patients with early RA compared to HC ( $p=0.002$ ) and the therapy initiation contributed to its normalization over time. The expression of cellular miRNA-10a was also lower in patients with early RA compared to HC ( $p<0.0001$ ) however it has not significantly changed during the therapy. Although both miRNAs did not correlate with disease activity, higher baseline and also one-month miRNA-31 expression predicted achievement of remission after 6 months (DAS28: AUC= 0.713,  $p=0.016$ ; SDAI: AUC= 0.732,  $p=0.011$ , and DAS28: AUC= 0.760,  $p=0.003$ ; SDAI: AUC= 0.734,  $p=0.010$ ; respectively). In addition, higher baseline expression of miRNA-10a predicted remission and low disease activity achievement after 12 months (DAS28: AUC= 0.750,  $p=0.012$ ; SDAI: AUC= 0.718,  $p=0.038$ ).

**Conclusion:** The expression of cellular miRNA-31 and miRNA-10a may represent potential biomarkers of treatment response in patients with early RA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Extracellular microRNAs, circulating in the bloodstream and extracellular space, have been proposed as attractive candidates as both diagnostic and prognostic biomarkers in various diseases, including a spectrum of autoimmune and cardiovascular conditions. Yet, the contribution of circulating miRNAs to the cardiovascular pathogenesis of Rheumatoid Arthritis (RA) patients and their potential role as biomarkers are still unknown. Purpose: To identify circulating miRNAs as potential biomarkers for the presence of cardiovascular disease (CVD) in RA.

**Methods:** Plasma samples of 80 healthy donors (HDs) and 195 RA patients, including 90 RA patients with cardiovascular events (Ischemic heart disease, Heart failure, Cerebrovascular accident or Peripheral arterial disease) were collected. In the discovery phase, an array of 2,083 human miRNAs was performed by using HTG EdgeSeq miRNA Whole Transcriptome Assay (Next generation sequencing) in 9 plasma samples (3 HDs, 3 RA and 3 RA with

CVD). Then, differentially expressed miRNAs, were selected and validated by RT-PCR in the whole cohort of patients. Potential targets of the validated miRNAs, were identified by using Ingenuity Pathway Analysis (IPA) software and analyzed at protein levels (Multiplex Assay). Correlation and association studies of altered miRNAs with analytical and clinical variables such as the type of cardiovascular events, the presence of a pathologic carotid intima-media thickness (CMT) and the autoimmune and inflammatory profile, were also performed.

**Results:** The miRNA whole Transcriptome assay showed that 360 miRNAs were differentially expressed in RA patients in relation to HDs, including 261 upregulated and 97 downregulated. Functional classification (IPA) demonstrated that deregulated miRNAs were mainly involved in processes such as inflammatory response, connective tissue development and function, haematological disease, tissue development and immunological disease. RA patients with CVD showed 17 differentially expressed plasma miRNAs in relation to RA patients, including 11 upregulated and 6 downregulated. In silico study identified that these CVD-associated miRNAs had potential targets related to cytokine signaling (TNF, TNFRSF, TNFSF, TRAF, IL1R, IL22, IL33, CCL21, CXCL12), atherosclerosis pathway (iNOS, VEGFA, LDL-R, COL1A1, COL10A1, COL5A3) and intracellular signal transduction (ERK and WNT). Furthermore, the altered levels of several miRNAs and target proteins were validated in the whole cohort of patients, and were linked to the clinical manifestations of the disease, such as the activity of the disease, the occurrence of cardiovascular events, presence of early atherosclerosis and endothelial dysfunction.

**Conclusion:** Circulating miRNAs levels in plasma of RA patients might be considered useful tools as biomarkers of cardiovascular disease in these patients. **Acknowledgements:** Supported by FIS (PI01333/2015) and CTS-7940.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate the role of miR-146a in the activation of toll-like receptor-4 (TLR4)/ nuclear factor kappa-light-chain-enhancer of activated B cells (NF- $\kappa$ B) signaling pathway, and the effect of miR-146a in cytokines expression and synoviocytes proliferation during rheumatoid arthritis (RA).

**Methods:** Synovial tissues were collected from RA patients who received arthroscopic synovectomy in the Department of Rheumatism at our hospital. Cells were categorized into a blank control group, a negative control group, a miR-146a mimics group and a miR-146a inhibitors group. The cholecystokinin (CCK)-8 assay was used to measure the inhibition on cell proliferation rate. TLR4 mRNA level, as well as the mRNA expressions of NF- $\kappa$ B, interleukin (IL)-1 $\beta$ , IL-6, IL-8, IL-17, cyclooxygenase (COX)-2, matrix metalloproteinase (MMP)-3, Seprase, and inducible nitric oxide synthase (iNOS) were detected by the reverse transcription-polymerase chain reaction (RT-PCR). Western blot was used to measure TLR4 and NF- $\kappa$ B proteins, and the expressions of IL-1 $\beta$ , IL-6, IL-8, IL-17, Seprase, MMP-3 and prostaglandin E2 (PGE2) were measured by enzyme linked immunosorbent assay (ELISA). The content of nitric oxide (NO) was measured by the Griess method.

**Results:** The CD3 and CD14 expression rate gradually decreased, and the CD90 expression rate gradually increased. After the third generation of cell culture, the CD90 expression rate (96.48%) was significantly higher than those of CD3 (1.17%) and CD14 (1.27%). After culturing for 48h and 72h, cell proliferation in the miR-146a mimics group was significantly increased (both  $P < 0.05$ ) as compared with the blank group, while that in the miR-146a inhibitors group significantly reduced (both  $P < 0.05$ ). With an extended time of cell culture, the change in cell proliferation was more significant, and differences were observed at each time point (all  $P < 0.05$ ). Compared with the blank group, the expressions of TLR4, NF- $\kappa$ B, IL-1, IL-6, IL-8, IL-17, COX-2, MMP-3, Seprase, iNOS and NO content in the miR-146a mimics group increased significantly (all  $P < 0.05$ ), but in the miR-146a inhibitors group, these values significantly reduced (all  $P < 0.05$ ).

**Conclusion:** The inhibition of miR-146a expression could block the TLR4/NF- $\kappa$ B signaling pathway, and inhibited synovial fibroblast proliferation and cytokine expressions in RA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the SIRROUND-D study, sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, significantly reduced radiographic progression after 52 wks compared with placebo (PBO) in patients (pts) with active rheumatoid arthritis (RA) despite DMARD treatment. Long-term data on radiographic progression after 104 wks of SIR treatment are presented.

**Methods:** In this Phase 3 study, 1,670 pts with moderate to severe active RA, defined as  $\geq 6/66$  swollen and  $\geq 6/68$  tender joints and a minimum CRP  $\geq 8.0$  mg/L, that was refractory to DMARDs were randomized (1:1:1) to SC SIR 50 mg q4w, SIR 100 mg q2w, or PBO q2w. Pts randomized to PBO who had  $<20\%$  improvement in swollen/tender joints at Wks 18 or 40 or were still taking PBO at Wk 52 were re-randomized to SIR; blinded treatment lasted 104 wks. Images of the hands and feet were taken at baseline, Wks 18 (early escape [EE] criteria met), 24 (EE criteria not met), 52, and 104. For this analysis of radiographic change over the second year of SIRROUND-D, only images taken at baseline, Wk 52, and after Wk 52 (eg, Wk 104) were evaluated. The endpoints included changes from baseline at Wks 52 and 104 in the modified Sharp/van der Heijde score (SHS) for radiographic damage, erosion score, and joint space narrowing (JSN) score and the proportions of pts with radiographic progression (change  $>$ smallest detectable change [SDC]) and with a change of  $\leq 0$  from baseline in SHS. Analyses only included pts who were still on study treatment at Wk 52 and had non-missing SHS score at both baseline and Wk 52. All analyses were based on observed data unless noted.

**Results:** A high proportion of pts had readable images at baseline, Wk 52, and post-Wk 52, ranging from 94.5% to 97.1%. Of 1218 pts who had not terminated the study or study treatment early, 1176 had evaluable Wk 104 x-rays. The mean change from baseline in the SHS at Wk 104 generally increased slightly versus Wk 52; changes from baseline at Wks 52 and 104 remained below the SDC for SHS scoring for pts originally randomized to SIR (both doses; **Table**). Mean changes in the SHS from Wk 52 to Wk 104 were negligible across all treatment groups. Similar results were observed for the erosion and JSN scores (**Table**). At Wks 52 and 104, the proportions of pts with radiographic progression based on SHS were similar for both SIR doses among pts randomized to SIR and those randomized to PBO who crossed over to SIR. The proportions of pts with a change in SHS of  $\leq 0$  were generally comparable for both SIR doses among pts randomized to SIR and those randomized to PBO who crossed over to SIR at Wks 52 and 104.

**Conclusion:** Treatment with SIR 50 mg q4w and SIR 100 mg q2w in pts with active RA despite DMARD therapy resulted in minimal radiographic progression over 2 years, indicating that inhibition of joint damage by SIR demonstrated at Wk 52 was maintained through Wk 104 of this study.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Blinded transitioning from originator infliximab (INX) to biosimilar CT-P13 was not inferior to continuing INX treatment.<sup>1</sup> Open label mandatory transitioning resulted in a slightly lower 1-year CT-P13 retention rate than for INX in a historical cohort.<sup>2</sup> However, non-mandatory transitioning might be preferred above mandatory. Therefore, we assessed the effects of open label non-mandatory transitioning from originator etanercept (ENB) to biosimilar SB4 on drug survival and effectiveness in rheumatic diseases in daily practice.

**Methods:** In 2016, 642 ENB treated patients were asked to transition to SB4 by a structured implementation strategy with opt-out option. Consenting patients were eligible for inclusion in our study [BIO-SPAN]. ENB treated patients in 2014 were recruited as historical cohort. The 6-months retention rate in the two cohorts was compared. Multivariable Cox regression analysis was used to calculate HR for discontinuation adjusted for baseline characteristics (age/gender/diagnosis/ENB treatment duration/ENB dose interval/csDMARD/CRP) and with a robust variance estimator to account for repeated subjects. Reasons for discontinuation and change in DAS28-CRP, BASDAI and CRP after 6 months were assessed.

**Results:** 635 (99%) patients agreed to transition to SB4 of whom 625 patients (433 RA, 128 PsA, 64 AS; 55% women; age 57 (14) years) were included in the transition cohort. 600 patients were included in the historical cohort. Crude 6-months retention rates of SB4 in the transition cohort and ENB in the historical cohort were: 90% (95%CI 88%-93%) vs 92% (95%CI 90%-94%). The transition cohort had a significantly higher relative risk of discontinuation than the historical cohort (adjusted HR 1.57, 95%CI 1.05-2.36). Reasons for discontinuing SB4 (n=60, 10%) and ENB (n=46, 8%) were: lack of effect (43% vs 61%), adverse events (47% vs 28%), malignancy (3% vs 4%), pregnancy (4% vs 4%) and other (3% vs 3%). In the transition cohort, 17 patients restarted ENB, 32 patients switched to another biologic and

11 patients maintained biologic-free. DAS28-CRP, BASDAI and CRP were not statistically different between baseline and month 6 in the transition cohort. Due to a slightly lower baseline CRP (1 [0-5] vs 3 [1-5],  $p<0.001$ ) and DAS28-CRP (1.9 [1.5-2.6] vs 2.1 [1.6-2.9],  $p<0.001$ ) changes in CRP (0.5 (12) vs -1.5 (14),  $p=0.01$ ) and DAS28-CRP (-0.01 (0.93) vs -0.26 (-0.99),  $p<0.001$ ) at month 6 favored the historical cohort.

**Conclusion:** Open label non-mandatory transitioning from ENB to SB4 showed a statistically significantly but clinically not relevant lower retention rate compared to a historical cohort, similar to retention seen after mandatory INX transitioning. Non-mandatory transitioning, when executed optimally, might therefore be an attractive alternative to mandatory transitioning.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biosimilars, biopharmaceuticals assessed by regulatory agencies to have efficacy and safety similar to their reference products, were introduced to the UK market in February 2015 for rheumatoid arthritis (RA). Switching patients from originator to biosimilars could result in significant costs savings to the NHS but real world data about efficacy and safety of such a switch are lacking. This analysis describes the characteristics and initial follow-up of RA patients switching from the originator to biosimilars participating in the British Society for Rheumatology Biologics Register for Rheumatoid Arthritis (BSRBR-RA).

**Methods:** Since 03/08/2015, the BSRBR-RA has captured data on patients starting biosimilars available in the UK: infliximab (Inflectra and Remsima) and later in May 2016, etanercept (Benepali). At biosimilar start, information is captured from the hospital including demographic and clinical data, previous biologic exposure and, if switching therapies, the reason for switch (as a tick box and free text). Follow-up data (disease activity, occurrence of adverse events and changes to treatment) are captured 6-monthly for 3 years and annually thereafter. Descriptive data are presented.

**Results:** To 10/05/2017, 1,165 patients were recruited at point of starting a biosimilar. Of these, over half (59%, 691/1,165) switched directly from the originator product (74% Benepali, 9% Inflectra, 17% Remsima (table). By far the most frequent reason cited to switch was cost. These patients switched from originator after a median (IQR) time of 5.3 (2.7-8.8) years and the majority had low disease activity (median DAS28 2.7 (IQR 2.0-3.8). To date, follow-up data are available in 99 patients (61% Inflectra, 27% Remsima, 6% Benapali), primarily in those receiving infliximab biosimilars. After 6 months, 85% of these patients stayed on the baseline biosimilar, 7% switched back to their originator, 4% switched between infliximab biosimilars, 3% stopped treatment with a biosimilar and 1% switched to a biologic other than the originator. Reasons for switching back to the originator were inefficacy (n=3) and adverse events (n=2) with two reasons missing. A deterioration in DAS28 of >1.2 after 6 months was experienced by 17% (13/78) of patients. Only one serious adverse event (drug hypersensitivity reaction) was reported in a Remsima patient.

**Conclusion:** In the UK, RA patients are actively switched from originator to biosimilars mostly for cost reasons. Limited short-term follow up data seem to indicate a high retention on biosimilars, yet a minority of patients had a clinically significant deterioration of their disease activity and some were reported to switch back to the originator already after 6 months of treatment. Data capture will continue and updated reports from the BSRBR-RA will build on these early findings.

## Long-Term Efficacy, Safety and Immunogenicity Results from a Randomized, Double-Blind, Phase III Confirmatory Efficacy and Safety Study Comparing GP2017, a Proposed Biosimilar, with Reference Adalimumab

Andrew Blauvelt<sup>1</sup>, Jean-Phillipe Lacour<sup>2</sup>, Joseph Fowler<sup>3</sup>, Ellen Schuck<sup>4</sup>, **Julia Jauch-Lembach<sup>4</sup>**, Alison Balfour<sup>4</sup> and Craig Leonardi<sup>5</sup>, <sup>1</sup>Oregon Medical Research Center, Portland, OR, <sup>2</sup>University of Nice Sophia Antipolis, Nice, France, <sup>3</sup>Dermatology Specialists, Louisville, KY, <sup>4</sup>Hexal AG, Holzkirchen, Germany, <sup>5</sup>Central Dermatology, St. Louis, MO

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Based on the evaluation of physicochemical, biological, preclinical, and clinical data, a biosimilar may be approved for use in the same indications for which the reference medicine is approved. A prerequisite for this extrapolation is clinical confirmation of biosimilarity in a population sensitive enough to detect potential differences in efficacy, safety, or immunogenicity between the proposed biosimilar and the reference medicine. GP2017, a proposed biosimilar to adalimumab, was investigated in patients with moderate-to-severe chronic plaque psoriasis.

**Methods:** Eligible patients were randomized to receive an initial dose of 80 mg subcutaneous GP2017 or reference adalimumab, followed by 40 mg every other week, starting one week after the initial dose. To evaluate long-term effects and the impact of multiple switches between GP2017 and reference adalimumab, patients with  $\geq$ PASI 50 at Week 16 were re-randomized at Week 17 in a 2:1 ratio to either remain on their initial study treatment or undergo a sequence of three treatment switches between GP2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

**Results:** Initially, 465 patients, including 98 (21.1%) with psoriatic arthritis, were randomized to GP2017 (n=231) or reference adalimumab (n=234). At Week 17, 379 patients were re-randomized to continue treatment with GP2017 (n=126) or reference adalimumab (n=127) or to switch between GP2017 and reference adalimumab, or vice versa (n=63 in each group). There were no clinically relevant differences in efficacy and safety between the continued and switched groups across the entire study duration (Table). At preferred term level, no severe/serious adverse events (AEs) were reported by more than one patient in a treatment group. Infections/infestations were the most common treatment-emergent AEs, with nasopharyngitis most frequently reported by 11.1% (reference adalimumab to GP2017), 12.6% (continued adalimumab), 12.7% (GP2017 to reference adalimumab) and 9.5% (continued GP2017) of patients. The incidence of injection site reactions was low and similar among the individual groups. Overall, from Week 1 to 51, differences in the frequency of antidrug antibody (ADA) detection were  $<11\%$  among the individual groups; most ADA (75–100%) were neutralizing.

**Conclusion:** There were no clinically meaningful differences in long-term efficacy among patients who received continued GP2017 and reference adalimumab, or who switched between GP2017 and reference adalimumab multiple times. Switching treatments was well tolerated; overall safety profiles and immunogenicity rates were similar between the individual treatment groups. The data add to the totality of evidence suggesting GP2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved.

<b>Table. Summary of efficacy, safety and immunogenicity during entire study period</b>				
	Reference adalimumab to GP2017 (n=63)	Continued reference adalimumab (n=127)	GP2017 to reference adalimumab (n=63)	Continued GP2017 (n=126)
<b>Mean reduction from baseline in PASI score, % (SD)</b>				
Week 17	86.58 (12.770)	82.39 (17.826)	84.87 (15.710)	84.82 (15.957)
Week 35	85.35 (17.456)	85.55 (16.681)	84.59 (21.033)	85.01 (19.739)
Week 51	85.01 (15.501)	84.71 (18.020)	83.91 (21.726)	86.84 (21.581)

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** LBEC0101 has been developed as a biosimilar to the etanercept reference product (ETN-RP). This study was to evaluate the similarities between LBEC0101 and ETN-RP as adjunctive therapy to methotrexate (MTX), in patients with active rheumatoid arthritis despite MTX treatment. In this abstract, not only the equivalence of the primary endpoint at Week 24 but also the results up to 52 weeks of the study comparing the long term efficacy, safety and immunogenicity between LBEC0101 and ETN-RP are reported.

**Methods:** This phase III, multicenter, randomized, double-blind, parallel-group, reference product-controlled study was conducted in Japan and Korea. Patients with active RA for  $\geq 6$  months who had an inadequate response to MTX were randomly assigned to receive weekly dose of 50 mg LBEC0101 or ETN-RP administered subcutaneously for 52 weeks. The primary efficacy endpoint was the mean change from baseline in the disease activity score in 28 joints based on erythrocyte sedimentation rate (DAS28-ESR) at Week 24. Efficacy, safety and immunogenicity outcomes were assessed up to Week 52.

**Results:** In total, 374 patients were randomized to LBEC0101 (N=187) or ETN-RP (N=187). The least square mean changes from baseline in DAS28-ESR score at Week 24 in the per-protocol set (PPS) were -3.009 in the LBEC0101 group and -2.859 in the ETN-RP group. The estimated treatment difference in change from baseline to Week 24 in DAS28-ESR between the two groups was -0.150 and the 95% confidence interval (CI) of the difference was -0.3768 to 0.0775, which was completely within the pre-specified equivalence margin of -0.6 to 0.6, indicating that equivalence in efficacy between LBEC0101 and ETN-RP was proved. As a secondary endpoint, ACR20 response rate was similar between the groups (93.3% for LBEC0101 and 86.7% for ETN-RP) at Weeks 24. The incidence of AEs up to Week 54 was comparable, except for injection site reaction which was reported in the ETN-RP group (438 events in 64 subjects [34.2%]) and in the LBEC0101 group (77 events in 19 subjects [10.2%]), respectively.

Three (1.6%) and 18 (9.6%) patients in the LBEC0101 and ETN-RP groups, developed anti-drug antibody (ADA) up to 52 weeks, respectively.

**Conclusion:** The clinical efficacy of LBEC0101 was equivalent to that of ETN-RP. LBEC0101 was well tolerated and had a comparable safety profile to ETN-RP.

**Background/Purpose:** Clinical equivalence has been shown for BI 695501 and the adalimumab reference product (RP) through similar ACR20 response at Weeks (wks) 12 and 24 in patients (pts) with moderately-to-severely active RA in the Phase III VOLTAIRE®-RA study (Cohen et al 2017. EULAR 2017. Abst FRI0189). Here we present the long-term safety, efficacy and immunogenicity data.

**Methods:** In this 58-wk, double-blind, multicenter, Phase III active-comparator study (NCT02137226), 645 adalimumab-naïve adults with moderately-to-severely active RA receiving stable treatment with methotrexate (prior exposure to one biologic allowed) were randomized (1:1) to BI 695501 or adalimumab RP 40 mg and treated every 2 wks up to Wk 24. At Wk 24, RP pts were re-randomized to switch to BI 695501 (SWITCH; n = 147 (full analysis set) / 146 (safety analysis set [SAF])), or to continue RP (RP-CONT; n = 148) until Wk 48; BI 695501 pts were dummy re-randomized and continued BI 695501 (BI 695501-CONT; n = 298). Data from pts treated only with BI 695501 (N=324) or RP (N=175) for the entire 48 wks were also analysed. Efficacy data were collected until Wk 48. Safety follow-up was to Wk 58 for all pts who did not enter the open-label extension trial (VOLTAIRE®-RAext).

**Results:** Baseline demographics were balanced across treatment groups. ACR20/50/70 response rates were similar across the groups up to Wk 48 (Figure 1). At Wk 48, mean changes from baseline in DAS28-ESR were  $-2.71$ ,  $-2.60$ , and  $-2.70$  in the SWITCH, RP-CONT, and BI 695501-CONT groups, respectively. Safety findings were similar between continuous arms from Day 1 to Wk 58, and re-randomization groups from Wk 24 to Wk 58 (Table 1). Among serious adverse events (SAEs), infections and infestations was the most common system organ class (0.6% for BI 695501 vs 4.0% for RP). No deaths were reported during the study. Similar immunogenicity (anti-drug antibody [ADA] frequency and titers, neutralizing antibody [nAb] frequency) was detected up to Wk 48 in all re-randomized groups. The proportion of pts with positive ADA response at Wks 24 and 48 was 44.5% and 36.2% for the SWITCH group, 50.3% and 49.6% for RP-CONT, and 42.8% and 41.8% for BI 695501-CONT. Positive nAb response frequency at Wk 24 and 48 was 15.8% and 15.2% (SWITCH), 23.8% and 21.6% (RP-CONT), and 15.8% and 19.1% (BI 695501-CONT). The single transition from RP to BI 695501 had no impact on efficacy, safety, and immunogenicity.

**Conclusion:** These data confirm that BI 695501 and adalimumab RP have similar efficacy, safety, and immunogenicity in pts with RA over 48 wks of treatment. These findings also held true for pts switching from adalimumab RP to BI 695501 at Wk 24.

Figure 1. ACR 20/50/70 response rates over 48 weeks

Table 1. Overview of treatment-emergent adverse events to 58 weeks (SAF)

	Overall (Day 1 to Week 58)		Re-randomization groups (Week 24 to Week 58)		
Pts, n %	BI 695501 (N = 324)	RP (N = 175)	SWITCH (n = 146)	RP-CONT (n = 148)	BI 695501-CONT (n = 298)
≥1 AE	193 (59.6)	105 (60.0)	62 (42.5)	51 (34.5)	126 (42.3)
≥1 drug-related AE	62 (19.1)	40 (22.9)	17 (11.6)	17 (11.5)	39 (13.1)
≥1 serious AE	18 (5.6)	17 (9.7)	6 (4.1)	5 (3.4)	6 (2.0)
AE leading to study drug discontinuation	13 (4.0)	12 (6.9)	6 (4.1)	1 (0.7)	5 (1.7)

AE = treatment-emergent adverse event.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** GP2017 is a proposed adalimumab biosimilar that has been shown to be similar to reference adalimumab at an analytical and preclinical level. The aim of this study was to determine the pharmacokinetics (PK), immunogenicity and safety of GP2017, EU-authorized adalimumab (EU-adalimumab) and US-licensed adalimumab (US-adalimumab) in healthy volunteers. As part of the global development program for GP2017, a further aim was to establish PK bridging data between EU- and US-adalimumab.

**Methods:** This was a randomized, double-blind, three-arm parallel study in healthy male volunteers aged 18 to 55 years, with a body mass index of 18.5 to 29 kg/m<sup>2</sup>. Subjects were randomized to receive a single 40 mg/0.8 mL subcutaneous injection of either GP2017, EU- or US-adalimumab, with follow-up until Day 72. The primary objective was to demonstrate PK bioequivalence between GP2017 and EU-adalimumab, and between EU-adalimumab and US-adalimumab, by describing maximum observed serum concentration (C<sub>max</sub>) and total area under the curve (AUC<sub>0-inf</sub>). Secondary objectives included the assessment of AUC<sub>0-360h</sub> and AUC<sub>0-last</sub>, the comparison of PK parameters between GP2017 and US-adalimumab, and the evaluation of safety, tolerability and immunogenicity of all three products.

**Results:** A total of 318 subjects were randomized to GP2017 (n=107), EU-adalimumab (n=106) and US-adalimumab (n=105). Baseline characteristics, including body weight, were well balanced across treatment arms. For C<sub>max</sub> and AUC<sub>0-inf</sub> the 90% confidence interval (CI) for the ratio of geometric means was contained within prespecified bioequivalence limits of 0.8 to 1.25 for the primary analysis of GP2017 and EU-adalimumab, and EU- and US-adalimumab (Table). For the analysis of secondary objectives, 90% CI were contained within 0.8 to 1.25 for all pairwise comparisons of C<sub>max</sub>, AUC<sub>0-inf</sub>, AUC<sub>0-360h</sub> and AUC<sub>0-last</sub> (Table). The incidence of drug-related, treatment-emergent adverse events (TEAEs) was similar across the GP2017/EU-adalimumab/US-adalimumab treatment groups (57.9%/61.3%/58.1%) and all were mild or moderate in severity. Infections/infestations were the most common TEAEs. Injection site reactions were infrequent and mild. Overall, antidrug antibodies were detected in 57.9%/69.8%/69.5% of subjects in the GP2017/EU-adalimumab/US-adalimumab groups up to Day 72, which were neutralizing in 54.2%/64.2%/62.9% of subjects, respectively.

**Conclusion:** The results show that GP2017 is bioequivalent to EU- and US-adalimumab and EU-adalimumab is bioequivalent to US-adalimumab. There were no clinically relevant differences in safety, tolerability and immunogenicity among the three treatment arms in healthy subjects.

<b>Table. Summary statistical analysis of primary and secondary objectives</b>

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CT-P13 is approved as a biosimilar of innovator infliximab for marketing in 81 countries. After approval, observational study has been conducted in Republic of Korea in patients with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS), Psoriatic Arthritis (PsA) and Plaque Psoriasis (PS). The objective of this study is to evaluate the effectiveness and safety of CT-P13 under routine care.

**Methods:** This study included both biologic naïve patients (Naïve group) and patients who switched from other anti-tumor necrosis factor (TNF)s such as infliximab, adalimumab, golimumab and etanercept to CT-P13 (Switch group). Effectiveness was evaluated based on remission (DAS28 $\leq$ 2.6 in RA, BASDAI $\leq$ 3 in AS and absence of swollen and tender joint counts in PsA) and response (BASDAI 20/50/70 in AS and PASI 50/75 in PS). Adverse events (AEs) were collected over 6 months.

**Results:** Total 940 patients (RA 400, AS 531, PsA 3 and PS 6) were registered and 338 (36.0%) patients (RA 108, AS 228, PS 2) who switched to CT-P13 were included.

The proportion of patients achieving remission was similar between Naïve and Switch groups in both RA and AS during post-baseline visits (Table 1). In RA, the proportion of patients achieving each disease activity category by DAS28 was similar between Naïve and Switch groups (Figure 1). The proportion of patients who achieved BASDAI 20/50/70 response gradually increased from week 6 to week 24 or 30 in AS Naïve group (Figure 1).

Fifty percent of 2 naïve patients in PsA achieved remission. The proportions of both PASI 50 and 75 response were 50% at Week 22 in Naïve and 100% and 50% in Switch group, respectively during post-baseline visits in PS.

Throughout this study, treatment-emergent adverse events (TEAE) and treatment-emergent serious adverse events (TESAE) were reported as Table 2. Only 11% of patients experienced infection.

Table 1. Clinical remission in RA and AS

	Naïve		Switch	
	Baseline	Post-baseline	Baseline	Post-baseline
<b>RADAS28</b>	0/181	24/182	0/25	5/25 (20.0%)
(ESR)	(0.0%)	(13.2%)	(0.0%)	
<b>DAS28</b>	0/180	43/179	2/25	6/24 (25.0%)
(CRP)	(0.0%)	(24.0%)	(8.0%)	
<b>AS BASDAI</b>	2/292	199/292	112/209	150/210
	(0.7%)	(68.2%)	(53.6%)	(71.4%)

Table 2. Summary of safety results

n/N (%)	RA	AS	PsA	PS
TEAE	198/400 (49.5)	183/531 (34.5)	1/3 (33.3)	3/6 (50.0)
TEAE related to CT-P13	73/400 (18.3)	64/531 (12.1)	0/3 (0.0)	2/6 (33.3)
TESAE	52/400 (13.0)	14/531 (2.6)	0/3 (0.0)	1/6 (16.7)
TESAE related to CT-P13	15/400 (3.8)	6/531 (1.1)	0/3 (0.0)	0/6 (0.0)
Infusion-related reactions	28/400 (7.0)	11/531 (2.1)	0/3 (0.0)	0/6 (0.0)

Figure 1. Clinical responses in RA and Naïve AS Patients

**Conclusion:** CT-P13 is efficacious and well-tolerated in RA/AS/PsA/PS patients. Efficacy and safety results in patients treated with CT-P13 were clinically consistent to historical data [1] [2] [3]. Especially, Switch group results showed that CT-P13 provides a useful alternative to other anti-TNFs.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Similarity of pharmacokinetic, efficacy and safety between CT-P10 and reference rituximab (RTX) were shown in the phase 3 randomized controlled trial (NCT02149121) up to 48 weeks in RA patients<sup>1,2,3</sup>. This is to investigate efficacy and safety of CT-P10 when used for long term and after switching from RTX in the extension phase of above study.

**Methods:** Patients who completed up to 48 weeks (Main Period), entered into the Extension Period. Patients who had received CT-P10 or EU-RTX in the Main Period received CT-P10 and patients who had received US-RTX randomly assigned in a 1:1 ratio to receive CT-P10 or US-RTX at Extension Weeks 0 and 2. Efficacy, pharmacodynamics (PD), safety and immunogenicity were evaluated for 24 weeks.

**Results:** A total of 295 patients (122 CT-P10 Maintenance, 64 US-RTX Maintenance, 62 CT-P10 Switched from US-RTX and 47 CT-P10 Switched from EU-RTX groups) were treated in the Extension Period.

The mean changes of DAS28 from baseline of Main Period and ACR response rate were comparable among the groups (Figures 1 and 2).

B-cell depletion after the 1<sup>st</sup> infusion was comparable and maintained until Extension Week 24 in all groups.

No remarkable changes in immunogenicity profile were observed following the drug switch. Two patients (1 patient each in the US-RTX Maintenance and CT-P10 Switched from US-RTX groups) had anti-drug antibody newly developed after Extension Week 0 infusion.

The safety profiles were also comparable among the groups (Table 1). All infusion related reactions were grade 1 or 2 intensity. Most frequent infections were upper respiratory and urinary tract infections. No malignancy, progressive multifocal leukoencephalopathy or death were reported.

**Conclusion:** Long term effectiveness and tolerability were achieved over 72-week treatment of CT-P10. The switched groups from RTX to CT-P10 were comparable to CT-P10 or US-RTX Maintenance groups in the efficacy, PD and safety profiles including immunogenicity.

## **Minimal and Comparable Radiographic Progression By Disease Activity States in Patients with Rheumatoid Arthritis Who Continued SB5 or Reference Adalimumab and Who Switched to SB5**

**Michael Weinblatt**<sup>1</sup>, Asta Baranauskaite<sup>2</sup>, Jeehoon Ghil<sup>3</sup>, Soo Yeon Cheong<sup>3</sup> and Evelyn Hong<sup>3</sup>, <sup>1</sup>Brigham and Women's Hospital, Boston, MA, <sup>2</sup>Lithuanian University of Health Sciences, Kaunas, Lithuania, <sup>3</sup>Samsung Bioepis Co., Ltd., Incheon, Korea, Republic of (South)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** SB5 is a biologic agent developed as a biosimilar of the reference adalimumab (ADL). One year results including radiographic progression from the phase III equivalence study have been previously presented. This study further evaluates radiographic progression by different disease activity states by disease activity score by 28 joint count (DAS28) based on erythrocyte sedimentation rate (ESR), simplified disease activity index (SDAI) and clinical disease activity index (CDAI).

**Methods :** Patients with rheumatoid arthritis (RA) were randomized to receive 40 mg of either SB5 or ADL every other week. At week 24, patients receiving ADL were re-randomised to either switch to SB5 (ADL/SB5) or continue on ADL (ADL/ADL) up to 52 weeks. Patients receiving SB5 continued to receive SB5 (SB5/SB5). The proportion of patients achieving remission, low disease activity (LDA), moderate disease activity (MDA), or high disease activity (HDA) in terms of DAS28, SDAI, and CDAI was compared at weeks 12, 24, and 52. Radiographic progression was measured

using the modified Total Sharp Score (mTSS) at weeks 0 and 52 and patients with mTSS  $\geq 0$  at week 52 were regarded as radiographic non-progressors.

**Results :** The proportion of patients with remission, LDA, MDA, or HDA was comparable across all treatment groups (SB5/SB5 vs. ADL overall vs. ADL/SB5 vs. ADL/ADL) in terms of DAS28 (Table 1) and also SDAI and CDAI (data not shown). The proportions of radiographic non-progressors by disease activity were comparable across treatment groups at week 12, 24 and 52 (Table 2). There was a general trend of higher radiographic progression (decreasing number of radiographic non-progressors and increasing change in mTSS) as disease activity worsened, but the overall radiographic progression was very low across all disease states in SB5 or ADL maintenance groups as well as in the ADL/SB5 switch group.

Table 1. Proportion of patients in each disease activity state by DAS28

Time-point	Disease activity state	SB5/SB5 n/n' (%)	ADL overall n/n' (%)	ADL/SB5 n/n' (%)	ADL/ADL n/n' (%)
Week 12	Remission	35/253 (13.8)	36/253 (14.2)	21/124 (16.9)	15/129 (11.6)
	LDA	32/253 (12.6)	35/253 (13.8)	11/124 (8.9)	24/129 (18.6)
	MDA	128/253 (50.6)	116/253 (45.8)	58/124 (46.8)	58/129 (45.0)
	HDA	58/253 (22.9)	66/253 (26.1)	34/124 (27.4)	32/129 (24.8)
Week 24	Remission	55/253 (21.7)	51/254 (20.1)	28/125 (22.4)	23/129 (17.8)
	LDA	28/253 (11.1)	34/254 (13.4)	14/125 (11.2)	20/129 (15.5)
	MDA	144/253 (56.9)	128/254 (50.4)	63/125 (50.4)	65/129 (50.4)
	HDA	26/253 (10.3)	41/254 (16.1)	20/125 (16.0)	21/129 (16.3)
Week 52	Remission	75/247 (30.4)	70/242 (28.9)	34/118 (28.8)	36/124 (29.0)
	LDA	41/247 (16.6)	34/242 (14.0)	18/118 (15.3)	16/124 (12.9)
	MDA	111/247 (44.9)	111/242 (45.9)	53/118 (44.9)	58/124 (46.8)
	HDA	20/247 (8.1)	27/242 (11.2)	13/118 (11.0)	14/124 (11.3)

Disease activity state by DAS28 defined as:

Remission: DAS28 < 2.6; LDA: 2.6  $\leq$  DAS28 < 3.2; MDA: 3.2  $\leq$  DAS28  $\leq$  5.1; HDA: DAS28 > 5.1

Table 2. % of radiographic non-progressors ( $\Delta$  mTSS  $\leq 0$ ) and mean  $\Delta$  mTSS (week 52-baseline) by 12-, 24-, 52-week disease activity states in DAS28

		SB5/SB5		ADL overall		ADL/SB5		ADL/ADL	
		Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change
Week 12	Remission	24/29 (82.8)	-0.31	30/33 (90.9)	0.18	17/19 (89.5)	0.05	13/14 (92.9)	0.34

	MDA	87/110 (79.1)	0.23	77/110 (70.0)	0.35	38/52 (73.1)	0.35	39/58 (67.2)	0.35
	HDA	13/20 (65.0)	1.50	18/26 (69.2)	0.87	9/12 (75.0)	1.21	9/14 (64.3)	0.57

Disease activity state by DAS28 defined as:

Remission: DAS28 < 2.6; LDA: 2.6  $\leq$  DAS28 < 3.2; MDA: 3.2  $\leq$  DAS28  $\leq$  5.1; HDA: DAS28 > 5.1

Results are based on patients with available mTSS at both baseline and week 52

**Conclusion :** The proportion of patients in each disease state was comparable upon treatment with SB5 or ADL. The overall radiographic progression was very low across all treatment groups with the lowest progression generally seen in patients with remission and higher scores seen with increasing disease activity. These data further confirm similar effects on clinical and radiographic status with SB5 and ADL, even after switching occurs.

## Effectiveness and Tolerability of Benepali in Rheumatoid Arthritis Patients Switched from Enbrel

**Sarah Dyball**<sup>1</sup>, Victoria Hoskins<sup>2</sup>, Sharon Christy-Kilner<sup>2</sup> and Sahena Haque<sup>3</sup>, <sup>1</sup>Rheumatology, University Hospitals of South Manchester NHS Foundation Trust, Manchester, United Kingdom, <sup>2</sup>University Hospitals of South Manchester NHS Foundation Trust, Manchester, United Kingdom, <sup>3</sup>Rheumatology department, University Hospitals of South Manchester NHS Foundation Trust, Manchester, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Benepali, the etanercept biosimilar, is licenced in the UK for rheumatoid arthritis (RA) and costs less than Enbrel. This study aimed to evaluate the comparative effectiveness and tolerance of Benepali in RA patients that were switched from Enbrel.

**Methods:** A retrospective observational study design. Data collected from 38 patients with RA who had previously been established on Enbrel and were switched to Benepali with unchanged dosing regimens. Patient's baseline characteristics, DAS-28, CRP, tender joints, swollen joints and global scores were collected before and after the switch from hospital records at a single centre.

Variables were analysed using the Bland-Altman 95% limits of agreement on the estimated mean bias between paired measurements  $\pm 1.96SD$ . Student's paired t-test was used to assess the significance of the mean difference.

**Results:** Patients had a mean age of 59.3 years, 69% were female and 88.5% were seropositive. There were 9/39 that had used a biologic prior to Enbrel.

<b>Table 1:</b> Markers of disease activity in Enbrel and Benepali				
	Enbrel average	Benepali average	Mean difference	P-value
DAS-28 (n=38)	3.08	3.42	+0.35	0.06
CRP (n=38)	7.00	6.95	-0.05	0.98
Tender joints (n=38)	3.10	3.84	+0.74	0.15
Swollen joints (n=38)	1.26	1.5	+0.24	0.54
Patient global health (n=38)	38.6	49.6	+11	0.05

The mean difference in DAS-28, CRP, tender and swollen joints is not statistically significant (Table 1). There was an average increased global score of 11/100 ( $p=0.05$ ) with Benepali. This suggests that the more objective scores were less likely to be affected by the switch to Benepali.

**Figure 1:** Bland-Altman 95% limits of agreement plot of patient's DAS-28 scores

Bland-Altman analysis (Figure 1) shows wide limits of agreement (-1.86 to 2.56), with a small mean difference of 0.348 (95% CI -0.01, 0.71) in DAS-28 scores. This suggests that although majority of patients did not have a significant variation in their DAS-28, there were a number of patients that did significantly better or worse on the Benepali.

Benepali was discontinued 17% of patients (6/36); 4 stopped due to ineffectiveness (all of which were switched back to Enbrel) and 2 stopped due to adverse drug reactions (1 patient developed injection site reactions and switched back to Enbrel, and the other patient developed a rash and had a significant fall in neutrophils and was re-challenged with Benepali).

**Conclusion:** In this RA clinical cohort, objective measures of disease activity were not statistically different for Benepali compared with Enbrel. The switch to Benepali resulted in a drug cost saving of £26400 per annum.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While tumor necrosis factor inhibitors (TNFi) have been proven to reduce progression of structural joint damage in rheumatoid arthritis (RA) in randomized clinical trials, this aspect of effectiveness has not been studied in real world clinical practice. We evaluated the relationship between cumulative exposure to TNFi therapy and progression of joint damage following initiation of TNFi therapy in US Veterans.

**Methods:** Veterans with RA who initiated TNFi use after at least six months of enrollment in Veterans Affairs (VA) health care were eligible for this study. Subjects were US Veterans with VA care between January 1, 2006 and June 30, 2016 with bilateral baseline hand x-rays during the interval between six months prior to and one month after TNFi initiation and follow-up bilateral hand x-rays taken between 10 and 18 months after TNFi initiation. Subjects with non-TNFi biologic drug exposure prior to TNFi initiation or between baseline and follow-up x-rays were excluded. Change in the modified Sharp Score (mSS) on hand radiographs that were interpreted by a single evaluator, blinded to TNFi history and sequence of x-rays, was assessed relative to cumulative TNFi exposure calculated from VA pharmacy data. A worsening of mSS of  $\geq 5$  points was considered clinically significant to account for reader variability. The population fraction with clinically significant change in mSS was explored using marginal structural models (MSM) with inverse probability of treatment weights (IPTW). Bootstrapping was used to compute 95% confidence intervals (CI.) Baseline patient disease characteristics (e.g., age, seropositive status, smoking history, co-morbidities, concurrent medication, and baseline mSS) and time-varying covariates (ESR, C-reactive protein, and prednisone treatment) were deemed potential confounders and included as covariates in the MSM.

**Results:** There were 250 patients from 81 sites enrolled. The population's baseline demographic features were: age  $58 \pm 11$  years, 81% male, 68% positive for rheumatoid factor, and 65% positive for anti-cyclic citrullinated peptide antibody (aCCP). Baseline mSS was  $19.5 \pm 33.2$  (median 8, range 0 to 214). The mean change in mSS was  $0.5 \pm 4.6$  (median 0, range -19 to 45). Increases in cumulative TNFi exposure were associated with decreases in mSS. In comparison to patients with less than one month of TNFi exposure, patients with 12-months of cumulative exposure exhibited less radiographic progression for weighted analysis.

**Conclusion:** While progression of radiographic changes as measured by mSS were small in the first year of use, increased cumulative TNFi exposure was associated with less progression of joint damage in US Veterans. These results demonstrate real-world effectiveness and support the findings of reduced radiographic progression with TNFi therapy reported in randomized clinical trials.

Cumulative treatment months	Percent of patients with $\geq 5$ point change in Modified Sharp Score			
	Crude Model		Adjusted Model	
	Percent with Progression	95% C.I.	Percent with Progression	95% C.I.

## **Comparative Effectiveness of Tocilizumab (TCZ) Monotherapy with Tumor Necrosis Factor Inhibitors (TNFi) in Combination with Varying Doses of Methotrexate (MTX) in Patients with Rheumatoid Arthritis**

**Leslie R Harrold**<sup>1</sup>, George W. Reed<sup>1</sup>, Jennie Best<sup>2</sup>, Steve Zlotnick<sup>2</sup>, Gioia Persuitte<sup>3</sup> and Joel Kremer<sup>4</sup>, <sup>1</sup>University of Massachusetts Medical School, Worcester, MA, <sup>2</sup>Genentech, Inc., South San Francisco, CA, <sup>3</sup>Corrona, LLC, Southborough, MA, <sup>4</sup>Albany Medical College and The Center for Rheumatology, Albany, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Clinical studies have shown that the efficacy of TCZ monotherapy (TCZ mono) is superior to that of TNFi monotherapy and comparable to that of TCZ in combination with MTX. The objective of this study was to compare the effectiveness of TCZ mono vs TNFi plus varying doses of MTX in patients with rheumatoid arthritis (RA) and prior exposure to TNFi in routine clinical practice.

**Methods:** Eligible participants were TCZ-naïve patients from the Corrona RA registry who had prior exposure to  $\geq 1$  TNFi, initiated TCZ mono or a TNFi + MTX between 2010 and 2016 and had a 6-month follow-up visit. The primary outcome was mean change from baseline in Clinical Disease Activity Index (CDAI) at 6 months. Secondary outcomes included achievement of low disease activity (LDA; CDAI  $\leq 10$ ) at 6 months. Patients initiating a TNFi + MTX were grouped by MTX dose ( $\leq 10$  mg;  $> 10$  to  $\leq 15$  mg;  $> 15$  to  $\leq 20$  mg;  $> 20$  mg); outcomes in each group were compared with those initiating TCZ mono using trimmed populations, excluding patients outside the propensity score (PS) distribution overlap (not on common support). The PS included age, sex, race, body mass index, smoking status, work status, disease duration, concomitant prednisone use/dose, prior biologic use, American College of Rheumatology functional class and baseline modified Health Assessment Questionnaire, CDAI and patient pain scores. As a sensitivity analysis, stratified-matched populations were created (stratified by 1 vs  $\geq 2$  prior biologics, then matched on PS). Linear and logistic regression models were estimated in the trimmed populations, adjusting for the same covariates as in the PS.

**Results:** Baseline demographics were generally comparable between the TNFi + MTX groups and their matched TCZ mono groups. Overall, the mean age was 54 to 59 years, and the mean disease duration was 10.5 to 15 years. A higher proportion of patients initiating TCZ mono had received  $\geq 3$  prior biologics compared with those initiating TNFi + MTX. Patients initiating TCZ mono had significantly longer mean disease duration than those initiating TNFi + MTX  $> 15$  to  $\leq 20$  mg (13.0 vs 10.5 years) or TNFi + MTX  $> 20$  mg (12.3 vs 9.3 years) and a higher mean baseline CDAI than those initiating TNFi + MTX  $\leq 10$  mg (28.1 vs 25.4). Patients in all groups had improvement in CDAI scores at 6 months. In adjusted models, improvement in CDAI and the likelihood of achieving LDA were similar between the TCZ mono group and all TNFi + MTX groups (**Table 1**). Similar results were observed in the PS-matched cohorts.

**Conclusion:** TCZ mono was as effective as TNFi + MTX, regardless of MTX dose, for improving disease activity in patients with prior TNFi exposure. These data suggest that TCZ mono is an effective treatment option for patients with RA who cannot tolerate or prefer not to use MTX.

**Table 1.** Disease activity outcomes at 6 months in patients who initiated TCZ mono compared with those who initiated TNFi + MTX.

	Change in CDAI		Achievement of LDA	
	Unadjusted Mean (SD)	Adjusted $\beta$ (95% CI)*	Unadjusted Response Rate, n (%)	Adjusted OR (95% CI)*
TCZ mono (n = 283)	-9.7 (14.6)	—	82 (29)	—
TNFi + MTX $\leq 10$ mg (n = 108)	-7.8 (13.6)	-0.15 (-2.92 to 2.62)	33 (31)	1.22 (0.71 to 2.10)
TCZ mono (n = 300)	-9.6 (14.5)	—	88 (29)	—
TNFi + MTX $> 10$ to $\leq 15$ mg (n = 186)	-9.0 (14.2)	-0.3 (-2.83 to 2.22)	70 (38)	0.94 (0.60 to 1.48)
TCZ mono (n = 292)	-9.6 (14.7)	—	85 (29)	—
TNFi + MTX $> 15$ to $\leq 20$ mg (n = 273)	-6.9 (12.8)	-1.65 (-3.84 to 0.54)	73 (27)	1.4 (0.89 to 2.18)
TCZ mono (n = 285)	-9.7 (14.7)	—	85 (30)	—
TNFi + MTX $> 20$ mg (n = 107)	-8.4 (15.0)	-1.43 (-5.12 to 2.25)	32 (30)	1.26 (0.70 to 2.25)

CDAI, Clinical Disease Activity Index; LDA, low disease activity; MTX, methotrexate; OR, odds ratio; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.

\*TCZ compared with TNFi + MTX. Adjusted for sex, age, race (white vs nonwhite), disabled, retired, baseline CDAI, baseline modified Health Assessment Questionnaire, baseline patient pain scores, baseline prednisone use/dose, baseline body mass index, prior biologic use, prior TNFi use and American College of Rheumatology functional class.

## Comparative Effectiveness of Abatacept Versus TNFi in Patients with RA Who Are CCP+ in the United States Corrona Registry

Leslie R Harrold<sup>1</sup>, Heather J. Litman<sup>2</sup>, SE Connolly<sup>3</sup>, E Alemao<sup>3</sup>, K Price<sup>3</sup>, S Kelly<sup>3</sup>, Sabrina Rebello<sup>4</sup>, W Hua<sup>2</sup> and Joel Kremer<sup>5</sup>, <sup>1</sup>University of Massachusetts, Worcester, MA, <sup>2</sup>Corrona, Southborough, MA, <sup>3</sup>Bristol-Myers Squibb, Princeton, NJ, <sup>4</sup>Corrona, LLC, Southborough, MA, <sup>5</sup>Albany Medical College and The Center for Rheumatology, Albany, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-cyclic citrullinated peptide positivity (CCP+) is associated with a better response to abatacept than anti-CCP negativity in patients with RA<sup>1,2</sup>; however, there are no head-to-head or comparative effectiveness research studies available evaluating responses to biologics in CCP+ patients in a real-world setting. The aim of this study was to compare the effectiveness of abatacept vs a TNF inhibitor (TNFi) in patients with RA who are CCP+. **Methods:** We identified adult patients with RA from a large observational US cohort (Dec 1, 2005–Aug 31, 2016) who initiated abatacept or a TNFi and who were CCP+ ( $\geq 20$  U/mL) at or prior to initiation. Both groups had to have no prior exposure to other non-TNFi biologics or targeted synthetic DMARDs. TNFi initiators were excluded if they had prior use of abatacept. Using propensity score matching (1:1) stratified by prior TNFi use (0, 1 and 2+), effectiveness at 6 months after initiation was evaluated. Mean change in CDAI over 6 months following initiation was the primary outcome and secondary outcomes were: achievement of remission (CDAI  $\leq 2.8$ ), modified (m)ACR20, 50 and 70 responses and achievement of LDA/remission (CDAI  $\leq 10$ ) in those with moderate/high disease activity at initiation. A subset analysis was performed to consider separately patients who were biologic naïve and those who were biologic experienced at initiation.

**Results:** The 330 pairs of propensity score-matched abatacept and TNFi initiators had no substantial differences in baseline characteristics. Both treatment groups had similar mean change in CDAI at 6 months as well as achievement of LDA, remission and mACR20/50/70 responses (Table). Among the 97 matched biologic-naïve pairs, there was no significant difference in change in CDAI for abatacept initiators vs TNFi initiators ( $p=0.19$ ). However, in the 233 matched biologic-experienced pairs, those initiating abatacept had a greater improvement in mean change in CDAI ( $p=0.033$ ) and were more likely to achieve an mACR50 response ( $p=0.014$ ).

**Conclusion:** Patients with RA who were CCP+ and received either abatacept or TNFi had a substantial improvement in clinical disease activity. In the overall propensity score-matched sample, similar outcomes were observed for both treatment groups. However, analysis of the biologic-experienced cohort found that abatacept initiators had a greater improvement in disease activity than TNFi initiators.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

There are unmet needs for patients (pts) suffering from rheumatoid arthritis (RA) in China, where a limited number of anti-TNFs are available.<sup>1, 2</sup> Certolizumab pegol (CZP), with its demonstrated efficacy and safety, would provide an additional option for Chinese RA pts.<sup>3, 4</sup> We report results from RAPID-C, which assessed the efficacy and safety of CZP in combination with methotrexate (MTX) in Chinese pts with active RA and an inadequate response to MTX.

### **Methods:**

RAPID-C (NCT02151851) was a 24-week (wk), phase 3, double-blind, placebo-controlled study conducted in 30 centers across China. Pts with active RA were randomized 3:1 to receive CZP or placebo (PBO), together with MTX. Pts received either loading doses of CZP 400 mg or PBO at Wks 0, 2 and 4, followed by CZP 200 mg or PBO every 2 wks thereafter. The primary endpoint was ACR20 at Wk24, analyzed using logistic regression in the full analysis set (FAS) with non-responder imputation for missing data. Secondary endpoints were ACR50/70 responses and physical function as measured by change from baseline (CFB) in HAQ-DI at Wk24. ACR core components, CRP, DAS28(ESR) and fatigue (measured using BRAF-MDQ) were assessed at selected study visits. CFB in HAQ-DI and other continuous variables were analyzed in the FAS using analysis of covariance with last observation carried forward imputation for missing data. Incidence of treatment-emergent adverse events (TEAEs) and other safety parameters were monitored over the treatment period.

**Results:**

The FAS included 312 CZP+MTX pts and 113 PBO+MTX pts. The demographic and baseline disease characteristics were balanced between treatment arms. Compared with PBO+MTX, a significantly higher percentage of CZP+MTX pts achieved ACR20 response at Wk24 (54.8% vs 23.9%; odds ratio: 3.9,  $p<0.001$ ). Greater improvements in HAQ-DI, higher ACR50/70 responses (Table A) and higher DAS28 remission rates were also observed in CZP+MTX pts at Wk24. Rapid onset of response was observed as early as Wk1 for most efficacy outcomes in CZP+MTX pts. The safety profile of CZP was in line with previous CZP studies (Table B).<sup>3, 4</sup> No new safety signals were identified in this population of Chinese pts.

**Conclusion:**

CZP in combination with MTX has shown an acceptable safety profile, a rapid onset of action and sustained effects in reducing the signs and symptoms of RA and improving physical function in Chinese RA pts with an inadequate response to MTX.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients (pts) with RA may be able to switch from IV to SC abatacept with no loss of efficacy or safety concerns, but data are inconclusive.<sup>1-4</sup> ACTION (AbataCepT In rOutiNe clinical practice; NCT02109666) examined abatacept formulation switching and the impact on clinical efficacy over 2 years. **Methods:** ACTION is a 2-year, prospective, observational study of pts with moderate-to-severe RA who initiated IV abatacept in Europe and Canada between May 2008 and December 2013. Assessments in biologic-naïve and biologic-failure pts were: baseline characteristics, rates of/reasons for switching (IV to SC), re-switching to IV over 2 years and clinical efficacy outcomes in pts who switched. Descriptive data were generated: mean (SD) for continuous variables and n (%) for categorical variables. Rates of switching were estimated by Kaplan–Meier analysis. Owing to low numbers, cohorts were pooled to analyze further pts who switched.

**Results:** In total, 2350/2364 pts (99.4%) were evaluable for this analysis (673 [28.6%] biologic naïve, 1677 [71.4%] biologic failure); 728 (43.4%) biologic-failure pts had received 1, and 949 (56.6%) had received  $\geq 2$  previous biologics. Baseline characteristics in biologic-naïve and biologic-failure pts, respectively, were: mean (SD) age 59.9 (12.7) and 56.9 (12.5) years; mean (SD) RA duration 7.2 (8.22) and 12.1 (9.13) years; 496 (73.7%) and 1379 (82.2%) were women; 621 (92.3%) and 1552 (92.5%) had received prior MTX; and 533 (79.2%) and 1386 (82.6%) had received corticosteroids. Over 2 years, 195 pts switched from IV to SC abatacept (57 biologic naïve, 138 biologic failure; Figure). The primary reason for switch was pt wish (in 28/51 [54.9%] biologic-naïve and 75/121 [62.0%] biologic-failure pts with reason for switch available). Only 8 pts (4.1%) re-switched to IV abatacept (2 biologic naïve, 6 biologic failure). Reasons for re-switch were: pt wish (n=4), lack of efficacy (n=4), safety issue (n=1) and other (n=2). Clinical efficacy outcomes, stratified by prior treatment history, were generally similar at last follow-up before switching from IV to SC abatacept and at last follow-up on SC abatacept treatment (Table).

**Conclusion:** Over 2 years, in real-world clinical practice, of the pts who switched from IV to SC abatacept, less than 5% re-switched from SC abatacept to the IV formulation. No adverse clinical impact was observed following switching from IV to SC abatacept.

## **Methotrexate Discontinuation from Combination Therapy with Adalimumab Is Not Associated with Inferior Outcomes at 6 Months**

**Dimitrios A. Pappas**<sup>1</sup>, Chitra Karki<sup>1</sup>, Ying Shan<sup>1</sup>, Jessica L. Suboticki<sup>2</sup>, Jenny Griffith<sup>3</sup> and Joel Kremer<sup>4</sup>, <sup>1</sup>Corrona, LLC, Southborough, MA, <sup>2</sup>AbbVie Inc., Mettawa, IL, <sup>3</sup>AbbVie Inc., North Chicago, IL, <sup>4</sup>Albany Medical College and The Center for Rheumatology, Albany, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate is frequently administered in combination with biologics for the therapy of Rheumatoid Arthritis (RA) as it leads to superior outcomes compared to biologic monotherapy. However, combination therapy may not be tolerated or may be associated with lower adherence.

**Objective:** To determine whether discontinuation of MTX from the combination regimen with adalimumab (ADA) will lead to inferior outcomes compared to continuation of both medications.

**Methods:** RA patients enrolled in the Corrona Registry who initiated ADA in combination with MTX were included in the analysis. Patients who discontinued MTX (MTX-DC) after at least three months of combination therapy with ADA were compared with patients who continued combination therapy (MTX-C). Baseline characteristics of both groups were described. Patients in the two groups were matched (1:3) using Propensity Scores (PS) on time from initiation to time to MTX discontinuation in the MTX-DC group and for a similar time point in the MTX-C group. Disease activity based on clinical disease activity index (CDAI) and patient reported outcomes (patient pain, fatigue, morning stiffness and disability index measured by modified health assessment questionnaire) were compared 6 months after the discontinuation of MTX and an equivalent time in the combination group. Multivariate regression was used to evaluate the aforementioned outcomes adjusted for statistically significant variables after PS matching.

**Results:** 137 MTX-DC patients were matched with 411 MTX-C patients. MTX-DC patients were more frequently females (82.5% vs 73.2%) and had shorter disease duration (mean±SD: 6.15±7.0 vs 8.03±8.84) compared to the MTX-C group, p<0.05. Baseline disease activity, rates of RF positivity, prior biologic use and concurrent steroid use did not differ between the two groups. Adjusted disease activity improvement outcomes at 6 months did not differ in the two groups; rates of achievement of low disease activity (CDAI≤10) were 39.7% vs 41.6% (p=0.7), minimal clinically important difference (MCID) for CDAI<sup>1</sup> was achieved by 58.6% vs 61.6% (p=0.8) in MTX-C vs MTX-DC respectively. Methotrexate discontinuation was not significantly associated with change in CDAI (Beta-Coefficient, β (95% CI): 0.29 (-1.7 – 2.3). Adjusted patient reported outcomes were similar at 6 months for both groups (Table).

**Conclusion:** Methotrexate discontinuation after at least 3 months of combined therapy with adalimumab was not associated with inferior disease activity and patient reported outcomes after 6 months of discontinuation of MTX.

**Table: Association of MTX discontinuation and change in patient reported outcomes at 6 months post-discontinuation**

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adalimumab (ADA) was approved in the US in 2002 for rheumatoid arthritis (RA), and subsequently approved for the management of other inflammatory diseases such as Crohn's disease, ulcerative colitis, plaque psoriasis, psoriatic arthritis, and ankylosing spondylitis. Expanded use of ADA has resulted in changes to manufacturing processes and production scale, making it important to examine the clinical response to ADA over time. This study aimed to assess the response rate to ADA in patients with RA over the years since its US approval.

**Methods:** Biologic-naïve patients with moderate to severe RA (Clinical Disease Activity Index [CDAI]>10) who initiated ADA during follow-up in the Corrona registry (2003–16) and had a 6-month registry visit (3–9 month window) were included in the study. Six groups were defined based on year of ADA initiation: 2003–05, 2006–07, 2008–09, 2010–11, 2012–13, and 2014–16. Patient characteristics at time of initiation were summarized by group year. Outcomes included percentage of patients with low disease activity (LDA)/remission (CDAI≤10) and modified American College of Rheumatology (mACR)20/50/70 (which do not include acute phase reactants) at 6-month follow-up. Non-response was imputed for patients switching to another biologic prior to 6 months. Chi-square tests were done

to examine differences in response rates by group. Response rates were also compared among groups adjusting for covariates that differed at time of initiation using logistic regression models.

**Results:** Of 23,169 biologic-naïve patients, 1949 initiated ADA, 1056 had baseline CDAI>10, and 820 who had a 6-month follow-up visit were included. In earlier year groups, patients were younger at time of disease onset (44.5 years in 2003–05, 47.1 years in 2006–07, 46.5 years in 2008–09, 51.6 years in 2010–11, 48.3 years in 2012–13 and 51.1 years in 2014–16;  $P=.0001$ ), but had longer disease duration (10.8 years in 2003–05, 8.0 years in 2006–07, 5.9 years in 2008–09, 3.7 years in 2010–11, 4.8 years in 2012–13 and 4.6 years in 2014–16;  $P<.0001$ ) compared with later year groups. At least 2/3 of patients remained on ADA at 6-month follow-up (range: 66% in 2014–16 to 77% in 2003–05). In each group, 43%–52% of patients achieved LDA/remission (Table). No significant differences in mACR20/50/70 rates were seen across groups.

**Conclusion:** No differences in clinical response rates (CDAI and modified ACR20/50/70) to ADA were noted over time among patients with RA in a real-world setting. The findings of this study indicate a consistent clinical response to ADA in RA patients since the market launch of the drug.

Edwards**<sup>1</sup>, Katherine Roshak<sup>2</sup>, Jack F Bukowski<sup>3</sup>, Ronald Pedersen<sup>4</sup>, Mazhar Thakur<sup>5</sup>, Lisa Marshall<sup>2</sup> and Heather Jones<sup>2</sup>, <sup>1</sup>University Hospital Southampton, Southampton, United Kingdom, <sup>2</sup>Inflammation & Immunology Global Medical Affairs, Pfizer, Collegeville, PA, <sup>3</sup>Clinical Affairs, Pfizer, Collegeville, PA, <sup>4</sup>Department of Biostatistics, Pfizer, Collegeville, PA, <sup>5</sup>Pfizer Ltd, Sandwich, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ageing is associated with declining immune cell function and age-related comorbidities.<sup>1,2</sup> In the US, the prevalence of rheumatoid arthritis (RA) is ~2% in individuals  $\geq 65$  y.<sup>3</sup> As life expectancy increases, there is a growing clinical need for data on the efficacy and safety of commonly used treatments in elderly patients with RA. The aim of this study was to compare the efficacy of etanercept (ETN) in patients with RA aged  $<65$  y vs those aged  $\geq 65$  y.

**Methods:** In a post-hoc study, efficacy data from the open-label period of 3 ETN (50 mg QW) studies in patients with RA (Treat-to-Target in Emerging Market RA Patient Populations study [T2T], NCT01578850; PRESERVE, NCT00565409; PRIZE, NCT00913458) were analyzed in 2 cohorts:  $<65$  y and  $\geq 65$  y. Descriptive statistics of 28-joint Disease Activity Score-Erythrocyte Sedimentation Rate (DAS28-ESR) scores, Health Assessment Questionnaire Disability Index (HAQ-DI), and modified total Sharp Scores (mTSS) in observed cases were collated. Least squares means were calculated and *P*-values were from F-tests from an analysis of covariance models testing the age group effect with baseline as covariate.

**Results:** Mean baseline DAS28-ESR and HAQ-DI scores were marginally higher in patients  $\geq 65$  y vs  $<65$  y (Table 1). Mean changes from baseline (Table 2) in DAS28-ESR scores showed no consistent trend, i.e., both higher and lower changes were observed at different times in patients  $\geq 65$  y vs  $<65$  y. Mean HAQ-DI scores were higher in patients  $\geq 65$  y vs  $<65$  y, and the mean changes from baseline were either similar or marginally smaller in patients  $\geq 65$  y vs  $<65$  y. mTSS were also found to be higher in patients  $\geq 65$  y vs  $<65$  y, whereas the mean changes from baseline showed only marginal differences for patients  $\geq 65$  y vs  $<65$  y. The smaller number of patients in the  $\geq 65$  y cohort compared with the  $<65$  y cohort was a study limitation.

**Conclusion:** There were no substantial differences in efficacy for ETN-treated patients  $\geq 65$  y vs  $<65$  y.

## **Disease Flares Among Early Rheumatoid Arthritis Patients Treated with Continued Methotrexate Either Alone or in Combination with Adalimumab (Humira)**

Arthur Kavanaugh<sup>1</sup>, Ronald F van Vollenhoven<sup>2</sup>, Prashanth Sunkureddi<sup>3</sup>, Ying Zhang<sup>4</sup>, Jessica L. Suboticki<sup>5</sup> and Josef S. Smolen<sup>6</sup>, <sup>1</sup>Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, CA, <sup>2</sup>Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands, <sup>3</sup>University of Texas Medical Branch, Galveston, TX, <sup>4</sup>AbbVie Inc., North Chicago, IL, <sup>5</sup>AbbVie Inc., Mettawa, IL, <sup>6</sup>Division of Rheumatology, Department of Medicine, Medical University of Vienna, and Hietzing Hospital, Vienna, Austria

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Some rheumatoid arthritis (RA) patients (pts) may experience flares in their disease even after reaching stable low disease activity (sLDA), but the consequences of even temporary elevations in disease activity are poorly understood. The purpose of this analysis was to explore the rates of flares after reaching sLDA in pts treated to target with either methotrexate (MTX) monotherapy or adalimumab combination therapy (ADA+MTX).

**Methods :** This post hoc analysis included pts from the randomized, double-blind, double-period OPTIMA<sup>1</sup> trial achieving sLDA [DAS28(CRP) <3.2 at weeks (wks) 22 and 26] at the end of period 1 (P1). In P1, pts were randomized to receive ADA+MTX or placebo (PBO)+MTX for 26 wks. Pts on ADA+MTX achieving sLDA were randomized to receive PBO+MTX (ADA Withdrawal) or continue on ADA+MTX (ADA Continuation) for an additional 52 wks in period 2 (P2). Pts who achieved sLDA on PBO+MTX in P1 continued their treatment in P2 (MTX Continuation). Pts achieving sLDA in each treatment group were categorized based on whether they experienced a flare [change in DAS28(CRP) ≥0.6 at consecutive visits and DAS28(CRP) ≥3.2]; the proportion of pts experiencing flares and time to flare were assessed. For each group, mean change from wk 26 to wk 78 in disease activity [DAS28(CRP)], functional (HAQ-DI) and structural (mTSS) measures were analyzed.

**Results :** In pts achieving sLDA at the end of P1, flare rates in P2 differed based on initial treatment assignment (ADA Continuation: 11.7% [11/94]; MTX Continuation: 22.4% [22/98]). Interestingly, flare rates in pts randomized to withdraw ADA in P2 (ADA Withdrawal: 25% [22/88]) were numerically similar to the MTX Continuation group. The mean time to flare was 193, 191, and 177 days in the ADA Withdrawal, ADA Continuation, and MTX Continuation

groups, respectively. During P2, the mean DAS28(CRP) scores were predictably higher in pts who flared compared with those who did not across treatment groups. In pts experiencing flares in P2, disease activity and functional measures worsened from wk 26 to wk 78 as compared with pts without flares (**Table**). Of the individual DAS28(CRP) components, pt global assessment of disease activity (PtGA) showed the greatest worsening. There were small differences in radiographic progression between pts experiencing flares compared with pts without flares.

**Conclusion :** In early RA pts achieving sLDA, flares were generally infrequent; however, they were more prevalent in pts receiving PBO+MTX compared with ADA+MTX. Flares were numerically associated with higher disease activity, functional deterioration, and higher PtGA, underscoring its impact on health-related quality of life and the importance of preventing flares as a therapeutic outcome.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The MONARCH study (NCT02332590) evaluated monotherapy with sarilumab 200 mg subcutaneous (SC) + placebo every 2 weeks (Q2W) versus adalimumab 40 mg SC + placebo Q2W in RA patients who were either intolerant of, inadequate responders to, or considered inappropriate candidates for continued treatment with methotrexate. The dose regimen could be changed to once weekly (qw) administration of adalimumab or matching placebo in the sarilumab group. This analysis examined 24-week per-patient drug costs (2017 US, wholesale acquisition) associated with effective treatment, based on outcomes from MONARCH.

**Methods:** The endpoint of effective treatment at 24 weeks was defined on three outcomes: ACR20, ACR50, and EULAR Moderate/Good (DAS28-ESR 0.6+ improvement). Cost per responder for each outcome was calculated in addition to incremental cost per effectively treated patient (difference in 24-week drug cost multiplied by the number needed to treat [NNT]) for sarilumab compared with adalimumab, with adalimumab costs based on the Q2W 40mg dose. One-way sensitivity analyses were conducted by varying the odds ratio of response rates for sarilumab on the three outcomes to the upper and lower bounds of their 95% confidence intervals, by increasing and decreasing sarilumab costs by 10%, and by varying the adalimumab cost based on a weighted average of patient proportions with dosing adjustments.

**Results:** The ITT population included 184 and 185 patients in the sarilumab and adalimumab arms, respectively. Estimated NNTs for sarilumab on ACR20, ACR50 and EULAR DAS28-ESR were 7.5, 6.3 and 7.5, respectively. Based on 24-week drug costs of \$18,000 for sarilumab 200mg SC Q2W and \$26,647 for adalimumab 40 mg SC Q2W, costs per responder for sarilumab versus adalimumab, respectively, were \$25,105 versus \$45,629 on ACR20; \$39,387 versus \$89,722 on ACR50; and \$21,378 versus \$37,584 on EULAR DAS28-ESR. Sarilumab was consistently the more effective and cost-saving treatment on all outcomes of incremental cost per effectively treated patient.

**Conclusion:** Sarilumab versus adalimumab was the economically dominant treatment with respect to incremental cost per effectively treated patient. Given the higher levels of responses on ACR20, ACR50 and 0.6 EULAR DAS25-ESR, coupled with the lower 24-week drug costs, sarilumab across all analyses was the favourable treatment in terms of cost per responder. These results were maintained within the sensitivity analyses.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In early rheumatoid arthritis (RA), starting therapy as soon as possible is important to reduce disease activity and preserve the joints. With application of biological disease modifying anti-rheumatic drugs (DMARDs), a remarkable gain is achieved in prevention of joint damage. Although with initiation of methotrexate (MTX) as only DMARD many patients achieve the treatment target of clinical remission, a large proportion (~30%) of them still shows radiographic progression as a result of ongoing subclinical inflammation. The aim of this study was to analyze whether tocilizumab (TCZ) in DMARD-naïve patients with early RA would result in significantly less joint damage when compared to a step-up methotrexate-based strategy and whether this would involve erosions and/or joint space narrowing (JSN) scores.

**Methods:** In U-Act-Early, patients initiated TCZ plus MTX, TCZ, or MTX therapy and were treated to target until sustained remission (defined as disease activity score assessing 28 joints (DAS28) <2.6 with ≤4 swollen joints for ≥24 weeks) was achieved. If no remission, hydroxychloroquine was added. Hereafter, if the target still was not achieved, the initial strategy ended and the subsequent strategy started; patients randomized to the TCZ or MTX arm switched to TCZ+MTX therapy. Those who initially started with this combination therapy switched to the standard of care (e.g. MTX combined with a tumor necrosis factor inhibitor). If sustained remission was achieved, medication was tapered and stopped. The Sharp-van der Heijde score (SHS) was used to evaluate radiographic progression; erosion and joint space narrowing (JSN) scores were also assessed separately. Furthermore, a computerized method was used to confirm the findings in JSN in the hand as evaluated by the SHS. Non-parametric testing was used to evaluate between-group differences as damage scores were not normally distributed.

**Results:** In total, 317 DMARD-naïve patients with early RA were randomized; 106 to the TCZ+MTX arm, 103 to the TCZ arm, and 108 to the MTX arm (Table). For changes from baseline in SHS, significantly lower scores when

compared to the MTX arm were found in the TCZ+MTX arm after 52 weeks ( $p=0.02$ ); after 104 weeks the difference compared with the MTX arm was significant for both TCZ strategies (TCZ+MTX,  $p=0.02$ ; TCZ,  $p=0.04$ ). For erosions, significant between-group differences were noted after 104 weeks in favor of the TCZ strategies (TCZ+MTX vs. MTX,  $p=0.02$ ; TCZ vs MTX,  $p=0.02$ ). However, for JSN, no significant differences were found between the strategies during follow-up ( $p\geq 0.20$ ), which was in accordance with the findings of the computerized method ( $p\geq 0.09$ ) and data from literature.

**Conclusion:** Initiation of a tocilizumab-based strategy in DMARD-naïve patients with early RA results in significantly less progression of erosive radiographic joint damage when compared to a step-up methotrexate-based strategy, improving long-term clinical outcome.

## Incidence of Disease Worsening in Inflammatory Arthritis Patients on Long-Term Infliximab (Remicade®) Therapy

A Marilise Marrache<sup>1</sup>, Allen J Lehman<sup>1</sup>, Brendan Osborne<sup>1</sup>, Eliafotisti Psaradellis<sup>2</sup>, Julie Vaillancourt<sup>2</sup>, Emmanouil Rampakakis<sup>2</sup> and Francois Nantel<sup>1</sup>, <sup>1</sup>Medical Affairs, Janssen Inc., Toronto, ON, Canada, <sup>2</sup>JSS Medical Research, Montreal, QC, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A recent randomized controlled study in a single country reported rates of disease worsening over a one-year follow-up period for innovator infliximab (IFX) and a comparator in various diseases including AS and RA. After a mean duration of treatment of 6.7 years of IFX, rates for disease worsening post-one year follow-up were 39.5% in AS and 36.7% in RA<sup>1</sup>. Other such data reporting disease worsening rates are rare. Using data from a longitudinal database, the objective was to determine the incidence of disease worsening in AS and RA patients on long-term therapy with IFX. PsA patients were not included in this study due to low numbers (n=49).

**Methods:** BioTRAC is an ongoing, prospective registry of inflammatory arthritis patients initiating treatment with infliximab, golimumab or ustekinumab that has been ongoing since 2002 in Canada. We included AS and RA patients who had been on IFX therapy for at least two, four or six years. Disease worsening endpoint was defined as follows<sup>1</sup>: for AS patients; an increase in ASDAS  $\geq 1.1$  from baseline and a minimum score of 2.1. For RA patients; an increase in DAS28  $\geq 1.2$  from baseline and a minimum score of 3.2.

**Results:** This analysis included a total of 196 AS and 425 RA patients. Among AS patients, 36.1% were female, 90.8% were bionative at IFX initiation and 50% were on concomitant NSAID(s) at the 2-year index. The mean (SD) ASDAS score was 2.17 (1.05). As for the RA patients, 75% were female, 88.5% were bio-naïve, and 93% were on concomitant DMARD(s) while 35% were on corticosteroids at the 2-year index. The mean (SD) DAS28 ESR and DAS 28 CRP were 3.37 (1.40) and 3.00 (1.24), respectively. As shown in table 1, the incidence of disease worsening in AS and RA patients on stable IFX for 2-6 years was low and varied from 2.7% to 11.5% at the subsequent 12 and 24 months visit.

**Conclusion:** In this prospective longitudinal cohort, patients on long-term IFX therapy show low rates of disease worsening of 2.7% to 11.5% at 1 and 2 years in AS and RA. Additional studies may elucidate the true rate of and reasons for disease worsening in rheumatologic populations.

**Table 1.** Incidence of disease worsening in AS and RA patients at the 2, 4, and 6-year index

Disease	Outcome	Index date post IFX initiation	Disease worsening at subsequent visits	
			n/N (%)	
			12 months	24 months
AS	ASDAS	2 years	9/79 (11.4%)	6/59 (10.2%)
		4 years	2/42 (4.8%)	1/37 (2.7%)
		6 years	1/25 (4.0%)	2/18 (11.1%)
RA	DAS28 ESR	2 years	20/184 (10.9%)	17/148 (11.5%)
		4 years	9/121 (7.4%)	7/106 (6.7%)
		6 years	8/73 (11.0%)	5/47 (10.6%)
	DAS28 CRP	2 years	16/160 (10.0%)	11/124 (8.9%)
		4 years	8/115 (7.0 %)	6/104 (5.9%)
		6 years	6/80 (7.5%)	4/54 (7.4%)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) often receive methotrexate (MTX) in combination with biologics; however, MTX may be discontinued due to intolerance or to reduce the medication burden once disease control is achieved. Whereas previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO) for the treatment of RA,<sup>1,2</sup> patient-reported outcomes (PROs) after MTX withdrawal in patients

achieving good clinical response to TCZ + MTX have not been evaluated. PROs are important measures when determining response to therapy in patients with RA with respect to health-related quality of life (HRQOL).<sup>3,4</sup> This study evaluated PROs between patients with RA who achieved low disease activity with TCZ + MTX and then continued or discontinued MTX in the COMP-ACT trial (NCT01855789).

**Methods:** US patients with RA who were inadequate responders to MTX were enrolled; initial combination therapy included MTX ( $\geq 15$  mg/week orally) plus TCZ 162 mg subcutaneous either weekly (qw) or every 2 weeks (q2w). Patients who achieved DAS28-ESR  $\leq 3.2$  at Week 24 were randomized 1:1 to receive TCZ-MONO or continue TCZ + MTX until week 52 (double-blind). Changes in PRO scores were measured between Week 24 and Weeks 40 and 52, and included patient global assessment of disease activity (PtGA; visual analog score [VAS], 0-100 mm), pain (VAS), Health Assessment Questionnaire Disability Index (HAQ-DI, 0-3) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue.

**Results:** Of the 296 randomized patients (TCZ + MTX, n = 148; TCZ-MONO, n = 148), 74.8% were women, mean age was 55.5 years, mean RA duration was 6.8 years and mean DAS28-ESR was 6.3 at baseline. At Week 24 (randomization), PRO scores were similar between the randomized treatment groups. The mean changes in PtGA, pain, HAQ-DI and FACIT-fatigue scores from Week 24 to Weeks 40 were similar between the TCZ + MTX and TCZ-MONO groups (Table). The proportion of patients with HAQ-DI  $< 0.5$  was similar between the groups at Week 24 (randomization), and remained similar at Weeks 40 and 52.

**Conclusion:** Patients receiving TCZ who discontinue MTX appear to have similar PROs across multiple measures compared with patients continuing TCZ + MTX. Differences observed in clinical parameters between TCZ-MONO and TCZ + MTX did not appear to achieve a threshold that would be considered clinically meaningful. Similarities in PROs on both treatments were consistent with the clinical efficacy measures previously reported from COMP-ACT.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** High body mass index (BMI) is known to be associated with inadequate clinical response to anti-TNF agents in RA patients.<sup>1</sup> However, there are limited data on how high BMI affects the response to rituximab in RA patients with an inadequate response or intolerance to anti-TNF agents. The objective is to investigate the impact of BMI on clinical response in the post-hoc analysis of Phase 3 randomized controlled trial comparing CT-P10 and reference rituximab, RTX<sup>2</sup> (NCT02149121).

**Methods:** A total of 332 patients who received 2 cycles of either CT-P10 or RTX at weeks 0 and 24 were included in this analysis. Patients were classified into 3 groups; normal weight (<25kg/m<sup>2</sup>), overweight (25 kg/m<sup>2</sup>~30 kg/m<sup>2</sup>) and obesity (>=30 kg/m<sup>2</sup>) as per WHO BMI category. Improvement in disease activity by the DAS28-CRP, remission (<=2.6), low disease activity rate (LDA, <=3.2), ACR response at Week 24 and Week 48 and duration of sustained LDA (from the first LDA observed to the last LDA observed up to Week 48) were analysed by BMI categories in the each and combined group of CT-P10 and RTX.

**Results:** In the pooled group of CT-P10 and RTX, the mean weights were 59kg in normal weight, 73kg in overweight and 91kg in obesity subgroups. All other baseline characteristics were comparable among BMI groups including baseline disease activity based on DAS28; Moderate, 22.3% vs. 22.8% vs. 25.7%, respectively; High, 77.7% vs. 77.2% vs. 74.3%, respectively. Mean change of DAS28 from baseline (Figure 1), ACR response rate (Figure 2) and rate of remission and LDA for DAS28 (Figure 3) were comparable among BMI groups and there were no statistical significant difference (p>0.05). No association was shown between DAS28 improvement and BMI (p>0.05). Mean duration of sustained LDA (months) for DAS28 were also comparable among the groups (5.1 vs. 5.2 vs. 5.6, respectively). Additionally, similar trends in all analyses were observed in each treatment group; CT-P10 and RTX.

**Conclusion:** The impact of BMI on the clinical response to rituximab treatment was not significant in RA patients. Therefore, these results support that rituximab could be a reasonable therapeutic option for obese RA patients with inadequate response to anti-TNF agents.

### Background/Purpose:

Current guidelines on RA treatment recommend tapering of biologic DMARDs for patients in persistent remission.

### Methods:

In this retrospective study we used the hospital administrative database to identify patients with a diagnosis of RA and a first time prescription of a biologic DMARD that was specifically limited to one of the 3 TNF inhibitors (etanercept, adalimumab, infliximab) between January 2012 and the end of December 2013. Patient demographics and information on treatment and outcome were retrieved from the medical charts.

## Results:

Of the 125 patients identified at the database search, 104 were registered in our clinic and had available follow-up until June 2016. Seventy-nine (76%) were women and 25 (24%) were men. Their mean age was  $47.7 \pm 13$  SD years and their mean disease duration was  $7.4 \pm 6.9$  SD years. The distribution of the prescribed TNF inhibitors was: Etanercept = 60%, Adalimumab = 23% and Infliximab = 17%. After a mean duration of  $14.0 \pm 7.6$  SD months tapering of TNF inhibitors was made in 44 patients (42%). This was in the form of spacing in 39 patients (Etanercept = 16, Infliximab = 14, Adalimumab = 9) and dose reduction in 5 (all Etanercept). All of these were due to good clinical response except for 1 patient's own request because of fear from possible adverse effects. Increased disease activity after tapering was seen in 16 patients (36%) mandating restoration of original dose schedule within a mean of  $8.8 \pm 9.7$  SD months with good response in all. On the other hand 28 patients (64%) preserved their good clinical response during a mean follow-up of  $46.1 \pm 6.3$  SD months which enabled further tapering in 20 of them. There was also reductions in the mean number of synthetic DMARD's ( $1.4 \pm 0.8$  SD at the initiation of TNF inhibitors and  $0.7 \pm 0.8$  SD at the end of follow-up) and in the percentage of patients using steroids (78% vs 33%). At the end of the follow-up, among the whole group of 104 patients, only 73 (70%) were using biologics (TNF inhibitors = 49, non-TNF biologics = 24). The reasons for stopping biologics in the remaining 31 patients were ongoing remission (16 patients; 15%), pregnancy (1 patient), non-compliance (4 patients), injection site reactions (3 patients), fear from adverse events (1 patient), decision for complementary medicine (1 patient) and other issues such as losing insurance and family issues (5 patients).

## Conclusion:

Tapering of TNF inhibitors was possible in 40% of RA patients during follow-up. One third of the patients flared after tapering whereas the remaining two thirds maintained their good outcome allowing cessation in 15%. Further studies are needed to identify factors predicting successful tapering.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Golimumab (GLM) has demonstrated efficacy and safety in several randomized clinical trials with biologic-naïve patients (pts.).

However, more data regarding the effectiveness and patient-reported outcomes (PROs) parameters in daily clinical practice in Germany are required and helpful.

The aim of this subanalysis is to assess Golimumab on the effectiveness and PROs in biologic-naïve pts. with established RA, PsA or AS.

### **Methods:**

Subanalysis of the non-interventional, prospective, 24-month study GO-NICE with biologic-naïve pts. with established RA, PsA or AS starting with GLM 50mg SC once monthly in a real life setting in Germany. Endpoint measures: disease activity DAS28, PsARC and BASDAI. PROs included QoL (EQ-5D-3L), functionality (FFbH), and fatigue (FACIT-F). Safety data were also collected.

### **Results:**

RA-pts. (n=265): Mean age 54.5 yr, 82.1% of the pts. were female, 77.3% (n=204) were rheumatoid factor (RF) positive, and 76.4% (n=201) had anti ccp-antibodies at BL. The DAS28 score at BL was 5.0 and dropped significantly to 2.9 within 24 months ( $p<0.0001$  v. BL). After 3 months of treatment, 45.2% of pts. had LDA (DAS28  $\leq 3.2$ ). The amount of pts. increased to 50.8% after 6 month and 64.9% after 24 months.

PsA-pts. (n=247): Mean age 49.7 yr, 53.8% of the pts. were female, 42.1% (n=104) had a nail involvement, 25.5% (n=63) dactylitis and 13.8% (n=34) enthesitis at BL. The proportion of pts. achieving a response (mod PsARC) was 64%, 72.2% and 77.7% at 3, 6 and 24 months, respectively.

AS-pts. (n=246): Mean age 41.9 yr, 70.7% of the pts. were male, 80.5% (n=198) were HLAB27 positiv. Most common extra-articular manifestations were: enthesitis (12.6%), iritis (12.2%), IBD (3.7%), and dactylitis (2.8%) at BL. The BASDAI at BL was 5.0 and dropped significantly to 2.0 within 24 months ( $p<0.0001$  vs. BL). The proportion of pts. achieving a response (BASDAI 50) was 62.2%, 66.9% and 76.9% at 3, 6 and 24 months, respectively. An improvement of quality of life (QoL) by EQ-5D-3L was seen after 6 months and was maintained over 24 months. The pts.' health state today (EQ VAS) improved from 52.3 at BL to 64.9 (RA), from 49.0 to 66.3 (PsA) and from 49.2 to 70.6 (AS). The functional ability (FFbH) improved significantly ( $p<0.0001$  vs. BL) from 73.1 to 80.4 points (RA), from 73.0 to 82.2 (PsA), and from 72.8 to 81.2 (AS). The mean Fatigue score (FACIT-F) increased from BL to visit 9 (month 24) 33.3 to 39.5 points (RA), from 31.6 to 38.4 points (PsA), and from 31.6 to 40.2 points (AS) (each  $p<0.001$  vs BL). No new safety signals were detected.

### **Conclusion:**

Across the three rheumatic diseases (RA, PsA, AS) in biologic-naïve pts. GLM SC once monthly showed remarkable improvements in clinical effectiveness, patient-reported quality of life, functionality, and fatigue parameters within 3 months.

These effects were maintained over 24 months: 64.9% of RA-pts. achieved LDA status, 77.7% of PsA-pts. a positive PsARC response and 76.9% of AS-pts. BASDAI 50. No new safety signals were detected.

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

It has been proven, in a pivotal RCT, that SC TCZ was non-inferior to IV TCZ [1]. However, the effectiveness of the SC TCZ formulation has not been evaluated in “real life”.

The objective was to describe the effectiveness and the characteristics of RA patients switching from IV to SC TCZ formulation in current practice.

### **Methods:**

We analysed all the RA patients of the shared medical file “RIC Nord de France” with at least 1 DAS 3 months before inclusion, treated with TCZ, switching or not from IV to SC TCZ, between April 30th 2015 and January 15th 2016. The primary efficacy endpoint was the proportion of patients remaining in their DAS28-ESR category remission/LDA or moving to an inferior DAS28-ESR category at 24 weeks (W24). DAS28-ESR was calculated at inclusion and at W24 for switch patients (IV-SC) and for non-switch patients (IV-IV). Permanent discontinuation of TCZ before W24 was considered as failure.

### **Results:**

From the 263 patients included, 30% switched from IV to SC TCZ.

At baseline, there were 77.6% females, mean BMI was 27.46±6.40, and mean RA duration was 15.11±9.38 years in the whole population. Mean IV TCZ duration before inclusion was 35.2±24.3 months in switch and 24.7±22.1 months in

non-switch patients. 51.1% of the switch patients were treated in monotherapy, 49.1% in the non-switch group. Mean DAS28-ESR were  $2.23 \pm 1.16$  in the switch and  $3.07 \pm 1.70$  in the non-switch patients. 79.3% of the switch patients were in DAS28-ESR category remission or LDA, and 20.7% in MDA. 53.8% of the non-switch patients were in DAS28-ESR category remission or LDA, 33.3% in MDA, and 12.9% in HDA.

At W24, 73.9% (CI<sub>95%</sub>=[63.4% - 82.7%]) of the switch patients, and 72% (CI<sub>95%</sub>=[64.4% - 78.8%]) of the non-switch patients stayed in DAS28-ESR category remission/LDA or move to an inferior DAS28-ESR category (Table).

Table: DAS28-ESR at W24

		Switch N=92	No switch N=171	All N=263
Primary criterion: patients moving to a fewer DAS28 category (or staying in the category LDA/remission) with imputation *	N	88	161	249
	Missing	4	10	14
	No	23 (26.1%) [ 17.3% - 36.6%]	45 (28.0%) [ 21.2% - 35.6%]	68 (27.3%) [ 21.9% - 33.3%]
	Yes	65 (73.9%) [ 63.4% - 82.7%]	116 (72.0%) [ 64.4% - 78.8%]	181 (72.7%) [ 66.7% - 78.1%]

\*Permanent discontinuation of treatment was considered as failure

## Conclusion:

In that “real life” population, the proportion of RA patients treated with TCZ in remission or LDA remains similar at W24 for switch patients (IV-SC) and for non-switch patients (IV-IV). Proportions of patients moving to an inferior DAS category were also comparable in both groups. Switch patients appear to have less active disease at baseline. Factors associated to switch will be investigated.

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is recommended and widely prescribed as the first-line, evidence-based therapy for rheumatoid arthritis (RA) patients. Previous studies have demonstrated a significant effect of MTX on biologic therapy; however, these were mainly conducted on bio-naïve patients. The aim of the present study was to evaluate the association of the concomitant use of MTX with efficacy of biologics in RA patients who switched to second-line biologics in a real-world clinical practice setting.

**Methods:** This study included patients enrolled in the Tsurumi Biologic Communication Registry. RA first-time switchers were eligible for inclusion. To assess the working hypothesis that combination therapy is superior to biologic monotherapy, the primary outcome measure was defined as a change in DAS28-ESR at 24 weeks. Multiple linear regression analysis adjusted for covariates was employed. Additionally, multiple imputation analysis was performed to provide missing data. Excluding individuals with missing data, known as listwise deletion, may yield biased estimates. All analyses were conducted in EZR version 1.35 and the package mice for the multiple imputation.

**Results:** Using linear multivariate regression models, we identified a significant association of the use of MTX with the treatment efficacy of second-line biologics (Table 1). This association did not differ between patients using TNF inhibitors and those using non-TNF inhibitors (Table 2). In the present study, the results from the multiple imputation analysis were consistent with those from the complete case analysis (Table 3).

**Conclusion:** In our multicenter study using a multiple imputation method, concomitant MTX was found to be associated with an improved second-line biologic therapy in a non-trial, real-world clinical practice setting.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Based on the totality of evidence, SB2 has shown to be similar with reference infliximab (INF) and has been approved as a biosimilar by the European Medical Agency and U.S. Food and Drug Administration. It is, however, hitherto unknown, if SB2 also shares similar structural efficacy in the different disease activity states when compared with INF. The objective of this study is to evaluate the disease activity by simplified disease activity index (SDAI) and clinical disease activity index (CDAI) at weeks 14, 30 and 54 in patients with rheumatoid arthritis (RA) treated with SB2 or INF from a phase III study and to assess the radiographic progression at week 54 in patients by disease activity states (remission, low disease activity [LDA], moderate disease activity [MDA], or high disease activity [HDA]).

**Methods:** Patients with RA were randomized to receive either SB2 or INF 3 mg/kg at weeks 0, 2, 6, and then every 8 weeks thereafter until week 46 with background methotrexate. Dose increments were allowed after week 30 by 1.5 mg/kg up to a maximum dose of 7.5 mg/kg. Disease activities by SDAI, and CDAI were compared at weeks 14, 30, and 54. The radiographic progression was measured by modified Total Sharp Score (mTSS) at weeks 0 and 54.

**Results:** Up to week 54, comparable proportions of patients achieved ACR-EULAR-index remission between SB2 and INF (by SDAI: 13/279 [4.7%] vs. 13/283 [4.6%] at week 14; 24/250 [9.6%] vs. 29/263 [11.0%] at week 30; 34/226 [15.0%] vs. 24/224 [10.7%] at week 54; by CDAI: 12/279 [4.3%] vs. 12/283 [4.2%] at week 14; 22/253 [8.7%] vs.

31/265 [11.7%] at week 30; 33/227 [14.5%] vs. 24/225 [10.7%] at week 54 in SB2 and INF, respectively). The proportions of radiographic non-progressors (defined as change in mTSS  $\leq 0$ ) by disease activity were comparable between SB2 and INF at week 14, 30 and 54 (Table 1). Patients treated with SB2 as well as INF also exhibited the lowest progression of radiographic damage in remission and the largest progression in HDA, but also very small increases in mTSS in LDA and MDA, in line with previous findings on INF.

Table 1. The proportion of radiographic non-progressors (mTSS progression  $\leq 0$ ) and mean change from baseline in mTSS at week 54 by disease activity states at weeks 14, 30, and 54

Disease activity state at each visit		CDAI				SDAI			
		SB2		INF		SB2		INF	
		Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change
Week 14	HDA	43/62 (69.4)	0.44	42/59 (71.2)	0.61	25/41 (61.0)	0.80	31/45 (68.9)	1.03
	MDA	64/86 (74.4)	0.27	57/82 (69.5)	0.64	81/105 (77.1)	0.10	63/89 (70.8)	0.45
	LDA	43/56 (76.8)	0.54	49/58 (84.5)	-0.38	44/58 (75.9)	0.63	53/64 (82.8)	-0.27
	Remission	7/9 (77.8)	0.17	6/8 (75.0)	1.44	7/9 (77.8)	0.17	7/9 (77.8)	1.00
Week 30	HDA	29/43 (67.4)	0.93	33/47 (70.2)	1.20	25/37 (67.6)	0.79	24/33 (72.7)	1.32
	MDA	57/76 (75.0)	0.14	49/71 (69.0)	0.43	59/80 (73.8)	0.24	58/84 (69.0)	0.54
	LDA	55/74 (74.3)	0.40	52/67 (77.6)	-0.10	56/74 (75.7)	0.42	54/69 (78.3)	-0.23
	Remission	16/20 (80.0)	0.05	22/24 (91.7)	-0.13	17/21 (81.0)	0.07	20/22 (90.9)	0.07
Week 54	HDA	31/43 (72.1)	0.39	25/42 (59.5)	1.59	25/36 (69.4)	0.65	23/36 (63.9)	1.71
	MDA	47/69 (68.1)	0.69	46/66 (69.7)	0.30	50/73 (68.5)	0.57	44/68 (64.7)	0.35
	LDA	51/67 (76.1)	0.20	62/78 (79.5)	0.29	54/69 (78.3)	0.18	66/82 (80.5)	0.24
	Remission	28/33 (84.8)	-0.11	23/23 (100.0)	-1.39	27/33 (81.8)	-0.08	23/23 (100.0)	-1.22

Disease activity was defined as following:  
CDAI remission: CDAI  $\leq 2.8$ ; LDA:  $2.8 < \text{CDAI} \leq 10.0$ ; MDA:  $10 < \text{CDAI} \leq 22.0$ ; HDA: CDAI  $> 22.0$   
SDAI remission: SDAI  $\leq 3.3$ ; LDA:  $3.3 < \text{SDAI} \leq 11.0$ ; MDA:  $11 < \text{SDAI} \leq 26.0$ ; HDA: SDAI  $> 26.0$   
Patients with available mTSS at both baseline and week 54 were included

**Conclusion:** The proportion of patients achieving remission or LDA was comparable up to week 54 upon treatment with both SB2 and INF. Inhibition of radiographic progression was also comparable in each disease activity state. The proportion of radiographic non-progressors was also similarly high in patients achieving remission, and overall very low radiographic progression rates were seen even in LDA and MDA in both treatment arms. These data further confirm the comparability of SB2 and INF.

# Evaluation of Radiographic Progression By Disease Activity States in Patients with Rheumatoid Arthritis Treated with SB4 or Reference Etanercept: Results from a Phase III Study

**Paul Emery**<sup>1</sup>, Jiri Vencovsky<sup>2</sup>, Jeehoon Ghil<sup>3</sup>, Soo Yeon Cheong<sup>3</sup> and Evelyn Hong<sup>3</sup>, <sup>1</sup>NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, <sup>2</sup>Institute of Rheumatology, Deartment of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, <sup>3</sup>Samsung Bioepis Co., Ltd., Incheon, Korea, Republic of (South)

**First publication:** September 18, 2017

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** SB4 has been approved as a biosimilar of the reference etanercept by the European Commission. **Results** including one year radiographic progression from the pivotal phase III equivalence study have been previously presented. In this report, the radiographic progression will be further evaluated by different disease activity states in terms of disease activity score by 28 joint count (DAS28) based on erythrocyte sedimentation rate (ESR), simplified disease activity index (SDAI) and clinical disease activity index (CDAI).

**Methods :** Patients with rheumatoid arthritis (RA) were randomly assigned to receive weekly dose of 50 mg SB4 or ETN for 52 weeks. The proportions of patients achieving remission, low disease activity (LDA), moderate disease activity (MDA), or high disease activity (HDA) in terms of DAS28, SDAI, and CDAI were compared at weeks 12, 24, and 52. Radiographic progression was evaluated using the modified Total Sharp Score (mTSS) at weeks 0 and 52.

**Results:** The proportion of patients with remission, LDA, MDA, or HDA was generally comparable between SB4 and ETN at weeks 12, 24, and 52 for different disease activity indices (DAS28, SDAI, CDAI) (Table 1). The proportions of radiographic non-progressors (defined as change in mTSS  $\hat{=}$  0) were comparable between SB4 and ETN in each disease activity state with a tendency to decrease as disease activity worsened. In a similar aspect, the radiographic progression evaluated by mTSS was lowest for patients in remission and largest in HDA, and the extent of progression was overall very low in patients with remission, LDA, and MDA (Table 2).

Disease activity state defined as:

**DAS28** remission: DAS28 < 2.6; LDA: 2.6 ≤ DAS28 < 3.2; MDA: 3.2 ≤ DAS28 ≤ 5.1; HDA: DAS28 > 5.1

**SDAI** remission: SDAI ≤ 3.3; LDA: 3.3 < SDAI ≤ 11.0; MDA: 11 < SDAI ≤ 26.0; HDA: SDAI > 26.0

**CDAI** remission: CDAI ≤ 2.8; LDA: 2.8 < CDAI ≤ 10.0; MDA: 10 < CDAI ≤ 22.0; HDA: CDAI > 22.0

Results are based on patients with available mTSS at both baseline and week 52

**Conclusion :** The proportions of patients achieving remission or LDA in the SB4 and ETN treatment groups were comparable at weeks 12, 24, and 52. The radiographic progression was also comparable in each disease activity state

with the rate of radiographic non-progressors being highest in patients achieving remission. The overall radiographic progression was very low even in patients with LDA and MDA but slightly higher in HDA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ASCERTAIN (NCT01768572) was a 24-week, randomized, double-blind, double-dummy, parallel-group, 3-arm, safety study in patients with RA and inadequate response to or intolerance of TNF inhibitors receiving background conventional synthetic (cs)DMARDs. The purpose of this post hoc analysis was to examine outcomes for patients completing ASCERTAIN who were switched to sarilumab 200 mg every 2 weeks (q2w) subcutaneously (SC) in an open-label extension study (EXTEND, NCT01146652).

**Methods:** In ASCERTAIN, patients receiving background csDMARDs were randomized 1:1:2 to sarilumab 150 mg q2w SC, sarilumab 200 mg q2w SC, or tocilizumab every 4 weeks (q4w) intravenously (IV) starting at 4 mg/kg and increasing to 8 mg/kg if clinically indicated. Patients were eligible to enroll in EXTEND and receive open-label sarilumab 200 mg q2w after completing ASCERTAIN. Clinical endpoints were based on all available data as observed and were summarized through week 84 of EXTEND according to the original randomized treatment. Definitions used as cutoffs for remission and low disease activity (LDA) were DAS28-CRP <2.6 and <3.2 and clinical disease activity index (CDAI) ≤2.8 and ≤10.0, respectively. All patients who had not achieved individual parameters of remission, LDA, and ACR20/50/70 at enrollment into EXTEND were classified as nonresponders for that specific category.

**Results:** Of the 175 patients who completed ASCERTAIN, 93/96 from the tocilizumab group, 37/40 from the sarilumab 150 mg group, and 38/39 from the sarilumab 200 mg group entered EXTEND. Improvements observed in DAS28-CRP and CDAI in ASCERTAIN were maintained after the switch to open-label sarilumab in EXTEND through week 84 (data not shown). Regardless of initial treatment in ASCERTAIN, the proportions of patients who achieved ACR20/50/70 response, and DAS28-CRP and CDAI remission and LDA increased after switch to sarilumab 200 mg

q2w in EXTEND (Table). The greatest increase in patients meeting definitions of remission and LDA was observed in patients initially receiving tocilizumab. Generally, a greater proportion of nonresponders who switched from sarilumab 150 mg q2w to 200 mg q2w achieved ACR20/50/70 response, and DAS28-CRP and CDAI remission and LDA compared with nonresponders who were maintained on 200 mg q2w. The most common treatment-emergent adverse events observed in the EXTEND safety population, which included all patients enrolled from ASCERTAIN and 4 other sarilumab studies, were infections and neutropenia.

**Conclusion:** Efficacy was maintained or improved in patients rolling over from ASCERTAIN into EXTEND. Increased efficacy was seen in all nonresponder categories, with the largest increases occurring in those who initially received tocilizumab. Although based on a limited population, these findings suggest that switching tocilizumab nonresponders to sarilumab may have favorable efficacy outcomes.

**Table.** Response Rates After 12 and 24 Weeks of Open-label Sarilumab Plus Background csDMARDs in Patients From ASCERTAIN Who Were Nonresponders<sup>a</sup> at Enrollment in EXTEND

	Tocilizumab 4/8 mg/kg q4w IV → sarilumab 200 mg q2w SC	Sarilumab 150 mg q2w SC → sarilumab 200 mg q2w SC	Sarilumab 200 mg q2w SC → sarilumab 200 mg q2w SC

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To analyze efficacy and safety of tocilizumab in patients with rheumatoid arthritis (RA) and an inadequate response to conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and/or tumor necrosis factor (TNF) inhibitors of the Swiss and Austrian patients from the ACT-SURE study.

**Methods:** Sub-analysis of RA patients from Switzerland and Austria, who participated in the international phase IIIb, open-label, ACT-SURE study. Patients with an inadequate response to csDMARDs or TNF antagonists receiving 8 mg/kg of IV tocilizumab every 4 weeks during a 24 week time period were included into the study. Therapy with one or more csDMARDs could be continued as combination therapy with tocilizumab (Combo) or stopped, resulting in tocilizumab monotherapy (Mono), at the treating physician's discretion. These two patient groups were analyzed in separate and compared.

**Results:** Overall, 107 (22 on Mono vs 85 on Combo) patients were treated with tocilizumab. The percentage of patients with at least one adverse event was significantly lower in the tocilizumab combination (58.8%) as compared to the monotherapy group (81.8%,  $p = 0.0458$ ). No differences in ACR20/50/70/90 response rates were observed between both treatment groups at week 24 (Mono: 63.6%, 40.9%, 22.7%, and 18.2% vs. Combo: 61.2%, 43.5%, 25.9%, and 10.6%). The median time to low disease activity (LDA) was significantly shorter in patients treated with tocilizumab combination therapy Mono: 9.1, Combo 7.9 weeks, Log Rank  $p = 0.038$ ).

**Conclusion:** In this post hoc regional sub-analysis of the ACT-SURE study no differences for disease activity were found comparing the two patient groups at week 24. However, median time to LDA was statistically shorter in patients treated with tocilizumab combination therapy as compared to tocilizumab monotherapy. Consequently, adding tocilizumab to csDMARD therapy rather than changing to tocilizumab monotherapy may be, in our opinion, the safest strategy to reach maximum effect in RA patients with active disease despite treatment with csDMARD. csDMARDs can be withdrawn either immediately due to adverse events or after at least low disease activity has been reached.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarilumab is a human mAb blocking the IL-6R $\alpha$ . In the phase 3 TARGET study (NCT01709578), sarilumab (150 or 200 mg subcutaneously every 2 weeks [q2w]) plus conventional synthetic (cs)DMARDs demonstrated efficacy in adults with active, moderate-to-severe RA and intolerance of or inadequate response to TNF inhibitors. The most common treatment-emergent adverse events in TARGET were infections, neutropenia, injection site reactions, increased lipids, and increased transaminases. It has been postulated that, in clinical trials, patients with higher baseline disease activity are more likely to show response than those with lower baseline disease activity.<sup>1</sup> The objective of this post hoc analysis was to examine the efficacy of sarilumab in patient subgroups based on median baseline disease activity levels.

**Methods:** All patients in the TARGET study randomized to placebo (n=181), sarilumab 150 mg q2w (n=181), and sarilumab 200 mg q2w (n=184) were included. Disease activity at baseline was defined according to < or  $\geq$  median levels (DAS28-CRP: 6.2, clinical disease activity index [CDAI]: 42.9, and CRP: 17.8). ACR20/50/70 response rates and changes in DAS28-CRP, CDAI, and CRP values were evaluated at week 24. Nominal *P* values were assessed using the Cochran-Mantel-Haenszel test for binary endpoints and mixed model with repeated measures for continuous endpoints.

**Results:** Regardless of disease activity at baseline, a higher percentage of patients treated with sarilumab vs placebo achieved ACR20/50/70 responses and had greater improvements in DAS28-CRP, CDAI, and CRP at week 24 (Table). Placebo-adjusted treatment effect with sarilumab was more pronounced in patients with higher baseline disease activity, with lower responses seen with placebo in these patients (data not shown). The odds ratio vs placebo for achieving an ACR20/50/70 response at week 24 was greater in sarilumab-treated patients with higher baseline disease activity than in those with lower baseline disease activity for each definition assessed. Likewise, change from baseline in DAS28-CRP, CDAI, and CRP at week 24 were greater in sarilumab-treated patients with higher baseline disease activity for each definition assessed.

**Conclusion:** Patients treated with sarilumab 150 and 200 mg q2w plus csDMARDs achieved greater clinical responses vs those treated with placebo, regardless of disease activity at baseline. The treatment effect of sarilumab was larger in patients with higher disease activity at baseline.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarilumab is a human mAb blocking the IL-6R $\alpha$ . In the phase 3 TARGET study (NCT01709578), sarilumab (150 or 200 mg subcutaneously [SC] every 2 weeks [q2w]) plus conventional synthetic (cs)DMARDs demonstrated efficacy in adults with active, moderate-to-severe RA and inadequate response or intolerance to TNF inhibitors. Consistent with IL-6 inhibition and the safety profile of SC sarilumab, infections, neutropenia, injection site reactions, increased lipids, and increased transaminases were among the most common treatment-emergent adverse events. The objective of this analysis was to examine whether patients who achieved clinical response and improvements in physical function at week 12 in TARGET continued to sustain response up until the end of study at week 24.

**Methods:** A sustained response was defined as a response at week 12 (see below) with continuous response until the end of the study. An additional definition of a sustained response allowed for a single visit in between without a response, with the exception of the last 2 visits. Patients were seen at baseline and at weeks 2, 4, 8, 12, 16, 20, and 24 of the study. The sustainability of the response was measured for the following clinical efficacy endpoints: ACR20/50/70 response, HAQ-Disability Index (HAQ-DI;  $\geq 0.22$  units of improvement from baseline), clinical disease activity index (CDAI;  $\leq 2.8$  [remission],  $> 2.8$  to  $\leq 10$  [low disease activity; LDA]), simplified disease activity index (SDAI;  $\leq 3.3$  [remission],  $> 3.3$  to  $\leq 11$  [LDA]), and DAS28-CRP ( $< 2.6$ ,  $\geq 2.6$  to  $\leq 3.2$ ).

**Results:** A significantly higher percentage of patients treated with sarilumab + csDMARDs achieved ACR20/50/70 response (both doses) and HAQ-DI  $\geq 0.22$  units of improvement from baseline (200 mg q2w dose only) at week 12 in TARGET vs those treated with placebo + csDMARDs (Table). The majority of patients treated with sarilumab who achieved a response at week 12 sustained that response, or had up to 1 nonresponse, until the end of the study (Table). In contrast, there were fewer patients in the placebo + csDMARDs group who achieved and sustained a response from week 12 to the end of the study. These observations were similar regardless of whether a patient maintained a response at every visit after week 12 through the end of the study or had 1 nonresponse at a visit in between. A similar trend was also observed for CDAI and SDAI remission and LDA, and DAS28-CRP  $< 2.6$  and  $\geq 2.6$  to  $\leq 3.2$ .

**Conclusion:** More patients with active, moderate-to-severe RA and inadequate response or intolerance to TNF inhibitors who were treated with sarilumab + csDMARDs achieved and sustained a clinically significant response compared with those treated with placebo + csDMARDs.

Table. Frequency of Patients Achieving a Response at Week 12 and Sustaining It Until Week 24

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, is in development for rheumatoid arthritis (RA) in the global SIRROUND Phase 3 trial program. SIR significantly reduced signs/symptoms of RA and inhibited radiographic progression. SIR has been well tolerated in RA patients (pts) with a safety profile similar to that of other drugs targeting the IL-6 pathway. Pooled safety data from SIRROUND trials are presented.

**Methods:** Safety data through July 29, 2016 from 5 Phase 3 trials of SIR were analyzed. These trials included pts with moderate to severe active RA who were refractory or intolerant to conventional DMARDs (SIRROUND-D, M, H) or anti-TNF therapy (SIRROUND-T). SIRROUND-LTE is a long-term extension study for pts completing SIRROUND-D or T. SIR was administered SC at 50mg q4w or 100mg q2w. Safety analyses are presented by SIR treatment group for adverse events (AEs), serious AEs (SAEs), mortality, and AEs of special interest (serious infections, gastrointestinal [GI] perforations, major adverse cardiovascular events [MACE], and malignancies).

**Results:** In Phase 3 trials, 2926 pts received SIR. Pts were treated for up to 3.9 years (approximately 5300 patient-years of drug exposure), with a median exposure of 1.76 years. Similar proportions of pts had treatment-emergent AEs, discontinuations due to AEs, and SAEs in the 50mg and 100mg groups (**Table**). Incidences of common AEs were generally comparable across dose groups; however, injection site reactions (ISRs) occurred more frequently with more frequent dosing: 100-mg q2w (21.9%) versus 50-mg q4w (12.7%) dose, with erythema, pruritus, and swelling most frequently reported. Pneumonia (1.8%) and cellulitis (1.1%) were the only individual SAEs reported in  $\geq 1\%$  of all SIR-treated pts. No dose effect was observed for the incidence of serious infections. Rates of GI perforation and malignancies were low in both dose groups. MACE rates for SIR 50mg q4w were similar to those reported for other agents and RA in general and were numerically lower with SIR 100mg q2w. The overall mortality rates were similar for the 2 SIR doses and also consistent with those observed with other agents and RA.

**Conclusion:** In this pooled safety analysis of SIR in pts with active RA, no new safety signals were observed. Overall, no dose response was observed between SIR 50mg q4w and 100mg q2w for types and frequencies of AEs, with the exception of hypersensitivity and ISRs.

**Table 1. Treatment-emergent AEs in Phase 3 Trials Through Data Cut-off (July 29, 2016)**

AEs, n (%)	Sirukumab 50mg q4w (n=1461)	Sirukumab 100mg q2w (n=1465)
AEs	1242 (85.0)	1267 (86.5)
AEs in >10% of pts		
Increased ALT	233 (15.9)	262 (17.9)
Nasopharyngitis	197 (13.5)	197 (13.4)
Injection site erythema	132 (9.0)	229 (15.6)
Upper respiratory tract infection	172 (11.8)	164 (11.2)
Increased AST	141 (9.7)	187 (12.8)
AEs leading to discontinuation	190 (13.0)	225 (15.4)
Hypersensitivity reactions	3 (0.2)	14 (1.0)
Incidence <sup>a</sup>	0.11 (0.02, 0.33)	0.52 (0.29, 0.88)

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, has demonstrated efficacy in rheumatoid arthritis (RA) using dose regimens of 50mg q4w and 100mg q2w. Maintenance of response throughout the dosing interval is beneficial, especially when treatment is given less frequently. A global Phase 3 study in patients (pts) with active RA refractory to conventional, synthetic, disease-modifying antirheumatic drugs (DMARDs; SIRROUND-D) demonstrated the efficacy and safety of both dose regimens of SIR. Post-hoc analyses of SIRROUND-D were performed to assess response maintenance with SIR 50mg q4w (less frequent dosing) and SIR 100mg q2w (more frequent dosing) over 2w and 4w intervals.

**Methods:** Pts (n=1,670) were randomized 1:1:1 to SC SIR 50mg q4w, SIR 100mg q2w, or placebo q2w. The primary efficacy endpoint was ACR20 response at Wk 16. Additional efficacy outcomes evaluated included change from baseline (BL) in CDAI, DAS28(CRP), and CRP, evaluated every 2-4w. Serum samples for pharmacokinetics were collected and analyzed at BL up to 52w. Post hoc subgroup analyses of patients who were EULAR Good-Moderate responders at 12w assessed the % of pts with loss of response (improvement  $\leq 1.2$  from BL) over 2w and 4w dosing intervals and change from BL in DAS28(CRP) over 2w and 4w intervals by treatment group for study visits up to 52w to determine any change in response based on dosing regimen.

**Results:** Following multiple SC doses of SIR 50 mg q4w or 100 mg q2w, trough serum SIR concentrations reached steady state (SS) by approximately 12w and remained stable through 52w. ACR20 response and improvements from BL in CRP, CDAI, and DAS28(CRP) were achieved and maintained over 2w intervals from 16w to 20w (post-SS) and through 52w for both SIR dose groups (Fig 1). In pts with EULAR Good-Moderate response at 12w, there was no evidence of a change in mean DAS28(CRP) between Wks 16, 18, and 20 for either the 2w or 4w SIR dose. Furthermore, <3% of pts on SIR 50mg q4w and  $\leq 5\%$  of pts on SIR 100mg q2w lost response at any individual study

visit between 16w and 52w. There was no increase in % of pts with loss of response over time, and 80% of pts with loss of response at a study visit had loss of response only at that visit or 1 other visit through 52w. The loss of response rates were similar for SIR 50mg q4w and SIR 100mg q2w.

**Conclusion:** In a SIR phase 3 clinical trial in RA pts refractory to DMARDs, trough serum SIR concentrations were stable during the time interval that efficacy was assessed in the majority of pts. The q4w and q2w dosing regimens were similar with respect to maintenance of response throughout the different dosing intervals, and the response was effectively maintained to 52w. These data demonstrate that sirukumab q4w dosing provides an effective treatment option for pts with RA.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** A period of 4 weeks (w) has been recommended for rheumatoid arthritis (RA) patients as the interval between tocilizumab (TCZ, 8mg/kg) infusions. However, A previous study has shown that the interval between successive TCZ infusions can be extended from 4 weeks to 6 weeks in more than 60% of patients suffering from RA who had previously shown good responses to TCZ infused at intervals of 4 weeks along with a constant low disease activity (LDA) for more than 2 years (1). Herein, we aimed to investigate the efficacy and safety of extending the interval from 4w to 6w.

**Methods :** The intervals between TCZ (8mg/kg) infusions were increased from 4 weeks to 6 weeks in patients responding favorably for more than 2 years. A retrospective observational study was conducted by enrolling patients in whom the intervals of TCZ infusions could be extended from 4w to 6w with an LDA for more than 2 years. We compared the efficacy and side effects of TCZ infusions at intervals of 4w and 6w in the same patients. We also examined serum levels of IL-6 and trough TCZ during the course of the study.

**Results :** A total of 125 patients were enrolled in this study, of which 78 patients showed a good response to TCZ infused at intervals of 6w. After extending the infusion intervals, the efficacy of the treatment was maintained, and the side effects decreased significantly. Parameters reflecting the disease activity such as serum CRP levels and DAS28-CRP scores were considerably low when the infusion interval was 4 weeks whereas they were slightly elevated when infusion interval was increased to 6 weeks, although within the LDA limit. During the course of the study, 11 patients who were administered TCZ at intervals of 4 weeks showed serious adverse events, whereas only 3 patients who were administered TCZ at intervals of 6 weeks showed similar adverse events. Common adverse events such as general fatigue, nausea, and dizziness were frequently observed in patients administered TCZ at intervals of 4 weeks. These common adverse events significantly decreased after the infusion interval was extended to 6 weeks. In addition, the levels of total cholesterol and triglyceride were returned to normal, and the serum trough levels of TCZ became undetectable.

**Conclusion :** We proved that intervals between TCZ infusions can be extended from 4w to 6w in more than 50% of RA patients along with a decrease in the side effects, thus suggesting the need to change the infusion intervals in suitable patients.

Table 1 Clinical assessments before and after extension of TCZ intervals in 6w-responders (n = 78)

TCZ interval	4w	6w	p-value (4w vs 6w)
CRP (mg/dl)	0.19 ± 0.17	0.22 ± 0.19	0.240
DAS28-CRP	2.2 ± 0.5	2.4 ± 0.5	0.070
PtGA(mm)	13.8 ± 9.7	15.8 ± 8.5	0.175
PGA (mm)	13.3 ± 7.4	13.8 ± 7.6	0.670
Tender JC	1.4 ± 1.2	1.6 ± 1.4	0.205
Swollen JC	1.3 ± 1.1	1.5 ± 1.1	0.166
CDAI	5.3 ± 2.5	6.1 ± 2.4	0.054

Patients' clinical assessments were examined before and after TCZ infusion. Values were given as mean ± SD. Seventy-eight patients were enrolled.

JC: joint count, PtGA: visual analog scale (0 mm ~ 100 mm) of patient global assessment of disease activity, PGA: visual analog scale (0 mm ~ 100 mm) of physician global assessment of disease activity, CDAI: Clinical Disease Activity Index.

Table 2 Comparison of serious and common adverse events between at 4w and at 6w intervals

Serious adverse events			Common adverse events		
n = 78	At 6w	At 4w	n = 78	At 6w	At 4w
total events	3 (3.8%)	11 (14.1%)	total events	34 (40.3%)	121 (155%)
pneumonia	1 (1.3%)	3 (3.8%)	*Hyperlipidemia	12 (15.4%)	29 (37.2%)
LCF	0	1 (1.3%)	*decrease of PLT	2 (2.6%)	15 (19.2%)
pyelonephritis	1 (1.3%)	2 (2.6%)	Neutropenia	2 (2.6%)	8 (10.2%)
herpes zoster	1 (1.3%)	1 (1.3%)	RTI	8 (10.2%)	27 (34.6%)
sepsis	0	1 (1.3%)	UTI	2 (2.6%)	12 (15.4%)
enterocolitis	0	1 (1.3%)	Gastroenteritis	1 (1.3%)	10 (12.8%)
DRF	0	1 (1.3%)	Dizziness	1 (1.3%)	8 (10.2%)
			General Fatigue	4 (5.1%)	23 (29.5%)
			Nausea	2 (2.6%)	9 (11.5%)

Serious and common adverse events were compared in the same patients for the last two years.

\*These are suggested to be dependent on the concentration of IL-6. LCF: Lumbar compression fracture, DRF: distal radius fracture, RTI: Respiratory tract infection, UTI: Urinary tract infection.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** the primary objective of this study was to assess the 24-week efficacy and safety of subcutaneous (SC) tocilizumab (TCZ) 162 mg weekly (qw) as monotherapy or in combination with methotrexate (MTX) or other synthetic (s) DMARDs in patients with active rheumatoid arthritis (RA) in the real world setting. Secondary objectives included to evaluate whether increasing the dose interval from TCZ-SC 162 mg qw to TCZ-SC 162 mg every two weeks (q2w) would be associated with a sustained clinical remission up to week 48.

**Methods:** this multinational, multicenter, phase IIb study was undertaken in subjects ≥18 years of age with active RA (DAS 28-ESR > 3.2) who have had inadequate response or intolerance to sDMARDs or to a first anti-TNF drug. The study comprised a phase 1 with open-label design in which patients received TCZ-SC 162 mg qw (+/- oral/SC MTX or

other sDMARDs) for 24-weeks and the main outcome was the percentage of patients achieving sustained clinical remission (DAS 28-ESR < 2.6) at Week 20 and Week 24 (primary outcome of the study); and a phase 2 where patients achieving sustained clinical remission during the phase 1 were randomized to receive TCZ-SC 162 mg qw or TCZ-SC 162 mg q2w (+/- oral/SC MTX or other sDMARDs) for an additional 24 weeks; the main outcome of the phase 2 was the percentage of patients who maintained the remission at week 48 (i.e. DAS 28-ESR<2.6).

**Results:** 401 patients were included in the phase 1, 74 patients received TCZ-SC monotherapy and 327 patients received TCZ-SC in combination with oral/SC MTX or other sDMARDs. Sustained clinical remission rates were comparable between the mono- and combination-therapy groups at 24 week (48.4% vs. 52.9%, p=0.523). Of the 179 patients who achieved sustained clinical remission during the phase 1, 89 were randomly assigned to receive TCZ-SC 162 mg qw and 90 to receive TCZ-SC 162 mg q2w. At the end of phase 2, the percentage of patients who maintained the remission at week 48 was 91.5% with TCZ-SC qw and 73.9% with TCZ-SC q2w (p=0.002). Main efficacy outcomes for both phases of the study are presented in the table. Rates of serious adverse events (AEs) and AEs leading to drug discontinuation were similar in patients treated with mono or combination therapy, and in patients treated with TCZ-SC qw or TCZ-SC q2w. At least one serious AE was reported in 3 (4.1 %) patients in the monotherapy group and in 10 (3.1%) patients in the combination therapy group (Phase 1); 2 (2.2%) patients in the TCZ-SC qw group and 1 (1.1%) patient in TCZ-SC q2w group reported at least one serious AE (Phase 2).

Phase 1			
Outcome	TCZ-SC monotherapy N=74	TCZ-SC Combination N=327	p-value
Sustained clinical remission, %	48.4	52.9	0.523
ACR20, %	79.7	83.3	0.495
ACR50, %	59.4	58.7	0.923
ACR70, %	40.6	37.7	0.666
ACR90, %	23.4	16.7	0.207
HAQ-DI (baseline/24 weeks), mean	1.49/0.85	1.36/0.82	NS
Phase 2			
Outcome	TCZ-SC 162 mg qw N=89	TCZ-SC 162 mg q2w N=90	p-value
Clinical remission, %	91.5	73.9	0.002
ACR20, %	96.4	88.8	0.056
ACR50, %	88.1	79.8	0.766
ACR70, %	71.4	65.2	0.377
ACR90, %	45.2	32.6	0.088
Mean change in DAS28	-0.02	0.35	0.037

**Conclusion:** in the real world setting, treatment with TCZ-SC 162 mg weekly in patients with active RA is associated with rate of sustained clinical remission of approximately 50% regardless it is administered as monotherapy or in combination with a sDMARD. The proportion of patients who remained in clinical remission at week 48 was significantly higher with TCZ-SC qw than with TCZ-SC q2w.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Vobarilizumab is a Nanobody consisting of an anti-IL-6R domain and an anti-human serum albumin domain in development for treatment of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Main efficacy and safety results of both RA phase 2b studies with vobarilizumab when used in combination with methotrexate (ALX0061-C201) and as monotherapy (ALX0061-C202) were previously reported (ref 1 and 2).

The effect of vobarilizumab on different pharmacodynamic (PD), cartilage degradation and joint inflammation biomarkers was investigated in both studies.

**Methods:** In study ALX0061-C201, 345 patients were equally randomized to receive during a 24-week treatment period one of the four subcutaneous (s.c.) vobarilizumab dosing regimens (75 mg q4w, 150 mg q2w, 150 mg q4w, 225 mg q2w) or placebo q2w. In study ALX0061-C202, 251 patients were equally randomized to receive during a 12-week treatment period one of the three dosing regimens of s.c. vobarilizumab (150 mg q2w, 150 mg q4w, or 225 mg q2w). An open-label tocilizumab (TCZ) arm was included to obtain parallel descriptive information.

The effect of vobarilizumab and TCZ on the PD biomarkers soluble IL-6 receptor (sIL-6R), C-reactive protein (CRP), fibrinogen and erythrocyte sedimentation rate (ESR) was evaluated descriptively. In addition, matrix metalloproteinase-3 (MMP-3) was evaluated as a cartilage degradation biomarker and chemokine (C-X-C motif) ligand 13 (CXCL13) as a joint inflammation biomarker. Using validated assays, all biomarkers were measured at baseline and over time in serum, except for sIL-6R which was measured in plasma.

**Results:** As expected, based on vobarilizumab's mechanism of action, mean plasma total sIL-6R concentrations increased following vobarilizumab administration and remained increased during the treatment period. A rapid decrease of the PD biomarkers CRP, fibrinogen and ESR was observed after the first administration of vobarilizumab. Over time, mean values of CRP and fibrinogen remained low for subjects in the 2 highest dosing regimens (i.e. 150 mg q2w and 225 mg q2w) (see Figure 1 for CRP results). ESR values remained low for all dosing regimens except for the 75 mg q4w dose used in ALX0061-C201 combination therapy study. Following administration of TCZ, comparable profiles were observed for the different PD biomarkers. Both vobarilizumab and TCZ also lead to a gradual decrease of MMP-3 and CXCL13. After vobarilizumab/TCZ treatment discontinuation, an increase of all biomarkers (except for sIL-6R) was observed.

**Conclusion:** The observed dose dependent PD biomarker responses and effects on cartilage degradation and joint inflammation biomarkers further support the strong potential for disease modifying activity of vobarilizumab in RA.

## Descriptive Patterns of Switches and Swaps in Patients with Rheumatoid Arthritis Initially Treated with Anti-TNF Agents in First Intention between 2000 and 2006, and 2007 and 2015 – Experience from a Real-World Database RHUMADATA®

**Denis Choquette**<sup>1</sup>, Louis Bessette<sup>2</sup>, L Coupal<sup>3</sup> and Kirsten Garces<sup>4</sup>, <sup>1</sup>University of Montreal Hospital Research Centre (CRCHUM), Notre Dame Hospital Montreal, Montreal, QC, Canada, <sup>2</sup>Groupe de Recherche en Rhumatologie et Maladies Osseuses, Quebec, Quebec, QC, Canada, <sup>3</sup>Institut de Recherche en Rhumatologie de Montréal (IRRM), Montréal, QC, Canada, <sup>4</sup>Amgen Canada Inc., Mississauga, ON, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Between 2000 and 2006, the only other treatment option for patients with rheumatoid arthritis (RA) first exposed to an anti-TNF agent was another anti-TNF agent. After 2006, agents with a different mode of action became available. The patterns of switches (anti-TNF to anti-TNF) and swaps (anti-TNF to another mode of action) have not been presented in detail. The real-world experience gathered since 2000 gives us a unique opportunity to examine change in prescribing patterns.

**Methods:** The data of biologic naïve RA patients starting a first anti-TNF [adalimumab (ADA), certolizumab (CER), etanercept (ETA), golimumab (GOL), infliximab (INF) or inflectra] between January 1, 2000 and December 31, 2006 (first era), and January 1, 2007 and December 2015 (second era) was extracted. Patients were followed until they stopped, changed their medication or were lost to follow-up. Switches or swaps could happen at any time. We analyzed the number of patients that stopped, switched or swapped in each treatment era and the time from initial treatment to second treatment or the cessation of treatment. Statistical analysis was performed using SAS version 9.4.

**Results:** The choice of a second biologic agent among patients having been prescribed their initial between Jan 1, 2000, and Dec 31, 2006, and Jan 1, 2007, and Dec 31, 2015, are presented Table 1. In the first era, switches accounted for 45.9% of cases, with most switching to ETN (42%), followed by ADA (30.6%), INF (19.7%), CER (3.8%), GOL (3.2%) and inflectra (0.6%). In the second era, switches accounted for 31.5% of cases, with most switching to ETN (31.7%), ADA (23.2%), CER (19.5%), GOL (15.9%), INF (7.3%) and inflectra (2.4%). Swaps accounted for 26.0% of cases in the first era. These swaps occurred towards abatacept (ABA), rituximab (RTX), tocilizumab (TOCI) and anakinra in 48.3%, 34.8%, 16.9% and 9.0% of cases. In the second era, the proportion of swaps increased to 38.8% and occurred towards ABA, RTX, TOCI and tofacitinib (TOFA) accounting for 42.6%, 26.7%, 24.8% and 5.9% of cases.

**Conclusion:** When switching occurs, most patients switched to a second anti-TNF in the first and second era. ETN was the anti-TNF more often selected for the in both eras. In the second era, there was an increased tendency to prescribe agents with a different mode of action after the first anti-TNF agent. This may be due to the availability of biologics with a different mode of action.

Table 1.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-TNFs have been used to treat RA since 2000. Since the availability of new agents with different mechanisms of action around 2007, the pattern of use has evolved. The long-term biologic retention rate is a good surrogate marker for effectiveness in the clinical setting. Randomized controlled trials and their open-label extension studies provide information on drug retention in a highly selected patient population. This information, however, is of limited use when prescribing biologics in a real-world setting. Real-world databases, such as RHUMADATA®, provides an excellent opportunity to examine the changes in retention rates over time.

**Objectives:** To assess the retention of the first-line anti-TNF and evaluate possible differences between two eras, early (2000-2006) and late (2007-2015).

**Methods:** Data of biologic naïve RA patients starting an anti-TNF [adalimumab (ADA), etanercept (ETA), golimumab (GOL) or infliximab (INF)] between Jan 1, 2000, and Dec 31, 2006 (early era), and Jan 1, 2007, and Dec 2015 (late era) was extracted. Patients were followed until they stopped, changed medication, or were lost to follow-up. Collected data included demographics, concomitant medication, comorbidities, laboratory variables, PROs, and disease activity measures. Infections occurring while on treatment, biologic status (ongoing or stopped) and the reasons for biologic cessation were also extracted. Overall retention was compared using Kaplan-Meier estimates (SAS 9.4). Cox proportional hazard models were used to adjust for differences between groups at baseline.

**Results:** Baseline variables were similar between the two eras, except that patients in the second era were older and had been diagnosed ~1 year sooner than first era patients. These patients were less exposed to corticosteroids, more

exposed to HCQ, and had lower ESR and CRP at treatment initiation. Over the entire period, ETN had a longest mean retention time of 6.32 years versus ADA (6.24y) and INF (5.6y). This difference was statistically significant between ETN and INF (p=0.026). When analyzed in the two eras, the mean retention times of all biologics were longer in the first era (6.72y) than the second (4.7y).

**Conclusion:** Patients treated in the first era appear to have more severe disease, greater exposure to corticosteroids and HCQ, and better retention rate compared to patients starting an anti-TNFi after 2006. More analysis should be done to understand these differences.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarilumab is a human mAb blocking the IL-6R $\alpha$ . In the phase 3, 52-week MOBILITY study (NCT01061736), sarilumab (150 or 200 mg subcutaneously every 2 weeks [q2w]) + MTX demonstrated clinical and radiographic efficacy in adults with active, moderate-to-severe RA and inadequate response to MTX.<sup>1</sup> The most common treatment-emergent adverse events were infections, neutropenia, injection site reactions, and increased transaminases. The objective of this analysis was to examine differences in the mean duration of response based on various definitions of response in MOBILITY.

**Methods:** Patients who achieved a response at any point during the study were considered responders and included in these analyses. If patients had a missing value or took rescue medication, they were considered nonresponders for those specific visits. Patients who did not respond at any visit were excluded from analysis. Five different definitions of duration of response were used: (1) *first response to loss of response* (time from initial response to loss of response); (2) *longest response* (all time segments of response were determined where each segment of response ended after first loss of response, and longest duration of response was selected); (3) *responder weeks* (cumulative number of weeks during which a patient was a responder, excluding nonresponder weeks in between responder weeks); (4) *responder weeks percent* (percentage of weeks during which a patient was a responder, excluding nonresponder weeks in between responder weeks); and (5) *sustained response* (binary analysis [yes/no] of whether the response was maintained until the end of the double-blind period). Duration of response was measured for ACR20, improvement in HAQ–Disability Index (HAQ-DI) of  $\geq 0.3$  units, clinical disease activity index (CDAI;  $\leq 2.8$ ), simplified disease activity index (SDAI;  $\leq 3.3$ ), and DAS28-CRP ( $< 2.6$ ).

**Results:** In patients achieving a response at any point in MOBILITY, those treated with sarilumab 150 or 200 mg q2w + MTX had significantly longer duration of response vs those treated with placebo + MTX regardless of definition of response used for ACR20, HAQ-DI, and DAS28-CRP (Table 1). Sarilumab-treated patients achieved significantly longer sustained response by both ACR20 and HAQ-DI, whether they achieved response at week 12 or 24 (Table 2).

**Conclusion:** This analysis examined 5 different definitions of clinical response. Regardless of definition of response used, patients treated with either dose of sarilumab + MTX experienced longer duration of response vs those treated with placebo + MTX.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarilumab is a human mAb blocking the IL-6Ra. Efficacy and safety of sarilumab (150 or 200 mg subcutaneously every 2 wks [q2w]) + conventional synthetic (cs)DMARDs were demonstrated in patients with active, moderate-to-severe RA in 2 phase 3 studies: the 52-wk MOBILITY study (NCT01061736) in patients with inadequate response to MTX (MTX-IR) and the 24-wk TARGET study (NCT01709578) in patients with inadequate response to or intolerance of TNF inhibitors (TNF-IR). The most common treatment-emergent adverse events in both studies included infections, neutropenia, injection site reactions, and increased transaminases. This post hoc analysis assessed benefit of sarilumab treatment by examining the proportion of patients who achieved treat-to-target goals of remission or low disease activity (LDA) by 1 year in MOBILITY and 6 months in TARGET.

**Methods:** Adults with active RA were randomized 1:1:1 to receive sarilumab 150 or 200 mg q2w or placebo + background MTX (MOBILITY) or csDMARDs (TARGET). Clinical efficacy was evaluated for remission and LDA using DAS28-CRP ( $<2.4$  and  $\leq 2.9$ ),<sup>1,2</sup> clinical disease activity index (CDAI;  $\leq 2.8$  and  $\leq 10$ ), and simplified disease activity index (SDAI;  $\leq 3.3$  and  $\leq 11$ ) at wks 4, 8, 12, and 24 in TARGET and additionally at week 52 in MOBILITY. Functional remission (HAQ–Disability Index [HAQ-DI]  $<0.5$ )<sup>3</sup> was also assessed.

**Results:** In both studies, more sarilumab-treated patients achieved remission (DAS28-CRP only) and LDA (all criteria) vs placebo (Table). Although remission and LDA generally became evident between wks 4 and 8 in most patient groups (nominal  $P < 0.05$  vs placebo, both doses), with ongoing sarilumab treatment (both doses), additional patients achieved remission and LDA at each successive time point assessed through wk 24 in both studies; some additional patients achieved remission and LDA between wks 24 and 52 in MOBILITY. Normalization of physical function (HAQ-DI  $<0.5$ ) was evident in both sarilumab-treated groups in MOBILITY by wk 12 (nominal  $P < 0.05$  vs placebo, both doses); a slight increase in the number of patients achieving normalization was observed by wk 52. In TARGET, a small numerical difference in HAQ-DI normalization was seen in favor of sarilumab treatment at all time points even though this endpoint did not achieve nominal significance.

**Conclusion:** In MTX-IR and TNF-IR patients with RA treated with sarilumab, efficacy became evident as early as wk 4. The numbers of patients who achieved remission or LDA increased through wk 24 with ongoing sarilumab treatment in both studies, with some further increases observed up to wk 52 in MOBILITY.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adalimumab is an anti-tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) agent indicated for the treatment of immune-mediated diseases. The long-term safety of adalimumab was previously reported in 23,458 patients representing up to 12 years of clinical trial exposure in rheumatoid arthritis (RA), juvenile idiopathic arthritis, ankylosing spondylitis (AS), psoriatic arthritis (PsA), plaque psoriasis (Ps), and Crohn's disease (CD). Here we report an updated analysis examining the long-term safety of adalimumab in adult patients with RA, AS, non-radiographic axial spondyloarthritis (nr-axSpA), peripheral SpA (pSpA), PsA, Ps, hidradenitis suppurativa (HS), CD, ulcerative colitis (UC), and non-infectious uveitis (UV).

**Methods:** Safety data from 78 clinical trials of adalimumab (RA, 33; AS, 5; nr-axSpA, 2; pSpA, 1; PsA, 3; Ps, 13; HS, 3; CD, 11; UC, 4; UV, 2; other, 1) were included in these analyses, including randomized controlled, open-label, and long-term extension studies conducted in Europe, North America, South America, Asia, Australia, New Zealand, and South Africa through December 31, 2016. Adalimumab postmarketing surveillance data were not included in this analysis. Safety assessments included all adverse events (AEs) and serious AEs (SAEs) that occurred after the first adalimumab study dose and up to 70 days (5 half-lives) after the last study dose.

**Results:** This analysis included 29,987 patients, representing 56,951 patient-years of exposure (**Table 1**). The majority of adalimumab exposure was in RA studies. The most frequently reported SAE of interest was infection (highest incidences in CD, RA, UV, and UC). Overall and for most of the adalimumab populations (AS, PsA, Ps, UC, CD, and RA), the observed number of deaths was below what would be expected in an age- and sex-adjusted population (**Table 2**). For HS, nr-axSpA, pSpA, and UV studies, the small size of these trials precluded accurate assessment of the standardized mortality ratio, and the 95% CIs all included 1.0.

Table 1. Incidence Rates of Serious Adverse Events of Interest\*

Characteristic	RA	AS	nr-axSpA	pSpA	PsA	Ps	HS	CD	UC	UV	Total <sup>b</sup>

CD (n=3896)	0.44	0.14, 1.02
UC (n=1739)	0.37	0.12, 0.87
UV (n=464)	1.23	0.45, 2.68
Total (N=29,986)	0.65	0.57, 0.74

AS, ankylosing spondylitis; CD, Crohn's disease; HS, hidradenitis suppurativa; nr-axSpA, non-radiographic axial SpA; Ps, plaque psoriasis; PsA, psoriatic arthritis; pSpA, peripheral SpA; RA, rheumatoid arthritis; SMR, standardized mortality ratio; SpA, spondyloarthritis; UC, ulcerative colitis; UV, uveitis.

**Conclusion:** This analysis of data from clinical trials of adalimumab demonstrated an overall safety profile consistent with previous findings and with the TNF inhibitor class. No new safety signals or tolerability issues with adalimumab treatment were identified and, for most indications, the mortality rate was below what would be expected in an age- and sex-adjusted population. Efficacy and safety data continue to support the well-established benefits of adalimumab for the approved indications.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarilumab is a human mAb blocking the IL-6R $\alpha$ . Efficacy and safety of sarilumab as monotherapy and combination therapy have been reported.<sup>1-3</sup> In MONARCH (NCT02332590), adults intolerant of, inappropriate for, or inadequate responders to methotrexate received subcutaneous sarilumab (200 mg every 2 weeks [q2w]) or adalimumab (40 mg) monotherapy for 24 weeks.<sup>2</sup> Sarilumab monotherapy demonstrated superiority to adalimumab monotherapy in reducing disease activity and improving physical function in patients with active RA.<sup>2</sup> Safety profiles of both therapies were consistent with published data. Patients in MONARCH who completed the initial double-blind phase could continue in the open-label extension (OLE) in which all patients received sarilumab 200 mg q2w monotherapy.

**Methods:** Disease activity, physical function, and safety were assessed regularly (Table). Data were used as observed.

**Results:** A total of 321 patients completed MONARCH, 320 of whom entered the OLE; 155 switched from adalimumab to sarilumab (switch group), and 165 remained on sarilumab (continuation group). At OLE entry, mean DAS28-ESR was 4.46 and DAS28-ESR  $\leq 3.2$  was 16.1% in the switch group vs 3.45 and 47.9%, respectively, in the continuation group ( $P < 0.0001$  for both endpoints). By week 24 of the OLE, the proportion of patients in the switch and continuation groups who achieved DAS28-ESR  $\leq 3.2$  was 49.7% vs 58.8% ( $P = 0.1033$ ), DAS28-ESR  $< 2.6$  was 40.0% and 42.4% ( $P = 0.6586$ ), CDAI remission was 12.3% and 18.8% ( $P = 0.1054$ ), and improvement in HAQ-DI of  $\geq 0.3$  was 63.9% and 66.7% ( $P = 0.6004$ ), respectively. At week 24 of the OLE, treatment-emergent adverse events (TEAEs; 63.9% vs 57.9%), serious TEAEs (9.0% vs 1.2%), infections (34.2% vs 23.6%), and serious infections (1.9% vs 0%) were

observed in the switch and continuation groups, respectively, with 1 death in the switch group (malignancy) and no deaths in the continuation group. Discontinuations due to TEAEs occurred in 5.8% of patients in the switch group and 3.6% in the continuation group.

**Conclusion:** In the OLE of a randomized clinical trial, patients switching from adalimumab 40 mg monotherapy to open-label sarilumab 200 mg q2w monotherapy demonstrated improvements in physical function and in the signs and symptoms of RA, which became numerically similar to patients who were initially randomized to sarilumab 200 mg q2w. Safety observations in the OLE were generally consistent with what was observed in the randomized portion of the study.

# Cycling Versus Swapping in Patients with Rheumatoid Arthritis with an Inadequate Response to at Least One Tumor Necrosis Factor Alpha Inhibitor: A Systematic Review and Meta-Analysis of Observational Studies

**Maria A. Lopez-Olivo**, Aliza Matusevich and Maria Suarez-Almazor, Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In patients with rheumatoid arthritis (RA) who do not respond or lose response to a tumor necrosis factor inhibitor (TNFi), opinions are divided on whether it is better to try an alternative TNFi (cycling) or switch to a therapy with a different mode of action (swapping). The purpose of the review was to compare the effectiveness and safety of the cycling versus the swapping strategies as reported in observational studies.

**Methods:** We searched 4 electronic databases, sources of gray literature, and bibliographic references of relevant articles for observational studies evaluating the efficacy and safety of targeted therapies in adult RA patients who failed to respond to at least one TNFi. Studies were excluded if they were single-arm or had insufficient data to evaluate the outcomes of interest. Two independent reviewers selected studies, extracted data and evaluated study quality using the Newcastle-Ottawa Scale (NOS). Our primary outcome measure was change in Disease Activity Score of 28 joints (DAS28). We also evaluated the modified American College of Rheumatology 20%, 50% and 70% response criteria (mACR which excludes acute phase reactants) and total serious adverse events. All analyses were based on the random-effects model.

**Results:** Of 33,716 citations, 24 observational studies (n=10,074 patients) representing 14 countries, met the inclusion criteria. Eight were conference abstracts. Most publications (13 of 24) were based on registries. Most studies had a NOS score equal to or greater than 7 (out of 9) with comparability being the weakest domain. The mean age of patients was 48.7-62.8 years, the majority were females (78%) with a disease duration of 6-17.3 years and a baseline disability score 0.6-2.0. Sixteen studies evaluated cycling versus swapping directly of which 13 were suitable for analysis. Most compared TNFi to rituximab (10 of 13) with two studies investigating tocilizumab or abatacept and one comparing non-TNFi as a group. Other comparisons reported were: (i) cycling vs. another cycling alternative, (ii) swapping vs. another swapping alternative, and (iii) swapping monotherapy vs. swapping combined with cDMARDs. At 12 and 24 weeks, DAS28 score improved significantly in those swapping compared to those cycling (mean difference (MD) 0.89, 95% confidence interval (CI) 0.05 to 1.74 and MD 0.34 95% CI: 0.2, 0.48; respectively). Similar results were observed for the mACR50 favoring the swapping strategy at 24 weeks (OR = 1.45 95%CI: 1.06, 1.98). However, at 52 weeks no difference was observed. No statistically significant differences were observed between groups in the odds of achieving DAS28 remission, mACR20 or mACR70, or experiencing a serious adverse event.

**Conclusion:** Current evidence from observational studies shows greater improvements with the swapping strategy compared with the cycling strategy in terms of efficacy for RA patients failing their first TNFi. No differences were observed regarding safety. Data were not available for anakinra, certolizumab pegol, golimumab, or tofacitinib.

## **When Etanercept Switch Fails – Clinical Considerations**

Oliver Hendricks and **Kim Hørslev-Petersen**, King Christian X's Hospital for Rheumatic Diseases, University of Southern Denmark, Institute of Regional Health Research, Denmark, Graasten, Denmark

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

On January 14th 2016 EMA approved the biosimilar Etanercept (SB4, Benepali) for clinical use. A non-medical switch from originator Etanercept (ETA, Enbrel) to SB4 was conducted in all Danish outpatient clinics in 2016. Disease activity was largely unaffected in the majority of patients; however 9 patients stopped treatment during the follow-up. There is limited outcome data in switch failures.

### **Methods:**

At King Christian X's Hospital for Rheumatic Diseases, a non-medical switch from ETA to SB4 was carried out in June 2016. Clinical assessment was performed at baseline, after 4 and 8 month. We recorded clinical outcome measurements according to the Danish DANBIO registry for RA and AS. In case of a lack of effect (LOE) and/or adverse events (AE) during the first 4 month after switch, we altered the biologic treatment based on the following objectives:

A. The clinical situation on Enbrel was stable, but Flare (ASDAS >2.1 or DAS28CRP > 3.2) observed at least once during a 24 month period before switch.

B. The clinical situation on Enbrel was characterized by complete remission (ASDAS rate < 1.2 or DAS28CRP < 2.6) for at least 24 months.

**Results:** We registered unchanged efficacy after switch in 76 out of 85 cases. In nine cases we recorded significant LOE and/or AE during the first 4 month after switch. Four of the nine cases matched scenario A. The treatment with Benepali continued in two of those cases. In the other two cases a change to a third biologic treatment was performed due to prolonged disease activity. Five cases matched scenario B (One case of AE, three cases of LOE and one case of combined AE & LOE). The patients had experienced complete remission at least for 2 (and up to 9) years. In these cases we interpreted Benepali to be potentially causative and performed the switch back to Enbrel. All five patients regained complete remission without further adverse events.

### **Conclusion:**

No studies exist, that investigate the outcome of Etanercept switch on an individual level. In our study, 89% of the patients experienced the non-medical switch to Benepali as the uncomplicated continuation of a successful treatment. For the last 11 % the situation was different. From the patient's perspective, it is obvious that experienced AE's and/or LOE's are suspicious to be a consequence of the switch. A meticulous assessment and documentation before

performing the switch is crucial. It is our experience that a prolonged SB4 treatment was adequate in those cases, where the doctor was able to illustrate that episode(s) of Flares also previously had occurred.

In contrast, complete remission before switch followed by significant LOE's or AE's after switch, led to considerations about the structural differences of the compounds. Furthermore, it has to be taken into account, that the patient's willingness to continue with Benepali is limited in this situation.

Explaining the patient that "the same current comes out of the socket, even though the new factory creates the electricity" keeps true in almost 90 % of the cases, but switch failure is a challenge. We switched back to Enbrel in five cases of significant contrast of clinical outcome before and after switch. The Switch back was successful in these cases.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tumor necrosis factor alpha (TNF $\alpha$ ) inhibitors have been used to treat rheumatoid arthritis (RA) for >10 years. The outcomes has revolutionized the treatment goal of RA to clinical remission, structural remission and functional remission. Although the efficacy of this drug as a treatment for patients with active RA has been widely demonstrated, some RA patients initially respond to treatment but subsequently their responsiveness decreases. One of the alleged reasons for this phenomenon is immunogenicity associated with the drug itself. Thus, it is useful to switch to a less immunogenic biologic agent to maintain disease activity and minimize adverse events. Golimumab is less immunogenic compared other TNF inhibitors.

The purpose of this study was to evaluate the efficacy and safety of switching from tumor necrosis factor (TNF) inhibitor to subcutaneous golimumab (GLM-SC) in RA patients for maintenance of disease activity or adverse events.

**Methods:** Thirty-seven patients who had treated with infliximab, etanercept or certolizumab pegol were switched to GLM-SC for maintenance of disease activity or adverse event. The patients were divided into three groups: the LDA group and the LDAq8w group, which included patients with low disease activity or remission who switched to GLM therapy at 50 mg at 4-week and 8-week intervals, respectively; and the MDA group, which included patients with

moderate disease activity who switched to GLM therapy at 50 mg at 4-week intervals. Effects of TNF inhibitors to GLM-SC switch were evaluated at week 12, 24 and 52 after switching.

**Results:** A total of 37 patients were analyzed during the survey period: 16 in the LDA group, 14 in the LDAq8w group, and 7 in the MDA group. The mean DAS28-ESR and -CRP values in the LDA and LDAq8w groups maintained from baseline throughout the 52-week treatment period. The proportions of patients who achieved DAS28-ESR remission (defined as < 2.6) in the LDA group and the LDAq8w group were maintained over time from 75.0% (12/16) and 78.6% (11/14) at baseline to 93.8% (15/16) and 92.3% (13/14) at week 52, respectively. There were no patients in flare to moderate or high disease activity. In the MDA groups, the mean ( $\pm$  SD) DAS28-ESR values improved significantly from 4.2 ( $\pm$  0.6) at baseline to 3.1 ( $\pm$  0.7) and 2.8 ( $\pm$  0.8) at 24 and 52 weeks, respectively. There were no patients in flare to high disease activity. Treatment discontinuations due to adverse events were occurred 1 patient in the MDA group, and no serious adverse events occurred during the observation period in the LDA group or the LDAq8w group. Treatment continuation rate at 52 weeks was 100% in the LDA and LDAq8w group and 85.7% in the MDA group.

**Conclusion:** Clinical efficacy in GLM-SC treated patients were sustained or improved in patients switched from TNF inhibitors without serious safety concerns. The present results indicate that therapeutic efficacy is adequately maintained in the majority of Japanese RA patients who switch from TNF inhibitors to GLM-SC. We also consistently demonstrated the safety of this therapy. These results provide supportive evidence for use of GLM-SC for continued control of RA disease activity.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Considering the huge burden of RA in India, the use of biologic DMARDs is miniscule. The major deterrents are cost, poor awareness and few rheumatologists. Despite an inherent appeal, Rituximab (RTX) is yet to find favour. Encouraged by a generous donation of Rituximab (Ristovos™/ RTX) vials, we designed a protocol driven

observational study to determine the response to RTX in RA and optimize outcome. We present initial results. The study is ongoing.

**Methods:** 60 consenting patients (ACR 1987 classified, 80% women, mean age 45.2 years, 100% seropositive RF/anti CCP, 92% erosive, 35% deformities) with active severe RA (mean disease duration 92 months, mean DAS 28 ESR 6.5) despite prolonged methotrexate (mean dose 18.5 mg weekly) and often steroid intake (8.5 mg daily) were enrolled to receive RTX (2 infusions, 500 mg each, fortnightly) in a community rheumatology centre; standard screening included that for TB. We use ACR recommended 68/66 joint count and efficacy measures in routine practise; validated Indian HAQ version. Clinical status and background medication (especially methotrexate and steroids) was monitored at week 6, 12, 24 and 36 as per protocol. 31 Patients failed ACR 50 (primary response) at week 6 and were randomized into 2 arms [500 mg RTX infusion (third) plus 120 mg injectable methylprednisolone (M-Pred) in 14 patients or only 120 mg M-Pred in 17 patients). At subsequent evaluations, all ACR 50 non-respondents received single 120 mg M-Pred. Comprehensive laboratory work up included CD 19 cell count (Beckman Coulter FC 500). Standard statistical analysis was performed; significant  $p < 0.05$ . 54 patients completed 24 weeks and 50 patients completed 36 weeks.

**Results:** Patients improved significantly in joint counts, pain VAS and HAQ by week 24 & 36 ( $p < 0.05$ ), mean DAS 28 reduced to 3.1 (low disease activity). General Health improved from 5.2 to 7.3 [mean VAS, 0 (poor) to 10 cm (optimum)]. Patients with ACR 50 response at week 6 had least CD 19 count and were likely to maintain response by week 34. Patients receiving 3 infusions had the lowest CD 19 count at week 12. Table shows (percent patients) ACR 50 & 70 response. The additional RTX infusion did not seem to confer any obvious benefit. Two patients withdrew soon after the initial infusions (1 developed severe febrile cytopenia, anaemia and mucositis). None of the patients completing 36 weeks withdrew due to AE, albeit mild (dyspepsia, skin rash, mucositis, upper respiratory infections and headaches). We admit several confounders and limitations.

**Conclusion:** In this true to life Indian study, patients with difficult RA were treated with a relatively lower dose Rituximab but showed a significant sustained improvement for least 36 weeks. The ACR 50 and 70 response was strikingly encouraging. The role of Rituximab in certain subjects (RA) may be profound. We beseech an early validation study by the innovator.

Patient Category / Evaluation visit (weeks)	R II (n=23)	NR II (n=17)	NR III (n=14)	TOTAL (n=54)
Week 6	*	*	*	43

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are many biological therapies for Rheumatoid Arthritis (RA) with different mechanisms of action and good efficacy rate; however, up to 40% of patients (pts) fail to respond to the 1st biologic agent, and it is still not clear what strategy to follow after showing inadequate response to tumor necrosis factor  $\alpha$  inhibitors (TNFi). Our objective was to assess the clinical response and survival (SVV), in our cohort of RA pts that discontinued the 1st

TNFi, of a 2nd TNFi vs a nonTNFi, both in the global cohort and in the subpopulation that dropped out the 1st TNFi due to inefficacy

**Methods:** This observational study included 149 pts in the RA-Paz cohort who previously suspended Infliximab, Adalimumab, Etanercept and Certolizumab between 1999-2016. Two groups were established as they switched to a TNFi or nonTNFi. Clinical response was evaluated by DAS28, Delta-DAS28 ( $\Delta$ DAS28) and EULAR response (E-resp). The assessments were performed at 6 (v-6) and 12 months (v-12) since initiating 2nd biological agent and during the last visit prior to drug discontinuation or ending of the study for those who did not interrupt the drug (v-end). T tests and Fisher's exact test were used to test statistical differences. Analysis was performed using SPSS 20.0

**Results:** Of the 149 pts who had stopped their 1st TNFi, 61% changed to a 2nd TNFi. The 81% of the overall pts were women. The mean age was  $62 \pm 14$  years and the mean time of 2nd biologic drug was  $3.03 \pm 3.2$  years. 58% associated methotrexate at the beginning of 2nd biologic agent, without differences between groups. At v-6 and v-12, there was no difference in  $\Delta$ DAS28 [at v-6:  $1.3 \pm 1.4$  in TNFi and  $1.2 \pm 1.2$  in nonTNFi ( $p=0.95$ ), at v-12:  $1.3 \pm 1.4$  in TNFi and  $1.4 \pm 1.1$  in nonTNFi ( $p=0.88$ )]. In contrast, at v-end, pts with nonTNFi showed a higher clinical improvement ( $\Delta$ DAS28:  $0.8 \pm 1.7$  in TNFi,  $1.7 \pm 1.2$  in nonTNFi,  $p=0.001$ ). At v-6, the TNFi group achieved higher good E-resp rate (39% vs 18%,  $p=0.01$ ), but there was no difference at v-12 (34% in TNFi vs 23% in nonTNFi,  $p=0.42$ ). However, at v-end, the nonTNFi group achieved better E-resp (good resp: 37% in nonTNFi vs 26% in TNFi, no resp 18% in nonTNFi vs 50% in TNFi,  $p=0.005$ ). Likewise, 100% ( $n=9$ ) of the pts that finished 2nd biologic agent by remission, had changed to a nonTNFi ( $p<0.00001$ ). There were no differences regarding 2nd biologic drug SVV (mean SVV time of  $5.2 \pm 0.6$  in TNFi,  $4.4 \pm 0.5$  in nonTNFi,  $p=0.507$ ). A multivariate analysis adjusted for possible confounding factors (sex, age, smoking, RF, anti-CCP and basal DAS28 and DMARDs) was performed; same behavior as in the main analysis was observed. When analyzing the cohort that discontinued 1st TNFi because of inefficacy, at v-6 and v-12 there were no differences between switchers to TNFi and nonTNFi in  $\Delta$ DAS28 ( $p=0.192$ ), but at v-end, the nonTNFi group reached a higher  $\Delta$ DAS28 ( $0.9 \pm 1.5$  in TNFi,  $1.7 \pm 1$  in nonTNFi,  $p=0.031$ )

**Conclusion:** In our sample of RA patients who suspended Ifx/Ada/Etn/Ctz as 1st TNFi, switching to a 2nd biologic agent did not show relevant clinical differences between a TNFi and a nonTNFi within the 1st year of treatment. However, in the long-term, switching to a nonTNFi shows enhanced clinical benefits with no impact on survival vis-à-vis a 2nd TNFi. Despite the efficacy of TNFi, new therapeutic targets are needed.

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The efficacy of Golimumab (GLM) treatment in rheumatoid arthritis (RA) has been widely documented. The aim of this study was to analyze the long-term retention of GLM and to identify independent predictors of drug retention in patients with AR.

**Methods:** Prospective monocentric cohort of RA patients treated with GLM according with clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analyzed with Cox proportional hazard regression model.

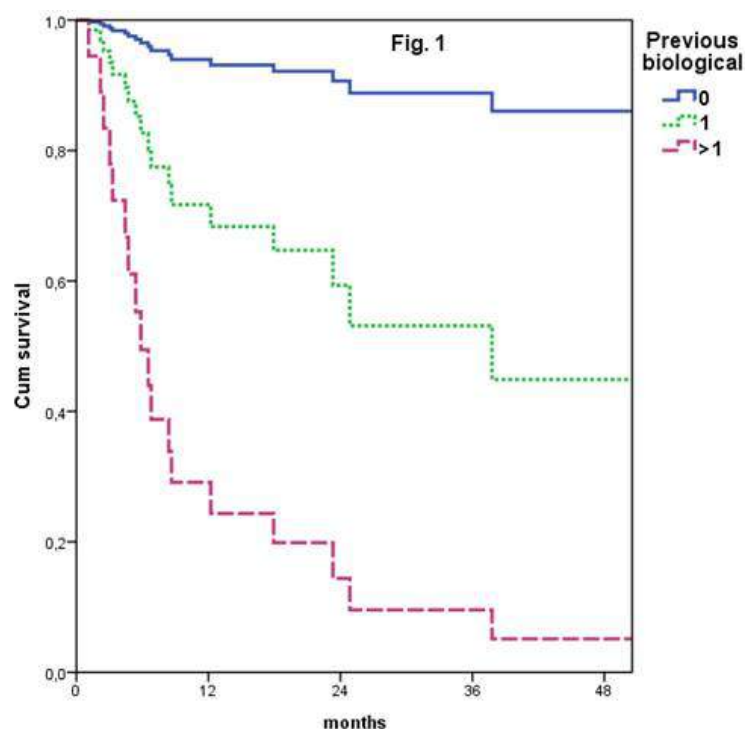

**Results:** 61 patients were included. The baseline characteristics of the patients are shown in Table 1. Mean follow-up time 26.8 months (SD 26.1). Mean survival time was 46,3 months (95% CI: 35.6-57.1) Age, gender, DAS28 at baseline, rheumatoid factor (RF), antibodies anti-cyclic citrullinated peptide (anti-CCP), concomitant DMARD and previous treatment with biological therapy were considered in the univariate analysis.

Table 1. Baseline demographic and clinical characteristics of the patients.

Age -mean (SD)- years	55.1 (14.1)
Female gender %	85.2%
Mean evolution time (SD) years	10.2 (8.1)
SCJ -mean-(SD)	4.1 (3.6)
DAS28 -mean-(SD)	4.7 (1.4)
RF+ %	70%
Anti-CCP + %	78%
Concomitant DMARD %	74,6%
Biological therapy naïve %	53.3%

Upon Cox regression analysis, concomitant DMARD [HR 2.6 (95% CI 1.2-5.8)] and use of GLM as first biological [HR 6.3 (95% CI 2.5-15.8)] were predictors of better GLM retention rate. When analyzing the number of previous biologicals, GLM retention rate was not statistically different as first or second biologic [HR 5.3 (95% CI: 0.8-32.4)]. GLM retention rate was significantly worst when used as third or fourth biological [HR 19.8 (95% CI 4.3-89.9)]. Figure 1. 27/61 (44.3%) patients discontinued GLM, 18/27 (66.7%) due to lack of efficacy, 8/27 (29.6%) due to adverse event and 1/27 (3.7%) for other reasons.

**Conclusion:** Real life long term Golimumab retention rate was good. Golimumab survival time was better when used as first or second biological and with concomitant DMARD.

## Efficacy and Survival of Biologic DMARD Therapies As Monotherapy: Real World Data

Jose A Gómez-Puerta<sup>1,2</sup>, Natalia Duque Zapata<sup>1</sup>, Luis Alonso Gonzalez<sup>1,3</sup>, Carmen Cerón<sup>1</sup>, Monica Vásquez<sup>1</sup> and Oscar Jair Felipe Diaz<sup>1,4</sup>, <sup>1</sup>Medicarte IPS, Medellín, Colombia, <sup>2</sup>Grupo de Reumatología, Universidad de Antioquia, Medellín, Colombia, <sup>3</sup>Grupo de Reumatología, Universidad de Antioquia, Medellín, Colombia, <sup>4</sup>Clinica Las Vegas, Medellín, Colombia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** According different international registries, around one third of patients under biologic DMARD (bDMARD) with rheumatoid arthritis (RA) are receiving bDMARD as monotherapy (1-4). In Latin-American countries, the efficacy and survival of bDMARD as monotherapy is less well known (5). Our aim was to analyze efficacy and survival rates of bDMARD therapies (either anti TNF and non anti TNF) in a cohort of Colombian RA patients.

**Methods:** We conducted a cross-sectional study including patients with diagnosis of RA treated at Medicarte IPS from March 2009 to December 2016. Medicarte is a referral center for the integral medical care and pharmaco-surveillance of patients under biologic therapies in 13 cities in Colombia. Clinical information was obtained from electronic clinical records. Only those patients with complete information including disease activity indexes at baseline and at the last follow-up were included. We defined remission if DAS-28 (ESR) was  $< 2.6$ . Survival rates were analyzed using Kaplan-Meier survival curve. Patients were censored if fail to maintain remission or due to loss of follow-up

**Results:** From 1,020 patients with RA under bDMARD, we identified 139 (13.6%) patients treated as monotherapy. 90% of them were female with a mean age of  $56.6 \pm 10.9$  years. Mean disease duration was  $16.8 \pm 9.9$  years and mean time under bDMARD was  $3.3 \pm 2.4$  years. Eighty three percent of patients were seropositive (FR and/or CCP) and mean DAS28 at baseline of bDMARD therapy was  $4.23 \pm 1.0$ . 102 (73%) out of 139 patients in monotherapy were on non anti TNF and 37 (27%) on anti TNF. From non-anti TNF therapies, tocilizumab was used in 52 patients, rituximab in 25 and abatacept in 25 patients. At last visit, remission rates were higher in patients under non-anti TNF vs anti TNF (70.6 vs 54%,  $p=0.069$ ). Low disease activity rates were similar in both groups (77.5% vs 70.3%,  $p=0.384$ ). Five year survival rates were significantly higher in patients treated with non-anti TNF vs anti TNF therapies. Among non-anti TNF therapies, survival rates were significantly higher in patients treated with tocilizumab, than in patients treated with rituximab or abatacept.

**Conclusion:** In our cohort of RA patients under bDMARD, 13% of patients are receiving biologic as monotherapy. Survival rates in terms of remission, were higher in patients under non anti TNF therapies, especially in patients treated with tocilizumab.

## **Sustained Clinical Response in Refractory Rheumatoid Arthritis Patients with a Low-Dose Rituximab Retreatment Regimen. a Single Center Experience**

**Sebastian C Rodriguez-Garcia**, Raul Castellanos-Moreira Sr., M. Victoria Hernández, Andrea Cuervo, Virginia Ruiz-Esquide, Julio Ramírez, Juan Cañete and Raimon Sanmartí, Rheumatology Service, Hospital Clínic de Barcelona, Barcelona, Spain

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** : The standard dose of rituximab (RTX) in rheumatoid arthritis (RA) is two intravenous (iv) 1 g infusions, separated by two weeks. Recently, the efficacy of a low-dose of RTX for retreatment in RA patients has been reported (1). Our aim is to assess the long-term sustained effectiveness of a low-dose of RTX in daily clinical practice.

**Methods:** Observational retrospective study in a tertiary hospital. We included all RA patients that have received at least one cycle of RTX, at a standard dose, between May 2006 and May 2017. We selected those patients who achieved a good or moderate EULAR response, and thereafter were down-titrated to a low-dose regimen (1 g), according to clinical judgment. Variables analyzed: age, sex, duration of RA, presence of ACPA (antiCCP2) and rheumatoid factor (RF), use and dosage of glucocorticoids (GC) and synthetic DMARD (csDMARD) before and after RTX treatment, number of biologic DMARD (bDMARD) used prior to initiate RTX. Disease activity was measured using the DAS28-ESR index (at baseline, at initiation and during the low-dose RTX period, and at the last follow-up visit).

**Results:** From 2006 until 2017, 53 RA patients received, at least, one cycle of 2g RTX. Thirty-seven patients (69.8%) achieved a good or moderate EULAR response (mean initial pre-RTX DAS-28:  $5.79 \pm 1.17$ ) and were step-down to a low dose re-treatment regimen. Baseline characteristics of patients receiving low-dose RTX: mean age  $56.4 \pm 10.9$  years; 13.5% male, mean disease duration  $12.7 \pm 9.8$  years, 91.9% RF + and 97.3 % ACPA +; mean pre-low dose RTX DAS-28:  $4.08 \pm 1.39$ . Thirty-four patients (91.9%) were on cs-DMARDs (51.4% with methotrexate (MTX) and 37.8% with leflunomide (LEF)), and 32 (86.5%) received concomitant GC. RTX was the first biologic only in 10 patients (27%). In the remaining cases, the mean number of previous b-DMARDs was  $2.52 \pm 1.5$ . Twenty-seven patients (73%) received only one standard cycle (2g) before RTX dose reduction.

A statistically significant reduction in the mean DAS-28 was observed between the first visit on 1g RTX ( $4.08 \pm 1.39$ ) with the last follow-up visit ( $3.04 \pm 0.95$ ;  $p < 0.0001$ ), as well as, with the mean DAS-28 during the low-dose RTX period ( $3.63 \pm 0.92$ ;  $p < 0.006$ ).

11 were able to reduce dosage (8 MTX, 3 LEF), with a significant reduction for MTX ( $16.5 \pm 4.4$  mg vs.  $11.92 \pm 8.0$  mg;  $p < 0.01$ ). From the 32 patients initially receiving GC, 18 (56.3%) were able to reduce dose ( $9.36 \pm 5.06$  vs  $4.80 \pm 4.04$ ;  $p < 0.0001$ ), and 9 (28%) discontinued GC therapy.

After a follow-up of  $3 \pm 1.8$  years, only 10 (25%) patients have withdrawn RTX. Reasons were: recurrent infections in 4 cases (11%), loss of efficacy in 2 cases (5.6%), and adverse event and patient preferences in one case, respectively.

**Conclusion:** A sustained clinical response was observed with the 1 gr retreatment of RTX over a long term period.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The efficacy and safety of subcutaneous (SC) abatacept in the management of rheumatoid arthritis (RA) has been demonstrated in numerous controlled clinical trials. However, real-world data of SC abatacept in routine care are scarce. The aim of this interim analysis is to compare the effectiveness and safety of SC abatacept used as first line or second biologic agent in Canadian patients enrolled thus far in Abatacept Best Care (ABC).

**Methods:** ABC is a prospective, multicenter, randomized study aimed at comparing a T2T approach vs. standard of care in real-life management of patients with RA starting SC abatacept as first line or second line biologic agent, and describing the adherence of physicians to the recommended T2T treatment guidelines while collecting data on the real-life use of SC abatacept. General linear models were used to assess the impact of prior biologic use on treatment effectiveness.

**Results:** 276 patients (74.3% females) were included with a mean (SD) age of 59.7 (11.7) years and duration since RA diagnosis of 7.5 (8.9) years; of these 214 (77.5%) and 189 (68.5%) had available follow-up data at 6 and 12 months, respectively. Prior biologic use was reported for 39.5% while 60.5% were biologic-naïve. Overall, baseline disease parameters were comparable with the exception of time since RA diagnosis (9.0 vs. 6.4 years;  $P<0.001$ ) which was significantly higher in biologic experienced patients and TJC28 (10.5 vs. 9.1;  $P=0.062$ ) which was numerically higher.

After 6 months of treatment, both patient groups experienced significant improvements in all disease parameters which were maintained or further enhanced by 12 months. However, upon adjusting for baseline disease activity, improvements in CDAI ( $P=0.020$ ), physician global ( $P=0.011$ ), TJC28 ( $P=0.031$ ), SJC28 ( $P=0.009$ ), and HAQ ( $P=0.037$ ) at 6 months were significantly higher in biologic-naïve patients (Table 1). Similar results were obtained at 12 months.

A total of 533 AEs were reported for 162 (58.7%) patients, 67.0% of biologic-experienced patients and 53.3% of biologic-naïve patients (256.1 vs. 211.2 events/100 PY). The most common AEs were upper respiratory infections (biologic-experienced vs. biologic-naïve: 4.6% vs. 9.0%; 5.2 vs. 14.6 events/100 PY) and bronchitis (7.3% vs. 7.8%; 8.4 vs. 10.2 events/100 PY). Serious AEs and serious infections were reported for 26 (9.4%) patients (10.1% vs. 9.0%; 16.8 vs. 13.2 events per 100/PY) and 5 (1.8%) patients (0.9% vs. 2.4%; 0 vs. 1.5 events/100 PY), respectively.

**Conclusion:** The results of the current analysis suggest that SC abatacept has similar safety in biologic-naïve and -experienced patients with more improvement in outcome measures in the former.

Kivitz<sup>2</sup>, Tsutomu Takeuchi<sup>3</sup>, Yoshiya Tanaka<sup>4</sup>, Satoshi Nakashima<sup>5</sup>, Jennifer Hodge<sup>6</sup>, Hong Tang<sup>6</sup>, Paula O'Connor<sup>6</sup> and **Barbara Finck**<sup>6</sup>, <sup>1</sup>Panorama Medical Centre, Cape Town, South Africa, <sup>2</sup>Department of Rheumatology, Altoona Center for Clinical Research, Duncansville, PA, <sup>3</sup>Keio University School of Medicine, Tokyo, Japan, <sup>4</sup>School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, <sup>5</sup>Daiichi Sankyo, Tokyo, Japan, <sup>6</sup>Coherus BioSciences, Inc., Redwood City, CA

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CHS-0214 is a proposed biosimilar to etanercept for the treatment of rheumatoid arthritis and other auto-immune diseases. Two randomized, double-blind studies demonstrated equivalence of CHS-0214 to etanercept in patients with rheumatoid arthritis (RA) and chronic plaque psoriasis (PsO). This ongoing, open-label, safety extension study evaluates the long-term safety of and durability of response to CHS-0214 in patients who completed Week 48 of a prior trial.

**Methods:** All patients are to receive open-label CHS-0214 50 mg weekly for at least 48 weeks. Patients are evaluated at 1 and 3 months post enrollment and every 3 months thereafter. Patients had to have achieved an ACR20 or a PASI50 at Week 48 in the prior trial. The primary endpoints are maintenance of response (ACR20 or PASI50) at Week 4, Week 12 and every 3 months thereafter during the study.

**Results:** This interim analysis included 359 patients with a mean duration of treatment of 31.45 weeks of open-label CHS-0214 in addition to 48 weeks of treatment in the prior study. Of those, 56.5% were female, 49.6% were Asian, and 44.3% were white. Mean age was 49.9 years, and mean body mass index was 27.1. Of the 359 (225 with RA and 134 with PsO), 357 received  $\geq 1$  dose of study drug.

Overall, 197 (87.9%) patients with RA had achieved a durable response (maintenance of ACR20), and 118 (90.1%) of patients with PsO had achieved a durable response (maintenance of PASI50) as of the data cut-off date. Loss of efficacy was a factor in study discontinuation for 5 patients. Treatment-emergent adverse events were reported in 216 (60.5%) patients, and serious TEAE were reported in 14 (3.9%) patients. Four (1.1%) patients had a TEAE that led to study drug discontinuation. The most common ( $>5\%$ ) TEAEs were nasopharyngitis and upper respiratory tract infection.

**Conclusion:** The majority of patients maintained an efficacious response to treatment with CHS-0214. Treatment was well tolerated and the incidence of TEAEs did not increase with ongoing drug exposure. No new safety signals were identified in these patients with an average of 80 weeks of treatment.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Patients (pts) with RA generally receive conventional synthetic DMARDs (csDMARDs) as first-line therapy, and inadequate responders (IR) to csDMARDs generally receive biological DMARDs (bDMARDs). We evaluated the efficacy and safety of tofacitinib in 3 RA pt populations (popns) who had incomplete response or were intolerant to prior lines of therapy (both referred to as IR).

**Methods:** Data from pts who were 1) non-MTX csDMARD-IR but not bDMARD-IR; 2) MTX-IR but not bDMARD-IR; and 3) bDMARD-IR (referred to as non-MTX csDMARD-IR, MTX-IR, and bDMARD-IR) were pooled from 8 Phase 2 and 6 Phase 3 trials evaluating the efficacy and safety of tofacitinib 5 or 10 mg BID vs placebo (PBO) in RA. Pts may have received >1 prior csDMARD, and in ~60% of the studies tofacitinib was given in combination with a csDMARD, commonly MTX. Month (M)3 efficacy outcomes included % of pts achieving ACR20/50/70 responses or Disease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28-4[ESR])<2.6 (remission), and change from baseline (BL) in DAS28-4(ESR) or HAQ-DI scores. No multiplicity adjustments were made. Crude incidence rates (CIR; unique pts with events/100 pt-yrs) based on adverse events (AEs) through M24 were calculated as safety outcomes.

**Results:** The non-MTX csDMARD-IR, MTX-IR, and bDMARD-IR popns comprised a total of 537, 3113, and 782 pts, respectively (Table; the non-MTX csDMARD-IR and bDMARD-IR popns were substantially smaller). Prior csDMARDs received by the total non-MTX csDMARD-IR, MTX-IR, and bDMARD-IR popns were chloroquine (17.7%, 13.8%, 4.1%), hydroxychloroquine (37.2%, 21.2%, 19.8%), leflunomide (19.4%, 20.5%, 24.2%), MTX (7.3% [not IR to MTX], 100%, 95.5%), sulfasalazine (31.1%, 26.8%, 18.0%), and others (8.0%, 10.7%, 10.4%), respectively. BL characteristics were similar between non-MTX csDMARD-IR, MTX-IR, and bDMARD-IR popns except for mean RA duration (5.2–7.2, 8.1–8.6, and 11.6–12.2 yrs, respectively). Most pts were female (80.3–85.4%), mean age range was 49.7–54.6 yrs, and mean DAS28-4(ESR) score ranged from 6.2–6.5. Significantly higher ACR response rates and greater changes from BL in DAS28-4(ESR) and HAQ-DI scores at M3 were recorded with tofacitinib 5 and 10 mg BID in all popns vs PBO (Table). A trend was observed for numerically higher proportions of non-MTX csDMARD-IR pts achieving efficacy outcomes vs MTX-IR and bDMARD-IR popns. CIRs for TEAEs, SAEs, and DC due to AEs were numerically lower in the non-MTX csDMARD-IR popn vs the MTX-IR popn and both popns had lower CIRs vs the bDMARD-IR popn. For numerical differences, 95%CIs generally overlap. AEs of special interest are reported (Table).

**Conclusion:** Tofacitinib is associated with improved efficacy and most safety outcomes vs PBO in each of the non-MTX csDMARD-IR, MTX-IR, and bDMARD-IR popns, and may be more efficacious when used in earlier lines of therapy.

Table. Efficacy outcomes at Month 3 and safety outcomes to Month 24									
	Tofacitinib 5 mg BID			Tofacitinib 10 mg BID			PBO

# Analysis of the Efficacy, Safety and Continuation Rate of Abatacept in Elderly Patients with Rheumatoid Arthritis

**Mayumi Matsuda**<sup>1</sup>, Yu Funakubo Asanuma<sup>2</sup>, Noritsune Kouzu<sup>3</sup> and Toshihide Mimura<sup>2</sup>, <sup>1</sup>Department of Rheumatology and Applied Immunology, Saitama Medical University, Moroyama-machi, Japan, <sup>2</sup>Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, <sup>3</sup>Saitama Medical University, Moroyama, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017  
**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars  
**Session Type:** ACR Poster Session C  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The elderly rheumatoid arthritis (RA) patients have declined physical performances and various complications. The efficacy of the biological DMARDs may decrease in elderly RA patients because not enough dosage of MTX could be used for them, due to some concerns such as risks of the infection increasing. The purpose of this study was to examine the efficacy, safety and continuation rate of abatacept(ABT) in elderly patients with RA.

**Methods:** sixty-three RA patients who had received ABT in Saitama Medical University Hospital between Oct. 2010 and May 2016 were divided into 2 groups. One was 64 years old and under (n=31), the other was 65 years old and over

(n=32). In these 2 groups, we examined the retrospective evaluation of the patients' background, disease activity, decline in physical performance, reduction of methotrexate (MTX) or prednisolone (PSL) dose, safety and continuation rate of ABT.

**Results:** In the patients background (younger group/elderly group), mean age of onset (46/60 year-old), rate of female (83.9/84.4%), naïve rate of biological DMARDs (51.6/28.1%), mean disease duration (7.9/12.1 years), rate of MTX use (64.5/37.5% p=0.045), rate of PSL use (64.5/87.5% p=0.041), mean dose of MTX (5.4/3.1mg/week), mean dose of PSL (5.0/5.1mg/day), DAS28-ESR4 (5.53/5.84), and HAQ (1.13/1.67 p=0.046), positive rate of RF (74.2/93.8% p=0.043) were observed. The elderly group showed higher HAQ (p=0.046) than the younger group. In effectiveness, DAS28-ESR4 and HAQ significantly decreased in both groups for the observational period of one year after initiation of ABT therapy (P<0.05). ABT therapy did not reduce the dose of MTX for one year, while reduction of the dose of PSL was observed in both groups. There were no significant differences in the continuation rate between the younger (87.1%) and the elderly group (75.0%). The cancellation reason of ABT (younger group/elderly group) were due to adverse events (6.5/12.5%), ineffective (6.5/6.3%), remission (0.0/3.1%) one year after ABT started.

**Conclusion:** The ABT treatment in the elderly RA patients was suggested useful as much as in the younger patients regarding the effectiveness, the reduction of PSL dose, and the continuation rate.

## **Biosimilarity between Humira® and the Biosimilar Candidate SB5 in Product Quality**

**Nayoung Lee,** Minlee Kim, JongAh Joanne Lee, Soohwan Kim and Hahymn Yang, Samsung Bioepis, Incheon, Korea, Republic of (South)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster III: Efficacy and Safety of Originator Biologics and Biosimilars

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A biosimilar is a biopharmaceutical product that is highly similar to an already licensed one in terms of quality, safety, and efficacy. We (Samsung Bioepis) have been developing a biosimilar of Humira® (adalimumab), designated as SB5. To demonstrate its biosimilarity in quality to Humira®, we performed a comprehensive characterization in terms of structure, heterogeneity in size and charge, and biological properties following the ICH, FDA, and EMA guidelines.

**Methods:** We analyzed all available lots of SB5 and more than 70 US- or EU-sourced lots of Humira®, using state-of-the-art methods whenever desirable, and compared the two sets of data. The structural properties comprised primary and higher-order structures and N-glycosylation. The physicochemical characteristics were categorized into liquid chromatographic patterns and electrophoretic pattern concerning size and charge heterogeneity. The biological properties were examined by *in vitro* functional assays.

**Results:** Amino acid sequence and modification were demonstrated by peptide mapping analysis using mass spectrometry, which resulted in the identity in amino acid sequence and the identical site of N-glycosylation between SB5 and Humira®. All N-glycan species were also identical to each other. To testify 3-dimension structural similarity, the butterfly plots of hydrogen/deuterium exchange (HDX) was conducted and showed that SB5 and Humira® are highly similar in terms of solvent accessibility. These results demonstrated a high degree of structural similarity.

The %contents of High Molecular Weights (%HMWs) were determined by size-exclusion HPLC (SE-HPLC) and were shown to be highly similar between SB5 and Humira®. The %contents of Low Molecular Weights (%LMWs) were determined by capillary-electrophoresis sodium dodecyl sulfate, with reduced samples and non-reduced samples (CE-SDS-R, and CE-SDS-NR, respectively). Non-glycosylated heavy chain (NGHC) by CE-SDS-R was the impurity that the amounts are not highly similar between SB5 and Humira®; however, the difference is not considered to be significant clinically.

The charge heterogeneity was investigated not only for the %contents of the variants, by cation-exchange HPLC (CEX-HPLC) and imaged capillary isoelectric focusing (icIEF) but also for the structural identities. The variants were found to contain identical structures, and although the %contents showed difference but it will not be considered to be significant clinically based on the result of clinical study.

With regard to TNF- $\alpha$  binding and neutralization, which are the primary modes of action of adalimumab, SB5 was similar to Humira®. The levels of apoptosis, another Fab-related function, and all the Fc-related functions analyzed, including Fc receptor binding, antibody-dependent cell-mediated cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) were found similar between SB5 and Humira®.

**Conclusion:** A comprehensive set of physicochemical and biological characterizations has demonstrated that SB5 is highly similar to Humira® in product quality.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The natural history of axial spondyloarthritis (axSpA) has not been clearly established yet. The aim of this study is to evaluate the natural course of axSpA patients and compare it between radiographic [(ankylosing spondylitis (AS))] and non-radiographic (nr-axSpA) sub-groups of the Turkish population of the PROOF study.

### **Methods:**

PROOF is a large observational study, ongoing in 29 countries, aiming to reveal the long-term clinical and radiographic outcomes of patients classified as axSpA according to ASAS criteria. Patients were eligible if diagnosed within  $\leq 1$  year prior to the study initiation. Besides assessing disease activity, function, productivity and quality of life (QoL), nr-axSpA patients were followed up annually with sacroiliac joint (SIJ) radiographs. In addition to the treating physician, a central evaluator assessed the SIJ images. In the presence of discrepancy between the two readings, the images were inspected third time by the 2nd central reader and the final result corresponded to 2/3 readings.

### **Results:**

PROOF cohort is consisted of 2126 participants worldwide and 274 axSpA patients were included from 24 centers in Turkey. In total 167 (60.9%) patients were classified as AS and 107 (39%) as nr-axSpA by local investigator. According to the central SIJ readings (n=229), 146 patients (63.8%) were evaluated as AS and 83 (36.2%) as nr-axSpA. The demographic and disease-related characteristics of the study groups are summarized in Table 1. In the first visit, patients were under non-steroidal anti-inflammatory drugs (78.5%), sulfasalazine (22.6%), corticosteroids (5.5%), and TNF inhibitors (9.9%) treatment. In one-year follow-up visit, disease activity measures (physician assessed or patients reported and composite outcome measures) and the percentage of current smokers showed a similar decrease independent of disease subgroup. QoL was improved and overall total activity impairment was decreased during one year of observation. Based on local X-ray grading 1/23 (4.3%) of AS patients are reclassified as nr-axSpA and 9/39 (23.1%) of nr-axSpA patients as AS.

### **Conclusion:**

Although there were differences between the AS and nr-axSpA groups, such as female gender and CRP, baseline disease burden of AS and nr-axSpA patients were quite similar. During one-year follow-up; disease activity and QoL were improved similarly in both subgroups. Based on local X-ray readings, substantial proportion of nr-axSpA patients seemed to be progressed to AS, even in one-year period.

**Table 1:** Demographic and disease related characteristics of ankylosing spondylitis and non-radiographic axial spondyloarthritis patients on baseline and one year of follow-up.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Spondyloarthritis (SpA) carries substantial financial costs, including direct costs (use of medical services and treatments) and indirect costs (loss of work productivity). While disease related factors have been repeatedly shown to be associated with work outcomes, information on the role of individual socio-economic (SE) factors (education) and country wealth is scarce.

To explore the role of individual and country SE factors on employment, absenteeism and presenteeism, across 22 countries, from different world regions.

**Methods:** Patients with a clinical diagnosis of SpA, fulfilling the ASAS SpA criteria and in working age ( $\leq 65$  years old) from the evaluation of co-morbidities in spondyloarthritis (COMOSPA) were included. Outcomes explored were employment-status, absenteeism and presenteeism (the last 2 only in employed patients, in the last 7 days) according to the Work Productivity and Activity Impairment Specific Health Problem (WPAI-SHP) questionnaire. Three multivariable models were built (one for each outcome) using a multilevel mixed-effects binomial regression (for work status) and ordinal regression (for absenteeism and presenteeism), with country as random-effect.

Independent contribution of individual (education) and country level socio-economic factors (human development index (HDI), country healthcare expenditures and gross domestic product (GDP) (all low vs medium/high tertiles) were assessed in models adjusted for clinical factors.

**Results:** In total 3,114 patients were included (mean (SD) age 40.9 (11.8) years; 66% males; and 63% employed). Unadjusted employment rates ranged from 28% (Colombia) to 83% (Canada). After adjustment for relevant confounders, differences between countries in work status persisted ( $p < 0.01$ ). At the individual level, higher education was positively associated with being employed (OR=4.21 [95%CI 3.14;5.64]) and lower presenteeism (OR=0.61

[95%CI=0.40;0.93]) (table). At a country level, a higher healthcare expenditure was associated with being employed (OR=2.32; [95%CI=1.48;3.63]) and a higher HDI was associated with a higher employment (OR=1.89 [95%CI=1.19;3.27]) and lower absenteeism (OR=0.48 [95%CI=0.24;0.95]). No significant association was found for GDP. No significant association between any country SE indicators and presenteeism was found.

**Table – Impact of individual and country socio-economic factors on work outcomes, in models adjusted for socio-demographic and clinical variables and for between-country effects**

	Being employed (N=2,898) OR (95% CI)	Absenteeism (N=1,614) OR (95% CI)	Presenteeism (N=1,468) OR (95% CI)
Healthcare expenditure (ref: low)			
– high level	2.32 (1.48;3.63)	0.61 (0.31;1.20)	0.78 (0.47;1.30)
Disease duration (years)	0.98 (0.97;0.99)	0.96 (0.95;0.98)	0.96 (0.95;0.98)
Gender (male)	2.38 (1.98;2.88)	¥	0.78 (0.61;0.99)
Education level (ref: lower)			
-Secondary	2.48 (1.87;3.29)	¥	0.91 (0.60;1.39)
-University	4.21 (3.14;5.64)		0.61 (0.40;0.93)
Marital status (ref: single)			
-married/living together	1.89 (1.55;2.30)	**	**
-divorced	1.98 (1.30;3.02)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

International recommendations for the management of axial spondyloarthritis including ankylosing spondylitis (AS) suggest a BASDAI level of disease activity of  $\geq 4$  to indicate treatment with biologics. Other cut-offs have rarely been studied so far.

Therefore, we were interested to learn about the level of disease activity used in daily routine to start anti-TNF therapy.

## Methods:

In a posthoc subanalysis of the non-interventional, prospective, study GO-NICE that has been performed in a real life setting in Germany we used data from biologic naïve patients with established AS to study the initial BASDAI values before the start of therapy with Golimumab 50mg SC once monthly. Established standardized outcome measures were used.

## Results:

Out of a total of 543 AS-patients (pts.) documented in 126 German centers, 244 biologic-naïve pts. were eligible. A total of 134 pts. (54.9%) completed the 24 month observational period. The majority of pts. (70.5%), had a BASDAI  $\geq 4$  (group (gr.).1), while 14.3% had a BASDAI of  $\geq 2.8$  -  $< 4$  (gr.2) and 15.1% even had a BASDAI  $< 2.8$  (gr.3, Table). The patient demographics did not differ much between these 3 groups, the proportion of males was numerically somewhat lower in gr.1. The proportion of pts. with an elevated CRP was highest in gr.2 at BL. The BASDAI in gr.1,2 and 3 was initially  $5.9 \pm 1.3$ ,  $3.4 \pm 0.4$  and  $2.0 \pm 0.8$ , dropped significantly to  $2.2^* \pm 2.0$ ,  $1.9^* \pm 1.2$  and  $1.0 \pm 1.2$  within 3 months (\* $p < 0.0001$  vs. BL), and decreased significantly ( $p < 0.005$ ) to  $2.2 \pm 1.7$ ,  $1.9 \pm 1.7$  and  $1.4 \pm 1.0$  at month 24, respectively (fig.). The BASDAI 50% improvement was 68.8%, 44.8%, and 45.2% at month 3, and increased to 84.9%, 61.9%, and 55.0% at month 24, respectively.

Demographics and baseline characteristics	BASDAI $\geq 4$ ; n=172	BASDAI $2.8 - < 4$ ; n=35	BASDAI $< 2.8$ ; n=37	total AS patients; n = 244
Mean age [years] $\pm$ SD (range)	$41.9 \pm 12.5$ (18-72)	$44.7 \pm 11.6$ (20-69)	$39.1 \pm 12.5$ (23-69)	$41.9 \pm 12.4$ (18-72)
Proportion males n (%)	117 (68.0%)	29 (82.9%)	27 (73.0%)	173 (70.9%)
Mean time since first diagnosis [years] $\pm$ SD (range)	$8.8 \pm 9.5$ (0-49.2)	$10.1 \pm 10.2$ (0.1-37.9)	$8.7 \pm 9.0$ (0.2-36.5)	$9.0 \pm 9.5$ (0.0-49.2)
Mean C-reactive protein (CRP) [mg/l] $\pm$ SD (range)	$18.4 \pm 52.8$ (0.3-660.0)	$27.7 \pm 74.1$ (0.3-426.0)	$18.3 \pm 17.8$ (1.0-60.6)	$19.7 \pm 52.7$ (0.3-660.0)
Outside normal range? yes, no, missing, n (%)	75 (45.2%) 91 (54.8%) 6	21 (65.6%) 11 (34.4%) 3	18 (51.4%) 17 (48.6%) 2	114 (48.9%) 119 (51.1%) 11

**Conclusion:** The most interesting observation of this real life study and posthoc analysis is certainly that almost a third of the pts. were included in the study who did not reach the recommended BASDAI cut-off of  $\geq 4$ . Furthermore the data show that the patients with a BASDAI  $2.8 < 4$  seem to have significant benefit of antiTNF treatment, while this was not really the case with in pts. with a BASDAI  $< 2.8$ . This finding should lead to a reevaluation of the established BASDAI cut-off of  $\geq 4$ . Future studies should also evaluate the performance of an ASDAS cut-off. It seems likely that especially pts. with elevated CRP levels and a BASDAI  $< 4$  will benefit from this new strategy. We think that in light of the rather weak correlation of pain and ‘objective’ parameters of inflammation such as CRP and MRI the here reported observation does make some sense.

Regarding the treatment with Golimumab no new safety signals were detected.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In patients with spondyloarthritis, published data indicate different manifestations and outcomes between genders. The evidence in this regard in patients with early and peripheral disease is lacking. The aim of this study is to describe if there are differences in the presentation between genders in patients with early axial and peripheral spondylarthritis (axSpA, pSpA).

**Methods:** This study was carried out within the framework of the ESPeranza program, which was a national multicenter initiative aiming to facilitate early diagnosis and follow-up of patients with spondylarthritis in Spain between 2008-2011. Out of 775 patients referred, 377 patients fulfilled the ASAS classification criteria for SpA: 291 (77%) axSpA and 86 (23%) pSpA. Demographic and disease characteristics were compared between genders using a descriptive analysis through Student t test (for continuous variables) and Chi-square test (for categorical variables).

**Results:** In total, 241 (64%) patients were males (191 axSpA and 50 pSpA). In axSpA, males had significantly more frequently radiographic sacroiliac damage, elevated CRP, HLA-B27+ and morning stiffness, while females had higher values of ESR and more frequency of peripheral arthritis (Table1-2). In pSpA, male gender was significantly associated with diagnostic delay, psoriasis and elevated CRP while women had higher rates of functional limitation.

**Conclusion:** There are differences in the manifestations between genders already from the onset of the disease. In patients with axSpA, males have worst prognostic factors compared with females. However, in pSpA, females report poorer functionality despite being diagnosed earlier than male patients. This difference in phenotypes may influence on therapeutic decision-making.

## **Are Work Outcomes Improved in Axial Spondyloarthritis (axSpA) Patients with Biologic Therapy? Results from the British Society for Rheumatology Register**

**Gary J. Macfarlane**, Gareth T. Jones and Joanna Shim, Epidemiology Group, School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with axial spondyloarthritis (axSpA) identify the ability to stay at work as a priority. Biologic therapy improves disease activity and quality of life but evidence is equivocal on whether it improves work outcomes.

**Methods:** BSRBR-AS is a prospective study of patients with axSpA, recruited from eighty five centres throughout Great Britain, who are naïve to biologic therapy. Patient recruitment commenced in December 2012. We compared work outcomes (using the Work Productivity and Activity Impairment Index (WPAI:SHP)) in those commencing biologic therapy at the time of recruitment with those who did not. Adjustment for differences in characteristics (age, Bath indices of disease activity (BASDAI) function (BASFI) global status (BAS-G), and smoking) was by propensity score matching to obtain estimates of treatment effect one year after commencing such therapy. .

**Results:** A total of 201 patients commencing biologics and 627 not commencing biologics have been followed up for one year and were eligible for the current analysis. The study population had a mean age of 53.5 years, a mean duration since diagnosis of 14.6 years, 71.6% were male and 67.8% were HLA-B27 positive. Patients who were commencing biologic therapy were younger (47.9 v. 55.3 years), more likely to be current smokers (22% v. 11.5%), with greater disease activity (BASDAI mean 6.3 v. 3.8), poorer function (BASFI mean 6.3 v. 3.8), and worse global status (BAS-G mean 7.0 v.3.8)(all  $p < 0.001$ ). At recruitment they reported more absenteeism (13.0% v. 3.0%); more presenteeism (41.5% v. 19.9%) greater productivity impairment (43.3% v. 20.6%); and greater overall activity impairment (59.9% v. 32.5%). At follow-up, biologics patients reported improvements across absenteeism (-7.5%), presenteeism (-30.0%), productivity impairment (-32.2%), and overall activity impairment (-41.3%). After adjustment, biologics patients demonstrated a significantly greater improvement (compared to those not starting biologic therapy) in presenteeism (-12.4%; 95% CI=-22.7, -2.0). There was also greater improvement in absenteeism (-3.9%; -14.4, 6.6); greater reduction in productivity impairment (-8.6%; -20.1, 2.8) and greater reduction in overall activity impairment (-7.3%, -15.2, 0.5) although these differences were not statistically significant.

**Conclusion:** After taking account of differences between groups, treatment with biologic therapy was associated with greater improvement in measures of work (particularly a reduction in presenteeism) amongst patients with axSpA, compared to those not starting biologic therapy. Thus biologic therapy delivers improved outcomes likley to have important economic benefits.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It has been recommended that the lower limit of high-sensitivity CRP (hsCRP) be restricted to 2 in the Ankylosing Spondylitis Disease Activity Score (ASDAS) calculation. Also, a definition of flare of ASDAS increase  $\geq 0.9$  was recently proposed. Using non-radiographic axial SpA (nr-axSpA) trial data, this analysis evaluated potential differences in patient (pt) categorization using different minimum values for hsCRP in the ASDAS calculation and different definitions of disease flare.

**Methods:** ABILITY-3 (NCT01808118) assessed the impact of continuation versus withdrawal of adalimumab (ADA) in nr-axSpA pts who achieved sustained remission with open-label ADA. All pts received open-label ADA 40 mg every other wk during a 28-wk lead-in period. Pts who achieved remission, defined as ASDAS inactive disease (ID, ASDAS < 1.3) at wks 16, 20, 24, and 28 were randomized to 40-wk, double-blind ADA (continuation) or PBO (withdrawal). ASDAS was calculated with the full range of hsCRP (protocol-defined) and limiting hsCRP to the lowest possible value of 2 mg/L (rederived). Flare was calculated as 2 consecutive study visits with ASDAS > 2.1 (protocol definition) or with ASDAS increase  $\geq 0.9$  (modified definition). Data are reported as observed (open label) and by nonresponder imputation (double blind).

**Results:** 673 pts were enrolled. At open-label baseline, mean ASDAS using the protocol-defined ASDAS calculation was 3.6 vs 3.7 when rederived. At wk 28, 295 (43.8%) pts achieved protocol-defined ASDAS ID vs 272 (40.4%) pts using the rederived ASDAS; mean ASDAS at double-blind baseline was 0.7 vs 0.9, respectively. At wk 68, significantly more pts treated with ADA vs PBO had no flare per protocol definition (69.7% vs 47.1%;  $P < 0.001$ ; **Table**). Similar results were observed with modified definitions (**Table**). At wk 68, significantly greater proportions of ADA vs PBO pts achieved ASDAS endpoints (all  $P < 0.001$ ), with similar results for protocol-defined and rederived ASDAS calculations, respectively: ID (57.2% vs 33.3% and 52.0% vs 29.4%), major improvement (58.6% vs 32.0% and 50.0% vs 30.7%), and clinically important improvement (67.1% vs 45.1% and 67.1% vs 44.4%).

**Table. Percentage of patients not experiencing disease flare at week 68 using protocol-defined or rederived ASDAS and/or modified flare definitions**

Variable, n (%)	Adalimumab (40 mg EOW) n=152*	Placebo n=153*	Difference, %	P value
Protocol-defined ASDAS and flare	106 (69.7)	72 (47.1)	22.7	<0.001
Rederived ASDAS, protocol-defined flare	100 (65.8)	69 (45.1)	20.7	<0.001
Protocol-defined ASDAS, modified flare definition	97 (63.8)	56 (36.6)	27.2	<0.001
Rederived ASDAS and modified flare definition	99 (65.1)	65 (42.5)	22.6	<0.001

ASDAS, Ankylosing Spondylitis Disease Activity Score; EOW, every other week; ID.

Nonresponder imputation; Pvalue using 2-sided Pearson chi-square test.

\*Efficacy outcomes were calculated based on the number of patients randomized, rather than those who would have qualified for randomization based on rederived ASDAS calculations.

**Conclusion:** At both open-label and double-blind baseline, mean ASDAS was similar, regardless of the hsCRP value cut-off used. Fewer pts in both treatment groups were categorized as not experiencing a flare when limiting the lowest possible hsCRP value to 2 mg/L in the ASDAS calculation and/or using a modified flare definition. However, treatment differences remained similar compared with the protocol-defined methodology. Results suggest infrequent clinically relevant differences in ASDAS values with use of either definition for minimum hsCRP and that the use of ASDAS >2.1 or ASDAS increase  $\geq 0.9$  as the definition of flare is reasonable.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disease flares are increasingly used as outcomes in axial spondyloarthritis (axSpA) trials or observational studies. The objective of this initiative was to define a cutoff for the ASDAS score that best defines the concept of ‘worsening in axSpA’, to be used in the context of clinical trials and longitudinal observational studies.

### Methods:

Various steps were followed between 2014 and 2017. after an SLR and a vignette-exercise among ASAS members: a theoretical 'paper' patient-vignette. After presentation of the results at the ASAS 2015 meeting it was decided that the proposed cut-off needed to be validated with real-life data. A real-life multicenter international study: data necessary to calculate different outcomes were collected from real patients at 2 consecutive visits (spaced 7 days to 6 months): the external standard was defined as a patient's report that he/she had worsened and he/she felt there was a need for treatment intensification. Different changes in the outcomes against both external standards for worsening (phy-worsening (vignettes) and pt-worsening) were tested followed by a consensus and voting procedure among ASAS members in January 2017.

### Results:

(a) There was consensus about worsening being an absolute change between 2 time-points (without defining time between the 2 time-points) and about exploring cutoffs for 3 outcomes: ASDAS-CRP, BASDAI and pain. (b) The literature review had yielded 27 different cutoffs in 38 studies indicating important heterogeneity. (c) The vignette-exercise yielded 12 preliminary definitions for worsening to be tested (as previously reported (ref)). (d) In the prospective study the sensitivity and specificity of each cutoff was tested against pt-worsening and judged by the ASAS-community. (e) No consensus was reached for a BASDAI-based definition due to limited performance of all cut-offs, and it was decided to not define a value for a pain-based definition for worsening. Based on aggregated data (Table), a consensus was reached among the ASAS-members to define worsening as a deterioration in ASDAS of at least 0.9 points. While this cutoff led to only moderate sensitivity when tested against pt-worsening, the overall balance of sensitivity and specificity as well as the overall face validity of this cut-off value for ASDAS was deemed most acceptable.

Table. Sensitivity and specificity of different ASDAS cutoffs to define worsening, against phy-worsening and pt-worsening considered as external standards.

Cutoff values for change in ASDAS	Vignette exercise study (N=1150 physician judgments) against the external standard 'phys-worsening' (worsening in N=591)		Prospective real-life study (N=1169 patients), against the external standard 'pt-worsening' (worsening in N=127)	
	Sensitivity (%)	Specificity (%)	Sensitivity (%)	Specificity (%)
≥0.6	97	65	55	91
≥0.9	85	87	38	96
≥1.1	60	94	33	98

## Conclusion:

This data-driven ASAS consensus process has allowed to propose an ASDAS-based cutoff value defining worsening in axSpA. As has been observed in other settings, the change defining worsening (at least 0.9) is smaller than the change defining improvement which is 1.2 for ASDAS. This definition should now be applied in trials.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) is an enthesitis index developed and validated as an outcome measure in ankylosing spondylitis (AS), but is also commonly used in patients

with psoriatic arthritis (PsA). We aimed to compare the MASES scores between AS, PsA and rheumatoid arthritis (RA) patients.

**Methods:** From January 2016 to April 2017 AS, PsA and RA patients treated with tumour necrosis factor inhibitors (TNFi) were included in a random manner at the outpatient clinic of the Hospital of Southern Norway Trust, Norway. All RA patients fulfilled the ACR/EULAR, the PsA patients the Classification criteria for Psoriatic Arthritis (CASPAR) and the AS patients the Assessment of SpondyloArthritis International Society (ASAS) diagnostic criteria. MASES scores (range 0-13) were measured by a trained nurse. Tenderness was recorded as absent (0) or present (1). The unadjusted analyses of MASES were conducted using a one way analysis of variance (ANOVA) with post hoc tests (Tuckey HSD: homogeneity of variance). The adjusted analyses were conducted using analysis of covariance (ANCOVA) with adjustments for age, sex, disease duration as well as with and without body mass index (BMI). Adjustment for multiple comparisons (Bonferroni) was performed.

**Results:** A total of 90 AS, 46 PsA and 94 RA patients were included. Mean (SD) age was 48.4 (11.4)/ 54.9 (11.0)/ 54.9 (12.6) years, disease duration 12.6 (9.8) / 14.4 (7.3)/ 13.8 (9.1) years, BMI 27.9 (12.7)/ 27.0 (3.5)/ 26.8 (10.7) kg/m<sup>2</sup> and percentages females 33.3/ 32.6/ 62.8%, respectively. Both in unadjusted as well as in adjusted analyses, no statistically significant differences in MASES scores between the AS, PsA and RA patients were found (table). Additional adjustment for BMI did not change the main findings.

	AS (n=90)	PsA (n=46)	RA (n=94)	p-value
<b>MASES scores</b>				0.857 <sup>a</sup>
<b>Unadjusted analyses</b>	2.64 (2.00-3.29)	3.44 (2.50-4.37)	2.87 (2.33-3.42)	0.534 <sup>b</sup>
<b>MASES scores</b>				0.296 <sup>c</sup>
<b>Adjusted analyses</b>	2.91 (2.22-3.60)	3.79 (2.93-4.65)	2.59 (1.92-3.24)	1.000 <sup>a</sup>
				0.088 <sup>b</sup>
				0.336 <sup>c</sup>

Data are shown as mean estimate (95% confidence interval)

a: AS-RA, b: PsA-RA, c: AS-PsA

**Conclusion :** Enthesitis is a clinically important feature of spondyloarthropathy, in contrast to RA. Nevertheless, no significant differences were found in MASES scores between the RA, PsA and AS patients, even after adjusting for BMI.

## The Validation of Istanbul Back Disability Index (IBDI) in Axial Spondyloarthritis Patients

**Tuncay Duruoz**, Hatice Sule Baklacioglu, Sevtap Acer Kasman and Didem Erdem, PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The IBDI was developed to assess the disability in patients with mechanical low back pain (1) which contains the 18 daily activities questions. The main symptom in Axial Spondyloarthritis (Ax-SpA) is inflammatory back pain which makes patient disabled in daily living. To assess the functional disability concerning to inflammatory back pain is important for accurate clinical approach to patients in daily practice. The aim of this study is to investigate the validation of Istanbul Back Disability Index (IBDI) in Ax-SpA patients.

**Methods:** The patients with Ax-SpA according to ASAS criteria were recruited into the study. Demographic, clinical and functional characteristics of patients were evaluated. Face and content validities were assessed via cognitive debriefing interviews with Ax-SpA patients. Classical psychometrics assessed, convergent validity (correlation of IBDI with Dougados Functional Index (DFI), Health Assessment Questionnaire (HAQ), ASAS Health Index (ASAS-HI), BASDAI, BASFI) and discriminative validity (correlation of IBDI with disease duration (month), Body Mass Index (BMI), Schöber's test (cm), finger-floor distance (cm), tragus-wall distance (cm), chest expansion (cm), MASES enthesitis score,). Spearman's correlation coefficient was used to assess the relation between quantitative variables. The SPSS 24.0 statistical package was used for analysis.  $P < 0.05$  was accepted as significant.

**Results:** Sixty patients (37 male, 23 female) with mean of age 39.18 (SD:8.95) years were recruited. The 43.3 % of patients were smoking. The mean of disease duration was 85.93 (SD:79,06) months and the mean of BMI was 26.98 (SD: 4.18)  $\text{kg/m}^2$ . The means of BASDAI and the BASFI were 4,49 (SD: 2,37) and 2,83 (SD: 2,67) respectively. Cognitive debriefing showed the IBDI to be clear, relevant, and comprehensive which shows its face and content validity. The IBDI has good correlation with DFI ( $\rho: 0,809$ ;  $p < 0,0001$ ), HAQ ( $\rho: 0,770$ ;  $p < 0,0001$ ), ASAS-HI ( $\rho: 0,673$ ;  $p < 0,0001$ ), BASDAI ( $\rho: 0,572$ ;  $p < 0,0001$ ) and BASFI ( $\rho: 0,821$ ;  $p < 0,0001$ ). This results show that IBDI has good convergent validity. The IBDI has not significant correlation with non functional parameters such as disease duration ( $\rho: 0,202$ ;  $p: 0,121$ ), BMI ( $\rho: -0,142$ ;  $p: 0,280$ ), Schöber's test ( $\rho: -0,150$ ;  $p: 0,252$ ), finger-floor distance ( $\rho: 0,189$ ;  $p: 0,149$ ), tragus-wall distance ( $\rho: 0,157$ ;  $p: 0,230$ ), chest expansion ( $\rho: -0,232$ ;  $p: 0,075$ ) and MASES ( $\rho: 0,168$ ;  $p: 0,200$ ). These results show that IBDI has discriminative validity.

**Conclusion:** The IBDI is practical, accurate and not time consuming scale which is valid to evaluate the functional disability in patients with Axial Spondyloarthritis.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

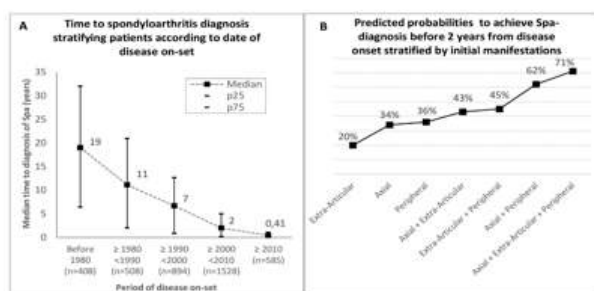

**Background/Purpose:** Diagnostic delay is one of the greatest challenges in Spondyloarthritis (SpA).

**Methods:** We designed a cross-sectional study, including adult patients fulfilling ASAS SpA criteria from a multicentric international study for the ASAS-COMOSPA study. We evaluate trends in time to diagnosis of SpA during last decades, and its association with 2009 ASAS SpA classification criteria and clinical presentation. Disease onset was defined as first SpA-related musculoskeletal manifestation and/or diagnosis of extraarticular disease [uveitis, inflammatory bowel diseases (IBD) or psoriasis]. In those patients who developed an isolate extraarticular disease as initial manifestation, we performed a secondary analysis defining disease onset at first musculoskeletal manifestations. Time to diagnosis was defined as the gap between SpA diagnosis and disease onset. We stratified patients according decade of disease onset and initial clinical presentation and developed a multivariate logistic model, using early diagnosis (<2 years) as dependent variable and decade of disease onset, initial clinical presentation, sacroiliitis on x-ray, sex and age at disease onset, as independent variables. We estimated predicted probabilities for different clinical presentations.

**Results:** We included 3984 patients. Median time to diagnosis was 2.9 (p25-75= 0.3 ÷ 9.8) years. This delay in diagnosis showed a progressive decrease during last decades (**Graph 1A**). Patients with disease onset after 2010, showed a shorter delay in diagnosis than those with disease onset in 2000-2010 decade. More frequent clinical presentations at disease onset were: isolated axial involvement (46%), isolated peripheral disease (20%), isolated extra-articular disease (19%), and multiple manifestations (15%). According to multivariate analysis, the probability to have an early diagnosis increased from 8% in patients before 1980 to 67% after 2010. Initial clinical presentation were independent predictors of time to diagnosis (**Graph 1B**).

**Conclusion:** Recognition and diagnosis of SpA have improved during the last decades. Type and number of initial clinical presentation were independent predictors of time to diagnosis.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Analysis of data from several cohort studies of patients with ankylosing spondylitis (AS) /axial spondyloarthritis (AxSpA) have confirmed earlier suggestions that current smokers have worse outcomes in relation to disease activity, quality of life, radiographic progression and response to biologic therapies. To date studies have not used pack years to assess if there is a dose related effect. The effect of smoking on quality of life has only been studied in a cross sectional analysis.

The aim of the current study was to investigate the effect of smoking on disease activity and quality of life in patients with AxSpA and determine if continued smoking worsens outcomes over time.

### **Methods:**

The Spondyloarthritis Genetics and the Environment (SAGE) study is a longitudinal multicenter study established in 2010 in New Zealand. Annual assessments were performed on a total of 368 patients fulfilling the ASAS criteria for AxSpA. A smoking history, including pack years, was obtained by interview from all participants. Standard outcome measures were recorded at each annual visit including BASDAI, BASFI, AS disease activity score (ASDAS-CRP) and quality of life measures both generic (EuroQol) and specific to AS (ASQol). The association between smoking and outcomes was assessed by linear regression analysis (statistical program R).

### **Results:**

At baseline (visit 1) complete smoking data was available for 361 participants: 189 (52%) had never smoked, 117 (33%) were previous smokers and 55 (15%) were current smokers which is similar to national population data for current smokers in New Zealand (17%).

At baseline, there was a significant association between current cigarette smoking, and worse disease activity and physical function (ASDAS-CRP  $\beta=0.95$ , 95%  $P=0.018$ , BASDAI  $\beta=0.95$  95%  $P=0.012$ , BASFI  $\beta=1.19$ , 95%  $P=0.0032$ ).

There was a linear relationship between quantity smoked (recorded as pack years/age) and higher CRP:  $\beta 0.59$   $P=0.047$ .

After 12 months (visit 2), complete smoking data were available for 191 participants: 97 had never smoked, 71 were previous smokers, and 23 were current smokers. At visit 2, there was a significant association between cigarette smoking and higher disease activity as measured by the ASDAS-CRP ( $\beta=0.60$ , 95%  $P=0.0097$ ). This remained significant even after adjusting for ASDAS-CRP at baseline ( $P<0.05$ ).

Quality of life (QoL) measures showed that current smokers compared to those who never smoked had significantly worse health related QoL: ASQoL  $\beta 3.35$   $P = 6.66e-05$ , EuroQoL  $\beta -0.189$   $[-0.28- -0.097]$   $P = 6.02e-05$ . At one year of follow up current smokers continued to record worse QoL measured by EuroQoL:  $-0.12$   $[-0.22- -0.028]$   $P = 0.012$ .

### Conclusion:

Smoking is associated with higher disease activity and worse quality of life at baseline. After one year of follow up these differences persist. Furthermore, there is a linear relationship between amount smoked and CRP, a marker for worse outcome. Patients with AS/AxSpA should be encouraged to quit smoking.

---

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

ASRI (Ankylosing Spondylitis Registry of Ireland) is a national registry, designed to provide descriptive epidemiological data on the axial spondyloarthropathy (axSpA) population of Ireland. Uveitis is a common extra-articular manifestation in patients with axSpA. The exact prevalence and associated characteristics are not clearly defined in the literature. The aim of this study was to determine the prevalence of uveitis in a large axSpA cohort and identify associated characteristics.

### Methods:

Patients enrolled in ASRI from 2013 until June 2017 were included in this study. A standardised detailed clinical assessment is performed on each patient at their inclusion. Structured interviews provide patient-reported data, including the presence of previous diagnosis of uveitis. Disease activity is assessed by Bath AS Disease Activity Index (BASDAI), spinal mobility by Bath AS Metrology Index (BASMI), function by the Bath AS Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) and quality of life by AS Quality of Life (ASQoL). Statistical analysis is performed using SPSS.

### Results:

As of June 2017, 683 patients have been entered in the database: 77% (n=526) male, mean age 45.9 years (SD 12.4), mean disease duration 19 years (SD 12.2), mean delay to diagnosis 8.6 years (SD 8.1), 78.8% fulfil modified New York criteria. Mean BASDAI is 3.9 (SD 2.5), BASMI is 3.6 (SD 2.5), BASFI is 3.6 (SD 2.7), HAQ is 0.52 (SD 0.52) and ASQoL is 6.4 (SD 5.5). HLA-B27 status is available for 74.1% (n=506) of the cohort: 92.7% of these are HLA-B27 positive.

The prevalence of uveitis in this cohort is 36.5%. With regards to other extra-articular manifestations, 6.9% have dactylitis, 18.3% have psoriasis, 9.2% have inflammatory bowel disease, 17.6% have enthesitis and 34.1% have peripheral arthritis.

Patients with uveitis are older (47 v 45 years,  $p=0.04$ ) and have a longer duration of axial symptoms (21.7 v 17.3 years,  $p<0.01$ ). There is no significant difference in markers of disease severity. Patients with uveitis have a higher prevalence of dactylitis (11.6% v 4.3%,  $p<0.01$ ), enthesitis (25.9% v 13.5%,  $p<0.01$ ), hypertension (26.1% v 18.6%,  $p=0.02$ ) and HLA-B27 positivity (95.9% v 90.4%,  $p=0.02$ ). There is a lower prevalence of smoking (22.2% v 32.2%,  $p=0.01$ ) in patients with uveitis. Use of biologics is similar in patients with and without uveitis (30.7% v 26.8%,  $p=0.3$ ). There is no difference in the use of NSAIDs (54.8% v 48.4%,  $p=0.1$ ). There is a trend towards lower prevalence of IBD (12.1% v 7.6%,  $p=0.06$ ) in patients with uveitis.

In multivariable regression analysis, disease duration, dactylitis and enthesitis are independently associated with the presence of uveitis, with dactylitis the strongest predictor (OR 3.2, 95% CI 1.5-6.8,  $p<0.01$ ), followed by enthesitis (OR 1.8, 95% CI 1.1-2.9,  $p=0.02$ ).

### Conclusion:

In this axSpA cohort, 36.5% of patients have ever had an episode of uveitis. Uveitis is independently associated with dactylitis, enthesitis and longer disease duration. There is a higher prevalence of smokers in patients without uveitis.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Obesity is a worldwide public health concern, due to its association with morbidity and mortality. Existing literature looking at obesity in axial spondyloarthropathy (axSpA) is sparse, but indicates increased BMI is prevalent. The impact of obesity on disease outcome is less well known. We aimed to determine the prevalence of obesity in a large axSpA cohort and describe its association with disease outcomes.

### **Methods:**

Ankylosing Spondylitis Registry of Ireland (ASRI) provided the cohort for this study. The objectives of ASRI are to provide descriptive epidemiological data on the Irish axSpA population. A standardised clinical assessment is performed on each patient. Structured interviews provide patient-reported data. Weight is recorded in kilograms (kg) and height in centimetres (cm). BMI is categorised per the World Health Organisation criteria: normal weight <25 kg/m<sup>2</sup>, overweight 25-29.9 kg/m<sup>2</sup> and obese ≥ 30 kg/m<sup>2</sup>. Statistical analysis is performed using SPSS.

### **Results:**

As of June 2017, 683 patients have been enrolled: 77% (n=526) male, mean age 45.9 ± 12.4 years, mean disease duration 19±12.2 years, mean delay to diagnosis 8.6±8.1 years, 78.8% fulfil modified New York criteria. Mean BASDAI is 3.9±2.5, BASMI is 3.6 ± 2.5, BASFI is 3.6± 2.7 and HAQ is 0.52 ±0.52.

Mean BMI in this cohort is  $27.8 \pm 5.3 \text{ kg/m}^2$ : 1.1% (n=7) underweight, 31.6% (n=205) normal BMI, 38.9% (n=252) overweight, 28.4% (n=184) obese. Overall, 67.3% are overweight or obese: these patients are significantly older, have longer disease duration and more comorbidities, especially hypertension and hyperlipidaemia, than normal weight patients. Obese patients have significantly higher disease activity and worse physical function, spinal mobility and quality of life than both normal weight and overweight patients (table 1). The prevalence of smoking is lower in obese patients than normal weight patients. In univariable linear regression, BMI and obesity are associated with higher BASDAI, ASQoL, BASMI, BASFI and HAQ scores (table 2). In multivariable regression analysis, obesity remains an independent predictor of higher disease activity and worse function.

## Conclusion:

Over two thirds of this axSpA cohort are overweight or obese. Higher BMI and obesity independently predicts worse disease outcomes. Strategies should be put in place to actively reduce axSpA patient's BMI.

## High Prevalence of Sarcopenia in Axial Spondyloarthritis Cohort

**Gillian Fitzgerald**<sup>1</sup> and **Finbar O'Shea**<sup>2</sup>, <sup>1</sup>Rheumatology, St James's Hospital, Dublin 8, Ireland, <sup>2</sup>St James, Dublin, Ireland

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Sarcopenia, or age-related loss of muscle mass, is well documented in the general population and is associated with functional limitation and increased mortality. Literature on sarcopenia in axial spondyloarthritis (axSpA) is sparse and therefore the extent of the problem is virtually unknown. The aim of this study is to determine the prevalence of sarcopenia in patients with axSpA and determine associations with severity of disease.

## **Methods:**

Forty-three consecutive patients (79.1% male, 97.7% Caucasian) with axSpA were included. Demographic data, spinal metrology, anthropometric measures, serum markers and patient-reported outcome measures were collected. Body composition analysis was performed using bioelectrical impedance analysis (BIA): fat mass, fat-free mass and predicted skeletal muscle mass were collected. Height was measured to the nearest 0.1 cm. Skeletal muscle mass index (SMI) was calculated by appendicular skeletal muscle mass (sum of predicted muscle mass in all 4 limbs) divided by height squared. Sarcopenia was defined as per the European Working Group on Sarcopenia in Older People definition as  $SMI \leq 8.87 \text{ kg/m}^2$  in men and  $\leq 6.42 \text{ kg/m}^2$  in women. BMI was categorised as normal if  $<25 \text{ kg/m}^2$ , overweight if  $>25 \text{ kg/m}^2$  and obese if  $>30 \text{ kg/m}^2$ . SPSS was used for statistical analysis.

## **Results:**

Baseline characteristics are outlined in table 1, along with significant differences between genders. Mean BMI is  $28.8 \text{ kg/m}^2$  (SD 6.3). A high BMI is present in 72.1% of the cohort: 27.9% have normal weight, 37.2% are overweight and 34.9% are obese. Sarcopenia is present in 41.9% (n=18) of the cohort (50% of men and 11.1% of women). In the males with sarcopenia compared to those without, BMI ( $24 \text{ v } 34.1 \text{ kg/m}^2$ ,  $p<0.01$ ), waist circumference ( $88.9 \text{ v } 105.1 \text{ cm}$ ,  $p=0.01$ ), hip circumference ( $95.6 \text{ v } 109.9 \text{ cm}$ ,  $p<0.01$ ) and fat percentage ( $20\% \text{ v } 30\%$ ,  $p<0.01$ ) are significantly lower. Testosterone is significantly higher in patients with sarcopenia ( $18.5 \text{ v } 13.8$ ,  $p<0.05$ ). There is no significant difference in disease activity parameters, although there is a trend towards lower BASMI in patients with sarcopenia ( $3.7 \text{ v } 4.8$ ,  $p=0.09$ ). There is no significant difference in number of co-morbidities between patients with and without sarcopenia.

Only 58.8% of men with sarcopenia have normal weight. The remaining 41.2% are overweight. No men with sarcopenia are obese, but all men with normal weight are sarcopenic.

## **Conclusion:**

Almost 42% of this axSpA cohort has sarcopenia. There is no association with disease outcome measures. Of the sarcopenic patients, just under half are overweight, which is at odds with our usual perception of sarcopenia. Physicians need to consider sarcopenia in axSpA, even in patients with high BMI.

Table 1: Baseline and anthropometric characteristics of cohort, along with significant differences between genders.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Sarcopenia is characterized by progressive and generalized loss of skeletal muscle mass and strength with a risk of adverse outcomes such as physical disability and poor quality of life. Sarcopenia is a common feature of all chronic inflammatory diseases and is related to elevated circulating proinflammatory cytokines like tumor necrosis factor. Low lean mass and sarcopenia are common in patients with inflammatory bowel disease and rheumatoid arthritis. However, the studies about sarcopenia in ankylosing spondylitis (AS) were lack. The aim of this study was to evaluate the prevalence and risk factors of sarcopenia in patients with ankylosing spondylitis.

### Methods:

Cross-sectional data were collected on 60 male patients with AS who fulfilled the modified New York criteria. For measurement of body composition, dual energy X-ray absorptiometry (DXA) for bone mineral density (BMD) of the lumbar spine, total femur and whole body was performed. Sarcopenia was defined by low skeletal muscle mass ( $SMI < 7.0 \text{ kg/m}^2$ ) and a low muscle strength (handgrip strength  $< 26 \text{ kg}$ ) according to Asian working group for sarcopenia (AWGS) criteria. We also define the sarcopenia according to Korean criteria based on the Korea National Health and Nutrition Examination Survey (KNHANES) 2008-2009. Clinical data (age, BMI, disease duration, BASDAI, BASMI, use of anti-TNF $\alpha$  agent and use of glucocorticoid) and laboratory data (ESR, CRP, Hemoglobin and level of vitamin D) were compared for AS patients without sarcopenia versus those with sarcopenia

### Results:

The prevalence of sarcopenia by AWGS and Korea criteria based on KNHANES was 15% and 26.7% for patients with AS. The mean age of patients with sarcopenia according to the Korea criteria was  $48.8 \pm 15.6$  years and the sarcopenia occurred at a relatively young age in AS. Mean age was higher in the sarcopenia groups both by AWGS criteria and Korea criteria ( $p=0.02$  and  $0.004$ ) and the level of ESR was higher in the sarcopenia group by Korea criteria ( $16.8 \pm 13.6$  vs.  $14.8 \pm 6.0$ ,  $p=0.03$ ). The patients with sarcopenia tended to show lower BMI, lower disease duration, more cumulative dose of glucocorticoid than the patients without sarcopenia, but there was no statistical significance. The older age ( $p=0.007$ ), longer disease duration ( $p=0.008$ ) and lower BMI ( $p<0.001$ ) were significantly associated with lower skeletal muscle mass in AS.

### Conclusion:

Sarcopenia occurred at a relatively young age in patients with AS. Mean age and level of ESR were higher in patients with sarcopenia. The older age, longer disease duration and lower BMI were significantly associated with lower skeletal muscle mass in AS.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While inflammatory bowel disease (IBD) is a well-known comorbidity in axial spondyloarthritis (SpA), little is known about functional bowel problems, such as irritable bowel syndrome (IBS), in these patients. In the general population, the IBS prevalence has been estimated to be around 11%.[1] In the present study, we examined the frequency of IBS-symptoms and their relation to patient-reported outcomes in an ongoing survey of axial SpA patients.

**Methods:** Consecutive axial SpA patients were examined and classified as non-radiographic axial SpA (nr-axSpA; ASAS criteria; n=37) or ankylosing spondylitis (AS; modified New York criteria; n=68). Patients with known IBD were excluded. The ROME III questionnaire was used to assess IBS criteria fulfillment,[2] and faecal (F) calprotectin was measured by a commercially available ELISA kit.

**Results:** Overall, 30% of patients fulfilled the IBS criteria (n=31; 32%/28% of nr-axSpA/AS patients, no significant between-group difference; Figure 1). In 11 of these subjects (35%), F-calprotectin was, however, also elevated ( $\geq 50$  mg/kg; F-calprotectin was available in 86 of the 105 patients; Figure 2), making it hard to rule out inflammation rather than functional disease as cause of the symptoms. Applying a stricter definition of IBS, i.e. a combination of fulfilled IBS criteria and a non-pathologic F-calprotectin level ( $< 50$  mg/kg), this was met by 19% of the patients (n=16; 23%/16% of nr-axSpA/AS patients, no significant between-group difference; Figure 1). Irrespective of F-calprotectin levels, the presence of IBS symptoms was associated with worse patient-reported outcomes, especially regarding disease activity and health-related quality of life (Table).

**Conclusion:** In axial SpA patients without known IBD, IBS-symptoms were substantially more common than described for the general population, affecting almost 1/3 of patients, and were linked to worse patient-reported outcomes. To establish the true IBS prevalence in the cohort would require colonoscopy of certain subjects, although even based on a highly conservative definition (fulfillment of IBS criteria and F-calprotectin  $< 50$  mg/kg) the observed prevalence was  $> 1.5$  times higher than that reported in the general population.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Inflammatory bowel disease (IBD) is a classical extra articular feature of spondyloarthritis (SpA), with increasing evidence of a pathophysiological relationship.

The aims of this study were to evaluate in the DESIR cohort (1) The prevalence of IBD at baseline, and factors (epidemiological, clinical, imaging, biological data available in the database) associated with IBD, (2) The occurrence of new cases of IBD during the M0-M60 follow-up, and factors associated.

### Methods:

DESIR is a prospective observational cohort of patients with recent onset (less than 3 years) inflammatory back pain, beginning before 50 years, suggestive of axial SpA, with a planned follow up of ten years. At baseline : identification of patients with IBD (with medical confirmation), analysis of factors (clinical, biological, imaging, treatment) associated with IBD : comparison of patients with and without IBD, for categorical variables : odds-ratio +/- 95% CI and chi-square/Fisher tests, for continuous variables : unpaired t-tests / Mann-Whitney, in uni and then multivariate analysis (logistic regression). Occurrence of new cases of IBD over the five first years of follow-up (database locked on June 20<sup>th</sup> 2016), and factors associated with IBD at M60 were assessed using uni- and multivariate analysis by logistic regression. Significance : p less than 0.05.

## Results:

At baseline, 706 patients were analyzed, 35 had a past history or a concomitant IBD : prevalence 4.94% [CI 95% : 3.3 – 6.5]. IBD was significantly associated (univariate) with ESSG criteria (OR = infinite [2.8-infinite], familial history of IBD (OR = 3.56 [1.01-110.22]) and negatively associated with psoriasis (OR = 0.09 [0.02-0.24]), HLA-B27 (OR = 0.47 [0.21-0.98]) and NSAID score (mean 30.25 (IBD) versus 45.49; p = 0.005). In multivariate analysis IBD was associated positively with familial history of IBD (OR = 5.69 [3.57-7.82]) and negatively with psoriasis (OR = 0.04 [0.035-0.048]) and HLA-B27 (OR = 0.28 [0.26-0.31]). IBD was not associated with phenotypic presentation (peripheral arthritis, enthesitis, dactylitis, uveitis) or baseline serum levels of cytokines (TNF, IL-6, IL-17 A, IL-17 F, IL-23, IL-23). At M60, 617 patients were analyzed, 58 with IBD : prevalence 9.4 %. 23 incident cases of IBD were recorded, giving an estimated occurrence rate of 0.7/100 patient-years in this population. In univariate analysis on prevalent cases, IBD was associated with lower NSAID score (mean 17 versus 19.9, p = 0.029) and a less frequent NSAID response (OR = 0.30 [0.13-0.76]), worse activity and function indexes (ASDAS-CRP mean 2.28 versus 2.02; p = 0.038, BASFI mean 29 versus 22; p = 0.019, SF-36 mean 39 versus 44; p = 0.004, HAQ mean 0.75 versus 0.5; p = 0.004, ASQoL mean 8.7 versus 6.6; p = 0.012), and with more family history of IBD (OR = 6.6 [1-40]), more sick leave (mean 21 versus 11 days; p = 0.029), and fulfillment of ESSG criteria. In multivariate analysis, IBD was associated with fulfillment of modified New York criteria (p = 0.04).

## Conclusion:

IBD occurs with a rate of 0.7/100 patient-years over 5 years in DESIR cohort, with a negative association at baseline with psoriasis and HLA-B27. At five years, IBD is associated with more severe disease and classification criteria.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Background/Purpose:** There has been much interest in smoking as a modifiable risk factor for increased disease severity in rheumatic diseases. However, the effects of alcohol consumption remain unclear. Alcohol intake has been associated with increased disease susceptibility in psoriatic arthritis but also with reduced disease severity in rheumatoid arthritis. Its role in axial spondyloarthritis (axSpA) has not been studied in detail. The aim of this study was to explore whether alcohol consumption is associated with disease severity in axSpA.

**Methods:** Alcohol histories were obtained from axSpA patients meeting the ASAS criteria. Participants were categorised as current drinkers or non-drinkers. Quantity of intake was estimated using units per week with heavy consumption defined as >14 u/week. Disease activity (BASDAI, spinal pain, ASDAS) and functional impairment (BASFI) were compared between alcohol drinkers and non-drinkers, using multivariable linear models adjusting for age, gender, TNF inhibition therapy (TNFi), smoking, index of deprivation and self-reported anxiety and depression (A&D). Given their recognised link, interaction terms between alcohol and A&D were included in these models. Association between heavy alcohol consumption and disease severity was explored within drinkers using multivariable models with the above covariates.

**Results:** We studied 229 axSpA patients: 76% were male with mean age 46.5 (SD±13.8) years. A third were treated with TNFi. The median BASDAI was 5.7 [interquartile range (IQR) 3.3, 7.6] and BASFI 5.7 [IQR 3.3, 7.6]. ASDAS was available for 79% of patients with mean of 2.7 (SD±1.1). Ever-smoking was reported by 47% and A&D by 54%. Alcohol drinking was reported by 64%, with drinkers reporting median intake of 6 u/week [IQR 2 to 20]. Compared with non-drinkers, drinkers had lower BASDAI, ASDAS and BASFI (Table 1). There were no differences in disease severity between heavy and moderate drinkers. Stratified by smoking status, associations between alcohol and disease severity were stronger in never-smokers. There was a significant interaction between alcohol and A&D in smokers: drinkers had lower BASDAI and BASFI in the absence of A&D.

**Conclusion:** Alcohol consumption appears to be associated with reduced axSpA disease severity in this cross-sectional cohort. These associations were influenced by smoking status and A&D. This novel finding supports the need for further investigation to explore whether lifestyle modification could lead to better disease outcomes in axSpA.

Table 1. Multivariable linear models of association between alcohol-drinking and measures of disease activity.			
	β coefficient (95%CI) without interaction terms	β coefficient (95%CI) in never-smokers	β coefficient (95%CI) in ever-smokers if A&D is absent
BASDAI	-0.80 (-1.47, -0.38)	-1.35 (-2.26, -0.45)	-1.68 (-3.28, -0.07)
ASDAS	-0.34 (-0.65, -0.03)	-0.51 (-0.93, -0.10)	-0.69 (-1.40, 0.01)
Spinal pain	-0.76 (-1.54, 0.02)	-1.70 (-2.74, -0.66)	-0.45 (-2.37, 1.46)
BASFI	-1.39 (-2.11, -0.67)	-2.22 (-3.18, -1.26)	-2.48 (-4.21, -0.75)
Total sample sizes for each regression model were 213 for BASDAI, BASFI and spinal pain, and 181 for ASDAS.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporosis and vertebral fractures are recognized complications in axial spondyloarthritis (axSpA). Anteroposterior (AP) DEXA is commonly used to assess spinal bone mineral density (BMD) but can become inaccurate in the presence of syndesmophyte formation. The 2015 European League Against Rheumatism (EULAR) imaging guidelines highlight the importance of assessing for osteoporosis in axSpA and suggest use of lateral DEXA to assess spinal BMD [1]. However, it is unclear when lateral DEXA should be performed. The aims of this study were 1) to explore AP-BMD changes with axSpA symptom duration, and 2) to identify when optimum assessment of spinal BMD should include lateral spinal DEXA.

**Methods:** A cross-sectional study was conducted with axSpA patients fulfilling the ASAS criteria and not using bisphosphonates. Each patient underwent AP-DEXA of the lumbar spine (L1-L4) and total hip. Simultaneous lateral lumbar DEXAs were performed in a random subgroup of patients. AP-BMD was plotted against symptom duration using lowess smoothing. Piecewise linear regression was used to estimate a transition point after which AP-BMD began to increase. The difference between AP and lateral spinal BMDs was compared against symptom duration using scatter plots.

**Results:** AP-DEXAs were performed in 259 patients, 32 also underwent lateral DEXAs. 75% were male with mean age of 38.8 (SD±12.7) years. Median symptom duration was 16.6 years [interquartile range (IQR) 8, 28.4]. Mean BMI was 28.4 (SD±5.7). TNFi was used by 30% and 7% were taking calcium and vitamin D supplements. The median BASDAI was 6.4 [IQR 4.6, 7.7] and BASFI 6.4 [IQR 3.7, 8.2]. Osteopenia and osteoporosis of the spine were present in 27% and 5% and for the hip 29% and 3%, respectively, on AP-DEXA. In the first decade after symptom onset, patients with longer symptom duration had lower AP-BMD (Fig 1). However after 20 years, AP-BMD was higher with increasing symptom duration. Piecewise regression for spine  $\text{g/cm}^2$  and T-score estimated the transition point to be 13 years (95%CI 2.7, 23.0). The difference between AP and lateral BMD increased with increasing symptom duration (Fig 2).

**Conclusion:** After 13 years, AP-BMD was higher with increasing symptom duration which likely reflects accrual of pathological new bone in this bisphosphonate-naïve cohort. This was supported by the increasing discrepancy between AP and lateral spinal BMD with increasing symptom duration. AP-DEXA can be used to assess BMD during the first decade of symptom duration, but lateral DEXA should be considered after 13 years, particularly for those with known syndesmophytes.

Figure 1. Locally weighted scatter-plot smoothing (LOWESS) of individual participant's bone mineral density against symptom duration for lumbar spine and total hip.

Figure 2. Scatter plot demonstrating greater difference in AP and lateral lumbar spine BMD with increasing symptom duration within individuals. Line of best fit is superimposed.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

To describe the prevalence of osteoporosis (1), the prevalence and incidence of fractures (2), and the frequency of risk factors for low bone mineral density (BMD) (3) in axial spondyloarthritis (Ax-SpA).

## **Methods:**

A systematic review and meta-analysis of observational studies was conducted. Medline, Embase, and Cochrane Library databases were searched with a sensitive strategy. Cross-sectional and longitudinal studies with representative samples of patients with Ax-SpA estimating the frequency of osteoporosis or fractures were selected for objectives 1 and 2. For objective 3, large cross-sectional or longitudinal studies in patients with Ax-SpA published in the last 10 years (Jan 2006 to 2016) were selected.

## **Results:**

After screening 3597 titles and abstracts, 46 studies were reviewed in detail, of which 35 studies had a cross-sectional design, 5 were prospective and 6 retrospective; 21 studies compared Ax-SpA patients with a control group—either healthy individuals (18 studies) or subjects with other diseases (6 studies)—. The prevalence of osteoporosis varied from 11.7% to 34.4% and that of fractures from 11% to 24.6%. Alcohol intake (58-61%), use of corticosteroids (11.7-66-9%), and 25-OH vitamin D deficiency (26-76%) were unexpectedly high in Ax-SpA patients.

## **Conclusion:**

The prevalence of osteoporosis and fractures in Ax-SpA varies between 11.7% and 34.4% and 11-24.6%, respectively. These wide ranges reflect inconsistency of the prevalence estimates. Alcohol intake, steroid use and low levels of 25-OH-vitamin D should be taken into account in osteoporosis assessment in patients with Ax-SpA. Inconsistent results, lack of bone quality assessment, and high likelihood of bias in the majority of the published studies confirm the need for well-designed studies.

# **Trabecular Bone Score As an Assessment Tool to Identify the Risk of Osteoporosis in Axial Spondyloarthritis: A Case-Control Study**

**Kwi Young Kang**, Internal Medicine, Catholic University of Korea, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The trabecular bone score (TBS) is a novel tool used to evaluate bone microarchitecture. It is a textural index that evaluates pixel gray-level variations in the lumbar spine DXA image, thereby providing an indirect index of trabecular microarchitecture. To date, no studies have compared TBS between patients with axSpA and matched controls. Therefore, the present study was conducted to assess TBS in these two groups and to identify the risk factors related to a low TBS in patients with axSpA.

**Methods:** TBS and bone mineral density (BMD) were assessed in the two groups (axSpA and control) using dual-energy X-ray absorptiometry (DXA). Osteoporosis risk factors and inflammatory markers were also assessed. Disease activity and radiographic progression in the sacroiliac joint and spine were evaluated in the axSpA group. Multivariate linear regression analysis was performed to identify risk factors associated with TBS.

**Results:** In the axSpA group, 248 subjects were enrolled; an equal number of age- and sex-matched subjects comprised the control group. The mean TBS was  $1.43 \pm 0.08$  and  $1.38 \pm 0.12$  in the control and axSpA groups, respectively ( $p < 0.001$ ); BMD at the lumbar spine did not differ between the two groups. The TBS was negatively correlated with erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels in the axSpA group only ( $p < 0.001$  and  $p = 0.007$ , respectively). Syndesmophytes in the axSpA group was associated with lower TBS ( $p < 0.001$ ) but higher lumbar BMD ( $p = 0.021$ ) versus controls. In the multivariate analyses, ESR, CRP, and spinal radiographic progression were significantly associated with TBS.

**Conclusion:** TBS assessments revealed poor bone quality in patients with axSpA compared with the matched controls. In axSpA, systemic inflammatory markers were negatively correlated with TBS and spinal radiographic progression and inflammatory markers were independently correlated with low TBS. TBS may, therefore, be a useful clinical tool to identify the risk of osteoporosis in patients with axSpA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ankylosing spondylitis (AS) is a disease characterized by spinal osteoproliferation (syndesmophytosis) and the general trabecular bone loss with increased fracture risk. Syndesmophytes in spine leads overestimation of the anteroposterior (AP) lumbar spine BMD measured by dual-energy X-ray absorptiometry (DXA) which is a gold standard of diagnostic tool for osteoporosis. Thus, more accurate fracture risk assessment tool is needed in AS patients.

**Objectives:** We aimed to compare various fracture risk assessment tools according to modified Stoke AS Spine Score (mSASSS), and to identify the tool which can best reflect the risk of fracture in AS patients.

**Methods:** Total of 215 AS patients were enrolled from a single university hospital in Korea. Demographic and clinical information was collected by questionnaires and physical exams. They completed simple X-ray of L-spine, AP and lateral BMD by DXA. FRAX was measured and TBS was obtained from DXA using TBS iNsight software. Quantification of spine ankyloses were determined by mSASSS. We classified patients into two groups: 1) high mSASSS group with mSASSS  $\geq 19$ , which is median value of study population, and 2) low mSASSS group with mSASSS  $< 19$ . We compared the clinical characteristics and fracture risk assessment tools between two groups. In addition, fracture risk assessment tools were compared according to history of fracture, which is known to be the strongest risk factor for fracture, using ANCOVA.

**Results:** The 109 patients (50.7%) were classified to high mSASSS group. Female patients were more in low mSASSS group ( $p < 0.01$ ), and smoking history were more prevalent in high mSASSS group ( $p < 0.01$ ). L-spine lateral BMD and TBS were lower, while right hip and L-spine AP BMD were significantly higher in high mSASSS group. After adjustment, mean TBS of L2-L3 was significantly lower and L-spine AP BMD was significantly higher in high mSASSS group ( $p = 0.02$  and  $p < 0.01$ , respectively). Total 53 patients (24.7 %) had fracture history of any type. Patients with fracture history showed higher 10-year probability of major osteoporotic fracture by FRAX<sup>®</sup> ( $p = 0.01$ ) and lower TBS of L2-L3 in patients with fracture history ( $p = 0.04$  after adjustment).

**Conclusion:** TBS was lower in patients with advanced syndesmophytes, and it was significantly associated with history of fracture. TBS can be a useful method in measuring bone strength and also predicting fracture risk in AS patients.

Table 1. Demographic and clinical characteristics, comparison of bone strength measurement methods in patients with ankylosing spondylitis

Characteristics	Total AS patients (n, 215)	High mSASSS (n, 109)	Low mSASSS (n, 106)	P	adjusted p*

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Ethnic heterogeneity of the United States (US) population makes it imperative to study the racial differences in clinical characteristics of Ankylosing Spondylitis (AS) patients, a disease mainly considered to be of Caucasians with HLA-B27 predominance. We hypothesize that African Americans (AA) have more severe disease compared to Caucasians in the US.

### Methods:

Data was collected using Explorys universe, a clinical research informatics tool that uses unified medical language system ontologies to standardize, normalize and aggregate clinical data from 26 US major healthcare systems that use Epic from 1999 to present comprising of over 50 million patients. De-identified data are presented through a secure web interface. The Power Search tool was utilized to create refined cohorts with specific search criteria. We identified 28,520 patients with AS. This was further stratified by having at least two rheumatology visits; adding race, gender, clinical characteristics, medication use or co-morbidity diagnoses to the search tool. Data sets were recorded as proportions, which were compared using chi-squared test ( $p < 0.05$ ).

## Results:

10,990 AS patients with at least two rheumatology visits of all races were identified of whom 50% were males. 84% of AS patients were Caucasian, whereas 8% were AA. Half of both races were males ( $p=0.17$ ). 25% of the AS cohort tested for HLA-B27 were positive (26% Caucasians vs 20% AA,  $p = 0.11$ ). Subgroup analysis of 101 AS patient records at our institution identified 78% HLA-B27 positive patients (64% Caucasians vs 42% AA,  $p=0.0018$ ).

65% of AS patients were smokers (67% Caucasians vs 59% AA,  $p<0.0001$ ). A greater proportion of AA had elevated erythrocyte sedimentation rate (62% AA vs 48% Caucasians,  $p < 0.0001$ ) and C-reactive protein levels (68% AA vs 54% Caucasians,  $p < 0.0001$ ). 73% of AS patients had peripheral arthritis (74% Caucasians vs 76% AA,  $p = 0.15$ ), 25% had enthesopathy (26% Caucasian vs 27% AA,  $p = 0.18$ ), 10% had psoriasis (10% Caucasians vs 7% AA,  $p=0.0002$ ) and inflammatory bowel disease (11% Caucasian vs 12% AA,  $p = 0.23$ ), 4% had anterior uveitis (4% Caucasians vs 8% AA,  $p < 0.0001$ ) and 5% had dactylitis (5% Caucasian vs 7% AA,  $p = 0.09$ ). Majority (87%) of the AS patients were treated with nonsteroidal antiinflammatory drugs (87% Caucasians vs 89% AA,  $p=0.62$ ) and 39% used TNF- $\alpha$  inhibitors (40% Caucasian vs 37% AA,  $p<0.08$ ). AA compared to Caucasians had higher prevalence of hypertension (29% vs 22%,  $n=2,350$ ,  $p<0.0001$ ), diabetes (27% vs 17%,  $n=1,940$ ,  $p<0.0001$ ), depression (36% vs 32%,  $n=3,380$ ,  $p=0.02$ ) and heart disease (24% vs 22%,  $n=2,290$ ,  $p=0.11$ ). Caucasians compared to AA had higher prevalence of fibromyalgia (14% vs 12%,  $n=1,480$ ,  $p=0.07$ ) and osteoporosis (18% vs 16%,  $n=1890$ ,  $p=0.36$ ).

## Conclusion:

Our findings from a large US electronic database confirm that AS is more prevalent in Caucasians with equal proportion of males and females between both races. Markers of inflammation, anterior uveitis and co-morbidities were significantly higher in AA. There was no significant difference in the use of TNF- $\alpha$  inhibitors. Study limitation was that Explorys could not capture the true proportion of HLA-B27 positivity due to it being a send out test with results not being electronically available in Epic.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Uveitis is the most common extra-articular manifestation occurring in patients with ankylosing spondylitis (AS). The purpose of this study is to evaluate the characteristics of uveitis in patients with AS using questionnaire survey.

**Methods:** A questionnaire-based survey was conducted for patients enrolled in AS registry at a rheumatology clinic in a tertiary hospital between September 2015 and December 2015. Patients responded to 10 questions, with several sub-questions related to eye disease including uveitis.

**Results:** A total of 750 patients participated in the survey. Among them, 266 (35%) answered that they had an eye disease including uveitis (64%), conjunctivitis (8%), dry eye (6%), and iritis (5%). The number of patients who were diagnosed with uveitis in the ophthalmology department was 218 (29%). The number of patients who experienced a flare of uveitis more than once a year was 109 (50%). In addition, at the time of the study, only 53 (24%) had been recommended to undergo testing for autoimmune disease. The most common symptoms of patients with uveitis were ocular congestion (61%), eye pain (54%), and decreased visual acuity (51%). Interestingly, 91 of the 532 patients (17%) who had not been diagnosed with uveitis before also experienced similar symptoms.

### **Conclusion:**

We identified various eye-related problems and the clinical characteristics of uveitis in patients with AS. Our survey revealed not only information about AS-related eye diseases but also the need for cooperation between rheumatologists and ophthalmologists.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Spondyloarthropathies (SpA) encompass a heterogeneous group of chronic inflammatory diseases affecting axial and peripheral joints. Besides articular symptoms, patients also experience extra-articular

manifestations (EAMs) including uveitis, psoriasis, inflammatory bowel disease (IBD) and multiple organ involvement. The aim of this analysis was to describe the incidence of new onset EAMs focusing on uveitis and IBD among SpA pts over 6 and 12 months of treatment with golimumab (GLM).

**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab or GLM for RA, AS, or PsA, or with ustekinumab for PsA. Eligible participants for this analysis comprised GLM-treated AS (n=395) and PsA (n=257) patients. Presence of EAMs was defined as patients with uveitis or IBD. IBD data, however, was not collected for PsA pts. **Results** were based on patients with available data. Safety was ascertained by the incidence of adverse events (AEs) and serious adverse events (SAEs), reported per 100 pt years (PY) of follow-up.

**Results:** Among AS pts, at baseline, the mean (SD) age was 45.3 (13.5) years and CRP was 14.1 (30.5) mg/L. Positive HLA B27 status was reported for 174 (174/264; 65.9%) pts. History of uveitis was reported among 14.2% (n=50/352) of AS pts. EAMs are reported over time in Table 1. New-onset uveitis and IBD was reported for 2.3% (3.2 events/100 PY) and 1.1% (1.5 events/100 PY) of pts during follow-up, respectively. Results showed that CRP and HLA B27 status were not significantly associated with presence of EAMs at baseline. Overall, 419 AEs and 26 SAEs were reported by 199 (50.4%) and 16 (4.1%) pts by 12 months of treatment, respectively, for a total of 144.1 AEs/100 PY and 8.9 SAEs/100 PY. A total of 5 AEs of uveitis were reported all of which were of mild severity, and either not (n=4) or unlikely related (n=1) to the study drug.

Among PsA pts, the mean (SD) age was 52.7 (13.2) years and CRP was 13.2 (32.4) mg/L at baseline. A total of 9 (9/80; 11.3%) pts had positive HLA B27 status. Patients with a history of uveitis was reported for 1.8% (n=4/224) of PsA pts. New-onset uveitis was reported for 0.4% (0.5 events/100 PY) of patients during follow-up. Overall, 254 AEs and 15 SAEs were reported by 123 (47.9%) and 12 (4.7%) patients by 12 months of treatment, respectively, for a total of 135.0 AEs/100 PY and 8.0 SAEs/100 PY.

Table 1. EAMs over Time and New Onset since Baseline

Diagnosis	EAM	Patients with EAMs n/N			New Onset at 6 Months	New Onset at 12 Months	New Onset over Follow-up <sup>‡</sup>
		Baseline	6 Months	12 Months	n/N*	n/N*	n/N
AS	Uveitis	4/390	8/278	1/197	8/272	1/189	9/386
	No uveitis	386/390	270/278	196/197	NA	NA	NA
	IBD	22/393	16/277	10/195	4/256	0/184	4/371
	No IBD	371/393	261/277	185/195	NA	NA	NA
PsA	Uveitis	0/256	1/187	0/131	1/186	NA	1/256
	No uveitis	256/256	186/187	131/131	NA	NA	NA

Patients with unknown EAM were excluded from the analysis. \*Denominator (N) represents patients at risk at the respective visit relative to the previous visit. <sup>‡</sup>Average follow-up per patient was 8.8 months for AS and 9.8 months for PsA. NA=not applicable

**Conclusion:** In patients with AS, development of uveitis and IBD was 2.3% and 1.1% during 12-month follow-up of GLM-treatment. Among PsA patients, lower rates of new-onset uveitis were observed with 0.4%. The current results should be interpreted with caution given the low number of cases of uveitis and IBD.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

An increased prevalence of metabolic syndrome (MetS) has been reported in psoriatic arthritis (PsA) suggesting an association between the inflammation and MetS. The aim of this study is to investigate its relationship with disease activity in patients with PsA. We also evaluated whether an association exists between MetS and axial involvement in PsA.

### **Methods:**

This study included patients with PsA followed in the Rheumatology outpatient clinic at Dokuz Eylul University. Age-matched patients with Takayasu arteritis (TA), an inflammatory systemic disease, were enrolled as diseased controls. The NCEP-ACT III criteria were used to identify subjects with MetS. Disease activity was assessed in patients with PsA by using several parameters including BASDAI, ASDAS, VAS patients' and physician' global, Tender and Swollen joint assessment (28/68), DAS28, DAPSA, CPDAI and SPARCC Enthesitis Index. ESR and serum CRP levels were measured. BASFI and BASMI were used to evaluate functional status and HAQ, ASQoL and DLQI to evaluate health and PASI to measure the severity of psoriasis. Hand and pelvis X-rays and sacroiliac joint MRIs were performed when indicated.

**Results:** There were 104 PsA patients (63.5% F; mean age: 50.9±13.0 years; mean disease duration: 8.69 ±6.5 years) who fulfilled the CASPAR criteria and 28 TA patients (89% F, mean age: 46.3±9.1) who fulfilled the ACR 1990 criteria. The prevalence of MetS was found to be considerably higher in PsA patients compared to TA patients (45.2% and 21.4% respectively, p<0.001). In the comparison of PsA patients with and without MetS, no differences were found regarding treatment frequencies of NSAIDs, glucocorticoids, DMARDs and anti-TNFs and also mean glucocorticoid dosages. PsA patients with MetS had higher BASDAI, BASFI, BASMI, VAS, ASqOL, CPDAI, ASDAS and HAQ scores compared to PsA patients without MetS (Table 1). More patients with syndesmophytes were found among PsA patients with MetS compared to those without MetS (p=0.027). There were no differences in indexes related predominantly peripheral involvement, such as tender and swollen joint counts, enthesitis score and presence of dactylitis.

**Conclusion:** This study demonstrates a higher prevalence of MetS in PsA patients compared to TA. It also suggests that MetS might be associated with high disease activity and more severe disease especially in patients with axial involvement.

**Table 1.** Clinical features and disease activity parameters in PsA patients with and without MetS.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Metabolic syndrome (MetS) and non-alcoholic fatty liver disease (NAFLD, potentially evolving into liver fibrosis-LF), are more frequent in patient with psoriasis (PsO) with respect to general population. Nevertheless, data about psoriatic arthritis (PsA) are lacking. Aims of the study were: 1) investigating if the presence of arthritis, other

than PsO, could determine any difference with respect to the prevalence of these comorbidities 2) assess the presence of NALFD and LF and their determinants in PsO/PsA.

**Methods:** PsA patients with concomitant PsO and PsO patients without history or manifestation of arthritis were consecutively enrolled in the period October 2015-June 2016. Exclusion criteria were: liver diseases potentially causing LF except for NAFLD, alcohol consumption $\geq$ 20 g/day, daily use of non-steroidal anti-inflammatory drugs, use of methotrexate currently/in the previous year. Anamnestic, biochemical, metrological data were collected, thus defining insulin-resistance index HOMA (Homeostatic Model Assessment) and the presence of MetS. All patients underwent 1) liver ultrasound to assess the presence of steatosis (therefore NAFLD) 2) transient elastography, which measures liver stiffness, to evaluate presence and grading of LF (stiffness $\geq$ 7 kPa=fibrosis). Disease activity was assessed through Psoriasis Area Severity Index-PASI and Disease Activity index for Psoriatic Arthritis-DAPSA. Statistical analysis included Mann-Whitney and Chi-square test to evaluate differences between PsA/PsO patients, regression analysis to identify predictors of NAFLD and liver stiffness, Spearman's coefficient to examine correlations;  $p\leq 0.05$  was considered as significant.

**Results:** PsA/PsO patients (43/33 individuals) had similar characteristics: age  $60.2\pm 8.4/54.5\pm 19.6$  years, male 74.4/63%, PsA/PsO duration  $12.6\pm 8.5/18.2\pm 14.2$  years. Significant differences were found in: Body Mass Index (BMI) ( $25.7\pm 3.4/29.1\pm 6.3$ ,  $p=0.0092$ ), PASI ( $1.5\pm 2.5/5\pm 4$ ,  $p=0.03556$ ), uric acid ( $4.9\pm 1.5/5.7\pm 1.4$  mg/dL,  $p=0.0001$ ), all higher in PsO. MetS and LS prevalence was similar between AP/PsO: 34.9%/33.3% and 30.8%/27.6% ( $p=ns$ ). NAFLD was significantly higher in PsO (64.7% vs 35.3% in PsA,  $p=0.044$ ). Multivariate regression analysis identified glycosylated haemoglobin as independent predictor of NAFLD (RRR 8.34,  $p=0.016$ ) and HOMA of liver stiffness grading (beta 0.33,  $p=0.046$ ) (Table). A strong correlation emerged between uric acid and HOMA ( $p=0.0001$ ,  $r=0.80$ ) and uric acid- liver stiffness ( $p<0.0001$ ,  $r=0.73$ ) in PsO.

**Conclusion:** In our study population the prevalence of MetS and LF was similar between PsA/PsO, while NAFLD was more prevalent in PsO. Insuline resistance, which has a key role in MetS, seems the main determinants to liver disease (in terms of NAFLD and LF) in PsA/Ps. In this scenario hyperuricemia could be a relevant co-factor.

# The Prevalence, Incidence and Associated Factors for Liver Abnormalities in Psoriatic Arthritis: Results from a Longitudinal Observational Cohort

**Rattapol Pakchotanon**<sup>1</sup>, Justine (Yang) Ye<sup>1</sup>, Richard J. Cook<sup>2</sup>, Vinod Chandran<sup>3</sup> and Dafna D Gladman<sup>3</sup>, <sup>1</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>2</sup>Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, <sup>3</sup>Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is a chronic inflammatory disease which affects the skin and musculoskeletal system. PsA patients frequently suffer from comorbidities: cardiovascular disease, metabolic syndrome, inflammatory bowel disease, liver disease, osteoporosis, malignancy, and ophthalmic disease. Among PsA patients, the prevalence of biochemical liver abnormalities has been reported as 24-36%. We aimed to determine the prevalence and incidence of liver abnormalities and identify the factors associated with liver abnormalities in PsA patients.

**Methods:** Patients with PsA have been followed prospectively according to a standard protocol which includes detailed clinical and laboratory tests collected at 6-12 month intervals. From this longitudinal cohort study we identified PsA patients with either elevated ( $>1.5\times$  normal) serum transaminase or alkaline phosphatase levels or liver disease (fatty liver, viral hepatitis, autoimmune liver disease, alcoholic liver disease, liver fibrosis, and cirrhosis) after the first visit to the PsA clinic (cases). Controls were subjects from the same cohort who never had such abnormalities or liver disease. Cases and controls were then matched 1:1 by sex, age at the first clinic visit, and follow-up duration. Variables at the first appearance of liver test abnormality were evaluated using univariable and multivariable regression analyses to identify the factors associated with liver abnormalities after controlling for demographic variables, disease activity, and treatment.

**Results:** Among 1061 patients followed in the PsA clinic, 343 had liver abnormalities. 256 patients who developed liver abnormalities after the first visit were identified as cases, 718 patients were identified as controls. The prevalence of liver abnormalities was 32% and the incidence was 39/1000 patient-years. Among 256 cases, the mean age (s.d.) of PsA patients at the onset of liver abnormalities was  $50.5 \pm 12.8$  years. Liver abnormalities were detected after mean (s.d.) follow up duration of  $8.3 \pm 7.8$  years. Twenty-nine percent of cases had an identified cause of liver biochemical abnormalities. The common causes of liver abnormalities were drug induced hepatitis (14%) and fatty liver (13%). Multivariable analysis in matched case-control study (204 pairs) revealed that higher BMI, daily alcohol intake, higher damaged joint count, elevated C-reactive protein (CRP), use of methotrexate (MTX), leflunomide (LFN) or TNF inhibitors were independent factors associated with liver abnormalities (Table 1).

**Table 1.** Multivariable analysis of factors associated with liver abnormalities in psoriatic arthritis (PsA) in matched case-control study (204 pairs).

Variables	OR (95%CI)	p-value
Body mass index	1.07 (1.02–1.12)	0.007
Daily alcohol intake	4.46 (1.30-15.28)	0.02
Damage joint count	1.04 (1.01–1.08)	0.01
Elevated CRP	2.00 (1.04-3.85)	0.04
Use of MTX/LFN	4.39 (1.67-11.54)	0.003
Use of TNF inhibitors	10.56 (3.63-30.69)	<0.0001

**Conclusion:** The prevalence of liver abnormalities among PsA was 32% and the incidence was 39/1000 patient-years. Higher BMI, daily alcohol intake, more damage joint count, elevated CRP, use of MTX/LFN or TNF inhibitors are

associated with liver abnormalities in PsA patients. Monitoring liver function tests in these high risk patients is recommended.

<sup>1</sup>Medicine/Rheumatology and Epidemiology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, <sup>3</sup>University of Pennsylvania Health System, Philadelphia, PA, <sup>4</sup>Clinical Epidemiology, Boston University School of Medicine, Boston, MA, <sup>5</sup>Landspítali University Hospital, Reykjavik, Iceland, <sup>6</sup>Rheumatology, University of Pennsylvania, Philadelphia, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) has been associated with weight loss around the time of diagnosis; little is known about weight change around diagnosis in psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Furthermore, while obesity is a risk factor for RA and PsA, little is known about the importance of weight change as a disease risk factor. We examined weight change before, around, and after diagnosis compared to matched controls in a population-based cohort.

**Methods:** Data between 1994-2015 from The Health Improvement Network were used. Patients age 18-89 with incident PsA, RA, and AS and population controls matched on start date and general practice and with at least one body mass index (BMI) in each of intervals surrounding diagnosis were eligible. Change in BMI over time was examined using linear regression models incorporating generalized estimating equations with cubic splines with two knots (one year prior to diagnosis and one year after diagnosis) and adjusting for age and sex. Mean BMI over the 10-year study interval was plotted. We examined the significance of slope (compared to zero) at each interval (t1-t3) for each disease group and differences in slope for each interval in the disease groups compared to controls.

**Results:** Among patients with incident PsA, RA or AS, and matched controls, 2,591, 11,380, 919, and 21,903 respectively met the inclusion criteria. Among those included, the mean number of BMI measurements over 7.5 years of follow up was 8.5. Sex was 58%, 71%, 40%, and 62% female for patients with PsA, RA, AS, and controls respectively. The mean BMI at diagnosis was 29.8, 28.0, 27.6, and 27.9 respectively. Patients with PsA had the highest BMI in all time intervals (Figure 1) although the absolute difference in mean BMI was small. Controls gained a modest amount of weight over all intervals. Patients with PsA, RA, and AS had greater fluctuations in weight (Figure 2). Patients with PsA and RA lost weight around the time of diagnosis, but this was not statistically significant in PsA. Prior to diagnosis, patients with PsA gained weight at a higher rate than controls and patients with AS and RA lost weight at higher rates than controls. Patients with PsA and RA gained more weight after diagnosis than the other groups.

**Conclusion:** This population-based natural history study suggests that weight fluctuates around the diagnosis of inflammatory arthritis and in some cases these weight changes preceded the diagnosis by 5 years or more. Further studies to understand the importance of weight change as a risk factor for these diseases are needed.

T1: 5 years before up to 1 year before diagnosis†  
T2: 1 year before to 1 year after diagnosis  
T3: 1 year after diagnosis to 5 years after diagnosis  
† Diagnosis was assigned for controls as the visit closest to the visit around the time the matched patient with PsA, RA, or AS was diagnosed. Longitudinal models employing GEE were adjusted for age at diagnosis and sex.

# Influence of Cardiovascular Comorbidity on Achieving Therapeutic Goals: A Comparative Study between Recent-Onset Psoriatic Arthritis and Established Disease

**Rubén Queiro**<sup>1</sup> and Juan D. Cañete<sup>2</sup>, <sup>1</sup>Rheumatology Department. Hospital Universitario Central de Asturias, Oviedo, Spain, <sup>2</sup>Rheumatology Department, Arthritis Unit, Rheumatology Dpt, Hospital Clinic of Barcelona, Barcelona, Spain  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Some cardiovascular risk factors (CVRF) have been associated with a lower probability of achieving a good therapeutic response in PsA<sup>1</sup>. However, the reason for this association is not known. We aimed to evaluate the potential link between the minimal disease activity (MDA)<sup>2</sup> response and the presence of CVRF in PsA patients treated with DMARDs.

**Methods:** Cross-sectional study carried out at 25 rheumatology departments from Spain. All patients fulfilled CASPAR criteria, had an established disease (disease duration  $9.6 \pm 7.6$  yr), and were receiving biological or synthetic DMARDs. The relationship between MDA and CVRF was evaluated by uni and multivariate analyses. To test the influence of CVRF on MDA achieving, an age-matched cohort of patients with recent-onset PsA (< 2 yr of evolution) not exposed to systemic treatment was selected.

**Results:** 227 patients were included and 133 (58.6%) achieved a MDA response. Among the classic CVRF, tobacco (crude OR: 0.54), sedentary lifestyle (crude OR: 1.95), hyperuricemia (crude OR: 2.01) and obesity (crude OR: 1.54) were related to the likelihood of MDA in the univariate model ( $p < 0.25$ ). The only CVRF related to the MDA response in the multivariate analysis was a sedentary lifestyle (OR 3.13, 95%CI: 1.50-6.53;  $p=0.002$ ). No association was found between the number of CVRF and MDA. No differences were found in the prevalence of cardiovascular comorbidity between the two cohorts.

Variable	Treated cohort N: 227	Not treated cohort N: 210	p-values
Age	53.2 $\pm$ 12.4 yr	49.8 $\pm$ 13.9 yr	NS
Hypertension	27.3%	22.4%	NS
Diabetes	12.1%	10.5%	NS
Obesity	21.1%	27.1%	NS
Dyslipidemia	30.4%	30.9%	NS
Tobacco	27.3%	30.4%	NS
CV events	5.8%	6.2%	NS

**Conclusion:** Contrary to what has been found in other studies, in this multicenter study we could not find any relationship between CVRF (except for sedentary lifestyle) and MDA. In any case, patients with psoriatic disease should be encouraged to maintain healthy lifestyle habits.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The natural history of psoriatic arthritis (PsA) is hardly known and the information regarding PsA prospective cohorts is very scarce worldwide. The information obtained from prospective cohorts of rheumatic diseases of recent onset is the only way to unravel the true natural history of these diseases. Our objective was to describe the baseline characteristics of the REAPSER (Recent-Onset PsA Registry of the Spanish Society of Rheumatology) cohort, a prospective cohort that seeks to know the natural history and the impact that the disease generates in Spanish patients with PsA.

### Methods:

REAPSER is an observational, multicenter study, with consecutive recruitment, which includes adults of both sexes aged 18 yr or older that meet CASPAR criteria for PsA, and have less than two years of disease evolution (recent-onset PsA). Annual follow-up visits will be carried out for 5 years. Measurements include socio-demographic data, employment status, impact of disease, family history of PsA and other inflammatory diseases, comorbidities, lifestyle, use of health

services, clinical status at disease presentation and during follow up, anthropometric data, clinical evaluation, radiographic progression, lab determinations, and treatment of the disease. The study has been approved by the ethical committees of the participating centers.

The statistical analysis is limited to describing percentages for qualitative variables and central measurements with dispersion values for the quantitative ones.

### **Results:**

Two hundred and fifteen consecutive patients were included, mean age  $49.8 \pm 13.9$  years.

### Conclusion:

The baseline situation of Spanish patients with recent-onset PsA corresponds to that of a disease with slight cutaneous involvement and predominance of oligoarticular arthritis. Unsurprisingly, structural damage is scarce but not zero. The impact of the disease is still low in these early stages, however 18% of patients have a high Charlson's comorbidity index (> 3) and almost 5% of patients changed their employment status in the last year due to their PsA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Surrogate markers of subclinical atherosclerosis and cardiovascular (CV) mortality such as carotid plaques (CP), arterial stiffness (AS) and carotid intima-media thickness (c-IMT), have been studied by carotid ultrasound (US) examination. In most studies done before, the results have shown an increased prevalence of CP and high values of c-IMT associated to greater CV risks. The same happens with the pulse wave velocity (PWV), which has become the gold standard to determine AS.

Our aim was to compare the prevalence of CP, PWV and c-IMT measurements between patients with moderate- severe psoriasis and the general population.

**Methods:** A cross-sectional study that included 40 patients with moderate- severe psoriasis (PASI>10, BAS>10 %), that fulfilled definitions for initiating treatment with a biological agent according to the Clinical Practice guidelines and 40 age-, sex- and traditional CV risk factors- matched healthy control subjects. Psoriatic arthritis (PsA) was present in 11 of 40 patients. Patients with history of CV events, diabetes mellitus, and chronic kidney disease or body max index> 35 were excluded. US was performed in the common carotid by a MyLab 70 scanner (Esaote; Genoa, Italy), QAS-RF and Q-IMT Maastricht (Holland). The results were obtained according to the Mannheim Consensus Conference criteria. Statistical analysis: Qualitative data were expressed as number and percentages and quantitative data as mean (SD). Student's t test or Mann-Whitney U were used to compare continuous variables, as appropriate. Chi2 test or Fisher test were used for qualitative variables.

**Results:** The main data of the patients are summarized in the **TABLE**. It is important to highlight that the study was based on a young population (mean age <40 years). Thus, the two groups did not present significant differences regarding the classic CV risks factors and other parameters studied, except for high sensitivity C -reactive protein (hsCRP).

As expected given the age of the group, CV risk measured by SCORE was low (0%) in most patients, with a mean of 0.2 (in the plaque psoriasis group) and 0.15 in the control group. No patient had a high-very high CV risk as measured by SCORE ( $\geq 5\%$ ). Patients with psoriasis had a long-standing disease ( $17.05 \pm 11.63$  years). The presence of carotid plaques was found in a total of 10 patients with plaque psoriasis (25%), 5 of them had bilateral plaques) and one in the control group (2.5%) without bilateral plaques),  $p < 0.003$ . Even if patients with psoriasis had a higher PWV (6.33 m/sec) and c-IMT (0.579 mm) compared to the control group (6.13 m/sec and 0.549 mm), the difference was not significant ( $p = 0.72$  and  $p = 0.17$ ). It could be explained by the age of the study population and the sample size.

**Conclusion:** Moderate- severe psoriasis is associated with increased prevalence of CP, but PWV and c-IMT shows no differences.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Psoriatic arthritis (PsA) is a heterogeneous inflammatory arthritis affecting multiple clinical domains. Untreated, PsA has the potential for significant morbidity and disability. Psychiatric disorders have been described as a major comorbidity in PsA. Although anxiety and depression are known to co-occur in PsA, the prevalence of attention deficit hyperactivity disorder (ADHD) in this population has not been reported. Further, little is known about the impact of psychiatric disorders on disease severity and patient reported outcomes. The objective of this study was to characterize the prevalence and gender-driven differences of psychiatric disorders among PsA patients followed at a combined psoriasis-PsA clinic in the US.

## Methods:

Two-hundred and fifty-three consecutive adult patients meeting CASPAR criteria for PsA were prospectively recruited at the New York University Psoriatic Arthritis Center and assessed for demographic characteristics, presence of psychiatric comorbidities, including anxiety, depression and ADHD. Diagnosis was defined by patients report and/or current use of psychiatric medications. Objective measures of disease severity included swollen and tender joint counts (SJC/TJC) and %body surface area (BSA) covered by psoriasis. A physician global assessment was recorded at the time of the visit, along with arthritis, skin and nail global scores. A RAPID3 score was also recorded. Data was analyzed with SPSS version 23. Associations between variables were evaluated by t-tests for continuous variables and chi-squared tests for categorical variables.

## Results:

Participants were 54% male, had mean age 47 years, and majority were Caucasians (73.1%). A psychiatric diagnosis was reported in 27.8% of PsA patients: depression (18.7%), anxiety (14.7%), and/or ADHD (4.8%). When stratified by gender, female PsA patients had significantly higher prevalence of overall psychiatric diagnosis (34.5% vs 22.1%;  $p=0.028$ ), depression (25% vs 13.2%;  $p=0.017$ ) and use of antidepressants (22.2% vs 11.8%;  $p=0.048$ ). Males had higher use of medications for bipolar disorder (9.1% vs 2.1%;  $p=0.037$ ). While there were no significant differences in disease severity, female patients reported a significantly higher RAPID3 scores than males (12.09 vs 8.95;  $p=0.007$ ). Intriguingly, male PsA patients (but not females) with any psychiatric diagnosis had a significantly lower SJC compared to those without these comorbidities (0.79 vs 1.82;  $p=0.14$ ). Similarly, female PsA patients with psychiatric diagnosis has a lower %BSA affected with psoriasis (1.46 vs 2.40;  $p=0.054$ ).

## Conclusion:

We report, for the first time, a relatively high prevalence of ADHD in a cohort of PsA patients managed in a Psoriasis and PsA clinic. We further validate prior reports of significantly increased levels of depression and antidepressant use in female patients with PsA. Higher RAPID3 scores in women, independent of disease activity or presence of comorbidities, represents a significant gap in how patients perceive their disease symptoms. Further understanding of these gender-driven differences is needed to evaluate the impact on PsA disease burden, adherence and management.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early diagnosis of psoriatic arthritis (PsA) is critical to prevent poor outcome. Several validated screening questionnaires have been developed to identify PsA patients in the psoriasis population in dermatology and general practice settings. We aimed to test the performance of the CONTEST questionnaire in diagnosing PsA compared to the other existing tools.

**Methods:** Psoriasis patients from a primary dermatology clinic and combined rheumatology-dermatology clinics in one medical center completed the Psoriatic Arthritis Screening and Evaluation tool (PASE), Toronto Psoriatic Arthritis Screen2 (ToPAS2), Psoriasis Epidemiology Screening Tool (PEST) and Early Arthritis for Psoriatic Patients (EARP) questionnaires prior to rheumatologic evaluation. A composite score was calculated by abstracting the score of each discriminatory item from the original tools that constitute the CONTEST questionnaire. The results were compared to the diagnosis of PsA according to CASPAR criteria. The sensitivity and specificity of the different instruments were calculated using the defined cut offs of each instrument. The association between questionnaires' performance and age, gender, level of education, and systemic therapy was assessed using non-parametric statistics as appropriate.

**Results:** Of the 208 patients screened, 108 fulfilled the CASPAR criteria. The sensitivity of PASE, ToPAS2, PEST and EARP and CONTEST was 57.9%, 60%, 79.4%, 78.5% and 70%, respectively. The specificity was 93%, 93.2%, 94.9%, 91.8% and 91%, respectively. The performance of the tools was not affected by age, gender or educational level. Patients on systemic therapy obtained significantly higher scores on the PASE ( $p=0.03$ ), PEST ( $p=0.003$ ), EARP ( $p=0.01$ ) and CONTEST ( $p=0.0001$ ) questionnaires, but not on the ToPAS2.

**Conclusion:** All screening questionnaires are helpful in excluding PsA, but cannot serve as substitutes for clinical diagnosis. The CONTEST questionnaire had no additive diagnostic value to the other screening questionnaires of which the PEST had the highest sensitivity and specificity.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Evidence suggests that timely and effective management can improve long-term outcomes in patients (pts) with psoriatic arthritis (PsA); however factors influencing treatment management decisions are not well understood. The objective of this study is to evaluate the association between the clinical specialty setting and time from inflammatory musculoskeletal symptom onset to PsA diagnosis and to different management steps in pts with a diagnosis of PsA.

**Methods:** LOOP is a large cross-sectional, multi-center observational study currently being conducted in 19 countries across Western and Eastern Europe, Latin America, and Asia. Adult pts ( $\geq 18$  years) with a suspected or an established diagnosis of PsA who are routinely visiting a rheumatologist (rheum), dermatologist (derm) or non-rheum/non-derm site are eligible to participate in this study. Each enrolled patient is being assessed by both rheum and derm in the study. The present interim analysis included pts enrolled by 23 May 2017, which corresponded to approximately 50% of the total protocol specified sample size.

**Results:** Of the 602 pts enrolled by database cut-off date, 518 pts with a confirmed diagnosis of PsA were included in this interim analysis. A majority of pts were recruited by rheums (308, 59.5%), followed by derms (210, 40.5%) and physiatrists (19, 3.7%). PsA was first diagnosed by a rheum in 372 (71.8%) pts and by a derm in 100 pts (19.3%). Baseline demographics and disease characteristics were mostly comparable between PsA pts in rheum and derm settings (**Table 1**). The timing of different disease management steps by clinical specialty is reported in **Table 2**. The mean time

from symptom onset to PsA diagnosis was 23 months (mo) in the rheum setting and 2 mo longer for derms. The mean time from PsA diagnosis to first conventional synthetic DMARD (csDMARD) and first biologic DMARD (bDMARD) for rheums were 9 and 53 mo, respectively. Compared with Rheums, Derms required additional 16 and 14 mo to prescribe first csDMARD ( $P = 0.015$  vs Rheum) and first bDMARD, respectively. The mean time from first csDMARD to first bDMARD was 46 mo for rheum; while it was 6 months shorter for derm.

**Conclusion:** Although the duration from musculoskeletal symptom onset to PsA diagnosis was similar between rheum and derm setting, there were differences in the timing of introduction of different DMARD classes. Notably, mean time to first csDMARD was significantly and mean time to first bDMARD numerically shorter in rheum setting. The data lend further support to the need for rheum-derm collaborative approach to optimize management of pts with PsA.

**Table 1. Baseline Demographic and Clinical Characteristics of PsA Patients in LOOP Study by Clinical Specialty.**

Characteristic*	Clinical Specialty		Overall (N=518)

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Psoriasis Epidemiology Screening Tool (PEST) is a 5-item questionnaire developed to help identify psoriatic arthritis (PsA) at an early stage, with a score  $\geq 3$  indicative of PsA.<sup>1</sup> A recent Korean study found that a PEST score of 2 may be a more favorable cutoff for screening patients with psoriasis (PsO).<sup>2</sup> The objectives of this study were to assess the risk of undiagnosed PsA among patients with PsO and characterize patients based on PEST scores in the US-based Corrona Psoriasis Registry.

**Methods:** This study included all patients enrolled in the Corrona Psoriasis Registry with data on all 5 PEST questions. Demographics, disease characteristics, patient-reported outcomes and medication use were analyzed at the time of enrollment and stratified by PEST score (0, 1, 2 or  $\geq 3$ ). Pairwise comparisons were made between PEST score = 0 (reference) and other PEST score groups using *t* tests for continuous variables and  $\chi^2$  tests for categorical variables.

**Results:** As of June 2016, 99.1% (1516/1529) of patients in the Corrona Psoriasis Registry had data on all 5 PEST questions; 612 patients (40.4%) had dermatologist-reported PsA at enrollment. Among the remaining 904 patients, 421 patients (46.6%) had a PEST score = 0, 225 (24.9%) had a PEST score = 1, 146 (16.2%) had a PEST score = 2 and 112 (12.4%) had a PEST score  $\geq 3$ . Of patients with a PEST score  $\geq 3$ , patients most commonly answered “yes” to “have you ever had a swollen joint (or joints)?” (89%) and “has a doctor ever told you that you have arthritis?” (86%). Compared with patients with a PEST score = 0, patients with a PEST score  $\geq 1$  all had a higher body mass index, longer duration of PsO, increased family history of PsA, increased prevalence of nail PsO and worse EQ VAS at enrollment (all *P* < 0.05; **Table 1**). In addition, patients with PEST scores  $\geq 2$  were older, more likely to be female, less likely to be employed and

had an increased family history of PsO, worse pain and fatigue, worse dermatology-related quality of life and higher percentage impairment of daily activities due to psoriasis at enrollment vs patients with a PEST score = 0 (all  $P < 0.05$ ). There were no significant differences across PEST scores in affected body surface area or PASI scores.

**Conclusion:** In this cohort of PsO patients with no diagnosis of PsA, patients with PEST scores  $\geq 2$  were significantly different from those with PEST scores = 0 for many characteristics at enrollment, including body mass index and patient-reported outcomes. These findings highlight the value of screening for PsA among patients with PsO in order to potentially improve patient outcomes.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prior studies have shown an inconsistent relationship between skin and joint symptoms in patients with comorbid PsO and PsA<sup>1-3</sup>. The objective of the study is to characterize the relationship between skin severity and joint activity in patients with comorbid PsA and PsO at enrollment.

**Methods:** Enrollment visit data from Corrona PsA/SpA registry were obtained from 3/21/2013-9/30/2016. To be included in the analysis, patients had to have a diagnosis of PsA and a history of PsO. PsA patients were evaluated for skin severity as defined by Body Surface Area (BSA) and joint activity as defined by the level of CDAI. Patient characteristics, including current and prior PsA medication use, were obtained during the enrollment visit. We evaluated the relationship of skin severity and joint activity with linear regression. Factors that modify the relationship between BSA and CDAI were separately evaluated using the likelihood ratio test.

**Results:** 1,542 patients met inclusion criteria. Most were female 816 (52.9%), mean (SD) age was 53.7 (13.2) years, median duration with PsA disease 9.0 years and with PsO disease 18.0 years, and 71 (4.6%) had fibromyalgia. Of the 1484 patients with known DMARD therapy, 266 (18%) patients were on no DMARD therapy, 430 (29%) were on csDMARDs only, 616 (42%) were on first line biologic/tsDMARD therapy, and 172 (12%) were on second line biologic/tsDMARD therapy. The correlation between the skin severity and joint activity was positive and statistically significant 0.183 ( $p < 0.0001$ ). (Figure 1). The relationship between skin severity and joint activity was stronger in patients of younger age, on current treatment of DMARDs and TNFs, with history of MTX use, a higher dactylitis count, not achieving MDA, working from home or being a student, and with higher scores of HAQ, patient reported pain, and fatigue.

**Conclusion:** Skin severity is directly and significantly related to joint activity. The relationship is modified by age, gender, current therapy, work status, MDA, HAQ, patient reported pain and fatigue. The findings underscore the importance of treating both skin and joint among patients with both PsO and PsA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Simultaneous control of joint symptoms and degree of skin involvement has been linked to improvement in health-related quality of life in patients with coexistent PsA and psoriasis (PsO). The objective of this analysis was to understand how the relationship between skin and joint severity is impacted by PsA therapy.

**Methods:** Enrollment visit data from Corrona PsA/SpA registry were obtained from 3/21/2013-9/30/2016. To be included in the analysis, patients had to have a diagnosis of PsA and history of PsO. Patients were subsequently stratified into three subgroups based on therapy at enrollment: a) not on DMARD therapy, b) on csDMARDs, or c) on anti-TNFs. Patient demographic and disease characteristics were compared.

The relationship of skin severity (BSA) and joint activity (CDAI) was evaluated using linear regression. To evaluate whether factors modified the relationship between CDAI and BSA, multiple linear regression was performed.

**Results:** 1,542 patients met inclusion criteria and 1484 had known therapy status. 266 (18%) patients were on no DMARD therapy, 430 (29%) were on csDMARDs only, and 765 (52%) were on anti-TNFs at time of enrollment. Patients on no DMARD therapy were more likely to be female, younger, have shorter PsA duration, more likely to have dactylitis, enthesitis and higher levels of joint activity, skin severity, and HAQ, and less likely to have MDA. (Table). Patients on TNFi therapy had better disease control (CDAI and BSA) than other therapy subgroups, but proportion of patients with MDA was similar to those on csDMARDs.

In the no DMARD therapy group, no variables tested resulted in a significant impact on the relationship. In both csDMARD and TNFi groups, age, BMI, SPARCC, HAQ, patient reported pain and fatigue significantly impacted the relationship between joint activity and skin severity. In csDMARDs group, dactylitis modified the relationship and in TNFi group, PsO onset and MDA modified the relationship.

**Table:** Descriptive statistics for patient characteristics, disease characteristics and PROs stratified by current drug therapy

		No DMARDs	csDMARDs only	1st or 2nd Line T
		N=266	N=430	N=765

	Disabled: n(%)	25 (9.4)	34 (8.0)	65 (8.6)
<b>CDAI:</b>	Mean	14.9 ±8.9	11.9 ±9.3	10.5 ±7.2
(SD)				
<b>BSA:</b>	Mean	7.5 ±14.3	5.2 ±10.0	5.2 ±10.3
(SD)				
<b>Enthesitis SPARCC Score:</b>	Mean (SD)	3.9 ±2.9	4.8 ±3.5	4.0 ±2.9
<b>Dactylitis: N<sub>o</sub></b>		266	430	765
	Mean (SD)	2.2 ±1.5	2.7 ±2.2	1.9 ±1.5
<b>Minimal Disease Activity:</b>		57 (22.9)	172 (43.8)	343 (48.4)
n(%)				
<b>28 Tender Joints Count:</b>	Mean	4.0 ±5.3	2.6 ±4.8	2.2 ±4.5
(SD)				
<b>28 Swollen Joints Count:</b>	Mean (SD)	2.7 ±3.7	2.0 ±3.7	1.1 ±2.4
<b>Nail Pso VAS (0-100):</b>	Mean (SD)	9.1 ±16.0	8.1 ±21.4	6.2 ±13.6
<b>HAQ (0-3):</b>	Mean (SD)	0.7 ±0.7	0.6 ±0.7	0.5 ±0.6
<b>Patient Pain VAS (0-100):</b>	Mean (SD)	46.0 ±29.0	37.4 ±28.7	34.0 ±28.7
<b>Patient Reported Fatigue (0-100):</b>	Mean (SD)	45.3 ±29.0	39.3 ±29.0	38.2 ±28.9

Proportions are calculated among patients with non-missing response. Enthesiitis SPARCC Score and Dactylitis Counts are among patients with enthesitis and dactylitis, respectively

**Conclusion:** There were significant differences in disease characteristics and patient reported outcomes in PsA patients with PsO history when stratified by type of therapy. The relationship between joint activity and skin severity is influenced by age, SPARCC, patient reported pain, fatigue, and HAQ among patients on DMARDs and TNFi therapies. Dactylitis and PsO onset also modified the relationship among csDMARD and TNFi therapy groups, respectively. For improved disease management of PsA patients with a history of PsO, consideration of these factors is important when determining type of therapy.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is a progressive disease bringing substantial socioeconomic burden. Gradual loss of productivity (PL) and daily activities can be modified by effective therapy, e.g. biological treatment (BT).

**Methods:** We described the cohort and methods elsewhere. 228 PsA patients diagnosed with CASPAR criteria were followed over 873 appointments in 6-month intervals. Activity (AI) and work impairment (WI) were assessed using WPAI questionnaire. Predictors of WI were explored with linear mixed-effect regression (ME) and statistical differences

between groups using Kruskal-Wallis test. PL was monetized via Human Capital Approach (HCA; costs until retirement at 62.7 years; discount rate 3%) with average gross wage of €1493.

**Results:** 53.5% patients were working and 25.4% were disabled. Mean baseline AI and WI in working patients ( $\pm$  SD) were  $0.28 (\pm 0.24)$  and  $0.33 (\pm 0.32)$ . Similarly to HAQ score ( $0.74 \pm 0.70$ ), WI and AI worsened with growing PsA activity measured either by DAPsA score or cDAPsA (excluding serum CRP) with  $p \leq 0.0001$ . The mean time to retirement was  $14.0 \pm 9.9$  years.

38.2% patients had BT (anti-TNF) in the 12 months prior to enrolment with the mean costs of €981 per patient-month. Compared to non-BT population, BT patients were younger (50.7 vs. 59.4) and more frequently disabled (17.1% vs. 8.3%). They had lower DAPsA at baseline (14.43 vs. 17.14;  $p = 0.02$ ) due to lower serum CRP (5.72 vs. 7.12;  $p = 0.0035$ ) contrarily to cDAPsA which differed neither in baseline (8.60 vs. 9.97;  $p = 0.075$ ) nor in longitudinal population (8.2 vs. 9.5;  $p = 0.056$ ). Number of swollen joints dropped in the longitudinal population (1.02 vs. 1.23;  $p = 0.0015$ ) while WI raised (0.38 vs. 0.41;  $p \leq 0.0001$ ).

HAQ, AI and time from diagnosis were the best predictors of WI. ME models translated into productivity costs using HCA showed that increase in either HAQ or AI (as sole predictors) by 0.1 represent a growth of PL by €2387 or €5367 (Figure 1). In the most robust model, increase of HAQ and AI together by 0.1 correspond to the growth of indirect costs by €6212. Both DAPsA and cDAPsA were significant, yet weak predictors of WI.

**Conclusion:** In view of the BT indication criteria (severity, failure of previous treatment), the clinical parameters of the BT population suggest that BT effectively slows PsA progression. Primary response was observed as attenuation of acute inflammation measured by CRP. HAQ and AI are the best predictors of WI in PsA. Therefore, we can conclude that decreasing HAQ, e.g. via more effective BT, will undoubtedly increase working productivity and thus decrease productivity losses in PsA patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many autoimmune diseases have both musculoskeletal and cutaneous manifestations, which historically have been managed separately by rheumatologists and dermatologists. Given the complex presentation of autoimmune dermatologic and rheumatologic diseases, new tools are now available for proper workup and diagnosis, and access to a wide array of novel targeted therapies, combined Rheumatology-Dermatology clinics have been developed across the country. These clinics are unique in that both rheumatologists and dermatologists work together to provide multi-disciplinary care for patients with skin and musculoskeletal diseases. In this study, we retrospectively reviewed the records from our combined Rheumatology-Dermatology clinic at Rhode Island Hospital, a tertiary care medical center in the Northeast.

**Methods:** We conducted a retrospective chart review of 324 patient visits to the newly formed Rhode Island Hospital Center for Skin and Musculoskeletal Diseases during the period from July 2014 to February 2016. A total of 167 new patients were identified. We collected data on patient demographics, past medical history, family history, referring physician, presenting diagnoses, change in diagnoses, escalation or reduction of pharmacologic management including biologic medication use, and development of adverse events

## Results:

Of 167 new patients seen in the combined Rheumatology-Dermatology Clinic between July 2014 and February 2016, 105 (63%) were female and the average age was 50 years. The average number of visits per patient over this period was 2.5. The majority (68%) of patients were referred by either dermatology or rheumatology for further evaluation and management. The most frequent diagnosis referred to the clinic was psoriasis, comprising 60% of referrals. Other diagnoses seen in the clinic included psoriatic arthritis, systemic lupus erythematosus, cutaneous lupus, dermatomyositis, scleroderma, vasculitis, pyoderma gangrenosum, and mixed connective tissue disease. 44 (26%) patients reported a history of a co-morbid autoimmune condition such as inflammatory bowel disease (IBD), thyroid disease, or pernicious anemia. 118 (71%) patients denied a family history of similar autoimmune condition. As a result of their consultation in the combined dermatology-rheumatology clinic, 55 (37%) patients received a change in diagnosis. One fifth of patients presenting with psoriasis were diagnosed with concomitant psoriatic arthritis. Treatment was changed in 94 (56%) patients overall. 68 (41%) patients had escalation of treatment, while 12 (7%) had treatment reduction. A small minority of patients 18 (11%) experienced adverse events from these treatments.

**Conclusion:** This study provides evidence to support improved patient outcomes by evaluation in a unique combined rheumatology-dermatology multidisciplinary setting. Patients with complex autoimmune diseases, including those with psoriasis and psoriatic arthritis, experienced benefits from co-management of their condition.

## **Comparison of Quality-of-Life, Function and Psoriasis Measures in Minimal Disease Activity and DAS28 States in Routine Care of Patients with Psoriatic Arthritis**

**Catherine Hughes**, Nora Ng, Toby Garrood and Bruce Kirkham, Rheumatology, Guy's & St Thomas NHS Foundation Trust, London, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Psoriatic arthritis (PsA) often occurs with skin psoriasis (PsO). Disease activity can be measured using several tools including Minimal Disease Activity (MDA/VLMDA) or 28 joint disease activity (DAS28). The Psoriasis Area and Severity Index (PASI) assess the severity of PsO. Patient reported outcome measures (PROMs) are increasingly accepted as key outcome measures (new OMERACT guidelines) including the Dermatology Quality of Life Index (DLQI) and EuroQol 5 dimensions questionnaire (EQ-5D). Our objective was to compare PROMs in MDA and DAS28 disease states, including severe psoriasis, defined as PASI >10 or DLQI >10 or Body Surface Area >10.

### **Methods:**

Patients with PsA attending our center completed PROMs and had clinician assessment. The following data was recorded: age, diagnosis, MDA components, DAS28 components, PASI, DLQI, EQ-5D-3L and Health Assessment Questionnaire (HAQ-DI), in a IRB approved cross-sectional analysis. Statistics were performed using SPSS Version 23.

### **Results:**

129 sequential patients attending between February and November 2016 were included. Population characteristics are outlined in Table 1. 82% of patients had psoriasis, with a DLQI score available for 88% (n=93). MDA and DAS28 low disease activity identified similar patients, with similar arthritis outcomes, generally better in MDA (Tables 1 and 2). Our population generally did not have high PASI (mean 1.38). DLQI scores were higher in active PsA. The DAS28 remission group had 11% of patients with a DLQI >10, in contrast the MDA group had fewer with DLQI >10 (3%).

### **Conclusion:**

MDA and DAS28 measures identify patients with similar arthritis outcomes. Patients in MDA and low DAS28 states have lower DLQI values. MDA is associated with significantly fewer patients with high DLQI. This suggests that MDA identifies patients who have a better overall psoriatic disease outcome.

## **Changes in Severity, Functional Status, and Wellbeing over Time Among Individuals with Ankylosing Spondylitis (AS) in Canada: Results from the RHUMADATA® Multicentre Registry**

Shelagh Szabo<sup>1</sup>, Sara Chehab<sup>2</sup>, Louis Coupal<sup>3</sup> and **Denis Choquette**<sup>4</sup>, <sup>1</sup>Broadstreet HEOR, Vancouver, BC, Canada, <sup>2</sup>Novartis Pharmaceuticals Canada Inc., Montreal, QC, Canada, <sup>3</sup>Institut de Recherche en Rhumatologie de Montréal (IRRM), Montréal, QC, Canada, <sup>4</sup>University of Montreal Hospital Research Centre (CRCHUM), Notre Dame Hospital Montreal, Montreal, QC, Canada

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While changes in disease severity, functional status, and patient wellbeing are commonly measured in AS trials, longitudinal data from real-world cohorts are fewer; particularly considering the impact of anti-tumor necrosis factor (TNF) therapy. The objective was to estimate changes in severity, function, and wellbeing over time, from a population of Canadians undergoing active management for AS.

**Methods:** This real-world analysis used up to 15 years of clinical and patient-reported outcomes (PRO) data from the broad set of patients treated at the IRRM and CORQ (RHUMADATA®). The frequency of use of anti-TNFs was tabulated. AS severity (by BASDAI), functional impact (by BASFI), and wellbeing (by BAS-G) were assessed; at the baseline visit, within the first year of follow-up (e.g. from second visit to 52 weeks), and at least annually thereafter. From those with PRO data post-baseline, mean (standard deviation [SD]) scores were plotted over the next 4 years; stratified by anti-TNF status (treatment-naïve; or treated with 1, 2, or  $\geq 3$  anti-TNFs over the period). A sensitivity analysis was performed to limit the cohort to those with  $\geq 2$  PRO measures post-baseline.

**Results:** Mean (SD) age at baseline was 36.0 (12.6) years, and 60.0% were male; median follow-up was 9.7 (10.6) years. Of the 341 patients with post-baseline PRO measures, 116 (34.0%) were never treated, 144 patients (42.2%) were treated with 1, 47 patients (13.8%) were treated with 2, and 34 (10.0%) patients were treated with  $\geq 3$ , anti-TNFs. Mean (SD) baseline PRO scores were higher with greater anti-TNF treatment (table); for example, BASDAI scores ranged from 4.1 (2.2; anti-TNF-naïve), to 5.5 (1.9;  $\geq 3$  anti-TNFs). Mean (SD) scores decreased over time, in each anti-TNF treatment category. As an example for the BASDAI, scores decreased to 3.0 (2.1) during year four (anti-TNF-naïve), and to 4.0 (1.7) for those with  $\geq 3$  anti-TNFs. Mean changes from baseline were less among those with more severe disease who received more anti-TNF treatment (data not shown). While the sample for the sensitivity analysis was smaller, the findings were consistent with the base case: improvements on the BASDAI, BASFI, and BAS-G were lower for patients exposed to  $\geq 2$  anti-TNFs, compared to those treated with 0 or 1 (data not shown).

**Conclusion:** The need for re-treatment was common in this Canadian cohort; almost 25% were treated with  $\geq 2$  anti-TNFs over 4 years. PROs showed improvements in disease severity, function, and patient wellbeing over time; although consistent with observations from rheumatoid arthritis, these were less pronounced for more severely affected AS patients (treated more heavily with anti-TNFs). These data are useful for demonstrating the clinical and functional burden experienced by AS patients, and suggest a potential role for newer treatments not targeting TNF.

Table: Mean (SD) scores over time, BASDAI, BASFI, and BAS-G; according to number of anti-TNFs (naïve, 1, 2, or  $\geq 3$  therapies)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Psoriatic arthritis (PsA) is a systemic inflammatory disease that can involve skin, nails, joints, entheses, and can be associated with systemic symptoms such as fatigue.

The disease may have a negative impact on patients, including their quality of life.

The aim of this study was to examine the effect of PsA on self-reported health status and fatigue.

## Methods:

We present longitudinal data on 36 973 participants of the population-based HUNT Study, Norway (HUNT2, 1995-97 and HUNT3, 2006-08). Overall, 0.67% of participants in HUNT3 was validated to have PsA according to the Caspar criteria [1](#), and 151 were diagnosed with PsA between HUNT2 and HUNT3.

We examined health status and fatigue before and after the PsA diagnosis, compared with people without PsA, excluding persons diagnosed with PsA before HUNT2.

Self-reported health was measured as “How is your health at the moment (1: Very Good; 2: Good; 3: Fair 4: Poor)”. The question on fatigue was “Do you feel, for the most part, strong and fit or tired and worn out (graded from 1: Very strong and fit to 7: Very tired and worn out). Variables were also dichotomized to classify people as having poor health (response option 3-4) and fatigue (option 5-7).

We used linear regression to estimate adjusted mean differences in outcome variables at HUNT3, and logistic regression to estimate adjusted odds ratios (OR) for poor health and fatigue. All estimates were adjusted for baseline health or fatigue, gender, age, BMI, education, and smoking.

Sensitivity analyses were performed excluding people who reported poor health or fatigue in HUNT2.

## Results:

There was no large differences at baseline in sex (57.6 vs. 55.2% women), age (43.9 vs. 46.8 years), BMI (27.3 vs. 26.2 kg/m<sup>2</sup>), or attainment of higher education (21.2% vs. 22.0%) between people developing PsA and those who did not. However, PsA developers smoked more (41.1 vs. 25.4%) and reported muscle and joint pain (66.9% vs. 46.5%).

Self-reported health status and fatigue before and after the PSA diagnosis are presented in Table. Compared to the controls, people developing PsA reported poorer health (30.5% vs. 23.3%) and more fatigue (31.8% vs. 19.4%).

After adjustment, they scored 0.37 (95% CI 0.28-0.47) higher on poor health and 0.40 (0.23-0.58) higher on fatigue compared to controls. Correspondingly, people developing PsA had an OR of 4.37 (2.95-6.46) for reporting poor health and 1.80 (1.22-2.65) for fatigue at HUNT3. The sensitivity analyses gave ORs of 3.72 (2.37-5.83) and 1.97 (1.31-2.96), respectively.

## Conclusion:

Individuals who developed PsA were four times more likely to report poor health and the risk of perceived fatigue was almost doubled. This shows that developing PsA has a negative impact on patients and could contribute to an impaired quality of life in these patients.

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease affecting peripheral and axial joints. For patients with active psoriasis, the added burden of skin disease can further reduce the health-related quality of life (HRQoL) of patients with joint disease. The objective of this analysis is to determine the contribution of joint and skin improvements in the HRQoL of patients with active PsA during phase 3 clinical trials investigating ixekizumab (IXE) treatment.

**Methods:** The SPIRIT trials are double-blinded phase 3 trials investigating the treatment of IXE, a high affinity monoclonal antibody selectively targeting interleukin-17A, for patients with active PsA. The integrated database of 2 SPIRIT trials consisted of patients who were biologic DMARD-naïve (SPIRIT-P1, NCT01695239) or were inadequate responders to TNF-inhibitors (SPIRIT-P2, NCT02349295). Patients were randomized to 80 mg IXE every 4 weeks (Q4W, N=229) or 2 weeks (Q2W, N=226) after a 160 mg starting dose or placebo (PBO, N=224). At baseline and Week 24, joint and skin disease were measured by the Disease Activity index for PSoriatic Arthritis (DAPSA; calculated post-hoc) and Psoriasis Area and Severity Index (PASI), respectively. HRQoL was measured by the EuroQoL 5 Dimensions Visual Analog Scale (EQ-5D VAS), Short Form-36 Health Survey (SF-36), and the Work Productivity and Activity Impairment-Specific Health Problem (WPAI). The synergistic contribution of skin and joint improvements to HRQoL was modeled using smoothing spline method and depicted with response surface (Figure 1). Missing data were imputed using last observation carried forward.

**Results:** Of the 679 PBO- and IXE-treated patients in the SPIRIT trials, 402 (65%) and 224 (36%) patients had  $\geq 3\%$  body surface area (BSA) and  $\geq 10\%$  BSA psoriasis at baseline, respectively. In these patients, we applied response surface modeling to investigate the relationship between DAPSA, PASI, and change from baseline in EQ-5D VAS at Week 24. The greatest improvement in EQ-5D VAS was associated with the largest percent improvements in both DAPSA and PASI together, rather than DAPSA or PASI alone (Figure 2). Similar observations, regardless of  $\geq 3\%$  or  $\geq 10\%$  BSA baseline psoriasis, were made in domains of SF-36 (General Health, Physical Functioning, Social Functioning, and Vitality; data not shown) and WPAI (Activity Impairment; data not shown).

**Conclusion:** For PsA patients with psoriasis, optimal improvements in patients' HRQoL, as measured by select domains of patient reported outcomes, were dependent on successful treatment of both joint and skin symptoms.

**Figure 1. Response surface modeling of the contribution of skin and joint improvements to patient HRQoL.** (A) Three dimensional scatterplot of skin (y-axis; PASI – percent improvement), joint (x-axis; DAPSA – percent improvement), and HRQoL (z-axis; EQ-5D – change from baseline) improvement at Week 24. A color spectrum is applied to HRQoL improvements (blue [least improvement] to red [greatest improvement]). (B) Response surface of scatterplot estimated by smoothing spline method.

Figure 2. Heat map view of the contribution of joint and skin improvement to the HRQoL of patients with psoriatic arthritis ( $\geq 3\%$  and  $\geq 10\%$  baseline BSA) at Week 24. Skin and joint improvement were measured by percent improvements from baseline PASI and DAPSA scores, respectively. Change from baseline in HRQoL is depicted in a color spectrum (blue [least improvement] to red [greatest improvement]) for EQ-5D VAS.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The impact that sleep has on patients' perception of disease activity in Psoriatic Arthritis (PsA) has been poorly understood. We assessed the association between sleep, as measured with a 21-point VAS, and various measures of disease activity.

**Methods:** All patients seen in the clinic of MB are asked to complete a questionnaire (MDHAQ) with additional questions regarding sleep, as part of the routine care in this practice. After a clinical exam, including a 28 tender (TJC) and swollen (SJC) joint count, the physician records an MDGlobal score, using a 21 point VAS (0-10). From these values, the RAPID3 (a composite score of Pt Pain+PtGlobal+Function) is calculated. Additionally, the CDAI can also be calculated (TJC+SJC+PtGlobal+MDGlobal). While neither measure has been extensively studied in PsA, they provide insight into the levels of disease activity as perceived by the patient and by the treating physician. We performed multiple regressions, using the Sleep VAS as the dependent variable, to investigate its impact on the various independent variables and composite scores.

**Results:** Random visits of 49 patients (45% male, mean age=59.36yrs, mean disease duration=6.63yrs, mean Sleep VAS=3.83) were included for study. Multiple regressions were performed "controlling for" age, sex and disease duration. Based on our results, Sleep VAS has a significant impact on TJC, Pain and PtGlobal scores ( $p<0.05$ ), with a trend toward significance for SJC ( $p=0.058$ ) (Table1). The composite scores were also significantly impacted: RAPID3 ( $p=0.018$ ) and CDAI ( $p=0.003$ ). When the PtGlobal score is removed from the CDAI ("C3"=TJC+SJC+MDGlobal), the significance remained ( $p=0.014$ ), suggesting that the impact of sleep was not only observed by the patient, but also by the treating physician.

**Conclusion:** Patients with PsA often report difficulty with sleep. We demonstrate a strong association between patient reported sleep problems and multiple measures of disease activity. While it might be assumed that this association would impact patient reported outcomes (PROs), there is also a strong association between sleep and physician measures, including the CDAI. While neither the RAPID3 nor CDAI have been validated for the monitoring of PsA, we feel that this study provides insight into the impact of sleep on disease activity. Based on this study, one cannot determine whether sleep disturbances influence disease activity or vice versa. Nevertheless, by monitoring a Sleep VAS, one can accurately assess levels of disease activity in PsA patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

PASS is the highest level of symptoms beyond which patients consider themselves well. Psoriatic Arthritis Disease Activity Score (PASDAS) is a recently developed composite disease activity measure that summarizes a patient's disease in a single 0-10 score. Disease Activity index for Psoriatic Arthritis (DAPSA) is a score recently validated for its utilization in PsA, focusing on the evaluation of disease activity in the joints. In this study, we aimed to **1)** identify the PASDAS and DAPSA cut-off points for PASS, **2)** to examine the agreement between PASS and the published PASDAS thresholds for low (<3.2), moderate (3.2-5.4), and high disease activity (>5.4), and **3)** to examine the agreement between PASS and the defined DAPSA thresholds for disease remission ( $\leq 4$ ), low (>4 and  $\leq 14$ ), moderate (>14 and  $\leq 28$ ), and high (>28) disease activity.

**Methods:** Patients were prospectively recruited from a PsA clinic. A standard protocol including physician assessment and patient-reported outcomes was used to record variables required to calculate PASDAS and DAPSA. In addition, each patient was asked, "Think about all the ways your PsA has affected you during the last 48 hours. If you were to remain in the next few months as you were during the last 48 hours, would this be acceptable to you?" to assess PASS. For analysis, the PASDAS and DAPSA thresholds for PASS were identified using ROC curve analyses to maximize specificity and sensitivity. Furthermore, the agreement between PASS and low, moderate, and high PASDAS disease activity cut-offs; as well as between PASS and disease remission, low, moderate, and high DAPSA disease activity cut-offs were evaluated.

**Results:** 229 patients [58.5% male, mean age 55.5, mean disease duration 17.2 years] were recruited. **1)** The PASDAS threshold for the patient acceptable symptoms state (PASS+) was identified to be 3.79 (AUC: 0.86, sensitivity 0.75, specificity 0.82), and the DAPSA threshold for PASS+ was 13.53 (AUC: 0.85, sensitivity 0.88, specificity 0.72) using ROC curve analyses. **2)** When examining the agreement between PASS and PASDAS, 90.3% of patients with low disease activity considered their symptoms state acceptable compared to 55.0% with moderate disease activity and 16.7% with high disease activity. The mean difference in PASDAS between those reporting unacceptable versus acceptable PASS was significantly different ( $p < 0.001$ ), with mean (SD) PASDAS of 4.4 (1.0) and 2.7 (1.1), respectively. **3)** With DAPSA, 97.0% of patients in disease remission considered their symptoms state acceptable compared to 89.4% with low, 45.4% with moderate, and 35.7% with high disease activity. The mean difference in DAPSA between those reporting unacceptable vs acceptable PASS was also significantly different ( $p < 0.001$ ), with mean (SD) DAPSA of 25.3 (16.3) and 11.6 (13.2) respectively.

## Conclusion:

The PASDAS threshold for patient acceptable symptoms state is 3.79, which is within the moderate disease activity range. Meanwhile, the DAPSA threshold for patient acceptable symptoms state is 13.53, in the low disease activity range. These cut-offs should be considered for shared decision making regarding initiating, changing, and/or escalating treatments in PsA patients.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Impact of dermatological disease is measured with the Dermatology Life Quality Index (DLQI) and Skindex-17. DLQI is commonly used in dermatology trials but the Skindex-17 has better psychometric properties and less floor effect. We aim to describe health-related quality of life (HRQoL) related to skin involvement using the DLQI and Skindex-17 and to assess impact of replacing DLQI by the Skindex-17 in determining overall PsA disease activity.

**Methods:** Data collected in the ongoing Dutch south-west Early Psoriatic Arthritis Cohort (DEPAR) and used for this analysis were Psoriasis Area and Severity Index (PASI), DLQI (range 0-30) and the Skindex-17 (Domains: Psychosocial 0-24 and Symptoms 0-10). Spearman's correlation was used to calculate correlation between questionnaires and correlation between change in questionnaire-score and change in PASI. The latter was performed within subgroups of psoriasis severity (PASI <7, 7-12 and >12) using change in the first three months after baseline. In the Composite Psoriatic Disease Activity Index (CPDAI), skin involvement is considered not involved, mild, moderate or severe. Using cutoff values of Skindex-17 Symptoms >5 and/or Skindex-17 Psychosocial >9, reclassification of skin assessment was analyzed.

**Results:** In total 1657 questionnaires of 390 patients were available (mean age 50 years, 51% male). At baseline, median DLQI was 1 (interquartile range, IQR 0-5), Skindex-17 Symptoms 4 (IQR 2-6) and Skindex-17 Psychosocial 2 (IQR 0-8). Correlation between DLQI and Skindex-17 domains was 0.78 (p<0.05). In mild psoriasis (PASI 0-7, n=200), change in PASI had a significant but low correlation with change in HRQoL (Table 1). In moderate psoriasis (PASI 7-12, n=27) the correlation was higher. 269 cases (16%) had CPDAI reclassification, the majority changing from mild with DLQI to moderate with Skindex-17 (n=250, Table 2).

**Conclusion:** In early PsA with mild/moderate psoriasis, impact of psoriasis is best reflected in the Skindex-17. Using the Skindex-17 in the CPDAI leads to higher rating of skin involvement than using the DLQI. Both suggest a more

subtle impact on HRQoL is missed in the DLQI and the Skindex-17 is preferred in PsA.

**Table 1. Correlations between change in PASI score and change in DLQI/Skindex-17 domains**

	PASI = 0 (n=41)	PASI >0-7 (n=200)	PASI 7-12 (n=27)	PASI >12 (n=8)
Change in DLQI	-0.01	0.18*	0.48*	0.25
Change in Skindex17-Symptoms	0.00	0.25*	0.44*	0.64
Change in Skindex17-Psychosocial	0.17	0.17*	0.64*	0.08

Change between baseline and 3 months assessment, \*significant correlation

**Table 2. Classification in skin domain of CPDAI**

Skin involvement using Skindex-17				
Skin involvement using DLQI	Not involved	Mild	Moderate	Severe
Not involved	450	0	0	0
Mild	0	836	250	0
Moderate	0	3	85	16
Severe	0	0	0	20

Not involved (PASI=0); Mild (PASI=10 & Patient-reported outcome, PRO low);

Moderate (PASI=10 & PRO high or PASI>10 & PRO low); Severe (PASI>10 & PRO high).

PRO low DLQI=10, Skindex17-Symptoms=5 & Skindex17-Psychosocial =9;

PRO high: DLQI>10, Skindex17-Symptoms>5 or Skindex17-Psychosocial>9

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Presence of Minimal Disease Activity (MDA) in Psoriatic Arthritis (PsA) is determined using a patient Visual Analogue Scale (VAS) global PsA activity and VAS pain. Electronic questionnaires for patients to complete at home have great advantages for both patient, researcher and physician, but this implies that physical examination and VAS does not occur simultaneously. We aim to compare a paper VAS at the clinic and electronic VAS at home in psoriatic arthritis and to assess impact of replacing VAS at the clinic by the at-home questionnaires.

**Methods:** Questionnaires collected in the Dutch south-west Early Psoriatic Arthritis CohoRt (DEPAR) were analyzed. Patients filled out the VAS during their appointment and received a link to the online data-base a week in advance. Patients without an email-address received questionnaires by post. The VAS questionnaire contains a VAS global, VAS joints, VAS psoriasis and VAS pain. Data with both visit- and home VAS present within two weeks of each other were used.

The number of patients without a clinically important difference in the two scores were calculated in two ways: difference of  $<0.5$  SD and  $<10$  mm. Impact on determining disease activity was analyzed using MDA (5/7 equals remission, with VAS criteria VAS-Global  $\leq 20$  and VAS-Pain  $\leq 15$ ). Reclassification of being in MDA based on VAS-Visit vs. VAS-Home was analyzed.

**Results:** In total 839 questionnaires of 221 patients were available for analysis (Table 1). The VAS-Home had significantly higher scores than the VAS-visit, with the biggest difference in the VAS-Global (mean difference 4 mm, 95%CI 3-5,  $P<0.05$ ). No significant differences were observed between the paper ( $n=86$ ) and electronic ( $n=753$ ) groups. In 66%, the two VAS-Global measurements were within 0.5 SD and in 60% within 10 mm. Using the VAS-Global remission criteria of MDA ( $\leq 20$ ) resulted in 12% low at visit and high at home and the reverse in 8%. Similar percentages are seen in the VAS-Pain assessment. Using different VAS scores in MDA reclassified 87 assessments (10%): in 54 measurements the patient was in MDA when using VAS-Visit but not when using VAS-Home and the reverse in 33.

**Conclusion:** In 1 out of 3 measurements replacing paper clinic VAS by electronic at home VAS would result in a difference that reaches clinical importance. Patients report higher scores at home than during a clinical visit, resulting in a lower number of patients reaching MDA and a reclassification of 10%.

**Table 1. VAS-Scores**

	<b>VAS- Global PsA (n=839)</b>	<b>VAS- Arthritis (n=839)</b>	<b>VAS- Psoriasis (n=831)</b>	<b>VAS-Pain (n=804)</b>
<b>VAS-visit, mean mm (95%- CI)</b>	30 (28-31)	32 (30-33)	20 (18-21)	33 (31-35)
<b>VAS-home, mean mm (95%- CI)</b>	34 (32-35)	34 (32-35)	22 (20-23)	35 (33-37)
<b>Difference, mean mm (95%- CI)</b>	4 (3-5)	2 (1-3)	2 (1-3)	2 (1-3)

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Background/Purpose:** The Psoriatic Arthritis Impact of Disease 12-item questionnaire (PsAID12) has been developed to measure impact of Psoriatic Arthritis (PsA) for purposes of monitoring and clinical management. We aim to investigate the relation between change in disease activity and change in PsAID, and which domains of the PsAID are main drivers of change in score.

**Methods:** Newly diagnosed PsA patients were included in the Dutch southwest Early Psoriatic Arthritis cohort (DEPAR). For this analysis, patients that have answered the PsAID12 (range 0-10) at two consecutive visits (i.e. 3 months apart) within the first year were included. In case longer periods per patients were available, data from the first period of three months was used. The change in PsAID was compared to the change in disease activity over this period, measured with the Composite Psoriatic Disease Activity Index (CPDAI) using Spearman's correlation. Change in score on PsAID domains was analyzed in subgroups of patients that perceived improvement in health and those that perceived worsening. The Short Form-36 question on self-perceived change in health was used to determine these subgroups.

**Results:** 143 unique patients had at least one period with two PsAID and CPDAI measurements (Table 1). Mean age was 51 (SD 13.7) and 70 (49%) were male. The difference in PsAID score was significantly but moderately correlated with the difference in CPDAI (Spearman's rho 0.267, P=0.0013). 58 patients (41%) reported a better health status compared to 3 months ago and 29 worsening of health status. Figure 1 shows that improved patients had higher scores in almost all domains, with the biggest improvement in pain. Domains of skin problems and embarrassment/shame did not improve significantly. Worsened patients only had significantly lower scores in fatigue, discomfort and social domains.

**Conclusion:** Improvement in CPDAI disease activity was significantly but moderately associated with improvement in PsAID score. This reflects that the PsAID partially measures disease activity, but measures other constructs of disease as well. In early PsA, a state of improved health is reflected in the PsAID in almost all domains, with the strongest effect in pain.

Table 1. CPDAI, PsAID and PsAID domain scores

	First score	Second score (+3 months)
Total CPDAI	4 (2, 7)	3 (1, 5)*
Total PsAID	3.35 (1.4, 5.1)	2.25 (0.95, 4.8)*
Pain	5 (2, 7)	3 (1, 6)*
Fatigue	4 (1, 7)	3 (1, 7)
Skin Problems	2 (0, 5)	2 (0, 4)*
Work/Leisure	3 (0, 6)	2 (0, 5)*
Function	3 (1, 6)	2 (0, 5)*
Discomfort	4 (1, 6)	2 (1, 5)*
Sleep	3 (0, 7)	1 (0, 5)*
Coping	2 (0, 5)	1 (0, 5)*
Anxiety	2 (0, 5)	1 (0, 4)*
Embarrassment/Shame	0 (0-1)	0 (0-1)
Social Participation	1 (0, 4)	1 (0, 4)
Depression	0 (0, 3)	0 (0, 2)

N=143, data shown as median (IQR), \*P<0.05, significant change in three months

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

PsA patients have higher cardiovascular disease risk due to underlying inflammation. While achieving MDA was associated with articular benefits, its effect on CVD risk remained uncertain. This study aimed to investigate the effect of achieving sustained MDA (sMDA) on subclinical atherosclerosis.

### **Methods:**

100 consecutive PsA patients without overt CVD were followed for 2 years with clinical assessment every 4 months. Protocolized treatment aiming at MDA were given. sMDA was defined as achieving MDA over 1 year. Carotid IMT at bilateral distal, bulb and proximal internal carotid artery were evaluated annually using high-resolution ultrasound. Carotid plaque progression was defined as increased number of plaque since baseline.

### **Results:**

54 PsA patients [male:29 (53.7%); 50 +/- 12years] who completed 24-months follow-up were included in this analysis. After 2-year intensive treatment, significantly more patient could achieve MDA [9 (16.7%) at baseline, 35 (64.8%) at 2 years,  $p<0.001$ ]. 23/54 (43%) patients achieved sustained MDA. Baseline characteristics were comparable between subjects who could or couldn't achieve sMDA. Numeric differences were observed in change in mean IMT between sMDA and non-sMDA group [-0.03mm +/- 9.8 vs +0.01mm +/- 0.08,  $p=0.061$ ]. In multivariate analysis, sMDA was associated with less progression of mean IMT [ $\beta$ ]=-0.045, 95%CI:-0.082 to -0.009,  $p=0.017$ ] after adjusting age, gender, disease duration, baseline CRP, PASI, dyslipidemia, NSAIDs use, and bDMARDs use throughout the year. 28/54 (52%) patient had plaque progression. The prevalence of plaque progression was numerically higher in non-sMDA group [19 (61%) vs 9 (39%),  $p=0.107$ ]. In multivariate analysis, there was a trend suggesting achievement of sMDA might have protective effect on plaque progression [OR=0.2, 95%CI: 0.036 to 1.112,  $p=0.066$ ].

### **Conclusion:**

Effective suppression of inflammation by achieving sustained MDA may prevent progression of subclinical atherosclerosis in PsA patients.

**Funding:** We would like to acknowledge the Health and Medical Research Fund (HMRF) for funding support (HMRF Project No. 01120496)

# Secukinumab Decreases Arterial Wall Inflammation in Patients with Peripheral Spondyloarthritis

Leonieke van Mens<sup>1</sup>, Simone Verweij<sup>2</sup>, Arno van Kuijk<sup>3</sup>, Erik Stroes<sup>2</sup> and Dominique Baeten<sup>1</sup>, <sup>1</sup>AMC, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands, <sup>2</sup>Vascular Medicine, Academisch Medisch Centrum, Amsterdam, Netherlands, <sup>3</sup>Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with spondyloarthritis (SpA), a chronic inflammatory disease, have an increased cardiovascular risk, which is partly due to increased inflammatory activity in the arterial wall. IL-17A blockade with secukinumab is an effective treatment for SpA. The role of IL-17A in atherogenesis is controversial, some studies suggest that IL-17A is pro-atherogenic, while others indicate that IL-17A is athero-protective. The effect of secukinumab on arterial wall inflammation is unknown. Therefore, we assessed the effect of 3 months treatment with secukinumab on arterial wall inflammation in SpA patients. To assess the effect of 3 months treatment with secukinumab on arterial wall inflammation in SpA patients with peripheral disease (pSpA).

**Methods:** 20 SpA patients with peripheral disease (pSpA) were treated in a 12 week open-label trial. Treatment consisted of 300 mg secukinumab once a week during the first 4 weeks and then every 4 weeks thereafter. EULAR DAS response was used to define a responder/non responder state. To measure arterial wall inflammation we performed 18-fluorodeoxyglucose positron emission tomography with computed tomography (<sup>18</sup>F-FDG PET/CT) imaging in 18 patients at baseline and at week 12.

**Results:** Sufficient quality scans were available for analysis in 16 patients (age 44±12, 72% male, no previous cardiovascular events). Overall, three months treatment with secukinumab resulted in a significant improvement of disease activity, with 15 patients achieving a EULAR DAS response (9 good and 6 moderate responders). Correspondingly, CRP levels decreased significantly (baseline: 3.2[1.2–12.40] mg/dl vs. wk 12: 2.0[1.1-5.8] mg/dl, p=0.011). Treatment with secukinumab did not affect cholesterol levels (LDL-c from 3.2±0.8 mmol/l to 3.5±0.9 mmol/l, p=0.219). Arterial wall inflammation as measured by PET-CT did not change over the course of the 12 weeks treatment with secukinumab (carotid TBR<sub>max</sub> baseline: 1.88±0.6 vs. wk 12: 1.76±0.4, p=0.067). Patients with a good response on secukinumab (n=9) showed a high TBR at baseline with a significant decrease of arterial wall inflammation, while there was a lower TBR in the patients with a moderate (n=6) or poor (n=1) response on secukinumab and there was no effect on arterial wall inflammation in these patients.

**Conclusion:** This pilot study in 16 patients with pSpA shows a successful clinical response upon secukinumab treatment for three months, with no change in arterial wall inflammation on group level. Sub analysis shows us a significant decrease of arterial wall inflammation in patients with a high TBR at baseline. Further research in larger patient groups, over a longer period of treatment remains warranted to fully elucidate the effect of secukinumab on vascular inflammation.

## the Ideal Target for Psoriatic Arthritis? Comparison of Remission and Low Disease Activity States in a Real Life Cohort

Leonieke van Mens<sup>1</sup>, Arno van Kuijk<sup>2</sup>, Dominique Baeten<sup>1</sup> and Laura C Coates<sup>3</sup>, <sup>1</sup>AMC, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands, <sup>2</sup>Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands, <sup>3</sup>LIRMM, University of Leeds, Leeds, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recommendations on psoriatic arthritis (PsA) state that the target of treatment should be remission or inactive disease with an alternative target of minimal or low disease activity(LDA). Multiple potential targets have been developed, each with a different composition of clinical measurements. Our aim is to use an existing real life dataset of a large group of patients in a low disease activity state, to compare different targets for LDA and provide further evidence to choose a target.

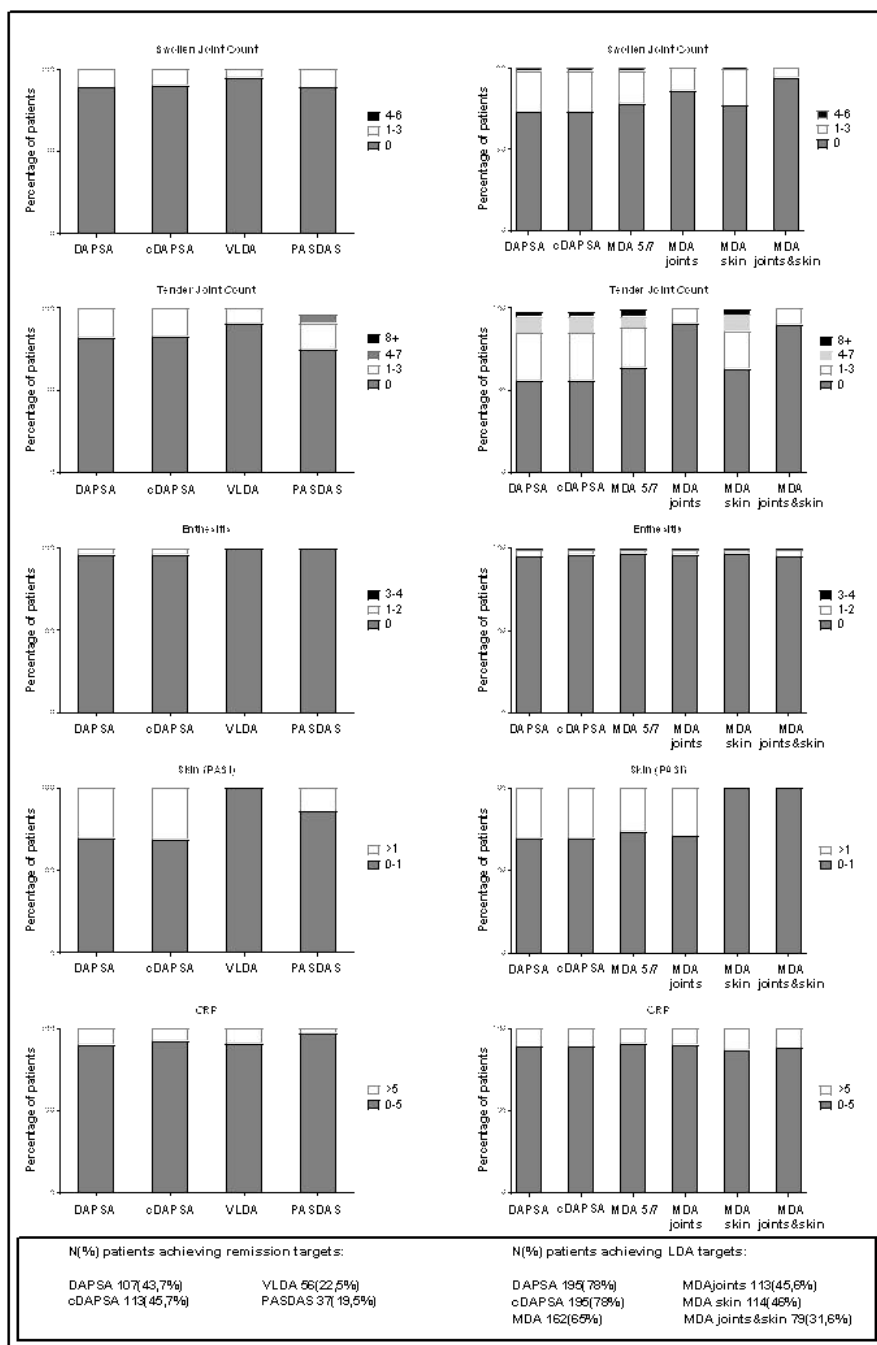

**Methods:** 250 PsA patients considered in an acceptable disease state according to their rheumatologist were included. Targets for remission were the DAPSA and cDAPSA remission ( $\leq 4$ ), VLDA and PASDAS  $\leq 1.9$  (NR). LDA targets analyzed were the DAPSA LDA  $\leq 14$ , clinical cDAPSA  $\leq 13$ , MDA, adjusted MDA targets: MDAjoints with both TJC and SJC cut-offs mandated, MDAskin where PASI was mandated, MDAjoint&skin where the TJC, SJC and PASI cut-offs mandated.

**Results:** Of the remission targets, DAPSA/cDAPSA and VLDA show the highest agreement (kappa of 0.516 and 0.544 resp.). The agreement between PASDAS NR and DAPSA/cDAPSA/VLDA was lower, (kappa of 0.403, 0.321, 0.319 resp). PASDAS NR was more stringent than DAPSA/cDAPSA remission. All patients who met VLDA were in DAPSA/cDAPSA remission.

Of the LDA targets, the highest agreement is seen between the DAPSA/cDAPSA and the MDA5/7 (kappa of 0.596 and 0.611 respectively). Agreement between the DAPSA and the alternative MDA measures (MDA joints, MDA skin and MDA joints and skin) is lower as these targets are more stringent (0.356, 0.372, 0.227 resp.).

Comparison of the several candidate measures demonstrates that VLDA is achieved by the lowest proportion of patients and includes patients with the lowest residual disease activity compared with the other remission measures. The modified MDA measures are the most stringent targets for low disease activity in terms of residual disease on joints, psoriasis and enthesitis within patients achieving the target. (see graph) In both remission and LDA measures the inclusion of CRP did not show an added value. A PASI $>1$  was more prevalent in (c)DAPSA in comparison with the 4 MDA measures. Patients with active psoriasis in the DAPSA group report significantly larger impact of skin disease on dermatology related quality of life (DLQI) (DLQI 0-1: 1.25(SD2.4) v.s. DLQI  $>1$ : 1.55(2.7).

**Conclusion:** The different remission and low disease activity targets show that despite significant overlap between the measures, measures targeting the same definition do differ from one another in terms of allowance of residual disease present within the patients. Inclusion of laboratory markers seems unnecessary although exclusion of a skin domain might result in negligence of skin disease in some patients despite a QoL impact.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treat to target recommendations in PsA state that the target of treatment should be remission or low disease activity (LDA). So far, the only validated target available was the minimal disease activity (MDA) criteria. Other potential targets have been developed including very low disease activity (VLDA) and the Disease Activity in PsA (DAPSA) score remission. Potential targets for LDA include DAPSA and clinical (cDAPSA) or the minimal disease activity (MDA) criteria for which modifications have been suggested to mandate individual components.

Using an existing real World cohort, the objectives were to calculate the proportion of patients achieving these criteria, their prognostic value and the overall patient impact of these disease states.

**Methods:** BioTRAC is an ongoing, prospective registry of inflammatory arthritis patients initiating treatment with infliximab, golimumab (GLM) or ustekinumab. PsA patients treated with GLM were included. Data collected at baseline, 6 and 12 months were used. The definition for MDA, remission and LDA outcomes are described in Table 1.

**Results:** A total of 188 patients (53% female) were included with a mean (SD) disease duration of 5.5 years. The proportion of patients achieving MDA, remission and LDA at baseline, 6 and 12 months is shown in Figure 1. 75% and 53.3% of patients in DAPSA and cDAPSA remission, respectively, also achieved VLDA ( $p<0.001$ ). Patients who did not achieve cDAPSA nor DAPSA never achieved VLDA. Higher HAQ scores ( $p<0.03$ ) were observed in patients achieving remission with remaining dactylitis or active skin disease ( $BSA\leq 10\%$ ; cDAPSA only). The proportions of patients achieving MDA also achieving MDA Joints, MDA Skin, MDA Joints & Skin and DAPSA LDA were 83.8%, 86.9%, 70.7% and 98.7%, respectively. Patients achieving any MDA target had significantly lower SJC, TJC, PASI, dactylitis and enthesitis scores compared to non-achievers ( $p<0.006$ ). Patients achieving DAPSA or cDAPSA LDA showed significant reductions in SJC, TJC, PASI, dactylitis and enthesitis scores compared to non-achievers ( $p<0.05$ ).

**Conclusion:** VLDA is the most stringent new potential targets for remission in PsA. There was a high level of correlation between scores although residual activity in dactylitis and skin despite DAPSA remission has some impact on patients' function. MDA Joints, MDA Skin, MDA Joints & Skin, DAPSA LDA and cDAPSA LDA represent new potential targets for LDA in PsA. Patients achieving either DAPSA endpoints, however, did not show a significant reduction in skin disease indicating that those two endpoints are more restricted to joint symptoms.

Target	Outcome	Definition
MDA	MDA	5/7 of TJC28 $\leq$ 1, SJC28 $\leq$ 1, PASI $\leq$ 1, Pain (VAS) $\leq$ 15mm, PtGA (VAS) $\leq$ 20mm, HAQ $\leq$ 0.5, tender enthesal points $\leq$ 1
Remission	VLDA	All 7/7 MDA criteria
	DAPSA Remission	TJC + SJC + PtGA + Pain + CRP $\leq$ 4
	cDAPSA Remission	TJC + SJC + PtGA + Pain $\leq$ 4
LDA	DAPSA LDA	TJC+SJC+PtGA+Pain+CRP $\leq$ 14
	cDAPSA LDA	TJC+SJC+PtGA+Pain $\leq$ 13
	MDA Joint	TJC and SJC cut-offs mandated. 3/5 remaining MDA criteria
	MDA Skin	PASI cut-off mandated. 4/6 remaining MDA criteria
	MDA Joint & Skin	TJC, SJC and PASI cut-offs mandated. 2/4 remaining MDA criteria

## Achievement of Minimal Disease Activity Is Associated with Improvements in Health-Related Quality of Life and Productivity in Psoriatic Arthritis Patients

Laura C Coates<sup>1</sup>, Ana-Maria Orbai<sup>2</sup>, Julie Birt<sup>3</sup>, Lisa Kerr<sup>3</sup>, Olivier Benichou<sup>3</sup> and Philip S. Helliwell<sup>4</sup>, <sup>1</sup>University of Oxford, Leeds, Great Britain, <sup>2</sup>Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>School of Medicine, University of Leeds, Leeds, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treatment goals in psoriatic arthritis (PsA) are moving toward attainment of absolute therapeutic thresholds rather than relative improvement. Minimal disease activity (MDA), a composite endpoint of up to 7 individual measures, has been recommended as an appropriate aim in PsA.

**Methods:** Data were analyzed from an integrated database of 2 double-blind, phase III SPIRIT trials investigating the efficacy and safety of ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A, for patients with active PsA. The integrated database consisted of patients who were biologic DMARD naïve (SPIRIT-P1, NCT01695239) or who had an inadequate response or were intolerant to TNF inhibitors (SPIRIT-P2; NCT02349295). Patients were randomized to placebo ( $n = 224$ ) or 80 mg IXE every 4 weeks (IXEQ4W,  $n = 229$ ) or every 2 weeks (IXEQ2W,  $n = 226$ ) after a 160 mg starting dose. Health-related quality of life (HRQoL) and productivity were evaluated using the 36-Item Short Form Health Survey (SF-36; higher scores indicate better functioning), European Quality of Life 5 Dimension 5 Level Health Questionnaire (EQ-5D-5L; higher values indicate better health utility), EQ-5D visual analog scale (EQ-5D VAS; 0-100 scale; higher scores indicate better health), and Work Productivity and Activity Impairment–Specific Health Problem (WPAI-SHP; higher scores indicate higher impairment). MDA was achieved if 5 of 7 criteria were met: tender joint count  $\leq 1$ ; swollen joint count  $\leq 1$ ; Psoriasis Area and Severity Index total score  $\leq 1$  or body surface area  $\leq 3\%$ ; patient's assessment of pain VAS  $\leq 15$ ; patient's global assessment of disease activity VAS  $\leq 20$ ; Health Assessment Questionnaire Disability Index  $\leq 0.5$ ; and tender enthesal points  $\leq 1$  (assessed by the Leeds Enthesitis Index).

**Results:** At Week 24, 474 of 679 patients had nonmissing MDA and HRQoL data. At Week 24, MDA responders had significantly improved SF-36 Physical Component Scores (PCS), EQ-5D-5L index values, and EQ-5D VAS scores but similar SF-36 Mental Component Scores (MCS) relative to MDA nonresponders (Table 1). MDA responders also had a significantly improved percentage of absenteeism, overall work impairment, and percentage of activity impairment on the WPAI-SHP relative to MDA nonresponders at Week 24 (Table 1). MDA responders were more likely to achieve the minimal clinically important difference on the SF-36 PCS, EQ-5D-5L index score, and EQ-5D VAS score but not the SF-36 MCS (Table 2).

**Conclusion:** Achievement of MDA is associated with improvement of patient-reported HRQoL and productivity.

**Table 1. Mean (SD) Change from Baseline at Week 24 by MDA Responder Status**

	MDA Nonresponder ( <i>n</i> = 322)	MDA Responder ( <i>n</i> = 152)	Mean Difference	<i>P</i> -Value

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The heterogeneity of psoriatic arthritis (PsA) that includes a possible combination of axial disease, peripheral arthritis, enthesitis, dactylitis, skin and nail involvement, makes its global assessment a significant challenge for clinical metrology. Over the last years different tools are used for measuring the disease activity in patients

with PsA. The Composite Psoriatic Disease Activity Index (CPDAI) is one of the more comprehensive, taking into account the assessment of five different domains. One of the problems with CPDAI is its complexity and the large number of instruments that need to be applied for a full assessment

The aim of this study was to evaluate the performance of a simplified CPDAI (sCPDAI) in a large group of PsA patients

**Methods:** We evaluated consecutive PsA patients included in the MOPSA database. Measuring Outcome in Psoriatic Arthritis (MOPsA) is a new web- based tool which calculates both MDA and CPDAI based on patient reported outcomes and assessment by physicians. Data collected included: joint counts, patient pain and global activity ratings, HAQ, PASI, BASDAI, DLQI, PsAQoL. Clinical DAPSA (Disease Activity for Psoriatic Arthritis), MDA (Minimal Disease Activity) and CDAI (Clinical Disease Activity Index) were also calculated. Pearson's correlations between CPDAIs and different measures of disease activity were calculated. CPDAI values between patients fulfilling and not fulfilling MDA were compared using Mann-Whitney U test. The area under the ROC curve (AUC) was calculated to quantify the discriminative performance for MDA

**Results:** 214 PsA patients, fulfilling CASPAR criteria, with mean age of 49 years (SD: 12), and 111 (52%) females, were included. Seventy-six (35.5 %) patients were in MDA. Median (IQR) CDAI, cDAPSA, CPDAI, and PASI were 7 (4-16), 10 (5-18), 3 (2-5), and 0.8 (0-3), respectively. Table 1 shows the variables used to construct sCPDAI, and table 2 shows sCPDAI correlation with different variables. Patients in MDA had significantly lower sCPDAI than patients not in MDA (mean (SD) 1.7 (1.4) vs 5.3 (2.8);  $p < 0.0001$ ). The sCPDAI AUC of the ROC curve for MDA was 0.87 (95% CI: 0.83-0.92), with 4 as the best cut off value to discriminate among patients not in MDA status (sensitivity: 68.42%; specificity: 87.67%; +LR: 5.55, -LR: 0.36)

**Table1:** Simplified CPDAI variables

	Not Involved (0)	Mild (1)	Moderate (2)	Severe (3)
<b>Peripheral arthritis</b>	Not involved	$\leq 4$ joints (TJC or SJC) & HAQ $\leq 0.5$	$\leq 4$ joints (TJC or SJC) & HAQ $> 0.5$ OR $> 4$ joints (TJC or SJC) & HAQ $< 0.5$	$> 4$ Joints (TJC or SJC) & HAQ $> 0.5$
<b>Skin disease</b>	Not involved	BSA $\leq 3$	BSA $> 3 \leq 30$	BSA $> 30$
<b>Enthesitis</b>	Not involved	$\leq 3$ sites & HAQ $< 0.5$	$\leq 3$ sites & HAQ $> 0.5$ OR $> 3$ sites & HAQ $< 0.5$	$> 3$ sites & HAQ $> 0.5$
<b>Dactylitis</b>	Not involved	$\leq 3$ digits & HAQ $< 0.5$	$\leq 3$ digits & HAQ $> 0.5$ OR $> 3$ digits & HAQ $< 0.5$	$> 3$ digits & HAQ $> 0.5$
<b>Spinal Disease</b>	Not involved	BASDAI $< 4$ & HAQ $< 0.5$	BASDAI $< 4$ & HAQ $> 0.5$  BASDAI $> 4$ & HAQ $< 0.5$	BASDAI $> 4$ & HAQ $> 0.5$

**Table 2.** Spearman correlation between sCPDAI and different outcome measures

	Spearman (rho) correlation coefficient with CPDAIs	P value
CPDAI	0.9717	<0.0001
CDAI	0.8364	<0.0001
cDAPSA	0.8042	<0.0001
PASI	0.4033	<0.0001
Tender Joint Count	0.7937	<0.0001
Swollen Joint Count	0.5995	<0.0001
DLQI	0.2626	0.001
PsAQoL	0.5339	<0.0001
Patient Pain (VAS)	0.6100	<0.0001
Patient Global Assessment (VAS)	0.6067	<0.0001
Physicians Global Assessment (VAS)	0.7362	<0.0001

**Conclusion:** A simplified CPDAI, that includes only HAQ and BASDAI over usual daily clinical practice assessment, showed very good correlation with most outcome measurements used in PsA, and a very good discriminatory power for patients not in remission by MDA

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Background/Purpose:** Two groups established cut-off values for Disease Activity Index for Psoriatic Arthritis (DAPSA)<sup>1-2</sup>. The clinical DAPSA (cDAPSA) excludes CRP from its calculation and the authors recommend the use of the same cut-off values as DAPSA. To evaluate the concordance between the two cut-off values established for DAPSA and to validate cDAPSA and develop its cut-off values. **Methods:** Patients <sup>3</sup> 18 years of age with Psoriatic Arthritis (PsA) according to CASPAR criteria belonging to RAPSODIA cohort were included. We recorded clinical data. DAPSA and cDAPSA were calculated. Patients were classified according to both cut-off values. Those patients who showed disagreement in the classification between both cut-off values were re-evaluated by the opinion of four rheumatologists with experience in the evaluation of PsA patients. **Results:** 119 patients were included, 62 males (52.1%), median age 54 years old (IQR 42-63), median disease duration 8 years (IQR 3-15). 49.6% of patients had pure peripheral involvement and 48.7% had mixed involvement. Median value for DAPSA was 12 (IQR 7-19) and for cDAPSA was 13 (IQR 7-19). Correlation between both DAPSA versions was very good  $Rho=0.85$ . Table 1 shows the classification of patients according to our cut-off values and those proposed by Schoels et al. A high agreement between cut-off values of both versions was observed  $K: 0.85$  ( $p= 0.0001$ ). Only 7 patients were discordant, and according to expert's opinion, the performance of Schoels's DAPSA- cut-off values was better. A lower agreement was observed between DAPSA and clinical DAPSA  $K: 0.79$  ( $p = 0.0001$ ), with 10 discordant patients. For this reason, we established new cut-off values for cDAPSA: Remission < 2.5, low disease activity 2.5 to <sup>2</sup> 11.5 (AUC: 0.94, Se: 92.6% and Sp: 100%), moderate disease activity >11.5 to <sup>2</sup> 23 (AUC: 0.99, Se: 100% and Sp: 96.3%) and high disease activity > 23 (AUC: 0.99, Se: 100% and Sp: 95.5%). These cut-off values showed a better balance in sensitivity and specificity than those previously proposed. **Conclusion:** The concordance between the two cut-off values of DAPSA was good, although Schoels's DAPSA cut-off values showed better discrimination according to expert opinion. The cut-off values for cDAPSA should be reviewed for better sensitivity and specificity.

# Inter-Connections between Fatigue, Pain and Patient Global Assessment in Patients with Active Spondyloarthritis Followed in the Daily Clinic

**Ole Rintek Madsen**, Center for Rheumatology and Spine Diseases & The DANBIO Registry, Copenhagen University Hospital Rigshospitalet Gentofte and Glostrup, Denmark, Hellerup, Denmark

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Assessment of SpondyloArthritis international Society (ASAS) has selected fatigue, pain and patient global assessment (PaGl) as key patient-reported outcome measures in clinical trials and clinical practice. However, although associations between fatigue, pain and PaGl have been examined to some extent on the group level, studies focusing on the agreement between these patient-reported measures in individual patients are missing. A better understanding of how tight the measures are bounded in individuals may improve our ability to deal with them in the daily clinic. The purpose of the study was to examine associations on the group level and agreements on the individual patient level between fatigue, pain and PaGl as scored on visual analogue scales (VAS) in the daily clinic by patients with active spondyloarthritis (SpA).

**Methods:** Data on 118 SpA patients with active disease planned to initiate treatment with a biological agent were extracted from the Danish registry for biological treatment in rheumatology (DANBIO). Data included fatigue, pain, PaGl, BASDAI, BASFI and physician global assessment assessed on VAS-scales (0-100) and age and CRP. Associations between variables were examined using simple and multiple regression analysis (all mentioned variables including sex was incorporated as independent variables). Agreements between fatigue, pain and PaGl on the individual patient level were examined by Bland-Altman analyses yielding 95% lower and upper limits of agreement (LLoA and ULoA) between intra-individual assessments. The difference between the scores on the group level was expressed as the bias.

**Results:** Mean age was  $42.9 \pm 12.6$  years, mean BASDAI  $56.0 \pm 19.0$ , mean CRP 12.9 mg/l and mean PaGl  $65.7 \pm 22.6$ . Significant differences in BASDAI, fatigue, pain, PaGl between men ( $n = 76$ ) and women were not demonstrated. Fatigue, pain and PaGl were significantly but only moderately inter-correlated with high standard errors of estimation (SEE): Fatigue vs. PaGl ( $r = 0.57$ ,  $p < 0.0001$ ,  $SEE = 21.4$ ), fatigue vs. pain ( $r = 0.55$ ,  $p < 0.0001$ ,  $SEE = 21.6$ ), and pain vs. PaGl ( $r = 0.81$ ,  $p < 0.0001$ ,  $SEE = 15.1$ ). In multiple regression analyses, pain was independently predicted by PaGl ( $\beta = 0.52$ ,  $p < 0.0001$ ) and BASDAI ( $\beta = 0.36$ ,  $p < 0.0001$ ) [ $R = 0.82$ ,  $SEE = 14.1$ ,  $p < 0.0001$ ], PaGl by pain ( $\beta = 0.54$ ,  $p < 0.0001$ ) and BASDAI ( $\beta = 0.33$ ,  $p < 0.001$ ) [ $R = 0.81$ ,  $SEE = 12.7$ ,  $p < 0.0001$ ], and fatigue by BASDAI ( $\beta = 0.44$ ,  $p < 0.0001$ ) and PaGl ( $\beta = 0.23$ ,  $p < 0.05$ ) [ $R = 0.63$ ,  $SEE = 20.2$ ,  $p < 0.0001$ ]. Biases between the patient-reported VAS-scores were small but intra-individual differences were substantial: LLoA and ULoA [bias] for fatigue vs. PaGl were -45.5 and 43.5 [-0.97], for fatigue vs. pain -42.3 and 52.9 [5.3], and for pain vs. PaGl -35.7 and 23.3 [-6.3]. LLoA and ULoA remained constant over the whole range of the VAS-scales.

**Conclusion:** In patients with SpA, fatigue, pain and PaGl scores were poorly associated and only poorly explained by other potential explanatory variables. On the individual level, disagreements between the scores were substantial. The findings emphasize the complexity of understanding patient-reported outcome measures and their diverging interplay across individuals.

## Patient and Physician Global Assessment Are Poorly Inter-Connected and Poorly Explained By Other Clinical Markers of Disease Activity in Individual Patients with Psoriatic Arthritis

**Ole Rintek Madsen**, Center for Rheumatology and Spine Diseases & The DANBIO Registry, Copenhagen University Hospital Rigshospitalet Gentofte and Glostrup, Denmark, Hellerup, Denmark

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Assessment of disease activity is important in the evaluation and monitoring of patients with psoriatic arthritis (PsA) in clinical care and research. As there is no single ‘gold standard’ variable for assessment of disease activity several markers of disease activity are used, among these “global assessment” by the patient (PaGI) and by the physician (PhGI). The agreement and interplay between PaGI and PhGI are not well clarified in patients with PsA, however. The objective of the study was to examine associations on the group level and agreements on the individual patient level between PaGI and PhGI as scored on visual analogue scales (VAS) in the daily clinic by patients with active PsA and by their rheumatologists.

### Methods:

Traditional disease activity data on 76 PsA patients with active disease planned to initiate biological treatment were extracted from the Danish DANBIO registry for biological treatment in rheumatology. Data comprised PaGI, PhGI and pain (0 - 100 VAS), 28 swollen and tender joint count, CRP, HAQ-DI and DAS28-CRP(4v). Analyses were performed using parametric statistics. The association between PaGI and PhGI was examined by simple linear regression analysis. The predictability of PaGI and PhGI, respectively, by all other disease markers mentioned and by age and sex was examined using stepwise multiple regression analysis. Agreement between the VAS scores was expressed as the bias (mean difference between intra-individual scores) and the 95% lower and upper limits of agreement (LLOA;ULOA) according to the Bland-Altman method.

### Results:

Mean age was  $52.2 \pm 11.1$  years and mean DAS28-CRP  $4.7 \pm 1.1$ . 59.2% of the patients were women. Mean PaGI was  $63.7 \pm 23.2$  and mean PhGI  $39.9 \pm 19.8$  ( $p < 0.0001$ ). Thus the difference between PaGI and PhGI was substantial on the group level. Differences between PaGI and PhGI were even more pronounced on the individual level, however. The average difference was 23.8 (bias) but differences on the individual level ranged from -21.9 (LLOA) to +69.5 (ULOA). The corresponding results for PaGI vs. pain was 4.9 (bias), -17.1 (LLOA) and 22.0 (ULOA), and for pain vs. PhGI 18.9 (bias), -23.0 (LLOA) and 60.8 (ULOA). PaGI was significantly but weakly correlated with PhGI ( $R = 0.42$ ,  $p < 0.0001$ ) with a high standard error of estimation (SEE) = 21.2. PaGI was independently predicted by pain ( $\beta = 0.76$ ,  $p < 0.0001$ ) and HAQ-DI ( $\beta = 0.19$ ,  $p < 0.01$ ) and was not predicted by PhGI ( $p = 0.61$ ) ( $R = 0.78$ , SEE = 10.5,  $p < 0.0001$ ). PhGI was independently predicted by SJC ( $\beta = 0.43$ ,  $p < 0.0001$ ) followed by pain ( $\beta = 0.41$ ,  $p < 0.0001$ ) and CRP ( $\beta = 0.20$ ,  $p < 0.05$ ) ( $R = 0.70$ , SEE = 14.4,  $p < 0.0001$ ) with no significant contribution by PaGI ( $p = 0.49$ ).

### Conclusion:

In patients with active PsA initiating biological treatment, PaGI was in general scored considerably higher than PhGI. On the individual patient level, differences between PaGI and PhGI varied substantially. PaGI was best explained by pain, and PhGI by SJC. The findings reflect strongly diverging attitudes between PsA patients and their rheumatologists to severity of disease and to the relative importance of different outcome measures.

## **Disease Activity in Psoriatic Arthritis-ESR Index Maybe a Valid Tool to Evaluate Disease Activity in Patients with Psoriatic Arthritis When CRP Is Not Available**

**Andrea Lujan Coronel Ale**<sup>1</sup>, Emilce E Schneeberger<sup>1</sup>, Osvaldo Luis Cerda<sup>1</sup>, Cecilia Zaffarana<sup>1</sup>, Marina Natalia Fornaro<sup>2</sup>, Margarita Landi<sup>1</sup> and Gustavo Citera<sup>3</sup>, <sup>1</sup>Section of Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, Buenos Aires, Argentina, <sup>2</sup>Section of Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, buenos aires, Argentina, <sup>3</sup>Section of Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, Buenos Aires, Argentina

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** DAPSA is a composite index to assess disease activity in patients with Psoriatic Arthritis (PsA) which includes joint count 66/68, pain and patient's global assessment (PtGA) and CRP. Since ESR is a more accessible acute phase reactant (APR), our aim was to develop a version of DAPSA using ESR instead of CRP and to estimate its cut-off values.

**Methods:** Patients with PsA according to CASPAR criteria  $\geq 18$  years old were included. Sociodemographic data, presence of comorbidities and current treatment were recorded. Morning stiffness, pain, PtGA, physician's global assessment (PGA) and fatigue were evaluated by Visual Numerical Scale (VNS). Joint count (66/68), presence of dactylitis and enthesitis by MASES. Psoriasis was assessed by PASI and axial mobility by BASMI. APR (ESR in mm/h and CRP in mg/dl) were consigned. Self-questionnaires were performed to assess, quality of life (PsAQoL, ASQoL), functional capacity (HAQ-A and BASFI), and disease activity (BASDAI). Three different DAPSA versions were calculated: DAPSA-CRP, DAPSA-ESR. We also evaluated DAS28, CDAI, SDAI, and CPDAI, and minimal disease activity (MDA). Statistical analysis: Student's T test and ANOVA. Chi<sup>2</sup> test, Fisher exact test. Spearman test. Multiple linear regression model. ROC curves with AUC.

**Results:** A total of 119 patients were included, 62 were males (52.1%), with a median age of 54 years (IQR: 42-63) and a median disease duration of 8 years (IQR: 3-15). 58 (48.7%) of the patients presented mixed involvement, 57 (49.6%) peripheral joint involvement and 2 (1.7%) axial involvement. Median DAPSA-CRP was 12 (IQR: 7-19), median DAPSA-ESR was 14.2 (IQR: 8.2-21.1). DAPSA-ESR showed a very good correlation with: DAPSA-CRP (Rho: 0.97), SDAI (Rho: 0.9), CDAI (Rho: 0.92), DAS28 (Rho: 0.91) and CPDAI (Rho: 0.69); number of swollen joints (Rho: 0.73),

morning stiffness (Rho: 0.64), PtGA (Rho: 0.83) and PGA (Rho 0.63), pain (Rho: 0.77), nocturnal pain (Rho: 0.74), BASDAI (Rho: 0.70), HAQ-A (Rho: 0.65), BASFI (Rho: 0.63), PsAQoL (Rho: 0.56) and ASQoL (Rho: 0.49). In the multiple linear regression, all the components of DAPSA influenced significantly on DAPSA-ESR. DAPSA-ESR cut-off values were extrapolated from DAPSA-CRP's because they showed the best balance between sensitivity/specificity. The following cutoff values were obtained, sensitivity (Se) and specificity (Sp): remission  $\leq 6.75$  (AUC 0.88, Se 80%, Sp 100%), low disease activity from 6.76 to 15.5 (AUC 0.99, Se 100%, Sp 96%), moderate disease activity from 15.6 to 30.7 (AUC 0.99, Se 100%, Sp 96%) and high disease activity  $\geq 30.8$  (AUC 0.98, Se 100%, Sp 95.7%).

**Conclusion:** DAPSA-ESR is a valid alternative index to measure peripheral joint activity in patients with PsA, in those places where the CRP can mean a higher additional cost. We determined its cut-off values, which should be validated in other cohorts.

## Clinical History of Psoriatic Arthritis over Four Decades

**Dafna D Gladman**<sup>1</sup>, Justine Y. Ye<sup>2</sup> and Vinod Chandran<sup>3</sup>, <sup>1</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Medicine, Krembil Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease associated with psoriasis. Over the past several decades it was recognized that PsA is more common and more severe than previously thought. It has also been noted that patients who present earlier to a rheumatologist do better. However, whether patients have been treated earlier and more aggressively over the decades is not clear. The objective of this analysis was to describe the demographic, clinical features of inflammation and damage, as well as comorbidities and therapies provided over 4 decades in a single clinic.

**Methods:** A special clinic for psoriatic arthritis initiated in 1978. Patients are included if they have psoriasis and an inflammatory arthritis and other forms of arthritis have been excluded. Patients are followed at 6-12 month intervals according to a standard protocol which includes demographic, clinical, and laboratory evaluations and detailed drug treatment. Radiographic assessments are done at 2 year intervals and include peripheral joints according to the modified Steinbrocker, and axial disease according to NY criteria. Patients who entered the cohort in the past 4 decades were included. Descriptive statistics are used.

**Results:** Over the 40 year period 1428 patients were entered into the clinic and recorded in the database. 635 females 793 males, mean age at diagnosis of psoriasis 28.8 and at PsA 38 years. Information on the clinical, laboratory, radiographic and therapeutic features is provided in the table. As can be seen age at diagnosis remains in the mid-40s, and disease duration of psoriasis remains similar across the decades. However, PsA disease duration has decreased over the decades, suggesting that patients are referred earlier in their course. Patients presented with similar degree of disease

activity but less patients had evidence of damage at presentation in more recent decades. This is also reflected in the radiographic evidence of damage and the functional class  $\frac{3}{4}$ . More patients have comorbidities in more recent decades. While NSAIDs use remains stable, there has been an increased in use of DMARDs, particularly biologics. This is partly related to the availability of the drugs since 2000, but also to the more aggressive approach to the management of the disease.

<b>Table 1:</b> demographic, clinical and therapeutic information by decade at presentation				
Variable	1978-1987	1988-1997	1998-2007	2008=2017
	N=326	N=238	N=427	N=437
Age	44.1 (14.5)	41.3 (11.8)	44.3 (12.9)	46.1 (12.8)
Disease duration Psoriasis	15.8 (12.6)	13.0 (10.6)	15.3 (12.5)	16.8 (13.6)
Disease duration PsA	8.3 (9.1)	6.2 (7.1)	6.6 (7.7)	4.7 (7.2)
Married	64%	70%	63%	57%
Post-secondary education	49%	73%	71%	74%
No. of actively inflamed joints	10.4 (9.3)	11.0 (9.7)	11.1 (9.9)	8.9 (10.3)
(at presentation)				
PASI score (at presentation)	NA	7.2 (8.3)	6.1 (8.8)	5.0 (6.6)
Elevated CRP	NA	NA	9%	28%
Clinically damaged joints	40%	34%	37%	26%
No. damaged joints	3.1 (6.9)	2.7 (7.2)	3.3 (7.9)	1.5 (4.5)
Sacroiliitis	24%	16%	24%	19%
Functional class $\frac{3}{4}$	11%	13%	11%	7%
Radiographic damage	59%	47%	54%	39%
HAQ	NA	0.6 (0.6)	0.7 (0.6)	0.6 (0.6)
Diabetes	3%	3%	7%	8%
Hypertension	12%	11%	20%	22%
NSAIDs	70%	77%	71%	68%
DMARDs	30%	62%	65%	59%
Biologics	NA	NA	26%	45%

**Conclusion:** Over the past 4 decades similar patients have been admitted to the PsA clinic. However, patients seem to be referred earlier in the course of their disease, and this is reflected in less damage both clinically and radiologically. This may also reflect the increased use of DMARDs both conventional and biologic in this patient population. Education regarding the severity of PsA and the need for early diagnosis and treatment is working. However, further efforts are required to have patients with PsA diagnosed earlier and treated more aggressively to prevent untoward outcomes.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In 1973 Moll and Wright published the first paper on the classification criteria for Psoriatic Arthritis (PsA). In their pioneering work, these authors additionally described 5 subtypes of PsA: Oligoarticular (Oli), Polyarticular (Pol), Axial (Axi), DIP form (DIP) and Mutilans (Mut). The classification criteria have been replaced by the CASPAR criteria, and as a consequence there has been a loss of emphasis on the importance of the subtypes. Arguments for decreased significance have been based on claims that these subclasses may overlap, are not stable, and can change over time.

The hypothesis of this study is that with some exceptions, the Moll and Wright subtype classification criteria are stable over time and may have important therapeutic implications.

**Methods:** This was a retrospective cohort study. All patients with ICD-9 or ICD-10 PsA codes seen at a single center from January 1, 2013 through December 31, 2016 were identified. Patients who met CASPAR classification criteria and who had a Moll and Wright subtype identified and at least a 2 year follow up were studied and described. The distribution of continuous variables was assessed using the Shapiro-Wilk test. Categorical variables are summarized as frequency (percent).

**Results:** 104 patients were identified. Pertinent demographics are presented in table 1. Distribution and persistence of PsA subtype are presented in tables 2a and 2b. As there is evidence that the Oli and Pol subtypes may overlap and be influenced by therapy, a subanalysis combined these forms and the persistence was 87.5%.

**Conclusion:** In this retrospective analysis, a striking persistence of the subtype of PsA was noted over time. This was particularly noted with the non-Oli forms of this disease. With the advent of therapeutically targeted therapy that may differentially affect the unique subtypes of PsA, this concept needs to be resurrected and perhaps modified. We would argue that Moll and Wright were right.

Table 1. Demographics

Characteristic	N=104
Age at latest visit, years, mean $\pm$ SD	59.1 $\pm$ 13.1
Years between earliest/latest visit, median [IQR]	5.2 [3.6, 6.8]
Male	49 (47.1%)
Race (White)	92 (88.0%)
Psoriatic nail dystrophy	34 (32.7%)
Dactylitis	24 (23.1%)

Table 2a. Percentages of each subtype, by first/last visit

Subtype	First visit	Last visit
Oli	28 (26.9%)	18 (17.3%)
Pol	57 (54.8%)	60 (57.7%)
Oli or Pol	85 (81.7%)	78 (75.0%)
Axi	4 (3.9%)	3 (2.9%)
DIP	30 (28.9%)	27 (26.0%)
Mut	3 (2.9%)	4 (3.9%)

Table 2b. Percentages unchanged from first to last visit for each subtype

Subtype	Unchanged from first to last visit
Oli	17/28 (60.7%)
Pol	48/57 (84.2%)
Oli or Pol	76/85 (89.4%)

## Do Psoriatic Disease Patients Who Participate in Clinical Research Differ from Those Who Do Not?

**Vivian G. Szeto**<sup>1,2</sup>, Justine Y. Ye<sup>1</sup>, Vinod Chandran<sup>3</sup>, Dafna D Gladman<sup>4</sup> and Cheryl F. Rosen<sup>5</sup>, <sup>1</sup>Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>2</sup>University of Alberta, Edmonton, AB, Canada, <sup>3</sup>Medicine, Krembil Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>4</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>5</sup>Dermatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster III: Outcomes, Outcome Measures, and Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease that affects 30% of people with psoriasis. The current understanding of these diseases involves patients who agree to participate in clinical studies. Therefore, it is not clear whether or not information gained from these studies is generalizable to all patients with psoriatic disease. The aim of this study was to determine whether the clinical features and outcomes of psoriatic disease patients who participate in clinical research are the same as those who do not.

### Methods:

Two cohorts of research patients were studied: patients with psoriatic arthritis (PsA cohort) and patients with psoriasis without psoriatic arthritis (PsC cohort). The PsA and PsC cohorts are defined as patients enrolled in clinical research whose follow-up assessments are based on a standardized protocol. A third cohort was studied which included patients who are not enrolled in research (Clinic cohort).

The information on the patients' disease history (age of onset, extent of psoriasis), demographic and social history (gender, smoking, employment), medication (past and current), and comorbidities (cardiovascular, respiratory, autoimmune) was collected from their charts. The Clinic cohort information was compared to both the PsA and PsC cohorts using one-way ANOVAs, Pearson's Chi – square, and logistic regression analysis to test association of variables.

## Results:

A total of 200 patients were included in each cohort studied. Of the 200 patients collected in the Clinic Cohort, 46 patients had PsA while 154 patients did not. The Clinic Cohort data was subsequently split into a PsA Clinic cohort and Psoriasis Clinic cohort to be compared to their respective research cohorts.

The average age of PsA patients studied was 53.3 for the Clinic cohort and 51.0 for the PsA cohort; whereas the average age of PsC patients included in the study was 52.0 for the Clinic cohort and 55.5 for the PsC cohort. The psoriasis disease duration varied among the cohorts with the average being 13.1 y for the PsA Clinic Cohort, 21.6 y for PsA cohort, 17.0 y for the Psoriasis Clinic cohort and 22.9 y for the PsC cohort. In terms of the comorbidities, 32% of the PsA Clinic cohort and 29% of PsA Cohort have cardiac disease while 32% of Psoriasis Clinic Cohort and 33% of the PsC Cohort have been diagnosed with heart disease. Analysis of the therapies and outcomes of the three cohorts is underway.

Table 1. Comparison of the demographic, social history variables, comorbidities and clinical features between the Clinic cohort and the research cohorts (PsA cohort and PsC cohort). The demographic and social variables were statistically analyzed using the Chi-square distribution. The Pearson's Chi-square test was performed on the comorbidities variables while an One-way ANOVA was used to analyze the clinical features, * significant difference at $p < 0.05$ .			
		<b>PsA Cohort vs.</b>	<b>PsC Cohort vs.</b>
	<i>Variables</i>	<b>PsA Clinic Cohort</b> <i>p-value</i>	<b>Psoriasis Clinic Cohort</b> <i>p-value</i>
Demographic & Social History Variables	Gender	0.2456	0.7796
	Smoking	0.0216*	0.0084*
	Employment	0.8474	0.4318
Comorbidities	Cardiovascular	0.63	0.92
	Respiratory	0.13	0.45
	Autoimmune	0.08	<0.001*
Clinical Features	Average Age of Patients in the Study	0.33	0.022*
	Average Age of Psoriasis Diagnosis	<0.001*	0.22
	Psoriasis Disease Duration	<0.001*	<0.001*

## Conclusion:

These preliminary results show similarities between the research cohorts and the cohort of patients not involved in clinical research, suggesting generalization of the results of clinical research to all patients with psoriatic disease may be possible. Patients are still being actively recruited to the Clinic Cohorts.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To identify new candidate genes regulated by DNA methylation and involved in the pathogenesis of systemic lupus erythematosus (SLE), we integrated genome-wide DNA methylation analysis and mRNA expression profiling in CD4<sup>+</sup> splenic T cells derived from MRL/lpr lupus-prone mice (MRL) and C57BL/6J mice (B6) as a control.

**Methods:** Chromatin immunoprecipitation (ChIP)-PCR was used to investigate the transcription factors binding to CGCG methylation sites. Murine T lymphoma cell line, EL-4, was treated with DNA methyltransferase inhibitor, 5-Azacytidine (5-azaC) or histone deacetylase (HDAC) inhibitor, Trichostatin A (TSA) for *in vitro* study. To analyze the expression levels of mRNAs, quantitative real-time PCR (qPCR) was performed on a Step One Plus Real-Time PCR System (Applied Biosystems) using the TaqMan Gene Expression assays. To identify the function of *Ctse*, the *Ctse* gene was depleted by siRNA in EL4 cells stimulated with phorbol 12-myristate 13-acetate (PMA) and ionomycin, and measured IL-10 in cell culture supernatants by ELISA. To examine the expression levels of *Il-10* and *Ctse* in CD4<sup>+</sup> T cell subsets in peripheral blood mononuclear cell (PBMC) from 15 SLE patients and 6 healthy controls.

**Results:** We show that expression levels of *Ctse* transcripts are elevated in MRL T cells compared to that in B6 T cells and that the 583 bp region in the 1<sup>st</sup> intron in the *Ctse* gene is hypomethylated. Bisulfite sequencing show that the CGCG

motif in this region is hypomethylated in MRL cells. Kaiso, known to specifically recognize the methylated DNA motif (mCGCG) through the C2H2 zinc-finger domains, recruits the SMRT (Silencing Mediator of Retinoic acid and Thyroid hormone receptors) / N-CoR (Nuclear hormone receptor Co-Repressor) HDAC3 (Histone deacetylase 3) complex, leading to suppression of its target gene. To demonstrate that Kaiso and HDAC3 are components of the transcriptional complex regulating *Ctse* expression, we performed ChIP of the endogenous *Ctse* promoter in CD4+ T cells and observed strong enrichment of a *Ctse*-derived amplicon including the CGCG motif in both Kaiso and HDAC3 chromatin immunoprecipitates. Moreover, we found that the recruitment of Kaiso to the *Ctse* promoter was suppressed in MRL cells compared to B6 cells. Additionally, EL4 cells treated with 5-azaC or TSA showed the reduced recruitment of both Kaiso and HDAC3 to the motif. . Moreover, we observed that depletion of the *Ctse* gene by siRNA in EL4 cells results in reduction of IL-10 expression in cell culture supernatants by ELISA and that the expression level of *Il-10* transcripts are up-regulated in MRL T cells compared to B6. Lastly, we observed that In CD4+ T cell subsets in PBMC from SLE, the expression levels of *CTSE* and *IL-10* transcripts were elevated in CD4+ T cells from SLE patients compared to that in healthy controls.

**Conclusion:** Our present study provides evidence that DNA methylation-mediated recruitment of both Kaiso and HDAC3 to the *Ctse* promoter regulates expression of *Ctse* and that demethylation of this promoter and subsequent elevation of *Ctse* and *Il-10* expression may be the pathogenesis of SLE.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The proteasome inhibitor bortezomib has been used successfully to treat patients with SLE. The immunoproteasome is a distinct class of proteasome found predominantly in immune effector cells. Here we describe KZR-616, an analog of ONX 0914 (*Nature Medicine* 2009 15;781-788), that selectively targets the LMP7 and LMP2 subunits of the immunoproteasome and examine its potential as a novel therapeutic for the treatment of SLE and lupus nephritis (LN).

**Methods:** Cytokine release was measured in human PBMCs stimulated with endotoxin and in CD4+ T-cells stimulated with antibodies to CD3 and CD28. Human peripheral blood B-cells were stimulated with IL-21 and antibodies to CD40

and IgM to induce plasmablast differentiation. Cytokines and IgG were measured by mesoscale detection. Immunoproteasome inhibition was measured in human PBMCs and in mice following administration of KZR-616 by measuring proteasome active site occupancy. The therapeutic effect of KZR-616 treatment alone or in combination with mycophenylate mofetil (MMF) was evaluated in the NZB/W F1 model of SLE. Nephritis was monitored by proteinuria. Kidneys were harvested and stained with H&E and anti-IgG. Serum anti-dsDNA were measured by ELISA. Spleen and bone marrow cells were analyzed by flow cytometry. T-dependent antibody responses (TDAR) were measured in mice and monkeys following 1, 4, or 13 weekly administrations.

**Results:** At a concentration resulting in inhibition of LMP7 and LMP2 by 89% and 59%, respectively, KZR-616 induced a decrease in pro-inflammatory cytokine production in human PBMCs, including TNF- $\alpha$ , GM-CSF, IL-6, and IL12/IL-23 p40. In lymphocytes, KZR-616 blocked T-cell production of IFN- $\gamma$ , TNF- $\alpha$  and GM-CSF, and the differentiation of B-cells to plasmablasts. KZR-616 administration to mice resulted in selective inhibition of LMP7 and LMP2 similar to levels *in vitro*. KZR-616 treatment in diseased mice resulted in a complete resolution of proteinuria and significant reductions in autoantibody production and renal IgG deposition. The halt in disease progression was durable as proteinuria levels did not significantly increase 8 weeks after treatment discontinuation. Histologic analysis following 12 weeks of treatment revealed a complete prevention in glomerular nephritis and sclerosis. Administration of KZR-616 in combination with MMF resulted in significantly greater disease inhibition and prolonged survival compared to either treatment alone. Levels of activated T-cells, B-cells and plasma cells were effectively depleted in diseased animals following KZR-616 treatment. KZR-616 had no significant effect on TDAR in mice or monkeys and did not affect the number of circulating lymphocytes in monkeys.

**Conclusion:** KZR-616 is a novel and selective covalent inhibitor of the immunoproteasome that potently blocks inflammatory cytokine production *in vitro* and disease progression in mouse models of SLE. Durable disease remission in animals was achieved at well tolerated doses without affecting normal T-cell dependent immune responses. KZR-616 is currently being developed for the treatment of LN and Phase 1 safety and pharmacokinetics results are presented elsewhere at this meeting.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Spleen tyrosine kinase (SYK) is a driver of B cell receptor and Fc receptor signaling pathways, which have central roles in initiating and driving pathogenesis of systemic lupus erythematosus (SLE). NZB/W F1 mice develop spontaneous lupus-like disease and are a model system for testing potential targeted therapies in SLE. Treatment of NZB/W F1 mice with SYK inhibitors has been previously reported to ameliorate symptoms of progressive disease (Bahjat *et al*, *Arth & Rheum* 2008). Since key pathological manifestations in studies using NZB/W F1 mice correlate with human SLE, we examined the immune cell populations that are affected in this model in order to translate to human SLE phenotypes. We compared splenic populations of healthy and diseased NZB/W F1 mice treated with a highly selective SYK inhibitor, SYKi-A, to PBMCs of healthy donors and SLE patients experiencing flares.

**Methods:** Spleens were harvested from NZB/W F1 mice without disease symptoms (16 weeks old, control), with progressive disease (40 weeks old), or from SYKi-A treated mice (40 weeks old with treatment initiated at 28 weeks). Splenic cells were analyzed by flow cytometry to identify B and T cell subpopulations modulated by disease and SYKi-A treatment. PBMCs isolated from blood of non-SLE and SLE patients were analyzed by flow cytometry to assess disease-mediated changes in disease-relevant lymphocyte populations.

**Results:** Treatment of NZB/W F1 mice with SYKi-A increased overall survival, reduced proteinuria, prevented renal inflammation, and preserved glomerular structure in the kidney. Immune cell populations were examined in the NZB/W F1 mouse cohorts. Splenic B cells from both control mice and SYKi-A treated mice showed a more naïve B cell phenotype than untreated mice with progressive disease as measured by the ratio of transitional B cells (IgM<sup>+</sup>IgD<sup>+</sup>) to class switched cells (IgM<sup>+</sup>IgD<sup>-</sup>) ( $p < 0.0001$  and  $p = 0.007$ , respectively). In human PBMCs, non-SLE individuals showed a more naïve B cell phenotype as measured by the ratio of transitional B cells (CD24<sup>+</sup>CD38<sup>+</sup>) to class switched cells (CD27<sup>+</sup>IgD<sup>-</sup>IgM<sup>-</sup>) compared to SLE subjects ( $p = 0.034$ ). Additionally, splenic T cells from both control mice and SYKi-A treated mice showed a more naïve phenotype than untreated mice with progressive disease as measured by the ratio of naïve (CD44<sup>-</sup>CD62L<sup>+</sup>) to memory (CD44<sup>+</sup>CD62L<sup>+</sup>) T cells (CD4<sup>+</sup>:  $p = 0.015$  and  $p = 0.002$ , respectively; CD8<sup>+</sup>:  $p = 0.0003$  and  $p = 0.0003$ , respectively). In human PBMCs, non-SLE individuals showed a more naïve CD8<sup>+</sup> T cell phenotype as measured by the ratio of naïve (CD45RA<sup>+</sup>CCR7<sup>+</sup>CD27<sup>+</sup>) to memory (CD45RO<sup>+</sup>CCR7<sup>+</sup>) CD8<sup>+</sup> T cells compared to SLE subjects ( $p = 0.042$ ).

**Conclusion:** SYK inhibition following disease onset shifts the balance of lymphocyte subsets to a more naïve phenotype identified in pre-disease NZB/W F1 mice. T and B cell subsets identified in PBMCs from SLE subjects reflect a similar phenotype to those observed in NZB/W F1 diseased mice.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bruton's tyrosine kinase (BTK) plays an important role in B cell and FcR mediated myeloid cell activation. We recently described a selective BTK inhibitor, BI-BTK-1, that attenuates nephrotoxic serum nephritis, an induced model of renal disease mediated by passively transferred pathogenic antibodies. In the current study, we examined the efficacy of BI-BTK-1 in SLE and lupus nephritis, using the classical NZB  $\times$  NZW F1 and MRL/lpr mouse models of spontaneous lupus.

**Methods:** NZB/W F1 female mice were treated with BI-BTK-1 via medicated chow at doses of 0.3, 1, 3, and 10 mg/kg (from 22-51 weeks of age). MRL/lpr female mice were treated with only the 10 mg/kg dose (weeks 9-27). Mice were monitored for proteinuria and serum autoantibodies. Extensive cytometric characterization of B cell subsets in the spleen and bone marrow, and qPCR of kidney RNA, were performed to understand the effects of BTK inhibition on kidney inflammation and the mechanisms of protection.

**Results:** Treatment with BI-BTK-1 significantly protected NZB/WF1 and MRL/lpr mice from the development of proteinuria ( $p < 0.05$  in NZB/WF1 at all doses and  $p < 0.0001$  in MRL/lpr mice at 10mg/kg and above) as well as renal dysfunction (serum BUN) at the time of sacrifice ( $p < 0.05$  for all doses of BI-BTK-1 vs control chow fed mice in NZB/WF1, and  $p < 0.0004$  in MRL/lpr mice). These beneficial effects of BI-BTK-1 were also reflected in the marked histological protection observed in both NZB/WF1 and MRL/lpr strains in glomerular as well as interstitial pathology scores. Mechanistically, BTK inhibition significantly reduced total B cell numbers and all B cell subsets (immature, transitional, follicular, marginal zone, and class switched) in the spleen ( $p < 0.05$  for BI-BTK-1 (3 mg/kg and 10 mg/kg) vs control chow fed mice in NZB/WF1 mice). Anti-dsDNA antibody titers were significantly decreased in the NZB/WF1 mice ( $p < 0.05$  for BI-BTK-1 (at doses of  $> 1$  mg/kg) vs control treated mice), but surprisingly not significantly affected in the MRL/lpr strain. qPCR of kidney RNA showed that BI-BTK-1 treated mice displayed a significant decrease in several nephritis associated serum biomarkers, including NGAL and MCP-1. Studies to examine the effects of BI-BTK-1 treatment on survival are currently in progress.

**Conclusion:** Treatment with BI-BTK-1 was dramatically effective in two different spontaneous lupus strains, supporting the potential use of BTK inhibition as a novel approach for the treatment of lupus nephritis.

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Spleen tyrosine kinase (SYK) mediates immunoreceptor signaling in hematopoietic cells important in the initiation and progression of systemic lupus erythematosus (SLE), including those from the B cell receptor (BCR) and Fc receptors (FcR) in B cells, monocytes, and dendritic cells<sup>1</sup>. SLE is a heterogeneous autoimmune disease characterized by immune system hyperactivation leading to the production of autoantibodies and immune attack on multiple organs including skin, kidney, and others. SYK inhibition is expected to reduce adaptive as well as innate immune cell activation, and immune complex signaling, which are all key drivers in SLE pathology. This work characterizes the disease modifying activity and mechanism of action of SYK inhibition in two spontaneous *in vivo* murine models of lupus: the MRL/lpr and NZB/W F1 models and estimates the required target engagement needed for efficacy in SLE. *In vitro* studies focused on GS-9876, a novel, highly selective, once-daily SYK inhibitor that Gilead Sciences is developing for the chronic treatment of rheumatoid arthritis and SLE. *In vivo* studies were performed with SYKi-A, a structurally similar analog that exhibits better mouse pharmacokinetics. *In vitro* properties of SYKi-A are similar to those of GS-9876.

### **Methods:**

SYK inhibition was characterized in biochemical and cellular assays demonstrating potency and selectivity. To determine the disease-modifying activity of SYK inhibition, SYKi-A was tested in the MRL/lpr and NZB/W F1 models of lupus. Efficacy was determined by measuring anti-dsDNA titers, proteinuria, renal histopathology, and survival. Splenic cell populations were analyzed by flow cytometry to measure changes in lymphocyte subsets and activation status following SYK inhibition. An *in vitro* murine whole blood pSYK assay and PK was used to estimate target engagement and correlate with efficacy.

### **Results:**

SYK inhibitors potently inhibited BCR-induced B cell signaling and activation, BCR and CD40 co-stimulation-induced B cell proliferation, and immune-complex stimulated cytokine production in human macrophages. In the murine models of SLE, SYKi-A decreased anti-dsDNA antibody titers, prevented the progression of proteinuria, reduced B cell activation, altered B cell subsets, and reduced T cell activation. In the NZB/W F1 model, there was a significant reduction of renal SYK immunolabeling, decreased renal inflammation, and improved glomerular morphology concurrent with decreased proteinuria, and increased survival. Average SYK target coverage of >50% was required for significant changes in disease activity.

### **Conclusion:**

Building on previously reported studies<sup>2,3</sup>, these results further support the role of SYK in SLE pathogenesis, provide important information about target coverage needed for efficacy in the murine model, and identify the therapeutic potential for SYK inhibition by GS-9876 in human SLE.

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of autoantibodies, leading to multiple organ dysfunction. SH3BP2 (Src homology domain 3 binding protein 2) is an adaptor protein, which is dominantly expressed in immune cells and regulates intracellular signaling pathways such as Syk and PLC $\gamma$ . We have previously reported that SH3BP2 deficiency suppresses autoantibody production and subsequent arthritis induction in a murine collagen-induced arthritis model (Mukai T, et al. Arthritis Rheumatol 2015). To further investigate the role of SH3BP2 in autoimmune inflammatory diseases, we here examine the effect of SH3BP2 gain-of-function in a murine SLE model. We hypothesized that the SH3BP2 gain-of-function exacerbates autoantibody production and organ damage in lupus-prone mice, contrasting the phenotype observed in the SH3BP2 deficient arthritis model.

**Methods:** SH3BP2 gain-of-function mutant (P416R knock-in; SH3BP2<sup>KI/+</sup>) mice and lupus-prone (B6.MRL-Fas<sup>lpr/j</sup>) mice were crossed to yield the double mutant (SH3BP2<sup>KI/+</sup>/Fas<sup>lpr/lpr</sup>) mice. Body weight and proteinuria were assessed until 12 months of age. At the end of the observation, mice were euthanized, and serum and organs were collected. Anti-double-stranded DNA (anti-dsDNA) antibody levels in sera were measured by ELISA. Organ involvement was assessed histologically. B-cell and T-cell subsets were analyzed by flow cytometry. To determine the role of SH3BP2 in B cells to mediate proliferation following cross-linking of the B-cell receptor (BCR), resting splenic B cells were isolated from wild-type and SH3BP2<sup>KI/+</sup> mice and stimulated with either anti-IgM antibody, anti-IgM antibody plus anti-CD40 antibody or LPS.

**Results:** Unexpectedly, we found that SH3BP2 gain-of-function mutation suppressed the development of renal disease. According to the amelioration of disease, SH3BP2<sup>KI/+</sup>/Fas<sup>lpr/lpr</sup> mice had lower titers of anti-dsDNA antibodies than

Fas<sup>lpr/lpr</sup> mice. The B220<sup>+</sup>CD4<sup>-</sup>CD8<sup>-</sup> (double-negative) T cell population characteristic of Fas<sup>lpr/lpr</sup> mice in the lymph nodes was decreased in the SH3BP2<sup>KI/+</sup>/Fas<sup>lpr/lpr</sup> mice. In vitro experiments, B-cell proliferation in response to BCR cross-linking with anti-IgM antibody was comparable between wild-type and SH3BP2<sup>KI/+</sup> cells, suggesting that the mechanism of suppression of disease was not B cell mediated.

**Conclusion:** Contrary to our initial hypothesis, SH3BP2 gain-of-function mutation ameliorated clinical and immunological phenotypes of the lupus-prone mice. Further analyses are required to reveal the immunoregulatory role of SH3BP2 in the autoimmune disease.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neutrophils are potential instigators of autoimmunity and effectors of organ damage in lupus. However, there is presently no consensus as to whether inhibition of neutrophil effector functions can be pursued as a therapeutic strategy. For example, NADPH oxidase inhibition prevents neutrophil extracellular trap release (NETosis), but exacerbates lupus (likely by interfering with the function of suppressive neutrophil subsets). Similarly, peptidylarginine deiminase inhibitors prevent NETosis and protect against lupus-mediated vascular damage, but raise the levels of key autoantibodies such as anti-double-stranded DNA. Here, we characterize neutrophil elastase, a key effector of neutrophil-mediated organ damage. Neutrophil elastase is required for NETosis and has also been reported to circulate at high levels in lupus patients; however, this key serine protease has been surprisingly little studied in lupus.

**Methods:** We tested the effects of specific inhibition of the serine protease neutrophil elastase in a mouse model of lupus, namely NZWxBXSB F<sub>1</sub> mice (which develop immune-complex nephritis, and also display a strong prothrombotic diathesis). NZWxBXSB F<sub>1</sub> mice were treated with daily oral administration of the potent, selective elastase inhibitor GW311616A. Endpoints assessed NETosis efficiency, circulating autoantibody levels, glomerulonephritis, cardiac fibrosis, and venous thrombosis.

**Results:** *In vitro*, the neutrophil elastase inhibitor GW311616A mitigated NETosis in response to stimulation with either phorbol 12-myristate 13-acetate (PMA) or lupus serum. Neutrophils isolated from GW311616A-treated mice also demonstrated reduced NETosis when challenged with stimuli such as PMA and lipopolysaccharide. In NZWxBXSB F<sub>1</sub> mice, a six-week course of daily oral GW311616A or vehicle control (n=24 per group) protected against several aspects of the lupus phenotype. Specifically, treated mice demonstrated reduced levels of autoantibodies against cathelicidin-related antimicrobial peptide (CRAMP, the mouse orthologue of LL-37) and beta-2 glycoprotein I ( $\beta_2$ GPI, the key autoantigen in antiphospholipid syndrome); in contrast, the levels of anti-double-stranded DNA antibodies were not affected. GW311616A-treated mice demonstrated improved proteinuria-free survival, reduced deposition of complement C3 in kidneys, and reduced expansion of CD4<sup>+</sup> CD44<sup>+</sup> CD62L<sup>-</sup> effector T cells in spleens. Cardiac fibrosis (a measure of the prothrombotic phenotype of NZWxBXSB F<sub>1</sub> mice) was reduced by GW311616A. Finally, a brief course of GW311616A in aged NZWxBXSB F<sub>1</sub> mice was effective in mitigating macroscopic venous thrombosis in response to inferior vena cava flow restriction.

**Conclusion:** These data reveal neutrophil elastase as a novel therapeutic target in lupus. Administration of the specific neutrophil elastase inhibitor GW311616A reduced autoantibody levels, and protected against nephritis as well as both arterial and venous thrombosis. This work once again emphasizes that the method of neutrophil inhibition must be carefully considered in lupus.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bruton's tyrosine kinase (BTK) is a clinically-proven target in several hematological indications. Due to its role in mediating the signaling of both B cell receptors (BCR) and Fc receptors (FcR), BTK is also a potential

target for the treatment of autoimmune diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), where B cell and innate immune cell activation are key drivers of pathology. We are developing evobrutinib, a novel, highly selective irreversible BTK inhibitor that may be suitable for the treatment of chronic diseases. This work aimed to characterize the activity of evobrutinib in various in vitro cellular assays and in disease models of RA and SLE. In vivo efficacy and target occupancy data were used to build a pharmacokinetic and pharmacodynamic (PKPD) model describing the correlation between BTK inhibition and disease severity reduction.

**Methods:** The potency and specificity of evobrutinib was characterized using biochemical and cellular assays. The SLE disease-modifying potential of evobrutinib was assessed in a NZB/W F1 mouse model induced using replication-deficient interferon (IFN)-alpha-expressing adenovirus. Efficacy was determined by measuring proteinuria and histological kidney damage. The RA disease-modifying potential of evobrutinib was tested in a mouse collagen-induced arthritis (CIA) model, with efficacy evaluated by paw scores. A biochemical assay was developed to determine BTK occupancy rates in blood cells and splenocytes. These assays were used to build a translational PKPD model relating target occupancy to efficacy.

**Results:** Evobrutinib potently inhibited BCR- and FcR-mediated signaling and subsequent activation and function of B cells and certain myeloid cells. In mouse models of RA and SLE, evobrutinib displayed robust efficacy as demonstrated by a marked reduction of disease severity. In the NZB/W F1 IFN-accelerated SLE model, efficacy correlated with B cell inhibition, reduction of autoantibodies, and decreased circulating memory B and T cells. In addition to SLE, RA-like symptoms were inhibited in a collagen-induced arthritis model. In order to translate preclinical efficacious doses to humans, we determined the degree of target occupancy necessary to achieve disease reduction. Pharmacodynamic modeling showed that BTK occupancy of 60 and 80% was linked to 80% and near complete disease inhibition, in both the RA and SLE models, respectively.

**Conclusion:** These results demonstrate the potential of evobrutinib to treat autoimmune disease and may inform rational dose decisions as evobrutinib is advanced for development in rheumatologic diseases.

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Diffuse alveolar hemorrhage (DAH) is an unusual complication of lupus with over 50% mortality. In both humans and mice, DAH is associated with ANCA-negative pulmonary capillaritis and hemosiderin-laden lung macrophages (M $\phi$ ). C57BL/6 (B6) mice develop lupus with severe DAH after intraperitoneal injection of pristane. We have shown that the pathogenesis of pristane-induced DAH requires M $\phi$  and the uptake of dead cells opsonized by immunoglobulin and complement via complement receptor 3 (CD11b/CD18). Serpins, such as the rabbit myxomavirus-derived Serp1 protein, regulate coagulation and inflammation by binding serine proteases. Serp1 inhibits both thrombolytic (e.g. urokinase plasminogen activator) and thrombotic (Factor Xa) proteases and downregulates inflammation in part via its effects on M $\phi$ . We asked if Serp-1 protects mice from pristane-induced DAH.

## Methods:

Pristane-treated B6 mice (21 per group) were given recombinant Serp1 or PBS i.p. from day 1 until d-14. In some experiments, Serp1 treatment was delayed until d-4 or Serp1 was given on days 1-3 only. The severity of DAH was evaluated by gross pathology and histology. Peritoneal cells and alveolar M $\phi$  collected by bronchoalveolar lavage (BAL) were analyzed by flow cytometry.

**Results:** DAH developed in 60% of pristane-treated mice with a 14-d mortality of 15%. In mice treated with pristane+Serp1, DAH developed in 10% and mortality was 0% ( $P<0.001$ ). The interferon signature and numbers of peritoneal Ly6C<sup>hi</sup> inflammatory M $\phi$  were reduced by Serp1 treatment ( $P<0.0001$ ). We recently identified a novel M2-like M $\phi$  expressing CD138 that promotes the resolution of inflammation. Serp1 significantly increased the number of pro-resolution (CD138<sup>+</sup>) M $\phi$  in both the peritoneum and the lung ( $P<0.01$ ). When Serp1 treatment was delayed by 3-d, the mice were not protected from DAH, even though hemorrhage does not become apparent until 7-d after pristane treatment. Interestingly, Serp1 treatment from days 1-3 after pristane reduced the incidence of DAH to 20%. High Ly6C<sup>hi</sup> inflammatory M $\phi$  and low CD138<sup>+</sup> M $\phi$  numbers correlated with lung hemorrhage. In addition, Serp1 treatment up-regulated the activity of liver X receptor- $\alpha$  (LXR $\alpha$ ), a transcription factor that promotes M2 M $\phi$  polarization, in both peritoneal and lung (alveolar) M $\phi$ . Mice that are resistant to DAH consistently exhibited higher levels of LXR $\alpha$  activity than susceptible mice.

## Conclusion:

The myxomavirus-derived protein Serp1 (effective in Phase IIa clinical trials for treating acute coronary syndromes) protects mice from DAH and is a potential candidate for treating this severe complication of lupus. Its mechanism of action appears to involve activation of LXR $\alpha$ .

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Application of B cell depletion therapy (BCDT) for treatment of SLE has shown promise in some patients, but some patients exhibit disease relapses. Anti-type I interferon (IFN) receptor therapy has recently been shown to be effective in SLE. We previously showed that type I IFN plays an important role in promoting autoimmune disease in the BXD2 mouse model of lupus. Here, we address the question of whether type I IFN blockade can prevent the relapse and return of autoreactive B cells after anti-CD20 depletion therapy using the BXD2 mouse model of lupus.

**Methods:** Groups of BXD2 mice (4 weeks old) were either untreated or treated with anti-CD20 and followed by treatment with control antibody, neutralizing antibody against IFN $\beta$ , or neutralizing antibody against IFN $\alpha$ R beginning at the time of B cell repopulation. FACS analysis was carried out using validated antibodies. Confocal imaging was carried out to determine areas of repopulation in the spleen. Sera antibody levels of anti-DNA, anti-La, and rheumatoid factor were determined by ELISA analysis.

**Results:** Compared to normal B6 mice, there was rapid repopulation of transitional and mature B cells in the spleens of BXD2 mice at weeks 2 and 3, after BCDT. Interestingly, treatment with anti-IFN $\alpha$ R normalized the kinetics of repopulation in BXD2 mice and decreased the rapid development from transitional B cells to more mature B cells, suggesting a “window of opportunity” to normalize B cell repopulation after BCDT. To determine superiority of anti-IFN $\alpha$ R during this “window”, groups of mice were treated with either anti-IFN $\beta$  or anti-IFN $\alpha$ R, during from 2 to 4 week (MOD, ip) and short and longterm effects of interferon inhibition were determined at week 4 and 12, after BCDT. Early repopulation, determined by confocal imaging at week 4 after BCDT showed a significant inhibition of class-switched (IgM, IgD<sup>+</sup>) transitional B cells in the MZ zone and outer follicles of anti-IFN $\beta$ -treated mice compared to IFN $\alpha$ R-treated mice. Decreased development of early-stage transitional (CD93<sup>+</sup>) La<sub>13-23</sub> tetramer<sup>+</sup> autoreactive B cells accompanied by decreased Ki67<sup>+</sup> proliferation was observed in both anti-IFN $\beta$ -treated and anti-IFN $\alpha$ R-treated mice with no significant difference between treatment groups. At week 12 after BCDT, there was a significant decrease in the percent of Fas<sup>+</sup> GL7 GC-B cells after short-term treatment with anti-IFN $\alpha$ R and anti-IFN $\beta$ . Sera levels of anti-DNA, La and rheumatoid factor were reduced in anti-IFN $\beta$  and anti-IFN $\alpha$ R blockade treated mice compared to anti-CD20 therapy alone.

**Conclusion:** Type I interferons exert a prominent effect on the development of autoreactive B cells during a critical “window of opportunity” where transitional B cells are repopulating the periphery following B cell depletion therapy. Importantly, transient blockade of type I IFN during B cell repopulation was sufficient to prevent development of autoreactive B cells and antibodies long-term. These results suggest that blockade of type I IFN may be an effective therapeutic option to enhance and prolong the effects of B cell depletion therapy in lupus. Also, specific inhibition of IFN $\beta$  may be sufficient as blockade of all type I IFN signaling in B cells using anti-IFN $\alpha$ R did not offer additional benefit.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Signaling of most cytokine receptors occurs through the JAK-STAT pathway. This is true of cytokines linked to the etiology of systemic lupus erythematosus (SLE) and Sjogren's syndrome (SS), such as type I interferon (IFN-I), IFN $\gamma$ , and IL-6. Thus, the JAK-STAT pathway is a potential target for the treatment of these diseases. IFN-I is of particular interest because a majority of SLE and SS patients have an IFN signature suggesting that levels of IFN are high in these patients. SLE is ameliorated in mice lacking the receptor for IFN-I (IFNAR) indicating that this cytokine is essential to the development of disease. In human SLE, blocking IFN-I binding to IFNAR with an anti-IFNAR mAb was efficacious in a phase 2 clinical trial in SLE patients that exhibited a high IFN signature. We show here that prophylactic and therapeutic treatment with a JAK1-selective inhibitor prevents and reverses disease in lupus-prone mice.

**Methods:** NZB/W-F<sub>1</sub> mice were prophylactically or therapeutically administered a JAK-1 inhibitor daily by gavage. Prophylactic treatment of NZB/W-F<sub>1</sub> mice began at 26 weeks of age, while therapeutic treatment was initiated after mice developed high proteinuria. Proteinuria was monitored weekly by urinalysis, and at study termination blood and spleen cells were analyzed by flow cytometry. Additionally, histological and gene transcription analyses of kidney, spleen, and salivary glands were performed.

**Results:** Prophylactic and therapeutic administration significantly impacted the number of splenic naïve B cells, germinal center B cells and plasmablasts. It also impacted splenic CD4 T cells, but not CD8 T cells. Daily administration of inhibitor prophylactically blocked development of proteinuria and extended survival in NZB/W-F<sub>1</sub> mice. Most significantly, JAK1 inhibition reversed established, severe proteinuria and extended survival. In agreement, the kidneys of therapeutically treated mice exhibited reduced inflammation compared to control mice, and the kidney and blood exhibited a lower IFN-I signature compared to controls. JAK1 inhibition also prevented a loss of saliva production and salivary gland inflammation.

**Conclusion:** JAK1 inhibition is efficacious in preventing the onset of nephritis and sialadenitis, and can reverse already ongoing nephritis in NZB/W-F<sub>1</sub> mice. Resolution of ongoing nephritis results in low or normal urine protein levels. Thus, JAK1 inhibition may be an efficacious therapeutic strategy in the treatment of SLE and SS.

## Serine/Arginine-Rich Splicing Factor 1 (SRSF1) Is a Novel Regulator of T Cell Function and Its Selective Deficiency in T Lymphocytes Leads to Autoimmunity and Lupus-like Nephritis

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

T cells from patients with systemic lupus erythematosus (SLE) exhibit defects in signaling including a reduced expression of the CD3 zeta signaling chain, and defects in cytokine production such as decreased IL-2 production. We used a discovery approach namely mass spectrometry analysis of proteins “pulled-down” by a CD3 zeta mRNA-defined oligonucleotide, and identified the splicing regulator serine arginine-rich splicing factor 1 (SRSF1). We showed that SRSF1 promotes normal expression of CD3 zeta chain, and upregulates IL-2 production in human T cells. We found that SRSF1 expression levels are decreased in SLE T cells, and associates with worse disease. Force expression of SRSF1 into SLE T cells rescued IL-2 production. These results suggest that SRSF1 deficiency is important in the SLE T cell dysfunction. However, it is unknown how SRSF1 deficiency contributes to immune-mediated disease. To this end, we have generated mice with a T cell-restricted deletion of SRSF1, and our goal is to evaluate the mechanistic role of SRSF1 in T cell dysfunction and the development of immune-mediated disease *in vivo*.

### Methods:

T cell *Srsf1* conditional knockout (*Srsf1*-cko) mice were generated by crossing *Srsf1*-flox mice with d.*Lck.Cre* (*distal promoter*) transgenic mice to delete SRSF1 in mature T cells. Mice were euthanized at 10-20 weeks of age, or aged to >1 year. Central (thymus) and peripheral (spleen, lymph nodes) lymphoid organs were analyzed for immune cell phenotype and function by flow cytometry. Serum and urine were collected to assess autoantibody levels and proteinuria respectively. Kidney tissues were fixed, sectioned and stained with hematoxylin and eosin to evaluate histopathology. To assess regulatory T cells (Treg) function *in vivo*, adoptive transfer of Tregs followed by induction of colitis in two models - dextran sodium sulfate (DSS)-induced colitis in B6 mice, and the naïve CD4 transfer-induced colitis in RAG-ko mice, were utilized.

### Results:

*Srsf1*-cko mice develop peripheral T cell lymphopenia at younger ages, whereas aged mice exhibit lymphocytosis and lymphoproliferation. CD4 T cells exhibit an activated phenotype and produce increased amounts of IFN- $\gamma$  and IL-17 but lower amounts of IL-2 upon *ex vivo* stimulation. The *Srsf1*-cko mice develop autoantibodies, and exhibit increased proteinuria compared to control mice. Kidney histopathology shows evidence of glomerular damage with glomerular hyperproliferation, glomerular capillary hyperplasia, and interstitial infiltration of mononuclear cells. Tregs from *Srsf1*-cko mice are dysfunctional and are unable to suppress colitis *in vivo*. These results indicate that a lack of SRSF1 selectively in T cells, leads to impaired T cell function with reduced IL-2 production, increased inflammatory cytokine production, and aberrant Treg function, resulting in autoantibody development and tissue damage.

**Conclusion:** SRSF1 is a novel regulator of T cell function, and its deficiency leads to autoimmunity and lupus-like nephritis. Therefore, deficiency of SRSF1 in T cells may represent a molecular defect that contributes to the pathogenesis of systemic autoimmune disease.

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Infiltrating macrophages are one of the hallmarks of renal inflammation and kidney damage in lupus nephritis. Increasing evidence suggests the crucial role of cell-specific metabolic reprogramming to regulate and modify inflammatory and immune responses. Inflammatory M1-like [TLR4/LPS] macrophages show enhanced glycolysis – which directly drives their inflammatory phenotype – and impaired oxidative phosphorylation (OXPHOS). In contrast, OXPHOS is prominent in tolerogenic M2-like [IL-4] macrophages. Using a systems approach we recently integrated immunologic and molecular profiles of murine LN kidney macrophages with human SLE renal biopsies, identifying shared pathways that link phagocytosis with disposal of excess cellular debris, activation of TLRs and metabolic pathways. Surprisingly, we observed overexpression of TLR8, but not other endosomal TLRs, in these resident renal macrophages. TLR8 overexpression was also detected in lupus nephritis kidneys. TLR8 is expressed primarily by myeloid cells; its role in systemic autoimmunity, and on macrophage immunometabolism, remains elusive as TLR8 function differs from mouse to man. Mice transgenic for multiple copies of human TLR8 develop spontaneous autoimmunity but do not reflect normal physiology. Herein, we aimed to evaluate the functional consequence of one or two copies of human (huTLR8) on macrophage immunometabolism and renal inflammation in murine SLE.

**Methods:** NZW/B6.Yaa and Sle1.Yaa mice expressing huTLR8 as a BAC transgene (huTLR8tg) were generated and followed clinically. HuTLR8 DNA copy number and mRNA expression was confirmed by qDigital and qRT-PCR respectively. 24-week-old huTLR8tg NZW/B6.Yaa mice were administered TL-506 (TLR8-agonist) subcutaneously for 4 weeks and spleen and kidney were harvested for analysis at 8 weeks. Using the Seahorse XF Analyzer, mitochondrial respiration and glycolytic capacity of LPS(TLR4)-, TLR7- and TLR8-stimulated bone marrow-derived macrophages (BMDMs) was assessed.

**Results:** TL-506-stimulated BMDMs from huTLR8tg mice show enhanced TNF production and glycolysis and impaired mitochondrial respiration compared to wild-type littermates, which was comparable to the profiles observed for LPS- and TLR7-stimulated wt BMDMs. A single copy of huTLR8 in NZW/B6.Yaa mice did not exacerbate/accelerate disease however subcutaneous TLR8-agonist administration appeared to enhance germinal center formation and plasma cell generation in male huTLR8tg mice. To generate lupus mice with 2 copies of huTLR8 we bred the huTLR8tg into the Sle1.Yaa strain. Preliminary findings in these mice show accelerated renal disease and mortality in the males.

**Conclusion:** One copy of huTLR8 does not seem to exacerbate lupus in NZW/B6.Yaa mice but disease is enhanced by a TLR8 agonist or by the introduction of two copies of the transgene. Interestingly, TLR8-stimulated huTLR8tg BMDMs have a similar immunometabolic profile to LPS-[M1-like] and TLR7-induced macrophages. Further elucidating how TLR8 influences macrophage immunometabolism and phenotype will improve our understanding in how reprogramming macrophage metabolic state might be a potential new avenue of therapeutic targeting in systemic autoimmunity.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have previously reported that IL-23 receptor deficiency in MRL.*lpr* mice ameliorates lupus by altering the balance of pro- and anti-inflammatory cytokines in secondary lymphoid organs. As IL-23 also may also impact thymic selection, we evaluated the effect of IL-23 on thymic selection in lupus prone mice.

**Methods:** We generated MRL.*lpr* mice that lack the IL-23p19 subunit by backcrossing with a B6.IL23p19 deficient mice for 11 generations. Thymic tissue was harvested from 6-8 week old mice and used for flow cytometry.

**Results:** IL23p19-/-MRL.*lpr* mice had decreased proteinuria when compared to wild type mice. IL-23p19 deficiency resulted in reduced expression of both IL-7Ra and ROR $\gamma$ t in thymocytes. This was associated with reduction of CD3 and TCR $\beta$  expression on thymocytes by 35% and 50% respectively. Overall IL-23p19-/-MRL.*lpr* mice had as much as 50% reduction in cells that underwent positive selection. On the contrary IL23p19 deficiency did not affect T cells lineage commitment, nor changed CCR7 expression, a major determinant of cortex-medulla intra-thymic migration. The resulting, post positive and negative selection, T lymphocytes in IL23p19 deficient mice displayed an immature phenotype as measured by CD44 and CD62L expression in both thymus and spleens.

**Conclusion:** IL-23 deficiency in lupus prone mice strongly influences thymic selection resulting in T lymphocytes exiting the thymus with an immature phenotype. We propose that IL-23 not only promotes the development of lupus like autoimmunity through T cell polarization and cytokine production in the peripheral lymphoid organs but also by influencing T cell selection in the thymus.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic lupus erythematosus (SLE) is a potentially fatal autoimmune disease that involves all organs of the body. Without a known cure, a detailed understanding of pathogenesis is vital for development of new treatments. The polymorphic Rab4a locus has been associated with genetic susceptibility and protection from lung disease in patients with SLE (Arthritis Rheum 58: 532-540). Rab4a is overexpressed in T cells of patients and mice with SLE (J Immunol 182: 2063-73). To determine the role of Rab4a in pathogenesis, its impact on intra-alveolar hemorrhage (IAH), a fatal complication of pulmonary involvement, was investigated in Rab4A-KO<sup>CD4Cre</sup> (KO) mice lacking expression of Rab4a in T cells relative to wild-type (WT) controls. Additionally, the role of Rab4a in T-cell lineage specification and underlying metabolic pathways was investigated in mice and human T-cell lines with modulated Rab4a activity.

### **Methods:**

Mice matched for age and gender were injected intraperitoneally with 0.5 ml per 20 g of body weight of pristane and evaluated for pulmonary capillaritis. 14 days after injection, spleen and lung tissues were harvested and examined for lineage specification within the adaptive and innate arms of the immune system by flow cytometry. CD4<sup>+</sup>CD25<sup>+</sup> T cells were analyzed for regulatory T cell (Treg) function. Metabolic studies were completed using the Seahorse Metabolic Flux Analyzer.

### **Results:**

Pulmonary vasculitis scores were increased in Rab4A-KO<sup>CD4Cre</sup> mice relative to WT controls, which was underlain by 5.7-fold (p=0.0003) expansion of Gr-1<sup>+</sup> neutrophils in the lung of KO mice. Among infiltrating T lymphocytes, CD4<sup>+</sup> cells were increased by 42% (p=0.0018) and CD8<sup>+</sup> cells were depleted by 45% (p=0.0037). T<sub>H</sub>1 cells, CD4<sup>+</sup>CD25<sup>+</sup> and CD8<sup>+</sup>CD25<sup>+</sup> Tregs were expanded by 9.4-fold (p=0.002), 4.6 fold (p=0.0009) and 2.6-fold (p=0.017), respectively. mTORC1 activities were decreased in all CD4<sup>+</sup> T cells and CD4<sup>+</sup>CD25<sup>+</sup> Tregs of the KO mice by 45% (p=0.01) and 29% (p=0.027), respectively. CD4<sup>+</sup>CD25<sup>+</sup> FoxP3<sup>+</sup>/Akt<sup>-</sup> Tregs were depleted by 45% (p=0.02). The suppressor activity of CD4<sup>+</sup>CD25<sup>+</sup> Tregs was diminished 3.8-fold (±0.05, p=0.04) in KO mice. Glycolysis in CD4<sup>+</sup> T<sub>H</sub>1 cells and Tregs of

Rab4A-KO<sup>CD4<sup>Cre</sup></sup> mice was diminished by 27% (p=0.02) and 35% (p=0.029). Along this line, glycolysis was also reduced by 22% in Jurkat T cells overexpressing dominant negative Rab4a<sup>S27N</sup> (p=0.004). In contrast, overexpression of wild-type Rab4a enhanced glycolysis in Jurkat cells by 72% (p=5.41E-06). 1 mg/kg of rapamycin, which blocked nephritis in lupus-prone mice (Ann Rheum Dis 73: 1888-97), failed to prevent pristane-induced IAH.

#### Conclusion:

Rab4a controls metabolic fitness and mTORC1-dependent expansion and function of Tregs, and thus it protects against IAH in a mouse model of SLE.

## Lack of CD137-CD137 Ligand Signalling Aggravates Glomerulonephritis and Reduces the Survival of Lupus-Prone B6.MRLlpr Mice

**Anselm Mak**<sup>1</sup>, Bhushan Dharmadhikari<sup>2</sup> and Herbert Schwarz<sup>2</sup>, <sup>1</sup>Medicine, National University of Singapore, Singapore, Singapore, <sup>2</sup>Physiology, National University of Singapore, Singapore, Singapore

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Costimulatory molecules, which are expressed on leukocytes that facilitate their cross-talks via stimulatory and inhibitory signalling, play a potentially important role in the inflammatory processes involved in SLE. Disappointment in clinical trials which tested the efficacy and safety of costimulatory molecule manipulation in SLE treatment prompts more in-depth understanding of the mechanistic impact of costimulatory molecules on the pathophysiology of SLE. We aimed to investigate the effect of the lack of CD137-CD137 ligand (CD137L) signalling in the phenotype and immunological profiles in a murine SLE model, based on our understanding that cognate interaction between CD137 expressed on activated T cells and CD137L constitutively present on antigen presenting cells potentially drives pro-inflammatory response.

**Methods:** To generate C57BL/6-MRL.Fas<sup>lpr/-</sup> (B6.lpr) lupus-prone mice devoid of CD137L, B6.lpr mice were crossed with B6.CD137L<sup>-/-</sup> mice to generate the B6.lpr<sup>-/-</sup>CD137L<sup>-/-</sup> double knockout (DKO) mice. The DKO and B6.lpr mice were phenotypically and immunologically compared to each other, and to B6 WT mice which served as a reference. Phenotypes including survival, lupus dermatitis by clinical scoring and glomerulonephritis by semi-quantitative urinalyses and light microscopy were compared between the DKO and B6.lpr mice. Frequencies, activation status and Th polarization of splenic T lymphocytes as studied by flow cytometry, and serum cytokine levels as measured by the multiplex platform were compared between the 3 groups of mice.

**Results:** After a 22-month observation, DKO mice (n=226) had significantly shorter survival than B6.lpr mice (n=137) (median ± SE: 44±4.5 vs. 74±3.3 weeks [p<0.001]). Significantly more DKO mice had severe cutaneous lesions, microscopic haematuria and proteinuria than their B6.lpr counterparts. Renal histopathological studies revealed that endocapillary proliferation (2.96±1.08 vs. 0.16±0.1, p=0.013) and glomerular proliferative lesions (33.3% vs. 7.9%,

p=0.005) were significantly more frequent in the DKO compared to the B6.lpr mice. Furthermore, DKO mice had a significantly higher mean activity index of lupus nephritis (LN) than their B6.lpr counterparts (0.48±0.1 vs. 0.08±0, p=0.002). While significantly higher frequencies of double negative T cells (CD3<sup>+</sup>CD4<sup>-</sup>CD8<sup>-</sup>) and activated T cells (CD3<sup>+</sup>CD69<sup>+</sup>), particularly the CD3<sup>+</sup>CD8<sup>+</sup>CD69<sup>+</sup> population, were found in the B6.lpr mice as compared to the DKO and B6 WT mice, the frequencies of Th17 cells (CD3<sup>+</sup>CD4<sup>+</sup>RORγt<sup>+</sup>[±Tbet<sup>+</sup>]) were significantly higher in the DKO than the B6.lpr and B6 WT mice. No difference in the frequencies of regulatory T cells (CD3<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup>FoxP3<sup>+</sup>) was found amongst the mice. Cytokine analyses demonstrated significantly lower mean serum IL-10 levels in the DKO mice compared to the B6.lpr and B6 WT counterparts (p=0.017).

**Conclusion:** Abrogation of bidirectional CD137-CD137L signalling which interrupts CD137-CD137L costimulation resulted in more severe dermatitis and LN and reduced survival in the B6.lpr mouse model. More severe SLE phenotype in B6.lpr mice without CD137-CD137L signalling is potentially mediated by Th17 polarization and lower serum anti-inflammatory IL-10 levels.

## **Interleukin-33 Ameliorates Murine Lupus Via Induction of Regulatory T Cells and M2 Macrophage Polarisation**

**Mo Yin Mok**<sup>1</sup>, Ka Sin Law<sup>2</sup>, Wing Yin Kong<sup>1</sup>, Ge Liu<sup>1</sup>, Wallace Lau<sup>2</sup>, C Luo<sup>2</sup>, FP Huang<sup>3</sup>, GC Chan<sup>4</sup> and Kwok Wah Chan<sup>3</sup>, <sup>1</sup>Department of Biomedical Sciences, City University of Hong Kong, Hong Kong, Hong Kong, <sup>2</sup>Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong, <sup>3</sup>Department of Pathology, University of Hong Kong, Hong Kong, Hong Kong, <sup>4</sup>Department of Paediatrics, University of Hong Kong, Hong Kong, Hong Kong

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The levels of IL-33, a Th2 promoting cytokine, and the soluble form of its receptor ST2 were reported to be elevated in serum of patients with active systemic lupus erythematosus (SLE), suggesting a role of the IL-33/ST2 axis in the pathogenesis of SLE. This study aims to examine the effect of IL-33 in disease severity of murine lupus.

### **Methods:**

IL-33 was injected intraperitoneally 3 times per week to pre-diseased MRL/lpr mice aged 12 weeks for 6 weeks. Control group was given 1% BSA injection. Urine protein was monitored weekly by albutix and protein assay. Immunophenotyping of splenocytes was examined by flow cytometry. Splenic CD11b<sup>+</sup> monocytic cells were isolated by microbeads for mRNA examination.

### **Results:**

IL-33-treated mice (n=9) developed significantly less proteinuria compared to BSA-treated group (n=9). Kidney histology of the IL-33-treated group showed remarkably less mesangial deposit, diffuse proliferative glomerular changes and crescents, and had significantly lower renal composite score compared to controls (median 2.0 vs 9.9,  $p<0.001$ ). Kidneys of these mice expressed lower mRNA levels of TNF- $\alpha$  (32.1+14.7 vs 77.0+27.8,  $p<0.001$ ), IL-6 (median 0.6 vs 4.7,  $p=0.003$ ), IL-1 $\beta$  (31.1+10.1 vs 77.8+24.6,  $p<0.001$ ) and iNOS ( $p=0.006$ ). Immunophenotyping of splenocytes showed significantly increased CD4+CD25+ regulatory T (Treg) cells (4.0+1.2% vs 2.2+0.2%,  $p<0.001$ ) that expressed remarkably higher Foxp3 (76.0+5.0% vs 59.3+12.6%,  $p=0.002$ ). Splenic extracts showed predominant Gata3 (0.37+0.20 vs 0.12+0.09,  $p=0.01$ ) and Foxp3 (0.42+0.16 vs 0.17+0.11,  $p=0.002$ ) mRNA in IL-33-treated mice. These Treg cells expressed high cell surface ST2 (8.9+2.7% vs 4.5+2.0%,  $p=0.008$ ). There was significant expansion of splenic CD11b+ population in IL-33-treated mice (17.8+10.5 vs 8.8+3.0,  $p=0.01$ ) that expressed significantly higher CD206 (5.2+0.9% vs 2.9+0.9%,  $p=0.002$ ). Isolated splenic CD11b+ cells expressed significantly higher mRNA of Arg1, FIZZ1 and Ym-1 and IL-10 (all  $p=0.01$ ) with reduced expression of iNOS ( $p=0.02$ ). Kidney extracts of IL-33 treated mice also had elevated mRNA levels of M2 markers including Arg1 (median 199.8 vs 36.1,  $p=0.004$ ) and FIZZ1 (median 25.0 vs 2.7,  $p<0.001$ ) and reduced MCP-1 (12.7+6.5 vs 35.1+12.0,  $p<0.001$ ). There was also significantly higher levels of mRNA of Foxp3 (median 43.0 vs 20.8,  $p=0.006$ ) and Gata 3 (1.7+0.5 vs 0.9+0.5,  $p=0.008$ ) but lower Rorc (2.6+1.0 vs 3.8+0.8,  $p=0.008$ ) and Tbx21 (12.6+6.0 vs 29.6+13.7,  $p=0.003$ ) in the kidneys.

### Conclusion:

Exogenous IL-33 led to significantly less proteinuria and renal inflammation. These mice had significantly higher splenic Treg cells with prominent Foxp3 expression. Isolated CD11b+ cells from spleen and kidney extracts demonstrated mRNA levels of M2 macrophage polarisation.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Ro60 protein is a prominent autoantigen in systemic lupus erythematosus (SLE) and Sjogren's syndrome (SS). Anti-Ro antibodies are strongly associated with UV-mediated skin rashes in lupus, especially in subacute cutaneous lupus erythematosus (SCLE), the most photosensitive form of lupus. Surprisingly, Ro60 knockout (KO) mice spontaneously develop a lupus-like syndrome associated with autoantibodies and glomerulonephritis. An association with type I interferon (IFN) has not previously been investigated. While it is known that Ro binds to small non-coding Y RNAs, it was recently reported that Ro also binds to Alu RNAs derived from short interspersed retroelements (SINEs). Loss of Ro60 in human cell lines resulted in the accumulation of Alu RNAs and the

dysregulation of IFN-stimulated genes (ISGs). Since SINE transcripts have been shown to be increased following DNA damage, we examined the relationship between Ro60, SINEs, and the inflammatory response after UV irradiation in mice.

**Methods:** C57BL/6 and Ro60 KO mice (n = 3) were irradiated with UVB 500 mJ/cm<sup>2</sup> once. Skin biopsies were performed at baseline and 1 day following UVB exposure. RNA was extracted from the skin, and RNA expression of retroelements [B1 and B2 SINEs (rodent equivalents of human Alu)], inflammatory markers including type I IFNs, ISGs and Y RNAs were quantified by RT-qPCR.

**Results:** At baseline, Ro60 KO mice exhibited increased expression of ISGs compared to C57BL/6 mice with a 7-fold increase found in Isg15, 4-fold increase in Isg20, and 18-fold increase in Mx1. Y1 and Y3 RNAs were virtually undetectable in Ro60 KO mice even after UVB irradiation. This supports the current theory that Ro60 is involved in RNA processing and quality control including the stabilization of RNA polymerase III transcripts as seen with La protein. While B1 and B2 SINEs were not elevated in Ro60 KO mice compared to C57BL/6 mice at baseline, SINEs were increased in both Ro60 KO and C57BL/6 mice after UVB. These results are consistent with the possibility that retroelements play a role in the inflammatory response following UVB irradiation, although a causal relationship remains to be determined.

**Conclusion:** Increases in ISGs observed at baseline in Ro60 KO mice compared to control C57BL/6 mice may contribute to autoimmunity and lupus-like syndrome reported previously. Furthermore, the accumulation of SINE transcripts after UV irradiation may overwhelm the binding capacity of Ro60, leading to stimulation of innate immune response. A clearer understanding of the relationship between autoimmunity in Ro60 KO mice and changes in the relative amounts of SINEs versus Ro60 protein could provide a new paradigm of how environmental stimuli trigger lupus.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies implicate dendritic cells (DCs) in the pathogenesis of systemic lupus erythematosus (SLE), yet the mechanisms underlying this involvement are not yet clear. Genome-wide association studies and experimental mouse models provide evidence of toll-like receptor (TLR) involvement in SLE. Immune complexes containing self nucleic acids activate endosomal TLRs 7/9, which require signaling adaptor MyD88 for subsequent up-regulation of proinflammatory gene expression, in part through the action of transcription factor IRF5.

Functional polymorphisms in TLRs 7/9, MyD88 and IRF5 are linked to SLE susceptibility, and mice with an underlying defect in Fas (MRL/lpr) on a TLR7-, MyD88- or IRF5-deficient background are protected from disease. We have shown that DC-specific loss of caspase 8, an enzyme in the Fas pathway classically linked to programmed cell death, induces a SLE-like disease that originates from heightened DC activation. The increased activation of caspase 8-deficient DCs is in part controlled by a MyD88-dependent mechanism, as DC-specific loss of MyD88 reduces disease. We therefore examined the interaction between DC-specific caspase 8, endosomal TLR signaling and IRF5 in disease development.

**Methods:** Mice lacking caspase 8 specifically in DCs were generated ( $Cre^{CD11c}Casp8^{flox/flox}$ ) and crossed with  $TLR7^{-/-}TLR9^{-/-}$  ( $TLR7^{-/-}TLR9^{-/-}Cre^{CD11c}Casp8^{flox/flox}$ ),  $TRIF^{mut/mut}MyD88^{flox/flox}$  ( $TRIF^{mut/mut}MyD88^{flox/flox}Cre^{CD11c}Casp8^{flox/flox}$ ) and  $IRF5^{flox/flox}$  ( $IRF5^{flox/flox}Cre^{CD11c}Casp8^{flox/flox}$ ) mice. Flow cytometric analysis was used to characterize cell populations. ELISA and Luminex bead-based assays detected serum antibody and cytokine levels. Immunohistochemical and immunofluorescent analyses were used to evaluate spleen and kidney pathology.

**Results:**  $Cre^{CD11c}Casp8^{flox/flox}$  develop a SLE-like disease characterized by splenomegaly, lymphadenopathy, autoantibodies, elevated serum cytokines, glomerulonephritis, immune complex deposition in the kidney and proteinuria. Caspase 8-deficient DCs are highly activated, leading to lymphocyte hyperactivation in a paracrine manner. Further, we observe a disruption of the splenic architecture in  $Cre^{CD11c}Casp8^{flox/flox}$  mice, with a severe reduction in the marginal zone and metallophilic macrophage populations. Moreover, kidney pathology correlates with increased influx of myeloid populations. Strikingly,  $TLR7^{-/-}TLR9^{-/-}Cre^{CD11c}Casp8^{flox/flox}$ ,  $TRIF^{mut/mut}MyD88^{flox/flox}Cre^{CD11c}Casp8^{flox/flox}$  and  $IRF5^{flox/flox}Cre^{CD11c}Casp8^{flox/flox}$  mice are virtually protected from all inflammatory phenotypes.

**Conclusion:** Our previous studies showed that DC-specific loss of MyD88 reduced, but not ablated, SLE-like disease pathogenesis associated with DC-specific deletion of caspase 8. We now show that deletion of TLR7/9, TRIF/MyD88 or IRF5 in caspase 8-deficient DCs prevents SLE-like disease in  $Cre^{CD11c}Casp8^{flox/flox}$  mice. These data substantiate a novel DC-specific mechanism whereby caspase 8 interacts with and regulates the action of endosomal TLR signaling and IRF5 to control DC activation and subsequent autoimmune disease development.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

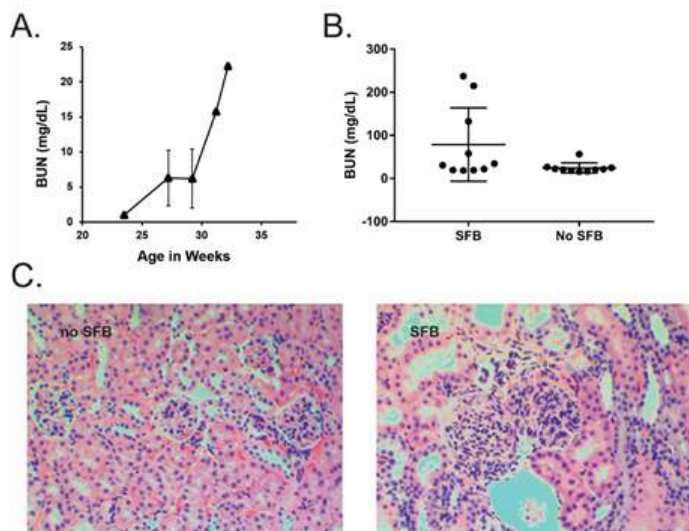

**Title:** Segmented Filamentous Bacteria Colonization Exacerbate Lupus Nephritis in NZM2410 Mice and Causes an Expansion of Intestinal Group 3 Innate Lymphoid Cells

**Background/Purpose:** Innate Lymphoid Cells (ILC3s) represent a newly described innate immune cell with parallel function and phenotype to Th17 cells. ILC3s primarily populate mucosal tissue such as the small intestine and tonsils. ILC3s secrete distinct cytokines such as IL-17, IL-22, and TNF that are thought to play an important role in autoimmunity. Moreover, gut-residing commensals such as Segmented Filamentous Bacteria (SFB) can significantly augment ILC3s and Th17 cells. Furthermore, SFB enhances Th17 cell presence and ILC3 secretion of IL-22 in the intestinal lamina propria of exposed mice. Because these cytokines have been shown to be important in Systemic Lupus Erythematosus (SLE), we examined the effects of SFB on NZM2410 disease phenotype.

**Methods:** We examined the presence of ILC3s in the gut of NZM2410 mice with and without intestinal colonization with SFB. Mice were colonized with fecal homogenates containing SFB or no SFB using oral gavage. Serum was collected from mice once per month and Blood Urea Nitrogen was calculated. Upon meeting removal criteria, the kidneys of these mice were processed for immunohistochemistry. Small intestine was digested and then processed for ILC3s and Th17 cells.

**Results:** Because of their rarity and lack of source material, SLE mucosal ILC3s are inherently challenging to study in humans. We examined, ILC3 in the mucosa of NZM2410 and utilized SFB to observe any effect that the microbiota may have on mucosal ILC3s in the setting of this mouse model of lupus. We observed that mucosal Th17 and ILC3s were expanded in the small intestine and that kidney damage was exacerbated in SFB exposed mice as compared to unexposed mice.

**Conclusion:** These findings support the hypothesis that the microbiota are able to negatively impact lupus clinical course, potentially through activation of ILC3s and Th17 cells and these mechanisms are the subject of ongoing investigations. Moreover, we are examining ILC3-like cells in the peripheral blood of NZM2410 mice and in patients with SLE.

**Figure 1.** The NZM2410 lupus model and exposure to the commensal organism segmented filamentous bacteria (SFB). (A) BUN elevates over the natural lifespan NZM2410 mice. (B) BUN of SFB-exposed mice is elevated as compared to unexposed mice. (C) H&E staining of kidney tissue reveals evidence of mild glomerulonephritis in the unexposed NZM2410 mouse (left) as compared to marked glomerular hypercellularity and interstitial tubulitis in an SFB exposed mouse (right). The same magnification was used in both images.

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a multisystem chronic inflammatory disease characterized by circulating antinuclear autoantibodies and dysfunction of B cells, T cells, and dendritic cells. Polymorphism of the HRES-1/RAB4 genomic locus has been associated with disease manifestations, such as nephritis, in SLE patients (Arthritis Rheum. 58:532-520), and its Rab4A gene product is overexpressed in T cells of SLE patients and in mice prior to disease onset and, remarkably, inhibition of Rab geranylgeranyl transferase prevented antinuclear antibody (ANA) production and nephritis in lupus-prone mice (Ann. Rheum. Dis. 73:1887-1897). To determine the role of Rab4a in lupus pathogenesis, its impact on ANA production and nephritis was investigated in Rab4A-KO<sup>CD4Cre</sup> (Rab4A<sup>KO</sup>) mice lacking expression of Rab4A in T cells relative to wild-type (WT) and floxed Rab4A<sup>Q72L</sup> knock-in (Rab4A<sup>Q72L</sup>) controls.

**Methods:** Four WT, three Rab4A<sup>Q72L</sup> and four Rab4A<sup>KO</sup> female mice matched for age were injected intraperitoneally with 0.5 ml per 20 g of body weight of pristane. 14 days after injection, ANA levels were measured in sera by ELISA and immunoglobulin G (IgG) and M (IgM) and complement 3 (C3) deposition as well as infiltration by CD11b<sup>+</sup> macrophages, CD11c<sup>+</sup> dendritic cells, CD138<sup>+</sup> plasma cells, and CD3<sup>+</sup> T cells were assessed by immunofluorescence using confocal microscopy. Statistical analyses were performed by t-test; two-tailed p<0.05 was considered significant.

**Results:** ANA levels were increased in Rab4A<sup>KO</sup> relative to Rab4A<sup>Q72L</sup> controls. Deposition of IgG and IgM was increased 2-fold, and C3 deposition was increased 4-fold in glomeruli of Rab4A<sup>KO</sup> relative to WT and Rab4A<sup>Q72L</sup> controls. Further, T cells (12-fold), plasma cells (2-fold), and macrophages (7-fold), but not dendritic cells, were accumulated in glomeruli and tubular interstitium of Rab4A<sup>KO</sup> mice relative to WT and Rab4A<sup>Q72L</sup> controls.

**Conclusion:** Based on these results, Rab4A protects against ANA production and nephritis in the pristane-induced model of SLE.

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Neutrophils are the most abundant circulating leukocytes and the earliest inflammatory cells to be recruited to the site of photodamage after ultraviolet B (UVB) exposure. However, little is known about the role of the neutrophils in UVB-induced skin inflammation. Neutrophil NETosis is a newly characterized neutrophil cell death that releases neutrophil extracellular traps (NETs), which have been shown to be important in autoimmune inflammation, including lupus. Recent studies from our and other groups indicate the importance of actin cytoskeleton in neutrophil NETosis. Since actin-myosin cytoskeleton is known to be regulated by Rho kinase (ROCK), our recent studies have demonstrated the role of ROCK in PMA-induced neutrophil NETosis in vitro and NETotic neutrophils in UVB-induced skin inflammation in vivo. However it not clear how ROCK and its regulated cytoskeleton is involved in neutrophil NETosis.

### **Methods:**

To explore the effects of ROCK on neutrophil NETosis, we investigated the effects of ROCK inhibition on neutrophil NETosis in vitro in human neutrophils and UVB-induced neutrophil NETosis in the inflamed skin in mice.

### **Results:**

Following PMA stimulation, cytosolic PKCa is gradually translocated to the nuclear membrane. In particular, activated PKCa (phosphor-PKCa at ser657) accumulated at the site of nuclear membrane rupture in the NETotic neutrophils in our confocal analysis. Inhibition of actin, myosin, or MLCK (myosin light chain kinase) of actomyosin networks with cytochalasin D, Blebbistatin, or ML7 can attenuate nuclear translocation of PKCa and neutrophil NETosis. Similarly, the dual ROCK1/2 inhibitor HA1077 attenuated nuclear translocation of PKCa and PMA-induced NETosis. In addition, application of HA1077 intraperitoneally (i.p.) can also reduce UVB-exposure-induced NETosis among the infiltrated neutrophils in the inflamed skin.

### **Conclusion:**

Our preliminary studies therefore elucidated a novel mechanism that ROCK-mediated nuclear translocation of PKCa regulates neutrophil NET formation, and confirmed the protective role of ROCK inhibition in neutrophil NETosis in vitro and in vivo. Our findings may provide insights into a novel therapeutic target for treatment of UVB-induced skin inflammation.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Animal Models Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The most serious manifestation of fetal exposure to maternal anti-Ro antibodies is the development of heart block. This work addresses the hypothesis that fetal disease occurs in the absence of checkpoint inhibition of inflammation initiated by anti-Ro. This study describes a novel murine model in which deficient PD1 signaling exacerbates mild conduction defects induced by anti-Ro and results in histologic evidence of fibrosis and multinucleated giant cells paralleling observations in human autopsies. Accordingly, these data suggest that checkpoint inhibition may play a role in the pathogenesis of CHB.

**Methods:** To inhibit PD1 signaling, pregnant wild type CD1 mice treated with anti-CD274 (anti-PD1) Abs, or pregnant PD1 knock out (KO) mice were selected. For both models, mice were injected at E12 and E15 with IgG fractions from either a healthy donor or a mother with anti-52Ro, 60Ro and La (anti-Ro) and 3 children with CHB. As controls, other pregnant CD1 mice received CHB IgG or anti-CD274 Abs alone.

**Results:** To assure access of autoantibodies to the fetal circulation, blood from embryos (N = 14) dissected from the uterus of a CHB IgG treated pregnant CD1 mouse contained antibody reactivities to all Ro/La components, which were not detected in embryos of mothers injected with control IgG. Exposure of mice to CHB IgG resulted in a prolonged PR interval ( $5.28 \pm 0.3$ ,  $p=0.004$  vs control), a result not obtained with anti-PDL1 alone ( $3.39 \pm 0.3$ ,  $p=0.69$  vs control). Exposure of CD1 mice to CHB IgG + anti-PDL1 resulted in an even more pronounced conduction defect as reflected by lengthening of the PR interval (PR/ $\sqrt{RR}$ , 81 total pups) versus Control IgG ( $11.3 \pm 0.2$  and  $3.4 \pm 0.1$ , respectively,  $p<0.0001$ ). Histology of anti-Ro injected mice showed diffuse positive staining using anti-CD274 Abs (for detection of PDL1 ligand) but not isotype control. Injection of the PD1KO mouse with CHB IgG resulted in the most advanced conduction abnormality as reflected by the PR interval (36 total pups) versus Control IgG ( $16.24 \pm 1.56$  and  $4.55 \pm 0.11$ , respectively,  $p<0.0001$ ). In one of the pups in this group, the block resembled retrograde V-A conduction and the heart removed for histologic evaluation. Consistent with autopsies of human fetuses dying with CHB, there was focal injury with myocyte calcifications, multinucleated giant cells and fibrosis, findings never demonstrated in any previous CHB murine model.

**Conclusion:** Diminished PD1 signaling exacerbates mild conduction defects induced by anti-Ro/La, which supports the hypothesis that checkpoint inhibitors may play a role in the pathogenesis of CHB.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although hydroxychloroquine (HCQ) is a mainstay of treatment for patients with Systemic Lupus Erythematosus (SLE), ocular toxicity can result from accumulated exposure. The introduction of highly sensitive tools has engendered even more concern. As the longevity of patients with SLE improves, additional data will help physicians accurately balance the risk of ocular toxicity and the risk of disease flare, especially in older patients who have stable/quiescent disease. Accordingly, this study was initiated to examine the safety of HCQ withdrawal in older SLE patients.

**Methods:** Data were obtained by retrospective chart review at three lupus centers. Twenty-seven patients met the following inclusion criteria:  $\geq 4$  ACR criteria, disease duration  $\geq 5$  years, HCQ use of 200-400mg per day  $\geq 5$  years, and discontinuation of hydroxychloroquine at age  $\geq 55$  years. The comparator group comprised 39 age, gender and racial/ethnic matched patients who remained on HCQ. The primary outcome was a clinically meaningful flare within one year of HCQ withdrawal, defined as moderate or severe, using a revised version of the SELENA-SLEDAI Flare composite that separates mild from moderate flares, evaluates each organ system separately, and incorporates increases in corticosteroid dose and/or addition of immunosuppressive agents. Mild flares were considered secondary outcomes.

**Results:** Demographics are provided in Table 1. There was a trend toward longer disease duration in the HCQ withdrawal group but no difference in prevalence of prior lupus nephritis between the groups. The reasons for HCQ withdrawal were maculopathy (N=13), presumed/biopsy proven cardiomyopathy (N=2), patient request (N=4), and miscellaneous other reasons (N=8). There was no difference in the primary or secondary outcomes between the groups (Table 1). Two patients had a moderate flare after discontinuing HCQ, of whom one had arthritis treated with methotrexate and one had thrombocytopenia ( $>30K$ ) and proteinuria of 2 grams/d (baseline 700 mg). Three patients had severe flares while continuing HCQ, of whom two were hospitalized, one for seizures and one for pericarditis; the third had worsening nephritis (urinary protein  $>4$  g/d, requiring treatment). Two patients had moderate flares while remaining on HCQ, one of whom had a rash and arthritis treated with tofacitinib and one a rash treated with prednisone.

**Conclusion:** In this retrospective study of older patients with SLE on long-term HCQ, withdrawal did not increase the risk of moderate or severe flares. These data provide reassurance regarding the safety of withdrawing HCQ in stable older SLE patients.

	HCQ Withdrawal (N=27)	HCQ Continuation (N=39)	P value
Age	59.9	60.6	0.52
Gender (% Female)	92.6%	97.4%	0.56
Race/Ethnicity			0.78
White	33.3%	35.9%	
Black	29.6%	25.6%	
Hispanic	18.5%	20.5%	
Asian	18.5%	17.9%	
Duration of SLE (years) (N=61)	26.7	21.1	0.088
Duration of HCQ Use (years) (N=52)	19.3	17.6	
Prior Renal Disease (N,%)	12 (44.4%)	13 (33.3%)	0.44
Moderate/Severe Flares (N,%)	2 (7.4%)	5 (12.8)	0.69
Moderate Flare	2 (7.4%)	2 (5.1%)

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Compliance and persistence with hydroxychloroquine in patients with systemic lupus erythematosus

**Background/Purpose:** Lifelong treatment with hydroxychloroquine (HCQ) is now recommended for all patients with systemic lupus erythematosus (SLE) irrespective of disease severity or other therapy mainly due to its efficacy in preventing flare, achieving remission and reducing the risk of damage accrual. However, there is lack of data regarding adherence of HCQ treatment in SLE patients. We investigated compliance and persistence with HCQ treatment in SLE patients in clinical practice and analyzed the risk factors for poor adherence.

**Methods:** We conducted a retrospective longitudinal study including 235 SLE patients undergoing HCQ treatment between 2002 and 2016 at a university rheumatology center in South Korea. Compliance was assessed using 1-year medication possession ratio (MPR) and non-compliance was defined as 1-year MPR <0.8. Persistence was determined as time from HCQ treatment initiation to discontinuation without interruption for longer than 56 days. The reasons for HCQ discontinuation were categorized as poor health literacy, adverse events, pregnancy or unknown factors. Poor health literacy was indicated as the discontinuation of HCQ due to lack of knowledge about its significance in SLE management.

**Results:** Mean age and median baseline SLEDAI-2K of participants were 31.5 years and 8, respectively. Mean 1-year MPR and the frequency of non-compliance were 88.4% and 19.9%, respectively. During the study period, HCQ discontinuation occurred in 115 (48.9%) patients and 1-year, 2-year and 5-year persistence rates were 80, 67.6 and 46.3%, respectively. The most common reason of non-persistence with HCQ treatment was poor health literacy (73%) followed by adverse events (10.4%), unknown factors (10.4%) and pregnancy (6.1%). SLE patients with SLEDAI-2K score <6 showed significantly worse persistence with HCQ than those with SLEDAI-2K score ≥6, while SLE patients with biopsy-proven lupus nephritis had better HCQ persistence than those without this feature (Fig. 1). SLEDAI-2K score <6 was a significant risk factor for non-compliance (OR=2.98,  $p=0.001$ ) and non-persistence (HR=1.55,  $p=0.046$ ) with HCQ after adjusting confounding factors. In addition, older age was significantly associated with better persistence with HCQ (HR=0.97,  $p=0.005$ ) and biopsy-proven lupus nephritis had a trend with better HCQ retention (HR=0.66,  $p=0.076$ ) in multivariable Cox regression model. But, neither HCQ dose nor concomitant immunosuppressive agents showed significant association with HCQ adherence.

**Conclusion:** Overall adherence with HCQ in SLE patients was suboptimal in real practice and SLEDAI-2K score <6 was a risk factor for poor HCQ treatment adherence. Our data suggest the need to improve adherence with HCQ treatment in SLE patients, especially for those with low disease activity.

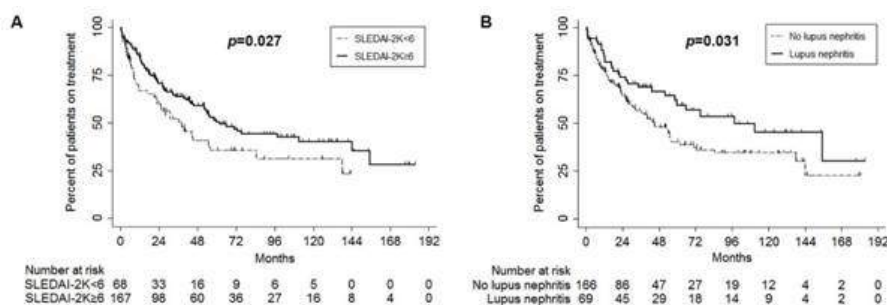

Figure 1. Persistence with hydroxychloroquine in patients with systemic lupus erythematosus according to SLEDAI-2K score (A) and the presence of biopsy proven lupus nephritis (B).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** MMF suppresses immune function by inhibiting T cell dependent and independent humoral immune responses. This study investigates the humoral immune response to the PPSV23 vaccine by MMF in a larger sample size. Furthermore, this study explores the effect of MMF dose and concurrent steroid use on the anti-pneumococcal antibody responses.

**Methods:** In this observational cross-sectional study, patients treated with immune suppressive medications who had received PPVS23 were identified and stratified based on receiving MMF or non-MMF immunosuppressants (control group). The humoral response was assessed in both groups using serum IgG titers against 14 pneumococcal polysaccharides (ELISA) as a surrogate marker. The stimulation index (SI) was calculated by dividing the post by the pre immunization titer, which was compared between the MMF and non-MMF groups. The primary endpoints of the study were protective titers of  $>1.3 \mu\text{g/ml}$  or either a 4-fold, 3-fold, or 2-fold increase in the SI for 70% of the 14 pneumococcal polysaccharides.

**Results:** The total study subjects included 39 patients. The MMF group included 23 patients: 21 with SLE, 1 with uveitis, and 1 with DM. The control group included 16 patients: 12 with SLE, 2 with RA, 1 with uveitis, and 1 with PsA. The humoral responses in the MMF group were significantly lower compared to the control group. 40 % of patients in the MMF group vs. 60 % of the control group had protective antibody levels ( $> 1.3 \mu\text{g/ml}$ ). However, statistically significant differences were only observed in serotypes 51 and 4 ( $p = 0.05$  &  $p = 0.025$ ). Suppressed antibody responses were observed in the MMF group as defined by a lack of a 4-fold ( $p = 0.0001$ ), 3-fold ( $p = 0.001$ ), and 2-fold ( $p = 0.0163$ ) increase in the SI vs. the control group. 20 % ( $n=3$ ) of the study group and 50% ( $n=8$ ) in the control group had more than a 2-fold increase in post-immunization antibody titers to 10 of the 14 serotypes. Patients receiving more than 1.5 g of MMF daily had more suppressed antibody responses defined as a lack of a 4-fold increase ( $p = 0.04$ ) in the SI compared to patients taking less than 1.5 g of MMF daily. Patients in both the MMF and control groups received less than 10 mg of prednisone that had no effect on the anti-pneumococcal antibody responses.

**Conclusion:** This data suggests that humoral responses to pneumococcal polysaccharides are more blunted in patients receiving MMF compared to other immunosuppressants. There was a dose effect of MMF on the humoral response. However, no effect of steroids was observed. Evaluation of post-vaccination humoral immunity should be considered in patients receiving MMF.

## Apremilast in Patients with Lupus Rashes

**Robert S. Katz,** Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Apremilast has been approved by the FDA for treatment of psoriasis and psoriatic arthritis. Because side effects are few, we decided to use it off-label in a number of patients with extensive cutaneous lupus rashes resistant to topical therapy and hydroxychloroquine, and as a steroid-sparing method.

**Methods:** We describe 6 patients with significant cutaneous lupus. 2 had subacute cutaneous lupus, and 4 had significant cutaneous lupus rashes which were chronic and associated with systemic lupus. All were treated with the topical corticosteroid clobetasol, and sometimes less-potent corticosteroid preparations for facial involvement. 2 patients were taking oral corticosteroids with a dosage range of 5 to 15. All 6 patients were taking hydroxychloroquine, 400 mg per day. The etiology of the rashes was confirmed by skin biopsy and/or Dermatology and Rheumatology clinical agreement. The mean age was 48; age range was 24 to 74. There were 3 men and 3 women.

**Results:** Of the 6 patients, 4 responded to apremilast, 30 mg bid, with a significant reduction in erythema and the size and extent of lesions within a 1-month period. Patients were satisfied with the amount of clearing of the lupus rash, and no significant side effects were noted. The 2 patients who did not have a significant reduction in their erythema discontinued apremilast after 6 weeks, and were placed on higher doses of steroids to help control their active lupus rash.

**Conclusion:** Apremilast may be an effective therapy for patients with resistant extensive rashes due to systemic lupus and subacute cutaneous lupus.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Atacicept targets the B-cell stimulating factors, BLyS and APRIL, and has demonstrated a clinical response in SLE patients (pts) with high disease activity (HDA; SLEDAI-2K  $\geq 10$ ) at Screening in the Phase IIb ADDRESS II study.

**Methods:** In ADDRESS II (NCT01972568), pts received weekly atacicept (75 or 150 mg SC injection) or placebo (PBO) for 24 weeks (wks) (1:1:1 randomization). Those who completed treatment were eligible to enter a long-term extension (LTE), to either continue on the same atacicept dose (atacicept groups), or switch from PBO to atacicept 150 mg (PBO/150 mg). The LTE primary objective was to determine the long-term safety and tolerability of atacicept in SLE pts. Current cumulative safety results from ADDRESS II and the LTE are reported here.

**Results:** Of the 306 pts in ADDRESS II, 253 (95% of completers) entered the LTE, of which 132 (52%) had HDA. By 48 wks (from start of Day 1 in ADDRESS II), most pts had  $\geq 1$  treatment-emergent adverse event (TEAE), with a slight increase in the atacicept groups vs PBO/150 mg. Herpes zoster incidence was low. Only one patient with asthma and allergic rhinitis on chronic inhaled corticosteroids developed a non-serious opportunistic infection (candida esophagitis, grade 1), which resolved with oral anti-fungal treatment. The most frequent serious TEAEs were infections (Table 1). There was no increase in the atacicept groups vs PBO/150 mg in the incidence of serious infections or exposure-adjusted annualized rates of serious/severe infections in the modified intention to treat population (Table 2) or the HDA subpopulation (data not shown). Serious/severe infections in the PBO/150 mg group occurred more frequently during the PBO-treatment period (15/18 [83%]). Serum IgG reductions (including IgG  $< 3$  g/L) were not associated with infections. Four pts in the atacicept 150 mg group developed IgG  $< 3$  g/L after 36 wks of treatment, which resolved without treatment discontinuation; 1 patient in the atacicept 75 mg group developed IgG  $< 3$  g/L after treatment discontinuation due to lupus nephritis flare. No safety new signals were identified. The two deaths reported in the LTE occurred after 48 wks; overall exposure-adjusted mortality rate of atacicept treatment was 0.57 /100 pt-years.

**Conclusion:** Cumulative data demonstrate an acceptable safety profile for atacicept, with no increased risk of serious/severe infections, or mortality. This was also seen in the HDA subpopulation, in which a greater atacicept treatment effect has been observed. IgG decreases were not associated with infections but should continue to be monitored.

**Table 1. Summary of Cumulative Treatment Emergent Adverse Events in ADDRESS II and LTE by 48 weeks (mITT)**

Adverse events, n (%)	PBO/150 mg*	Atacicept 75mg	Atacicept 150mg
	(n=100)	(n=102)	(n=104)
Any TEAEs	82 (82.0)	88 (86.3)	90 (86.5)
TEAEs leading to treatment discontinuation	9 (9.0)	7 (6.9)	8 (7.7)
Infections and infestations	53 (53.0)	55 (53.9)	64 (61.5)
Herpes zoster	1 (1.0)	0 (0.0)	2 (1.9)
Influenza	1 (1.0)	4 (3.9)	4 (3.8)
Serious TEAEs	16 (16.0)	12 (11.8)	11 (10.6)
Serious/severe infections	7 (7.0)	7 (6.9)	6 (5.8)
Death	0 (0)	0 (0)	0 (0) <sup>†</sup>

PBO, placebo; TEAE, treatment-emergent adverse event; LTE, long-term extension; mITT, modified intention to treat TEAEs include the onset date of the AE from the first dose date in ADDRESS II to the last dose date in the LTE study +7 days (i.e., from the first dose date up to 343 days)

\*Patients receiving PBO in ADDRESS II who entered LTE at Week 24 switched immediately to atacicept 150 mg

<sup>†</sup> Two deaths occurred after 48 weeks of treatment: one at Week 55 due to abdominal pain and hematemesis and one at Week 80 due to stroke

**Table 2. Exposure-Adjusted Annualized Rate of Serious/Severe Infections in ADDRESS II and LTE by 24-Week Intervals (mITT)**

ADDRESS II (24 weeks)	PBO	Atacicept 75 mg	Atacicept 150 mg
	(n=100)	(n=102)	(n=104)
Subjects with serious/severe infections, n (%)	7 (7.0)	9 (8.8)	1 (1.0)
Total number of serious/severe infections	15	10	4
Annualized rate (95% CI) <sup>†</sup>	0.35 (0.21, 0.58)	0.23 (0.12, 0.43)	0.09 (0.03, 0.23)
024 LTE (24 weeks)	Switched to 150 mg	Atacicept 75 mg	Atacicept 150 mg
	(n=83)	(n=82)	(n=88)
Subjects with serious/severe infections, n (%)	2 (2.4)	2 (2.4)	5 (5.7)
Total number of serious/severe infections	3	2	6
Annualized rate (95% CI) <sup>†</sup>	0.08 (0.02, 0.24)	0.05 (0.01, 0.20)	0.14 (0.06, 0.32)
Pooled ADDRESS II and 024 LTE (cumulative 48 weeks)	PBO/150 mg*	Atacicept 75 mg	Atacicept 150 mg
	(n=100)	(n=102)	(n=104)
Subjects with serious/severe infections, n (%)	9 (9.0)	11 (10.8)	6 (5.8)
Total number of serious/severe infections	18	12	10
Annualized rate (95% CI) <sup>†</sup>	0.22 (0.14, 0.35)	0.15 (0.08, 0.26)	0.11 (0.06, 0.21)

CI, confidence interval; PBO, placebo; LTE, long-term extension; mITT, modified intention to treat

The treatment period started with the first dose of study medication [in ADDRESS II or 024 LTE] and ended 7 days after the last dose of study medication.

\*Patients receiving PBO in ADDRESS II who entered LTE at Week 24 switched from PBO to atacicept 150 mg at Week 24

<sup>†</sup> Annualized rate is calculated as the total number of events divided by the total number of patient-years (per one patient-year)

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

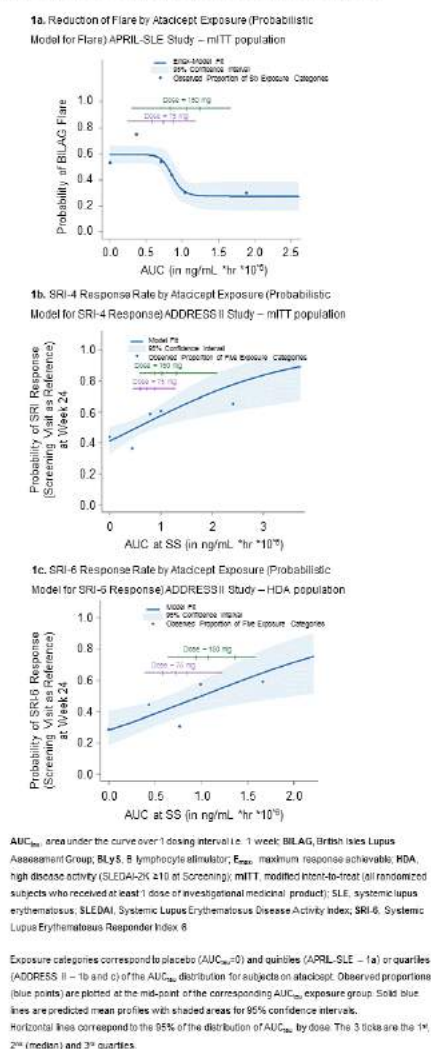

**Background/Purpose:** Atacicept targets the B-cell stimulating factors BLYS and APRIL, and has been shown to reduce SLE disease activity. Our analyses evaluated the exposure-response and exposure-safety relationships for atacicept 75 mg and 150 mg doses.

**Methods:** APRIL-SLE (NCT00624338) and ADDRESS II (NCT01972568) were phase II, placebo-controlled multicenter studies in patients (pts) with autoantibody-positive SLE. Pts were randomized (1:1:1) to weekly SC injections of atacicept (75 or 150 mg) or placebo (PBO). In APRIL-SLE, pts had BILAG A/B flare at Screening that was reduced to BILAG C/D before randomization using corticosteroids with taper; the primary endpoint was BILAG A/B flare over 52 weeks. In ADDRESS II, pts had SLEDAI-2K  $\geq 6$  at Screening; the primary endpoint was SRI-4 response at Week 24. SLE responder index (SRI)-6 response was analysed post-hoc in pts with high disease activity (HDA; SLEDAI-2K  $\geq 10$ ). Population pharmacokinetic (PK) model-derived exposure vs the probability of response (BILAG A/B flare, SRI-4, SRI-6), exploratory analysis of exposure vs safety, and population model simulations of serum IgG were analyzed.

**Results:** Exposure-response modelling suggests a relationship between atacicept exposure and SLE clinical response [Fig. 1], including serum IgG changes from baseline [Fig. 2]. The optimal atacicept exposure was  $AUC_{\tau,ss} \geq \sim 1$  mg.hr/mL, which is more achievable with weekly SC doses of atacicept 150 mg than 75 mg across a range of body weights. Body weight-based dosing is unlikely to offer any value over a fixed 150 mg dose, based on comparable predicted clinical response. In HDA pts, serum IgG change from baseline was linked to the probability of SRI-6 response. Greater IgG reductions from baseline were associated with higher atacicept exposure [Fig.2]; however, even at the highest exposure range, mean IgG reductions did not exceed  $\sim 40\%$ . There was no association between serious/severe infections and exposure by PK quartile.

**Conclusion:** Exposure-response modelling indicated that there are robust relationships between atacicept exposure and clinical response or IgG levels in SLE pts over time; this supports the proposed mechanism of action for atacicept. Atacicept 150 mg weekly SC is likely to provide an effective level of exposure with an acceptable safety profile. There was no evidence of an increased risk of severe or serious infections at higher exposures. Based on these results, the 150 mg dose merits further evaluation.

**Figure 1.** Probabilistic Models for Clinical Responses by Atacicept Exposure

**Figure 2.** Relationship between Serum IgG Reductions from Baseline and Atacicept Exposure by Quartiles

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Proteasome inhibition is a standard of care for plasma cell malignancies. The first-generation inhibitor, bortezomib (BTZ), targets the constitutive proteasome and immunoproteasome and has been used in the treatment of Systemic Lupus Erythematosus and lupus nephritis (LN). However, BTZ therapy is associated with hematologic (thrombocytopenia, anemia, neutropenia) and constitutional (fatigue, peripheral neuropathy) adverse events (AEs). We report here the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of KZR-616, a first-in-class selective inhibitor of the immunoproteasome, in healthy volunteers (HV) following single or repeat subcutaneous (SC) or single intravenous (IV) administration (ACTRN12616001040459).

### **Methods:**

Cohorts of HV (6 drug:2 placebo) received single SC or IV (30-minute infusion) doses or 4 weekly SC doses. Safety assessments, PK and PD were measured to Day 7 (SAD) or Day 28 (MAD). SAD cohorts included 7.5, 15, 30 and 60 mg (SC) and 7.5 and 15 mg (IV). MAD cohorts (all SC) included 30, 45, 60 mg and 2 intrasubject escalation cohorts with 1 dose at 30 mg and 3 subsequent doses at 45 mg. PK was measured by LC/MS<sup>2</sup>. PD was measured using enzymatic and active site binding assays.

### **Results:**

42 HV (31:11) were enrolled in 6 SAD cohorts. The most common AEs with SC administration were injection site reactions (ISRs), which were generally mild and transient. No clinically-significant laboratory or ECG abnormalities or dose limiting toxicities were observed in the SAD subjects.

Following SC administration, drug exposure increased dose proportionally and was characterized by rapid absorption ( $T_{max}$  15 – 30 minutes) and clearance ( $T_{1/2}$  ~2 hours). SC bioavailability was ~100%. Dose dependent and selective

inhibition of the immunoproteasome exceeded 80% at  $\geq 30$  mg with significant recovery noted over 7 days. Constitutive proteasome inhibition was  $<37\%$  in all cohorts.

40 HV (30:10) were enrolled in 5 SC MAD cohorts. In the initial cohort of 60 mg, an infusion reaction-like syndrome (chills, elevated heart rate, nausea) occurred  $\sim 8$  hours after the first dose in 4 subjects. Further dosing in this cohort was withheld. Subsequent MAD cohorts (initiated at 30 mg) received prophylactic treatment with antihistamines +/- prednisone 1 hour prior to the first and second dose. No similar AEs occurred with repeat dosing of 30 or 45 mg. No clinically-significant laboratory or ECG abnormalities were seen in the remaining 4 MAD cohorts. ISRs did not increase in severity or frequency with repeat SC dosing, there were no AEs of peripheral neuropathy or infection, and 45 mg was well tolerated across 3 cohorts.

Consistent PK was noted following repeat administration and no drug accumulation was observed. At 45 mg, inhibition of 2 key subunits of the immunoproteasome, LMP7 and LMP2, was  $\sim 95\%$  and  $\sim 70\%$ , respectively.

#### **Conclusion:**

KZR-616 was well tolerated in HV and demonstrated consistent PK and PD. Selective immunoproteasome inhibition did not induce hematologic or constitutional toxicities associated with dual proteasome inhibitors. This study has identified candidate doses of KZR-616 to explore the safety, tolerability and efficacy of KZR-616 in patients with rheumatic diseases, such as LN, in an upcoming Phase 1b/2 study.

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The guideline or recommendation for lupus nephritis (LN) has been recently established by both ACR and EULAR, and hydroxychloroquine (HCQ) is recommended for all patients unless there is a contraindication. Although HCQ improves outcomes by reducing renal flares and limiting the accrual of renal damage, its therapeutic effect on renal response has been rarely investigated. In this study, we evaluated its therapeutic effect by focusing on the renal response in Japanese patients with LN class III or IV.

**Methods:** Patients who were diagnosed as LN class III or IV and treated with mycophenolate mofetil (MMF) as induction therapy were retrospectively investigated. We divided them into two groups according to whether HCQ was received. In this study, we selected patients who were treated with HCQ from early phase of induction therapy, within 4-weeks from high-dose glucocorticoid initiation for HCQ users. Clinical features including renal pathological findings and cumulative complete renal response (CR) were compared.

**Results:** We identified 7 (38.9%) patients with HCQ and 11 (61.1%) patients without. Although a significantly higher percentage of LN class III was determined in HCQ users comparing to non-HCQ users, there was no other difference in two groups at baseline. A significantly higher cumulative CR rate was detected in HCQ users comparing to non-HCQ users for 1 year ( $p=0.02$ ) (Figure 1). Multivariate analysis indicated that HCQ use was the independent factor correlated with CR achievement (OR 15.9, 95%CI 1.76-380.1,  $p=0.02$ ).

**Conclusion:** HCQ use from early phase of induction therapy may have additional therapeutic effect on renal response in Japanese LN patients with MMF treatment.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Increased type I interferon (IFN) activity is associated with the pathogenesis of SLE. Anifrolumab, a fully human immunoglobulin (Ig) G<sub>1</sub> κ monoclonal antibody in clinical development for the treatment of SLE and lupus nephritis, targets the interferon alpha receptor 1 (IFNAR1) and blocks IFNAR1-dependent signaling. Here we characterize the mechanistic and functional properties of anifrolumab.

**Methods:** Binding between anifrolumab and the IFNAR1 was measured by surface plasmon resonance. IFNAR1 internalization on monocytes was assessed by flow cytometry and confocal microscopy. The effect of three mutations in the fragment crystallizable region (Fc) of anifrolumab on Fcγ receptor-dependent cytotoxicity was assessed in antibody-dependent cell-mediated cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) assays. IFNAR1-dependent signaling induced by recombinant human type I IFN (including IFN-α, -β, and -ω) and by plasmacytoid dendritic cell (pDC)-derived type I IFN was assessed in signal transducer and activator of transcription 1 (STAT1) phosphorylation and IFN-stimulated response element-luciferase reporter assays. Production of IFN-α, TNF, IL-6, and IL-8 by stimulated pDC was measured by enzyme-linked immunosorbent assay or Meso Scale Diagnostics, and expression of cluster of differentiation 80 and 86 was measured by flow cytometry. Expression of type I IFN-regulated genes was measured by quantitative PCR. B-cell differentiation in pDC/B-cell cocultures was assessed by flow cytometry and Ig production.

**Results:** Anifrolumab blocked type I IFN-dependent IFNAR dimerization and STAT1 phosphorylation with high affinity and specificity. Anifrolumab elicited rapid IFNAR1 internalization and markedly reduced IFNAR1 cell surface levels. Fc mutations on anifrolumab reduced Fcγ receptor-dependent cytotoxicity. Anifrolumab potently inhibited recombinant human type I IFN (including 12 subtypes of α, β, and ω) and pDC-derived type I IFN activities. Anifrolumab suppressed IFN-α, proinflammatory cytokine induction, and upregulation of costimulatory molecules from stimulated pDCs and type I IFN-inducible genes in peripheral blood mononuclear cells. Blockade of IFNAR1 also suppressed plasma cell differentiation and Ig production.

**Conclusion:** Anifrolumab inhibits type I IFN-dependent signaling by sterically inhibiting and rapidly internalizing IFNAR1 on target cells. Anifrolumab has no detectable CDC or ADCC activity. Blockade of type I IFN signaling suppresses pDC functions and B-cell differentiation. Anifrolumab has the potential to be a promising therapeutic agent for treating SLE and other diseases that demonstrate chronic dysfunctional type I IFN signaling.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Organ manifestation domain score improvement was assessed with subcutaneous (SC) belimumab (BEL) plus standard SLE care (SoC) in active, autoantibody-positive SLE.

**Methods:** BLISS-SC (BEL112341; NCT01484496) was a randomized, double-blind, multicenter (177 centers in 30 countries across North, Central and South America, Western and Eastern Europe and Asia) 2-week trial of weekly BEL 200 mg SC or placebo (PBO), plus SoC, in patients with SLE with a SELENA-SLEDAI  $\geq 8$  at screening (where randomization to PBO would be to maintain treatment with SoC). The primary endpoint was the SLE Responder Index 4 (SRI4;  $\geq 4$ -point decrease in SELENA-SLEDAI,  $< 0.3$  increase in Physician's Global Assessment, and no new BILAG A or  $\leq 1$  B organ domain scores, from baseline) at Week 52. Efficacy and safety data (including adverse events) have been published<sup>1</sup>; here, organ-specific responses by BILAG and SELENA-SLEDAI are reported. Analyses included improvements in patients with BILAG baseline A or B scores, measured at each visit (every 4 weeks) between baseline and Week 52 (improvement defined as a shift to B, C, or D; worsening defined as a shift from BILAG E, D, or C to B or A, or from B to A). An increase in total SELENA-SLEDAI domain scores between baseline and Week 52 defined worsening; a decrease defined improvement.

**Results:** 836 patients comprised the intent-to-treat population. BILAG (Grade A/B) and SELENA-SLEDAI organ system involvement at baseline were similar for both treatment groups, with mucocutaneous and musculoskeletal domains most prominent. The SELENA-SLEDAI immunologic domain was also prominent (not recorded by BILAG).

BEL demonstrated significant improvement versus PBO in the BILAG mucocutaneous, musculoskeletal and vasculitis domains at Week 52 (Table). No statistically significant differences were observed between BEL and PBO for worsening in any BILAG domain. Among patients with baseline SELENA-SLEDAI organ involvement, a statistically significant improvement was observed at Week 52 for BEL versus PBO for the immunologic, mucocutaneous, musculoskeletal, and vascular domains (Table). No statistically significant differences were observed between BEL and PBO for worsening in any SELENA-SLEDAI domain.

**Table. Improvement in BILAG (in patients with an A or B domain score at baseline) and SELENA-SLEDAI (in patients with organ involvement at baseline) organ domains at Week 52 in patients (double-blind phase, last observation carried forward)**

BILAG				SELENA-SLEDAI			
n/N (%)	PBO (n=280)	BEL (n=556)	p value	n/N (%)	PBO (n=280)	BEL (n=556)	p value
General	22/29 (75.9)	32/39 (82.1)	0.5586				
Cardiovascular and respiratory	4/7 (57.1)	7/13 (53.8)	1.0000	Cardiovascular and respiratory	10/18 (55.6)	20/29 (69.0)	0.3710
Hematology	13/48 (27.1)	32/91 (35.2)	0.3492	Hematologic	9/25 (36.0)	22/49 (44.9)	0.6190
Mucocutaneous	88/201 (43.8)	201/363 (55.4)	0.0107	Mucocutaneous	135/248 (54.4)	312/487 (64.1)	0.0132
Musculoskeletal	116/209 (55.5)	273/413 (66.1)	0.0110	Musculoskeletal	110/218 (50.5)	282/438 (64.4)	0.0007
Neurological	0/0 (0.0)	4/4 (100.0)	–	Central nervous system	1/2 (50.0)	4/7 (57.1)	1.0000
Renal	19/30 (63.3)	30/53 (56.6)	0.6446	Renal	15/41 (36.6)	25/59 (42.4)	0.6788
Vasculitis	9/24 (37.5)	35/47 (74.5)	0.0041	Vascular	5/18 (27.8)	29/46 (63.0)	0.0138
				Immunologic	34/211 (16.1)	127/427 (29.7)	0.0002

**Conclusion:** Weekly BEL 200 mg SC plus SoC improved organ manifestations in mucocutaneous, musculoskeletal, vascular, and immunologic domains after 52 weeks of therapy, compared with PBO (SoC).

## **Association of Smoking and Cutaneous Manifestations in Systemic Lupus Erythematosus (SLE): Post-Hoc Results from Phase IIb Studies of Anifrolumab and Sifalimumab**

Victoria P Werth<sup>1</sup>, Gabor Illei<sup>2</sup>, Gabriel Abreu<sup>3</sup>, Liangwei Wang<sup>2</sup> and Warren Greth<sup>2</sup>, <sup>1</sup>University of Pennsylvania and the VA Medical Center, Philadelphia, PA, <sup>2</sup>MedImmune, Gaithersburg, MD, <sup>3</sup>AstraZeneca, Gothenburg, Sweden

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Studies have demonstrated an association between smoking and more severe cutaneous lupus erythematosus, resulting in decreased health-related quality of life and treatment response.<sup>1</sup> We analyzed the influence of smoking on cutaneous manifestation severity *post hoc* in adults with moderate to severe SLE who enrolled in either of two Phase IIb randomized, placebo-controlled studies of anifrolumab or sifalimumab.

**Methods:** Baseline mucocutaneous disease activity in current smokers (stopped for <1 year) and never/past smokers (stopped for >1 year) enrolled in randomized placebo-controlled studies of anifrolumab (NCT01438489; MUSE)<sup>2</sup> or sifalimumab (NCT01283139)<sup>3</sup> was evaluated by the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) and SLE Disease Activity Index 2000 (SLEDAI-2K) mucocutaneous descriptors. Disease activity was compared between smoking status-defined subgroups. Smoking status was collected as part of the baseline cardiovascular risk assessment.

**Results:** A total of 736 patients were randomized in both studies. Patients were mostly female (92.8%), with a median age of 39 years and median disease duration of 5.9 years. Baseline CLASI and SLEDAI–2K scores, and smoking status, were available for 729 patients. At baseline, 81.5%, 70.8%, and 44.6% of patients had SLEDAI–2K-defined rash, alopecia, or mucosal ulcers, respectively. Current smokers had significantly greater CLASI activity and damage scores, compared with never/past smokers (table). Where group numbers were large enough to make sufficient evaluations, CLASI activity scores were consistently greater in current smokers irrespective of race, ethnicity, or SLE medication. There was no significant difference in CLASI activity scores between never and past smokers ( $6.9 \pm 5.8$ ,  $7.5 \pm 6.3$ , respectively;  $p=0.4857$ ). A significantly greater percentage of current smokers had a moderate or severe rash, defined by  $\text{CLASI} \geq 10$  ( $p < 0.0001$ ).

**Conclusion:** Cutaneous disease activity was consistently greater in current smokers compared with never/past smokers, irrespective of race, ethnicity, or SLE medication; this suggests that smoking may actively worsen skin disease. CLASI appears to be a more sensitive measure of inflammatory skin involvement than the SLEDAI–2K mucocutaneous descriptors. As CLASI activity was similar in never/past smokers, smoking cessation should be encouraged in SLE inflammatory skin management.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anifrolumab is a fully human anti–interferon- $\alpha$  receptor 1 monoclonal antibody in Phase III development as an intravenous (IV) therapeutic for systemic lupus erythematosus (SLE). In Phase IIb trials, IV anifrolumab (300 mg every 4 weeks) significantly decreased SLE disease activity and was well-tolerated.<sup>1</sup> In this Phase I, blinded, randomized, controlled study (NCT02601625), we profiled the pharmacokinetics (PK), safety, and tolerability of anifrolumab administered subcutaneously (SC) and IV to healthy volunteers.

**Methods:** Thirty male and female adults were assigned to three sequential treatment cohorts of equal size (anifrolumab 300 mg SC injection, anifrolumab 300 mg IV, anifrolumab 600 mg SC by infusion). Individuals were randomized within each cohort to receive a single dose of either anifrolumab (n=6/cohort) or placebo (PBO) (n=4/cohort). Serial blood samples were collected up to Day 84. Serum anifrolumab concentrations were analyzed with a validated assay. PK parameters were estimated by noncompartmental analysis. Immunogenicity of anifrolumab was assessed by measuring serum anti-drug antibodies (ADAs).

**Results:** Anifrolumab serum concentration–time profiles and PK parameters in healthy volunteers are presented in the figure and table, respectively. Anifrolumab serum concentrations were below the limit of detection in all individuals by 84 days post dose. Maximum serum concentrations in the SC cohorts occurred after 4–7 days. Exposure to SC anifrolumab increased approximately dose proportionally from 300 mg to 600 mg based on AUC. Anifrolumab exposure after SC administration of the 300-mg dose reached approximately 87% of the IV administration exposure. SC administration of anifrolumab 300 mg and PBO elicited minimal injection-site reactions. Transient injection-site induration occurred in five of six individuals in the anifrolumab 600-mg group and two of four in the PBO group. Transient, mild to moderate injection-site induration and pruritus occurred simultaneously in two of six individuals in the anifrolumab 600-mg group, but not in those in the PBO group. Adverse events were reported by 50% (n=9) of anifrolumab-treated and 33% (n=4) of PBO-treated individuals. No serious adverse events were observed. ADAs were detected in only one individual in the anifrolumab 300-mg IV group at the Day-84 assessment.

**Conclusion:** Exposure of anifrolumab 300 mg SC was approximately 87% of IV administration, with single SC administrations of anifrolumab being generally well-tolerated in healthy volunteers.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Belimumab, an inhibitor of B lymphocyte stimulator, is approved in adults with active, autoantibody-positive systemic lupus erythematosus (SLE) receiving standard of care.

**Methods:** Retrospective analysis was conducted in the Truven Health MarketScan® Commercial Claims and Encounters database (Sept 01, 2010 to Dec 31, 2015) (study 206345). Patients 18–64 years of age at first belimumab infusion (index) with a SLE diagnosis (ICD-9: 710.0 or ICD-10: M32) and continuous enrollment of 6 months pre-index and  $\geq 3$  post-index were analyzed. Patients diagnosed with lupus nephritis were excluded. The 6-month pre-index period was analyzed to characterize patients initiating treatment with intravenous belimumab. A previously published disease activity algorithm, developed based on claims data, was used to estimate the frequency of mild, moderate or severe flare symptoms.<sup>1</sup>

**Results:** This analysis comprised 2067 patients; 94.7% were female, mean (standard deviation [SD]) age was 43.9 (11.1) years and mean (SD) length of follow-up was 649.7 (434.8) days. In the 6-month pre-index period, mean (SD) Charlson Comorbidity Index score was 1.4 (0.9). Commonly observed comorbid conditions included hypertension (23.4%), myositis/myalgia (21.0%), and pulmonary disease (18.3%). The most frequent SLE-related clinical manifestations included arthralgia (28.4%) and hematologic disorders (20.8%). SLE-related organ involvement included diseases of the musculoskeletal (98.5%), nervous (46.7%) and respiratory systems (40.5%).

Pre-index concomitant medications prescribed included corticosteroids (80.2%), antimalarials (66.0%), nonsteroidal anti-inflammatory drugs (38.2%), immunosuppressive agents (59.1%), and rituximab (1.1%). Mean (SD) daily prednisone-equivalent dose was 27.7 mg (87.5), with 12.7%, 25.7% and 40.9% receiving  $\leq 7.5$  mg/day,  $>7.5$  to  $\leq 15$  mg/day and  $>15$  mg/day, respectively. Patients had a mean (SD) of 2.9 (5.9) primary care visits and 4.2 (7.0) rheumatologist visits in the 6-month pre-index period (Table). The proportions experiencing a mild, moderate or severe flare pre-index were 43.9%, 91.2% and 12.7% (92.9% had a moderate/severe flare).

**Table. Six-month pre-index all-cause healthcare resource utilization and costs among patients with SLE initiating belimumab (n=2067)**

	Patients with $\geq 1$ utilization, n (%)	PPPM healthcare costs, US\$, mean (SD)
Inpatient admissions	371 (17.9)	1067 (4623)
Outpatient services	2064 (99.9)	2759 (4899)
Emergency room visits	813 (39.3)	169 (518)
Physician office visits	2059 (99.6)	299 (223)
Hospital-based outpatient visits	1706 (82.5)	1178 (2855)
Laboratory services	1910 (92.4)	130 (175)
Other outpatient services	2024 (97.9)	983 (3664)
Outpatient pharmacy prescriptions	2010 (97.2)	966 (2276)

PPPM, per patient per month

**Conclusion:** In this large sample of belimumab IV initiators in usual care settings, patients with SLE demonstrated substantial SLE-related clinical manifestations in the 6 months prior to initiating, with approximately 90% having evidence of a moderate/severe flare. Concomitant medications included many commonly prescribed therapies, with corticosteroids being the most frequently prescribed, and per patient monthly costs were high. Future studies will investigate whether belimumab treatment reduces healthcare utilization and costs.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Belimumab, an inhibitor of B lymphocyte stimulator, is approved for the treatment of adult patients with active, autoantibody-positive systemic lupus erythematosus (SLE) receiving standard of care. The recommended dosing regimen for intravenous belimumab is 10 mg/kg at 2-week intervals for the first 3 doses (loading dose period) and at 4-week intervals thereafter (maintenance period), for a total of 15 doses in the first year of therapy. However, in routine clinical practice, many patients may not be receiving the recommended number of loading or maintenance doses. This study evaluated the frequency of infusions in patients with SLE under routine care settings, using data from a US administrative claims database.

**Methods:** A retrospective analysis (study 206345) was conducted using the Truven Health MarketScan® Commercial Claims and Encounters database (Sept 01, 2010 to Dec 31, 2015). The analysis cohort comprised patients 18–64 years of age with a SLE diagnosis (ICD-9: 710.0 or ICD-10: M32) and  $\geq 1$  belimumab infusion. The index date was defined as the date patients received their first belimumab infusion. Continuous enrollment was required for 6 months pre-index and  $\geq 3$  months post-index date. The loading dose period was defined as the 34-day period post-index date; patients were divided into subgroups according to the number of infusions received in this time (1–2 or  $\geq 3$ ). Here we present data for those patients with 12 months of follow-up data.

**Results:** Overall, there were 2067 patients; the majority were female (94.7%) and had a mean (standard deviation [SD]) age of 43.9 (11.1) years. From this population, 1537 patients had 12 months of follow-up data; 877 (57.1%) received 1–2 infusions during the loading dose period and 660 (42.9%) received  $\geq 3$  infusions. The mean number of infusions and time between infusions are summarized (Table).

**Table. Frequency of belimumab infusions during the first 12 months of follow-up in patients with SLE**

	<b>Overall (N=1537)</b>	<b>1–2 infusions during the loading dose period (n=877)</b>	<b>≥3 infusions during the loading dose period (n=660)</b>
<b>Loading dose period<sup>a</sup></b>			
Number of infusions, mean (SD)	2.2 (0.8)	1.6 (0.5)	3.0 (0.1)*
Number of days between infusions, mean (SD)	15.9 (5.2)	20.7 (7.4)	14.1 (2.0)
<b>Maintenance period<sup>a</sup></b>			
Number of infusions, mean (SD)	6.1 (4.4)	5.1 (4.5)	7.5 (4.0)*
Number of days between infusions, mean (SD)	31.9 (15.7)	32.6 (17.7)	31.2 (13.7)*
<b>Entire follow-up period</b>			
Number of infusions, mean (SD)	8.3 (4.7)	6.7 (4.6)	10.5 (4.0)*
Patients with ≥3 infusions, n (%)	1290 (83.9)	630 (71.8)	660 (100.0)*
Number of days between the 1 <sup>st</sup> and 3 <sup>rd</sup> infusion, mean (SD)	50.0 (39.1)	72.9 (45.9)	28.2 (2.5)*

\*p<0.001; p value represents a comparison between patients with 1–2 infusions and ≥3 infusions during the loading dose period.

<sup>a</sup>belimumab is administered intravenously at 10 mg/kg at 2-week intervals for the first 3 doses (loading dose period) and at 4-week intervals thereafter (maintenance period), for a total of 15 doses in the first year of therapy.

**Conclusion:** In this sample of US patients with SLE in a routine care setting, a high proportion did not receive the recommended number of belimumab loading doses. Furthermore, compared with those who completed the recommended loading dose period, patients who did not complete the loading dose period received significantly fewer belimumab infusions during the maintenance period. This study provides valuable information on belimumab treatment patterns in a real-world setting using a US claims database. These data suggest that belimumab is not always administered as recommended; the effects of this on treatment outcomes remain to be determined.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the change in ANA titers as a proxy for progression in patients with undifferentiated connective tissue disease (UCTD) treated with hydroxychloroquine (HCQ) in a large academic clinical practice.

**Methods:** This study included all patients diagnosed with UCTD according to the preliminary classification criteria (Mosca et al 1999) seen at the Columbia University Lupus Center in New York from January 2015 to December 2016 that had at least 6 months of follow-up. Clinical and immunological variables were ascertained. Chi squared tests were used to compare the characteristics between treated and untreated patients: demographic characteristics, number of ACR criteria, SLICC criteria, individual symptoms and laboratory values.

**Results:** 114 patients were identified; 94% female, mean age at diagnosis of 44 years (range 19 – 81); 42% were Caucasian, 16% Hispanic and 12% Black/African American; median disease duration of 5.6 years (1-27). The most prevalent symptoms that required medical attention are described in Figure 1.

51 % of patients had a family history of autoimmune diseases.

94% of patients had positive antinuclear antibody (ANA) titers and 6% were ANA negative Ro/SSA+, 88.6% had titers  $\geq 1:160$ . Interestingly, 17.5 % of the patients studied met SLICC SLE criteria. Over half of the patients, 65(57%) were treated with HCQ and 49(43%) were not treated. The patients treated with HCQ were more likely to also meet SLICC criteria (16 vs. 4,  $p=0.04$ ), have arthritis (33 vs. 12;  $p=0.03$ ), have a history of low complements (19 vs. 5,  $p=0.03$ ); arthralgia and fatigue were common but not different between groups, arthralgia (52 vs. 34;  $p=NS$ ), and fatigue (36 vs. 15;  $p=NS$ ).

Of 62 patients that had follow-up ANA testing in the same laboratory, 40 had no change in ANA titer (ANA titer within  $\pm$  one dilution was considered stable), 10 had an increase, and 11 had a decrease in ANA titer. 35/62 (56 %) patients had been treated with HCQ for  $\geq 5$  months, the majority remained ANA+ with stable/decreased titers. Of patients with dsDNA+ on HCQ 4/5 became negative.

**Conclusion:** Data from this single-center cohort of patients with UCTD show that patients treated with HCQ have multiple clinical criteria and low complement, suggesting that rheumatologists treat pre-clinical autoimmunity in the setting of clinical symptoms. Follow-up ANA/dsDNA testing suggests that HCQ may prevent increase in ANA titers or dsDNA autoantibodies and disease progression in UCTD. Longitudinal studies are needed to evaluate the long-term impact of HCQ on clinical and serologic outcomes in UCTD.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The antimalarial drug hydroxychloroquine (HCQ) has been used for decades to treat various rheumatic diseases including systemic lupus erythematosus (SLE). The efficacy of HCQ in lupus is well-demonstrated, and leads to a decreased number of lupus flares. Although multiple mechanisms have been proposed for HCQ, the systemic immunologic effects of HCQ treatment still remains ill-defined in human lupus and may help elucidate the immune mechanisms of HCQ in SLE.

**Methods:** SLE patients receiving HCQ (n=9) or not receiving HCQ (n=9) were matched and assessed in a cross-sectional design. Single-cell analysis of surface markers were completed by mass cytometry on PBMCs and cellular heterogeneity was visualized using viSNE and manual gating in Cytobank. Further, phospho-specific flow cytometry was used to measure basal levels of pERK, pPLC $\gamma$ 2, pSTAT5 and p38 and expression following CD3/CD28 (TCR) and anti-IgG and IgM (BCR) stimulation. Soluble mediator levels in plasma were assessed using a 51-plex (Affymetrix) and by ELISA (eBioscience). All SLE patients met ACR criteria for SLE classification.

**Results:** In PBMCs of SLE patients taking HCQ, there was a small non-significant trend towards fewer total cells/mL compared to SLE patients not receiving HCQ (p=0.1200) (Figure 1). There was a significant reduction in the number of B cells (p=0.0269) and CD4+ T Cells (p=0.0124), most significantly transitional B cells (p=0.0053) and effector T cells (p=0.0039) (Th1-type, Th17-type, and Tfh-type) in HCQ patients compared to non-HCQ patients (Figure 1). Cell activation was also reduced in SLE patients receiving HCQ with lower expression of HLA-DR and CD38 on B cells, IL-2 receptor and CCR6 on T cells, and CD86 expression in dendritic cells (p<0.05). Plasma soluble mediators produced primarily by monocyte, platelet and endothelial cells were significantly reduced in patients receiving HCQ, namely PDGF-BB (p=0.0009), MCP-1 (p=0.0041), PAI-1 (p=0.0114), sEselectin (p=0.0118), resistin (p=0.0360) and IL-7 (p=0.0380). No significant differences were observed in TCR and BCR signaling following stimulation, but reduced levels of PLC $\gamma$  in CD4+ effector T cells were found in SLE patients receiving HCQ following BCR stimulation (p=0.0275).

**Conclusion:** Our results indicate that SLE patients on HCQ have reductions in circulating lymphocytes, HLA-DR expression on antigen-presenting cells, and monocyte and platelet derived soluble mediators compared to patients off HCQ. In addition, reduced T cell signaling following B cell stimulation suggests that the effects of HCQ on T cells may be a result of altered antigen presentation and reduced IL-7 levels. Together these data provide potential insights into HCQ mechanisms of action in SLE patients, while suggesting use lowers the risk of thrombotic events by reducing platelet activation.

# Phenotype of SLE patients Off/On HCQ

**Figure 1. Decreased lymphocytes distinguish HCQ-treated SLE patients from non-HCQ treated patients.** A radar plot using cell numbers converted to modified Z scores illustrates significant differences between Off-HCQ SLE patients (blue) and On-HCQ SLE patients (red). Significant cell differences are indicated with an asterisk. \* $p < 0.05$ , \*\* $p < 0.01$ .

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Even if randomized trials EXPLORER and LUNAR failed to prove the superiority of rituximab versus placebo in patients with systemic lupus erythematosus, several encouraging indications as refractory lupus nephritis and new clinical trials renewed interest for this molecule.

We hypothesized that SLE response criteria used in EXPLORER were not sensible enough to show rituximab efficacy and that new response criteria could show a significant difference. Our objective was to reanalyze EXPLORER trial's raw data using the newly described SLE response criteria.

## **Methods:**

We proceeded to a pre-specified re-analyze of EXPLORER trial's raw data. The patients included in EXPLORER study had active SLE disease defined by a British Isles Lupus Assessment Group (BILAG) score A or 2 BILAG B despite immunosuppressive regimen. Renal and neurological SLE were excluded. Patients were randomized through a 2/1 ratio to receive either two 1gr rituximab infusion (day 0 and day 15) repeated at month 6 or a placebo. Standard SLE treatment including immunosuppressants were continued. Patients received in a stratified manner prednisone ranging from 0.5 to 1.0 mg/kg depending on disease severity at inclusion. The original efficacy criterion was a composite clinical score using BILAG at week 52.

In our new analysis, rituximab efficacy was assessed at week 52 using 4 criteria: SRI-4 (Systemic lupus erythematosus Responder Index) with and without a concomitant oral prednisone tapering objective of < 10mg at months 6 (SRI-4 with and without OCS tapering), Lupus Low Disease Activity Score (LLDAS) and BILAG-based Combined Lupus Assessment (BICLA).

## **Results:**

Data from all 257 patients were available. There was 234 women (91%) with a mean age of 40,3 years among which 177 (69%) received hydroxychloroquine.

At week 52, SRI-4 response rate was 27,2% in the rituximab group vs 22,7% in the placebo group ( $p=0.43$ ); SRI-4 with OCS tapering was 16% in the rituximab group vs 13.6% in the placebo group ( $p=0.62$ ); LLDAS was 16% in the rituximab group vs 12.5% in the placebo group ( $p=0.46$ ) and BICLA was 15.4% in the rituximab group vs 15.9% in the placebo group ( $p=0.91$ ).

Subgroup analyses demonstrated a trend for better efficacy of rituximab compared to placebo in the subgroup of patients co-treated with methotrexate: SRI-4 of 30.6% in the rituximab group vs 12% in the placebo group ( $n=74$ ,  $p=0.08$ ). This trend was not found in the subgroup of patients co-treated with azathioprine: SRI-4 of 26.7% in the rituximab group vs 30.6% in the placebo group ( $p=0.68$ ), nor in the subgroup treated with mycophenolic acid: SRI-4 of 23.1% in the rituximab group vs 21.6% in the placebo group ( $p=0.86$ ). In the subgroup of patients with an BILAG A/B in hematological system or vasculitis at baseline, there was a significantly higher SRI-4 response rate with rituximab: 28,6% vs 5,3% in the hematological group ( $p=0.047$ ) and 39,3% vs 0% in the vasculitis group ( $p=0.037$ ).

Cumulative dose of steroids at week 52 were not statistically different: 4223mg in the rituximab group vs 4390mg in the placebo group ( $p=0.65$ ).

## **Conclusion:**

Our study confirms the results from the original EXPLORER Study. These results might be partly related to the study's design, notably the additional daily oral prednisone.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Exercise and psychological stress have been shown to produce opposite effects on immunomodulation. Prior studies in patients with Systemic Lupus Erythematosus (SLE) have demonstrated a decrease in inflammatory cytokine expression with exercise and improved disease activity with psychological stress reduction. In agreement, our prior study in a murine model of lupus nephritis showed an increase in inflammatory cytokine secretion with psychosocial stress induction, while exercise correlated with decreased inflammation and disease pathology. Therefore, to translate our previous findings, this study aims to utilize Tai Chi in exploring the effects of moderate exercise and psychological stress reduction on cytokine levels and perceived stress in SLE patients.

**Methods:** A cohort of 12 SLE patients >18 years of age participated in Tai Chi group classes twice a week and completed a Tai Chi DVD the remaining 5 days for 2.5 months. Selected participants scored low on a physical activity questionnaire and above average on the perceived stress scale. They were provided with FitBit activity trackers to monitor activity, sleep and caloric expenditure. Data collection included bi-weekly blood samples, monthly questionnaires, and weekly FitBit data compared to baseline measurements.

**Results:** Relative to baseline data, questionnaires revealed a significant increase in metabolic equivalent of task (MET) and physical activity, and a decrease in perceived stress in SLE patients. FitBit data showed an increase in steps, distance and activity calories, without significant change in body mass index or vigorous activity levels. Analysis of pro-inflammatory serum cytokines in Tai Chi patients demonstrated a relative suppression of IL-6 by 23% ( $p=0.05$ ), IL-8 by 30% ( $p=0.006$ ), IFN- $\gamma$  by 21% ( $p=0.05$ ) and TNF- $\alpha$  by 11% (Figure 1).

**Conclusion:** Our results suggest that moderate exercise and psychological stress reduction have clinically detectable immunosuppressive properties. We see a reduction in pro-inflammatory cytokine expression with Tai Chi along with a decrease in perceived stress levels. Thus, we propose Tai Chi as an adjuvant therapy to current pharmacologic interventions in the treatment of SLE, although larger studies are needed given the limitations herein, including a small sample size and short duration.

**Figure 1.** Average decrease in cytokine expression in SLE patients 2.5 months after participation in a Tai Chi exercise program

## **Efficacy and Toxicity of Antimalarials in Systemic Lupus Erythematosus: A Systematic Review**

Gaurav Sharma<sup>1</sup>, Jasvinder A. Singh<sup>2</sup>, Mohammed Sohaib Khaleel<sup>3</sup> and Shristi Shrestha<sup>4</sup>, <sup>1</sup>Department of Medicine, Division of Immunology and Rheumatology, UAB School of Medicine, Birmingham, AL, <sup>2</sup>Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Department of Molecular Cardiology, University of Louisville, Louisville, KY, <sup>4</sup>Internal Medicine, Kathmandu Medical College Teaching Hospital, Kathmandu, Nepal

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To determine the efficacy and adverse effects of antimalarials in patients with systemic lupus erythematosus (SLE).

**Methods:** A literature search from inception to December 2016 was performed using MEDLINE, EMBASE, Cochrane, CINAHL and ClinicalTrials.gov. All randomized control trials, clinical control trials, cohort, case control and cross-sectional studies of interest were included. Duplicate, independent screening of titles and abstracts was done to identify relevant studies. The primary outcome were effects of antimalarials (AMs) on lupus activity, irreversible organ damage, survival and adverse effects. Secondary outcomes were thrombosis, atherosclerosis, cardiovascular disease, neuro-psychiatric disease, effect on bone metabolism.

**Results:** 5364 abstract and titles were screened for studies assessing the efficacy and toxicity of antimalarial therapy in patients of SLE. 406 full texts were screened and 51 studies with 17349 patients qualified for final analyses. Mean ages were 6-70 years and mean follow-up was 6 months to 10 year.

We found that antimalarials significantly reduce the number of flares and disease activity in SLE patients (*high level evidence*). Patients on HCQ have increased odds of achieving remission (*weak evidence*) (**Table 1**). Outcomes remained similar and significant in pregnant women. We also found that antimalarials have significant toxic effects on skin, eyes and GI tract. Of these, most severe is retinal toxicity which is more evident in patients on Chloroquine as compared to HCQ (p=0.001). Risk of retinal toxicity is more at high doses of chloroquine (>4 mg/kg/day) and longer duration exposure (>7 years). We found *weak evidence* for antimalarials in preventing/delaying development of new organ damage in patients with SLE. *High evidence* was found for role of AMs in reducing the risk of mortality in patients with SLE (HR, 0.32 95% CI 0.16 to 0.66, I<sup>2</sup> of 81%; 4 studies). Antimalarial use also improves lipid profile, bone mineral density and have better cardiovascular outcomes (data is not presented).

**Conclusion:** Broad spectrum effects and safety profile of AMs qualifies them as a drug of choice in management of patients with SLE. They are effective in preventing flares, reducing systemic disease activity, mortality and have also shown preventive effect on irreversible end organ damage in SLE patients. They do have some adverse effects on long

term use, which can be prevented by appropriate screening practices and using less toxic formulations like hydroxychloroquine.

**Table 1: Summary of results for major outcomes**

Outcome	Number of studies	Design of Included studies	Number of participants	Age range (mean)	Gender	Results
<b>SLE activity</b>	23	5 RCT; 16 cohort; 1 cross sectional and 1 case control study	4849	17 -70 years	Females:4278; Males: 485	<p><b>Low SLE disease activity is associated with high serum HCQ concentration</b> based on data from three studies (p &lt;0.0001; p=0.005; p=0.04). AMs use reduce SLICC/ACR DAI (r=0.22, p=0.015), SLAM R (p=0.0157, and p &lt;0.001) sores and general symptoms and swollen/painful joint counts (p=0.02).</p> <p><b>Flares on AMs:</b> A randomized trial showed that patients on antimalarials have significantly less numbers of SLE flares (defined by American Rheumatic association criteria)(p&lt;0.02). Antimalarial drugs increase the odds of clinical quiescent phase (HR, 2.8 95% CI 1.4 to 5.57, p=0.004). In one cohort study patients with high number of flares during follow up had significantly low serum</p>

concentration of HCQ ( $p=0.006$ ). On multivariate analysis low HCQ concentration is a risk factor for SLE flares (OR: 3.82, 95% CI 1.16 to 2.58,  $p=0.027$ ). One trial showed significantly lower incidence of disease exacerbation in chloroquine group as compared to placebo ( $p<0.01$ ).

**Remission:**

Antimalarial use was significantly associated with remission in SLE patients (OR: 12.91, 2.87 to 58.13).

**HCQ vs Corticosteroids:**  
HCQ have less number of flares, severity of flare and better economic outcomes as compared to patients on corticosteroids.

**HRQOL:** Blood HCQ concentration is not predictive of HRQOL.

**Pregnancy outcomes:**  
Holding HCQ during pregnancy can lead to 3.6 times more flares and use of HCQ

					<p>during pregnancy have significant improvement in SLEDAI score during pregnancy (<math>p&lt;0.038</math>).</p> <p><b>Time lag:</b> In one study early HCQ use was associated with increase time lag between 1<sup>st</sup> symptom and full SLE criteria as compared to controls (<math>p&lt;0.018</math>).</p>
<b>Adverse reactions</b>	17	1 RCT, 4 case control studies, 9 cohort studies and 3 cross sectional	3893	6-56 years	<p>Females 2470; Males: 1423</p> <p><b>Cutaneous side effects:</b> Three studies described cutaneous pigmentation as adverse effect of antimalarials. In one case control study, 159/209 chloroquine users had skin toxicity.</p> <p><b>Cardiotoxicity:</b> No significant changes in heart rate, premature beats, heart rate variability and repolarization after treatment with chloroquine.</p> <p><b>Retinal toxicity:</b> Retinopathy developed in 21 out of 85 patients (24.7%), patients on CQ (13) had significantly higher risk compared to on HQ(8) treatment (<math>p=0.001</math>). In</p>

two studies, 2/58 and 7/2000 developed retinal toxicity with the use of HCQ. Risk of retinal toxicity increase significantly after 7 years of exposure.

**Retinal nerve fibre layer thickness:** Patients on Chloroquine in dose of 4mg/kg/day have significantly lower thickness. Retinal function improves after discontinuations of drug for 6 months.

**All adverse effect:** One trial and one retrospective cohort study showed that HCQ is associated with dermatological, gastrointestinal and ocular toxicity. Significant difference between incidence of HCQ and CQ toxicities was found ( $p < 0.00001$ ).

**Irreversible organ damage**

6 studies

6 cohort studies

5107

36 to 44.1 years

Females: 4573, Males: 534

HCQ user have low hazard ratio for development of new organ damage (SDI score); HR 0.57, 95% 0.37 to 0.88. Similarly, HCQ delays the time to first

					change in SDI score.
					Non-AM user have longer disease (p=0.004) duration and high SDI (p<0.001).
					Based on data from two cohort studies showed that HCQ use was associated with reduced risk for new organ damage (SDI >= 1), but the results did not reach statistical significance.

**SLICC/ACR DAI:** Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index for SLE; **SLAM-R:** Systemic lupus activity measure-Revised; **BILAG:** The British Isles Lupus Assessment Group index; **DAI:** Disease Activity Index; **HRQOL:** Health related quality of life

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** MMF is a key therapy for moderate to severe SLE. MMF inhibits inosine monophosphate dehydrogenase, an enzyme needed in nucleotide synthesis required for lymphocyte proliferation. MMF can also inhibit B-cell activation and plasma cell differentiation. Antibody production, interferon elevation, dysregulated inflammatory soluble mediators, and altered lymphocyte activity are molecular features of SLE. One soluble mediator, stem cell factor (SCF), was recently noted to be elevated in patients who transitioned from pre-SLE to SLE. Examination of cellular activity in patients undergoing MMF therapy may elucidate ongoing immune processes in patients who fail to respond, as up to 50% of MMF-treated LN patients are non-responders.

**Methods:** Immunologic profiling was conducted on 194 patients who met ACR classification criteria for SLE. Molecular assessments included whole blood gene expression profiling (microarray, analyzed as modules normalized to healthy controls, described by Chaussabel) and plasma soluble mediator assessment (24 cytokines, chemokines, and soluble receptors which passed quality control). We used these data for 3 key analyses. Patients who demonstrated clinical response to MMF (n=12) were compared to those with inadequate response (n=12). High disease activity (SLEDAI  $\geq$  6) patients on MMF (n=17) were compared to those on AZA (n=19). Wilcoxon test was used to analyze patients with one visit while taking MMF and another while not receiving MMF (n=8 pairs) (Table 1).

**Results:** The patients in the cohort whose biospecimens were assayed while on MMF (n=32) were younger (p=0.01) and had more Hispanic and Asian patients with less white patients (p=0.04) than those without MMF exposure (n=162). No significant differences in gender, race, or age were present between the other comparison groups. Plasma cell downregulation differentiated responders from non-responders and T-cell downregulation differentiated MMF from AZA treated patients. MMF was less effective at controlling elevated interferon and elevated SCF than AZA (Figure 1). Additionally, in the paired data, monocyte chemoattractant protein 1 was lower while on MMF as compared to off (p=0.04, not shown).

**Conclusion:** In this translational study of SLE, we showed that resistance to plasma cell suppression in some patients likely contributed to their ineffective MMF treatment. Also, we demonstrated that MMF differentially modulated T-Cell and IFN pathways compared to AZA. Understanding these distinct molecular profiles responding to MMF and AZA can lead to more effective personalized combination therapies.

**Table 1. Patient Characteristics.** Basic demographic data and SLEDAI scores shown, represented as number and % for categorical data assessed by Fisher's exact test, or median and interquartile range (IQR) for continuous data assessed by Mann-Whitney test. Response was defined by SLEDAI <6 at the time of biospecimen analysis and at the next clinic visit and Non-Response was defined by SLEDAI ≥6 for the timepoint and at the follow-up visit. Patients with SLEDAI ≥6 on MMF were compared to those with SLEDAI ≥6 on AZA. Patients with one timepoint on MMF and another off MMF (and not on another immunosuppressive) were compared as paired data.

Characteristics	MMF (n=32)	No MMF (n=162)	Response (n=12)	Non-Response (n=12)	MMF (n=17)	AZA (n=19)	On MMF (n=8)	Off MMF (n=8)
Female (n,%)	27 (84.4)	148 (91.4)	10 (83.3)	10 (83.3)	14 (82.4)	18 (94.7)	7 (87.5)	7 (87.5)
Race/Ethnicity (n,%)								
Black/African American	8 (25)	37 (22.8)	4 (33.3)	3 (25)	3 (17.6)	6 (31.6)	3 (37.5)	3 (37.5)
Hispanic/Latino	7 (21.9)	14 (8.6)	2 (16.7)	4 (33.3)	4 (23.5)	1 (5.3)	1 (12.5)	1 (12.5)
White/Caucasian	9 (28.1)	82 (50.6)	4 (33.3)	2 (16.7)	4 (23.5)	6 (31.6)	1 (12.5)	1 (12.5)
Native American	4 (12.5)	21 (13.0)	1 (8.3)	2 (16.7)	4 (23.5)	3 (15.8)	2 (25)	2 (25)
Asian	4 (12.5)	8 (4.9)	1 (8.3)	1 (8.3)	2 (11.8)	3 (15.8)	1 (12.5)	1 (12.5)
Age (median, IQR)	32 [26.3, 40.1]	39 [28.2, 48.7]	42.3 [26.6, 53.3]	39.0 [30.4, 42.0]	40 [29.6, 46.5]	37 [31.1, 40.1]	30.0 [22.5, 35.2]	32 [22.4, 35.4]
SLEDAI (median, IQR)	5.5 [2, 8]	4 [0, 7]	2 [0, 2.5]	9.5 [8, 11]	9 [8, 12]	8 [6, 12]	2 [1.5, 5]	8 [5.5, 8.8]

**Figure 1. Modular gene expression and soluble mediator results.** The plasma cell gene expression module was downregulated in those responsive to MMF (median -0.11) compared to those non-responsive to MMF (median 0.07) using Mann-Whitney, p=0.035. Two T-Cell modules, 4.1 and 4.15, were significantly downregulated in MMF (median -0.034 and -0.025) compared to AZA (median 0.017 and 0.025), using Mann-Whitney, p=0.018 and p=0.006. Multiple interferon modules noted higher modular scores for interferon and interferon activity in MMF, module 5.12 shown (median 0.19) compared to AZA (median 0.083), p=0.047. SCF was also higher in MMF (median 30.89) compared to AZA (median 14.27), p=0.039.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Type I interferon (IFN-I) is strongly implicated in the pathogenesis of Systemic Lupus Erythematosus (SLE) as well as rare monogenic ‘interferonopathies’ such as Aicardi-Goutieres Syndrome (AGS) caused by mutations in the DNA exonuclease, TREX1. A recently described DNA-activated IFN-I pathway, cyclic GMP-AMP (cGAMP) synthase (cGAS), was linked to subsets of AGS and Lupus. Because of these clinical associations, we performed in silico screening for cGAS inhibitors and synthesized a novel drug we named X6, that belongs to the antimalarial drug (AMD) class of aminoacridines. Our previous data showed that, X6, blocked cGAS in vitro and, in a proof of principle in vivo experiment, it significantly reduced the interferon stimulated genes (ISGs) and cGAMP production in the Trex1<sup>-/-</sup> mouse model of AGS. Here, we compared X6 to a standard care AMD for SLE, Hydroxychloroquine (HCQ), for the treatment of murine AGS and also examined the effects on ISG expression in Peripheral Blood Mononuclear Cell (PBMC) from SLE patients.

**Methods:** Trex1<sup>-/-</sup> mice were treated orally with either X6 or HCQ 25mg/kg/day (n=10 in each group) for 8 weeks from birth. ISGs expressions from mouse heart and spleen tissues were quantified by qPCR. Multiple Reaction Monitoring (MRM) by Ultra-Performance Liquid Chromatogram coupled with tandem Mass Spectrometer (UPLC-MS/MS) was used to quantify cGAMP. SLE PBMCs (n=7) were incubated with X6 or HCQ for 20 hours at different dose concentrations. ISG expression was quantified by qPCR.

**Results:** Trex1 deficiency in mice leads to an autoimmune myocarditis and lupus-like systemic autoimmunity with increased ISG expression and cGAMP production. When efficacy of X6 was compared with HCQ, X6 was significantly more effective than HCQ in attenuating cGAMP (p<0.05) production in the heart and ISGs expression in both the spleen (ISG15: p<0.01 and ISG20: p<0.01) and the heart (ISG15: p<0.05, Mx1: p<0.05, CXCL10: p<0.01, IFNb: p<0.05). Surprisingly, HCQ in contrast to X6, increased cGAMP production and certain ISGs were also increased compared to vehicle control treated mice. To explore the potential application of drug X6 in complex autoimmune diseases such as SLE and to examine whether X6 is superior to HCQ at reducing IFN signature genes in SLE PBMC, we incubated SLE PBMC with X6 or HCQ for 20 hours and quantified ISG expression by qPCR. We observed that X6 was superior to HCQ in reducing ISG expression (IFI27: p<0.05, IFI44L: p<0.01, PKR: p<0.01, MX1: p<0.05) in SLE PBMC. Interestingly HCQ increased rather than reduced ISG expression compared to untreated controls.

**Conclusion:** Our studies demonstrate that X6 is superior to HCQ for the treatment of a cGAS-STING (Stimulator of Interferon Genes) mediated autoimmune myocarditis in vivo. Furthermore, X6 was superior to HCQ in the suppression of ISGs expression (Interferon activity) in SLE PBMC. These results indicate that the drug X6 could potentially be beneficial for the treatment of AGS and/or Lupus.

## **Identification of Clinical and Serological Predictive Factors of Response to Rituximab Treatment in Systemic LUPUS Erythematosus (SLE) Patients**

**Hiurma Sanchez-Perez**<sup>1</sup> and David A. Isenberg<sup>2</sup>, <sup>1</sup>Rheumatology, Rheumatology Division, Hospital Universitario de Canarias, La Laguna. Tenerife, Spain, <sup>2</sup>Centre for Rheumatology Research, Division of Medicine, University College London, London, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Response to Rituximab (RTX) varies significantly between Systemic Lupus Erythematosus (SLE) patients. Ethnicity may play a role in these differences, and a possible relationship has been suggested between the clinical response to RTX and the presence of certain auto-antibodies (ab), such as anti-ENA and anti-dsDNA ab, and C3 levels at baseline. The aim of this study was to identify biomarkers that could predict the response to RTX treatment in SLE patients.

**Methods:** This was a cross-sectional study of 121 SLE patients treated with RTX in UCLH between 2000 and 2016. Demographic, clinical and serological data were analysed. Disease activity was evaluated using the BILAG index. Patients were categorised as “Responders” if all or some of the As and Bs from the BILAG score at the time the RTX was given were lost at 6 and at 12 months, and as “Non-Responders” if none of the As and Bs were lost. Relapse after RTX treatment was defined as development of a new BILAG Grade A or B in any system. A uni and multivariate regression analysis were performed to identify predictive factors of response to RTX utilising a combination of clinical and biological markers.

**Results:** At 6 and at 12 months, 85% and 70% respectively of our patients had responded clinically to the RTX treatment. 24% of patients relapsed during the year after RTX. In the univariate analysis, constitutional symptoms at diagnosis (crude OR (95% CI); 5.66 (1.53-20.88),  $p=0.009$ ) and the absence of musculoskeletal disease at the time of RTX (0.27, (0.09-0.81),  $p=0.019$ ) were related to response at 6 months. In the multivariate analysis, both remained significant, (adjusted OR (95% CI): 5.33 (1.39-20.41),  $p=0.014$  and 0.26 (0.08-0.81),  $p=0.021$  respectively. With respect to the response at 12 months, in the univariate analysis the presence of arthritis as the main indication for RTX (3.16 (1.31-7.58),  $p=0.010$ ), the absence of renal disease at diagnosis (0.36 (0.15-0.86),  $p=0.022$ ) and of cardiorespiratory disease at the time of RTX (0.29 (0.09-0.89),  $p=0.031$ ), less than one anti-ENA ab (0.28 (0.12-0.66),  $p=0.003$ ), low levels of C3 at diagnosis (0.29 (0.09-0.89),  $p=0.031$ ), increased anti-dsDNA ab levels (0.38 (0.17-0.89),  $p=0.025$ ) and decreased C3 levels (0.27 (0.11-0.63),  $p=0.002$ ) before RTX were related to the response. In the multivariate analysis, only the absence of more than one anti-ENA showed significance (0.30 (0.11-0.82),  $p=0.020$ ). Having more than one anti-ENA was related to relapse (3.30 (1.36-8.05),  $p=0.009$ ), while having arthritis as the main indication for RTX therapy was associated with a lower risk of flare (0.26 (0.10-0.64),  $p=0.004$ ). On the multivariate analysis, having arthritis remained significant (0.29 (0.11-0.75),  $p=0.010$ ).

**Conclusion:** There is a relation between the presence of more than one anti-ENA ab and a worse response to treatment at 12 months and a higher risk of flaring. Having arthritis at the time of RTX leads to a negative response at 6 months but a lower risk of flare before 1 year.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low-dose intravenous cyclophosphamide (Euro-lupus) and Mycophenolate mofetil (MMF) are well established in lupus nephritis induction therapy, but there are few studies comparing both treatments. Our aim was to compare their efficacy and safety after 6-month induction therapy

**Methods:** Retrospective analysis of a prospective cohort of a single tertiary center. Patients with active lupus nephritis were treated with Euro-lupus (500mg, 15/15 days for 3 months, followed by MMF / azathioprine) or MMF (3g/day) as induction therapy. Clinical and laboratory data were evaluated at baseline and after 6 months. Serious infectious were defined as infections requiring hospitalization and/or intravenous antibiotics. Exclusion: creatinine clearance <10mL/min and pregnancy.

**Results:** 40 patients received Euro-lupus and 70 patients received MMF. Euro-lupus and MMF groups were comparable in age ( $35.23 \pm 10.32$  vs.  $37.43 \pm 11.43$  years,  $p=0.316$ ), female gender (85.0 vs. 84.2%,  $p=1.0$ ), white race (75.0 vs. 62.9%,  $p=0.212$ ) and disease duration ( $5.65 \pm 5.64$  vs.  $6.20 \pm 6.44$  years,  $p=0.653$ ). Baseline laboratory parameters, SLEDAI and glucocorticoid therapy data are shown in table 1. The frequency of previous nephritis ( $70.0 \pm 60.0\%$ ,  $p=0.312$ ), systolic blood pressure (BP) levels ( $p=0.597$ ) and diastolic BP ( $p=0.217$ ) were comparable in the two groups. Six-month laboratory parameters, SLEDAI and glucocorticoid therapy data are shown in table 2. After 6 months, Euro-lupus had a higher increase in C3 ( $p=0.038$ ) and C4 ( $p=0.046$ ) levels and a greater reduction in prednisone daily dose ( $-24.69 \pm 14.72$  vs.  $-18.43 \pm 13.97$  mg/day,  $p=0.029$ ) than MMF. Euro-lupus presented higher frequency of serious infections (22.5 vs. 7.1%,  $p=0.034$ ) than MMF.

**Conclusion:** Euro-lupus and MMF protocols were effective as induction therapy for active lupus nephritis with a comparable frequency of patients achieving the proteinuria target and in spite of worse baseline parameters in the former group. The higher frequency of serious infection in Euro-lupus group may be associated with more aggressive glucocorticoid regimen in these patients.

Table 1: Baseline laboratory parameters, SLEDAI and glucocorticoid therapy data of Euro-lupus vs. MMF

	Euro-lupus	MMF	p
Creatinine, mg/dL	$1.08 \pm 0.82$	$0.85 \pm 0.32$	0,039*
Albumin, g/dL	$3.20 \pm 0.56$	$3.35 \pm 0.59$	0.243

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Reduced corticosteroid use is considered a key goal in SLE treatment. This concept of ‘steroid-sparing’, seen with intravenous (IV) belimumab based on cumulative steroid use over 52 weeks<sup>1</sup>, was investigated in patients with SLE treated with subcutaneous (SC) belimumab.

**Methods:** This was a Phase 3, multicenter, double-blind, 52-week study (112341/NCT01484496) in adult patients with active SLE (SELENA-SLEDAI score ≥8). Patients were randomized (2:1) to weekly belimumab 200 mg SC or placebo, plus standard care (SoC). The primary endpoint was SLE Responder Index response rate at Week 52<sup>2</sup>; efficacy and safety data have been published<sup>3</sup>. Here, the effects on corticosteroid use (prednisone equivalent) are reported, evaluating multiple pre-specified measures including the proportion of patients (>7.5 mg/day at baseline) with a ≥25% reduction from baseline to ≤7.5 mg/day during Weeks 40–52 (key secondary endpoint).

**Results:** Baseline corticosteroid use was comparable between groups (belimumab, 481 [86.5%]; placebo, 241 [86.1%]), with most patients receiving >7.5 mg/day (60.2%). A numerically greater proportion of patients with baseline dose >7.5 mg/day in the belimumab group had a dose reduction of  $\geq 25\%$  to  $\leq 7.5$  mg/day during Weeks 40–52 compared with patients receiving placebo (belimumab, 18.2%; placebo, 11.9%; OR [95% CI] 1.65 [0.95, 2.84];  $p=0.0732$ ). Fewer patients in the belimumab group versus the placebo group required  $\geq 50\%$  increase (min  $\geq 5$  mg/day) in dose during Weeks 40–52 (Week 52: belimumab, 4.9%; placebo, 7.9%; OR [95% CI] 0.56 [0.31, 1.02];  $p=0.0574$ ) or any increase in corticosteroid from Weeks 20–28 and 36–52 (Week 52: belimumab, 8.1%; placebo, 13.2%; OR [95% CI] 0.55 [0.34, 0.87];  $p=0.0117$ ). The percentage of patients with  $\geq 50\%$  reduction in corticosteroid dose by Week 52 was similar in the belimumab (range: 0.2–15.2%) and placebo (range: 0–14.1%) groups. A small number of patients in each group required an increase ( $\geq 50\%$ , min  $\geq 5$  mg/day) in dose from baseline (range: belimumab 2.7–5.2%; placebo, 1.4–8.6%). Mean (SD) cumulative corticosteroid dose at Week 52 was 3933.8 mg (3660.76) in the belimumab group and 4567.3 mg (5981.53) in the placebo group; the median (IQR) was the same in both groups (3650.0 [1825–5475];  $p=0.4299$ ). Median (IQR) corticosteroid dose at baseline was 10 mg/day (IQR 5–15) in both groups; no meaningful change occurred in either group by Week 52. Mean dose at baseline was 10.8 mg/day and 11.2 mg/day in the belimumab and placebo groups, with mean changes at Week 52 of -1.76 mg and -0.03 mg, respectively. Adverse events incidence ( $\geq 1$ ) was similar (belimumab, 80.8%; placebo 84.3%).

**Conclusion:** SC belimumab decreased the need for raising corticosteroid dose during the study. Other outcomes showed trends towards a corticosteroid-sparing effect of belimumab, consistent with IV studies of belimumab.<sup>1,4</sup>

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

## Background/Purpose:

There is a pressing need for novel biologic therapies in systemic lupus erythematosus (SLE). We sought to systematically review the outcomes of recent phase 3 clinical trials of biologic therapies for SLE and lupus nephritis, and conduct a meta-analysis of steroid sparing effect in these trials.

## Methods:

A systematic review of the outcomes of phase 3 clinical trials of biologic therapies for SLE and lupus nephritis was undertaken. Studies were identified by searching the Medline (via Pubmed), EMBASE, CINAHL and SCOPUS databases, the Cochrane library, and clinicaltrials.gov. Adult human studies published in English in the last ten years (until 18 April 2017) were included. All articles that reported outcomes of phase 3, randomized, placebo-controlled clinical trials of biologic therapies for SLE or lupus nephritis were included. A random-effects meta-analysis to compare a common corticosteroid reduction endpoint in the trials of rituximab, belimumab, tabalumab and epratuzumab in SLE, was conducted.

## Results:

A total of twenty-eight studies were identified, with nine being conducted in SLE, five in lupus nephritis and the remaining fourteen being post hoc analyses of phase 3 trials in SLE. All biologic therapies trialed targeted B cells (rituximab, belimumab, tabalumab, epratuzumab, atacicept, ocrelizumab), except for abetimus sodium and abatacept. Only the three phase 3 trials of belimumab in SLE met their primary endpoints, although benefit in secondary endpoints and reduction in serological activity was often seen in the other studies. In particular, the meta-analysis (*Figure 1*) showed that most therapies (belimumab IV and SC, tabalumab and epratuzumab) had a steroid sparing effect, compared to placebo (pooled relative risk 0.76; 95% CI: 0.64, 0.91). Therapies were generally well tolerated, however, three studies were terminated prematurely due to serious side effects, and another due to discontinuation of drug supply. Several ongoing phase 3 trials of B cell and non-B cell agents are currently underway.

**Figure 1.** Meta-analysis of percentage of patients with decrease in corticosteroid dose from baseline:-

- to  $\leq 7.5$ mg/day, by  $\geq 25\%$  from baseline between weeks 40-52 (BLISS-SC, BLISS-52, BLISS-76)
- to  $\leq 7.5$ mg/day, between weeks 24-52 for  $\geq 3$  consecutive months without an increase in antimalarial or immunosuppressant therapy (ILLUMINATE-1 and -2)
- to  $\leq 10$ mg/day or  $\leq 7.5$ mg/day by week 24 (ALLEVIATE-1 and -2)
- $< 10$ mg/day between week 24-52 in addition to a major clinical response (EXPLORER)

## Conclusion:

Although almost all phase 3 clinical trials (with the exception of belimumab) have failed to meet their primary efficacy endpoint, meta-analysis shows a significant steroid sparing effect for novel biologic therapies in SLE. This highlights allowance of background steroid dose as a major methodologic consideration in the design of future SLE clinical trials.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Invasive pneumococcal disease and respiratory tract infections are both frequent and severe in patients with systemic lupus erythematosus (SLE). This study aimed to compare the immunological efficacy and safety of pneumococcal vaccination with the 23-valent polysaccharide (PPS) vaccine alone to a sequential immunization with the 7-valent pneumococcal conjugate (PnCj) vaccine followed by PPS in patients with SLE and stable disease.

#### Methods:

Multicenter randomized placebo-controlled double-blind trial: PPS vaccine alone (placebo-PPS group) or PnCj vaccine followed by PPS vaccine (PnCj-PPS group) 24 weeks later. The primary endpoint was the rate of responders at week 28 to at least 5 of the 7 serotypes (4, 6B, 9V, 14, 18C, 19F and 23F) shared by both PPS and PnCj. The response to each serotype was defined as both a two-fold increase between inclusion and week 28 of pneumococcal IgG antibody titers (ELISA) and an antibody titer  $\geq 1$   $\mu\text{g/mL}$  at week 28. Pneumococcal IgG antibodies' opsonophagocytic activity (OPA) was also assessed at baseline and at week 28, and the response to a specific serotype was defined by both  $\geq$  four-fold increase of the opsonization index (OI, defined by the serum dilution killing 50% of the bacterial inoculum) between baseline and week 28, and an OI  $\geq 8$  at week 28.

#### Results:

Twenty-five patients in the placebo-PPS group and 17 in the PnCj-PPS group were included in a modified intention-to-treat analysis. The primary endpoint was reached in 72% (18/25) in the placebo-PPS and 76% (13/17) in the PnCj-PPS group ( $p = 0.75$ ). There was no difference in the rates of responders with OPA. At week 52, 13/18 (72%) patients in the placebo-PPS group and 10/13 (77%) patients in the PnCj-PPS group ( $p=0.77$ ) that met the primary endpoint at week 28 were still responders to  $\geq 5/7$  serotypes shared by both PPS and PnCj vaccines. Nine SLE flares were reported in 6 patients (4 in the placebo-PPS and 2 in the PnCj-PPS groups respectively,  $p=0.70$ ).

#### Conclusion:

Sequential administration of PnCj vaccine followed by PPS vaccine is safe and shows short-term immunological efficacy in patients with SLE but was not superior to the PPS vaccine alone. Future studies with new vaccines and/or innovative schedule designs are warranted in order to better protect SLE patients against pneumococcal infections.

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon activation, inhibits the production of inflammatory factors by human pDCs, including IFN- $\alpha$  a major player in the pathogenesis of SLE. This 3-Part Phase 1 study evaluated the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and clinical efficacy of single and multiple ascending doses (SAD-MAD) of BIIB059 in HV and SLE subjects (NCT02106897). Comparison of PK and PD parameters between HV and SLE as well as final PK-PD results from the SAD in SLE and MAD results are presented.

### **Methods:**

In the SAD part, 12 subjects with active SLE were randomized 2:1 to receive a single IV dose level of BIIB059 (20mg/kg) or placebo. In the MAD part, HV received either 2 (Cohort 9 to 11) or 3 (Cohort 12) SC administrations of Placebo or BIIB059 20, 50 or 150mg (Cohort: 9, 10, 11) Q4W or 3 SC 300mg (Cohort 12) Q2W. Subjects with active SLE, received either 2 (Cohort 13) or 3 (Cohort 14) SC placebo or BIIB059 50 mg (Cohort 13) or 300 mg (Cohort 14). The dose levels were selected based on emerging data from the Part 1 in HV and was not to exceed the maximum tolerated dose or the highest evaluated and tolerable dose. Blood samples were obtained before and after each dose administration to characterize PK and PD (BDCA2 on pDC) relationship for BIIB059.

### **Results:**

Part 1 PK and PD results (SAD) in healthy volunteers, HV) and Part 2 PD results have been previously presented (single dose in SLE)<sup>1-2</sup>. In Part 2 of the study, following IV administration, mean  $t_{1/2}$  in SLE subjects was 18.1 days, with a mean CL of 0.251 L/day and a mean volume of distribution  $V_{ss}$  of 5.41 L. Following SC administration, in Part 3a, mean  $t_{1/2}$  in HV subjects ranged from 13.3 to 19.5 days, mean  $CL_{ss}/F$  ranged from 0.28 to 0.367 L/day and  $V_z/F$  ranged from 7.23 to 9.36 L. In Part 3b, mean  $t_{1/2}$  in SLE subjects ranged from 12.6 to 20.5 days with a mean  $CL_{ss}/F$  of 0.455 to 0.485 L/day and a mean  $V_z/F$  of 5.93 and 12.8 L. Exposure (AUC and  $C_{max}$ ) for BIIB059 increased with dose in both HV and SLE subjects. However exposure in SLE subjects was approximately 40% lower compared to HV which could not be attributed to body weight. The observed mean accumulation ratio for AUC was slightly lower in SLE subjects (2.58) compared to HV (2.66) after BIIB059 SC administration. Complete BDCA2 internalization was achieved at all dose levels, the duration of which was dose dependent, and was similar for HV and SLE subjects. Reappearance of BDCA2 on circulating pDCs occurred when serum concentrations of BIIB059 dropped to  $\sim 1$   $\mu\text{g/mL}$ . BIIB059 was generally well tolerated; the incidence of adverse events (AEs) was similar between BIIB059- and placebo-treated HV and/or SLE subjects in both SAD and MAD.

### **Conclusion:**

BIIB059 was well tolerated with an acceptable safety profile.

Exposure in SLE subjects was lower compared to HV while BDCA2 internalization was similar. Based on the Phase 1 data, BIIB059 is currently evaluated in a Phase 2 trial (NCT02847598).

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** there is no consensus on the use of Tacrolimus (TAC) in patients with SLE; clinical studies on TAC, including all the RCT, are mostly limited to patients of Asian ethnicity and hampered by significant heterogeneity. To analyze the real-life practice on the use of TAC in SLE from 3 European referral centers.

**Methods:** this is a retrospective analysis of prospectively collected data. Adult patients with SLE, according to the 1997 ACR criteria, followed at 3 European referral centers were included. For each patient, demographics, organ involvement and treatment history were collected; concomitant medications, SLEDAI, laboratory features and physician's global assessment (PGA) were collected at baseline and at 3-6-12 months after starting TAC. Renal response was defined as complete (CR) in case of 24-hour proteinuria <500 mg/dl + inactive urinary sediment + normal creatinine.

**Results:** 29 patients were included in this analysis (89% female, mean age 38±9 years, mean disease duration 12.9±6 years). Ethnicity was White (82%), Black (14.5%), Hispanic (3.5%). The main indication for TAC prescription was renal involvement (79%), joint (7%), skin (7%), hematological (7%), serositis (3.5%). The median daily dose of TAC was 4.5 mg (IQR 3-5.5). When renal involvement was the main indication, TAC was prescribed for a renal flare in 72% of cases, and for renal disease onset in the remaining cases. In 65.5% of patients, TAC was a second-choice treatment either for the failure of, or for the intolerance of a previous IS therapy. The median number of previous IS was 2 (IQR 1-3). Concomitant medications at TAC institution included GC (89.6 %; median daily dose 7.5 IQR 3.75-12.5), HCQ (67%),

MMF (30%), AZA (11%), RTX (3%), belimumab (14%). At 3 months, according to the PGA, there was a complete resolution of symptoms in 8 pts (32%), partial resolution in 11 pts (44%) and no improvement in 6 pts (24%). This corresponds to: 1) a significant decrease in the mean SLEDAI, ( $p=0.0006$ ); 2) a significant decrease in the mean 24-hour proteinuria ( $p=0.001$ ); a significant increase in C3 ( $p=0.009$ ) and stable creatinine values. In patients with renal involvement, a CR was documented in 6 pts (27.3%), a PR in 7 (31.8%) and no response in 7 (31.8%). At 6 months, the physician declared a complete resolution in 47%, a partial resolution in 29% and no improvement in 23%. The same trend was maintained at 12 months of follow-up. Four patients discontinued the therapy before 3 months. At the time of this analysis, TAC was discontinued in 9 pts (31%); reasons for discontinuation were inefficacy (13 %), drug intolerance (10%), disease remission (6.8 %) and infections (3.4 %), (table 1).

**Conclusion:** this study describes the use of TAC in a multicenter cohort of non-Asian SLE patients. Despite the limitation due to the small number of patients and the uncontrolled nature of the study, these data show that TAC can be considered a valid therapeutic option in SLE patients, especially in renal involvement.

	Baseline	3 months	6 months	12 months
N of patients tot-renal	29-23	25-17	18-17	18-16
SLEDAI (median±IQR)	8 (5.5-12)	4 (3-6)	4 (2-7)	5 (2-8)

## A Systematic Literature Mining and Gene Expression Analysis Identifies Possible Drug Candidates for Repositioning in Lupus

**Peter E. Lipsky**, Matt Ryals, Adam Labonte, Sarah Heuer, James Dittman, Michelle Catalina and Amrie Grammer, AMPEL BioSolutions and RILITE Research Institute, Charlottesville, VA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Since new therapies for lupus have been extremely slow to develop and lupus patients have a great unmet medical need, an independent pharma-external effort has been undertaken to evaluate drugs for potential use in this autoimmune disease. In addition, bioinformatic analyses of gene expression profiles were used to confirm the potential utility of identified drug candidates.

## Methods:

A comprehensive effort to, identify possible drug candidates for repositioning into lupus was initiated in 2013 by crowd-sourcing suggestions from the lupus community ([www.linkedin.com/lrx1stat](http://www.linkedin.com/lrx1stat)) in conjunction with a comprehensive effort at literature mining for information relevant to the more than 1000 compounds approved for human use by the FDA. In 2013, the evidence-based Composite Lupus Treatment Scoring (CoLTs) of each of 157 therapies considered potentially appropriate for lupus was carried out<sup>1</sup>. Since the initial evaluation, the FDA has approved > 125 new drug indications, 7 of which targeted a rheumatic disease, but none of which was approved for in lupus. Additionally, >50 drugs-in-development for other indications were identified as possible lupus treatments. All drugs were ranked by the CoLT scoring system that takes into account scientific rationale, experience in lupus mice/human cells, previous clinical experience in autoimmunity, drug properties and adverse event profile. In addition, potential utility of a drug target in SLE was gauged by bioinformatic analysis of gene expression from tissues (kidneys, skin, synovium) and the periphery (whole blood, B cells, T cells, myeloid cells) from both active and inactive patients. Microarray and RNASeq data were analyzed for differentially expressed genes compared with healthy patients and for correlations with clinical parameters.

## Results:

Of the >125 newly FDA-approved drug indications, fifty were judged to be potentially relevant for lupus and were evaluated in detail and nine were identified as high-priority candidates for repositioning including drugs targeting cellular metabolism, cell cycle checkpoints, kinases and various pathways in the immune system. Scoring of drugs-in-development added 25 high priority candidates including inhibitors of complement, HDAC, PARP, ubiquitin ligases and as well as antagonists of cell surface receptors and cytokines. In each circumstance, evidence from literature mining was confirmed by gene expression analysis.

## Conclusion:

Independently scoring the properties of newly approved drugs and potential drug targets has not only identified unique candidates that could be useful in lupus and possibly other autoimmune/inflammatory conditions, but has also yielded a rigorous evidence-based process by which therapies can be objectively rated for possible clinical application to treat these conditions, thereby mitigating risk in drug development.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tuberculosis (TB) has been reported to occur at a higher rate in SLE patients than in the general population. As a result, most clinical trials of new therapeutic agents in SLE seek to exclude patients with untreated latent or active TB. Unfortunately, there is no gold standard test for the detection of latent TB infection (LTBI). Interferon gamma release assays (IGRAs) are potentially confounded by underlying immunologic impairments, e.g., lymphopenia, immunosuppressant use and disease activity, which can lead to indeterminate (IND) results even in the presence of LTBI. There can also be technical error impacting the results. A common resolution to resolve IND results involves repeat testing. In this post hoc analysis, we sought to evaluate the utility of the QuantiFERON-TB GOLD test (QFT) and repeat testing for IND results in the screening of patients entering an SLE clinical trial.

**Methods:** Patients with active SLE who had signed informed consent to enter the Phase IIb ADDRESS II study (NCT01972568) with no prior history of TB infection were evaluated for LTBI either locally via IGRA or TB skin test; or QFT centrally. Data for those who received centralized QFT were evaluated. Patients with a positive (POS) QFT result were excluded from trial participation. Patients with an IND QFT result were to be retested: only if negative (NEG) on retest was a patient eligible for inclusion.

**Results:** Ninety-nine patients from sites in Bulgaria, Chile, Germany, Poland, Russia and the United Kingdom received QFT centrally. Of these, 84 (84.8%) had a NEG QFT, 8 (8.1%) were POS and 7 (7.1%) were IND on the initial test (Table). Nine patients with an initial NEG result underwent repeat testing for various reasons, and all remained NEG. Of the 7 patients who were initially IND: 2 were IND on repeat testing; 1 had no repeat result since screen failed; 1 was NEG based on a repeat QFT performed locally, and 3 were NEG on repeat QFT centrally. Three of the 4 patients NEG on repeat QFT were enrolled. Even if meeting exclusion criterion for LTBI, patients were often screen failed for another reason, minimizing the impact of the exclusion criterion on overall enrollment. No patients developed TB during the study. In those patients who had IND results, the absolute lymphocyte count was numerically lower with a higher percentage of patients having lymphocyte counts below the lower limit of normal, than in those with POS or NEG results (p-values by t-test > 0.05).

	Initial screening QFT results			Repeat QFT indeterminate
	Negative	Positive	Indeterminate	
	(n=84)	(n=8)	(n=7)	(n=2)
Age, mean $\pm$ SD, y	44.1 $\pm$ 12.56	48.6 $\pm$ 8.72	43.6 $\pm$ 10.20	51 $\pm$ 9.90
Females, n (%)	79 (94.0)	8 (100.0)	6 (85.7)	1 (50.0)
Lymphocyte count*, mean $\pm$ SD, $\times 10^3/\mu\text{L}$ (n)	1.46 $\pm$ 0.747 (82)	1.73 $\pm$ 0.863 (8)	1.09 $\pm$ 0.546 (7)	0.65 $\pm$ 0.057 (2)
Lymphocyte count below normal limits*, n (%)	23 (28.0)	1 (12.5)	4 (57.1)	2 (100.0)
Screen failed for LTBI, n (%)	0 (0.0)	3 (37.5)	1 (14.3)	1 (50.0)
Enrolled, n (%)	39 (46.4)	0 (0.0)	3 (42.9)	0 (0.0)
* Normal range 1.02 – 3.36 $\times 10^3/\mu\text{L}$				

**Conclusion:** In our study, repeat IND QFT results for TB occurred infrequently. Consistent with previous reports, low lymphocyte counts may contribute to generation of IND results. Limitations of evaluating only screening data include not being able to evaluate the impact of disease activity or immunosuppressants on the QFT results. As only 2 of 99 patients had IND results twice, excluding patients on this basis should be considered a viable approach to confirm eligibility for a clinical trial in SLE.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fatigue and arthritis are common sources of impairment in SLE patients that persist despite lifestyle and pharmacologic interventions. *Walk with Ease (WWE)* is the Arthritis Foundation's 6-week evidence-based walking program developed for adults with arthritis that has been shown to improve physical function, pain, stiffness and fatigue in individuals with arthritis. *WWE* is offered in two formats – group (instructor led) or self-directed. The goal of this study was to examine the feasibility of self-directed *WWE* in SLE patients.

**Methods:** In an interim analysis, pre- and post-6 week evaluation with no usual care comparison group was conducted in 48 patients with SLE in North Carolina. Self-reported outcomes including symptoms (pain, stiffness and fatigue visual analog scales [VAS]) and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-fatigue) scale were evaluated. Means and effect sizes (ES) with 95% confidence intervals were computed for changes in symptoms between baseline and 6 weeks, adjusted for gender, age, race, and baseline outcome. Participant satisfaction measures with *WWE* are reported as percentages.

**Results:** Two participants were screen failures, 29 participants completed the *WWE* program at the time of analysis, 7 discontinued the study and 6 were lost to follow-up. There were no statistically significant differences between those who did not complete the study and those who did. Participants were mainly women (90%), aged  $\geq 40$  years, self-identified as black (48%) and 11 years from initial SLE diagnosis. Three participants also had a physician diagnosis of OA, while four participants had concurrent fibromyalgia. At the end of 6 weeks, participants reported having reduced FACIT-fatigue scores (ES=0.33), and having less VAS pain, stiffness and fatigue (ES=0.42, 0.24 and 0.10, respectively). Most participants reported walking for at least 30 minutes/day (46%),  $\geq 3$  days/week (89%) and utilized the workbook for motivation (74%). Participants also reported increased physical activity (86%), confidence to continue exercising (100%) and satisfaction from the program (97%).

**Conclusion:** *WWE* is a feasible, low-cost program that may decrease SLE-related fatigue, pain and stiffness, improve activity and promote long-term lifestyle changes.

Table: Effect Sizes and means (SD) for overall effectiveness of WWE from baseline and follow-up

Outcome Measures	Baseline Mean(SD)	Follow-up Mean(SD)	Effect Size
FACT-Fatigue	27 (17)	22 (18)	0.33
VAS-Fatigue	55 (16)	31 (16)	0.42
VAS-Pain	45 (15)	36 (16)	0.24
VAS-Stiffness	45 (17)	41 (12)	0.3

Graph: Patient-reported characteristics of WWE program

## Disparities in Antimalarial Prescribing for Systemic Lupus Erythematosus Using a Real-World, Electronic Health Record

**J.B. Boone**, Wendy Xiong, Cecilia P. Chung, Leslie Crofford and April Barnado, Medicine, Vanderbilt University Medical Center, Nashville, TN

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antimalarials (AMs) reduce disease activity and improve survival in patients with systemic lupus erythematosus (SLE) and are recommended regardless of disease severity. Prior studies using mostly patient self-reported medication data showed that AMs are not universally prescribed. Using a real-world electronic health record (EHR) cohort, we investigated if patient or prescriber characteristics impacted AM prescribing frequency in SLE.

**Methods:** We identified potential SLE cases from a de-identified EHR with over 2.8 million subjects using a previously validated and published algorithm. A subject was a case if diagnosed with SLE by a specialist (rheumatologist, dermatologist, or nephrologist). Subjects excluded had alternative autoimmune diagnoses (i.e. cutaneous or drug-induced lupus), uncertainty in diagnosis, or missing notes. On chart review, we collected current age at time of analysis, sex, race, presence of SLE nephritis, and specialist managing SLE. SLE nephritis was defined as a positive renal biopsy or clinical diagnosis by a specialist. We assessed for ever use of AMs from inpatient and outpatient electronic prescribing and natural language processing that searched for medications in clinic notes and phone messages. We evaluated for

differences in SLE cases prescribed AMs vs. those not prescribed using the Mann-Whitney U test for continuous variables and chi-square or Fisher's exact test for categorical variables.

**Results:** We identified 566 cases confirmed on chart review. The SLE cases had a mean current age of  $50 \pm 18$  years and were predominantly female (89%) with race breakdown of 63% Caucasian, 30% African American, 5% Hispanic, and 2% Asian. Of the 566 cases, 534 (94%) patients were ever prescribed an AM. Of the 32 (6%) patients not prescribed an AM, no contraindications were found on chart review. There were no differences in sex or race between SLE cases prescribed AMs vs. cases who were not (Table 1). SLE cases prescribed AMs were younger compared to cases not prescribed AMs ( $49 \pm 18$  vs.  $57 \pm 21$ ,  $p = 0.05$ ). SLE cases who primarily saw a nephrologist were less likely to have AMs prescribed compared to cases who saw a rheumatologist or dermatologist (64% vs. 98% vs. 100%,  $p < 0.001$ ). SLE nephritis cases trended towards having less AMs prescribed compared to cases without nephritis (91% vs. 95%,  $p = 0.06$ ).

**Conclusion:** Using a large EHR cohort, we found 94% of SLE patients were ever prescribed an AM. Our high rate of AM prescribing compared to prior studies suggests that prescribing AMs is becoming more standard practice. SLE patients that were older, primarily followed with a nephrologist, and had nephritis were less likely to have AMs prescribed. Recognizing prescribing practices for AMs in SLE can target future quality improvement efforts.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although existing evidence demonstrates the efficacy of antimalarials for rheumatic skin disease, the safety of these medications, and particularly quinacrine, remain debated. Quinacrine may soon become increasingly difficult to prescribe as a result of these concerns. We investigate the toxicity risk associated with various antimalarial combinations in rheumatic skin disease patients.

**Methods:** 532 patients (mean age=52.29 years, female=85.15%, male=14.85%) were selected from two ongoing databases of cutaneous lupus erythematosus (69.92%) and dermatomyositis (30.08%). Details regarding antimalarial treatment and toxicities were extracted and five different treatment courses were defined [i.e., hydroxychloroquine, chloroquine, and quinacrine monotherapies, as well as hydroxychloroquine+quinacrine and chloroquine+quinacrine combinations]. The hazard ratio of each major toxicity on the five different treatment courses was estimated using the Cox proportional hazard model to compare the risk associated with each type of treatment to that of hydroxychloroquine.

### Results:

Over 90% of patients had a history of hydroxychloroquine, and nearly half (42.9%) had a history of hydroxychloroquine+quinacrine. Only 21.3% of patients had a history of chloroquine either as monotherapy (11.1%) or as chloroquine+quinacrine combination (10.2%). Over half of the patients had a history of quinacrine, usually in combination with hydroxychloroquine or chloroquine, but also as monotherapy (11.8%).

The most prevalent side effects included cutaneous eruption (n=61), gastrointestinal upset (n=38), mucocutaneous dyspigmentation (n=26), neurologic toxicities [i.e., including dizziness and headache (n=10), ototoxicity (n=5), sleep disturbances (n=5), mental fog (n=5), peripheral neuropathy (n=4), tremors (n=2), and psychosis (n=1)], and retinopathy (n=17). Compared to hydroxychloroquine, the hazards of cutaneous eruption, gastrointestinal upset, and neurologic toxicities were lower with hydroxychloroquine+quinacrine. However, based on a post-hoc analysis, this may represent the selection of patients able to tolerate hydroxychloroquine in the cohort of those who received hydroxychloroquine+quinacrine. Although there was increased risk of retinopathy with chloroquine and chloroquine+quinacrine relative to hydroxychloroquine, ophthalmic toxicity was not seen with quinacrine (Table I).

**Conclusion:** Our study provides evidence that the safety profile of quinacrine is comparable to that of first-line hydroxychloroquine and that quinacrine has an advantage over hydroxychloroquine and chloroquine for patients at risk of retinopathy. Furthermore, adding quinacrine to hydroxychloroquine or chloroquine does not increase the risk of toxicities, and limiting access to quinacrine may leave patients without alternatives to this safe drug.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

◇**Background/Purpose:** Hydroxychloroquine (HCQ) is a cornerstone of systemic lupus erythematosus (SLE) care. The major long-term adverse event risk is vision-threatening toxic retinopathy. The 2012 EULAR, 2009 Royal College of Ophthalmology, and 2011 American Academy of Ophthalmology (AAO) guidelines recommended a maximum dosing of the lower of 6.5mg/kg/day of ideal body weight (IBW) or 400 mg daily to minimize the risk of retinopathy, whereas the 2016 AAO guidelines revised this to a maximum of 5mg/kg/day of actual body weight (ABW). We assessed the trend of HCQ prescribing patterns for treating SLE in relation to these dosing guidelines over the past two decades in a general population context. Furthermore, we examined associations with purported risk factors of HCQ retinopathy.

**Methods:** Using a United Kingdom general population database, we conducted an incident user study of adult SLE patients, identified by Read codes, who initiated HCQ between January 1, 1996 and December 31, 2015. We examined the secular trend of the proportion of initial prescribed HCQ doses exceeding 6.5mg/kg/day IBW as well as 5mg/kg/day ABW and assessed whether excess doses according to these guidelines varied by age, sex, body mass index (BMI; lean, overweight, and obese), and chronic kidney disease (CKD; defined by a eGFR <60).

**Results:** Of 2741 SLE patients who initiated HCQ over this 20-year period, 36.2% of the prescribed doses were > 6.5mg/kg/day IBW, and 38.12% were > 5mg/kg/day ABW. There was no significant change in the rate of initial excess dosing over time for either dose cut-off (p for trends=0.09 and 0.25, respectively) (**Table 1**). Women had an increased risk of excess initial dosing compared with men, with OR=12.28 (95% CI, 7.46-20.23) for IBW and 2.00 (95% CI, 1.50-2.66) for ABW dose recommendations. Obesity was associated with a lower risk of excess HCQ dosing using ABW (OR 0.14 for obese vs. lean (95% CI, 0.10-0.18), and a higher risk of excess dosing using IBW (OR 1.30 [95% CI, 1.06-1.59]). Age had no effect on the risk of excess HCQ dosing according to either recommendation (OR 1.11; 95% CI, 0.93-1.32 for IBW, and OR=1.07, 95% CI, 0.89-1.27 for ABW). For the subgroup with available eGFR data (n=657), CKD was associated with an increased risk of excess dosing per ABW (OR 1.85, 95% CI, 1.02-3.37) after adjusting for BMI.

**Conclusion:** In this general population-based study, over one-third of SLE patients were initiated on HCQ doses exceeding both dosing guidelines, and these rates have not changed over the past two decades. This rate of excess dosing is strikingly higher among women. Obesity posed opposing risk of excess dosing between the two weight-based dosing guidelines. Furthermore, excess dosing is also higher amongst CKD patients per the recent ABW-based guidelines. These findings highlight the potential need to improve excess HCQ dosing, and call for unifying, robust, and evidence-based recommendations.

# Non-Pharmacological Treatment on Fatigue, Depression, Disease Activity, and Quality of Life of Systemic Lupus Erythematosus: A Systematic Review

Monthida Fangtham<sup>1</sup>, Jacob Louis Nash<sup>2</sup>, Stephanie Hyon<sup>3</sup>, Raveendhara R. Bannuru<sup>4</sup> and Chenchen Wang<sup>3</sup>,

<sup>1</sup>Internal Medicine, University of New Mexico, Albuquerque, NM, <sup>2</sup>Health Sciences Library and Informatics Center, University of New Mexico, Albuquerque, NM, <sup>3</sup>Rheumatology, Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA, Boston, MA, <sup>4</sup>Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In recent years, non-pharmacological therapies have been deemed as potentially beneficial for patients with systemic lupus erythematosus (SLE). These include complementary and integrative approaches, physical and psychological interventions. We conducted the systematic review to determine the effects of these therapies to inform practice in SLE patients.

**Methods:** Literature search was performed using PubMed (MEDLINE), EMBASE, Cochrane, PsychINFO, CINAHL, Web of Science, and Google Scholar until March 2017. We included any randomized controlled trials (RCTs) of non-pharmacologic interventions in SLE patients with sample size > 10 and measuring outcomes including fatigue, depression, disease activity, and quality of life. SLE was defined by 1982 or 1997 ACR criteria in all studies. Articles in both English and Chinese were included. Due to the heterogeneity of interventions and comparisons, a meta-analysis was not performed.

**Results:** Nine RCT studies totaling 651 participants met the inclusion criteria and were included in this review. SLE disease duration ranged between 2.5 to 12 years, mean age ranged from 13 to 48 years, and 96% were female. **Table 1** summarizes the randomized controlled trials evaluating the effects of non-pharmacological treatment in patients with SLE. Of the 9 trials, 4 used exercise interventions, 4 used psychological interventions (1 group psychotherapy, 2 cognitive behavioral therapies, 1 psychoeducation intervention) and 1 used electro-acupuncture. Three of 9 studies utilized control groups consisting of usual medical care. Other studies included control interventions of relaxation, attention placebo, symptom monitoring support, minimal needling, and isotonic and resistance exercise. Compared with the control conditions, non-pharmacological interventions were associated with a significant improvement in fatigue in 3 out of 4 studies (1 exercise, 1 psychological and 1 acupuncture intervention). Four studies reported improvement in overall quality of life as measured by SF-36, compared to control. Two out of six studies also reported improved anxiety and depression, and 3 studies improved pain after interventions. However, one psychotherapy study did not find any clinically important improvement in psychological distress, disease activity, and quality of life compared to usual care. Also, no studies demonstrated a greater improvement in disease activity with 6-20 weeks of non-pharmacological interventions.

**Table 1. Non-pharmacological Treatment on Fatigue, Depression, Disease Activity and Quality of Life of SLE**

Author, Yr Country	N	Intervention	Control	Outcomes Measure	Duration (Weeks)	Results
Tench 2003, UK	93	Home exercise (walking, cycling, swimming), 30-50 min x 3 times/wk, x 12 weeks	1. Relaxation audiotape, 30 min x 3 times/wk + supervised relaxation session q 2 wk x 12 wks  2. Usual medical care	- Fatigue (Chalder Fatigue Scale)  - Depression, anxiety (HADS)  - Disease activity (SLAM)  - Quality of Life (SF- 36)	12	- Greater improvement in fatigue (P=0.04) for exercise than relaxation or usual medical care  - No improvement in depression and anxiety, disease activity, quality of life, between 2 exercise groups
Bogdanovic 2015, Serbia	60	Aerobic exercise, 15 min x 3 times/wk x 6 weeks	Isotonic exercises, 30 min x 3 times/wk x 6 weeks	- Fatigue (FSS)  - Depression (BDI)  - Quality of Life (SF- 36)	6	- No significant difference in fatigue  - No significant difference in depression between 2 exercise groups  - Improvement in Quality of Life (P<0.05)
Abrahão  2016, Brazil	63	Cardiovascular exercise (CT), 50 min x 3 times/wk x 12 weeks	1. Resistance exercise (RT), 50 min x 3 times/wk x 12 weeks  2. Usual medical care	- Depression (BDI)  - Disease Activity (SLEDAI)  - Quality of Life (SF- 36)  - Aerobic Capacity	12	- No significant different in depression or disease activity between groups  - Improvement in Quality of Life in CT and RT groups (P<0.05)  - Improvement in aerobic capacity in CT and RT groups (P<0.05)
Prado 2013, Brazil	19	Supervised Aerobic exercise, 30-60 min 2x weekly x 12 weeks	Usual medical care	- Disease activity (SLEDAI-2K)  - Exercise tolerance	12	- No change in disease activity  - Improvement in exercise tolerance (P<0.05)
Karlson  2004, USA	122	Psychoeducational intervention 1 time, followed by a phone call once a month x 5 months	Attention Placebo + Video presentation about lupus, 45 min once	- Fatigue  - Disease activity (SLAQ, SLAM)  - Quality of Life (SF- 36)  - Self efficacy	20	- Reduction in fatigue score in experimental group (P<0.05)  - No improvement in disease activity  - Improvement in quality of life (P=0.03), global mental health status (P=0.03), and self-efficacy (P=0.004)
Dobkin  2002, Canada	133	Group psychotherapy, 90 mins x weekly x 3 months + booster session, 1	Usual medical care	- Psychological symptoms (SCL-90- R)  - Disease activity (SLAM-R)	12	- No significant group differences in psychological symptoms, disease activity, and quality of life

		time/month x 3 months		- Quality of life (SF-36)		
Greco 2004, USA	92	Biofeedback-assisted/Cognitive-behavioral therapy + relaxation techniques (BF/CBT), 6 sessions x 3 months	1. Symptom monitoring support intervention (SMS)  2. Usual medical care	- Psychological Functioning (CES-D, STRESS, ASES)  - Disease Activity (SLEDAI, SLAM-R)  - Quality of life: Physical function (SF-36-PF)  - Pain (AIMS2-pain)	12	- Greater improvement for BF/CBT in long-term psychological function (P=0.02)  - No improvement in disease activity in all groups (P>0.05)  - Greater improvement for BF/CBT in physical function (SF-36-PF) (P<0.05) and pain reduction (P=0.04)
Navarrete 2010, Spain	45	Cognitive-behavioral therapy + relaxation techniques + social skill training, 120 min/wk x 10 weeks	Usual medical care	- Psychological parameters (SVI, BDI, Anxiety Spielberger's STAI)  - Disease activity (SLEDAI)  - Quality of Life (SF-36)	10	- Improvement in stress (P<0.04), depression (P<0.002) and anxiety (P<0.001)  - No improvement in disease activity  - Improvement in SF-36 scales (P<0.05) including physical role (P<0.05), pain (P<0.013), social function (P<0.04), mental health (P<0.02), general health (P<0.05)
Greco 2008, USA	24	Electrical Acupuncture 10 sessions x 5 wks 30 min/session	1. Minimal needling, 10 sessions x 2 times over 5 wks  2. Usual medical care	- Fatigue (FSS)  - Disease activity (SLAM-R)  - Pain (AIMS2-pain, MPI, SF-36 body pain)	5	- Both acupuncture and needling improvement in fatigue compared to usual care  - No improvement in disease activity  - Both acupuncture and needling improvement in pain compared to usual care

CFS = Chalder Fatigue Scale; HADS = Hospital Anxiety and Depression Scale; SLAM = Systemic Lupus Activity Measure; SF-36 = Short-Form Health Survey; FSS = Fatigue Severity Score; BDI = Beck Depression Inventory; SLEDAI = The Systemic Lupus Erythematosus Disease Activity Index; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000; SLAQ = Systemic lupus activity questionnaire for population studies; SCL-90-R = The Symptom Checklist 90-Revised; SLAM-R = The Systemic Lupus Activity Measure-Revised (SLAM-R); CES-D = The Center for Epidemiological Studies Depression scale (CES-D); STRESS = Cohen's Perceived Stress Scale; ASES = Arthritis Self-Efficacy Scale; AIMS2-pain = The Revised Arthritis Impact Measurement Scales; SVI = Stress Vulnerability Inventory; STAI = Spielberger's State-Trait Anxiety Inventory; MPI = Multidimensional Pain Inventory

**Conclusion:** The review showed promising results for physical exercise and psychological interventions as an adjunct to traditional medical therapy for improvement in fatigue and quality of life. However, many studies had small sample sizes and short intervention durations. Further high-quality RCTs with longer follow-up periods are warranted.

## Mesenchymal Stem Cells Induce CD1c<sup>+</sup> Tolerogenic Dendritic Cells Via up-Regulating FLT3L in Systemic Lupus Erythematosus

Xinran Yuan<sup>1</sup>, Dandan Wang<sup>2</sup> and Lingyun Sun<sup>3</sup>, <sup>1</sup>Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, <sup>2</sup>Department of Rheumatology and immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, <sup>3</sup>Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital, Nanjing University Medical School, nanjing, China

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several tolerogenic dendritic cell (DC) subsets have been identified in human such as CD1c<sup>+</sup> DCs, which could be elevated by injection of Flt-3 ligand (FLT3L). CD1c<sup>+</sup> tolerogenic DCs play important roles in the induction of peripheral tolerance and control of adaptive immune response, hence, they have become appealing targets in the treatment of systemic lupus erythematosus (SLE). Umbilical cord (UC)-derived mesenchymal stem cells (MSCs) also exhibit immunoregulatory effects in SLE. However, the underlying immunosuppression mechanism of MSCs via tolerogenic DCs in SLE remains largely unknown. The aim of this study is to examine tolerogenic DCs levels in SLE patients, and to further investigate the mechanism of MSCs in the regulation of tolerogenic DCs.

**Methods:** Tolerogenic DCs were isolated as Lin(CD3/19/56/14)<sup>-</sup> HLA DR<sup>+</sup>CD11c<sup>+</sup>CD1c<sup>+</sup> from peripheral blood mononuclear cells (PBMCs). Level of tolerogenic DCs was determined by flow cytometry, and serum concentration of FLT3L was assessed by ELISA from 17 healthy controls and 25 SLE patients. Eight SLE patients were given UC MSCs infusions. We compared the levels of tolerogenic DCs and serum FLT3L before and 24 hours after UC MSCs transplantation. PBMCs from 8 patients were collected and co-cultured with UC MSCs at ratios of 1:1, 10:1 and 50:1, for 24 hours, 48 hours and 72 hours, respectively, to detect the level of tolerogenic DCs. The level of FLT3L in the supernatant solution was analyzed. FLT3L siRNA was added to the co-culture system, and the level of tolerogenic DCs was detected.

**Results:** The levels of peripheral CD1c<sup>+</sup> DCs and serum FLT3L were significantly decreased in SLE patients compared to healthy controls. Moreover, the level of CD1c<sup>+</sup> DCs was remarkably negatively correlated with SLE disease activity index (SLEDAI) scores. After UC MSCs transplantation, the level of CD1c<sup>+</sup> DCs increased, along with an increase in serum FLT3L. In vitro studies showed that UC MSCs time-dependently up-regulated peripheral CD1c<sup>+</sup> DCs, but not dose-dependently. The supernatant FLT3L level significantly increased after co-cultured with MSCs. However, the addition of FLT3L siRNA significantly abrogated the up-regulation of CD1c<sup>+</sup> DCs by MSCs, which could be reversed by adding extra FLT3L to the co-culture system.

**Conclusion:** UC MSCs induce CD1c<sup>+</sup> tolerogenic DCs through up-regulating FLT3L in lupus patients.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Anti-malarials (AM), such as hydroxychloroquine (HCQ) and chloroquine (CQ), have long been used for the treatment of systemic lupus erythematosus (SLE). However, despite their general safety, both drugs have the potential to cause serious toxicity. These drugs have significant lysosomal affinity and induce the prominent development of autophagic vacuoles in several tissues. Cardiotoxicity with potential conduction/structural abnormalities on electrocardiogram (ECG) have been reported with AM. We aimed to study whether cumulative AM is associated with ECG abnormalities.

### **Methods:**

A standard resting supine ECG was performed on consecutive patients attending the Lupus Clinic since 2012. ECGs were analyzed and tracings were coded by a single cardiologist blinded to identifying data and previous AM exposure on the basis of the Minnesota criteria. ECG abnormalities were grouped into structural [left ventricular hypertrophy or atrial enlargement] and conduction abnormalities [prolonged corrected QT interval (QTc), short PR interval, left bundle branch block (LBBB), right bundle branch block (RBBB) and atrioventricular block (AVB), bradycardia, tachycardia, premature atrial complex, ectopic atrial rhythm, atrial fibrillation, premature ventricular complex and ventricular bigeminy].

Clinical and laboratory variables from the baseline (corresponds to the ECG visit) were studied as potential factors associated with ECG abnormalities. Associations between cumulative AM [calculated after equating 3.0 mg of CQ with 6.5 mg of HCQ] and ECG abnormalities (structural or conduction) were assessed using logistic regression analysis (after adjusting for baseline patient characteristics) and in a nested case control study (1:3) [matching for sex, SLE duration at ECG within 5 years, ECG testing year within 5 years and hypertension status].

### **Results:**

Of 453 patients treated with AM, the median cumulative AM was 1207 grams at ECG. The mean age at ECG was  $49.2 \pm 13.8$  years and SLE duration was  $19.8 \pm 10.4$  years. CQ or HCQ had been used by 409 (90.3%) before the ECG.

Conduction abnormalities were more prevalent than structural abnormalities, 71 (15.7%) vs. 58 (12.8%). AM cumulative dose did not show a statistical significant association with ECG structural abnormalities, (OR 1.82,  $p=0.07$ ) while it was

protective for conduction ECG abnormalities (OR 0.42, p=0.006) (table 1).

The nested case control analysis also found that AM cumulative dose is protective against conduction ECG abnormalities (OR 0.36; 95% CI: 0.17-0.75; p=0.007). SLE duration was a risk factor for both structural and conduction ECG abnormalities.

### Conclusion:

This study suggests an association between cumulative AM dose above the median (1207 g) and structural ECG abnormalities. More importantly, cumulative AM decreases the odds of ECG conduction abnormalities.

<b>Table 1: Multivariable logistic regression analysis for structural or conduction abnormalities</b>			
<b>ECG Abnormality</b>	<b>Variables</b>	<b>OR 95% CI</b>	<b>p value</b>
ECG structural abnormality	SLE duration at ECG test (years)	1.03 (1.004, 1.06)	0.0248
	Hypertension vs. normotension	2.21 (0.98, 4.99)	0.0567
	eGFR at ECG (each 10 mL/min/1.73 m <sup>2</sup> )	0.83 (0.76, 0.92)	0.0002
	Cumulative AM dose prior to ECG higher than median dose (1207 grams)	1.82 (0.95, 3.47)	0.0707
ECG conduction abnormality	SLE duration at ECG test	1.03 (1.01, 1.06)	0.0080
	Hypertension	1.66 (0.85, 3.25)	0.1357
	Pulmonary hypertension	2.37 (0.82, 6.80)	0.1090
	Treatment with N-CCB or beta-blockers	2.75 (1.42, 5.33)	0.0026
	Cumulative prednisone 3 years before ECG (each 100 grams)	1.05 (1.01, 1.09)	0.0147
	Cumulative AM prior to ECG higher than median dose (1207 grams)	0.42 (0.22, 0.77)	0.0057

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although previous SLE treatment guidelines recommended judicious use of antimalarials, there is a growing body of evidence demonstrating that HCQ prevents flares, protects against irreversible organ damage, and increases long-term survival in SLE patients. As a result, there has been a paradigm shift: current guidelines recommend treatment with HCQ for all patients with SLE unless there are specific contraindications. Nonetheless, the rates of HCQ use in many SLE cohorts remain at 65% or less. We reviewed a large, diverse cohort of SLE patients at an academic center in order to identify reasons why many SLE patients are not on HCQ.

**Methods:** A retrospective chart review was conducted of patients in our longitudinal SLE cohort. There were 287 SLE patients reviewed at baseline (2004-2006), 229 at first follow-up (2008-2010), and 102 at second follow-up (2015-present). Active medications were recorded at each time point as well as the primary reason for HCQ non-use when applicable. SLICC Damage Index (SDI) was measured at baseline.

**Results:** 67% of patients in our cohort were taking HCQ at baseline, 66.8% at first follow-up, and 73.5% at second follow-up (p=NS). Overall, patient preference (43%) was the most common reason for HCQ non-use, followed by physician preference (21%) and allergy/side effects (11%). Although less than 2% of patients had documented eye toxicity as a reason for HCQ discontinuation at baseline and first follow-up, this increased to 9.8% at second follow-up (p=0.001).

We compared SDI at baseline among patients who were actively taking HCQ (n=194), those who had never taken HCQ (n=52), and those who discontinued HCQ for any reason (n=41). We found evidence of SLE-related damage (SDI  $\geq 1$ ) in 54.6% of patients on HCQ, 75.6% of HCQ never users and 78.8% of former users (p=0.001 by Chi-squared analysis).

**Conclusion:** Although the rate of HCQ use in our longitudinal SLE cohort has remained stable, the percentage of patients who discontinued HCQ due to eye-related toxicity has increased. Further studies are required to determine whether this increase in eye-related toxicity can be attributed solely to cumulative HCQ dose, or whether adherence to ophthalmology guidelines and availability of more sensitive testing modalities has led to earlier and more frequent detection. Our data also demonstrate that rates of damage accumulation are comparable between HCQ never and former users and lowest in patients taking HCQ, which reinforces the importance of consistent HCQ use in SLE. This study elucidates an important disconnect between current evidence and clinical practice. Quality improvement initiatives are needed to address this discrepancy in an effort to improve patient outcomes.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is an autoimmune systemic rheumatic disease that, in our area, presents hematologic manifestations in approximately 70% of cases<sup>1</sup>. Some of them are very rare so there are no large series whose analysis could provide relevant information.\_

**Objectives:** To study the characteristics of patients with Hemophagocytic Syndrome (HS) in a large sample of SLE patients.

**Methods:** SLE patients from RELESSER database were studied. We analysed the SLE manifestations present at 12 different domains (mucocutaneous, renal, musculoskeletal, constitutional, hematologic, vascular, cardiac, respiratory, neuropsychiatric, gastrointestinal, ophthalmic and serological) before, during and after HS diagnosis and until the last available assessment. We also studied activity (SELENA-SLEDAI) and damage (SLICC/ACR DI) indices in each of those moments. We evaluated the treatment received, HS recurrences and the number of deaths by this entity.\_

**Results:** 3,656 patients from 45 Rheumatology Units across Spain were studied. Seven patients with SLE and HS were identified. 71.4% were women, with a mean age ( $\pm$  S.D.) at the diagnosis of SH of 35.1 ( $\pm$  17.1) years. In 5 of the 7 cases the HS occurred 115.5 ( $\pm$  162.9) months after the diagnosis of SLE. In the remaining 2 cases the diagnosis of both entities was simultaneous. The main triggers of HS were infections, followed by SLE activity flares. At the time of HS diagnosis, they had high SLE activity with a mean SLEDAI score of 13.1 ( $\pm$  11.3) and 1.4 ( $\pm$  2.3) SDI scores. Clinically, 100% of the patients presented fever and alterations of the liver profile, 85.8% cytopenias and 71.5% dermatological manifestations. Respiratory manifestations and hemolytic anemia were present in 57.2% of the cases. Lymph nodes and coagulopathy in 42.9%. Hepatomegaly was detected in 28.6%, as well as neuropsychiatric, digestive and renal manifestations. Splenomegaly was detected in 14.3%. The mean hemoglobin level was 8.6 ( $\pm$  1.1) g / dl, platelets 85,585 ( $\pm$  83,390), ferritin 7,410 ( $\pm$  6,470) ng / ml and triglycerides 404.7 ( $\pm$  235.6) mg/dl. All patients underwent a bone marrow study. All patients were admitted. They required an average of 2.2 ( $\pm$  1.5) treatment lines, using 2.8 ( $\pm$  1.7) drugs. One patient died during the HS episode and another 2 patients had 2 and 3 recurrences respectively.

The following table shows the characteristics of each patient.

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6	Patient 7
<b>Number of organ systems affected by SLE before HS diagnosis</b>	9	4	5	5	6	Simultaneous diagnosis of SLE and SH	Simultaneous diagnosis of SLE and SH
<b>Number of organ systems affected by SLE at HS diagnosis</b>	4	1	2	4	2	4	3
<b>Number of organ systems affected by SLE until last assessment</b>	Died	2	2	Follow-up lost	1	5	1
<b>SLEDAI//SLICC-ACR DI at HS diagnosis</b>	4//6	4//0	5//0	29//3	4//1	25//0	21//0

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Whether a repeat renal biopsy is helpful during lupus nephritis (LN) flares remains debatable. Our objective was to analyze the clinical utility of repeat renal biopsy in this complex situation.

**Methods:** From a total of 190 patients with LN treated between 1988 and 2014 at Bellvitge University Hospital (Barcelona, Spain), we selected for analysis 54 patients with two or more renal biopsies. Renal biopsy was repeated only on the basis of one of these clinical indications: 1) increase, persistence, or recurrence of proteinuria, nephrotic syndrome, or active urinary sediment (hematuria and/or cellular casts), or 2) increase in serum creatinine level or unexplained progression to renal failure. This study did not include patients with protocol biopsies performed to evaluate the response to therapy.

Additionally, we reviewed 686 well-documented similar cases previously reported (PubMed 1990-2016).

**Results:** The analysis of all patients reviewed showed that histological transformations are common during a LN flare, ranging from 40% to 76% of cases. However, the prevalence of transformations and the clinical value of repeat biopsy vary when they are analyzed according to proliferative or non-proliferative lesions.

The great majority of patients with class II (78% in our series and 77.5% in the literature review) progressed to a higher grade of nephritis (classes III, IV or V), resulting in worse renal prognosis. The frequency of pathological conversion in class V is lower (33% and 43%, respectively) but equally clinically relevant, since almost all cases switched to a proliferative class. Therefore, repeat biopsy is highly advisable in patients with non-proliferative LN at baseline biopsy, because these patients have a reasonable likelihood of switch to a proliferative LN that may require more aggressive immunosuppression.

In contrast, the majority of patients (82% and 73%) with proliferative classes in the reference biopsy (III, IV or mixed III/IV + V), remained into proliferative classes on repeat biopsy. Although rebiopsy in this group does not seem as necessary, it is still advisable since it will allow us to identify the 18% to 20% of patients that switch to a non-proliferative class. In addition, consistent with the reported clinical experience, repeat biopsy might also be helpful to identify selected cases with clear progression of proliferative lesions despite the initial treatment, for whom it is advisable to intensify immunosuppression. Thus, our experience and the literature data support that repeat biopsy also brings more advantages than threats in this group.

**Conclusion:** Although there is still a need for new randomized, prospective studies to confirm clinical observations, in daily practice kidney repeat biopsies are useful in guiding treatment of LN flares. The results of the repeat biopsy led to a change in the immunosuppressive treatment in more than half of the patients on average, intensifying it in the majority of the cases, but also reducing it in 5% to 30%.

## **Minimal Renal Affection in Patients with Systemic LUPUS Erythematosus: Characteristics and Evolution**

**TC Salman-Monte**<sup>1</sup>, Eva Rodriguez<sup>2</sup>, José Luis Arevalos<sup>3</sup>, María José Soler<sup>3</sup>, Clara Barrios<sup>3</sup>, Jordi Carbonell<sup>4</sup> and Julio Pascual<sup>3</sup>, <sup>1</sup>Rheumatology, Hospital del Mar/Parc de Salut Mar, Barcelona, Spain, <sup>2</sup>Nephrology, Hospital del Mar/Parc de Salut Mar, Barcelona, Spain, <sup>3</sup>Nephrology, Hospital del Mar/Parc de Salut Mar, Barcelona, Spain, <sup>4</sup>Rheumatology Unit, Hospital del Mar/Parc de Salut Mar, Barcelona, Spain

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Lupus nephritis (LN) is the most common organ involvement in Systemic Lupus Erythematosus (SLE). Indications of renal biopsy (RB) are deterioration of renal function and / or activity in sediment and / or proteinuria > 0.5g / 24h or urine protein: creatinine ratio (P:C ratio) > 0.5 (SEN consensus 2012). There are patients who show data of "minimal renal involvement" (MRI) without indication of RB. Our objective is to determine if these patients present clinical and analytical characteristics that allow them to differentiate from patients with LN.

### **Methods:**

We reviewed 171 patients with SLE diagnosis, classifying them as MRI if they showed > 3 occasions at least 1 year, proteinuria determinations = 0.3 g / 24h or P:C ratio = 0.3, ruling out urologic pathology. We have compared clinical and analytical variables of MRI vs LN at the time of SLE diagnosis, at renal involvement diagnosis and last visit.

### **Results:**

We identified 38 (18.7%) patients with MRI and 41 (24%) patients with LN. At the time of SLE diagnosis, the MRI group had a lower titer of anti-DNAs (14.8% vs 42.1%,  $p = 0.01$ ), anti-Sm (12% vs 32.2%,  $p = 0.04$ ), presence of lupus anticoagulant (38%,  $p = 0.01$ ) and anticardiolipin IgG (11% vs 38%,  $p = 0.01$ ), less severe C3 hypocomplementemia ( $70 \pm 34$  vs  $86.9 \pm 32.7$  mg / dl,  $p = 0.04$ ), C4 ( $14 \pm 10$  vs  $17$  (p = 0.04) and CH50 ( $33.3 \pm 15$  vs  $49.6 \pm 17.4$  mg / dl,  $p = 0.04$ ); and lower inflammatory parameters: ESR ( $23.1 \pm 20$  vs  $58.9 \pm 42$  mg / dl,  $p = 0.01$ ), CRP ( $12.7 \pm 11.8$  vs  $27.3 \pm 17$  mg/dl,  $p = 0.02$ ). At the diagnosis of the renal involvement, these results were confirmed (Table) and we observed that, in MRI patients, proteinuria appeared at an older age, with a higher evolution of SLE ( $12.7 \pm 11.8$  vs  $27.3 \pm 17$  mg / dl,  $p = 0.02$ ) and with absence of previous immunosuppressant therapy. After a mean follow-up of  $10 \pm 6.6$  years, no MRI patient presented a renal flare, maintaining stable the renal function.

Immunosuppressants	15 (38.5%)	25 (78,1%)	0.001
• Micophenolic acid	20%	4%	0.1
• Azathioprine	13%	88%	0.001
• Hydroxyclochlorine	20%	32%	0.003
Corticosteroids	19 (50%)	15 (46.9%)	0.4

## Conclusion:

Our results showed that patients with MRI had a lower clinical and biological SLE activity, both at SLE diagnosis and at the diagnosis of renal involvement. No MRI patients presented a LN flare during the follow-up although it is difficult to know the role played by the immunosuppressant treatment.

## **The Benefit of Vitamin D on SLE Disease Activity Is Largely Explained By Renal Activity**

**Michelle Petri**<sup>1</sup>, Daniel Goldman<sup>2</sup> and Laurence S Magder<sup>3</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low vitamin D is commonly found in SLE. In previous studies, supplementation of vitamin D resulted in improvement in the Physician Global Assessment and SLEDAI. We now present the first analysis of the relationship between vitamin D and individual organ activity, based on a large clinical cohort.

**Methods:** This analysis is based on cohort visits where vitamin D was measured starting in 2010. There were 16,519 visits from 1,345 different patients (92% female, 50% Caucasian, 41% African American). If the patient received any score for an organ system component on the SELENA-SLEDAI, then the patient was defined as having that type of activity.

**Results:** The following activities were observed (percentage of visits): immunologic (33%), cutaneous (32%), renal (7%), musculoskeletal (5%), hematologic (5%), serologic (2%), vasculitic (1%), CNS (<1%), and constitutional (<1%). The association between levels of Vitamin D and disease activity in the top three organs is shown in Table 1.

Table 1. Estimated association between vitamin D levels and odds of organ-specific lupus disease activity, adjusting for age, race, sex, calendar year, prednisone use and plaquenil use.

Vitamin D Level (ng/mL)	Cutaneous Activity		Renal Activity		Musculoskeletal Activity	
	OR (95% CI)	P-value	OR (95% CI)	P-value	OR (95% CI)	P-value
<10 (n=163)	1.4 (1.0, 2.1)	0.049	3.1 (2.0, 4.9)	<0.0001	1.3 (0.7, 2.6)	0.39
10 - <20 (n=1039)	0.9 (0.8, 1.1)	0.41	2.2 (1.5, 3.1)	<0.0001	1.1 (0.8, 1.6)	0.61
20 - <30 (n=2760)	1.0 (0.9, 1.2)	0.53	1.6 (1.2, 2.0)	0.0008	1.0 (0.7, 1.3)	0.93
30 - <40 (n=3959)	1.1 (1.0, 1.2)	0.13	1.2 (0.9, 1.5)	0.23	0.9 (0.7, 1.2)	0.43
40 - <50 (n=3578)	1.0 (Ref Grp)		1.0 (Ref Grp)		1.0 (Ref Grp)	
50 - <60 (n=2308)	1.1 (0.9, 1.3)	0.19	1.0 (0.7, 1.3)	0.91	1.2 (0.9, 1.5)	0.23
60 - <70 (n=929)	1.0 (0.8, 1.3)	0.74	0.8 (0.5, 1.3)	0.33	1.2 (0.9, 1.7 )	0.19
70 - <80 (n=504)	1.3 (1.0, 1.7)	0.072	0.8 (0.4, 1.4)	0.41	0.7 (0.4, 1.2)	0.19
80+ (n=356)	1.4 (1.0, 1.9)	0.072	0.6 (0.3, 1.6)	0.32	1.3 (0.8, 2.1)	0.36

For cutaneous activity, there was a significantly elevated risk among those in the very extreme low level of vitamin D. For Renal Activity, vitamin D > 40 ng/mL lowered the risk of renal disease activity. For musculoskeletal activity, there was no association with vitamin D levels.

We then conducted a “within person” analysis between vitamin D and renal disease activity. In this analysis, each person serves as her own control, and the question is: “When a person has a vitamin D level lower than his/her average, are they more likely to have renal disease activity”. This analysis implicitly adjusts for race, sex, and all variables (measured and unmeasured) that are invariant within a person. The results are shown in Table 2.

Table 2. Within-person analysis of the relationship between vitamin D levels and renal activity adjusting for prednisone use, plaquenil use, and implicitly for all time-invariant characteristics.

Vitamin D Level	Renal Activity	P-value
	Odds Ratio	
10 ng/mL or more lower than personal average	1.5 (1.3, 1.8)	<0.0001
Within 10 ng/mL of the personal average	1.0 (Ref Grp)	
10 ng/mL or more higher than personal average	0.8 (0.7, 1.0)	0.080

There was a relationship between vitamin D and all three components of SELENA-SLEDAI Renal Activity: hematuria, proteinuria, or pyuria.

**Conclusion:** Low vitamin D was associated with mucocutaneous activity only at extremely low vitamin D levels. The major association was with renal activity. This association held true in “within person” analysis and held true for proteinuria, hematuria and pyuria, as well. Given the safety of vitamin D supplementation, this immunomodulator should now be considered standard of care for lupus nephritis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cigarette smoking regulates both innate and adaptive immunity and is associated with numerous diseases. In some inflammatory diseases smoking is associated with deleterious effects but in others, i.e. Ulcerative Colitis, with beneficial effects. The effect in SLE is controversial. This study aims to investigate the associations of current smoking and clinical and serological characteristics of patients with systemic lupus erythematosus at the onset of the disease.

**Methods:** We included patients with SLE of recent onset (within 12 months of diagnosis), participating in an ongoing lupus cohort since 1970. We analyzed the information of Never Smokers (NS) and Current Smokers (CS) gathered at entry into the cohort, including demographic (age, sex, ethnicity), clinical (lupus criteria, SLEDAI-2K score, treatment, SLICC-DI), and laboratory (ANA, anti-ds-DNA, -Sm, -RNP, -Ro, -La, -aCL, lupus anticoagulant, C3, C4). We also analyzed these variables at one and two years of follow-up. *Statistical analysis:* Descriptive statistics, chi-square, t-test; multivariable analysis included linear and logistic regression. A p-value of <0.05 indicated statistical significance.

**Results:** The study included 467 patients [317 (68%) NS, and 150 (33%) CS]; 87% female; mean age  $36.1 \pm 13.3$  years; SLE duration at entry into the cohort  $0.2 \pm 0.3$  years; Caucasian 60%, Black 14%, Other 26%. Males (21.5%) and Caucasians (85.3%) predominated CS ( $p < 0.001$ ). At entry into the cohort, CS had significantly lower values of ACR

criteria ( $4.1 \pm 1.6$  vs  $5.1 \pm 1.3$ ), SLEDAI-2K score ( $7.7 \pm 6.4$  vs  $9.9 \pm 7.8$ ), fewer showed positive ANA (82% vs 95%), anti-dsDNA (35% vs 67%), anti-Sm (11% vs 31%), anti-RNP (29% vs 47%), anti-Ro (34% vs 49%), low C3 or C4 (39% vs 53%), and fewer used steroids (47% vs 61%), anti-malarials (30% vs 44%), and immunosuppressants (12% vs 26%) than NS (all  $p < 0.03$ ). In multivariable analyses, adjusting for age, sex, and ethnicity, smoking was independently associated with lower values of ACR criteria, ANA, anti-Sm antibodies, and abnormal C3/C4 (all  $0.0001 < p < 0.05$ ).

After one-year ( $n = 376$ ) and two-years ( $n = 336$ ) of follow-up, CS continued with lower frequency of positive ANA ( $p < 0.0001$ ), anti-dsDNA ( $p < 0.001$ ), and use of steroids ( $p < 0.05$ ), anti-malarials ( $p < 0.0001$ ), and immunosuppressants ( $p < 0.0001$ ). The adjusted mean SLEDAI-2K at one year was lower among CS than NS ( $5.7$  vs  $6.6$ ,  $p = 0.05$ ), but not at two years ( $5.3$  vs  $5.6$ ,  $p = \text{NS}$ ), likely due to treatment.

**Conclusion:** Smoking status seems to be associated with differences in clinical and serological phenotype at the onset of lupus. If these results are confirmed, the underlying mechanisms need to be elucidated.

## A Renal Biopsy Should Not Delay Treatment Initiation in Suspected Lupus Nephritis

Astrid Baumann<sup>1</sup>, Angela Pakozdi<sup>2</sup>, Andrea Cove-Smith<sup>2</sup>, Debasish Pyne<sup>2</sup>, Michael Sheaff<sup>1</sup> and Ravindra Rajakariar<sup>2</sup>,  
<sup>1</sup>Barts Lupus Centre, London, United Kingdom, <sup>2</sup>Barts Lupus Centre, Barts Health NHS Trust, London, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Renal biopsies are considered the gold standard in diagnosing lupus nephritis (LN). ALMS (1), the largest randomized trial in LN, reported the non-inferiority of mycophenolate mofetil (MMF) compared to cyclophosphamide. The mean serum creatinine in this trial was 100 micromoles/L. Since its publication, MMF has been standard therapy in proliferative LN, but there may be delays in obtaining a histological diagnosis due to practical considerations. Renal biopsy also has a recognized complication rate. We therefore investigated whether histological findings influenced treatment in patients with SLE and clinical features consistent with LN.

### Methods:

Histopathology and renal databases were used to identify all cases of new biopsy-proven active LN, diagnosed between February 2012 and November 2016 and managed at the Barts Lupus Centre ( $n=62$ ). Demographic and clinical data were

collected using case records and pathology systems. LN classes based on glomerular pathology were defined according to the ISN/RPS 2003 classification. Patients were divided into sub groups based on their renal function (eGFR above or below 50 ml/min/1.73m<sup>2</sup>).

**Results:** The mean age at LN diagnosis was 37 years (+13 SD). 55 patients were female (89%) whilst 7 were male (11%). The ethnic distribution was the following: 46% South Asian, 34% Black, and 11% Caucasian. The histological class was either pure proliferative (class III or IV) or mixed proliferative (with additional class V) in 24 cases (39%). 42 (64%) patients had an eGFR > 50mL/min at presentation with a mean albumin and urine PCR of 30 g/dL and 520 mg/mmol respectively. Of this group, 37 patients (88%) received MMF, and only 3 patients were treated with cyclophosphamide (1- clinician decision, 2- severe extra renal manifestations). The remaining two patients received Azathioprine and both had sub-nephrotic proteinuria. At six months, 85% of LN patients were either in partial remission, defined as proteinuria below 200 mg/mmol (44%), or complete remission defined as proteinuria below 50 mg/mmol (41%). The treatment choice was different in the group with eGFR ≤ 50mL/min, with 65% of these patients receiving cyclophosphamide.

## **Conclusion:**

Current guidelines strongly recommend performing a kidney biopsy in every patient presenting with suspected LN. Our findings indicate that in patients with preserved renal function (eGFR > 50mL/min) and significant proteinuria, treatment decision is not influenced by biopsy result. We therefore propose that induction treatment with MMF should not be delayed until a renal biopsy result is available. This study also questions the necessity of baseline histology in LN patients with preserved renal function, as the majority respond to standard therapy, and raises the possibility that biopsy could be reserved for patients who are resistant to induction therapy.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

The course of systemic lupus erythematosus (SLE) varies with periods of quiescence punctuated by flares. Predicting exacerbations allows clinicians to select patients who need closer monitoring and guides therapy. However, such data are limited, especially in Asians. We aim to identify the clinical predictors of flares in patients with stable SLE.

**Methods:**

We enrolled patients  $\geq 21$  years old with SLE into a prospective observational study. All patients fulfilled either the 1997 ACR Criteria or the 2012 SLICC Classification Criteria. We collected demographic and clinical data by examination and chart review at baseline and three-monthly intervals for up to 5 years. We defined stable disease as SLE Disease Activity Index-2K (SLEDAI-2K) of  $\leq 4$  and flares using the SLE Flare Index. We determined the predictors of flare in patients with stable disease using Cox proportional hazards. We included variables with  $P < 0.2$  on univariate analysis in the multivariate model. **Results** are expressed as hazard ratios (HR) and 95% confidence intervals (CI).

**Results:**

We followed 210 patients for a median (IQR) of 31.5 months (24.1, 36.3). The median age (IQR) was 30.6 years (22.3, 42.5) and 91.4% were female. The majority were Chinese (70.5%). The median (IQR) disease duration from diagnosis was 9.96 years (4.5, 15.5). The median baseline SLEDAI-2K was 2 (2, 6) and the baseline SLICC damage score was 0 (0, 2). 152 (72.4%) patients had stable disease at baseline. Table 1 shows the baseline demographic and disease variables. In 5729 patient-months of follow-up, 109 (51.9%) patients had a flare. Median time to first flare was longer in patients with stable disease (10.7 vs. 8.3 months). Figure 1 shows the Kaplan-Meier Failure Curve of the risk of first flare in patients with stable versus active SLE. In the multivariate model of patients with stable SLE, younger age, longer disease duration, thrombocytopenia, hypocomplementemia and higher baseline prednisolone dose predicted flares. Table 2 shows the results of the univariate and multivariate analysis.

**Conclusion:**

Rheumatologists should closely monitor patients with stable SLE who are (i) younger; (ii) have longer disease duration; (iii) thrombocytopenic; (iv) hypocomplementemic; (iv) requiring higher baseline prednisolone doses; as these patients are more likely to develop flares.

## Proton Pump Inhibitor Induced Subacute Cutaneous Lupus Erythematosus: Clinical Characteristics and Outcomes

Yih Jia Poh<sup>1</sup>, Shirish Sangle<sup>1</sup>, Eleanor Higgins<sup>1</sup>, Emma Benton<sup>1</sup>, David McGibbon<sup>1</sup> and David D'Cruz<sup>2</sup>, <sup>1</sup>Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom, <sup>2</sup>Louise Coote Lupus Unit, Guy's and St. Thomas' Hospital, London, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Drug induced subacute cutaneous lupus erythematosus has rarely been described. There is a growing literature reporting the association between proton pump inhibitor use and subacute cutaneous lupus erythematosus (SCLE). We aim to describe the clinical characteristics of a cohort of patients with proton pump inhibitor induced subacute cutaneous lupus erythematosus, their clinical course and treatment options.

**Methods:** We retrospectively reviewed twelve patients with proton pump inhibitor induced subacute cutaneous lupus erythematosus at the Louise Coote Lupus Unit. Clinical details recorded included presence of underlying systemic lupus erythematosus (SLE) and SCLE, extent of cutaneous involvement, time to presentation, type of proton pump inhibitor and dosage, histological characteristics, immunological characteristics, treatment and time to resolution.

**Results:** There were 12 patients of whom 10 were female (83%). Eleven patients were Caucasians (92%). The median age at diagnosis was 61 years (range 37-71). Nine patients (75%) had underlying SLE. In this subgroup, only one patient had SCLE as part of their initial SLE presentation. Patients with coexisting SLE were younger with a median age of 53 years compared to patients without coexisting SLE. There were 8 patients with omeprazole, 3 patients with lansoprazole and 1 patient with pantoprazole induced SCLE.

All patients developed typical SCLE lesions clinically. The extent of SCLE was widespread involving the sun-exposed areas of the trunk, upper extremities and the lower limbs in 50% of the patients. Eleven (92%) demonstrated antinuclear antibody positivity and 9 patients (75%) anti-Ro (SS-A) antibody positivity. Seven patients underwent a skin biopsy and 6 patients had histological results in keeping with SCLE. The median time to presentation was 12 months (range 3 weeks -10 years) and the median resolution period was 19 days (range 3 days- 2 months). Proton pump inhibitors were stopped in all patients. Five patients (42%) received concurrent oral corticosteroids and 3 patients (25%) were newly initiated on hydroxychloroquine. Two patients received adjunctive topical therapy including topical steroids alone or in combination with topical tacrolimus. Four patients were re-exposed to proton pump inhibitors and 3 experienced a similar SCLE flare, which resolved following cessation of the proton pump inhibitor. (Table 1)

**Conclusion:** Proton pump inhibitor induced subacute cutaneous lupus may be commonly associated with anti-Ro (SS-A) antibody and this is likely a class effect with all proton pump inhibitors. In July 2015, the European Medicines Agency issued a warning that SCLE is likely to be a class effect for proton pump inhibitors. We recommend judicious use of proton pump inhibitors particularly in SLE patients with anti-Ro (SS-A) antibody positivity.

Patient, sex/age (years)	Presence of underlying Systemic Lupus Erythematosus	Antibody Profile (Extractable Nuclear Antigen, ENA)	Proton pump inhibitor /dose (mg)	Extent of SCLE skin lesion	Incubation period	Treatment	Resolution period

## Characterization of Emergency Department Visits in an Urban Underserved Lupus Cohort

**Justin Levinson**<sup>1</sup>, Maushmi Savjani<sup>1</sup>, Diane Zisa<sup>2</sup> and Ellen M. Ginzler<sup>3</sup>, <sup>1</sup>Internal Medicine, Division of Rheumatology, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY, <sup>2</sup>Division of Rheumatology, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY, <sup>3</sup>Rheumatology, Division of Rheumatology, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

SLE patients frequently utilize the Emergency Department (ED), impacting the cost of care and quality of life. We performed a retrospective analysis of ED visits over a 5.5 year period among SLE patients from an urban, underserved population. Aims were to: 1) define most common complaints 2) examine sociodemographic statistics 3) analyze most common complaints resulting in admission.

### Methods:

Charts of patients who met ACR criteria for SLE presenting to the ED or Rheumatology clinic between 1/1/2010 and 6/20/2015 were reviewed for demographics, chief complaint, and ED course. In evaluating level of admissions over the 5.5 year period, patients were classified as Non-users (no ED visits, only clinic visits), Occasional Users (1-5 ED visits) or Frequent Users (>5 visits). Excluded charts were those for pediatrics, medication refills, social work needs, and those for the dialysis or renal transplant services.

## Results:

Of an initial cohort of 363 patients and 1700 ED visits, 359 patients were reviewed. 258 patients (72%) had  $\geq 1$  visits with a total of 1451 ED visits (range 1-72). Patient demographics are shown in Table 1, with mean age at ED visit of 39.4 years with 31 men, 328 women. The mean number of visits was  $6.24 \pm 6.40$  ( $\pm$ SEM) with 44% of all patients as Occasional Users. Shown in Table 2, most visits were related to musculoskeletal pain (MSK) in 196 patients(13.5%), chest pain in 147(10.1%), and shortness of breath (SOB) in 112(7.7%). The most common complaints to prompt hospital admission were fever(80.9%), SOB(75.0%), and syncope(70.0%). 62.3% of chest pain complaints led to admission compared to 27.0% of MSK. Only 36 visits(2.5%) were recorded as complaining of lupus flare, with resulting admissions in 55.6%.

Lower Extremity Swelling	33	16 (48.48%)	<b>Total</b>	<b>1451</b>	<b>621</b> (42.80%)

## Conclusion:

We present an analysis of characteristics of ED presentation and rate of resulting admissions of SLE patients. Physicians should be aware that the average SLE patients will present to the ED roughly yearly. Unnecessary ED visits of SLE patients can be avoided with patient education and outpatient symptomatic control for the most common complaints.

## **Raynaud's Symptoms and Pregnancy Induced Hypertension in Patients with Systemic Lupus Erythematosus**

**Sakiko Isojima**, Mayu Saito, Yoko Miura and Nobuyuki Yajima, Showa university, Tokyo, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several reports suggested that the incidence of obstetric complications such as pregnancy induced hypertension (PIH) and preterm birth was higher in a pregnant woman with systemic lupus erythematosus (SLE) than in a healthy woman. Dysplasia of placental vessels was thought to be one of the putative cause for PIH. It followed by maternal vascular endothelial dysfunction, which lead to vasospasm and hypercoagulation. As a result, maternal blood pressure rose and renal impairment occurred. In the meantime, vascular endothelial dysfunction is also involved in the mechanism of Raynaud's symptoms, which is often seen in patients with SLE. Therefore, there may be an association between the high incidence of PIH and Raynaud's symptoms in pregnant women with SLE. However, there is no report investigating the association. To that end, we studied the association between PIH and Raynaud's symptoms in women with SLE.

**Methods:** We conducted a questionnaire survey to SLE patients aged 20 to 50 who visited Showa University Hospital between December 2015 and April 2017. We investigated the following three contexts: 1) Raynaud's symptoms before pregnancy 2) Pregnancy experience 3) PIH and preterm birth.

**Results:** In total, 109 female SLE patients were applicable, and 43 patients had experienced pregnant. Among 43 patients with SLE, 17 patients developed SLE before pregnancy. Of 17 patients, Raynaud's symptoms were observed in 5 patients, of whom 4 was complicated with PIH during pregnancy. In contrast, among 12 people without Raynaud's symptoms, only one person had experienced PIH. There was significant different occurrence of PIH between those with and without Raynaud's symptoms ( $p=0.0099$  Fisher exact test). We found that PIH occurred more frequently in patients with SLE when Raynaud's symptoms were seen before pregnancy. The mechanism of this association was beyond our scope, but we speculate the involvement of endothelin-1. It is considered that high serum concentration of endothelin-1 contributed to the development of PIH. On the other hand, serum concentrations of endothelin-1 were reported to be high in patients with SLE having Raynaud's symptoms. As we could not examine the activity of SLE in this study, we are planning to investigate prospective study for uncovering the detailed association and underlying causative mechanism.

**Conclusion:** We identified the association between PIH and Raynaud's symptoms in patients with SLE for the first time. We should pay attention to the onset of PIH in SLE-associated pregnant women who have Raynaud's symptoms before pregnancy.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A clinical feature of patients with primary Raynaud's phenomenon (PRP) is the presence of low skin blood perfusion (BP) at the level of hands (1-3). Conversely, few studies investigated skin BP in patients with systemic lupus erythematosus (SLE) (4,5). The aim of this study was to investigate skin BP in different skin areas of hands and face in three groups of subjects: SLE patients not complaining clinical symptoms of Raynaud's phenomenon, PRP patients and healthy subjects (CNT).

**Methods:** Fourteen SLE patients without Raynaud's phenomenon (ACR criteria) (mean age 51±14 years, mean disease duration 7±4 years), 14 PRP patients (LeRoy, criteria) (mean age 53±21 years, mean Raynaud duration 6±5 years) and 14 CNT, (mean age 53±17 years), after informed consent (6,7). Skin BP was assessed by laser speckle contrast analysis (LASCA) at the level of hands and face, and the mean BP reported as perfusion units (PU) (4). Patients were not taking vasodilator drugs at the time of the study. Statistical analysis was performed by non parametric tests.

**Results:** BP was found significantly lower in both SLE and PRP patients when compared with CNT at the level of fingertips (median PU 113, 84, 187, respectively; p<0.0001), periungual (median 102, 72, 143, respectively; p<0.0001), dorsal (median 73, 60, 122, respectively; p<0.0001) and palm areas of hands (median 93, 74, 117, respectively; p<0.0001). However, PRP patients showed lower BP values than SLE patients in all areas of hands (fingertips p=0.03, palm p=0.02, periungual p=0.006, dorsum p=0.05), but not at the level of face (p=0.90). SLE, PRP and CNT subjects displayed similar BP values at the level of face (median PU 145, 147, 125, respectively; p=0.40).

**Conclusion:** Statistically significant differences in skin BP were detected between SLE patients and controls. BP of hands was found lower in SLE patients not complaining clinical symptoms of RP than in healthy subjects. The clinical value of this new finding need to be investigated by further analysis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Assessing patient-reported outcomes validated to be associated with disease activity has helped clinicians better understand treatment response of patients with systemic rheumatic disease. Such questionnaire for systemic lupus erythematosus (SLE) are rarely used in daily practice; the utility of out-patient targeted questionnaire for SLE has never been studied in Korea.

**Methods:** The Systemic Lupus Activity Questionnaire, or SLAQ, was translated in Korean (K-) and back-translated, then reviewed by a committee specifically organized for this purpose. This K-SLAQ was then applied to SLE patients followed (out-patient) at institute 1 (SMG-SNU); SELENA-SLEDAI and Systemic Lupus Activity Measure (SLAM)-R was measured on the same day. K-SLAQ was measured again 2 weeks later to assess its reliability. Finally, K-SLAQ was validated in the same manner at a separate institute (2, SNUH). The receiver operating characteristic (ROC) curve was obtained to study K-SLAQ cut-off values in relation to those indicating high disease activity in SELENA-SLEDAI and SLAM-R.

**Results:** Forty-two patients were enrolled at institute 1, where the median (min-max) age of patients were 40 (19-70), and disease duration was 3.0 (0-18.1) years. The mean K-SLAQ, SELENA-SLEDAI, SLAM-R values were 10 (10-29), 7 (0-26), 5 (1-18), respectively. The correlation between K-SLAQ and the disease activity indices are depicted in the presented table. These results were validated at institute 2 (N= 44). The interclass correlation between repeated K-SLAQ

measures was 0.912 (95% CI 0.847-0.949,  $p < 0.0001$ ), and the area under the ROC curve of SLAQ for SELENA-SLEDAI  $\geq 6$  was 0.705 (95% CI 0.59-0.82,  $p = 0.002$ ), and SLAM-R  $\geq 7$  was 0.704 (95% CI 0.595-0.812,  $p = 0.001$ ).

**Conclusion:** K-SLAQ is a useful tool which correlated well with commonly used SLE disease activity indices. This may also facilitate identifying key determinants of flares in daily clinical practice.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Childhood-onset systemic lupus erythematosus (cSLE) is a multisystem autoimmune disease that is characterized by episodes of flares followed by improvement in response to therapy. To assess the clinically relevant response and the efficiency of therapies in cSLE, sensitive and well-correlated criteria with changes in improvement are needed.

**Objective:** To prospectively validate the PRINTO/ACR Criteria of Response to Therapy (PCI) & assess their ability to capture clinically relevant improvement (CRI).

**Methods:** Consensus formation methodology (Delphi, nominal group technique; 77 % consensus level) was used to newly define CRI. Using prospective cSLE data, patient profiles (PPs) were developed which provided information at a baseline & follow-up visit, including the cSLE core response variables [CRVs: SLEDAI, the urinary protein-creatinine ratio (PCR), physician global assessments of cSLE disease activity, patient global assessment of well-being, quality of life score]. Twelve experts (>10 yrs experience managing cSLE) were asked to rate disease courses of up to 200 PPs using 2 scales: (1) no change/worsening, minor, moderate, or major improvement; and (2) clinically relevant improved, yes/no. Each PP was determined of the “true” course based upon the majority opinion of the raters. Multinomial logistic regression models (MLRs) were used to predict the true course and develop algorithms to calculate the continuous “improvement score” using absolute or percentage changes of the CRVs. ROC curves were analyzed for the MLR algorithms and AUC, specificity, sensitivity, and kappa statistics were calculated to assess the improvement scores for accuracy. **Results** were reviewed by the expert panel for further discussion and recommendation.

**Results:** The consensus definition of CRI was: “*A clinically relevant improvement has occurred in a child with lupus if there are reduced signs of disease from active lupus. Although there may not be an improvement of lupus activity in all organ systems, there cannot be increased lupus activity in major organ systems (neuropsychiatric, hematological, gastrointestinal, renal, ophthalmological, and cardiopulmonary). Patient symptoms must be at least stable, and immunosuppressive therapy should be unchanged or decreased*” (100 % consensus). All 4 top PCI were highly sensitive and moderately accurate but specificity was lacking to various degrees of improvement or CRI. The MLR-based algorithms appeared more accurate than the PCI for CRI and minor/moderate/major improvement (Table 1).

**Conclusion:** The PCI are moderately accurate in this validation data set, but the MLR-derived criteria considering absolute CRV changes perform better in capturing CRI and cSLE improvement in general. If confirmed in larger validation studies, MLR-based algorithms may allow for a more effective assessment of response to therapy in cSLE.

## Table 1. Multivariate Models for Improvement Criteria

Change of CRVs*	Reference standard	Sensitivity	Specificity	Average "kappa"	AUC
Absolute Change	CRI	89.5%	92.6%	0.91	96.9%
	At least minor improvement	88.9%	93.9%	0.91	96.4%
	At least moderate improvement	96.6%	88.4%	0.93	97.5%
	Major improvement	100%	90.8%	0.95	98.4%
Relative Change	CRI	87.6%	92.6%	0.90	96.1%
	At least minor improvement	86.7%	83.1%	0.85	93%
	At least moderate improvement	92.1%	93.8%	0.93	97.1%
	Major improvement	100%	80.3%	0.90	95.8%

## The Southern California Lupus Registry: I. Baseline Characteristics of Patients with Systemic Lupus Erythematosus in an Uncharted Territory

Joshua Liu<sup>1</sup>, Kathleen Teves<sup>2</sup>, Van La<sup>2</sup>, Arlene Bravo<sup>3</sup>, Sheila Lezcano<sup>4</sup>, Talha Khawar<sup>4</sup>, Ebrahim Sadeghi<sup>4</sup>, Cong-Bin Wang<sup>5</sup>, Karina Torralba<sup>6</sup>, Howard Yang<sup>5</sup> and Vaneet K. Sandhu<sup>7</sup>, <sup>1</sup>Internal Medicine, Loma Linda University Medical Center, Loma Linda, CA, <sup>2</sup>Internal Medicine, University of California, Riverside, Riverside, CA, <sup>3</sup>Internal Medicine, Loma Linda University, Loma Linda, CA, <sup>4</sup>Rheumatology, Loma Linda University Medical Center, Loma Linda, CA, <sup>5</sup>Loma Linda University Medical Center, Loma Linda, CA, <sup>6</sup>Internal Medicine/Rheumatology, Loma Linda University, Loma Linda, CA, <sup>7</sup>Division of Rheumatology, Loma Linda University, Loma Linda, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Southern California Lupus Registry (SCOLR) is a population-based, longitudinal, multi-ethnic cohort of subjects with SLE directed toward studying health and healthcare disparities in the Inland Empire, an under-recognized region of southern California inhabiting more than 3 million individuals where the percentage population living below the federal poverty line exceeds the general population in California. We report herein a

preliminary analysis of baseline characteristics and clinical manifestations to establish a platform for future studies on regional disparities.

**Methods:** Subjects were enrolled into the SCOLR study from June 2016 to June 2017 using the Systemic Lupus International Collaborating Clinic (SLICC) classification criteria for SLE. Retrospective review of medical records as well as clinical visits yielded more than 80 variables including demographic and clinical data, disease activity, comorbidities, serologic identifiers for SLE, and treatment history. Data involving clinical manifestations including renal involvement were analyzed with descriptive statistics.

**Results:** Of the 147 subjects enrolled, the majority resided in the surrounding geographic areas of the participating institution (Loma Linda University Medical Center). Ninety-two percent (135) were women and 8% (12) were men (female:male ratio, 11) with a mean age of 42 years (range 19-85). Thirty-seven percent were White non-Hispanic, 37% White Hispanic, 10% Asian, and 16% Black. Positive antinuclear antibody was demonstrated in 90%, dsDNA antibody in 52%, and Smith antibody in 34% of subjects. Lupus nephritis was noted in 46 subjects, of whom greater than 50% were of Hispanic origin. SLEDAI score was also notably greater in the Hispanic population compared to other subsets.

**Conclusion:** Subjects with SLE residing in the Inland Empire demonstrate findings in line with other cohorts with greater disease activity and severity among non-White groups compared to Whites and Hispanic subjects specifically in our cohort appearing to be at greater risk of morbidity and mortality. Our preliminary data warrants further analysis of racial/ethnic subsets in serologies and disease manifestations.

<b>Table 1. Baseline Characteristics</b>

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose :**

Sjögren's syndrome occurs in isolation (primary Sjögren's syndrome, pSS), but it is also often secondary (sSS) to, and sometimes difficult to delineate from, other rheumatic diseases, in particular from systemic lupus erythematosus (SLE). Consequently there is a need to investigate similarities and differences between SLE patients with (SLE-sSS) and without sSS (SLE-noSS).

Objective s was to investigate the occurrence of sSS in a large cohort of SLE patients and to explore clinical and laboratory characteristics associated with SLE-sSS as compared to SLE-noSS and controls.

### **Methods:**

We included 504 consecutive SLE patients and 322 population controls, individually matched for age and gender to the first patients. All patients fulfilled the 1982 revised ACR criteria for SLE. SLE-sSS was defined according to the American-European consensus criteria (AECC). Accordingly, subjective and objective quantifications of sicca symptoms were recorded on all subjects. All underwent a thorough clinical investigation. SLE-associated autoantibodies, (ANA screening by BioPlex 2200 system, Bio-Rad) and Rheumatoid factor (Rf, Phadia Immunocap 250) were

determined with standardized methods for all subjects, Routine laboratory workup and a panel of cytokines (MSD 30-plex cytokine assays, performed on samples from 433 consecutive SLE patients and 319 controls) were measured on fasting blood samples..

## Results:

SLE-sSS, as defined by AECC, occurred in 23% of the SLE patients. Compared to SLE-noSS the SLE-sSS group was older, both at inclusion (55 vs 43yrs,  $p<0.0001$ ) and at disease onset (40 vs. 32 yrs  $p<0.0001$ ), and more enriched in females (96 vs. 83 %,  $p=0.0007$ ), patients with leucopenia (57 vs. 45 %,  $p=0.02$ ) and peripheral neuropathy (15 vs 7 %,  $p=0.01$ ). Nephritis was less common in SLE-sSS (32 vs 43 %,  $p= 0.03$ ). Higher levels of total IgG, positivity for anti-SSA/Ro52, anti-SSA/Ro60, anti-SSB antibodies, Rf IgM and Rf IgA further characterized the SLE-sSS group. 20/30 investigated cytokines were detectable, of these 19/20 were higher in SLE than in controls. 6/20 cytokines (TNF- $\alpha$ , IL-6, MCP-4, MIP-1 $\beta$ , IL12/IL-23p40 and IP-10) were upregulated in SLE-sSS vs. SLE-noSS (see table for figures).

## Conclusion:

Through strictly applying the AECC criteria we report that the frequency of SLE-sSS increases with age and affects roughly ¼ of SLE patients. Nephritis was less common while leucopenia and peripheral neuropathy were more common among SLE-sSS patients. In addition to excess of well-known SS-associated autoantibodies we report higher levels of six pro-inflammatory cytokines in SLE-sSS as compared to SLE-nonSS. These findings demonstrate that, though often regarded as a milder version of SLE, patients with SLE-sSS are characterized by a state of chronic systemic inflammation.

## Immunoglobulins, autoantibodies and pro-inflammatory cytokines

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster III: Therapeutics and Clinical Trial Design

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Studies to date have reported that up to 30% of lupus patient have a first degree relative with an autoimmune disorder (AD). The most recent study from the Danish registry (1) reports an increase in risk of lupus, rheumatoid arthritis (RA), type 1 diabetes (T1DM) and inflammatory bowel disease in individuals with an SLE-affected first-degree relative. Here we describe the prevalence of ADs amongst family members in a multi ethnic lupus cohort.

## **Methods:**

Questionnaires were distributed to consecutive lupus patients attending our Lupus clinic between April 2017 and June 2017. All patients fulfilled the 2012 SLICC ACR criteria for lupus. Patients were asked about their family history with specific questions on the presence of a range of ADs.

## **Results:**

74 patients completed questionnaires. 24 were incomplete, the remaining 50 were analysed. The average age of patients with SLE was 41.6years (21- 78) 90% of the patients were female. South east Asians (40%) and afro- Caribbean (36%) represented the majority of our cohort. Others included Caucasian (14%), Turkish (4%), oriental (2%), Malaysian (2%) and one mixed race (2%) Caucasian-afro Caribbean.

13 (26%) patients with SLE had another autoimmune condition with RA the most common (n= 7, 14%), followed by antiphospholipid syndrome (APS) (n =4, 8%), sjogrens (n=1) and hashimotos (n=1).

The prevalence of a second AD in lupus patients was highest in Afro-Caribbeans (n=16, 89%). Afro-Caribbean patients were significantly more likely to have another AD than South East Asians (n=7, 35%) (p=0.001) and Caucasians (n=1, 14%) (p=0.001).

A family history of AD was found in 17 patients (34%). SLE was the most prevalent AD in relatives with 8 cases (16%) identified, followed by RA in 5 (10%), T1DM (n=3), graves' disease (n=3) and multiple sclerosis (n =2). Other AD identified were sjogrens, hashimotos and psoriasis (n=1). In 54% the family history was in a first degree relative, second degree relative in 37.5% and 3<sup>rd</sup> degree relatives in 8.3%. The majority of relatives with an autoimmune history were female ( 70.8%). There was no significant difference in the incidence of a family history of autoimmune disease between the various ethnic groups.

## **Conclusion:**

Within our multi ethnic cohort of patients with SLE, RA was the most common second AD followed by APS. Afro-Caribbean were more likely to have a second AD than either south east Asians or Caucasians. SLE, RA, T1DM and Graves' disease were the most common ADs found in family members. Ethnicity did not affect the likelihood of patients having a relative with an AD. Larger sampling is warranted for future studies.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hydroxychloroquine retinopathy (HCR) is a potentially blinding but largely preventable disease. The true prevalence of HCR is unknown among the 350,000 Americans who take the drug,<sup>1</sup> but it appears to be rising, related in part to changes in the definition of HCR. Despite improvements in diagnostic testing, it is still challenging to detect early signs of hydroxychloroquine toxicity.<sup>2,3</sup> Moreover, once the disease is detected, there is no treatment and retinopathy often continues to progress even when the medication is stopped. Thus, primary prevention offers the best chance of managing HCR. Critical parameters that increase risk for HCR include the magnitude of dose and duration of therapy. Prescribing providers may not routinely calculate the optimal dose of hydroxychloroquine due to a number of factors, including: (1) toxicity is a cumulative effect and takes years to develop; (2) the calculations are cumbersome and time during a clinical encounter is short; (3) lack of familiarity with recommended dosing guidelines; and (4) controversy exists over how to calculate appropriate dosages.

**Methods:** Equations for calculating a low-risk hydroxychloroquine dose based on a patient's actual body weight (ABW) and ideal body weight (IBW) were used to develop a novel iOS app to compare the two calculation methods and recommend a dosing strategy to maximize patient safety. The *Smart BASIC* iOS app was used for programming to devise a hydroxychloroquine dose calculating app compatible with the iOS operating system.

**Results:** We developed a free iOS App, *DoseChecker*, to provide a tool for rapid comparison of ABW and IBW hydroxychloroquine dose calculations for a patient at the point of care. Calculated data for an individual patient's height and weight are reported for the two methods on a single screen output. The *DoseChecker* app recommends a maximum weekly hydroxychloroquine dose based on whichever dosing strategy (ABW vs. IBW) yields the lower weekly dose. The app then proposes an optimal weekly dosing strategy using a combination of 200mg and 400mg daily doses to reduce the risk of HCR by safely maximizing dosing of hydroxychloroquine.

**Conclusion:** By using *DoseChecker* to engage the patient in clinical decision making, the prescribing provider can educate patients regarding the risk factors for HCR and reinforce the critical need for ongoing ophthalmologic monitoring for HCR. We therefore anticipate that using the *DoseChecker* app in clinical practice will provide a convenient and practical bedside tool to facilitate the safe prescribing of hydroxychloroquine for primary prevention of HCR.

## EZH2 Modulates the DNA Methylome and Controls T Cell Adhesion through Junctional Adhesion Molecule-a in Lupus Patients

Pei-Suen Tsou<sup>1</sup>, Patrick Coit<sup>1</sup>, Nathan Kilian<sup>2</sup> and Amr H Sawalha<sup>1</sup>, <sup>1</sup>Division of Rheumatology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Rheumatology, University of Michigan, Ann Arbor, MI

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** EZH2 is an epigenetic regulator that trimethylates lysine 27 of histone 3 (H3K27me3) and modulates DNA methylation patterns. We have previously suggested that EZH2 might be mediating a pro-inflammatory epigenetic reprogramming in naïve CD4<sup>+</sup> T cells as an early event in lupus flares. The aim of this study is to characterize the role of EZH2 in CD4<sup>+</sup> T cells upon lupus pathogenesis.

**Methods:** Naïve CD4<sup>+</sup> T cells were isolated from lupus patients and healthy controls. EZH2 expression levels were determined, and the epigenetic effects of EZH2 overexpression in CD4<sup>+</sup> T cells was evaluated using a genome-wide DNA methylation approach. Gene expression and miRNAs were assessed by qPCR while protein expression was examined by Western blotting. A cell adhesion assay was used to assess adhesion of CD4<sup>+</sup> T cells to human microvascular endothelial cells (HMVECs).

**Results:** EZH2 expression and H3K27me3 levels were increased in naïve CD4<sup>+</sup> T cells in lupus compared to healthy controls. Both miR-26a and miR-101 downregulate EZH2, and were reduced in lupus CD4<sup>+</sup> T cells. Overexpressing EZH2 in naïve CD4<sup>+</sup> T cells followed by T cell stimulation *in vitro* resulted in significant DNA methylation changes. Genes involved in leukocyte adhesion and migration, such as *F11R* encoding JAM-A (junctional adhesion molecule A), and *SELPLG* encoding PSGL-1 (P-selectin glycoprotein ligand 1), become hypomethylated in CD4<sup>+</sup> T cells when EZH2 is overexpressed. Indeed, overexpression of EZH2 resulted in increased JAM-A expression and ~ 2 fold increased adhesion of CD4<sup>+</sup> T cells to endothelial cells. Pre-incubation of EZH2-transfected CD4<sup>+</sup> T cells with neutralizing antibodies against JAM-A significantly blunted cell adhesion. Similarly, CD4<sup>+</sup> T cells from lupus patients overexpressed JAM-A and adhered significantly more to endothelial cells compared to T cells from healthy controls. Blocking JAM-A

via neutralizing antibodies or blocking EZH2 using an inhibitor significantly reduced endothelial cell adhesion of lupus CD4+ T cells.

**Conclusion:** We identified a novel role for EZH2 in T cell adhesion mediated by epigenetic remodeling and upregulation of JAM-A. EZH2 is overexpressed in lupus naïve CD4+ T cells and leads to increased T cell adhesion mediated by JAM-A. Blocking EZH2 or JAM-A might have a therapeutic potential in lupus by reducing T cell adhesion, migration, and extravasation.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic Lupus Erythematosus (SLE) is a multi-factorial disease and the conventional oligo-dimensional investigative approach involving one or a few cell subsets at a time is inadequate for its study. We hypothesize that multiple immunological abnormalities contribute to lupus pathogenesis and hence, a comprehensive holistic interrogative strategy is required. To address these issues, we employ a multi-dimensional, deep immunophenotyping approach using mass cytometry to unravel the pathogenic mechanism underpinning childhood onset SLE (cSLE).

### **Methods:**

Peripheral blood mononuclear cells from 14 cSLE patients and 14 healthy paediatric controls, were stained with 37 immune phenotypic markers for mass cytometry. Subsequent analysis of the data was done with dimensional reductions followed by automated cell classification, clustering and visualization using an in-house customized machine learning software (MARVis: Multi-dimensional Automated Reduction and Visualization). Unique nodes representing immune subsets enriched in cSLE patients were statistically evaluated with reference to the healthy cohort and the association with lupus disease activity determined (Mann Whitney U Test,  $p < 0.05$ ).

## Results:

A statistically significant enrichment of a memory IL10 positive B cell subset (CD19<sup>+</sup>CD27<sup>+</sup>) with CD11c<sup>+</sup>CD25<sup>+</sup>HLA-DR<sup>+</sup>CD40<sup>hi</sup>CD86<sup>hi</sup> was found in the SLE cohort. This cell population was significantly associated with an inactive lupus disease state, suggestive of an immunoregulatory function. In the healthy cohort, a reciprocal increase in the transitional/naive B cell population negative for CD11c, CD25, CD40 and CD86 was found.

Secondly, a significant enrichment of the memory regulatory T cell population (CD4<sup>+</sup>CD45RO<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>+</sup>) was present in the diseased cohort, especially during disease inactivity, with some of these cells being positive for CXCR5, a homing chemokine receptor to the lymph node germinal centre. Expression of CXCR5 is mechanistically relevant and signifies a potential regulatory role of these cells as the lymph node is an important lupus related microenvironment.

## Conclusion:

A holistic multi-dimensional approach was able to distill the immunoregulatory components of the cSLE immunome. The identification of a novel regulatory B cell subset, typified by the presence of IL10, with phenotypic markers for antigen presentation (HLA-DR, CD86) and T-B cell interaction (CD25, CD40) suggests its potential regulatory role during direct cell-to-cell interaction. In addition, the concomitant increase in the memory regulatory T cell subset suggests at least a dual regulatory mechanism responsible for quiescent disease. Further mechanistic study of these subsets is necessary and have the dual translational potential of being used as a predictor of clinical fate and identification of new therapeutic targets.

## Inducible cAMP Early Repressor Promotes Glycolysis By Inhibiting the Pyruvate Dehydrogenase Phosphatase Catalytic Subunit 2 in Th17 Cells

**Michihito Kono**, Nobuya Yoshida, Nicole E. Skinner and George C. Tsokos, Beth Israel Deaconess Medical Center, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Th17 cells are key players in SLE. Because Th17 cells use mainly glycolysis, blocking glycolysis can inhibit Th17 cell differentiation and treatment of lupus-prone mice with a combination of glycolysis and mitochondrial metabolism inhibitors reverses disease manifestations. In Th17 cells, pyruvate dehydrogenase (PDH), the enzyme which converts pyruvate to acetyl coenzyme A, is decreased. PDH kinase (PDHK) inactivates PDH whereas PDH phosphatase (PDP) activates PDH. Although previous reports showed PDHK was increased in Th17 and inhibition of PDHK suppressed Th17 differentiation, the underlying molecular mechanisms have not been elucidated yet. cAMP response element modulator (CREM) modulates the transcription of c-AMP responsible genes. We have shown that the

inducible cAMP early repressor (ICER) isoform of CREM promotes Th17 cell differentiation and ICER/CREM deficient mice have less autoimmune disease and CD4<sup>+</sup> T cells from the patients with SLE have more ICER/CREM expression than those from health donors<sup>1</sup>. Because many genes associated with cell metabolism have cAMP response element (CRE) sites, to which ICER/CREM binds, we sought to identify metabolic enzymes controlled directly by ICER/CREM in Th17 cells.

**Methods:** Naïve CD4<sup>+</sup> T cells from ICER/CREM sufficient or deficient mice were cultured under Th17 conditions. Glycolysis and glycolytic capacity were analyzed by extracellular flux analyzer. PDHK and PDP catalytic subunit 2 (PDP2) expression were measured by qPCR and Western blotting. These experiments were repeated after ICER $\gamma$  overexpression. Then the effect of ICER to *Pdp2* promoter was assessed by luciferase reporter and chromatin immunoprecipitation assays. We also analyzed the effect of PDP2 overexpression on glycolysis and Th17 cell differentiation *in vitro*. Finally, CD4<sup>+</sup>CD45RA<sup>-</sup>CCR6<sup>+</sup>CCR4<sup>+</sup> cells (memory Th17 cells) were sorted from patients with SLE or healthy donors and *Pdp2* gene expression was assessed by qPCR.

**Results:** ICER/CREM deficiency decreased glycolysis and glycolytic capacity in Th17 polarized cells and this was reversed by ICER $\gamma$  overexpression. PDP2 expression increased in ICER/CREM-deficient Th17 polarized cells compared to that recorded in ICER/CREM-sufficient counterparts. ICER $\gamma$  overexpression corrected the increased levels of PDP2 in ICER/CREM-deficient Th17 cells. On the other hand, decreased PDHK was observed in ICER/CREM-deficient Th17 cells, however, ICER $\gamma$  overexpression did not restore its expression. Furthermore, *Pdp2* promoter reporter assay revealed that *Pdp2* activity was increased by site-direct mutation of putative ICER binding site. ICER accumulation at those CRE sites was confirmed by chromatin immunoprecipitation assays. PDP2 overexpression reduced glycolysis and Th17 differentiation. *Pdp2* gene expression in memory Th17 cells tended to be decreased in lupus compared to healthy donors.

**Conclusion:** ICER increases glycolysis and promotes Th17 differentiation by inhibiting directly the expression of PDP2. Because PDP2 overexpression reduces Th17 cell differentiation, PDP2 might be a new therapeutic target.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Increasing evidence points to immunological heterogeneity in the pathogenesis of SLE. Indeed, targeted therapy for SLE showed considerable variability of efficacy. Thus, it seems to be important to explore the characteristic and interaction among the immune cell phenotypes in this disease. The aim of this study was to assess the comprehensive peripheral immunophenotyping in a correlation with clinical manifestations in patients with SLE.

**Methods:** Peripheral blood mononuclear cells were obtained from 143 SLE patients and 49 healthy controls (HC) and the phenotype of circulating B, T, NK and dendritic cells was defined based on flow cytometric analysis for human immune system termed "the Human Immunology Project". The correlation of immune cell phenotypes with clinical characteristics and responsiveness to immunosuppressive therapies, such as cyclophosphamide, mycophenolate mofetil, or calcineurin, in addition to high-dose glucocorticoids, were evaluated.

**Results:** The frequency of CD3<sup>+</sup>CD4<sup>+</sup>CXCR5<sup>+</sup>ICOS<sup>+</sup>CD69<sup>+</sup> activated T follicular helper (Tfh) cell, but not CD3<sup>+</sup>CD4<sup>+</sup>CXCR3<sup>+</sup>CCR6<sup>-</sup> Th1 cell and CD3<sup>+</sup>CD4<sup>+</sup>CXCR3<sup>-</sup>CCR6<sup>+</sup> Th17 cell, were higher in SLE than that in HC (mean 0.4 vs 0.2, p=0.03). The frequency of CD19<sup>+</sup>CD20<sup>+</sup>IgD<sup>-</sup>CD27<sup>+</sup> class-switched memory B cell and CD19<sup>+</sup>CD20<sup>+</sup>IgD<sup>-</sup>CD27<sup>-</sup> double negative B cell were higher in SLE than that in HC (mean 23.6 vs 13.2 and 10.7 vs 5.5, p=0.03 and p=0.04, respectively). The largest difference relative to the HC was observed in the proportion of CD19<sup>+</sup>CD20<sup>-</sup>CD27<sup>+</sup>CD38<sup>+</sup> plasmablast, which was higher in SLE (mean 16.2 vs 3.3, p=0.001) and correlated with BILAG index (r=0.24, p<0.001). The proportion of activated Tfh cell significantly correlated with serum IgG level (r=0.20, p=0.02) and with serum anti-Sm antibody level (r=0.26, p=0.01). Among helper T cell subsets (Th1, Th17, Treg and Tfh), the proportion of Tfh cell or activated Tfh cell showed positive correlation with that of plasmablast (r=0.21, p=0.02). Treatment resulted in significant decreased proportions of plasmablast and Tfh cell (plasmablast; mean 17.6 to 10.1, p<0.01, Tfh; mean 1.1 to 0.7, p<0.01). The percentage of patients who showed treatment resistance was highest among patients with high percentage of Tfh cell (p=0.03).

**Conclusion:** Peripheral immunophenotyping indicated the pathological relevance of Tfh cell and plasmablast in patients with SLE, *i.e.* activation of Tfh cell correlated with autoantibody production while plasmablast did with disease activity of SLE. The peripheral immunophenotyping might be useful in evaluating the pathogenesis and in determining the therapeutic target of each patient.

## **Response Gene to Complement-32 Expression Is Upregulated in Lupus T Cells and Promotes IL-17A Expression**

Vinh Nguyen<sup>1</sup>, Alexandru Tatomir<sup>2</sup>, Cornelia Cudrici<sup>3</sup>, Horea Rus<sup>2</sup> and Violeta Rus<sup>1</sup>, <sup>1</sup>Medicine, University of Maryland School of Medicine and Veteran Affairs Medical Center, Baltimore, MD, <sup>2</sup>Neurology, University of Maryland School of Medicine and Veteran Affairs Medical Center, Baltimore, MD, <sup>3</sup>NIAMS, NIAMS, NIH, Bethesda, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** RGC (Response Gene to Complement)-32 is a cell cycle regulator widely expressed in normal tissues including brain, kidney, spleen, thymus, multiple tumors and in a variety of cell lines. RGC-32 is localized in the cytoplasm and translocates to the nucleus upon upregulation by complement activation, growth factors and cytokines. RGC-32 is induced by TGF $\beta$  in fibroblasts, astrocytes and human renal proximal tubular cells and mediates TGF $\beta$  dependent profibrotic pathways. Depending on the cell type, physiological or pathological conditions, RGC-32 can either stimulate or suppress cell growth. We have shown that RGC-32 is preferentially upregulated in murine Th17 cells and promotes their differentiation in vitro and in vivo. Patients with Systemic Lupus Erythematosus (SLE) display increased serum levels, expanded frequency of IL-17 producing cells in blood and organs such as the kidney. Whether RGC-32 is expressed in human CD4<sup>+</sup> T cells and whether it plays a role in the Th17 pathway abnormalities in lupus patients has not yet been investigated.

**Methods:** RGC-32 mRNA expression was first assessed with the Autoimmune Disease Profiling cDNA Array (BD Bioscience) spotted with cDNA from CD3<sup>+</sup>, CD19<sup>+</sup> and CD14<sup>+</sup> cells from 10 lupus patients and 10 controls. PBMC were obtained from 20 patients with lupus and 18 controls. RGC-32 expression was determined by RT-PCR and flow cytometry in CD4<sup>+</sup> T cells and CD19<sup>+</sup> B cells. RGC-32 expression in naïve CD4<sup>+</sup> T cells from normal controls stimulated under Th1, Th2, Th17 and Treg conditions was determined by RT-PCR. RGC-32 overexpression and silencing was performed by nucleofection and the effect on IL-17A mRNA levels in CD4<sup>+</sup> T cells under Th17 conditions was determined by RT-PCR.

**Results:** RGC-32 mRNA expression was significantly increased in CD19<sup>+</sup> B cells, CD14<sup>+</sup> monocytes and CD3<sup>+</sup> T from lupus patients compared to controls. By intracellular staining, CD4<sup>+</sup> and CD19<sup>+</sup> cells SLE lupus patients display higher intracellular RGC-32 expression ex vivo ( $1.5 \pm 0.5$  fold and  $1.9 \pm 0.7$  fold, respectively) as compared to controls. By RT-PCR, RGC-32 mRNA expression was significantly higher in CD4<sup>+</sup> T cells from patients vs. controls. In vitro, RGC-32 mRNA expression increased upon TCR stimulation and was further increased by TGF $\beta$  in CD4<sup>+</sup> T cells from healthy controls. Other cytokines such as IFN $\alpha$ , IL-1 $\beta$ , TNF $\alpha$  did not upregulate RGC-32 mRNA either alone or in combination with TCR stimulation. RGC-32 mRNA upregulation was more robust under Th17 ( $3.2 \pm$  fold) and Treg ( $2.6 \pm 0.8$  fold) as compared to Th1 ( $1.3 \pm 0.4$  fold) and Th2 ( $1.8 \pm 0.1$  fold) conditions. Overexpression of RGC-32 in CD4<sup>+</sup> T cells upregulated IL-17A mRNA expression while RGC-32 silencing significantly downregulated IL-17A transcript levels under Th17 polarizing conditions.

**Conclusion:** These results suggest that T cells from patients with SLE exhibit increased expression of RGC-32 compared to normal controls. In vitro, RGC-32 promotes the differentiation of human Th17 cells. These data support the idea that RGC-32 signaling may enhance disease expression in SLE by promoting abnormalities in the Th17 pathway and provide a compelling rationale for further investigating the therapeutic potential of blocking RGC-32 in SLE.

## Immune Complex-Driven Neutrophil Activation in Systemic Lupus Erythematosus – Novel Biomarkers of Disease Activity and Severity

**Hsin-Hsuan Juo**<sup>1</sup>, Edward Chiou<sup>2</sup>, Keith B. Elkon<sup>3</sup> and Christian Lood<sup>4</sup>, <sup>1</sup>Rheumatology, University of Washington, Seattle, WA, <sup>2</sup>University of Washington, Seattle, WA, <sup>3</sup>Department of Medicine & Immunology, University of Washington, Seattle, WA, <sup>4</sup>Department of Medicine, Division of Rheumatology, University of Washington, Seattle, WA  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neutrophil activation is linked to inflammation and autoimmune diseases, including systemic lupus erythematosus (SLE) where nucleic acid-containing immune complexes (ICs) drive inflammation through engagement of immune cells, including neutrophils. We recently demonstrated that neutrophils, upon internalization of ICs, undergo a programmed form of necrosis, NETosis, with extrusion of neutrophil extracellular traps (NETs) exposing key lupus autoantigens such as DNA, histones, and mitochondrial components, including oxidized inflammatory mitochondrial DNA. Further, activated neutrophils release proteases able to shed FcγRIIA restricting IC-mediated phagocytosis, while promoting NETosis. The aim of this study was to investigate the clinical utility of neutrophil-derived biomarkers in SLE patients.

**Methods:** Markers of neutrophil activation (S100A8/A9) and NETosis (8-OHdG DNA, MPO-DNA complexes, cell-free DNA, peroxidase activity) were analyzed by ELISA, fluorimetry and enzymatic assays in healthy controls (HC, n=20) and SLE patients (n=44). The SLE patients were female (91%), of non-Caucasian origin (66%), with an average SLEDAI score of 6 (range 0-22). FcγRIIA shedding was analyzed by flow cytometry. Mitochondria were isolated by density gradient and, upon incubation with macrophages, analyzed for inflammatory potential in presence of SLE autoantibodies.

**Results:** SLE patients had significantly increased levels of NET-related markers as compared to HCs ( $p<0.0001$ ), with many of the markers, including 8-OHdG DNA and MPO-DNA complexes being increased in patients with active disease ( $p<0.05$ ), and related to active kidney involvement and complement consumption ( $p<0.05$ ). Considering the elevation of mitochondrial components (e.g. 8-OHdG DNA,  $p<0.01$ ) in SLE, we next asked if SLE patients had antibodies to mitochondrial surface antigens (MSA). Using a novel in house developed flow cytometry technique we demonstrated the presence of anti-MSA antibodies in 35/44 of SLE patients, with the antibody level correlating with SLEDAI ( $r=0.55$ ,  $p<0.0001$ ). Further, *in vitro*, presence of anti-MSA antibodies promoted inflammatory clearance of mitochondria by macrophages with generation of IL-6 and IL-8 ( $p<0.05$ ), suggesting a pathological role of those autoantibodies. As NETosis is mediated through IC uptake, we analyzed the capacity of lupus serum to induce FcγRIIA internalization and shedding *in vitro* by flow cytometry. FcγRIIA internalization was highly increased in lupus patients ( $p<0.0001$ ) and related to disease activity ( $r=-0.35$ ,  $p=0.02$ ). Further, FcγRIIA internalization could distinguish SLE patients from HC and RA patients with good sensitivity and specificity (HC: 79.5%, 95%,  $p<0.0001$ ; RA: 79.5%, 69%,  $p<0.0001$ ). Finally, FcγRIIA shedding was a better predictor of disease activity as compared to anti-dsDNA antibodies (OR 5.5  $p<0.0001$  vs OR 2.0  $p=0.19$ ).

**Conclusion:** Our data demonstrate a clear contribution of IC-mediated neutrophil activation in the SLE pathogenesis and identifies several novel, and superior, biomarkers able to monitor disease activity and severity in lupus patients.

# Lupus Serum Induces Glomerular Endothelial Cell Neutrophil Adhesion in Association with Soluble Mediators of Chemotaxis and Adhesion

Dayvia Russell<sup>1</sup>, Margaret Markiewicz<sup>2</sup> and **Jim C. Oates**<sup>3,4</sup>, <sup>1</sup>Research Service, Ralph H. ## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is associated with endothelial dysfunction, which can accelerated inflammation. Ingress of neutrophils into tissue requires chemotaxis and adhesion to endothelial cells. The goal of this project was to explore possible mechanisms leading to increased adhesion of neutrophils to glomerular endothelial cells induced by lupus serum.

## Methods:

SLE patients in a longitudinal cohort that met four or more ACR criteria had serum collected and stored at -80°C during paired clinic visits with less activity (SLE Disease Activity Index (SLEDAI) score 0-6) and more activity (SLEDAI score 4-14 but always 4 points higher than inactive visit). Primary human renal glomerular endothelial cells (HRGECs) were cultured according to the manufacturer's protocol and used at passages 3-4 and were seeded at  $8 \times 10^4$  cells per fibronectin-coated well and grown to 90% confluence. HRGECs were cultured in SLE serum (2.5% in culture medium) for 3 hours in triplicate. Serum was removed and replaced with culture medium. Calcein AM-stained neutrophils isolated from healthy controls were cultured with HRGECs for 20 minutes. Neutrophil adherence to serum-treated HRGECs after five washes was measured as percent of cells (in fluorescence units) adhering relative to a TNF $\alpha$  positive control. Supernatant from "active disease" cultures was collected after neutrophil culture and analyzed for mediators of inflammatory cell vascular adhesion and transmigration (intracellular adhesion molecule-1 (ICAM), vascular CAM-1 (VCAM), neural CAM (NCAM), platelet-derived growth factor, myeloperoxidase, cathepsin D, plasminogen activator inhibitor-1, and interleukin 8 (IL8)) by commercial multiplex bead array. Associations between variables were determined using Spearman correlation and Mann-Whitney U test. Group values were reported as the median (interquartile range).

## Results:

32 SLE patients (13 with lupus nephritis) were enrolled with paired active/inactive visits. Patients were 95% female and 73% African-American and had a median age of 40 (18). To explore factors that associated with increased adhesion, supernatant concentrations of mediators were correlated with relative neutrophil adherence and the fold change adherence from inactive to active disease visits. Cathepsin D ( $r=-0.46$ ,  $p=0.05$ ) and IL8 ( $r=0.77$ ,  $p<0.001$ ) correlated significantly with relative neutrophil adherence. NCAM ( $r=-0.54$ ,  $p=0.002$ ), cathepsin D ( $r=-0.63$ ,  $p=0.005$ ), and IL8 ( $r=0.50$ ,  $p=0.03$ ) correlated significantly with fold change in adherence with high versus low disease activity.

**Conclusion:** This study suggests that lupus serum induces expression of mediators that affect neutrophil adhesion. The association of neutrophil adhesion with IL8 is consistent with reports of elevation of IL8 in lupus nephritis and induction by anti-dsDNA antibodies. The negative association with soluble NCAM (not previously reported in HRGECs) may be the result of soluble NCAM competing with the membrane-bound form. Cathepsin D can both induce neutrophil apoptosis and increase the adhesiveness of fibronectin. Neither of these hypotheses was tested in this study.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It is well established that up to 70% of systemic lupus erythematosus (SLE) patients will develop Lupus Nephritis (LN). Recent studies have revealed that infiltrating monocytes and macrophages are associated with LN pathogenesis. Studies by our group and others have studied the potential role of HO-1, a haem-degrading enzyme with anti-inflammatory properties, in the modulation of immune cells and SLE development. Therefore, we decided to explore the contribution of HO-1 expression to LN pathogenesis.

**Methods:** All patients were recruited at Hospital Clínico of Pontificia Universidad Católica de Chile, fulfilled the ACR SLE classification criteria and had proliferative LN confirmed by renal biopsy (Class III, IV or V ISN/RPS). All individuals signed an informed consent form. Monocytes were purified using pan-monocytes MACS kit from peripheral blood mononuclear cells (PBMCs) of LN patients and healthy controls (HC). The CD16<sup>+</sup> inflammatory monocytes were quantified. FACS was used to measure phagocytosis, HO-1 expression and ROS levels. The latter were determined using a CellRox Kit.

**Results:** We found that monocytes purified from LN patients show significant differences as compared to healthy controls (HC) in all parameters analyzed. LN patients have increased the CD16<sup>+</sup> inflammatory monocytes (LN: 6.72±0.98%, HC: 4.07±0.48%; p<0.05). HO-1 protein expression is decreased in monocytes from LN patients compared with HC (LN: 1572±481, HC: 4789±911; p=0.005). ROS levels are elevated in LN monocytes showing similar values to monocytes from HC treated with a ROS inducer (HC: 3509±584, HC+TBHP: 8436±1909, LN: 8355±1714). Furthermore, the phagocytic activity is increased in LN monocytes (77.97±3.31%) compared to HC (39.63±2.75%). Moreover, our preliminary data indicate that HO-1 induction leads to down regulation of ROS production in LN (~60%) and HC (~40%) leaving both in similar ROS production. In addition, phagocytic activity is also decreased in LN and HC monocytes in the presence of HO-1 inducer (~30%). Furthermore, in renal biopsies of LN patients we observed that HO-1 expression is increased in renal tubular epithelial cells compared to HC.

**Conclusion:** Decreased HO-1 expression in circulating monocytes of LN patients leads to higher ROS production and higher phagocytic activity, which contributes to renal injury. We propose that increased HO-1 levels in epithelial renal cells might be an attempt of the kidney to protect itself from damage. Since ROS levels and phagocytosis are reduced when a HO-1 inducer is used, we also speculate that HO-1 induction in monocytes might exert a cytoprotective role in LN by regulating innate immunity. FONDECYT N°1150173.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Toll-like receptor 7 (TLR7) is implicated in the production of type I IFNs and the activation of B cells in systemic lupus erythematosus (SLE). Genetic studies support a link between *TLR7 rs3853839 C/G* polymorphism, associated with an increase in TLR7 expression and SLE susceptibility. While much has been reported on TLR7 in murine lupus, very little is known about how increased TLR7 signaling may contribute to human B cell function and to SLE pathology. This study was undertaken to determine how variations in *TLR7* expression affects peripheral B cell populations, auto-Ab production and cytokine expression levels in SLE patients.

### **Methods:**

Human peripheral blood mononuclear cells (PBMCs) were collected from SLE patients and healthy controls (HC) and analyzed for the expression of *TLR7* and IFN-stimulated genes (ISGs) by real-time PCR. SLEDAI scores were obtained from clinical records. Frequencies of peripheral B cell population were analyzed by multicolor flow cytometry. Autoreactive cells were identified by fluorescently-labeled SmRNP. Autoantibody profiles were quantified by protein microarray and analyzed by Significance Analysis of Microarrays (SAM). Cytokines in the serum were measured by bead-based ELISA.

### **Results:**

High *TLR7* expression in SLE patients was associated with a more pronounced IFN signature. 75.0% of *TLR7*<sup>hi</sup> SLE patients were *TLR7 rs3853839 G* (risk) allele-carriers, compared to 47.06% in *TLR7*<sup>norm/lo</sup> SLE and 33.33% in HC. High *TLR7* expression correlated with an increase in IFN $\alpha$  and IFN $\gamma$  levels in the serum but did not correlate with serum BAFF levels. Analysis of peripheral B cell subsets in *TLR7*<sup>hi</sup> SLE patients showed an increase of CD19<sup>+</sup> B cells, expansion of transitional B cells and pre-plasma cells as compared to *TLR7*<sup>norm/lo</sup> and HCs. *TLR7*<sup>hi</sup> B-cells showed an

increase in *IL-6* and a decrease in *IL-10* gene expression. TLR7<sup>hi</sup> SLE patients displayed increased frequencies of Sm/RNP-specific B cells, which were found mostly within the CD27-IgD<sup>+</sup> naïve B cell pool. IgG microarray revealed an increase in auto-Ab titers, enrichment for more autoantibody specificities, and skewing towards Sm/RNP specificities in the TLR7<sup>hi</sup> SLE group. Importantly, TLR7<sup>hi</sup> SLE patients had a higher disease activity (mean  $\pm$  SD SLEDAI 6.56  $\pm$  0.95 versus 3.07  $\pm$  0.6 in TLR7<sup>norm/lo</sup>,  $p=0.007$ ) and were more likely to develop lupus nephritis, supporting the clinical significance of our findings.

## Conclusion:

Our studies provide new insights into the role of TLR7 signaling in human SLE. Variation in TLR7 expression dictated by genetic variation affecting TLR7 RNA turnover appears to “shape” B cell maturation and the auto-Ab repertoire. In addition, high TLR7 is associated with IFN production, possibly linked to immune complex production. TLR7 expression may, therefore, serve as a useful biomarker in SLE. TLR7<sup>hi</sup> SLE patients, particularly the *TLR7* rs3853839 G (risk) allele-carriers, represent a distinct population who could respond well to anti-TLR7 and/or type I and type II IFN – targeted therapies.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Podocytes are postmitotic visceral epithelial cells, located at the Bowmans capsule of the kidney building up the slit diaphragm with their foot processes to filtrate the blood and keep valuable large proteins in the vessels. Loss of these cells leads to proteinuria.

In Systemic Lupus Erythematosus (SLE) different organs are affected by autoantibodies which results in chronic inflammation and a high percentage of patients develop Lupus nephritis (LN) resulting in podocyte damage and disruption of the slit diaphragm. The risk for LN correlates directly with the level of anti-double stranded DNA antibodies (adsDNAabs).

## Methods:

In this study, we wanted to identify the direct effect of adsDNAabs on podocytes.

We established an in vitro system to investigate the specific impact of monoclonal antibodies and their immune complexes directly on podocytes (AB8 cell line). Monoclonal antibodies were generated by transfecting HEK293T cell line with Ig heavy and corresponding light chain encoding plasmid DNA obtained from single B cells of patients with SLE and LN. Podocytes were incubated with the produced monoclonal antibodies and the internalization process and functional consequences were analyzed by immunofluorescence, Western Blot, FACS and electron microscopy. For comparison, primary podocytes were isolated from LN patient urine and analyzed by immunofluorescence. To clarify the endocytotic pathway of antibody internalization, cells were treated either with chlorpromazine, MDC or nystatin.

## Results:

The recombinantly produced adsDNAabs from LN patients were specific against nuclear structures and build complexes with double stranded DNA, essential for the internalization by cultivated podocytes. Interestingly, viability and migratory capacity were not influenced by the exposure to adsDNAabs for 48h. The internalized antibodies were enclosed by membranous structures and reach the cytosol via clathrin dependent endocytosis. The process of internalization was time and dose dependent and reversible. Furthermore, internalized antibody complexes could also be detected in primary human LN podocytes.

## Conclusion:

In our in vitro model the specific uptake of adsDNAabs was observed, in line with human LN data. Podocytes from patients with LN show IgG positive aggregates in the cytosol. The internalization depends on the complex formation of the antibodies with dsDNA and could be important part of the LN pathogenesis.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The pool of naïve CD4<sup>+</sup> T-cells is reduced in patients suffering from systemic lupus erythematosus (SLE). We aimed to study if the occurrence of early thymic involution and premature senescence potentially contributes to reduced naïve CD4<sup>+</sup> T-cell numbers.

## Methods:

Peripheral blood mononuclear cells were obtained from 50 SLE patients and 50 healthy controls (HC) in a prospective, cross-sectional study. Prevalence of memory and naïve CD4<sup>+</sup> T-cells was assessed by flow cytometry. Naïve CD4<sup>+</sup> T-cells were isolated by MACS technology for telomere length and T-cell receptor excision circle (TREC) assessment by real-time PCR. Telomere length was chosen as parameter for cellular senescence and TRECs for the evaluation of thymic function and replicative history. Moreover, telomerase activity was analyzed according to the Telomeric Repeat Amplification Protocols (TRAP). Patients and HCs were separated into two distinct age-groups for analysis of age-dependent differences ( $\leq 48$  years [SLE n=34, HC n=26];  $>48$  years [SLE n=16, HC n=24]).

## Results:

Naïve CD4<sup>+</sup> T-cells were significantly reduced in older SLE patients as compared to HCs (SLE 2.06% [0.99-4.47] vs. HC 4.89 [0.55-21.90],  $p=0.003$ ); no difference was observed between young patients and respective controls. We observed a drastic decline in the number of TRECs in naïve CD4<sup>+</sup> T-cells of SLE patients compared to age-matched HCs. TREC numbers were already reduced in younger SLE patients (SLE 168 copies/ng DNA [16-893] vs. HC 2058 [5-64444],  $p=0.000$ ) and similar results were obtained for older patients (SLE 33 [6-1477] vs. HC 117 [0-2347],  $p=0.006$ ). Telomeres were shorter in young SLE patients compared to age-matched controls (SLE mean 6.5kbp [ $\pm 0.5$ ], vs. HC 7.0 [ $\pm 0.9$ ],  $p=0.011$ ). In healthy individuals shortening of telomeres induces an increase in telomerase activity resulting in an inverse correlation of telomere length and telomerase activity. We found such a correlation in naïve CD4<sup>+</sup> T-cells of HCs ( $\text{corr}_{\text{coeff}}=-0.532$ ,  $p=0.000$ ) but not in naïve CD4<sup>+</sup> T-cells of SLE patients.

## Conclusion:

Our data indicate extensive replicative history of naïve CD4<sup>+</sup> T cells of SLE patients leading to a premature decline in telomere length. Unlike in HCs naïve CD4<sup>+</sup> T cells of SLE patients are unable to respond with increased enzymatic function of telomerase. These findings may partially explain the abnormally low number of naïve CD4<sup>+</sup> T cells found in older SLE patients.

## Epstein Barr Virus Interleukin-10 (vIL10) in Systemic Lupus Erythematosus

Neelakshi R. Jog<sup>1</sup>, Eliza Chakravarty<sup>1</sup>, Joel M. Guthridge<sup>2</sup> and Judith A. James<sup>3,4</sup>, <sup>1</sup>Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>2</sup>Arthritis and Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>3</sup>Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>4</sup>Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease characterized by autoantibody production and periods of elevated and suppressed disease activity. Various genetic and environmental factors likely contribute to disease pathogenesis. Epstein Barr Virus (EBV) is one such environmental factor that has been consistently associated with SLE. EBV maintains latency in infected B cells and shows frequent reactivation, which can be measured indirectly in terms of antibodies to EBV Early Antigen (EA). Our data show that elevated concentrations of EA IgG increase the probability of transitioning to SLE in unaffected SLE family members, suggesting that viral reactivation may contribute to development or worsening of SLE autoimmune responses. EBV encodes homologs of cellular cytokines to escape host anti-viral response and establish latency. One such protein is a late lytic phase protein encoded by BCRF-1 gene and is an IL10 homolog. Monocytes are one of the first cells to respond following infection and dysregulation of monocytes plays a dynamic role in the initiation and continuation of the systemic autoimmune response in SLE. However, the effects of vIL-10 on monocyte function have not been studied. In this study we examine whether vIL10 has similar inhibitory effects on monocytes as hIL10.

**Methods:** Plasma from 8 SLE patients with varying disease activity and 6 healthy unrelated controls were concentrated and vIL10 was detected by western blotting. The band intensities were normalized to known concentration of recombinant vIL10. Monocytes were enriched from peripheral blood mononuclear cells from healthy donors and stimulated with human or viral IL10. STAT phosphorylation, expression of cell surface markers, and uptake of apoptotic Jurkat cells were determined by flow cytometry. Gene expression was performed using microfluidics quantitative PCRs (Fluidigm).

**Results:** SLE patients showed significantly higher levels of plasma vIL10 ( $25423 \pm 5968$  vs  $12968 \pm 8432$ ,  $p < 0.05$ ). No correlation was observed between vIL10 and hIL10. To determine whether this increased vIL10 has functional consequences, we performed in vitro stimulation of healthy monocytes with human or viral IL10. vIL-10 induced significantly lower STAT-3 phosphorylation compared to hIL-10, and failed to downregulate IL10R1 gene expression, suggesting differences in signaling cascades activated by vIL10. Although less efficient in downregulating pro-inflammatory gene expression, vIL-10 significantly reduced the expression of scavenger receptor CD163 compared to hIL-10, suggesting inhibition of M2 polarization. In line with inhibition of M2 polarization, vIL10 stimulated monocytes were less efficient in clearance of apoptotic cells.

**Conclusion:** Our data show that lupus patients have increased levels of vIL-10 which may be a result of increased EBV reactivation. We show that vIL-10 increases pro-inflammatory cytokine secretion by monocytes while reducing the phagocytic capability. The reduced clearance may lead to accumulation of cell debris and fuel the autoimmune response through death associated molecular patterns prior to initial disease flare.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Genome Wide Association studies (GWAS) have identified several variants in the tumor necrosis factor alpha-induced protein 3 (*TNFAIP3*) gene associated with autoimmune disease. *TNFAIP3* encodes A20, an ubiquitin-editing enzyme that inhibits Nuclear Factor-kappa B (NF-κB) signaling to modulate innate and adaptive immune responses. Loss of *TNFAIP3* expression is implicated in the pathogenesis of autoimmune disease; however, mechanisms responsible for impaired expression remain unclear. Encyclopedia of DNA Elements (ENCODE) and Chromatin Interaction analysis by paired-end Tag Sequencing (ChIA-PET) suggests *TNFAIP3* expression is regulated through a long-range interaction with a putative upstream enhancer. In this study, we investigated the functional importance of a predicted SLE risk variant reference single nucleotide polymorphism (rs)10499197 situated near this enhancer.

## **Methods:**

Electrophoretic Mobility Shift Assays (EMSA) and affinity purification of nuclear factors were performed to screen for specific proteins with altered affinity for the rs10499197 risk allele. **Results** were validated using Epstein-Barr Virus (EBV) transformed B cell lines carrying non-risk or risk genotypes by Chromatin Immuno-Precipitation (ChIP) followed by quantitative PCR. To investigate the regulatory function of the putative enhancer, we cloned the non-risk and risk alleles into a minimal promoter vector containing the luciferase gene, and performed luciferase assays on immune cells (Jurkat and Tamm-Horsfall Protein 1 (THP-1)).

## **Results:**

The rs10499197 risk allele bound the nuclear-protein complex with reduced affinity in EBV-B cells and Jurkat T cells, and increased affinity in THP-1 monocytes, suggesting a cell-specific effect. Affinity purification and ChIP studies revealed reduced binding of the risk allele to NF-κB subunits, NF-κB p50 Subunit (p50) and NF-κB p65 Subunit (p65), and enhanced binding for the risk allele to transcription factors, E2 Transcription Factor1 (E2F1) and Cyclic adenosine monophosphate Responsive Element Binding protein1 (CREB1). E2F1 and CREB1 negatively regulate NF-κB signaling by disrupting NF-κB p50-p65 heterodimer formation, thereby affecting NF-κB-mediated transcription of *TNFAIP3*. Consistently, luciferase assays demonstrated that the regulatory element functions as an enhancer of *TNFAIP3* expression and that the risk allele impaired enhancer activity.

## **Conclusion:**

Results suggest that the SLE risk variant rs10499197 is likely a causal variant that disrupts the function of a putative enhancer upstream of *TNFAIP3*. Disrupting the enhancer may impair *TNFAIP3* expression, enhance NF-κB signaling, and heighten immune responses in a cell type specific manner. Following our work on the TT>A enhancer, this is the second likely causal variant to impact *TNFAIP3* expression. Future Chromatin Conformation Capture assay (3C) will determine how the upstream DNA element physically interacts with the *TNFAIP3* promoter, and help establish a comprehensive mechanistic understanding for how *TNFAIP3* transcriptional regulation is modulated by SLE risk alleles.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic lupus erythematosus (SLE), an autoimmune disorder characterized by the production of pathogenic autoantibodies and inflammatory mediators, involves multiple organ systems. Neuropsychiatric systemic lupus erythematosus (NPSLE) is often difficult to diagnose and distinguish from other diseases, partly because no NPSLE-specific antibodies have been identified. Suprabasin (SBSN) gene was originally identified in mouse and human differentiating keratinocytes as an epidermal differentiation marker. SBSN also plays a role in the growth and invasiveness of tumors. It was demonstrated that the knockdown of SBSN inhibited cell migration and tube formation in tumor endothelial cells, but the pathological role of SBSN in autoimmune disease is not well understood.

### **Methods:**

We developed a novel proteomic strategy for identifying and profiling antigens in immune complexes (ICs) in the cerebrospinal fluid (CSF), and we used this strategy for 26 NPSLE patients. As controls, 25 SLE patients without neuropsychiatric manifestations (SLE), 15 with relapsing remitting multiple sclerosis (RRMS) and 10 normal pressure hydrocephalus (NPH) patients were included. We analyzed the titer of anti-SBSN antibodies in CSF, using a luciferase immunoprecipitation system (LIPS) assay. Real-time quantitative polymerase chain reaction (qPCR) and microarray analysis following exposure of astrocytes to anti-SBSN antibodies were performed. We also performed a multiplex cytokine bead assay using undiluted CSF supernatants and the Bio-Plex Pro Human Cytokine Group I 27-Plex Panel analyzed with a Bio-Plex® MAGPIX™ Multiplex Reader.

### **Results:**

We identified ICs of SBSN in the CSF of the NPSLE group. We also analyzed the CSF of a total of 103 patients (NPSLE=31, SLE=22, MS=30 and NPH=20) from another cohort for anti-SBSN antibodies, using a luciferase immunoprecipitation system (LIPS) assay. The LIPS assay showed that the CSF antibody index (A.I.) of anti-SBSN antibodies was significantly higher in the NPSLE group compared to the A.I. values of the SLE, MS and NPH groups. Among them, the CSF of 41.9% (13 of 31) NPSLE patients was positive for anti-SBSN antibodies. Of note, the CSF concentrations of IL-10, IL-13, GM-CSF, IP-10 and MCP-1 were significantly higher in the CSF anti-SBSN antibodies-

positive group of NPSLE patients compared to those of the negative group. The expression of *SERPINE1* mRNA was significantly upregulated as measured by a qPCR, and microarray data showed that the senescence and autophagy pathways were significantly changed in astrocytes exposed to anti-SBSN antibody compared to normal immunoglobulin G exposure.

**Conclusion:** Our findings indicate that SBSN could be a novel autoantibody for the evaluation of suspected NPSLE, and its use may help elucidate the pathogenesis underlying this disease.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The most frequent genetic cause of Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal Lobar Dementia (FTLD) is a large hexanucleotide expansion (>30, mostly hundred/thousand repeats) within a non-coding region of the *C9orf72* gene (1). The cut-off to distinguish normal and pathogenic expansions has not yet been defined, but most healthy individuals have 2-20 repeats on both alleles (usually 2, 5, 8). The pathogenic mechanism of the dominant mutation is most probably toxic gain of functions, through the production of repetitive transcripts and proteins. Nonetheless, *C9orf72* reduced expression has been observed in post-mortem brains of mutated ALS/FTLD patients (2). Interestingly, while *C9orf72* haploinsufficiency alone seems insufficient to cause neurodegeneration, decreased transcriptional activity with increasing numbers (7-24) of repeats has been demonstrated *in vitro* (3) and knockout mice exhibit immune dysregulations, developing features of autoimmunity, reminiscent of systemic lupus erythematosus (SLE), suggesting a protective role for the *C9orf72* protein against autoimmune diseases (4). Recently, increased prevalence of autoimmune diseases has been observed in *C9orf72* expansion-positive FTLD patients (5). We hypothesized that normal but in the upper range *C9orf72* expansions could influence the immune system and investigated their size in a cohort of patients with rheumatoid arthritis (RA) and SLE. As a control group we studied a cohort of 49 ALS patients without pathogenic expansion.

## Methods:

29 SLE and 6 RA pts were screened for *C9orf72* expansion, by the use of a PCR-based protocol, validated in our laboratory (6). Clinical and serological data were collected from clinical charts. A cut-off of  $\geq 9$  repeat units was considered in our analysis.

## Results:

As expected, no patients with large expansions were found. The average and median values of repeat units were 5.29 (SD 2.87) and 6 in SLE (range 2-11), 5.08 (SD 4.14) and 3.5 (range 2-15) in RA and 4.8 (SD 3.05) and 5 (range 2-19) in the control population. We individuated  $\geq 9$  repeat units in 5/30 (16.7%) SLE patients and 2/6 (33.3%) RA patients; a prevalence higher than what found in ALS group (8.16%). We searched for clinical or serological differences among SLE pts with the normal and  $\geq 9$  repeat size expansion. Although those differences were not statistically significant, we reported a higher prevalence of kidney involvement in patients with a number of repeats  $\geq 9$  (5/6; 83.3% versus 7/23; 30.4%),  $p=0.056$ .

## Conclusion:

Conclusion: our preliminary results indicate that  $\geq 9$  repeats within the *C9orf72* gene are detectable in a non negligible number of patients with systemic autoimmune disease, confirming the possible role of *C9orf72* in autoimmune system. The possible association with specific subset of disease must be confirmed in a larger cohort of patients.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

ITGAM (Integrin- $\alpha$ -M, also known as CD11b) gene located at chromosome 16p11.2, encodes for the  $\alpha$ -chain of Integrin- $\alpha_M\beta_2$ , a leucocyte specific integrin receptor, also known as complement receptor 3 (CR3). It is important in the adherence of leucocytes to stimulate endothelium and in the phagocytosis of complement coated particles such as apoptotic cells. Single nucleotide polymorphism (SNP) rs1143679 G/A in ITGAM gene encodes an amino-acid change from arginine to histidine at position 77 (R77H) which impairs the integrin-mediated cell adhesion of ligands and reduces phagocytosis of complement-coated particles, hence, predisposing to SLE. SNP rs1143679 has been shown to be associated with SLE in European, African, Hispanic or native American populations. We aimed to verify this association in North Indian population and to study the genetic relations between this SNP and sub-phenotypes of SLE.

**Methods:**

395 SLE patients (classified according to the 1997 ACR classification criteria for SLE) and 593 controls were enrolled. All samples were genotyped for SNP rs1143679 using TaqMan genotyping assay in Roche LC480 real-time polymerase chain reaction (PCR) system. A case-control association study and a genotype phenotype correlation were performed.

**Results:**

The mean age of the SLE patients was 30.7 years, and 94.3% were females. Allelic and genotypic frequencies did not deviate from Hardy-Weinberg equilibrium in the controls ( $p > 0.05$ ). Allele contrast showed that the variant allele A was associated with increased risk for SLE when compared with the G allele (OR = 1.63, 95% CI = 1.23 - 2.17,  $p < 0.001$ ). A significant difference was detected both under recessive model [AA vs (GA + GG): OR = 4.31, 95% CI = 1.90 - 9.79,  $p < 0.01$ ] and dominant model [(AA + GA) vs GG: OR = 1.18, 95% CI = 0.85 - 1.64] with regard to the distribution of genotype frequencies between SLE patients and healthy controls. On sub-phenotype analysis, an association was observed between SNP rs1143679 and oral ulcers, under the dominant model (OR = 1.65, 95% CI = 1.01 - 2.70,  $p < 0.05$ ). None of the other clinical manifestations showed association with SNP rs1143679.

**Conclusion:**

SNP rs1143679 in ITGAM gene predisposes to SLE in North Indian population. In accordance with the results of the previous studies conducted in European, African, and Hispanic populations, ITGAM rs1143679 polymorphism is associated with SLE susceptibility in different ethnic groups.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interferon plays prominent role in systemic lupus erythematosus (SLE) pathogenesis while the source of high interferon in SLE is still confused, several cell types can produce interferon, neutrophils as one of important interferon source cells have been arousing growing attention, however the interferon production capacity of neutrophils in SLE and the regulation of neutrophils interferon production still remain unclear. Many long noncoding RNAs (lncRNAs) have been identified abnormally expressed in SLE that act on multiple signal pathways, we presume that there could be a role of lncRNAs in neutrophils interferon production regulation.

**Methods:** Interferon production was measured by qPCR and ISRE reporter gene assay, neutrophils interferon production capacity enhanced after interferon prime. We aimed to find out lncRNA that work in it. RNA-seq was performed in two sets of samples, interferon stimulated neutrophils samples and SLE versus healthy controls neutrophils samples. lncRNA-CMPK2 was screened out by cross-reference the two RNA-seq results. Expression of lncRNA-CMPK2 was knocked down in primary neutrophils using antisense oligos (ASO) by electroporation. To dissect the mechanism that lncRNA-CMPK2 act on TLR7/8 pathway interferon production, western blot was conducted to measure expression of key molecules in this pathway.

**Results:** 1. Neutrophils from SLE patients produced two fold more interferon than that from healthy controls by TLR7/8 agonist R848 stimulation. 2. Neutrophils interferon production capacity enhanced after interferon prime. 3. lncRNA-CMPK2 highly expressed in SLE neutrophils, it was the top 2 differently expressed lncRNA in lupus versus healthy controls and was also among the top significantly interferon stimulated lncRNAs according to the two sets of RNA-seq profiling. 4. lncRNA-CMPK2 expression level correlated with lupus interferon score and disease activity. 5. Knockdown of lncRNA-CMPK2 in neutrophils can attenuate interferon production. The mechanism may rely on reducing expression of IRAK4 and IRF7.

**Conclusion:** lncRNA-CMPK2 facilitates neutrophils interferon production in lupus. Over expression status of lncRNA-CMPK2 may provide new understanding of high interferon in the disease, targeting lncRNA-CMPK2 could probably help to control high interferon level in lupus.

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Infections are linked to morbidity in systemic lupus erythematosus (SLE). This study was undertaken to evaluate oral infections by dental plaque bacteria in SLE patients and the influence of this bacterial exposure on disease in patients and in lupus mice.

**Methods:** Circulating IgG antibodies against dental plaque bacteria identify exposure to the organism. In a pilot study, sera from 72 SLE patients in the Lupus Family Registry and Repository (LFRR) were tested for antibodies to 7 dental plaque bacteria by ELISA. Antibodies to *Aggregatibacter actinomycetemcomitans* (*Aa*) were measured in a confirmatory study of 587 patients from the Oklahoma Lupus Cohort and 75 healthy volunteers. Correlations between anti-*Aa* antibody titers and autoantibodies, complement levels, and clinical features of lupus were studied. NZM2328 lupus mice were infected orally with *Aa* and the effects on disease severity was evaluated.

**Results:** SLE patients show varying levels of serum antibodies to plaque bacteria. Of the antibodies tested, only anti-*Aa* antibody levels were significantly associated with anti-dsDNA titers, a hallmark of SLE. This association was confirmed in patients from the Oklahoma Lupus Cohort. Absorption of anti-*Aa* with *Aa* did not affect anti-dsDNA reactivity, indicating that this association was not solely due to cross-reactivity. An exploratory analysis of clinical variables showed that higher anti-*Aa* titers in SLE patients were associated with low C4 complement levels and increased disease activity as measured by SLEDAI and BILAG scores. In lupus mice, *Aa* activated histone reactive T cells and accelerated onset lupus nephritis.

**Conclusion:** Exposure to the periodontal pathogen, *Aa*, is associated with higher autoantibodies and increased disease activity in SLE patients. Evidence from mouse studies suggests that this worsening of disease may be driven by exacerbated auto-reactivity.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

DNA methylation has emerged as an important contributing factor in the pathogenesis of systemic lupus erythematosus (SLE). SLE typically requires continuous treatment to control the disease, but the effect of different treatments on DNA methylation is still elusive. Therefore the aim of this study was to investigate the association between methylation levels in SLE patients and the most commonly prescribed medications in SLE.

**Methods:**

Whole blood samples were obtained from 347 SLE patients in a discovery cohort and from 201 SLE patients in a replication cohort, all fulfilling at least four ACR criteria for SLE. Clinical data regarding medication were collected at the time of blood sampling, and treatment with glucocorticoids, chloroquines, azathioprine, mycophenolate mofetil and methotrexate were included in the analysis. DNA methylation profiles were generated on the Illumina HumanMethylation 450k BeadChip array, interrogating 485,000 CpG sites across the genome. The association model included differential cell count estimations, age and sex as covariates. Differential methylated CpG sites (DMCs) were called in the discovery phase if they had a  $p < 1.3 \times 10^{-7}$  and an average difference in methylation-beta between treated and untreated cases of  $> 0.05$ . For the replication phase significance was determined as  $p < 6.8 \times 10^{-6}$  and the same direction of effect as observed in the discovery phase.

**Results:**

We identified and replicated treatment-associated DMCs at a total of 5,177 CpG sites. The vast majority of medication DMCs ( $n=5,046$ ) were observed by comparing SLE patients that received glucocorticoid treatment at time of blood sampling ( $n=347$ ) to those who did not ( $n=201$ ). Glucocorticoid treatment was typically associated with decreased methylation, where the strongest effect was observed at the *FK506 binding protein 5 (FKBP5)* involved in immune regulation. The top DMCs with increased methylation in glucocorticoid treated patients were located in *RUNX3*, *TMEM63A*, *ZFP36L1* and *LTA*. In addition, we identified 130 DMCs for azathioprine and one DMC for mycophenolate mofetil treatment, all of these with decreased methylation levels in the treated patients. We were not able to replicate any DMCs associated with methotrexate or chloroquine treatment.

**Conclusion:**

Our results indicate a role for treatment-associated DNA methylation patterns in SLE, although the possible impact of clinical manifestations and disease activity on methylation levels must be taken into account. Changes in methylation may reflect exposure to treatment and contribute to treatment response and adverse effects. Additional studies including analyses of longitudinal medication data will further elucidate the potential functional impact of treatment-associated changes in DNA methylation in patients with SLE.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite emerging data on disease-specific associations for various blood- and plasma-derived miRNAs, consensus is lacking as to whether a cellular, extracellular, or a mixed sample might be utilized to define disease mechanisms and serve as biomarkers for therapeutic response. Although studies showed that B-cells are relevant in the development of CVD, the effect of RTX in the context of CVD in SLE patients has not been fully elucidated yet. Objective: To identify and characterize the microRNA profile in SLE monocytes, along with their association with cardiovascular disease (CVD)-related factors, their contribution to the altered miRNA profile in plasma, and their modulation by in vivo RTX treatment.

**Methods:** Fifty-three SLE patients, and 27 healthy donors were included in the study. Among them, 20 patients were treated with RTX for 3 months. Blood samples were obtained before and at the end of treatment. nCounter microRNA Expression Arrays (NanoString Technologies) and HTG EdgeSeq system (Next generation sequencing) were performed, respectively, to analyze miRNA expression profiles on isolated monocytes and plasma. Target genes of the differentially expressed miRNAs were identified by using the Ingenuity Pathway Analysis Software (IPA). A number of altered miRNAs were validated by RT-PCR on the whole cohorts of SLE patients. Extensive clinical/analytical evaluation was performed, and inflammatory, atherosclerosis and pro-thrombotic profiles were quantified by RT-PCR. Then, correlation and association studies were performed.

**Results:** MicroRNA profiles showed significantly differential expression of 37 microRNAs in SLE monocytes. Functional analysis showed that those miRNAs were mainly related to connective tissue disorders, inflammatory response and reproductive system disease. The expression of several of these miRNAs (i.e. miR-30, miR-149, miR-199) correlated with parameters related to inflammation (i.e. STAT3, PPAR $\gamma$ , IL-6, CRP), oxidative stress (mitochondrial membrane potential) and microvascular dysfunction. Moreover, associations of these miRNAs with the occurrence and type of thrombotic events, obstetric complications and presence of early atherosclerosis were demonstrated. Transfection studies further confirmed the relationship between these identified target genes and specific miRNAs. miRNA profile in plasma demonstrated differential expression of 335 microRNAs in SLE patients of which a 60% were reversed by RTX. Among them, 12 miRNAs were found simultaneously deregulated in monocytes and plasma. Interestingly, those 12 miRNAs displayed a number of CVD-related target genes, and were further reversed by in vivo RTX treatment.

**Conclusion:** We have identified and characterized a specific miRNA profile in monocytes from SLE patients, mostly related to CVD. Although expression from cellular vs circulating miRNAs was mostly divergent in SLE, there was an intriguing association between monocytes and plasma in terms of common deregulated miRNAs involved in CVD, further reversed by RTX treatment.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent studies emphasize the relevance of alternative splicing in the development of genetic and autoimmune diseases. The aim of this study was to identify alterations in the leukocyte splicing machinery of systemic lupus erythematosus (SLE) patients and to evaluate its influence on the development and activity of the disease, its atherothrombotic profile, and the response to specific therapies.

**Methods:** An array of selected components of the major- (n=12) and minor-spliceosome (n=4) and associated splicing factors (n=28) was developed, and their expression levels were evaluated using a Fluidigm methodology, in purified leukocytes from 36 SLE patients and 29 healthy donors (HD). In parallel, an extensive clinical/serological evaluation was performed. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. Endothelial activity was

monitored by laser-doppler flowmetry, and pro-inflammatory and oxidative stress markers were quantified by flow cytometry and RT-PCR. In a parallel cohort of SLE patients (n = 12), the effects of in vivo treatment with ubiquinol on spliceosome components was evaluated. Transfection studies with splicing machinery components were also carried out on lupus leukocytes.

**Results:** As a general feature, a significant reduction in splicing machinery components was found in all the SLE leukocyte subtypes. Interestingly, we found a specific altered profile of splicing factors and spliceosome components when compared monocytes (U2AF1, FBP11, SRSF9), lymphocytes (RBM22, PRP8, SRSF5) and neutrophils (RNU4, CA150). The reduced levels of some components of spliceosome in both monocytes and neutrophils were linked to the occurrence of thrombotic events, foetal loss and arterial hypertension. In lymphocytes, those reduced levels were strongly related to the positivity for anti-dsDNA antibodies in SLE patients, thus suggesting that reduced spliceosome machinery would contribute to increase in altered autoantigen assembly, inducing increased autoantibody production. Correlation studies demonstrated an inverse relationship among reduced levels of spliceosome components/splicing factors and high activity of the disease (SLEDAI), endothelial dysfunction, and increased peroxide and peroxynitrite levels, as well as of altered mitochondrial membrane potential in monocytes and neutrophils. In vitro treatment of leukocytes from HDs with anti-dsDNA promoted a reduction in spliceosome components associated with the expression of proinflammatory and oxidative mediators. In vivo treatment with ubiquinol reversed the SLE expression of spliceosome components related to their proatherothrombotic profile. Finally, transfections with splicing machinery components were translated in the modulation of the expression of markers related to inflammation and oxidative stress in lupus.

**Conclusion:** These results reveal the existence of SLE-associated spliceosome alterations -promoted by anti-dsDNA antibodies- which could be related to the development and activity of this autoimmune condition and have influence on the induction of mechanisms that drive atherothrombosis as well as the therapeutic response.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Most confirmed SLE-risk loci are found near or in genes with immune function, yet how these loci influence diverse immune cell subsets remains unknown.

**Methods:** We performed single cell eQTL analysis in SLE monocytes to determine the impact of SLE-risk loci in single human monocytes. Purified classical (CL) and non-classical (NCL) monocytes from SLE patients were analyzed for expression of 90 genes, and patients were genotyped for 7 SLE-risk SNPs. Each monocyte subset was analyzed separately using non-parametric analyses.

**Results:** We observed a large number of significant eQTL associations that surpassed the 5% FDR. The SLE-associated SNPs demonstrated more eQTLs in NCLs as compared to CLs ( $p=2.5 \times 10^{-8}$ ). For a given SNP, the eQTL associated transcripts differed between monocyte subsets ( $p < 0.001$  for all 7 SNPs for discordance). For NCLs, TNFAIP3, IRF5, IRF7, PTPN22, and SPP1 shared a significant proportion of eQTL associations. For CLs, TNFAIP3 shared many eQTLs with SPP1 and ITGAM, while SPP1 and ITGAM showed limited overlap. Thus, SLE-associated risk loci exert coordinated effects on gene expression within individual human monocytes, and the risk loci interact in different ways in different cell types.

**Conclusion:** Our study revealed striking differences, using single cell gene expression, in the occurrence and interaction of SLE risk associated eQTLs within different but closely related cell types. This suggests pleiotropic effects from each locus across various immune cell types, and a high degree of complexity when considering how these loci impact the immune system.

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Systemic lupus erythematosus (SLE) is a chronic, complex disease and autoantibodies to self-antigens are a characteristic feature of the disorder. Our group and others have observed free radical mediated oxidative damage in SLE. Our previous data implicated red cell membrane catalase as a target of 4-hydroxy-2-nonenal (HNE; a by-product of oxidative damage) modification in SLE subjects. Here, we tested the hypothesis that HNE- or malondialdehyde- (MDA) modification occurs in the sera of SLE subjects and that antibodies to HNE would be present in SLE sera, and may precede lupus autoantibodies.

## **Methods:**

Serum proteins from 8 SLE subjects and 8 age and sex-matched normal subjects were analyzed for HNE- or MDA protein-adducts by ELISA. Three additional SLE subjects, who had sera collected longitudinally for 12- 15 years, were tested for the presence of anti-HNE antibodies by ELISA. One SLE subject developed anti-Ro60 under observation and another developed anti-P similarly (after disease diagnosis). The third SLE subject had anti-Sm from time of diagnosis. Ro60, Sm and a multiple antigen peptide synthesized from the P autoantigen were coated on ELISA plates, HNE-modified and used as substrate for anti-HNE ELISA. Unmodified Ro60, Sm and P multiple antigen peptide served as control. To test for HNE or MDA-protein adducts in sera from SLE subjects or normal controls, the sera were coated on ELISA plates as antigen. HNE or MDA adducts in sera was determined with rabbit anti-HNE or anti-MDA antibodies. HNE-modified proteins in sera from SLE or normal controls were also studied by immunoblotting.

## **Results:**

We found significantly increased oxidative damage in the sera of SLE subjects compared to normal controls by ELISA and immunoblotting. There was significantly more HNE-protein adducts in SLE sera compared to controls as determined by ELISA ( $0.084 \pm 0.022$  versus  $0.055 \pm 0.012$ ,  $p=0.0044$ ; average  $OD \pm SD$ ). But, we did not observe any significant difference in MDA-modified proteins between SLE subjects and controls. Analysis of SLE sera by immunoblotting showed HNE modification of two proteins migrating at 24 kD and 38 kD respectively. Anti-HNE P autoantibodies preceded anti-P autoantibodies in the SLE subject that developed anti-P antibodies several months after SLE diagnosis. Anti-HNE P antibodies developed strongly in the anti-P SLE subject in the 68<sup>th</sup> month (1.2 OD), while anti-P response developed only by month 112. Anti-P response was strong by 125<sup>th</sup> month (1.7 OD). Anti-HNE P response at this time point was 3.0 OD, almost twice as the anti-P response. Anti-HNE Ro60 response preceded anti-Ro60 antibody response by 20 months in the subject developing anti-Ro60 under observation. Anti-HNE Ro60 response correlated with anti-Ro60 response in this subject for the rest of the dates for which samples were available for testing. However, there was no difference in anti-Sm or anti-HNE Sm antibody levels over time for the subject that had anti-Sm autoantibodies right from the time of diagnosis.

## **Conclusion:**

Increased HNE-modified protein occur in sera of SLE subjects. Anti-HNE antibody may precede anti-Ro60 or anti-P autoantibodies in SLE. HNE-products are potential neoantigens and thus could be involved in the pathogenesis of SLE.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is a critical need to define the cells that mediate tissue damage in lupus nephritis. Here we aimed to establish a protocol to preserve lupus nephritis kidney biopsies and urine cell samples obtained at multiple clinical sites for subsequent isolation and transcriptomic analysis of single cells.

**Methods:** We developed a method to cryopreserve intact, viable kidney tissue in a 10% DMSO-containing solution. Viable cryopreserved kidney tissue from tumor nephrectomies and lupus nephritis kidney biopsies were disaggregated by enzymatic digestion and compared to freshly processed tissues. Cell yields and cell composition were assessed by flow cytometry. Transcriptomes of flow-sorted CD45+ leukocytes and CD10+ kidney epithelial cells were evaluated by low-input and single cell RNA-seq.

**Results:** Cryopreserved kidney tissue from tumor nephrectomies and lupus nephritis biopsies can be thawed and dissociated to yield intact, viable leukocytes and epithelial cells. Cryopreservation of intact kidney tissue provides higher epithelial cell yields compared to cryopreservation of single cell suspensions from dissociated kidneys. Epithelial cell and leukocyte lineage markers are easily detected on cells from cryopreserved kidney tissue by flow cytometry (Figure 1). Cell yields and flow cytometric cell phenotypes are comparable between cryopreserved kidney samples and paired kidney samples shipped overnight on wet ice. High-quality single cell and low-input transcriptomic data were generated from flow-sorted leukocytes from both cryopreserved lupus nephritis kidney biopsies and urine, typically with 3000-4000 genes detected in single cell transcriptomes (Figure 2).

**Conclusion:** We propose that this method of acquisition of viable cells from cryopreserved intact kidney tissue may serve as a model for robust, centralized cellular analyses of kidney samples acquired in multi-site clinical studies. More broadly, this strategy enables accumulation of a valuable biobank of tissues containing viable cells that can be used for multiple downstream analyses.

Figure 1: Flow cytometric analysis of cells obtained from cryopreserved intact lupus nephritis kidney biopsy tissue.

Figure 2: Number of genes detected by single cell RNA-seq of sorted leukocytes from lupus nephritis kidney biopsies from 4 donors processed as indicated and from cryopreserved urine cells from a lupus nephritis donor.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Systemic sclerosis (SSc) is a severe connective tissue disease characterized by vascular and fibrotic changes in the skin and various internal organs. Pathogenesis of SSc includes early-onset vasculopathy with endothelial cell activation, microvascular injury and impaired angiogenesis.

**Objectives:** We aimed to determine the association of several biological molecules reflecting endothelial cell activation or dysfunction: E-selectin (E-sel), inter-cellular adhesion molecule 1 (ICAM-1), endothelin 1 (ET-1), von Willebrand factor (vWF) and interleukin 6 (IL-6), with distinct capillaroscopic SSc patterns and with more severe disease.

## Methods:

Forty consecutive SSc patients attending our EUSTAR SSc clinic, aged [median (IQR)] 52 (18) years, male gender 4/40 (10%), diffuse cutaneous subset (dcSSc) 14/40 (35%) were enrolled in this study. Extensive clinical and nailfold capillaroscopy (NFC) pattern assessment, as well as quantification of serum E-sel, ICAM-1, ET-1, vWF, IL-6 and C-reactive protein (CRP) were performed on all patients. Associations between vascular biomarkers and disease characteristics were evaluated by Mann-Whitney U-test and Spearman correlations. We analyzed the confounding effect of CRP on the association between vascular markers and NFC pattern by multivariable logistic regression.

## Results:

NFC “late” pattern was found in 21 patients, while 6 had “early” and 13 had “active” NFC pattern. All 5 vascular biomarkers correlated with each other good to moderately, with  $r$  indices varying between 0.660 and 0.332, the only exception being ET-1 which did not correlate with E-sel. Good correlations ( $r$  0.465 to 0.727) were also found between all 5 biomarkers and CRP. Patients with severe vasculopathy, as reflected by the NFC “late” pattern, had higher levels of IL-6 (median 12.06 vs. 3.08 pg/mL,  $p=0.001$ ), ET-1 (median 2.06 vs 1.59 pg/mL,  $p=0.029$ ), vWF (median 3284 vs 2730 IU/mL,  $p=0.013$ ) and E-sel (median 52.6 vs. 42.3 ng/mL,  $p>0.05$ ), compared to patients with NFC “early” or “active” patterns (Mann-Whitney U-test). In the logistic regression analysis, IL6 (OR (95% CI) 1.175 (1.005, 1.374),  $p=0.04$ ), ET1 (2.802 (1.157, 6.784),  $p=0.022$ ) and vWF (1.001 (1.000, 1.003),  $p=0.034$ ) were significantly associated with “late” capillaroscopy pattern even after adjustment for CRP.

There was a significant, negative correlation between lung transfer for carbon monoxide (DLCO) and E-sel, ICAM-1 (both  $p<0.001$ ) and vWF ( $p=0.013$ ). ET-1 was higher in patients with more severe disease (dcSSc, patients positive for anti-topoisomerase antibodies and patients with a history of digital ulcers – all  $p<0.05$ ).

## Conclusion:

Serum biomarkers reflecting endothelial cell activation and/or dysfunction are elevated in patients with more severe SSc-associated vasculopathy even when adjusting for inflammation markers. Together with NFC data they might be used for assessing vasculopathy severity in SSc and identifying patients who would benefit from more aggressive vasoactive treatment.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Malnutrition is a major concern in systemic sclerosis (SSc) however literature is scarce on the subject, especially on micronutrient or vitamin deficiency and its relationship to disease outcomes. The aim of our study was to determine the prevalence and the risk factors associated with malnutrition, selenium (Se) and vitamine C (vitC) deficiency in SSc patients.

**Methods:** We included all unselected and consecutive adult SSc patient fulfilling the 2013 ACR/EULAR criteria the Toulouse University Hospital cohort between 2011 and 2016 who underwent a nutritional workup including (albumin, vitC and selenium plasma/serum levels). Patients were followed according to standard clinical guidelines with visits at least every 6 months. Data collected included clinical characteristics, organ involvement, pulmonary function tests, echocardiography parameters and drug exposure. Se deficiency was defined as serum Se < 70ng/mL. VitC deficiency was defined as serum vitC (determined by HPLC) < 0.4mg/dL. Comparisons were done using the Fisher's exact test and the Wilcoxon signed-rank test and Association between malnutrition, Se or vitC deficiency was analyzed with logistic regression model.

**Results:** 82 consecutive SSc patients were included, mostly men (76%), mean aged was 59.7 ±13.5 years. SSc was limited, diffuse or sine scleroderma in 75%, 24% and 1% of cases respectively, with Scl-70 or centromere antibodies in 32% and 44% of cases. Mean disease duration was 9.4 ±9.9 years. 67.1% had a digital ulcer history. The mean modified rodnan skin score (mRSS) at baseline was 11 ±10. Cardiac, pulmonary or GI tract were involved in 19%, 63% and 39% of patients respectively; of whom 9% had pulmonary artery hypertension (PAH). Overt malnutrition was present in 13 (15.9%) patients. Micronutrient deficiencies included Se 19 (23.2%), vitC (26.8%), B6 37(45.1%), folate 11 (23%) and/or B1 4 (4.9%). Malnourished patients were significantly older (68.4 vs 58.1 y., p=0.01) and had more frequently PAH (27% vs 6%, p=0.05). Cardiac involvement was significantly associated with Se deficiency with an OR 6.2, IC95[1.48-32.7], p=0.02. Risk factors associated with vitC deficiency were BMI (OR 0.72 per point, IC95[0.54-0.89], p=0.01), Rodnan ≤ 14 (OR 0.16, IC95[0.03-0.68], p=0.02), interincisive distance (OR 0.91 per mm, IC95[0.81-0.99], p=0.04), esophagitis or Barrett's mucosa (OR 4.85, IC95[1.48-17.0], p=0.01), pulmonary artery systolic pressure by echocardiography (OR 1.05 per mmHg, IC95[1.00-1.11], p=0.04), (OR 0.95 per %, IC95[0.90-0.99], p=0.04), DLCO (OR 0.95 per %, IC95[0.91-0.99], p=0.01), hemoglobin (OR 0.38 per g/dL, IC95[0.21-0.60], p=0.0002), albumin (OR 0.91 per g/L, IC95[0.82-0.99], p=0.05) and proton-pump inhibitor (OR 4.7, IC95[1.33-22.3], p = 0.03).

**Conclusion:** Se testing should be considered as soon as heart involvement is suspected. We believe that targeted Se supplementation could be beneficial to patients with heart involvement. VitC testing should be considered in SSc patients with extensive skin involvement and severe disease, and its supplementation should be a part of SSc close management.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patient reported outcome measures (PROM) are acknowledged a key role in clinical trials in systemic sclerosis (SSc). Given the unmet need of a validated, comprehensive PROM in SSc, the ScleroID questionnaire was developed by a team of patients with SSc and medical experts in the field. This is intended as a brief, disease-specific, patient-derived, disease impact score for research and clinical use in SSc. Here, we present the preliminary analysis from the ongoing ScleroID validation study.

### Methods:

This EULAR-endorsed project involves 11 European expert SSc centers. Patients fulfilling the ACR/EULAR 2013 criteria were prospectively included since 05/16 in the ongoing observational cohort study. Patients filled in the ScleroID questionnaire (Figure 1), as well as selected comparators SHAQ, EQ5D, SF36. Additionally, they weighted the 10 dimensions of the ScleroID by distributing 100 points according to the perceived impact on their health. The final score calculation will be based on the ranking of the weights. The study includes a reliability arm (follow-up questionnaire 7-10 days from baseline), as well as a longitudinal arm, looking at sensitivity to change at follow-up visits after 6 and 12 months from baseline.

## Results:

As of 01/2017 the study cohort included 224 patients with valid baseline data, 44 also had a reliability visit and 6 a 6-months follow-up visit. 84.4% of patients were female, 54.4% had limited SSc, median age 58, and median disease duration 8 years. The highest preliminary median weights for ScleroID domains were for Raynaud, impaired hand function, fatigue and pain (Table 1). Except for pain, these dimensions were also scored most highly in the ScleroID questionnaire at baseline. As of 06/2017, 362 patients (72.4% of target) were enrolled into the study.

## Conclusion:

The EULAR ScleroID score is a novel tool designed for use in clinical practice and clinical trials to display the disease impact of SSc. In this preliminary analysis, Raynaud syndrome, impaired hand function, and fatigue were the main patient reported drivers of disease impact. However, further recruitment and validation of this new instrument is ongoing.

### Figure 1. The EULAR Scleroderma Impact of Disease Score (ScleroID)

How much have the different aspects of systemic sclerosis affected you during the last week? Please mark your responses on the scale by choosing the appropriate number for each of the following dimensions:

#### Raynaud's phenomenon:

Circle the number that best describes the severity of your Raynaud's phenomenon during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Hand function:

Circle the number that best describes your hand function limitations due to your systemic sclerosis during the last week:

No limitation 0 1 2 3 4 5 6 7 8 9 10 Extreme limitation

#### Upper gastrointestinal tract symptoms (e.g. swallowing difficulties, reflux, vomiting):

Circle the number that best describes the severity of your upper gastrointestinal tract symptoms due to your systemic sclerosis during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Pain:

Circle the number that best describes the pain you felt due to your systemic sclerosis during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Fatigue:

Circle the number that best describes the impact of overall fatigue due to your systemic sclerosis during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Lower gastrointestinal tract symptoms (e.g. bloating, diarrhea, constipation, anal incontinence):

Circle the number that best describes the severity of lower gastrointestinal tract symptoms during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Limitations of life choices and activities (e.g. social life, personal care, work):

Circle the number that best describes how severe the limitations of life choices and activities due to your systemic sclerosis were during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Body mobility:

Circle the number that best describes how much your body mobility was affected due to your systemic sclerosis during the last week:

Not affected 0 1 2 3 4 5 6 7 8 9 10 Extremely affected

#### Breathlessness:

Circle the number that best describes how severe your breathlessness due to systemic sclerosis was during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

#### Digital ulcers:

Circle the number that best describes how much your digital ulcers affected you overall during the last week:

None 0 1 2 3 4 5 6 7 8 9 10 Extreme

No.	Health dimensions	Mean rank	Median rank	Order by median rank	%Patients giving rank 1 to the dimension	%Patients giving rank 1-3 to the dimension	%Patients giving rank 1-10 to the dimension
1	Raynaud	5,78	5	1	19,4	36,1	84,3
2	Hand function	6,65	5	1	8,3	25	78,7
3	Upper GI	7,16	6	2	7,4	24,1	73,1
4	Pain	6,94	6	2	10,2	25,9	75,9
5	Fatigue	6,67	6	2	9,3	26,9	78,7
6	Lower GI	7,82	7	3	10,2	24,1	69,4
7	Limitation of life choices and activities	8,34	8	4	4,6	20,4	66,7
8	Body mobility	8,71	8,5	5	2,8	11	65,7
9	Breathlessness	8,57	9	6	12	27,8	52,8
10	Digital ulcers	9,45	10	7	1,9	17,6	54,6
11	Anxiety	10,18	10	7	2,8	9,3	50,9
12	Dryness	10,13	10	7	1,9	9,3	54,6
13	Appearance	10,31	11	8	3,7	9,3	49,1
14	Concentration difficulties	10,87	12	9	1,9	9,3	39,8
15	Cough	11,26	13	10	1,9	10,2	38,9
16	Depression	11,63	13	10	0,9	7,4	35,2
17	Calcinosis	12,52	14	11	0,9	6,5	31,5

The top 10 dimensions with the lowest median rank (highest importance) were selected for the questionnaire. The 10<sup>th</sup> dimension had an equal median rank but clearly higher role for more patients (% giving top rank, last 2 columns) and was consequently chosen in favor of dimensions 11,12. Abbreviations: No, number; GI, gastrointestinal.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The burden of disability of systemic sclerosis (SSc) is increasingly recognised. What is less known are the factors driving this disability and how it changes over time. At a tertiary centre for SSc, clinical and disability data (including the Health Assessment Questionnaire Disability Index, HAQ-DI) have been collected systematically at annual review visits for over 20 years and stored electronically. This allowed us to test the hypothesis that disability is greater in patients with diffuse (dcSSc) compared to limited cutaneous disease (lcSSc) and that disability is associated with the degree of skin thickening in patients with dcSSc but not with lcSSc.

### **Methods:**

This was a retrospective analysis of data collected from 1994 to 2016. For each patient, data were retained from the first simultaneous record of the HAQ-DI (0-3) and modified Rodnan skin score (mRSS, 0-51), measuring skin fibrosis. For each patient, HAQ-DI and mRSS trajectories were assessed separately for the early and late stages of the disease (with 5 years post first non-Raynaud's manifestation as the cut-off). For the first visit, HAQ-DI and mRSS scores were compared according to disease stage and subtype. The yearly change in HAQ-DI and mRSS was computed for each patient using linear regressions for early and late disease phases and Spearman correlations were computed between changes in HAQ-DI and mRSS.

### **Results:**

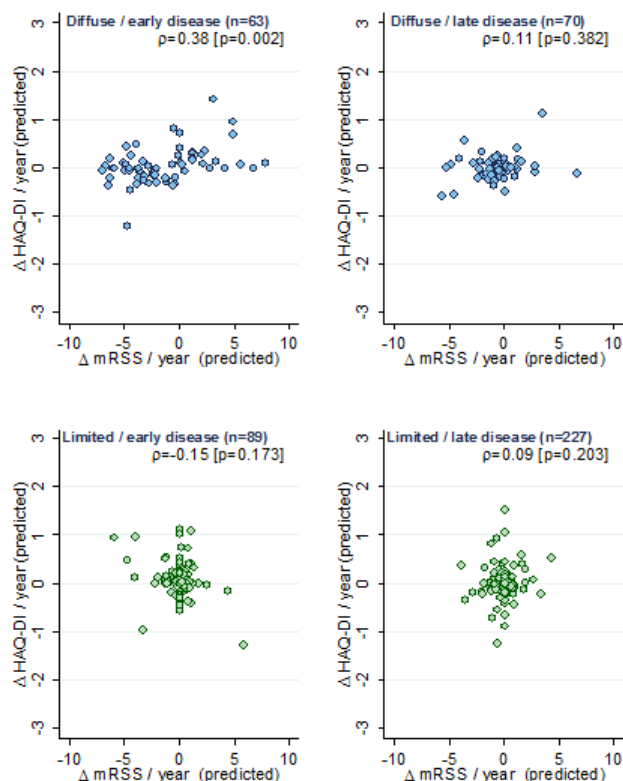

401 patients were included in the analysis, 292 (72.8%) with lcSSc and 109 (27.2%) with dcSSc. The mean disease duration at the first visit was 8.0 years (SD 7.9) and mean length of follow-up 5.9 years (SD 3.6). 73 patients were followed during early disease, 218 during late disease and 110 during both stages. At the first visit, patients with dcSSc had higher mean HAQ-DI scores (indicating more disability) than patients with lcSSc for early disease (1.4 vs. 0.9,  $p=0.003$ ) but there was no difference in 'late' patients (1.6 vs. 1.4,  $p=0.221$ ). The yearly change in HAQ-DI was very variable, with approximately half of the cohort improving while the other half deteriorated. In dcSSc, the changes in disability were associated with changes in mRSS in early ( $\rho=0.38$ ,  $p=0.002$ ) but not in late disease ( $\rho=0.11$ ,  $p=0.382$ ). In lcSSc, changes in mRSS did not associate with changes in disability in early or late disease ( $p=0.173$  for early and  $p=0.203$  for late) (Figure).

### **Conclusion:**

These findings further benchmark the high disability in patients with SSc, and confirm that patients with the diffuse subtype tend to exhibit higher levels of musculoskeletal disability than those with limited disease. In early dcSSc, disability tracks over time with skin thickening, suggesting that in this subgroup skin fibrosis is a driver of disability, whereas in late dcSSc and in lcSSc other factors (e.g. severity of digital ischaemia) may contribute more.

*Figure. Yearly changes in HAQ-DI and mRSS, according to disease subtype and stage.*

Each point represents a patient. More than two observations were used to compute the HAQ-DI and mRSS changes per year (up to five observations/patient for the early and 14 for the late phases).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-SSA (Ro52/Ro60) and anti-SSB autoantibodies are the cardinal serological markers for Sjogren's syndrome. They are also present in other systemic autoimmune diseases. There is a limited data on their prevalence in systemic sclerosis (SSc). The objectives of this study were to: 1) determine the prevalence of SSA (Ro-52 and Ro-60) and SSB antibodies in consecutive SSc patients using immunoprecipitation (IP) testing, and 2) compare the clinical features and survival among these subsets of SSc patients.

**Methods:** We studied an inception cohort of consecutive new SSc patients first evaluated at the UPMC Scleroderma Center between 2006 and 2011. All patients underwent complete serologic testing using ANA, protein, and RNA immunoprecipitation (IP) testing to detect SSc-associated antibodies, Ro52, Ro60 and SSB antibodies. Prevalence, demographic, clinical features, and survival were compared between SSA/SSB positive and negative SSc patients. Statistical analyses were done using SAS 9.4.

## Results:

There were 474 patients met the inclusion criteria. The mean age of cohort at first SSc visit was  $53.7 \pm 14.9$  years, 79% were female, 90% were Caucasian, and 40% had diffuse skin thickening. Of all patients, 65 (14%) were positive for anti-SSA/SSB antibodies (22 had Ro-52, 45 had Ro-60, and 2 had both, 4 had SSB). There was no patient with SSB-only serotype. There were no significant differences in demographics and frequency of major SSc-related internal organ involvement between seropositive and seronegative groups (Table 1). SSA/SSB positive patients had higher frequency of overlap syndrome (22% vs. 13%,  $p=0.05$ ). The distribution of other SSc-associated autoantibodies did not differ. Over time, SSA/SSB positive patients developed higher rates of photosensitivity (9% vs 4%;  $p=0.03$ ) and peripheral neuropathy (16% vs 7%;  $p=0.02$ ). Among the SSA/SSB subsets, Ro-60 only patients developed more frequent gastrointestinal involvement compared to Ro52-only and seronegative patients (85% vs. 37% vs. 75%;  $p=0.001$ ). No other clinical or serological differences existed between these three groups. Five-year survival was not significantly reduced in the SSA/SSB positive group ( $p=0.38$ ).

**Conclusion:** In this inception cohort of SSc patients, 14% had SSA/SSB antibodies. These patients at presentation were less likely to have key phenotypic features of Sjogren's syndrome compared to seronegative patients. The seropositive group developed more photosensitivity and neuropathy over time; however, objective Sjogren's evaluation testing was not performed systematically. A previously unreported association of GI complications and Ro60 status was observed. Further studies are needed to confirm this association.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Prospective Registry of Early Systemic Sclerosis (PRESS) cohort is an early diffuse cutaneous systemic sclerosis (dcSSc) that provides an opportunity to assess the causes of mortality in this decade. The objective of this analysis was to assess the causes of death and describe the clinical features associated with mortality in the PRESS cohort.

**Methods:** The PRESS cohort includes dcSSc patients with < 2 years' duration (from 1<sup>st</sup> non-RP) who are recruited at 11 U.S. Scleroderma Centers. Patients participate in detailed baseline and biannual clinical and laboratory assessments that permit characterization of patient characteristics and patient-reported clinical outcomes (PRO) measures.

**Results:** As of May 2017, of 194 patients, 12 have died (6.2%) at median follow-up of 9.6 months (1-20 months). The characteristics of the 12 deceased patients are described in Table 1. In these deceased patients, 6 (50%) had interstitial lung disease (ILD) on a high resolution computed tomography (HRCT) of the chest with abnormal pulmonary function tests (PFT) [mean FVC% 52.4 (range 29-77); DLCO% 51.3 (24-82)]. Ten of the deceased patients had a baseline ECG at enrollment, and 40% had either arrhythmia or conduction block. Echocardiogram in 11 of the deceased population had a mean ejection fraction of below or at the lower limit of normal 57.5% (24-68%). Almost all patients who had a right heart catheterization (RHC, n=5) had an abnormality of either pulmonary hypertension or an elevated pulmonary capillary wedge pressure. The etiology of death was attributed to SSc in 11 of the patients (64% cardio-pulmonary) and esophageal cancer in one of the patients. The mean Patient Global Assessment for Overall Health was 6.4 (4-10), but extensive PRO was not complete at the last PRESS visit in the deceased patients.

**Conclusion:** In this early dcSSc cohort, we found a 6.2% mortality at median follow up 9.6 months. When compared to data from a single U.S. cohort (Steen and Medsger 1997-2001), cardio-pulmonary involvement continues to be leading cause of mortality in dcSSc. This underscores the importance of screening dcSSc patients with PFT, echocardiogram, and ECG, and confirmatory testing with HRCT chest and RHC. While PRO is an important component of research, the burden of questionnaire-based assessments on patients with significant disease features needs to be better clarified.

Table 1: PRESS patient characteristics

Characteristic	Number (n=12) of deceased patients	Number (n=182) of alive patients
Female	9	133
Age, mean (range)	58 (24-77)	49 (19-78)
Disease duration in years, mean (range)	0.8 (0.1-2)	2.5 (0.1-5.2)
Race:

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc, scleroderma) patients can have the end-stage vasculopathy manifestation of a digital ulcer (DU). Brachial artery flow mediated dilation (FMD) is an established non-invasive vascular marker of endothelial function in SSc. We hypothesized that FMD could stratify the timeline of DU development and role of vasodilators in management.

**Methods:** Patients were recruited from our scleroderma center at the time of a routine care visit. All vascular measures were assessed by duplex ultrasound Doppler at baseline and after 6 months follow-up for up to two years. Specifically, resting brachial artery blood flow, shear rate, and diameter and BP cuff induced ischemia, vascular reactivity (peak reactive hyperemia), vascular shear rate (peak hyperemia/area under the curve [AUC]), and FMD ( $\Delta$ mm and %) were measured for 2 min after cuff release. We examined FMD variables in SSc patients that (1) had a DU at baseline, (2) developed a new DU, and (3) never had DU in up to 24 months of follow-up. General linear models were used to compare these continuous variables between SSc patients with and without DU controlling for the days from baseline FMD measurement and use of any vasodilatory drug.

**Results:** FMD was determined in 136 SSc patients at baseline and 55 patients in follow-up. Baseline SSc clinical features are described in Table 1. In those patients with follow-up FMD, 10 (48%) with a baseline DU healed over the course of two years. The timeline for healing for initial DU patients included 3 within 12 month and 4 within 18 months. Seven of 115 patients with no DU at baseline developed a DU at the time of repeat FMD measures. Resting blood flow differed between patients with healed DU and developed DU, in that they had higher blood flow at baseline ( $p=0.03$ ), which correlated to vasodilator use. When FMD variables were analyzed over time, resting arterial wall shear rate increased over time for all patients and was lowest for those with no DU. The difference in the DU groups (developed and no DU) trended towards significance ( $p=0.10$ , Figure 1).

**Conclusion:** FMD applied to routine clinical care of SSc patients identified that DU trial length may require up to 18 months to document complete healing. FMD variables may be important secondary outcome measures in DU trials. Higher resting blood flow in individuals with a healed DU and those who never had a DU supports the role of vasodilators for this indication. The role of therapeutics that reduce vascular shear rate may be an opportunity for both SSc-DU prevention and healing.

Figure 1: Follow-up vascular shear rate of SSc patients (mean, SEM) that never had DU ( $n=41$ ) versus developed DU ( $n=7$ ).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Background/Purpose:** Gastrointestinal (GI) system involvement is commonly seen in systemic sclerosis (SSc) up to 90% of the patients during disease duration and one of the substantial causes of morbidity and mortality in SSc. We aimed to investigate self-reported questionnaires and capillaroscopy in terms of severity of GI involvement and malnutrition in SSc patients.

**Methods:** GI involvement and nutrition status were evaluated by UCLA SCTC GIT 2.0 questionnaire and 'malnutrition universal screening tool (MUST) in SSc patients fulfilling ACR/EULAR classification criteria (2013). Simultaneously; early, active and late scleroderma patterns (Cutolo et al.) were determined qualitatively and capillary number (CN) was calculated per linear mm at distal row quantitatively by using nail fold video-capillaroscopy (NVC) in all patients.

## Results:

In 126 SSc patients (115 female) with the mean age of  $50 \pm 12$ , duration of non-Raynaud symptom of  $10 \pm 9$  years and follow-up of  $53 \pm 58$  months; diffuse cutaneous form was found to be 25% (n=32), anti-Scl70 positivity 32% (n=37), telangiectases 81% (n=102), digital ulcers 44% (n=55), lung disease 40% (n=49) and flexion contractures 15% (n=18). Of the NVC patterns, early was found in 31 (25%), active was in 18 (14%), late was in 68 (54%) and normal in 9 (7%). The scores of skin, telangiectasia, disease activity and UCLA SCTC GIT 2.0 total, reflux and distension items were shown to be higher in patients with late NVC pattern (table-1). The patients with  $CN \leq 5$  were found to have higher scores of UCLA SCTC GIT 2.0 total, reflux, distension, soilage, social items and MUST ( $p < 0,001$ ,  $p < 0,001$ ,  $p = 0,001$ ,  $p = 0,002$  and  $p = 0,002$ ) and scores of skin, telangiectasia, disease activity and severity ( $p < 0,001$ ,  $p < 0,001$ ,  $p = 0,001$  and  $p = 0,003$ ). Of the patients with MUST score of  $\geq 1$  (n=18), 16 had late, 1 early NVC pattern and 1 normal pattern.

**Conclusion:** This SSc cohort predominantly had vascular manifestations. Late scleroderma pattern and decreased capillary density was found to be related to severe GI complaints, disease activity, skin severity and telangiectases. Undernutrition was also frequently seen in patients with late pattern. NVC might be useful to predict the severity of GI and malnutrition.

**Table-1: The scores of disease activity and severity and UCLA SCTC GIT 2.0 in SSc patients**

	NVC (normal)	NVC (early)	NVC (active)	NVC (late)	p
Modified Rodnan skin score	2,2 $\pm$ 2,5	3,9 $\pm$ 4,6	7,3 $\pm$ 5,9	9,63 $\pm$ 6,9	P<0,001

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Gastrointestinal tract (GIT) involvement in systemic sclerosis (SSc) is the most common internal organ involvement. Among the few validated patient-reported outcome measures for GI involvement are the University of California Los Angeles Scleroderma Clinical Trial Consortium (GIT2.0) and intestinal visual analogue scale (GI-VAS) The latter is a component of the Scleroderma Health Assessment Questionnaire[SHAQ]). Our aim was to evaluate the comparative responsiveness of these outcome measures when pts are treated and to evaluate the correlation between UCLA-SCTC GIT 2.0 and GI-VAS in our SSc population.

### Methods:

115 SSc pts with two or more consecutive visits were enrolled in our study. Values of UCLA-SCTC GIT 2.0 and GI-VAS were completed by all patients at both visits,; any change in GI medication at the baseline visit was reported. ). UCLA-SCTC GIT2.0 includes 34 questions in 7 domains (reflux, distension, soilage, diarrhea, social function, emotional wellbeing and constipation). GI-VAS is a 100 mm VAS that asks the patient, how did GI symptoms interfere with patient function. Paired T test was used to detect the change between the two visits in both GIT 2.0 and GI-VAS. Pearson correlation was used to correlate tests at base line.

### Results:

Ninety eight (85%) of SSc pts were females, Mean age 52 yrs (SD  $\pm$  12.9); median disease duration 7 (4-11), diffuse subtype 57 pts (50%), (47%), median baseline GIT 2.0 is 0.3 (0.1-0.7) and median baseline GI-VAS 0.8 (0-4.1) table 1.

Out of the 115 pts, only 41 pts needed a change of GI medication at base line visit (37.0%). A statistically significant difference was noted when comparing GIT scores before and after adding a new GI treatment ( $p=0.006$ , 95% CI= .05956 to 0.29258). On the other hand, GI-VAS did not show statistical differences between baseline visit and follow-up after adding medications ( $p=0.963$ , 95% CI =-0.937 to 0.89588). Baseline correlation between GIT2.0 (total score) and GI-VAS were ( $r= 0.657$  ) moderate.

## Conclusion:

: Both UCLA-SCTC GIT2.0 and GI -VAS reflect GIT involvement. Unlike the GI-VAS, the UCLA-SCTC GIT2.0 was responsive to treatment . These results also, shows that both tests may represent different aspects of GI involvement and might be considered separately in clinical evaluation of GI system in SSc patients. Discussion: More patients are to be included in this cohort, as the pts had low GIT scores( few symptoms ), multiple GI treatments were used and this is a retrospective evaluation of prospectively gathered data.

**Table 1: Baseline characteristics of systemic sclerosis patients**

Variable	Mean(SD, Range), number (percentage)
Age	52 (12.9)
females	98(85%)
Body mass index (BMI), mean (SD)	24.1(5.7)
Disease duration	7 (4-11)
Intestinal GI- VAS	0.8(0-9.5)
UCLA GIT 2.0	0.3 (0.1- 2.15)
Interstitial lung disease	66 (57%)
FVC	89% (23.2)
<i>Pulmonary artery hypertension</i>	<i>19 (16%)</i>

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Background/Purpose:** Virtual skin biopsy by Optical Coherence Tomography (OCT) has been proposed as quantitative outcome measure of fibrosis in Systemic Sclerosis (SSc). Dynamic OCT (D-OCT) is a newly developed technology that allows quantification of blood flow in vivo during OCT scans. Here we aimed to determine the validity of skin D-OCT as outcome measure of the skin microvascular disease, employing as comparator nailfold video-capillaroscopy (NVC) capillary patterns in SSc patients, and as clinical gold standard the presence of digital ulcers (DU).

**Methods:** One hundred and four subjects were enrolled in this study in 2 independent cohorts. In cohort 1 (Criterion Validity), 40 SSc patients fulfilling the ACR/EULAR 2013 criteria with different NVC pattern (10 for each normal/non-specific, early, active, ad late NVC pattern) and 10 healthy volunteers (HV), underwent nailfold D-OCT. In cohort 2 (Face/Content Validity) 36 SSc patients with (18) or without (18) DU and 18 patients with Raynaud's phenomenon (RP) and SSc specific ANA, who did not fulfill ACR/EULAR 2013 criteria (SRP group) underwent D-OCT of index and middle fingers on the proximal phalanx. Microvascular flow (MVF) was analyzed using the proprietary software from Michelson Diagnostics Ltd.

### **Results:**

Nailfold D-OCT allowed visualization of the corresponding SSc patterns seen at NVC. Furthermore, within D-OCT images, MVF measurements were significantly different between HV and SSc patients with any specific capillary pattern ( $0.16 \pm 0.02$  vs  $0.10 \pm 0.01$ ,  $p=0.0028$ ) and between SSc patients without and with specific capillary pattern ( $0.14 \pm 0.01$  vs  $0.10 \pm 0.01$ ,  $p=0.02$ ). Concordantly, MVF was significantly lower in patients displaying capillary loss as main feature compared with those with remarkable angiogenesis ( $p=0.03$ ). Skin D-OCT showed a median MVF significantly different among the 3 groups: 0.134 (DU) vs 0.153 (no DU) vs 0.167 (SRP) ( $p<0.0001$ ), and in the DU vs no DU ( $p<0.001$ ) or vs SRP ( $p<0.001$ ). Further, DU patients on Sildenafil ( $n=6$ ) had a significantly higher MVF than DU patients on no Sildenafil ( $p<0.01$ ).

**Conclusion:** MVF assessed by D-OCT shows face/content and criterion validity as biomarker of skin microvascular disease in SSc. Future longitudinal studies are needed to evaluate its sensitivity to change over time.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Trigeminal neuralgia (TN) is characterized by pain and spasms affecting one or more divisions of the fifth cranial nerve. Of note, TN is one of the peripheral nervous system manifestations of systemic sclerosis (SSc), reported to be present in approximately 4% of patients. Proposed pathophysiologic mechanisms in this context have included nerve entrapment and compression from mandibular bone resorption, a phenomenon seen in SSc due to pressure ischemia from overlying tight sclerotic skin compromising blood supply to the bone. Previous studies of TN identified an association with overlap syndromes notably in patients with inflammatory myositis (IM), arthritis and interstitial lung disease (ILD). It has also been suggested that facial numbness can precede or follow other manifestations of SSc. However, since there is a paucity of evidence concerning TN in SSc, we undertook a nested case-control study to identify associations between SSc and TN in a multi-centered SSc cohort.

### **Methods:**

Data were retrieved from the Canadian Scleroderma Research Group (CSRG) registry, an open cohort of 1652 SSc subjects enrolled since 2004. Subjects with a physician-reported diagnosis of TN were identified at the baseline study visit (prevalent cases) and during follow-up (incident cases). Four SSc subjects without TN and matched to each case on study visit were identified as controls for either prevalent or incident cases. Sociodemographic, clinical and serological characteristics of cases and controls were compared. P values < 0.05 were considered statistically significant.

### **Results:**

43 (43/1652; 2.6%) prevalent and 36 incident (36/6193 total person-years follow-up; incidence rate 5.8 per 1000 person-years) TN cases were identified and matched to 144 and 172 controls, respectively. There were no significant differences in mean age, gender distribution and mean disease duration between cases and controls. Compared to controls, prevalent cases had more IM (24.4% vs. 5.2%,  $p<0.001$ ) and arthritis (46.5% vs. 30.2%,  $p=0.043$ ). Similarly, incident cases also had more IM (19.4% vs. 6.3%,  $p=0.033$ ) and arthritis (50.0% vs. 16.2%,  $p<0.001$ ) compared to controls. There was a trend towards more ILD in prevalent (32.6% vs 23.8%,  $p=0.241$ ) and incident (55.6% vs 40.6%,  $p=0.105$ ) cases compared to controls. U1RNP was numerically more frequent in cases versus controls (prevalent cases vs controls 9.4% vs 5.4%; incident cases vs controls 17.1% vs 5.8%). Pm/Scl antibodies were infrequent and similar in prevalent (2.9% vs 3.5%) and incident (5.9% vs 5.7%) cases compared to controls.

### **Conclusion:**

This study provides novel evidence for a syndrome linking TN, IM, arthritis and possibly ILD. We propose that TN could be a consequence of active inflammation and represent a sign of disease activity in SSc.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Scleroderma renal crisis (SRC), a life-threatening complication of systemic sclerosis (SSc), arises despite therapy combining an angiotensin-converting–enzyme inhibitor (ACEI) and/or dialysis. Endothelin-1 (ET-1), a powerful endothelium-derived vasoconstrictor peptide, has been implicated in SSc pathogenesis. Plasma ET-1 levels are elevated in SSc patients with SRC. Bosentan, a non-selective ET-1–receptor antagonist, was approved to treat pulmonary arterial hypertension and prevent SSc ischemic digital ulcers. Those findings suggested that bosentan could have therapeutic benefits on other vascular manifestations of SSc, particularly SRC. This open-label national prospective study evaluated the efficacy and tolerance of bosentan for 6 months combined with an ACEI and/or dialysis on renal and overall survival of SSc patients with SRC.

## Methods:

SRC was defined as rapidly progressive oliguric renal insufficiency and/or rapidly progressive arterial hypertension. All patients received Bosentan 62.5 mg twice daily for 4 weeks and 125 mg twice daily thereafter for 5 months, in addition to the usual recommended treatments. The primary end-point was kidney survival at 12 months. Secondary endpoints were patient survival and Bosentan side effects at 12 months.

## Results:

Between March 2011 and April 2014, 16 patients (10 (62.5%) females; median age 65.3 [range 46.3–71.3] years) were enrolled. Twelve (75%) patients had diffuse SSc, 1 (6.3%) had limited cutaneous SSc and 3 (18.8%) had limited SSc. Four (25%) had pulmonary fibrosis, 3 (18.8%) left ventricular insufficiency and 3 (18.8%) severe bowel involvement. Renal biopsies obtained from 14 patients showed specific vascular SRC lesions. Prior to SRC, 11 (68.8%) patients had taken corticosteroids and 6 (37.5%) were taking an ACEI for hypertension. SRC recurred in 1 patient 2 years after kidney transplantation. Four (25%) patients had normotensive SRC. Seven (43.8%) patients achieved the primary end-point of dialysis-free status. Only 9 (56.3%) patients were alive at 12 months. Seven (43.8%) patients were dialyzed, 6 of them within the first 10 days of inclusion. One patient was dialyzed at month 4 for multivisceral failure and septic shock. No patients on dialysis at baseline came off dialysis. One patient developed an SRC relapse at 6 months. Renal function of dialysis-free survivors did not improve on bosentan, with a mean [range] estimated glomerular filtration rate at entry of 22 [22–49] vs. 16 [11.5–23.5] ml/min/1.73 m<sup>2</sup> at SRC onset. Seven (43.8%) patients died; 4 (57.1%) of those deaths were not SSc-related. The 3 SSc-related deaths resulted from severe organ involvement (lung fibrosis, intestinal involvement or associated myositis). No patient suffered serious adverse effects requiring bosentan withdrawal.

## Conclusion:

Bosentan does not seem to improve renal outcomes and survival is no better than in historical series<sup>1</sup>. However, the high non-SSc-attributable mortality makes drawing any definitive conclusion difficult. Further investigations are needed.

## Perceived Barriers to Mental Health Care Among Patients with Systemic Sclerosis: A Qualitative Study

Karima Becetti<sup>1</sup>, Laura Robbins<sup>2</sup>, Carol Mancuso<sup>3</sup>, Jessica K. Gordon<sup>1</sup> and Robert F. Spiera<sup>1</sup>, <sup>1</sup>Rheumatology, Hospital for Special Surgery, New York, NY, <sup>2</sup>Education & Academic Affairs, Hospital for Special Surgery, New York, NY, <sup>3</sup>Medicine, Hospital for Special Surgery, New York, NY

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Sclerosis (SSc) is characterized by disfigurement, morbidity, and increased mortality. The diagnosis carries significant psychosocial impact on patients, and many suffer with depression, anxiety, and body image distress. Interventions to address this impact are recommended as an essential aspect of care. However, previous studies identified mental health care as an unmet need for many SSc patients. Using a qualitative approach, this study aimed to evaluate perceived barriers to mental health care in SSc.

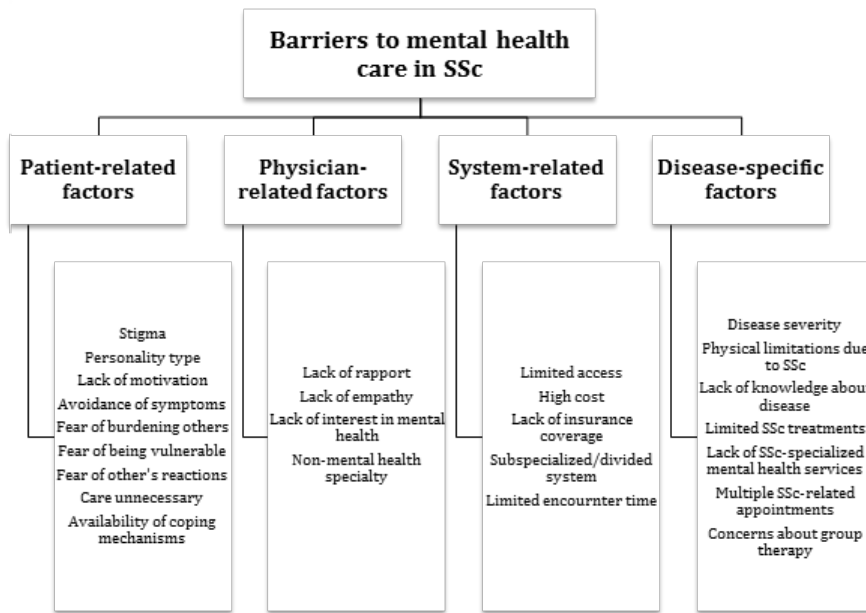

**Methods:** A qualitative study was conducted in a sample of consecutive SSc patients presenting to a single center. After obtaining informed consent, one-to-one interviews were conducted in-person using open-ended questions on individual patients' experience with SSc and barriers to mental health care. Demographic and clinical data were obtained to characterize the study sample. A grounded theory approach was used to code interview transcripts and identify emergent concepts, categories, and themes. Interviews were continued until data saturation was reached.

**Results:** Twenty SSc patients with a median (range) age of 56.5 years (21-74) and disease duration of 4.5 years (1-34) were interviewed. 100% were female, 55% were white, 60% had private insurance, and 70% had diffuse SSc. Patients reported multiple psychological symptoms in association with SSc including sadness, anxiety, anger, uncertainty, and suicidal ideations at the time of diagnosis. Interview analysis identified four major themes relating to barriers to mental health care; patient-related, physician-related, system-related, and disease-specific factors (Figure 1). Patient-related factors included stigma about mental illness, avoidance of symptoms, fear of being vulnerable or burdening others, fear of other's reaction, and lack of need due to available coping mechanisms. Lack of physicians' rapport, empathy, and interest in emotional symptoms, and their subspecialty (non-mental health) emerged as barriers. System-related factors

included high cost, lack of insurance, division within the healthcare system, and limited access and appointment time. Patients identified disease severity, physical limitations due to SSc, poor understanding of disease process, paucity of effective treatments, lack of SSc-specialized mental health services, and the numerous SSc-related appointments as barriers. The heterogeneity of SSc, variable patient experiences, and fear of contact with other patients with more aggressive disease were barriers to SSc group therapy.

**Conclusion:** In addition to the known barriers to mental health care such as access, cost, and stigma, SSc patients also identified disease-specific barriers. Identifying, understanding, and addressing these barriers are important for the effective dissemination of psychosocial interventions in this unique patient population.

## Real-Life Treatment Strategies for Systemic Sclerosis According to Experts

Andreu Fernández-Codina<sup>1,2</sup>, Kyle M Walker<sup>3</sup> and Janet E. Pope<sup>4</sup>, <sup>1</sup>Rheumatology, University of Western Ontario, London, ON, Canada, <sup>2</sup>Systemic Autoimmune Diseases, Hospital Universitari Vall d'Hebron, Barcelona, Spain, <sup>3</sup>Dept. of Medicine, Division of Rheumatology, University of Ottawa, Ottawa, ON, Canada, <sup>4</sup>University of Western Ontario, London, ON, Canada

**First publication:** September 18, 2017

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

Background/Purpose:

Second line treatment options for Systemic Sclerosis (SSc) are limited, and scarce data are available for choosing the order of treatment. The aim of this study is to update the SSc treatment algorithms obtained in 2012<sup>1</sup>, based on SSc experts' daily practice.

### **Methods:**

An initial survey was designed based on the 2012 algorithms. The survey asked experts whether they agreed with the 2012 algorithms or not, and which changes should be considered. The questionnaire was completed by 62 of 168 surveyed (67% response) between August and October 2016.

### **Results:**

For scleroderma renal crisis (SRC), there was 65% to 69% agreement with the previous algorithms (1st line angiotensin converting enzyme inhibitors [ACEI], 2nd and 3rd adding: calcium channel blockers [CCB] or angiotensin receptor blockers [ARB], and 4th alpha-blocker). In mild pulmonary arterial hypertension (PAH), only 45% of the experts agreed with the old algorithm. The majority suggested first phosphodiesterase 5 inhibitors (PDE5i) or endothelin receptor antagonists (ERA) plus PDE5i, then prostanoids. In severe PAH, 65% agreed with the preexistent scheme (1st prostanoids, 2nd ERA plus PDE5i, 3rd ERA plus prostanoids). For mild Raynaud's phenomenon (RP) 66% agreed with the previous algorithm (1st CCB, 2nd adding PDE5i, 3rd ARB or switching to another CCB, 4th prostanoids). Regarding severe RP, 52% agreed with previous (1st CCB, 2nd adding PDE5i, 3rd ERA, 4th prostanoids). Conversely, 60% of the experts did not agree with the prior active digital ulcer (DU) treatment, suggesting 1st CCB, 2nd PDE5i, 3rd prostanoids. For interstitial lung disease (ILD), for induction only 24% agreed with the older proposal. There was a 65% agreement on ILD maintenance. Both algorithms are shown in figure 1. For skin involvement, agreement for patients with a modified Rodnan skin score (mRSS) of 10 was 57% (1st methotrexate [MTX]), 2nd MMF); if the mRSS was 24, 32% suggested 1st MMF, 2nd MTX; and mRSS 32, 36% chose 1st MTX, 2nd MMF, 3rd IV CYP, 4th autologous stem cell transplantation (ASCT). In inflammatory arthritis 45% agreed with the previous algorithm, whereas others suggested 1st MTX, 2nd low dose steroids, 3rd hydroxychloroquine, 4th rituximab or tocilizumab.

### **Conclusion:**

There remains some disagreement for 2nd line treatment of SSc. Combination of PDE5i and ERA are prescribed now in mild PAH treatment. Prostanoids have been incorporated as 3rd line agents in active DU treatment. MMF is the new 1st line treatment for ILD induction and rituximab the 3rd. IV CYA and ASCT were recommended as 3rd and 4th line treatments in patients with severe skin involvement. Rituximab and tocilizumab have been incorporated into inflammatory arthritis treatment. This can guide therapy in SSc.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To estimate whether severity of skin thickness is associated with disease severity, function, quality of life (QoL) and progression of internal organ involvement over 12 months in early diffuse cutaneous systemic sclerosis (dcSSc).

**Methods:** We included dcSSc patients from the Canadian Scleroderma Research Group (CSRG) database with disease duration of ≤5 years from the onset of first non-Raynaud's symptom at initial visit and 1-year follow-up (FU). We assessed severity of skin involvement with the modified Rodnan skin score (mRSS); internal organ involvement with the Medsger organ severity scores; global measures of disease status with patient- and physician-reported 11 point numerical rating scales (NRS); disease activity with the European Scleroderma Study Group (EScSG) activity index; function with

the HAQ and S-HAQ 11 point NRS scales; and QoL with the SF-36. Bivariate, ANOVA, linear and logistic regression analyses were used to study the associations between mRSS and outcomes, adjusted for potential confounding factors.

**Results:** At baseline (N=204, 74% female, mean age 51±12 yrs, disease duration 2.1±1.3 yrs), higher mRSS was significantly associated with worse total disease severity (Medsger's score without skin component, physician and patient global NRS, S-HAQ overall disease rating), functional disability (HAQ-DI) and worse QoL (SF-36 PCS) ( $p<0.0001$  for all). Higher mRSS was also associated with the presence and severity of tendon involvement ( $p<0.0001$ ), severity of gastrointestinal disease ( $p=0.021$ ), S-HAQ digital ulcer severity ( $p=0.008$ ) and S-HAQ intestinal problems ( $p=0.008$ ) by adjusted regression analysis.

At 1-year FU visit (N=174, 74% female, mean age 51±12 yrs, disease duration 2.1±1.3 yrs) we found a significant reduction in mRSS ( $22.51\pm9.27$  vs  $19.42\pm10.45$ ,  $p=0.006$ ). There was also a decrease in disease activity by both EScSG-activity index ( $3.06\pm1.8$  vs  $2.41\pm1.8$ ,  $p=0.003$ ) and physician-assessed disease activity on NRS scale ( $4.61\pm2.37$  vs  $3.52\pm2.17$ ,  $p<0.0001$ ). There were no changes in other measures of disease characteristics.

We also examined the associations between baseline mRSS and outcomes at 1-year FU visit using adjusted regression analysis. Higher baseline mRSS was associated with worse HAQ-DI ( $p=0.0001$ ) and SF-36 PCS ( $p=0.0001$ ), higher total Medsger's severity score ( $p=0.014$ ), physician-assessed disease damage ( $p=0.001$ ), severity ( $p=0.008$ ) and joint involvement ( $p=0.0001$ ) at FU. Baseline mRSS was not associated with presence/severity of kidney, lung or heart disease at baseline or 1-year FU visit, nor predictive of new/progression of organ involvement over time.

**Conclusion:** Greater skin involvement at baseline was associated with worse joint and GI involvement, worse function and QoL. Baseline mRSS also predicted function, severity of joint involvement and QoL at 1-year FU. No association between skin involvement and burden of other organ-based complications was found, but follow-up was limited to 1-year in this analysis.

## **Lung Transplant Trends in Patients' with Systemic Sclerosis Using UNOS (United Network Organ Sharing) Database from 2000-2014**

**Osman Bhatti**<sup>1</sup>, Rouhin Sen<sup>1</sup>, Douglas Moore<sup>2</sup> and Joseph Nahas<sup>3</sup>, <sup>1</sup>Department of Medicine, CHI Creighton University Medical Center, Omaha, NE, <sup>2</sup>Department of Pulmonary/Critical Care, CHI Creighton University Medical Center, Omaha, NE, <sup>3</sup>Department of Rheumatology, CHI Creighton University Medical Center, Omaha, NE

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Systemic sclerosis (SSc) is a chronic autoimmune disease once characterized by high mortality rates now with better outcomes. Pulmonary disease has overtaken renal failure as the leading cause of death. Unfortunately medical therapies are still lacking in this regard and lung transplantation ultimately becomes the most viable option. For many years these patients were not offered lung transplants due to the perception that they would do poorly. In 2006 the International Society of Heart and Lung Transplantation (ISHLT) endorsed Lung transplant (LT) as an option for SSc although many programs still considered SSc a contraindication due to concerns of poor allograft function and presumed low patient survival due to the extra pulmonary organ involvement. Since then retrospective cohort studies [1] have shown survival data post transplant very similar to other similar processes i.e IPF and IPAH which have well-established indications for lung transplant and acceptable outcomes. The question remains if this new literature is resulting in more patients with systemic sclerosis being waitlisted for or actually undergoing transplant since for those that are not mortality is high.

## Methods:

We looked retrospectively at all patients with a scleroderma, scleroderma – restrictive, and scleroderma – pulmonary hypertension diagnosis within The United Network Organ Sharing Database from the years 2000 to 2014. This database captures the lung transplants in the United States including those that are waitlisted. The diagnoses above will be used to trend the rates of patients with SSc being waitlisted and undergoing transplants from 2000-2014.

## Results:

The data shows that since the year 2000 the percent of patients on the UNOS waitlist and those actually undergoing lung transplantation with a diagnosis of systemic sclerosis has risen. Percent of patients in 2000 with SSc on the waitlist was .29 percent which increased to 2.54 percent in 2014. Percent of patients with SSc who received lung transplant was zero in 2000 increasing to 1.67 in 2014.

## Conclusion:

Since the ISHLT endorsed LT as an option for SSc the number of patients with this diagnosis make up a higher proportion of those being waitlisted and undergoing transplant. As data continues to show that these patients do better than what was once believed, efforts should focus on assessing clinical phenotypes and investigating how this may influence not only waitlisting itself, but time to transplant and other outcomes such as mortality.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Esophageal involvement is common in Systemic Sclerosis (SSc). It is estimated to occur in 70-90% of patients. Esophageal motor dysfunction is characterized by hypotonia of lower esophageal sphincter (LES) and mild peristalsis or aperistalsis in 2/3 of the esophagus. There is evidence that interstitial lung disease (ILD) and pulmonary fibrosis in SSc are associated with episodes of microaspirations secondary to gastroesophageal reflux disease (GERD).

The aim of this study was to determine if GERD is associated with ILD in SSc patients.

**Methods:** An observational retrospective cohort study was conducted during the period 1983-2016 in a single hospital centre. Diagnosis of GERD was established by typical clinical symptoms of heartburn and regurgitation. Esophageal manometry was performed to evaluate motility and was classified as: hypotensive LES (<10mmHg) and ineffective or absence of peristalsis at the distal esophagus. Pulmonary involvement was performed by high resolution computed tomography. Pulmonary function tests were performed with carbon monoxide diffusing capacity (DLCO) and forced vital capacity (FVC). Demographic, serological, clinical, and respiratory functional tests were analyzed. For quantitative and qualitative variables, Student's T, Mann-Whitney, and Chi-2 were used, respectively. The hazard ratio values were obtained with a 95% confidence interval. Values of  $p \leq 0.05$  were considered statistically significant.

**Results:** 125 patients with SSc were included, of whom 91 (72.8%) had GERD, with female predominance in both groups. Comparatively between the groups that presented GERD and those that did not, the age at diagnosis was similar and the time of evolution of the disease was 7 years vs 2 ( $p < 0.001$ ) respectively. In terms of disease subtypes, no statistically significant differences were found between patients with GERD and those who did not. Among the clinical characteristics analyzed, the presence of GER was not associated with cardiac involvement while it was for digital ulcers (36/91 vs 4/34;  $p = 0.003$ ). There were no significant differences in the immunological profile. The decrease in DLCO <70% and FVC <70% were more frequent in patients with GERD (49.4% vs 23.5%, 47.2% vs 23.5%;  $p = 0.009$ ). Alterations in esophageal manometry were more frequent in patients with GERD 59.34% ( $p = 0.035$ ) All data are detailed in the table below.

**Conclusion:** Significant differences were found when evaluating complementary studies such as DLCO <70%, FVC <70% and esophageal manometry, indicating that there is an association between GERD and ILD. A statistically significant finding was the association between the presence of digital ulcers and the presence of GERD.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

The evaluation of patients who develop interstitial lung disease (ILD) includes an assessment for underlying rheumatic disease or connective tissue disease (CTD). Delineating a CTD phenotype in patients with ILD is important as these patients may have a different prognosis compared to idiopathic pulmonary fibrosis (IPF) and other idiopathic interstitial pneumonias (IP). The subset of patients with ILD and predominantly fibrotic radiographic features are particularly challenging as they may be mislabeled as IPF. This study focused on the utility of a Rheumatologist's clinical diagnosis and serologic testing in identifying those with CTD /ILD in a cohort of patients with fibrotic features.

**Methods:**

We retrospectively identified 100 new patients who presented to our multidisciplinary ILD clinic from 2013-2014. All were evaluated by a Pulmonologist and the same experienced Rheumatologist who stratified the likelihood of a CTD into 3 groups (no evidence, possible diagnosis or definite diagnosis). Age, sex and serologic data including ANA, RF, CCP, myositis panel, Scl-70, and muscle enzymes were recorded. Each patient was given an initial clinical diagnosis and a final diagnosis based on multidisciplinary consensus from chest CT, biopsy results, and serologic testing.

**Results:**

Of the 100 patients, 34% had a final diagnosis of IPF, 39% had CTD/ILD, and 27% other IP. (Table) In a subgroup of patients with fibrosis based on CT, a final diagnosis of IPF was made in 48% and final diagnosis of CTD/ILD was noted in 34%. Patients with CTD/ILD were younger and more likely to be female. However, there was no significant difference in age for females with fibrotic features between CTD/ILD and IPF. (Table) Amongst patients with no evidence of CTD on Rheumatologist evaluation, the final diagnosis was IPF in 79%. Serologic testing was positive in 9% but did not change the final diagnosis. In those with possible CTD a final diagnosis of CTD/ILD was made in 56%. Serologic testing was positive in 50% and resulted in a change in diagnosis for 3 patients. In those with a certain CTD all had CTD/ILD and positive serologic testing, but no changes in diagnoses. (Table)

**Conclusion:** In patients with fibrotic forms of ILD based on CT, CTD is present in a significant number of cases and when the Rheumatologist's evaluation does not suspect a CTD diagnosis, serologic data is of no significant benefit. In patients where a rheumatologic diagnosis is suspected but not certain, serologic testing does offer benefit diagnostically. Assessment by a rheumatologist is a valuable aspect of the evaluation of the patient with ILD and may obviate the need for extensive serologic testing in a subset of patients.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Relatively little data exist in the literature to characterize the differences between patients with scleroderma-associated isolated pulmonary arterial hypertension (SSc-PAH, WHO Group 1) and pulmonary hypertension that coexists with interstitial lung disease (SSc-ILD-PH, WHO Group 3). Our aim was to compare the characteristics of SSc-PAH and SSc-ILD-PH patients from the Cleveland Clinic Pulmonary Hypertension Database to help define differences that may exist between these two groups.

**Methods:** We performed a retrospective chart-review comparing demographic, laboratory, and hemodynamic data from a total of 176 patients (155 with SSc-PAH and 21 with SSc-ILD-PH) enrolled in the Cleveland Clinic Pulmonary Hypertension Database. The diagnosis of PAH was confirmed by right-heart cardiac catheterization (RHC). The diagnosis of SSc was confirmed by a rheumatologist and that of ILD was confirmed by a pulmonologist. Thirty-three variables were ultimately chosen for evaluation; the decision to include a given variable was based either on previous evidence in the literature that said variables were relevant in predicting outcomes in SSc-PAH or SSc-ILD-PH patients. Multivariate and univariate evaluations were performed using ANOVA, the Kruskal-Wallis test, Pearson's chi-square test, and Fisher's Exact test. A p-value of  $<0.05$  was considered significant.

**Results:** Statistically significant differences between the SSc-PAH and SSc-ILD-PH groups were found for age, forced vital capacity (% estimated), pulmonary vascular resistance, cardiac index by thermodilution, and NT-proBNP level. Additionally, we observed that in our cohort SSc-ILD-PH patients tended to live longer than those with SSc-PAH. Among SSc-ILD-PH, the estimated median time-to-death was 13.19 years (95% CI: 3.79 – 20.72 years), whereas in SSc-PAH patients, the estimated median time-to-death was 4.89 years (95% CI: 4.01 – 6.98 years). However, this difference in survival was not statistically significant ( $P = 0.1743$ ).

Statistics presented as Mean  $\pm$  SD, Median [P25, P75], Median (min, max) or N (column %). p-values: a=ANOVA, b=Kruskal-Wallis test, c=Pearson's chi-square test, d=Fisher's Exact test.

**Conclusion:** In our study, statistically significant differences were found between SSc-PAH and SSc-ILD-PH patients. The suggestion of longer survival in SSc-ILD-PH patients may be explained by some lurking variables that were not available for analysis, such as autoantibody subsets. SSc-PAH patients were older and possibly were more likely to have limited SSc with positive anti-centromere antibody, representing a subpopulation that is distinct from the SSc-ILD-PH patients. More research is necessary to elucidate these differences.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Survival in scleroderma associated pulmonary arterial hypertension (SSc-PAH) is known to be significantly worse compared to that in idiopathic pulmonary arterial hypertension (iPAH). However, specific factors contributing to the worse survival in SSc-PAH is currently unknown. Our objective was to investigate how the age at diagnosis of PAH and systolic blood pressure may influence mortality in these patients.

**Methods:** A retrospective chart-review was conducted comparing demographic, clinical and hemodynamic data from a total of 862 patients (686 with iPAH and 176 with SSc-PAH) enrolled in the Cleveland Clinic Pulmonary Hypertension Database. The diagnosis of PAH was confirmed by RHC, and the diagnosis of SSc was confirmed by a rheumatologist. We focused on the characteristics of age, systolic blood pressure (SBP) and cardiac output/cardiac index (on right heart catheterization) with regards to their effect on mortality in both the SSc-PAH and the iPAH groups.

**Results:** Among younger patients (age < 63) those with SSc-PAH had significantly worse survival compared to those with iPAH. Interestingly, a similar difference in mortality between the 2 groups was not seen in patients of age ≥ 63 years.

PAH Status Group	Age	P-value*	N	Est. Median Time-to-Death (years)	95% CI
Idiopathic PAH	Any non-missing	0.0002	598	10.26	(8.45, 12.00)
Scleroderma Associated	Any non-missing		159	5.33	(4.22, 7.59)
Idiopathic PAH	< 63	0.0087	439	14.41	(10.81, 16.49)
Scleroderma Associated	< 63		76	6.74	(4.22, 20.72)
Idiopathic PAH	≥ 63	0.9752	159	5.11	(4.58, 6.62)
Scleroderma Associated	≥ 63		83	4.75	(3.78, 7.59)
Scleroderma Associated	< 63	0.1061	76	6.74	(4.22, 20.72)
Scleroderma Associated	≥ 63		83	4.75	(3.78, 7.59)
Idiopathic PAH	< 63	<0.0001	439	14.41	(10.81, 16.49)
Idiopathic PAH	≥ 63		159	5.11	(4.58, 6.62)

A statistically significant difference in survival was also noted when comparing SSc-PAH patients with SBP >125 mmHg with those with SBP < 125 mmHg; the group with lower SBP had worse survival. A similar mortality difference was not noted in the iPAH patients.

PAH Status Group	Systolic Blood Pressure	P-value*	N	Est. Median Time-to-Death (years)	95% CI
Idiopathic PAH	Any non-missing	0.0007	559	10.02	(8.24, 11.84)
Scleroderma Associated	Any non-missing		151	5.33	(4.24, 7.68)
Idiopathic PAH	< 125	< 0.0001	277	9.48	(6.98, 12.31)
Scleroderma Associated	< 125		63	4.01	(2.51, 6.03)
Idiopathic PAH	≥ 125	0.2313	282	10.26	(8.23, 12.75)
Scleroderma Associated	≥ 125		88	7.68	(4.70, 18.60)
Scleroderma Associated	< 125	0.0099	63	4.01	(2.51, 6.03)
Scleroderma Associated	≥ 125		88	7.68	(4.70, 18.59)
Idiopathic PAH	< 125	0.8082	277	9.48	(6.98, 12.31)
Idiopathic PAH	≥ 125		282	10.26	(8.23, 12.75)

To determine if SBP served as a surrogate for cardiac output, we assessed Kendall tau-b correlations of SBP versus cardiac output and cardiac index (CI) (both by thermodilution and by the Fick equation); no strong correlation was noted. However, a correlation between CI < 2.5 L/min/m<sup>2</sup> and mortality was noted. A similar mortality difference was not noted in the iPAH patients.

PAH Status Group	Cardiac Index (FICK) [L/min/m <sup>2</sup> ]	P-value*	N	Est. Median Time-to-Death (years)	95% CI
Idiopathic PAH	Any non-missing	0.0126	470	9.38	(7.72, 11.50)
Scleroderma Associated	Any non-missing		142	5.59	(4.24, 8.19)
Idiopathic PAH	< 2.5	0.0003	261	9.38	(7.51, 14.41)
Scleroderma Associated	< 2.5		73	4.10	(3.38, 6.03)
Idiopathic PAH	≥ 2.5	0.9208	209	9.02	(6.81, 11.84)
Scleroderma Associated	≥ 2.5		69	10.74	(5.37, 18.59)
Scleroderma Associated	< 2.5	0.0192	73	4.10	(3.38, 6.03)
Scleroderma Associated	≥ 2.5		69	10.74	(5.37, 18.59)
Idiopathic PAH	< 2.5	0.5030	261	9.38	(7.51, 14.41)
Idiopathic PAH	≥ 2.5		209	9.02	(6.81, 11.84)

**Conclusion:** Younger age, lower SBP, and lower CI influences survival in SSc-PAH patients, but not in iPAH patients. Younger SSc-PAH patients have markedly lower survival times than similarly aged iPAH patients for unclear reasons. The relationship between lower SBP, decreased CI, and increased mortality has been previously noted in some smaller studies. These data may have important implications for treatment of SSc-PAH especially since some PAH therapies may decrease SBP.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) associated pulmonary arterial hypertension (SSc-PAH) is a serious and often life-threatening complication of SSc. Perhaps the most important enigma in the context of SSc-PAH care is the fact that the prognosis of SSc-PAH patients is substantially worse than that of demographically similar patients with idiopathic PAH (iPAH). Moreover, it has been shown that these differences in survival are *not* related to a higher prevalence of left-heart disease in SSc-PAH patients. Previous studies have not extensively compared demographic, laboratory, and hemodynamic data from cohorts of iPAH and SSc-PAH patients to determine which specific characteristics of these groups may explain the worsened clinical course and prognosis of SSc-PAH sufferers. The aims of our study were to identify specific characteristics that distinguish these two groups in a large cohort of SSc-PAH and iPAH patients.

**Methods:** A retrospective chart-review was conducted comparing demographic, laboratory, and hemodynamic [echocardiographic and right heart catheterization (RHC)] data from a total of 862 patients (686 with iPAH and 176 with SSc-PAH) enrolled in the Cleveland Clinic Pulmonary Hypertension Database. The diagnosis of PAH was confirmed by RHC, and the diagnosis of SSc was confirmed by a rheumatologist. Thirty variables were chosen for evaluation; the decision to include a given variable was based either on inclusion of the variables in previous studies on SSc-PAH or on theoretical suspicion that specific variables may be relevant in distinguishing the two conditions. Multivariate and univariate analyses were completed utilizing ANOVA, the Kruskal-Wallis test, Pearson's chi-square test, and Fisher's Exact test.

**Results:** Statistically significant differences between the SSc-PAH and iPAH groups were found for the variables of age, gender, forced vital capacity, total lung capacity, 6-minute walk distance, FEV1/FVC ratio, transfer factor (DLCO), right ventricular systolic pressure (on transthoracic echocardiogram), mean pulmonary artery pressure and pulmonary vascular resistance (on RHC), systolic blood pressure, BNP and NT-proBNP level, and mortality status.

**Conclusion:** Our analysis confirms findings from previous studies that have shown that SSc-PAH patients demonstrate important differences in hemodynamic and pulmonary function parameters compared to iPAH patients (table). Additionally, patients with SSc-PAH demonstrated much higher BNP and NT-proBNP levels compared to iPAH patients with similar hemodynamic parameters. Further research will be necessary to help delineate other relevant factors that may aid in caring for these patients.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is an immune disorder characterized by vasculopathy and fibrosis. SSc may overlap with another disease such as systemic lupus erythematosus (SLE). Little is known about the epidemiology, clinical characteristics, and survival of SSc-SLE overlap syndrome (also called lupoderma). We evaluated the prevalence of SSc-SLE overlap syndrome, differences in SSc clinical characteristics and survival compared with SSc without SLE.

**Methods:** A retrospective cohort study was conducted between 1970 – 2017 including subjects who fulfilled the ACR/EULAR classification criteria for SSc and/or who fulfilled the ACR classification criteria for SLE. The primary outcome was the time from diagnosis to death from all causes. Survival was evaluated using Kaplan Meier curves and Cox proportional hazard models. Secondary outcomes included the prevalence of SSc-SLE overlap syndrome, and differences in clinical characteristics.

**Results:** We identified 1252 subjects (SSc n=1166, SSc-SLE n=86) with a SSc-SLE prevalence of 6.8%. SSc-SLE subjects were more frequently female (92% versus 81%, p=0.02), had lupus anticoagulant (6% versus 0.3%, p<0.001), anticardiolipin antibody (6% versus 0.9%, p<0.001), and pulmonary hypertension (52% versus 31%, p<0.001). SSc-SLE subjects less frequently had calcinosis (13% versus 27%, p=0.007), telangiectasia (49% versus 75%, p<0.001) and diffuse subtype (12% versus 35%, p<0.001). There were no significant differences in the occurrence of renal crisis (7% versus 7%), interstitial lung disease (40% versus 34%), digital ulcers (38% versus 32%), hypertension (19% versus 21%), diabetes (6% versus 6%), dyslipidemia (5% versus 7%) or cancer (7% versus 11%) between groups.

**Figure 1.** Kaplan Meier curves comparing survival of SSc-SLE overlap to SSc subjects.

The Kaplan Meier curves suggest that SSc-SLE overlap subjects have better survival, but this was not statistically significant (log rank  $p=0.06$ ). Accounting for female sex and diffuse subtype attenuated survival differences between the two groups (Hazard Ratio 0.70, 95%CI 0.45, 1.11).

**Conclusion:** SSc-SLE subjects are more frequently female and less frequently have cutaneous manifestations of SSc. However, these subjects should be monitored for serious complications of SSc including pulmonary hypertension, interstitial lung disease, renal crisis and digital ulcers.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is characterized by increase of dermal thickness (DT) and impairment of microvascular system (1). Several studies demonstrate that nailfold capillaroscopy (NVC) patterns of microangiopathy correlate with organ involvement, but few studies investigated the correlation between nailfold microangiopathy and skin involvement. The modified Rodnan skin score (mRss) is the validated method to assess the severity of skin damage (2,3), high frequency skin ultrasound (US) is able to detect skin damage in SSc (4,5), and the plicometer skin test (Plicometry) is a further method to evaluate cutaneous involvement in SSc patients (6). The aim of this study was to identify possible correlations between different patterns of nailfold microangiopathy and three different methods (mRss, US and Plicometry) to assess DT in SSc patients.

**Methods:** Sixty-three SSc patients (ACR/EULAR criteria) (mean age  $64 \pm 11$ SD years, mean disease duration  $7 \pm 6$  years, 43 lcSSc and 20 dcSSc) and 63 sex and age matched healthy subjects were enrolled, after written informed consent. All subjects were assessed by mRss, US and Plicometry to evaluate DT in the seventeen skin areas of the body usually evaluated by mRss (zygoma, fingers, dorsum of hands, forearms, upper arms, chest, abdomen, thighs, legs, feet) (1-6).

NVC was performed to assess the proper pattern of microangiopathy ("Early", "Active" or "Late" pattern) and to calculate the microangiopathy evolution score (MES) (7-8). Statistical evaluation was performed by non-parametric tests.

**Results:** There was a statistically significant positive correlation between DT values and severity of nailfold microangiopathy: all methods detected a progressively higher DT in patients with "Early", "Active" and "Late" pattern of microangiopathy ( $p < 0.005$ ), and a positive correlation was observed also with MES ( $r = 0.71$   $p < 0.001$ ). Finally, a positive correlation was observed in SSc patients between the three methods to evaluate DT (Plicometry vs mRss  $r = 0.98$ ,  $p < 0.0001$ ; Plicometry vs US  $r = 0.53$ ,  $p < 0.0001$ ; US vs mRss  $r = 0.53$ ,  $p < 0.0001$ ). As expected, the group of SSc patients had a statistically significant higher DT at level of all areas, as evaluated by the three methods, when compared to the control group ( $p < 0.0001$ ).

**Conclusion:** This study demonstrates a relationship between skin damage and microangiopathy impairment in SSc patients, as well as a correlation between different methods to assess DT.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pulmonary arterial hypertension (PAH) is a severe complication of systemic sclerosis (SSc), and its diagnosis requires right heart catheterization (RHC). The DETECT study developed an algorithm to select SSc patients with high suspicion of PAH for referral to RHC, identifying patients with early stage PAH and minimizing missed diagnoses. In this longitudinal follow up study, we aimed to identify factors associated with PAH progression in the DETECT cohort.

**Methods:** DETECT enrolled patients with SSc fulfilling the 1980 ACR classification criteria with a disease duration <3 years since the first non-Raynaud symptom, and who had a pulmonary diffusing capacity for carbon monoxide (DLCO) < 60% of the predicted value. Patients who had been previously diagnosed with pulmonary hypertension (PH) by RHC, who received treatment for PH, and who were at risk for developing PH other than PAH were excluded. A broad range of clinical and laboratory parameters potentially associated with PAH were assessed and RHC was performed in all patients at baseline. Patients diagnosed with PAH at baseline were followed up for up to 3 years in centers that agreed for the longitudinal part of the DETECT study, collecting data on survival, World Health Organization (WHO) Functional Class (FC), hospitalization, and PAH-specific treatment. Disease progression was defined as the occurrence of any of the following: WHO-FC worsening, PAH therapy with a drug combination, PAH-related hospitalization, or death. Associations between baseline variables and disease progression were assessed by univariable logistic regression.

**Results:** Of the 145 SSc patients with PH enrolled in the DETECT study, 87 patients were diagnosed with group I PH (PAH), of whom 57 participated in the longitudinal follow up study (median follow-up time 12.6 months, interquartile range 10.7-21.7 months). Among these 57 patients, 33 (57.9%) had mild PAH, in WHO FC I or II, and 52 received PAH-specific therapy. During follow-up, 25/57 (43.9%) patients had disease progression (4 deaths, 11 hospitalizations for PAH, 14 with worsening in WHO FC, and 8 received PAH-specific combination treatment), with a 1-year survival rate of 93%. The following factors [odds ratio, (95% confidence interval, CI)] were associated with disease progression: male gender [4.1 (1.1-14.1)], high Forced Vital Capacity (FVC) % predicted/ DLCO % predicted ratio [3.6 (1.2-10.7)], and high Borg dyspnoea index [1.7 (1.1-2.6)]. Low DLCO (% predicted) was also significantly associated with progression [area under the curve (95% CI) 0.8 (0.6-0.9)], but the relationship was not linear. A sensitivity analysis, excluding 4 patients with missing outcome data, was also performed and found similar results.

**Conclusion:** Although the large majority of these patients with early-diagnosed SSc-PAH were treated with PAH-specific drugs, more than 40% had disease progression during a rather short follow-up time, with male gender, functional capacity, and pulmonary function tests (low DLCO, high FVC%/DLCO % predicted ratio) at PAH diagnosis being associated with progression. This suggests that even mild and early detected PAH should be regarded as a high-risk complication of SSc.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Gastrointestinal tract (GI) is one of the most commonly affected systems in systemic sclerosis (SSc), impacting the lives of up to 90% of patients, irrespective of their disease subtype. Of the GI manifestations in SSc, GI dysmotility impacts as many as 90% of patients with SSc. Various GI modalities are used to assess and aid in the diagnosis of GI tract motility compromise. The wireless motility capsule (WMC) is an ambulatory, noninvasive and ingestible device that measures intraluminal pressure, pH, and temperature changes as it moves through the GI tract. This helps evaluate regional and whole gut transit times, as well as phasic GI motor activity.

**Objective:** To describe the regional and whole gut transit times in patients with SSc and to evaluate relationship between GI transit time and other organ manifestation in SSc disease.

**Methods:** This was a retrospective analysis of all SSc patients from the *UCLA SSc program* and the UCLA- database, meeting the 2013 ACR/EULAR SSc classification criteria,  $\geq 18$  y.o, and having had a WMC test performed from July 1, 2013 to July 1, 2016. We reported both regional (gastric emptying, small bowel, and colonic transit times) as well as whole gut transit times. We evaluated other rheumatologic manifestations, including: interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), creatinine clearance (CrCl), and diffuse vs. limited disease. Additionally, we reported patient-reported symptoms related to upper and lower GI transit, including GERD, heartburn, regurgitation, vomiting, dysphagia, constipation, and diarrhea. Statistical analyses of numerical variables were assessed using Wilcoxon rank sum tests and T-tests and categorical variables were assessed using Fisher's exact tests.

**Results:** A total of 35 patients met our inclusion criteria. The median age was 57.5 years. There were 34 (97%) women; 23 (65%) were white/Caucasian; 28 (80%) were non-Hispanic/Latino; 25 (71.4%) had limited SSc; 22 (62.9%) had ILD; 16 (45.7%) had PAH. The mean CrCl was 78.1 with SD of 24.8. No statistically significant correlation was noted between regional and/or whole gut motility and other SSc organ manifestation. We found that 42.9% had decreased gastric emptying; 37.5% had decreased small bowel transit time; 33.3% had decreased colonic transit time.

**Conclusion:** In this small cohort, we did not find a significant correlation between regional and whole gut transit times and other manifestations of SSc. Interestingly, we found a discrepancy between patient-reported symptoms and WMC transit times, indicating that symptomatology may not be correlated with a decrease in regional GI transit times. A larger cohort study is needed to verify our findings.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is an intractable connective tissue disease that causes fibrosis of the skin and organs. The prognosis of this disease is affected by interstitial pneumonia (IP) and pulmonary arterial hypertension (PAH). Chitinase-like protein YKL-40 has been implicated in inflammation and tissue remodeling. A previous study in our department demonstrated elevated blood levels of YKL-40 in Japanese SSc patients. Examinations of the relationship between YKL-40 and PAH in SSc using immunohistochemistry (IHC) have yet to be reported in detail.

**Methods:** Subjects comprised 50 SSc patients without complications examined in our department between August 2014 and April 2017 (Group 1), 18 SSc patients with IP (Group 2), 5 SSc patients with PAH (Group 3), and 5 SSc patients with both IP and PAH (Group 4), as well as a control group of 17 healthy individuals (Group 0). IHC was performed on 7 samples of normal skin and 7 stored samples of SSc skin. Serum levels of YKL-40 were measured by Enzyme Linked Immuno Sorbent Assay and age-adjusted reference levels were calculated [age-percentile strata for YKL-40 = 100/(1 + (YKL-40<sup>-3</sup>) × (1.062<sup>age</sup>) × 5000)].

**Results:** We first examined Groups 0, 1 and 2. The YKL-40 age-percentile was 23.9 ± 17.1 in Group 0, significantly higher than in Group 1 (46.3 ± 26.6) or Group 2 (54.2 ± 26.7) (Steel-Dwass test between Groups 0, 1 and 2, p < 0.01). No significant difference was evident between Groups 1 and 2 (p = 0.52). We then performed immunostaining with YKL-40 antibody for specimens from healthy individuals and SSc patients. All normal skin remained unstained by IHC, whereas subcutaneous vascular endothelium showed prominent staining in all SSc samples. Finally, we examined SSc patients with PAH. YKL-40 age-percentile was 89.7 ± 10.4 in Group 3 and 94.0 ± 11.2 in Group 4. No significant difference was seen between Groups 3 and 4 (Steel-Dwass test between Groups 1-4, p = 0.63), or between Groups 1 and 2 (p = 0.69). A

significant difference was found between the other groups ( $p < 0.05$ ). YKL-40 age-percentile was more increased with PAH than with other conditions. SSc patients were divided based on presence or absence of PAH and ROC analysis was performed. SSc complicated with PAH could be diagnosed with 80.0% sensitivity and 94.1% specificity.

**Conclusion:** YKL-40 appears to reflect regeneration from capillary injury in SSc, as capillary vessels of the superficial dermis showing staining under IHC. PAH may reflect angiogenesis due to capillary injury in SSc, along with significant rises in YKL-40 in Groups 3 and 4 that complicated PAH and IHC results. YKL-40 may offer a useful and easily applied diagnostic biomarker for SSc and complicated PAH.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pulmonary arterial hypertension (PAH) associated with connective tissue disease should always be diagnosed with the gold-standard method of right heart catheterization (RHC). On the other hand, transthoracic echocardiography (TTE) is well validated for initial assessment when PAH is suspected. Whether TTE has a role in the follow-up of PAH is less known. The purpose of this study was to test the hypothesis that TTE can predict follow-up RHC-derived hemodynamic measurements in connective tissue disease-associated PAH.

**Methods:** This retrospective study included two independent cohorts of 30 and 14, patients, respectively, with systemic sclerosis (n=34) and mixed connective tissue disease (n=10) (mean age $\pm$ SD: 59.09 $\pm$ 12.16 years, 86% women), in whom PAH had been suggested by baseline TTE and confirmed by RHC [pulmonary artery systolic pressure (PASP): 59.3 $\pm$ 16.8, range 25-90mmHg; pulmonary vascular resistance (PVR): 6.2 $\pm$ 3.2, range 0.7-14.5 Wood units). All 44 patients underwent a second RHC and TTE at follow-up after 9.6 $\pm$ 5.7 (range 4-29) months. Seventeen patients had a 3rd

follow-up RHC and TTE  $18.7 \pm 7.1$  (range 10-37) months from baseline, thus producing in all 50 and 28 pairs of baseline/follow-up measurements, in each cohort, respectively. By considering as the gold-standard the follow-up RHC, we examined whether clinically meaningful hemodynamic changes from baseline (i.e. greater than +15% change) in either RHC-derived PASP or PVR could be predicted by the corresponding TTE-derived PASP changes from baseline to follow-up. RHC and TTE were always performed, each, by the same examiner.

**Results:** In 72% and 93% of comparisons between baseline and follow-up, in the first and second cohort respectively, the latter TTE measurements could safely replace RHC in terms of PASP estimation. Using Mc Nemar's test we confirmed that the two methods did not differ significantly in either cohort ( $p=0,79$  and  $p=0,48$  for the first and the second cohort, respectively). When in addition to changes in PASP, PVR changes were also considered, follow-up TTE could again safely replace the second RHC in terms of PASP and PVR estimation in 74% and 89% of patients retests ( $p=0,58$  and  $p=0,25$  for the first and the second cohort, respectively). Of note, baseline hemodynamic values or TTE measurements did not differ between patients in whom TTE could predict RHC-derived PASP and PVR and those in whom the results of the two methods at follow-up were divergent.

**Conclusion:** In a study where operator-dependent methodological errors are limited, we found, in two independent cohorts, that 4 out of 5 patients with connective tissue disease-associated PAH, PASP and PVR can be safely monitored in the long-term non-invasively. Further studies to help identify those patients at need for follow-up RHC are warranted.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with connective tissue diseases (CTDs) positive for anti-U1RNP antibody (U1) is characterized by overlapping feature of systemic sclerosis (SSc), systemic lupus erythematosus (SLE), and/or polymyositis/dermatomyositis (PM/DM). Anti-U1RNP antibody is reported to associate with development of pulmonary arterial hypertension (PAH), which is an important organ involvement that determines the prognosis of these patients. The aim of this study was to clarify whether the antibody profile or underlying disease component can determine the characteristic of PAH in this group of patients.

**Methods:** Thirty-two patients with U1(+)CTD-PAH were involved and 7 U1(-)SLE patients complicated with PAH were used as controls. Patients with SSc, SLE, PM/DM were fulfilled 2013 ACR/EULAR classification criteria, 2012 SLICC classification criteria, and Bohan and Peter's criteria, respectively. Baseline clinical information retrospectively collected from records, the changes of parameters of right heart catheterization (RHC) within 12 months as a response to the initial treatment and survival rate were compared among patients with overlap syndrome (OL), U1(+)SLE and U1(-) SLE.

**Results:** Of 32 patients with U1(+)CTD-PAH, underlying diseases were OL (58 %), SLE (29 %), Sjogren's syndrome (9 %), and SSc (6 %). Interestingly, all patients with OL fulfilled criteria of SSc and SLE components. Age at diagnosis of PAH was tended to be higher in OL ( $44 \pm 14$  years) compared to U1(+)SLE ( $36 \pm 14$  years) or U1(-) SLE ( $35 \pm 10$  years), and frequency of having ILD was higher in OL compared to U1(+) or U1(-)SLE (72 % versus 11 %,  $P < 0.001$  or 14 %,  $P < 0.03$ , respectively). The change of RHC parameters from baseline such as mean pulmonary arterial pressure ( $-3.3 \pm 8.4$  versus  $-13.3 \pm 10.0$  mmHg,  $P < 0.04$ ), pulmonary vascular resistance ( $0.2 \pm 9.2$  versus  $-5.5 \pm 2.0$  wood units,  $P < 0.05$ ), or cardiac output ( $0.4 \pm 1.6$  versus  $1.0 \pm 2.3$  L/min) were worse in patients with OL compared to those with U1(+)SLE. There was no difference in survival rate among patients with OL, U1(+)SLE, and U1(-)SLE. However, all 4 deceased cases with SLE-PAH, both U1(+) and U1(-), were observed within 13 months, but those with OL-PAH were distributed through the course and only 1 of 6 patients died within 13 months ( $P < 0.05$ ).

**Conclusion:** Characteristic of PAH complicated with OL patients, who had clinical features of SSc and SLE, was different from those with SLE patients, irrespective of U1-positivity, suggesting that clinical characteristic of PAH complicated with CTD patients with anti-U1RNP antibody was determined by underlying disease components rather than autoantibody profile.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Biomarkers that can monitor the fibrotic burden will aid in trial enrichment and personalized health care in SSc. SSc is associated with internal organ involvement (lung, renal, and gastrointestinal) in the form of fibrosis. Fibrosis is unbalance in extracellular matrix (ECM) turnover and protease specific protein fragments are released during fibrosis. The main family of protein in ECM is collagen, with type I, III and VI localized to interstitial matrix and type IV collagen localized to basement membrane. The aim of our study was investigating biomarker levels relation to the amount of internal organ involvement. **Methods:**

Serum from 79 SSc and 19 asymptomatic individuals were included in the study. Biomarkers of type I, III, IV, V and VI collagen formation (P1NP, PRO-C3, P4NP7S, PRO-C5, PRO-C6) and degradation (C3M, C4M2, C5M, C6M) and citrullinated and MMP-degraded vimentin (VICM) were detected by ELISA. Modified Rodnan skin score (mRSS) and extent of internal organ involvement (renal, lung, vasculopathy, and upper and lower gastrointestinal) were recorded for SSc patients with a scoring between 0 and 4 with 0 being no involvement and 4 being severe involvement. Patients were categorized as having no internal organ involvement when 0 and minor with 1. A score of 2, 3 or 4 were classified as definite. Statistics was Mann-Whitney t-test, Spearman's and trend analysis. **Results:**

SSc patients had a mean age of 63.0 years, mean disease duration of 98.3 months and a mean mRSS of 11.1. Patients compared to controls had higher levels of C5M, C6M and PRO-C6 ( $p=0.0001$ ,  $p<0.0001$ ,  $p<0.0001$ , respectively). Type VI collagen formation and degradation (PRO-C6 and C6M) were twice that of healthy controls (12.6 vs. 5.4 and 26.0 vs 16.7 ng/ml, respectively). C4M2, PRO-C3 and PRO-C6 was associated with skin fibrosis assessed by mRSS (Spearman's  $\rho=0.24$ ,  $0.39$  and  $0.29$ , respectively). mRSS was significantly increased with the amount in internal organ involvement ( $p<0.005$ ). C3M, C4M2 and P4NP7S levels were lowest in the group of patients with some internal organ involvement ( $p<0.05$ ) and PRO-C6 trended to increase with the number of organs involved ( $p=0.035$ ). **Conclusion:**

Biomarkers of collagen turnover, a surrogate of fibrosis, were increased in SSc and were related to the number of internal organs involved. This study illustrates that biomarker levels of ECM turnover needs to be carefully evaluated in SSc patients in regards to the amount of internal fibrosis.

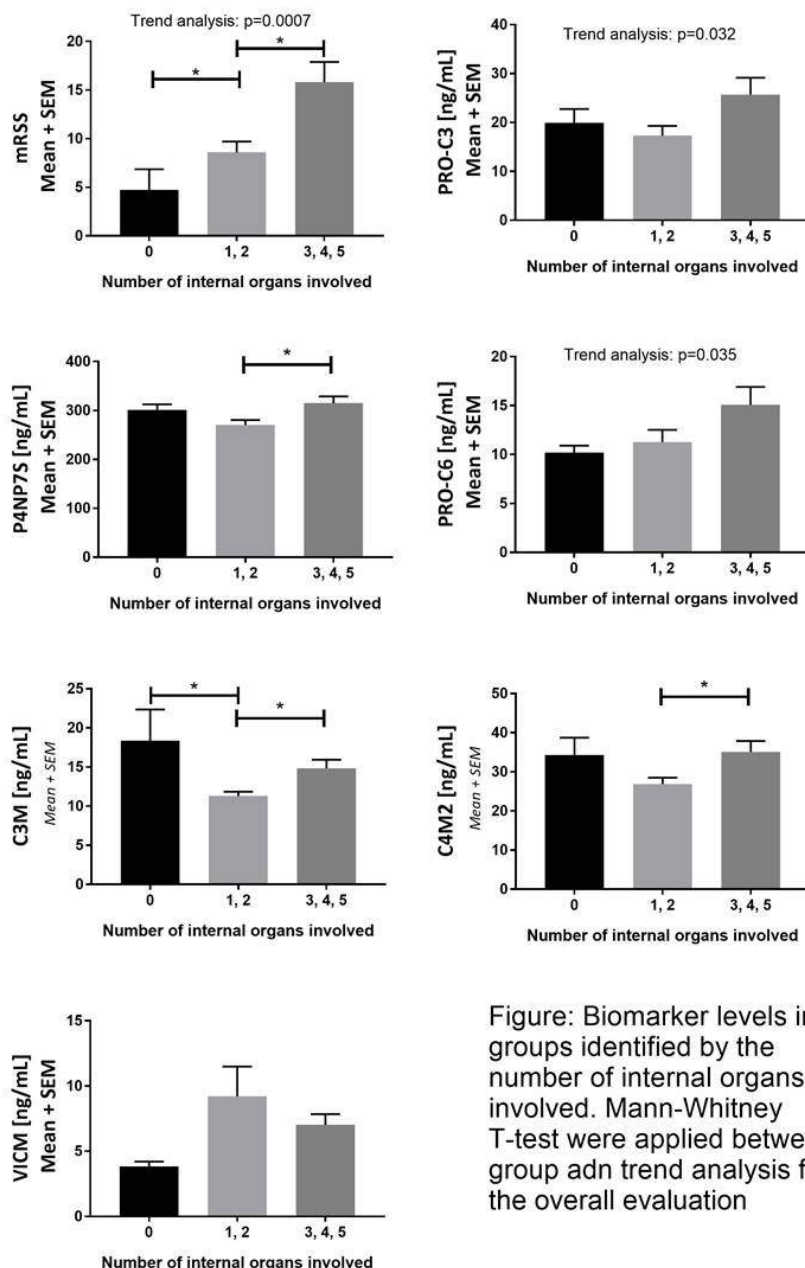

Figure: Biomarker levels in groups identified by the number of internal organs involved. Mann-Whitney T-test were applied between group and trend analysis for the overall evaluation

Title: Troponinemia independently associates with mortality in systemic sclerosis

**Background/Purpose:** Cardiac involvement is common in systemic sclerosis (SSc) and in the early asymptomatic stages, elevated troponin, or troponinemia, may be the only sign of ongoing myocardial disease.

**Methods:** This retrospective, cross-sectional study included SSc patients with any troponin measurement in the past 10 years, as identified using our institution's electronic medical record system. Elevated troponin was defined as any value above or at the cut off of normal value in a commercially available laboratory. Clinical data including SSc subtype, disease duration, maximum modified Rodnan skin score (mRSS), maximum serum creatine kinase, aldolase, pro-B-type natriuretic peptide (BNP), echocardiographic and right heart catheterization data were compared between those with elevated troponin and normal troponin. Survival analyses including Cox proportional hazards regression analyses were used to compare both groups.

**Results:** 272 patients were identified with a troponin evaluated during the study period. 83 (31%) had an elevated troponin. Compared to those with a normal troponin, SSc patients with troponinemia were more likely to have the diffuse SSc subtype (55% vs. 37%,  $p=0.004$ ), shorter disease duration since first non-Raynaud's symptom ( $5.8 \pm 8.4$  vs.  $6.1 \pm 7.6$  years;  $p=0.30$ ), lower ejection fraction (EF) ( $49.8 \pm 12$  vs.  $54.8 \pm 7.3$ ,  $p<0.0001$ ), lower FVC ( $61.2 \pm 18.8$  vs.  $66.8 \pm 20.4$ ,  $p=0.03$ ), higher RVSP ( $51.7 \pm 21.2$  vs.  $43.8 \pm 16.2$ ,  $p=0.002$ ), more renal crisis (8.4% vs. 2.6%,  $p=0.04$ ), higher Medsger muscle ( $p=0.001$ ) and heart severity scores ( $p=0.001$ ). Patients with troponinemia also have higher CK values ( $514 \pm 783$  vs.  $300 \pm 553$ ,  $p=0.01$ ) and higher aldolase ( $15 \pm 11$  vs.  $11.3 \pm 6.3$ ,  $p=0.002$ ). There was higher frequency of death (28% vs. 9.5%,  $p<0.0001$ ). Cox proportional regression analyses demonstrated that patients with troponinemia are 3.2 times (95% confidence interval, 1.33 to 7.7,  $p=0.009$ ) more likely to have death than those without an elevated troponin even after controlling for SSc subtype, age, gender, race, duration of disease, diabetes, coronary artery disease, smoking, CK, BNP, and World Health Organization dyspnea classification.

**Conclusion:** SSc patients with troponinemia have increased all-cause mortality when compared to those without an elevated troponin even after controlling for demographic and disease-specific confounders.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

D-dimers are degradation products of cross linked fibrin and are biomarkers of activation of the coagulation system. Plasma D-dimer levels can be raised in physiological and pathological non-thrombotic conditions and are thought to be related to a pro-thrombotic state.

Studies have shown raised D-dimer levels in systemic sclerosis (SSc), particularly in diffuse SSc (DcSSc). An association between raised D-dimer level and peripheral ischaemia in SSc has also been described, suggesting that this could be related to a pro-thrombotic state.

## Methods:

Blood samples were drawn from 60 outpatients who met the 2013 ACR/EULAR classification criteria for SSc. Samples were analysed for Factor XIII (FXIII) activity (U/dL), D-dimer (ng/ml), and fibrinogen (g/L) levels, and activated partial thromboplastin time (aPTT) (s). Clinical data gathered included age, gender, disease subtype, autoantibody details, duration of SSc and complications of SSc. Associations of demographic and clinical characteristics with FXIII were assessed using linear regression, while associations with D-dimer were analysed using Fisher's exact test and logistic regression.

## Results:

Of the 60 patients assessed, 83.3% were female. Age range was 20-82 years, with a mean age of 60.4 years. In terms of SSc subtype, 51.7% had limited SSc (LcSSc). The duration of SSc ranged from 0.62 to 50.6 years, with a mean duration of 14 years. Antibody status was collected; 36.7% were anti-centromere antibody positive, 11.7% were anti-Scl 70 antibody positive, 16.7% were anti-RNA polymerase antibody positive, and 35% had other positive autoantibodies. An overlapping rheumatological condition was found in 15% of patients. Of all patients, 25% had diagnosis of pulmonary fibrosis (PF), 31.7% had a history of digital ulceration (DU), and 8.3% had active DU at the time of blood draw.

D-dimers were raised in 62.7% of the patients. Raised D-dimer was seen more frequently in LcSSc patients (77.4%) compared to dcSSc (46.4%,  $p=0.017$ ). In addition, older age increased the odds of having raised D-dimer (OR 1.1,  $p=0.001$ ). Higher fibrinogen was associated with increased odds for raised D-dimer (OR 6.5,  $p=0.001$ ). There was no association between raised D-dimer level and PF, current or previous digital ulceration (DU).

Factor XIII activity was positively associated with age (for each year older, this increased by 0.75,  $p=0.007$ ) but did not associate with diffuse subset, disease duration, autoantibody specificity, fibrinogen level or APTT. There was evidence for a weak association between raised D-dimer and FXIII, where patients with raised D-dimer had on average 13.4 U/dL higher FXIII levels compared to those with normal D-dimer,  $p=0.089$ .

## Conclusion:

This study confirms that D-dimer levels are frequently elevated in SSc. In contrast to previous studies, our data suggest raised D-dimer level is more commonly associated with LcSSc.

There was no correlation between raised D-dimer level and duration of SSc. This is in contrast with other inflammatory markers such as CRP, which are raised in early SSc only. There was no association between D-dimer level and current or previous DU, suggesting that this feature of vascular dysfunction in SSc is not related to a thrombotic state.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is a chronic systemic disease characterized by skin and internal organs fibrosis along with vasculopathy. Previous studies have reported increased cadherin-11 (Cad11) levels in skin of SSc patients and identified Cad11 as a mediator of skin and lung fibrosis. The aim of this study is to determine if circulating Cad11 levels are increased in SSc patients as compared to healthy controls.

**Methods:** 300 SSc patients with early SSc enrolled in the Genetics versus Environment in Scleroderma Outcome Study (GENISOS) were studied. All patients fulfilled the ACR/EULAR for SSc and had disease duration < 5 years at the time of enrollment. Baseline or the earliest available serum samples from SSc patients were compared to 153 healthy controls matched for age, gender and race. Serum Cad11 levels were determined by ELISA. Sera with Cad11 levels above the lowest test standard in the ELISA (156 pg/ml) were considered positive for Cad11. Categorical variables were analyzed using the Chi-square method and the Fisher's Exact Test. P value of <0.05 was considered significant.

## **Results:**

SSc patients were enrolled with the median age of 50.1+/-13.1 years of which 83% were females. Average disease duration was 3.9 +/- 2.9 year. 42% of patients had limited SSc and 57% had diffuse SSc. SSc-associated autoantibodies were positive for anti-centromere (ACA) in 14%, for anti-topoisomerase (ATA) in 16% and anti-polymerase III (POLIII) in 22% of patients.

SSc patients had increased levels of serum Cad11 (574.8 +/- 140.7 pg/ml) compared to healthy controls (80.1 +/- 45.1 pg/ml). Serum Cad11 levels were above the lower limit of detection of the ELISA in 16.1% of SSc patients compared to 4.6% of controls. SSc patients were more likely to have detectable levels of serum Cad11 than controls (OR 4.1, 95%CI 1.9-8.8), which remained significant after adjusting for age, gender and race. Compared to patients with limited SSc, patients with diffuse SSc were less likely to have detectable levels of Cad11 in serum samples (limited 24%, diffuse 14%, OR 0.5, 95% CI 0.3-0.9). Chi squared analyses comparing ACA, ATA, and POLIII positivity did not reveal any differences between the autoantibody positive subsets or between the autoantibody positive subset versus the autoantibody negative subsets. Compared to healthy controls, the ACA+ and POLIII+ patients were more likely to have detectable Cad11 levels (p value 0.0006 and 0.027 respectively)

## **Conclusion:**

SSc patients are more likely to have detectable levels of serum cadherin-11 compared to healthy controls. These data add to the paradigm that suggests an important role for cadherin-11 in systemic sclerosis.

## Vitamin D Deficiency In Systemic Sclerosis Patients:

### Relations With Multiple Clinical Parameters and Standard Treatment

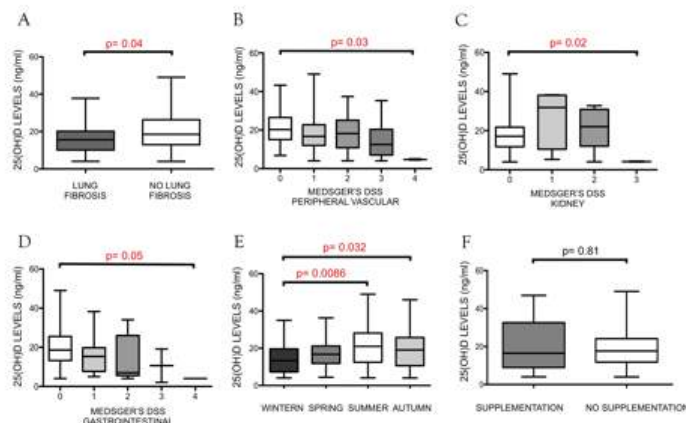

**Background/Purpose :** In SSc patients, low 25-hydroxyvitamin D (25(OH)D) serum concentrations have been shown [1]. Primary aim of the study was to evaluate possible correlations between 25(OH)D serum levels and multiple clinical parameters, in patients with systemic sclerosis (SSc). Secondary aim was the evaluation of the effectiveness of standard vitamin D replacement therapy.

**Methods:** 154 SSc patients were recruited in all seasons of the year. 25(OH)D serum concentrations were evaluated using LIAISON 25-OH system (Diasorin, Italy). In addition, Medsger's disease severity scale (DSS), nailfold video capillaroscopy (NVC) and all examinations covered by the international guidelines were evaluated [2]. Treatments assumption, including oral colecalciferol, was considered. Non-parametric tests were used for statistical analysis.

**Results:** 25(OH)D mean serum concentration was  $18.7 \pm 9$  ng/ml (<20 classified as a deficiency). A statistically significant correlation was found with presence/absence of fibrotic abnormalities at lung CT scan ( $16.1 \pm 8$  ng/ml and  $20 \pm 10$  ng/ml respectively,  $p = 0.04$ ) (Figure 1A). DSS parameters correlating with serum concentrations of 25(OH)D were: peripheral vascular ( $p = 0.03$ ), kidney ( $p = 0.02$ ), gastrointestinal ( $p = 0.05$ ) (Figure 1B, 1C, 1D). No significant correlation was observed with digital ulcers incidence, which was closely related to NVC patterns ( $p < 0.0001$ ).

As expected, a statistically significant difference was observed between 25(OH)D serum concentrations in different seasons (winter:  $14.6 \pm 7.8$  ng/ml, spring:  $17.2 \pm 7.9$  ng/ml, summer:  $21.43 \pm 10$  ng/ml, autumn:  $20.2 \pm 10$  ng/ml,  $p = 0.032$ ) (Figure 1E).

No effect of oral colecalciferol (1000 UI per day for at least 6 months) was observed on serum 25(OH)D both in treated ( $18.8 \pm 10$  ng/ml) or untreated patients ( $18.7 \pm 9$  ng/ml,  $p = 0.81$ ) (Figure 1F).

**Conclusion:** 25(OH)D deficiency correlated with advanced lung involvement and peripheral vascular system, kidney, and gastrointestinal tract involvement (according to the Medsger's DSS). Supplementation with standard doses of oral colecalciferol was not effective in increasing serum concentrations of 25(OH)D. Therefore, for substitutive therapy, higher doses of colecalciferol should be evaluated [3].

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patient activation refers to the ability and confidence people have to be engaged in managing their health care [Hibbard, 2004]. Knowledge and beliefs about one's chronic condition and self-efficacy are both part of patient activation. In a rare, disease, such as systemic sclerosis (SSc), patients must manage their symptoms and advocate for their treatment. Patients with SSc were reported to have low self-efficacy compared to other chronic conditions [Thombs, 2017], they

may also have low patient activation. Thus, the purpose of this study was to examine relationships between patient activation, self-efficacy and demographic variables that could influence patient activation.

## Methods:

SSc participants, who were part of a larger study on self-management, completed the Patient Activation Measure (PAM). The PAM is a 13 item questionnaire that measures confidence in self-management of one's chronic condition [Hibbard, 2005]. Higher scores indicate more confidence and knowledge in managing their condition. Based on total scores, patients are categorized into 4 levels: Level 1 (beginning to take role), Level 2 (building knowledge), Level 3 (taking action) and Level 4 (maintaining behaviors). Patients also completed a demographic questionnaire, the Patient Health Questionnaire (PHQ), the PROMIS-29 and PROMIS self-efficacy scales. Significant differences in PAM scores between subgroups were determined using t-tests, Wilcoxon tests or Fisher's exact tests depending on the distribution of the variables. t-tests were used for variables that were approximately normally distributed, non-parametric Wilcoxon tests for non-normally distributed variables and Fisher's exact tests for discrete, categorical variables. Pearson correlation coefficients were calculated to determine relationships between the PAM, PROMIS-29, PHQ-8 and PROMIS self-efficacy scales.

## Results:

267 participants completed the questionnaires. Mean age was 53.7 years, disease duration from onset of first SSc symptoms was 11.9 yrs. 91% were women and 82.8 % were white. On the PAM, the majority of our sample (60%) were at Level 4 with 18.7% at Level 3, 11.2% at Level 2 and 10.5% at Level I. There were significant differences in PAM scores between patients without depressed mood (PHQ-8 <10) vs depressed mood (PHQ-8 >10) and for employment status (working full time vs not working full time). PAM activation scores moderately correlated with PROMIS self-efficacy scales for managing emotions ( $r=0.54$ ,  $p<.0001$ ), symptoms ( $r=0.65$ ,  $p<.0001$ ), social interactions ( $r=.58$ ,  $p<.0001$ ) and medications and treatment ( $r = 0.57$ ,  $p<.0001$ ). Correlations between the PAM and PROMIS self-efficacy for managing daily activities ( $r = .38$ ,  $p < .0001$ ) and all PROMIS-29 subscale scores were fair [ $r = -0.23$  (PROMIS-29 pain intensity) to  $-0.49$ ,  $p < .0001$  (PROMIS-29 social and PROMIS-29 anxiety)]. Participants in Levels 3 or 4 had significantly better PROMIS-29 and PROMIS self-efficacy scores than participants at Levels 1 or 2.

## Conclusion:

Conclusion: Our cohort with SSc had high levels of activation. The moderate correlations with self-efficacy suggest Participants with high activation had high self-efficacy but that they are still conceptually distinct constructs.

## Performance of Patient-Reported Outcomes Measurement Information Systems (PROMIS) Promis-29 and Promis Self-Efficacy in Systemic Sclerosis (SSc)

**Janet L. Poole**<sup>1</sup>, **Veronica J. Berrocal**<sup>2</sup>, **Jennifer Serrano**<sup>3</sup>, **Erica Bush**<sup>3</sup> and **Dinesh Khanna**<sup>3</sup>, <sup>1</sup>Health Sciences Ctr OT Program, 1 University of New Mexico, Albuquerque, NM, <sup>2</sup>Div of Rheumatology, University of Michigan, Ann Arbor, MI, <sup>3</sup>University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient reported outcomes are important to measure the effectiveness of non-pharmacological and pharmacological interventions. The goal of PROMIS is to develop standardized items banks for use across different conditions [1]. The PROMIS-29, which assesses difficulty with activities and symptom severity, has been shown to be valid for patients with SSc [2]. However, other PROMIS measures, such as the PROMIS Self-Efficacy scales may be important to the management of a chronic disease such as SSc.

**Methods:** Participants with SSc, who were part of a larger study on self-management, completed the PROMIS Self-Efficacy Scales and PROMIS-29. PROMIS-29 includes physical function, anxiety, depression, fatigue, sleep disturbance, pain interference, and satisfaction with social roles, while the PROMIS self-efficacy scales measure self-efficacy for emotions, symptoms, daily activities, social interactions, and medication and treatment. Patients also completed a demographic questionnaire and the Patient Health Questionnaire (PHQ). Significant differences in PROMIS and PROMIS-29 scales between subgroups were determined using t-tests, Wilcoxon tests or Fisher's exact tests depending on the distribution of the variables. t-tests were used for variables that were approximately normally distributed, non-parametric Wilcoxon tests for non-normally distributed variables and Fisher's exact tests for discrete, categorical variables.

### Results:

267 participants completed the questionnaires. Mean age was 53.7 years, disease duration from onset of first SSc symptoms was 11.9 yrs. 91% were women and 82.8 % were white. There were significant differences in all PROMIS self-efficacy and all PROMIS-29 scale scores between patients without depressed mood (PHQ-8 <10) vs depressed mood (PHQ-8 >10). Married patients had significantly better PROMIS Self-Efficacy for social interaction and PROMIS-29 scores for social role, anxiety, depression, and fatigue. Participants who were employed full time had significantly better scores on the PROMIS self-efficacy scales for managing symptoms, daily activities and medications and treatment compared to participants not employed full time. For the PROMIS-29, significant differences were found for scales relative to physical function, social role, depression, fatigue, pain interference and pain intensity.

Disease duration (< median value or > median value) significantly affected PROMIS self-efficacy scales only with respect to managing daily activities and physical function. No significance differences in PROMIS self-efficacy or PROMIS-29 scores were observed between patients with different subtypes of SSc (diffuse vs limited/sine), education level (< or > 12<sup>th</sup> grade) or race (white versus non-white).

### Conclusion:

Patients with SSc who did not have depressed mood, had education above the 12<sup>th</sup> grade, were married and employed full time had higher PROMIS-29 and PROMIS Self-Efficacy scores.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A common and distressing manifestation of systemic sclerosis (SSc, or scleroderma) is disfigurement in socially relevant areas of the body, including the face and hands. Disease-related changes in appearance have been associated with body image dissatisfaction and social anxiety. Although there have been studies identifying correlates of body image dissatisfaction, there is a need for an examination that considers the complex relationships among the personal and social aspects of appearance changes. The present study used latent profile analysis (LPA) to identify body image typologies based on variables representing body image and social anxiety. Identified groups were compared on key sociodemographic, medical, and psychosocial variables.

**Methods:** The sample consisted of 942 patients with physician-confirmed SSc enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort who completed study questionnaires from April 2014 through October 2016. Patients in the SPIN Cohort were enrolled at 28 centers from Canada, the United States, and the United Kingdom. The sample was randomized into two groups (Sample 1:  $N = 469$ ; Sample 2:  $N = 473$ ) in order to conduct the analysis and provide an opportunity to replicate the findings. For the first aim, exploratory LPA was used to derive categorical latent variables that signified profiles of similarly scoring individuals using three indicators of subjective body image (i.e., dissatisfaction with appearance, social discomfort, and body concealment) and three indicators of social anxiety (i.e., social interaction anxiety, social appearance, anxiety, and fear of negative evaluation). For the second aim, differences in groups derived from the LPA were examined for select sociodemographic, medical, and psychosocial variables.

**Results:** The combined samples were predominantly female (87.4%) and White (79.8%), with limited disease (59%) and an average age of 55 years. In both samples, a two-profile solution was derived. These two classes were substantively analyzed for patterns of scores and termed the *Appearance Comfortable* ( $n = 336$  and  $n = 375$  in Samples 1 and 2, respectively) and *Appearance Distressed* ( $n = 133$  and  $n = 98$  in Samples 1 and 2, respectively) groups. In both samples, younger age, diffuse disease subtype, and the presence of hypo/hyper-pigmentation were associated with membership in the *Appearance Distressed* group. The mean modified Rodnan skin scores for patients in the *Appearance Comfortable* groups were 7.05 ( $SD = 7.3$ ) and 7.67 ( $SD = 8.3$ ) in Samples 1 and 2, respectively. The mean modified Rodnan skin scores for patients in the *Appearance Distressed* groups were 9.83 ( $SD = 9.6$ ) and 9.60 ( $SD = 9.7$ ), in Samples 1 and 2

respectively. Additionally, patients in the *Appearance Distressed* group had significantly higher scores on measures of depressive and anxious symptoms and disability.

**Conclusion:** This analysis was the first study to identify typologies of patients based on indicators of body image in any disfiguring condition. Two distinct groups were identified distinguishing between an *Appearance Comfortable* group and an *Appearance Distressed* group. The results also elucidated variables that can indicate likely group membership.

## Things Left Unsaid: Important Topics That Are Not Discussed between Patients with Systemic Sclerosis, Their Carers and Their Healthcare Professionals

Christopher Denton<sup>1</sup>, Bee Laird<sup>2</sup>, Lizette Moros<sup>3</sup> and José Luis Luna Flores<sup>4</sup>, <sup>1</sup>Department of Rheumatology, University College London, Royal Free Hospital, London, United Kingdom, <sup>2</sup>Reframe Research, East Sussex, United Kingdom, <sup>3</sup>Boehringer-Ingelheim, Ingelheim, Germany, <sup>4</sup>Boehringer Ingelheim, Ingelheim, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is a serious rare condition that can be complicated by internal organ damage including interstitial lung fibrosis (SSc-ILD), which is a major cause of mortality. The prognosis and course of disease is unpredictable and treatment is difficult with no approved treatment options for SSc-ILD. It is very challenging for patients and carers to get a clear understanding of the disease, treatment options and likely outcomes. This study explored and identified the information and communication needs of patients with SSc-ILD and their carers.

**Methods:** Qualitative research with 42 physicians who treat patients with SSc (rheumatologists, pulmonologists, internal medicine specialists, dermatologists), 21 patients with diagnosed SSc-ILD, 16 specialist nurses and 5 carers across 5 countries. Included individual in-depth interviews and observed conversations between pairs of patients, physicians and nurses discussing their experiences of SSc-ILD. All interactions were audio recorded, transcribed and analysed using linguistic techniques based on interactional sociolinguistic discourse analysis, to understand whether the information and emotional needs of patients and carers were met.

**Results:** Prognosis and mortality were the main unspoken topics acknowledged by patients, carers and healthcare professionals. These questions were difficult for physicians and nurses to definitively address, especially early in the disease. Patients and carers felt afraid to ask their physicians about mortality, and were unsure how to ask. Most physicians said that they tried to avoid the question because their duty was to give patients some optimism and hope, and not to cause them any additional distress. Other key questions for patients and carers were about relationships, family, and work. These were questions patients were often unable to ask their physicians because of time constraints or because

they felt these were not topics their physicians should or would be concerned about. Often, specialist nurses felt that they had insufficient disease information or knowledge to provide sufficient support.

**Conclusion:** Topics of key importance to patients, carers, physicians and nurses, such as mortality and disease course, are rarely openly discussed, leaving patients uncertain and anxious about the future. By proactively facilitating communication about difficult but important topics, physicians and nurses could help patients and carers manage and plan their lives with SSc. This study shows that a multi-professional team based approach is likely to give better communication and address patient needs and priorities.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic sclerosis (SSc) is a chronic rheumatic disease that disturbs the patients' biological, social, emotional spiritual, and physical functioning; resulting in reduced quality of life. The objective of this study was to assess if the newly adapted and validated tool, the Systemic Sclerosis Quality of Life (SScQoL) tool captures the complex health problems experienced by people with SSc.

### **Methods:**

This was a cross-sectional analytical study, which included patients with SSc from 11 rheumatology clinics in Poland. We used the SScQoL (score range 0-29) to assess quality of life in people with SSc. We also assessed their functional status (Health Assessment Disability Index, HAQ-DI); psychological status (Hospital Anxiety and Depression Scale, HADS) and severity of other health problems (0-100 mm Visual Analogue Scale, VAS).

## Results:

Patient characteristics are summarised in Table 1. Age was correlated with physical functioning domain QoL ( $r_p=0.171$ ;  $p=0.009$ ) and breathing problems ( $r_p=0.168$ ;  $p=0.011$ ). There was a correlation between disease duration and the following health problems: breathing problems ( $r_p=0.217$ ;  $p=0.001$ ), Raynaud's phenomenon ( $r_p=0.184$ ;  $p=0.005$ ), fingers ulceration ( $r_p=0.168$ ;  $p=0.011$ ), pain ( $r_p=0.154$ ;  $p=0.019$ ) and the level of disability ( $r_p=0.153$ ;  $p=0.020$ ).

Quality of life (SScQoL) was correlated with: HAQ-DI ( $r_p=0.735$ ;  $p<0.001$ ), HADS-Anxiety ( $r_p=0.631$ ;  $p<0.001$ ), HADS-Depression ( $r_p=0.596$ ;  $p<0.001$ ), Pain-VAS ( $r_p=0.593$ ;  $p<0.001$ ), Fatigue-VAS ( $r_p=0.592$ ;  $p<0.001$ ) and the severity of Raynaud's phenomenon (0-100 mm VAS) ( $r_p=0.417$ ;  $p<0.001$ ).

## Conclusion:

With the duration of SSc, the severity of clinical symptoms significantly reduced the quality of life of patients. The results suggest that SScQoL captures a range of complex health problems experienced by people with SSc. The improvement of the QoL in patients with SSc should be a priority objective for health professionals.

Table I. Patient characteristics, health problems and quality of life in patients with SSc

Variables studied (score range)	Mean (SD) – except where stated		
Age			55.82 (12.55)
Disease duration			8.39 (8.18)
HAQ-DI (0 to 3)			0.99 (0.75)
Pain VAS (0 to 100)			33.08 (28.36)
Fatigue VAS (0 to 100)			43.00 (29.04)
Raynaud's attacks (0 to 100)			38.10 (31.90)
Intestinal problems (0 to 100)			20.18 (27.73)
Breathing problems (0 to 100)			26.57 (27.59)
Finger ulceration (0 to 100)			17.50 (27.85)
HADS A (0 to 21)			8.96 (4.67)
HADS D (0 to 21)			6.70 (4.12)
SScQoL (0 to 29)			14.81 (5.08)
SScQoL (domain)			* Degree of QoL
	Function (0-6)	3.66 (1.57)	0.61
	Emotional (0-13)	6.43 (3.04)	0.49
	Social (0-6)	2.25 (1.87)	0.38
	Sleep (0-2)	0.96 (0.91)	0.48
	Pain (0-2)	0.98 (0.84)	0.49

\*SScQoL domains have different number of items, therefore the degree of QoL is determined by average score divided by the maximum possible score for that domain

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mechanistic target of rapamycin (mTOR) activation has emerged as a prominent mediator of pro-inflammatory T-cell expansion and regulatory T (Treg) cell depletion in systemic lupus erythematosus (SLE). While Treg dysfunction has been documented in SLE, it is unknown i) whether the mTOR pathway is activated within Tregs, ii) what pro-inflammatory cues regulate mTOR in Tregs, and iii) how mTOR controls their function.

**Methods:** Naïve CD4<sup>+</sup> T cells from matched SLE and healthy control (HC) subjects were cultured for 3 days in the presence of anti-CD3/CD28, TGF-β, and IL-2 with or without IL-6, IL-21, or rapamycin. Next, CD4<sup>+</sup>CD25<sup>+</sup> Treg function was determined in the presence or absence of IL-21 or IL-2 by assessing the % suppression of proliferation of CFSE-stained autologous CD4<sup>+</sup>CD25<sup>-</sup> responder T cells cultured for 5 days in the presence of anti-CD3 and irradiated PBMCs. In some experiments, Tregs were expanded *in vitro* for 4 weeks with or without rapamycin before coculture. Upon Treg isolation, -polarization, and -suppression assay, expression of FOXP3, GATA-3, and CTLA-4 in the Treg were determined by flow cytometry. Using lysates of naïve CD4<sup>+</sup> T cells cultured under Treg-polarizing conditions with or without IL-21, or SLE Tregs expanded in the presence or absence of rapamycin, phosphorylation of STAT3 at tyrosine 705, Akt at Serine 473, S6K1 at Threonine 389, and 4E-BP1 at Threonine 37 and 46, FOXP3, and LC3 were detected by immunoblotting. Cytokine secretion by CD3<sup>+</sup> T cells cultured in the presence or absence of rapamycin was determined by LUMINEX assay. Statistical analyses were done using Student's t-test.

**Results:** SLE Treg exhibits increased mTOR complex 1 (mTORC1) and 2 (mTORC2) activities, but diminished autophagy, GATA-3 and CTLA-4 expression (% CTLA-4<sup>+</sup> cells among CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> cells, HC: 6.96±0.79%, SLE: 5.11±0.75%; p=0.034), and function. IL-21, but not IL-6, activates mTORC1 and mTORC2, inhibits autophagy, and abrogates Treg differentiation and function (% suppression with or without IL-21, HC: 38.21±3.78%, 46.63±4.90%; p=0.013, SLE: 18.99±4.95%, 30.25±4.48%; p=0.042) although both of these cytokines phosphorylate STAT3 to comparable levels. IL-2 upregulates while IL-21 constrains GATA-3 and CTLA-4 expression selectively in CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> Tregs (% GATA-3<sup>+</sup> cells with or without IL-21, HC: 47.78±6.12%, 71.20±4.14%; p=0.0075, SLE: 33.49±5.28%, 66.85±6.29%; p=8.15x10<sup>-5</sup>, % CTLA-4<sup>+</sup> cells with or without IL-21, HC: 36.18±2.31%, 43.92±3.87%; p=0.016, SLE: 39.82±4.38%, 52.11±5.66%; p=0.0058). mTORC1 blockade by three-day rapamycin treatment reverses TGF-β deficiency, while dual blockade of mTORC1 and mTORC2 by four-week rapamycin treatment induces autophagy and restores GATA-3 and CTLA-4 expression specifically in CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> cells (GATA-3<sup>+</sup> cells with or without rapamycin, 25.48±5.73%, 10.78±3.31%; p=0.037, CTLA-4<sup>+</sup> cells, 23.11±9.08%, 7.51±5.88%; p=0.035), and Treg function (% suppression with or without rapamycin, 57.77±9.62%, 45.41±8.83%; p=0.04).

**Conclusion:** The data identify IL-21-driven mTOR activation as a pharmacologically targetable checkpoint of deficient autophagy and diminished expression of TGF-β, GATA-3, and CTLA-4 which underlie Treg dysfunction in SLE.

## **Mosaic, a Novel Gene, Mediating Autoimmunity in Mice**

**Alice Chan**<sup>1</sup>, Mark Anderson<sup>2</sup>, Hong-Erh Liang<sup>3</sup> and Elizabeth Li<sup>2</sup>, <sup>1</sup>Pediatrics, UCSF, San Francisco, CA, <sup>2</sup>Diabetes Center, UCSF, San Francisco, CA, <sup>3</sup>Department of Medicine, UCSF, San Francisco, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A novel candidate gene, *Mosaic* (Multi-Organ System Autoimmunity in Canines), was identified as the culprit causing an early and severe multiorgan autoimmunity in a unique subset of dogs. Affected dogs develop early onset Addison's disease, arthritis, autoimmune cytopenias, hepatitis and uveitis. Adrenal tissue from affected dogs reveal a T cell infiltrate suggesting a T cell mediated autoimmune process. Little is known about *Mosaic* function. It is conserved across all known vertebrate species including humans and mice, and it is highly expressed in immune cells, particularly in T regulatory cells based on BioGPS. Thus, we hypothesize that disruption of *Mosaic* function results in a breach in T cell tolerance and leads to multiorgan autoimmunity.

**Methods:** To assess the effects of *Mosaic* deficiency, two mouse models were produced. First, *Mosaic* knockout mice were generated using a B6 ES cell line by deleting at 2.5kb region containing the start codon and inserting a reporter cassette. This reporter will allow tracing of the endogenous gene expression pattern. The 5' and 3' regions of the targeted locus was confirmed using long-range PCR and *Mosaic* transcript was absent. Second, floxed *Mosaic* mice were generated using CRISPR-Cas9 by inserting two LoxP sequences flanking exon 3 which contains the start codon. Two gRNAs, two oligonucleotides, and Cas9 protein were injected into B6 fertilized eggs. Mice were screened for insertion of LoxP sequences that were in cis position and had no other indels in the targeted region. 3 founders were generated and bred to the CD4-Cre strain to generate deletion of *Mosaic* in the T cell compartment. *Mosaic* transcript was absent in the T cells. These mouse models were phenotyped using flow cytometry and histology.

**Results:** Using the reporter cassette, *Mosaic* was identified to have the highest expression level in memory T cells and T regulatory cells. Global deletion of *Mosaic* resulted in partial embryonic lethality. However, viable knockout pups showed increased memory T cells and decreased naïve T cells. Aged mice showed lymphocytic infiltrates in the adrenal and lacrimal glands compared to littermate controls. Analysis of the *Mosaic*<sup>fl/fl</sup>CD4-Cre mice also showed a skewed memory T cell compartment in mice as young as 1 month of age.

**Conclusion:** Deletion of *Mosaic* in mice resulted in an autoimmune phenotype with lymphocytic infiltrates in the adrenal and lacrimal glands. These mice also have a skewed memory T cell phenotype which is consistent with other autoimmune mouse models. Further investigation on *Mosaic* will reveal the molecular mechanism on how *Mosaic* functions in tolerance.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fos-related antigen 2 (Fra-2) is a transcription factor belonging to the Fos family proteins which is part of the AP-1 transcription factor complex. We recently described a fra-2 transgenic (tg) mouse model which develops a multi-organ inflammatory phenotype. We have observed abnormalities in the T cell compartment, which led us to hypothesize that fra-2<sup>tg</sup> mice develop a T cell-driven autoimmune phenotype.

Here we aimed to assess the autoimmune nature of the phenotype in fra-2<sup>tg</sup> mice and to characterize the potential role of Treg cells.

**Methods:** We used previously generated fra-2<sup>tg</sup> overexpressing mice. T lymphocyte populations were analyzed by flow cytometry for expression of activation markers (CD62L, CD44 and CD25) and secretion of cytokines. We transferred purified CD4<sup>+</sup> T cells into Rag2<sup>-/-</sup> mice lacking T and B cells, and we generated Rag2<sup>-/-</sup>-fra-2<sup>tg</sup> mice. We used IL-2-IL-2 antibody complexes (JES6.1A12 clone) to induce the proliferation of CD25<sup>+</sup> cells *in vivo*.

**Results:** Rag2<sup>-/-</sup>-fra-2<sup>tg</sup> did not develop inflammatory manifestations (n=10), demonstrating that the phenotype in fra-2<sup>tg</sup> mice is autoimmune and requires the presence of T and/or B cells to develop. Accordingly, we tested the ability of CD4<sup>+</sup> T cells to induce the phenotype. We found that the transfer of 1\*10<sup>6</sup> purified CD4<sup>+</sup> cells from 16 week-old fra-2<sup>tg</sup> mice into Rag2<sup>-/-</sup> recipients was sufficient to induce the phenotype (n=3).

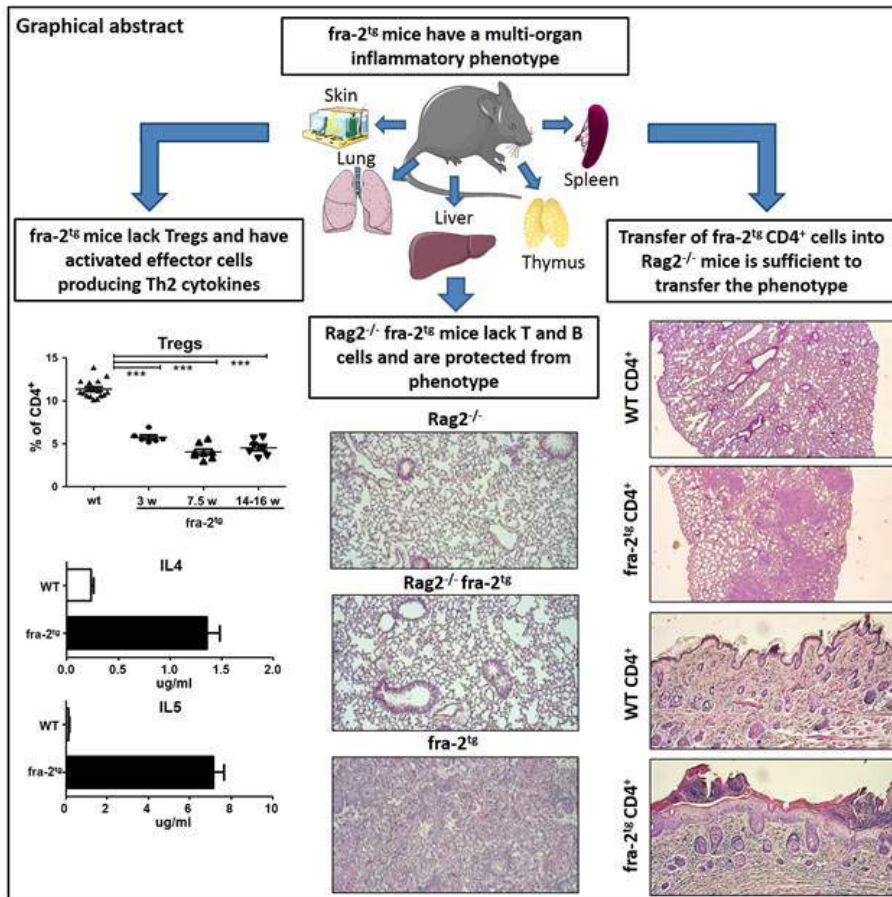

Analysis of T cell populations from fra-2<sup>tg</sup> mice confirmed the presence of activated CD4<sup>+</sup> and CD8<sup>+</sup> cells in spleen and lung (n=6). After *in vitro* stimulation, CD4<sup>+</sup> T cells from fra-2<sup>tg</sup> mice had increased Th2 cytokines production (IL-4, IL-5 and IL-13) and we observed an increase in IgE levels in the serum of fra-2<sup>tg</sup> mice. Thus, these data strongly suggest a Th2 T cell-driven autoimmune disease in these mice.

We also observed a striking decrease of Treg cells in fra-2<sup>tg</sup> mice, which might explain the observed autoimmune phenotype. Supporting this hypothesis, we found that 3 week-old mice, which were devoid of organ manifestations and of T cell activation, showed already the same defect in the Treg cell population as older mice (n=6, p<0.001).

Interestingly, we also found that *in vivo* stimulation with IL-2-IL-2 antibody complexes failed to induce the proliferation of Treg cells in fra-2<sup>tg</sup> mice compared to WT mice, suggesting that fra-2 overexpression affects IL-2 dependent

proliferation of fra-2<sup>tg</sup> Tregs. These data indicate that Fra-2 affects Treg homeostasis by modulating IL-2 responsiveness, resulting in the development of an autoimmune phenotype.

**Conclusion:** Our data suggest that Fra-2 controls Treg cell development or homeostasis, possibly by modulating IL-2 signaling in T cells, which leads to autoimmunity in this mouse model. This new pathway could be targeted in a translational approach to modulate the capacity of T cells to differentiate in Tregs during autoimmune disease.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In rheumatoid arthritis (RA), regulatory T cells (Tregs) are defective in their suppressive capacities and fail to control chronic inflammation. TNF- $\alpha$  is involved in inhibition of Treg differentiation and activation, likely via activation of TNF- $\alpha$  type 1 receptor (TNFR1)<sup>1</sup>. Conversely, activation of TNFR2 on Tregs is critical for their phenotypic and functional stability in the inflammatory environment<sup>2</sup>. Moreover, it has been shown that therapeutic TNF blockade with the anti-TNF monoclonal antibodies restores the potency of Treg cell suppression in RA by binding to membrane TNF- $\alpha$  on monocytes and promoting Treg cell expansion through enhanced TNFR2 signaling<sup>3</sup>.

In the present work, we studied the role of TNFR2 on Tregs in control of inflammation at multiple levels, by: 1) studying the action of TNF on Treg function in the presence and absence of TNFR2 *in vitro*, 2) testing the severity of a model of skin inflammation in TNFR2KO mice, 3) evaluating the evolution of TNFR2-expressing Tregs from RA patients during anti-TNF treatment.

**Methods:** Mice deficient in the TNFR2 gene (TNFR2 KO) and TNFR2 lox/lox mice to conditionally delete TNFR2 specifically in Tregs were used. CD4<sup>+</sup>CD25<sup>+</sup>Treg cells were purified by magnetic sorting. Cell phenotype was evaluated by flow cytometry. Tregs stability was evaluated by analyzing methylation status of 9 CpG motifs of the Foxp3 locus, assessed by bisulfite sequencing of CD4<sup>+</sup> CD25<sup>+</sup> purified cells. Skin inflammation was induced by cutaneous application of an imiquimod-containing ointment. Peripheral blood Tregs were characterized before and after 3 months of anti-TNF treatment in 12 RA patients and in 19 patients with axial spondyloarthritis (AxSpA) that were used as control.

**Results:** *In vitro*, TNF- $\alpha$  enhanced Foxp3 maintenance in cultured Tregs. With two models of TNFR2 inactivation (a TNFR2-blocking antibody and a TNFR2 knock-out mouse) this effect was mediated by TNF-TNFR2 -and not TNFR1- interaction. *In vivo*, TNFR2-negative Treg cells, from both TNFR2KO and TNFR2 lox/lox mice, had lower spontaneous suppressive capacities (lower inhibition of effector T cell proliferation and IFN- $\gamma$  production). FoxP3 methylation was higher in Tregs from TNFR2 KO mice than *wt* mice. This suggested that TNFR2 expression confers higher stability to Tregs.

Compared to *wt* mice, TNFR2KO mice had enhanced skin-inflammation and decreased Tregs and CD39<sup>+</sup> Tregs frequencies in lymph nodes. In RA patients responding to anti-TNF treatment, an increase in the frequency of TNFR2-expressing Tregs was evident at 3 months of treatment vs. the baseline. Conversely, no variation in the frequency of these cells was observed in AxSpA patients

**Conclusion:** TNFR2 signaling on Tregs may play a major role in controlling inflammation and can be activated both by TNF- $\alpha$  and anti-TNF treatment. Further studies to dissect TNFR2 dependent pathways on Tregs are warranted.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A key pathogenic event in rheumatoid arthritis (RA) is the formation of lasting lymphoid microstructures in the synovial tissue. It requires the transmigration of T cells from blood vessels into the tissue and the maneuvering of such T cells through the tissue matrix. T cells move in the tissue microenvironment by assembling cell membrane extensions, so-called podosomes. Regulation of podosome formation in T cells from RA patients is unexplored.

**Methods:** CD4 T cells were isolated from patients with seropositive RA and age-matched healthy controls. Tissue-residing T cells were examined in synovial biopsies. T cell motility was tested in 3D-collagen gels and in vivo by measuring T cell invasion into synovial tissue in a human synovium-SCID chimera model. Cellular metabolism of T cells was evaluated by quantifying stores of pyruvate, ATP, acetyl-CoA, and neutral fatty acids. We defined a module of 10 genes involved in regulation of the actin cytoskeleton and podosome formation, which was analyzed by RT-PCR, flow cytometry and immunohistochemistry.

**Results:** Compared to age-matched controls, RA T cells were high expressers of the Tyrosine Kinase Substrate with Five SH3 Domains (TKS5), an adaptor molecule critically involved in podosome formation, migrated more efficiently through 3D-gels and rapidly invaded into synovial tissues. TKS5 overexpression was sufficient to render T cells tissue-invasive; TKS5 knockdown abrogated the tissue-invasive behavior of RA T cells. TKS5 overexpression was associated with arthritogenic effector functions in the synovial tissue site, was regulated as part of a motility gene module and was found to be under metabolic control. Specifically, dampened glycolytic flux, resulting in low cellular pyruvate and ATP, induced TKS5 production and enhanced T cell hypermobility. T cells responded to energy deprivation with the

accumulation of cytoplasmic lipid droplets, a prominent feature of tissue-resident synovial T cells. Restoring pyruvate stores or inhibiting fatty acid synthesis was sufficient to correct for the hypermobility of RA T cells in vitro and in vivo.

**Conclusion:** Synovial tissue invasion and arthritogenic T cell effector functions in RA patients are associated with dysregulated membrane function, specifically the formation of tissue-invasive podosomes. Defects in the T cell locomotion program are mechanistically linked to metabolic reprogramming, which diverts RA T cells from energy production to synthetic and proliferative functions. Understanding tissue invasiveness of RA T cells provides new opportunities to interfere with T cell trafficking and T cell invasion into specific tissue sites.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sjögren's syndrome (SS) is an autoimmune exocrinopathy characterized by focal lymphocytic infiltration of the salivary and lacrimal glands, severe dry eyes and mouth, fatigue and musculoskeletal pain. How the T cell-dominated salivary gland (SG) inflammation is connected to pathologic and clinical features of SS is poorly understood. We reported that SG CD4<sup>+</sup> T cell clonal expansion is antigen-driven and correlated with reduced salivary flow and increased SG fibrosis. To determine whether the extent of SG CD8<sup>+</sup> T cell clonal expansion is related to pathologic features of disease, we evaluated the CD8<sup>+</sup> TCR repertoire of the same subjects.

**Methods:** Multiplex single cell RT-PCR was used to retrieve paired TCR  $\alpha$  and  $\beta$  sequences from SG and peripheral blood (PB) memory CD8<sup>+</sup> T cells from 11 subjects meeting the 2016 ACR/EULAR classification criteria for primary Sjögren's syndrome. The extent of SG and PB CD8<sup>+</sup> T cell clonal expansion was compared between SG and PB and evaluated for relationships with pathologic and clinical disease features using Mann-Whitney and Spearman rank correlation tests.

**Results:** Our cohort repertoire consisted of over 2,800 TCR sequences isolated from a median of 28 (range 4-67) SG and 19 (range 4-52) PB cells evaluated per subject. Clonal expansions of SG and PB CD8<sup>+</sup> T cells were detected in all subjects. Expansions were extensive in both tissue compartments, ranging from 8.3-66.3% in SG (mean 34.9) and 5-48.5% in PB (mean 23.1). Although the percentage of clonally expanded CD8<sup>+</sup> T cells did not differ significantly between SG and PB, there were significantly higher levels of clonally expanded SG CD8<sup>+</sup> T cells compared to SG CD4<sup>+</sup> T cells from the same individuals. Further, many subjects exhibited large expansions, with 60% of individuals having at

least one clonal expansion of 4 or more cells. In contrast to our prior observations in CD4<sup>+</sup> T cells, the degree of SG CD8<sup>+</sup> T cell clonal expansion did not significantly correlate with measures of oral disease. However, identical clonal expansions were detected in SG and PB in 5/11 patients (45%), indicating significant trafficking of CD8<sup>+</sup> T cells in both tissues. Further, several clonotypes of expanded cells shared between SG and PB were identified as viral-specific, indicating the presence of activated viral-specific T cells in the SG of SS patients.

**Conclusion:** Although relatively small numbers of T cells were evaluated in this study, clonally expanded CD8<sup>+</sup> T cells were abundant in both the SG and PB of SS patients but did not obviously correlate with measures of disease. Known viral-specific T cells were found in SG and PB from SS patients, adding evidence for viral-initiated or -driven CD8<sup>+</sup> T cell proliferation in SS.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Current treatments to control autoimmune arthritis and vasculitis use broadly immunosuppressive drugs, associated with undesirable side effects. Antigen-specific immunological tolerance strategies are preferable to control both cellular and humoral immune responses in autoimmune diseases, using the natural process of antigen presentation by dendritic cells (DCs) to control the balance of regulatory T cells (Treg) relative to pathogenic effector (Teff) T cells and B cells. In a phase I clinical trial, intradermally-injected autologous DCs exposed to citrullinated peptides and BAY11-7082 reduced circulating Teff and increased the ratio of Treg to Teff in rheumatoid arthritis. However, simpler strategies are desirable for widespread clinical use. In skin draining lymph nodes (dLN), migratory but not resident DCs are required for tolerance. We developed a strategy for passive targeting of DCs in situ after s.c. delivery of a nanoparticulate liposome formation encapsulating peptide and NF-κB inhibitor.

## Methods:

Egg phosphatidylcholine liposomes encapsulating 1,25 dihydroxycholecalciferol (calcitriol) and OVA<sub>323-339</sub> or aggrecan<sub>89-103</sub> peptide were prepared by thin film hydration. Distribution of DiI-labeled liposomes was assessed with in vivo imaging and flow cytometry. DO11.10 OVA-specific memory T cells were generated ex vivo. The response of transferred T cells to liposomes administered i.v. or s.c. was assessed by flow cytometry. Proteoglycan-induced arthritis (PGIA) was induced with recombinant human proteoglycan and DDA adjuvant. IAd-aggrecan tetramers identified aggrecan-specific T cells.

## Results:

Liposomes encapsulating calcitriol and peptide were 90-130 nm. After s.c. administration, liposomes encapsulating calcitriol and peptide rapidly distributed to the subcapsular sinus then penetrated dLN, with the majority taken up by CD11b+CD11c+MHC class II+ migratory DCs. Two s.c. injections of OVA<sub>323-336</sub>/calcitriol liposomes suppressed antigen-specific CD4+ T cell expansion and IFN- $\gamma$  production and induced antigen-specific Foxp3+ peripheral (p)Treg. The induced pTreg suppressed proliferation of and promoted IL-10 production by a second cohort of OVA-specific Teff. In the proteoglycan-induced arthritis (PGIA) model, s.c. aggrecan<sub>89-103</sub>/calcitriol but not OVA<sub>323-339</sub>/calcitriol liposomes prevented disease development and suppressed the severity of established arthritis, associated with reduced autoreactive T cell expansion and reduced memory and follicular-helper T cell differentiation relative to naïve T cells.

## Conclusion:

Skin migratory DCs are targeted and tolerized by calcitriol-peptide liposomes, triggering “infectious” antigen-specific tolerance mechanisms to regulate autoimmune arthritis.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To study the expression and function of T follicular helper cells and its subsets in IgG4-related disease(IgG4-RD).

**Methods:** Flow cytometry was performed to analyze the expression of Tfh cells and its subsets in untreated IgG4-RD patients(n=46) and healthy controls(n=33). With RT-PCR technique, the mRNA levels of Bcl-6, Blimp-1 and IL-21 from IgG4-RD patients were tested. The immunohistochemistry and immunofluorescence technique were used to assess the location of IL-21 and Tfh cells in the involved tissues of IgG4-RD patients, respectively. Furthermore, by cells co-culture in vitro, the abilities of cTfh and its subsets to help B cells proliferation, apoptosis, differentiation, and producing IgG4 in IgG4-RD were explored.

**Results:** The frequencies of (CD4+CXCR5+)T, (CD4+CXCR5+ICOS+)T, (CD4+CXCR5+PD-1+)T, PD-1 in (CD4+CXCR5+ICOS+)T and (CD4+CXCR5+ICOS+PD-1) T in IgG4-RD patients were significantly higher in the peripheral blood and involved tissues of IgG4-RD patients compared with healthy controls, and the expression of these cells in those involved tissues were significantly higher than blood. Especially, the percentages of PD-1 in (CD4+CXCR5+ICOS+) cTfh cells was positively correlated to the serum levels of IgG, IgG4, IgG4/IgG%, the number of organ involved, and (CD19+CD24-CD38hi) B cell subset, which has been proved producing higher IgG4 than other B cells. mRNA Bcl6 in CD4+ T cells of IgG4-RD showed no difference with healthy controls while the mRNA Blimp-1 did. mRNA IL-21 in PBMCs of IgG4-RD was also higher compared with healthy controls, and positively correlated with serum levels of IgG4, IgG, IgG4/IgG%. In the involved tissues of IgG4-RD, both of the Tfh cells and IL-21 showed highly expression, mainly distributed around glandular cells or ectopic GC. Importantly, compared to healthy controls, cTfh cells in IgG4-RD patients could more efficiently facilitate B cells proliferation but inhibit cell apoptosis, and enhanced naive B cells differentiate into S memory B cells and (CD19+CD24-CD38hi) B cells, which resulted in much more IgG4 secretion. Furthermore, it was mainly cTfh1 and cTfh2 were significantly higher in IgG4-RD patients compared with healthy controls, and it was mainly cTfh1 and cTfh17 enhanced the ability of B cells proliferation but inhibited apoptosis, while it was mainly cTfh2, as well as cTfh1 promote B cells differentiate into plasma B cells and producing much more IgG4 antibodies in IgG4-RD.

**Conclusion:** Tfh cells, especially the expression of PD-1 in (CD4+CXCR5+ICOS+) T, as well as IL-21 play vital roles in the pathogenesis of IgG4-RD. Compared to healthy control, Tfh cells from IgG4-RD patient could more efficiently facilitate B cells proliferation but inhibit cell apoptosis, and promote B cells differentiation into S memory B and (CD19+CD24-CD38hi)B cells, which result in strong immune response and more IgG4 secretion. And it was cTfh2, as well as cTfh1 mainly performing the function.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Lymphocytic aggregates in the salivary glands (SG) of Sjögren's syndrome (SS) can organize in ectopic lymphoid structures (ELS) forming functional germinal centers (GCs), which are linked to the development of MALT lymphoma (MALT-L). T follicular-helper cells (Tfh) and follicular T regulatory cells (Tfr) are specialized CD4+ T helper cells that positively and negatively regulate, respectively, the magnitude of the GC response and possibly the development of autoimmunity. We aimed to characterize the infiltration of Tfh and Tfr in the SG of patients with SS in the presence/absence of ectopic GCs and MALT-L.

### Methods:

SG biopsies with matching histology and RNA from 37 SS and 38 non-specific chronic sialadenitis (NSCS) patients were stratified as ELS-/ELS+ based on CD3/CD20/CD21/CD138 immunostaining (IHC). Histological samples and mRNA from 12 parotid MALT-L were also studied. Gene expression was performed with Taqman rt-PCR. Multicolor immunofluorescence/confocal microscopy for CD3, CD4, CD45RO, ICOS, PD1, BCL6 and FoxP3 was used to identify Tfh and Tfr.

### Results:

Tfh cells (CD4+CD45RO+PD1+ICOS+Bcl6<sup>+</sup>) and Tfr cells (CD4+CD45RO+PD1+ ICOS+FoxP3<sup>+</sup>) were significantly increased in the ELS+ SG tissues from SS patients vs ELS- and NSCS. Tfh cells densely infiltrated the B cell rich areas and preferentially localized within ectopic GCs in the SG tissues. Furthermore, Tfh infiltration correlated with SG IL-21 mRNA expression, which in turn was strongly correlated with CD3, CD20 and CD138 IHC scores and with CXCL13, LTb, BAFF, AID and Pax5 gene expression. Finally, MALT-L samples displayed 10-fold higher IL-21 mRNA and twice as many PD1+ICOS+BCL6<sup>+</sup> Tfh-cells/field compared to ELS+ SS samples. The Tfh:Tfr ratio in ELS+ SG was approximately 2:1. Interestingly, while in tonsils Tfr were routinely detected within GC, in ELS+ SG Tfr were predominantly excluded from the B cell follicles and accumulated in the T cell rich areas at the periphery of the B-cell aggregates.

### Conclusion:

Within the SG of SS patients Tfh cells closely segregate with lesional IL-21 expression, localize within ELS and are strongly enriched during MALT-L development. Conversely, although Tfr cells are also present in ELS+ SG in SS patients, they are excluded from ectopic GCs. This suggests that Tfr in SS SG fail to exert their physiological immunoregulatory function in controlling the magnitude of the GC response and B cell autoreactivity, as observed in secondary lymphoid organs.

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Systemic lupus erythematosus (SLE) is a complex autoimmune disease with multifactorial etiopathogenesis that primarily afflicts women in the childbearing years. Hormones especially estrogen are implicated in the pathogenesis of disease, however the precise molecular events regulated by estrogen in immune cells are not well understood. T cells play a key role in SLE pathogenesis and display abnormalities in gene expression and function. We previously identified a novel role for the multifunctional protein serine arginine rich splicing factor 1 (SRSF1) in T cell gene regulation and function. We showed that SRSF1 promotes IL-2 production in normal T cells, and its overexpression into SLE T cells rescues IL-2 production. SRSF1 expression is decreased in SLE T cells, and associates with severe disease activity. We recently generated a T cell specific *Srsf1*-conditional knockout mouse, which exhibits defects in T cell function and develops autoimmune disease. These results suggest that the deficiency of SRSF1 is an important molecular defect in immune-mediated disease. However, not much is known about the regulation of SRSF1 in T cells, and if or how hormones may contribute to its expression. Here we asked whether estrogen regulates the expression of SRSF1 in human T cells.

## Methods:

Peripheral blood was collected from healthy women in the follicular phase of the menstrual cycle. T cells were isolated by negative selection from peripheral blood. T cells were cultured (in RPMI without phenol red supplemented with charcoal-stripped serum), with increasing concentrations (0, 1nM, 10nM, 100nM) of beta-estradiol for 18 – 24 hours. Total protein and RNA were isolated and the expression of SRSF1 assessed by Western blotting and RT-qPCR. To assess mRNA stability, transcription was blocked with actinomycin D, and cells collected at 0, 0.5, 1, 1.5 and 2 hours, and *Srsf1* expression assessed by RT-qPCR. To assess posttranslational protein degradation mechanisms, the proteasome inhibitor MG132 or the lysosome inhibitor Bafilomycin A1 were added to cultures.

## Results:

We found that exposure to beta-estradiol led to a dose dependent increase in *Srsf1* mRNA expression, but a decrease in protein levels in T cells. This discrepancy between mRNA and protein expression suggests that estrogen may downregulate protein levels via post-transcriptional mechanisms such as mRNA decay, translation or protein degradation. The discrepancy between high mRNA versus low protein levels was not due to reduced mRNA stability because the rate of *Srsf1* mRNA decay in control versus estrogen-treated T cells did not show significant differences. Culturing estrogen-treated T cells in the presence of inhibitors of the lysosome or proteasome showed that the proteasome but not the lysosome is involved in the degradation of SRSF1. In silico analysis of the *Srsf1* 3'UTR revealed microRNA (miR) target sites, of which miR-21-5p, miR-27, and miR-200b-3p are known to be regulated by estrogen and to be dysregulated in SLE.

## Conclusion:

Our results suggest that estrogen can modulate the expression of SRSF1 via posttranscriptional mechanisms in human T lymphocytes, thus revealing a potential molecular link between hormones, immune cells and autoimmune disease.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** T-helper (Th) cells actively communicate with adjacent cells by secreting soluble mediators, and yet crosstalk between Th cells and endothelial cells is poorly understood. Here, we demonstrated that the placental growth factor (PlGF), an angiogenic factor, was selectively secreted by Th17 cells, and promoted angiogenesis *in vitro* and *in vivo*.

**Methods:** Concentrations of PlGF and interleukin-17 (IL-17) in culture supernatants of stimulated T cells were measured using Enzyme-linked immunosorbent assay (ELISA). The angiogenic effect of PlGF produced by CD4<sup>+</sup> T was assessed by measuring the tube formation, wounding migration, and chemotaxis of endothelial cells. Expression of Th17, Treg, and phospho Stat was analyzed by flow cytometry. Experimental Th17 disease model was induced in mice either by immunization with type II collagen (CII) or by injection of MOG<sub>35-55</sub> peptide.

**Results:** 'Angio-lymphokin' PlGF, in turn, specifically induced Th17 cell differentiation and plasticity by activating STAT3 via binding to the FLT1 and NRP1 receptors and substituted for IL6 activity in IL-17 production, whereas it suppressed FOXP3<sup>+</sup> Treg cell generation. The disruption of *PlGF* attenuated the severity of delayed-type hypersensitivity and experimental autoimmune encephalomyelitis in mice by reducing IL-17 production; the adoptive transfer of *PlGF*-overexpressing CD4<sup>+</sup> T cells to these mice restored their disease phenotypes. On the contrary, selective overexpression of *PlGF* in T cells increased disease severity and IL-17 and STAT3 expressions in mice with autoimmune arthritis. Finally, we observed a correlation between concentrations of PlGF and IL17 in the synovial fluids of rheumatoid arthritis patients.

### Conclusion:

Our findings provide novel insights into the PlGF-dictated links between angiogenesis, Th17 cell development, and autoimmunity, indicating that PlGF inhibitors could be used to control autoimmune and inflammatory diseases in hope of dual inhibition of angiogenesis and Th17 cell generation.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoreactive T cells drive the inflammatory process, which leads to an irreversible destruction of the joints. Gene transcription and regulation of proinflammatory cytokine production in T cells is regulated by epigenetic mechanisms. Among them histone deacetylases (HDACs) modify the epigenetic landscape by removing acetyl groups of lysine residues of histones, resulting in chromatin condensation and repression of transcription. The application of pan-HDAC inhibitors has been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underline the need of more specific HDAC inhibitors. Therefore we addressed the effects of selective HDACs on the development of autoimmune diseases.

**Methods:** Mice with a T cell specific deletion of HDAC1 (HDAC1cKO) were generated by using the CD4Cre/LoxP system. The clinical and the histological phenotype were assessed in the collagen-induced arthritis (CIA) and the experimental autoimmune encephalitis (EAE) model. Anti-collagen antibody levels were determined by ELISA. Qualitative and quantitative analysis of T cell subsets of the spleen and draining LN were assessed using flow cytometry. Additionally comparative RNA-sequencing of CD4<sup>+</sup> T cells from wild type (WT) and HDAC1cKO mice was performed.

**Results:** To address whether HDAC1 is involved in the pathogenesis of autoimmune diseases we induced the CIA and the EAE in WT and HDAC1cKO mice. Surprisingly, despite the presence of serum anti-CII antibodies, HDAC1cKO mice did not develop any clinical or histological signs of inflammation in the CIA model. These data were confirmed in an additional T cell dependent model, the EAE model. HDAC1cKO mice were completely protected against the development of EAE. The total number of cells isolated from the CNS, consisting predominately of CD4<sup>+</sup> T cells, was significantly reduced in the absence of HDAC1. Molecular analysis of HDAC1cKO CD4<sup>+</sup> T cells revealed diminished

expression of CCR6, which is an essential chemokine receptor for the development of arthritis and EAE. This was accompanied with an increased production of IFN $\gamma$  and with an enhancement of STAT1 phosphorylation in activated HDAC1cKO CD4<sup>+</sup> T cells in comparison to WT cells. In line with this finding we observed increased expression of CCR6 in STAT1<sup>-/-</sup> CD4<sup>+</sup> T cells. This indicates a negative role of STAT1 in the regulation of CCR6 expression in HDAC1cKO CD4<sup>+</sup> T cells, suggesting an impairment to migrate to the site of inflammation to initiate arthritis and EAE.

**Conclusion:** Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of the CIA and EAE model. Therefore it might be considered as an interesting novel therapeutic target in autoimmune diseases, in particular patients with RA.

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Background/Purpose:** The advent of biological therapy has made a remarkable progress in the management of rheumatoid arthritis (RA). Abatacept (ABA), a non-TNF inhibitor, is a CTLA4-Ig and ameliorates synovial inflammation and bone damage in RA. Recent findings showed that anti-cyclic citrullinated peptide antibody (ACPA)-positive RA patients are good responders to ABA therapy in comparison with TNFi therapy, however the temporal impact of ABA on immune cells, particularly T and B cells, and its relationship with clinical response remain to be fully elucidated. In this study, we have sought to uncover these aspects by analyzing immunological changes in RA patients treated with ABA.

**Methods:** Twenty-five RA patients initiated with ABA as first biologic between May 2014 and March 2015 were prospectively studied with informed consent. Effects of ABA were evaluated sequentially from baseline to 52 weeks by the proportions and activation of lymphocyte subsets in peripheral blood and the titers of autoantibodies including rheumatoid factor (RF) and ACPA, along with the assessment of clinical activity.

**Results:** In the treatment of ABA, the proportion of  $CD4^+CCR7^+CD45RA^-$  (central memory) T cells enriching T follicular helper (Tfh) cells and  $CD4^+CCR7^-CD45RA^-$  (effector memory) T cells significantly decreased, while that of  $CD4^+CCR7^+CD45RA^+$  (naive) T cells increased. Overall, activation of pathogenic Th subsets was remarkably suppressed by ABA therapy. Additionally, the proportion of  $CD4^+CD25^+CD127^{lo}CCR4^+$  T cells (Treg) decreased. On the other hand, the proportion of B cell subsets, activation state of  $CD8^+$  T cells and titers of autoantibodies were minimally affected. Notably, a change in RF levels correlated well with that in Tfh numbers and disease activity (DAS28-CRP). By comparing patients who achieved good EULAR response (GR) with patients who didn't achieve good EULAR response (non-GR) at 3 month after ABA therapy, higher RF titers and lower proportion of  $CD4^+CXCR3^+CCR6^+$  T cells (Th1Th17) among  $CD4^+$  T cells at baseline were significantly noted in the GR group ( $p=0.01$ ,  $p=0.04$ , respectively). Generation of Th1Th17 cells can be induced by myeloid cells stimulated with endogenous TLR4 ligands including various citrullinated proteins at joints. Using ROC curve, the cutoff values of RF and proportion of Th1Th17 were defined as 144IU/mL and 3.25%, respectively. A subpopulation of RA patients with RF titer  $\geq 144IU/mL$  or Th1Th17  $\leq 3.25\%$  at baseline clearly achieved lower disease activity and better GR rates to ABA therapy.

**Conclusion:** Together, these findings suggest that clinical response to ABA therapy is prospectively predicted by RF titers and the proportion of a novel T cell subset in RA patients, thus helping to choose the optimal treatment strategy with the use of this biologic.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CD8<sup>+</sup> T cells have been described to comprise up to 40% of the rheumatoid arthritis (RA) synovial T cell compartment but their pathogenic function is largely unknown. Mucosal associated invariant T (MAIT) cells are predominantly CD4-CD8<sup>+</sup> innate-like lymphocytes which comprise up to 10% of circulating T cells and enter mucosal sites. They express a semi-invariant T cell receptor restricted to the MHC class I-like molecule, MR1. MR1 presents ligands derived from the riboflavin synthesis pathway, common to a range of bacteria and yeast. There is evidence for oral and gastrointestinal microbial dysbiosis in RA, and the majority of abundant bacterial species in RA patients are capable of riboflavin synthesis. However, the mechanisms underlying these disease associations are unclear. Furthermore, TNF is both an effector cytokine produced by activated MAIT cells and a key cytokine driver of RA. Therefore, we investigated the relationship between MAIT cells and TNF response to the riboflavin ligand 5-OPRU in RA patients and healthy controls (HC).

**Methods:** We identified the proportion of MAIT cells based on the expression of CD3, CD4, CD161 and TRAV1-2 or positivity for MR1-5-OPRU tetramers using flow cytometry in peripheral blood (PB) of 14 RA patients and 12 HC and synovial fluid of 8 RA patients. We analysed cellular activation of MAIT cells after stimulation with 5-OPRU by defining the expression of activation markers CD25 and CD69 and the production of TNF and IFN- $\gamma$ .

**Results:** MAIT cells comprised 0.5-17.5% of the CD4-CD3<sup>+</sup> T cells in RA PB. MR1-tetramer<sup>+</sup> MAIT cell frequencies in PB of HC and RA patients were comparable and on average 85% of MAIT cells were CD4 negative. CD161 expression decreased after MAIT cell stimulation, indicating that the MAIT cells are incompletely identified by the expression of TRAV1-2 and CD161. MAIT cells in RA patients were constitutively more activated than conventional T cells suggesting prior ligand exposure. MAIT cells produced multiple cytokines after PMA and ionomycin stimulation. However, after stimulation with MR1 ligand 5-OPRU, MAIT cells from PB and synovial fluid produced predominantly TNF. In RA patients, disease activity score was negatively correlated with the proportion of PB MAIT cells and with 5-OPRU-stimulated TNF production.

**Conclusion:** MAIT cells account for a substantial proportion of CD4<sup>+</sup> T cells. RA PB and synovial MAIT cells produce TNF in response to 5-OPRU ligand derived from microbial riboflavin synthesis. Reduction of TNF-competent MAIT cells in PB of patients with high disease activity suggests migration to tissue inflammatory sites, where the TNF they secrete may drive RA pathology.

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IL-1 $\beta$  blockade is a highly effective therapy for systemic juvenile idiopathic arthritis (sJIA). However, the rate of inactive disease attained in these trials is lower than reported in sJIA patients treated with IL-1 blockade at disease onset. We have hypothesized that sJIA is a biphasic process in which an initial IL-1 $\beta$ -driven systemic phase directly promoting Th17 differentiation from both Th0 and T regulatory T (T<sub>reg</sub>) cells and gives rise to IL-17-driven chronic inflammatory arthritis. We sought to test this hypothesis in the IL-1ra<sup>-/-</sup> model, a spontaneous T cell-mediated murine arthritis dependent upon both IL-1 $\beta$  and IL-17.

**Methods:** Synovial tissue, lymph nodes and spleen from IL-1ra<sup>-/-</sup> were characterized via flow cytometry for FOXP3, ROR $\gamma$ t expression and cytokine production. In addition, we examined the transcriptomic landscape of sorted T<sub>reg</sub> cells from newly generated IL-1ra<sup>-/-</sup> Foxp3-eGFP mice and WT Foxp3-eGFP controls. We sorted 50,000 WT and IL-1ra<sup>-/-</sup> T<sub>reg</sub> cells from 3 mice and performed low-input RNA-Sequencing. Differential expression testing was performed using EdgeR. Additionally, we performed Gene Set Enrichment Analysis between WT and IL-1ra<sup>-/-</sup> groups. In order to assess osteoclastogenic potential, sorted T<sub>reg</sub> cells were co-cultured with macrophage precursor cells (1:2 ratio) in presence of anti-CD3/CD28 beads, M-CSF and RANK-L. After 5 days of co-culture, TRAP<sup>+</sup> multinucleated cells (more than three nuclei) were counted.

**Results:** The percentage of T<sub>reg</sub> cell among CD4<sup>+</sup> cells in periphery and locally in synovial tissue was similar between WT and IL-1ra<sup>-/-</sup> mice. However, T<sub>reg</sub> cells from IL-1ra<sup>-/-</sup> synovium showed an up-regulation of ROR $\gamma$ t expression. Interestingly, a significant number of FOXP3<sup>+</sup> cells also produced IL-17 upon *in vitro* stimulation. To gain molecular insight into the mechanism underlying T<sub>reg</sub> cell plasticity in our model, we performed RNAseq-driven characterization of T<sub>reg</sub> cells from IL-1ra<sup>-/-</sup> and WT mice. Notably, Gene Set Enrichment Analysis revealed distinct metabolic programs between both subsets. The oxidative phosphorylation gene set was enriched in WT T<sub>reg</sub>. On the other hand, mTOR and glycolysis pathways that orchestrate a metabolic checkpoint for the differentiation of Th17 cells were enriched in IL-1ra<sup>-/-</sup> T<sub>reg</sub> cells. This finding confirms the ongoing conversion of Foxp3<sup>+</sup> cells into Th17 cells. In addition to this Th17-skewed phenotype, T<sub>reg</sub> from IL-1ra<sup>-/-</sup> mice over-expressed RANK-L and facilitate osteoclastogenesis *in vitro* whereas WT T<sub>reg</sub> inhibited osteoclast differentiation, suggesting a novel pathogenic role for IL-1ra<sup>-/-</sup> T<sub>reg</sub> cells.

**Conclusion:** All together our results suggest that chronic inflammatory arthritis in IL-1ra<sup>-/-</sup> mice is associated with the conversion of Foxp3<sup>+</sup> T<sub>reg</sub> cells into pathogenic Th17 cells. These findings suggest that early IL-1 $\beta$  blockade could modulate the development of arthritogenic T cells in IL-1-driven arthritis, a result that may inform the understanding and treatment of sJIA.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CD6, an important regulator of T cells, has one known ligand, CD166, but studies performed during the treatment of autoimmune conditions and *in vitro* experiments suggest that the CD6-CD166 interaction might not account for important functions of CD6 in autoimmune diseases. The antigen recognized by mAb 3A11 has been proposed as a new CD6 ligand distinct from CD166, yet the identity of this ligand is hitherto unknown.

**Methods:** To determine the identity of the antigen recognized by mAb 3A11, we investigated HBL-100 cell surface proteins pulled down by this mAb by mass spectrum (MS) analysis. We then probed whole HBL-100 cell lysates with an anti-CD318 Ab in western blot and assessed CD318 expression levels on HBL-100 cells by flow cytometry before and after IFN $\gamma$  stimulation. We next studied transfected MDA-468 cells that overexpress CD318 after doxycycline induction and transfected MDA-468 cells knocked down for CD318 expression using shRNA, by flow cytometry using a commercial anti-CD318 mAb and mAb 3A11. We also studied binding of CD6 to HT-1080 sarcoma cells in which expression of CD166 but not CD318 was selectively ablated by CRISP-R technology, and measured binding of rCD318 to CHO-CD6 transfectants. We then assessed the role of CD318 in autoimmunity *in vivo* using CD318-knockout mice and the experimental autoimmune encephalomyelitis (EAE) model of multiple sclerosis.

**Results:** CD318-related peptides were abundant in mAb 3A11 precipitates from HBL-100 cells. Mab 3A11 and anti-CD318 immunoprecipitated identical bands at 130kDa, and binding of each mAb to the cell surface was identically upregulated by pre-exposure of cells to IFN $\gamma$ . Moreover, each mAb bound to CD318 in western blots. In a CD318-

inducible system, staining with mAb 3A11 resulted in exactly the same pattern as seen with anti-CD318 mAbs, while in CD318 knockdown cells neither mAb showed detectable staining. An HT-1080 CD166 KO cell line was developed that expresses CD318 but not CD166 -binding of CD6 to the surface of these cells was attenuated but still evident, and was further reduced by rCD318 in a dose-dependent manner. Recombinant CD6 precipitated a protein from lysates of these cells that was recognized by anti-CD318. Recombinant CD318 bound to human CD6-expressing CHO cells but not control CHO cells. Moreover, CD318 KO mice had markedly attenuated disease severity of EAE, with reduced antigen-specific Th1 and Th17 responses and significantly decreased inflammation and CD4+ T cell infiltration in the central nervous system.

**Conclusion:** These data establish CD318 as a novel second ligand of CD6, and indicate a previously unknown role for CD318 in regulation of T cell driven autoimmunity. The engagement of CD6 by CD318 is an unusual example of a ligand-receptor interaction between a lymphocyte-specific cell surface glycoprotein that can participate in T cell activation (CD6) and a molecule (CD318) that is found only on cells that are traditionally considered not to be components of the immune system. This interaction points to an ability of T cells to specifically recognize distinct signals from “non-immune system” tissue cells that may be important in organ-targeted autoimmune diseases.

## **The Paracaspase MALT1 Plays a Central Role in the Pathogenesis of Rheumatoid Arthritis**

Elisabeth Gilis<sup>1</sup>, Jens Staal<sup>2</sup>, Rudi Beyaert<sup>2</sup> and **Dirk Elewaut**<sup>3</sup>, <sup>1</sup>Molecular Immunology and Inflammation Unit, VIB Inflammation Research Center, Ghent, Belgium, <sup>2</sup>Molecular Immunology and Inflammation Unit, VIB Inflammation Research Center, Ghent, Belgium, <sup>3</sup>VIB Inflammation Research Center, University of Ghent, Ghent, Belgium

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** One of the hallmarks of many inflammatory arthritides is their strong linkage with MHC-signalling, which is mirrored by the marked role for adaptive immunity. Accordingly, rheumatoid arthritis (RA) is characterized by the activation of auto-reactive T-cells and the development of auto-antibodies. T-cells may additionally respond to non-TCR mediated signals, which are essential in driving their effector functions. Pathways leading to the modulation of both innate and adaptive signals are therefore of marked interest to study in arthritic diseases. The paracaspase MALT1 is a key player in the activation and proliferation of immune and non-immune cells. These cells include the lymphoid, myeloid and mast cells, indicating MALT1's crucial role in both innate and adaptive signaling. Therefore, MALT1 is regarded a promising target for the treatment of autoimmune diseases and defining its role in the pathogenesis of inflammatory arthritis is a critical first step.

**Methods:** To unravel MALT1's role in inflammatory arthritis, we initially assessed MALT1-activation in mice that were challenged with collagen-induced arthritis (CIA), the prototype model for antigen-induced RA. We then addressed the role of MALT1 in the pathogenesis of inflammatory arthritis by challenging MALT1-deficient mice to distinct models of arthritis (CIA and CAIA). Additionally, CIA was induced in CD4-specific MALT1-deficient mice to determine the

importance of MALT1 in T-cells. Bone homeostasis was assessed by micro-CT analysis, a 3 point bending test to test bone strength and by osteoclastogenesis assays using RANKL induced osteoclastogenesis and resorption pit assays. Immunophenotyping of T cell and regulatory T cell subsets was conducted in spleen and lymph nodes and anti-collagen II specific antibody development was measured by ELISA.

**Results:** We provide evidence that MALT1 plays a crucial role in the pathogenesis of RA as MALT1-deficient mice were completely protected against CIA. This complete protection was additionally observed in CD4-specific MALT1-deficient mice, indicating that the selective ablation of MALT1 in CD4-positive cells is sufficient for the observed resistance against CIA. This was reflected by markedly lower induction of anti-collagen type II antibodies. CAIA on the other hand, which is a T- and B-cell independent model of RA, did not depend on the presence of MALT1, since both MALT1<sup>+/+</sup> and MALT1<sup>-/-</sup> mice showed comparable symptoms of RA. MALT1 deficient mice show an osteoporotic phenotype but osteoclastogenesis was normal suggesting an indirect effect. MALT1 deficient mice lack natural Tregs which could account for the osteoporotic phenotype. Accordingly, CD4-specific MALT1-deficient mice also had an osteoporotic phenotype on microCT with impaired bone strength.

**Conclusion:** Overall, our data highlight that MALT1 plays a crucial role in the pathogenesis of inflammatory arthritis but has a dual role on inflammation versus bone homeostasis. Our data indicate an osteoporotic phenotype in the absence of MALT1 caused by lack of Tregs.

## **NKTR-358: A Selective, First-in-Class IL-2 Pathway Agonist Which Increases Number and Suppressive Function of Regulatory T Cells for the Treatment of Immune Inflammatory Disorders**

**John Langowski**, Peter Kirk, Murali Addepalli, Thomas Chang, Vidula Dixit, Grace Kim, Yolanda Kirksey, Peiwen Kuo, Myong Lee, Mekhala Maiti, Werner Rubas, Paul Sims, Yuan Song, Yinyan Tang, Laurie VanderVeen, Ping Zhang, Stephen Doberstein and Jonathan Zalevsky, Nektar Therapeutics, San Francisco, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Impaired IL-2 production and regulatory T cell (Treg) dysfunctions have been implicated as an immunological mechanism in multiple autoimmune diseases. While low-dose IL-2 can be used to stimulate Tregs for clinical benefit, poor pharmacokinetics necessitates daily delivery, adverse events are dose-limiting, and Treg increases are modest and short-lived. Nektar Therapeutics is developing NKTR-358, a novel product which utilizes the aldesleukin (Proleukin<sup>®</sup>) amino acid sequence chemically conjugated with stable polyethylene glycol (PEG) moieties, intended for low dose subcutaneous administration to selectively restore Treg homeostasis with no impact on Tcon function.

**Methods:** The affinity to the IL-2 receptor was assessed by surface plasmon resonance. Activity in cynomolgus and human PBMC was measured by pSTAT5 induction in multiple lymphocyte populations utilizing flow cytometry. In vivo activity after subcutaneous administration in C57BL/6 mice or cynomolgus monkey was measured by changes in lymphocyte numbers and activation by flow cytometry. Ex vivo Treg function was determined by the inhibition of Tcon proliferation by isolated splenic Treg. Efficacy was examined in a model of cutaneous hypersensitivity in mice using keyhole limpet hemocyanin (KLH), and in cynomolgus monkey using tetanoid toxin. Efficacy in a model of systemic lupus erythematosus (SLE) was assessed using MRL/MpJ-Fas<sup>lpr</sup> mice

**Results:** NKTR-358 has greatly attenuated affinity for human IL-2R $\beta$  relative to IL-2R $\alpha$  and IL-2R $\alpha\beta$  complexes, suggesting biological engagement favors activation of Treg which express the high affinity IL-2R $\alpha\beta\gamma$  over Tcon, which express the low-affinity IL-2R $\beta\gamma$ . In vitro, Treg were far more sensitive to NKTR-358 stimulation relative to all other lymphocyte subsets in cynomolgus or human PBMC. In mice, a single administration led to sustained Treg mobilization for 7 to 10 days in blood and spleen without Tcon activation, an effect concomitant with increased Treg activation and suppressive capacity. In cynomolgus monkey, plasma exposure was even more prolonged leading to sustained Treg mobilization and activity for over 14 days after a single administration - a response superior in magnitude, duration and specificity compared to an equivalent total dose of rhIL-2 administered daily for five days. NKTR-358 administration suppressed the antigen-induced inflammatory response in the KLH hypersensitivity model, an effect which was antigen-specific and associated with establishment of Treg memory. Similar results were achieved in cynomolgus monkey using tetanus toxoid. Finally, NKTR-358 was efficacious in a mouse model of SLE, with repeat administration over 12 weeks sustaining Treg elevation, significantly reducing blood urea nitrogen and returning urine protein levels and kidney histopathology to normal.

**Conclusion:** NKTR-358 delivers sustained, preferential activation of Tregs. Currently, NKTR-358 is being studied in a Phase 1 study in healthy subjects to measure Treg mobilization, functional activity, pharmacokinetics and safety, with the goal of establishing a range of dose levels to be advanced into a multiple-ascending dose trial in patients with SLE.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gastrointestinal (GI) involvement during adult IgA vasculitis (IgAV) occurs in roughly half the cases. In many other systemic vasculitides, GI involvement represents a poor-prognosis factor, leading to the use of immunosuppressive agents combined glucocorticoids. This study was undertaken to describe the first manifestations and prognoses of GI involvement in adult IgAV patients.

### Methods:

This nationwide, retrospective study analyzed the data from 260 adult IgAV patients to describe and compare the initial symptoms and outcomes of those with GI involvement (GI+) vs. those without it (GI-).

**Results:** Among the 260 patients analyzed, 137 (53%) were GI+ vs. 123 (47%) GI-. The initial GI manifestations included: abdominal pain for 135/137 (99%), intestinal bleeding for 43/137 (31%) and diarrhea for 36/137 (26%). Abdominal computed-tomography (CT) scans and/or ultrasonography were obtained for 65% of GI+ patients. The most frequent imaging finding was thickening of the intestinal wall (61%). Upper and/or lower GI endoscopies of 78 (57%) patients revealed abnormalities in 77%, including mucosal ulceration (53%), erythema (34%) and/or purpura (26%). In contrast, intestinal biopsies were obtained from only 8 (6%) patients. The most frequent histological finding was nonspecific inflammatory infiltrates seen in all biopsies, but specific vasculitis features were rarely described (e.g., fibrinoid necrosis seen in only 1). At diagnosis, GI+ patients vs. GI- patients, respectively, were younger (mean±SD age 46.3±1.5 vs. 54.5±1.7 years; P=0.0004), had more constitutional symptoms (43% vs. 23%; P=0.0005), more frequent joint manifestations (72% vs. 50%; P=0.0002) and higher C-reactive protein (3.7 vs. 1.9 mg/dL; P=0.001). Renal involvement frequency and severity were similar for the 2 groups. Finally, GI+ patients vs. GI- patients, respectively, had comparable overall clinical response rates (80% vs. 76%; P=0.53); minor (12% vs. 13%; P=0.91) or major relapse rates (6% vs. 9%, P=0.54); renal outcomes (1 transplanted vs. 1%, P=1.00; 4 on dialysis vs. 2%, P=0.42); and vasculitis-related mortality (2% vs. 3%; P=0.68). None of the cohort patients had life-threatening GI manifestations at diagnosis, but 2 patients developed GI perforations 1 and 3 months after starting glucocorticoids.

**Conclusion:** GI involvement is a frequent manifestation of adult IgAV but does not seem to negatively impact overall prognosis. Therapeutic management should not necessarily include immunosuppressive agents as first-line therapy, as for systemic necrotizing vasculitis, but more data are needed to confirm these findings.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Immunoglobulin A vasculitis (IgAV), formerly called Henoch–Schönlein purpura, is a small-vessel vasculitis characterized by immune-complex deposits with predominant IgA. Although the disease is often benign in children, adult IgAV has been described as being more severe. Moreover, renal involvement represents the main cause of morbidity and mortality in adults. This study was undertaken to determine whether age could impact IgAV initial manifestations and outcomes.

**Methods:** In this nationwide retrospective study, data from 260 IgAV patients were analyzed to describe their first symptoms and outcomes according to age at IgAV onset: 90 (35%) >60 years (late-onset) and 170 (65%) <60 years.

**Results:** Mean±SD age at IgAV diagnosis for the entire cohort was 50.1±18 years and 63% were male. Baseline manifestations included: purpura (100%), renal involvement (70%), arthralgias or arthritis (62%), gastrointestinal involvement (53%) and renal failure (30%), defined as estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m<sup>2</sup>. Patients with late-onset IgAV, compared to those <60 years old, respectively, had more frequent renal involvement (89% vs. 60%; P<0.0001), more frequent microscopic hematuria (78% vs. 53%; P=0.0001); and more severe disease at diagnosis, with a higher renal failure rate (44% vs. 10%; P<0.0001) and higher urine protein excretion (1.20 vs 0.45 g/day; P=0.002). Only tubulointerstitial lesions in renal biopsies were more frequent in patients >60 years (44% vs. 21%; P=0.003). Median serum IgA was significantly higher for patients >60 years than those <60 years (4.4 vs. 3.3 g/L; P=0.0007). Therapeutic management was similar for both groups: glucocorticoids (70% vs. 60%; P=0.20) and cyclophosphamide (23% vs. 24%; P=0.85). Renal failure at the end of follow-up was more frequent for late-onset patients (42% vs. 13%; P<0.0001) and their vasculitis-related mortality was higher (4% vs. 0%; P=0.02). However, percentage±SD eGFR variation (deltaGFR) and annual DeltaGFR variation were similar for patients >60 and <60 years, respectively: 0.05±5.2% vs. 14.2±8.9% (P=0.27) and -2.2±10.9% vs. 11.1±8.3% (P=0.34).

**Conclusion:** Late onset of IgAV is associated with more frequent and severe renal involvement, and more frequent tubulointerstitial lesions. Comorbidities and physiological age might be involved.

## Is Smoking Important in Adult IgA Vasculitis?

Alojzija Hočevar<sup>1</sup>, Ziga Rotar<sup>1</sup>, Vesna Jurcic<sup>2</sup> and Matija Tomšič<sup>3</sup>, <sup>1</sup>Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, <sup>2</sup>Institute of Pathology, University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia, <sup>3</sup>University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nicotine may predispose to kidney injury by increasing the oxidative stress, and there is known association between smoking and the progression of chronic kidney disease, including IgA nephropathy. Currently, there is no information about the influence of smoking on the presentation of IgA vasculitis (IgAV) in adults. The aim of our study was to evaluate the role of smoking on the clinical manifestations of acute adult IgA vasculitis.

**Methods:** We analyzed medical records of histologically proven, adult IgAV cases, diagnosed between January, 1 2010 and April, 30 2017 at our at our secondary/tertiary rheumatology center. The disease activity was assessed using Birmingham vasculitis activity score-3 (BVAS-3). Renal disease was defined severe in case of nephrotic syndrome or nephritic syndrome with acute renal failure. Gastrointestinal (GI) disease was severe in case of bloody diarrhoea, ileus or bowel perforation. We looked at the potential differences in the clinical manifestations of acute IgAV with regard to smoking habits at the time of IgAV presentation (nonsmokers vs. ever smokers vs. current smokers).

**Results:** During the 76 month period we identified 207 new IgAV cases (56.5 % males, median (IQR) age 64.6 (44.6; 77.3) years). Skin, GI, renal and joint involvement were present in 207 (generalized purpura above the waist in 102 and necrotic in 98), 68 (severe in 17), 94 (severe in 23), and 87 patients, respectively. 87 patients (42.0%) had a positive history of smoking, and 38 of them were current smokers, smoking daily on average (SD) 13 ( $\pm$  8) cigarettes (range 1 to 30).

Clinical characteristics of nonsmokers vs. ever vs. current smokers are presented in the Table 1. There were no significant differences regarding the frequency of overall GI tract, renal or joint involvement between the groups. However, current smokers had 4.5 times higher risk of clinically severe renal involvement vs. nonsmokers (95%CI 1.8 - 11.0;  $p=0.001$ ). Past smokers developed severe renal involvement as frequent as nonsmokers ( $p=0.202$ )

**Conclusion:** Current smoking was associated with the clinically more severe kidney involvement in adult IgAV. This increased risk disappeared with smoking cessation.

Table 1.

Clinical characteristics	Nonsmokers (120)	Ever smokers (87)	Current smokers (38)
Male gender	44.2	73.6	65.8
Age (years)*	69.2 (41.4;80.6)	62.0 (49.5;74.9)	50.3 (39.6;64.2)

## Can Annexin A1 Expression on Neutrophils Distinguish Adult IgA Vasculitis from Other Small Vessel Vasculitides?

Tadeja Kuret<sup>1</sup>, Katja Lakota<sup>1,2</sup>, Polona Žigon<sup>1</sup>, Manca Ogrič<sup>1</sup>, Boris Lestan<sup>1</sup>, Snezna Sodin Semrl<sup>1,2</sup>, Saša Čučnik<sup>1,3</sup>, Matija Tomšič<sup>1,4</sup> and Alojzija Hočevár<sup>1</sup>, <sup>1</sup>Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, <sup>2</sup>Faculty of Mathematics, Natural Science and Information Technology, University of Primorska, Koper, Slovenia, <sup>3</sup>Faculty of Pharmacy, University of Ljubljana, Ljubljana, Slovenia, <sup>4</sup>University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Immunoglobulin A vasculitis (IgAV, formerly Henoch–Schönlein purpura) is a small vessel, immune complex vasculitis characterized by dominant IgA deposits in the vascular wall. Clinical symptoms include skin, joint, gastrointestinal (GI) or renal involvement. Adults frequently develop more severe disease than children<sup>1</sup>. Recently, the neutrophil to lymphocyte ratio (NLR) has been proposed as a potential marker for predicting systemic involvement in adult IgAV<sup>2</sup>. Moreover, neutrophil phenotypes have been shown to be differentially involved in disease progression of other vasculitides<sup>3</sup>. We aimed to determine the percentage of neutrophils, T- and B-cells, NLR and mean fluorescence intensity (MFI) of CD62L and Annexin A1 (AnxA1) on CD16<sup>+</sup> neutrophils in peripheral blood of newly diagnosed, biopsy-proven adult patients with IgAV compared to other small vessel vasculitides (non-IgAV) and healthy blood donors (HBD).

**Methods:** Flow cytometry of stained, lysed and fixed whole blood was performed in IgAV (n=15; n=9 for AnxA1), non-IgAV patients (n=11; n=6 for AnxA1) and HBD (n=16; n=7 for AnxA1). The diagnoses of non-IgAV included infection-associated small vessel vasculitis, vasculitis associated with tubulointerstitial nephritis and uveitis, ANCA vasculitis and, cryoglobulinemic vasculitis. IgAV patients were further divided into two groups based on organ involvement (patients with isolated skin involvement; n=9 and patients with concomitant renal or GI involvement; n=6). In the IgAV group only one patient had concomitant infection (of urinary tract).

**Results:** Percentage of CD16<sup>+</sup> neutrophils and NLR were significantly higher, while percentages of T- (CD3<sup>+</sup>) and B-cells (CD19<sup>+</sup>) were significantly lower in newly diagnosed IgAV and non-IgAV cases compared to HBD. Expression of AnxA1 was significantly elevated on CD16<sup>+</sup> neutrophils in IgAV (16.1 (12.9-19.4); median (IQR)) compared to non-IgAV (10.0 (8.1-15.2); p=0.029 (Table 1)). IgAV patients with skin and renal or GI involvement had a significantly higher percentage of CD16<sup>+</sup> neutrophils (77.1 (67.2-83.6)) compared to skin limited IgAV cases (64.5 (57.1-69.1); p=0.012).

<b>Table 1:</b> Neutrophil/Lymphocyte percentages, their ratio and expression of AnxA1 and CD62L in IgAV patients as compared to HBD and non-IgAV patients						
	<b>MEDIAN (IQR)</b>			<b>P VALUE</b>		
	<b>HBD</b>	<b>IgAV</b>	<b>Non-IgAV</b>	<b>HBD vs. IgAV</b>	<b>HBD vs. non-IgAV</b>	<b>IgAV vs. non-IgAV</b>
Neutrophils (%)	51.0 (47.1-56.9)	67.5 (63.6-73.3)	69.0 (59.4-78.2)	<b>&lt;0.0001</b>	<b>&lt;0.0001</b>	0.9586
T-cells (%)	26.4 (23.0-31.8)	16.6 (10.2-21.4)	17.8 (19.2-21.4)	<b>0.0004</b>	<b>0.0096</b>	0.8355
B-cells (%)	3.8 (2.9-4.7)	2.4 (1.6-2.9)	1.5 (0.9-2.7)	<b>0.0042</b>	<b>0.0083</b>	0.3502
NLR	1.7 (1.4-2.1)	3.3 (2.8-5.8)	3.4 (2.2-7.1)	<b>0.0001</b>	<b>0.0043</b>	0.8967
<b>Annexin A1 (MFI)</b>	21.3 (18.4-23.7)	16.1 (12.9-19.4)	10.0 (8.1-15.2)	0.0549	<b>0.0023</b>	<b>0.0290</b>
CD62L (MFI)	56.4 (44.9-72.0)	83.7 (58.6-102.8)	92.2 (61.0-127.1)	0.0575	<b>0.0256</b>	0.4743

**Conclusion:** Our study reports that neutrophil AnxA1 might represent a good surface marker for distinguishing IgAV from other small vessel vasculitides.

## Behcet's Disease in Southeastern Michigan: A Single Center Comparative Study

Nathan Kilian<sup>1</sup> and Amr H Sawalha<sup>2</sup>, <sup>1</sup>Rheumatology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Division of Rheumatology, University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Behçet's disease is a heterogeneous immune-mediated disease, with clinical variability across ethnicities and geographic locations. In this study, we describe and analyze the clinical characteristics of our multi-ethnic Behçet's disease cohort and provide a comparative analysis comparing the International Criteria for Behçet's Disease (ICBD) with the International Study Group (ISG) criteria in our patients.

**Methods:** A retrospective analysis was performed, in which the presence and absence of common Behçet's disease manifestations were recorded in our cohort. Differences in disease characteristics between men and women, and between ICBD and ISG derived cohorts were determined using chi square tests and Yates' correction. In addition, the associations between major and minor disease manifestations were also calculated.

**Results:** A total of 114 patients with a male to female ratio of ~ 1:4 were included. All patients met the ICBD criteria, including 76 who also met the ISG criteria. Over 95% of patients had recurrent genital ulcers, which is higher than generally reported. Retinitis was 5.3 times more common in men than women (p-value= 0.009), and arthralgia was 3.3 times more likely in women than men (p-value= 0.048). When comparing cohorts derived from the two different criteria, the ISG cohort had more skin manifestations (OR= 3.3, p-value= 0.0006). Acne was associated with ~8 times higher odds of developing retinitis in our patients (p-value= 0.0008), and superficial thrombophlebitis was associated with a trend for higher odds of developing uveitis (OR= 4.1, p-value= 0.057). Using the ICBD criteria, 38 additional patients were identified compared to only using the ISG criteria. Of these patients, 28 presented with only mucosal ulceration with or without joint involvement.

**Conclusion:** We characterize Behçet's disease in a multi-ethnic cohort from North America. Using the ICBC criteria in the United States significantly increases the likelihood of identifying Behçet's disease patients, particularly in patients with isolated mucosal involvement, who constitute a substantial subset of our patients in this region.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess the efficacy of Tocilizumab (TCZ) in refractory uveitis associated to extraocular manifestations due to Behçet's disease (BD).

**Methods:** Multicenter study of patients with BD refractory to standard systemic treatment (conventional immunosuppressive drugs and/or anti-TNF- $\alpha$  agents).

**Results:** We studied 11 patients (7 men/4 women) (20 affected eyes); mean age  $38.4 \pm 20.4$  years. Uveitis was bilateral in 9 patients. The pattern of ocular involvement was: panuveitis (n=8; with retinal vasculitis in 4), anterior uveitis (n=2) and posterior uveitis (n=1). Cystoid macular edema (CME) was present in 7 patients. The clinical course was recurrent (n=7) or chronic (n=4). Apart from the visual complications, at TCZ onset the following extraocular manifestations were present: oral and/or genital ulcers (n=7), arthritis (n=4), folliculitis/pseudofolliculitis (n=4), erythema nodosum (n=2), livedo reticularis (n=1), and neurological involvement (n=2). Before TCZ, they had received systemic corticosteroids, conventional immunosuppressive drugs and biologic agents, adalimumab (n=8), infliximab (n=4), golimumab (n=3), canakinumab (n=1), or etanercept (n=1). TCZ was used in monotherapy or combined with conventional immunosuppressive drugs at 8 mg/kg/iv/4 weeks (n=10) or 162 mg/sc/week (n=1). TCZ yielded rapid and maintained improvement in all ocular parameters (TABLE). After a mean follow-up of  $9.5 \pm 8.05$  months using TCZ, all patients experienced ocular improvement, with complete remission in 8 of them. However, TCZ was only effective in 3 of the 11 patients with extraocular manifestations. This biologic agent had to be withdrawn in 2 cases, 1 due to a severe infusion reaction and 1 due to arthritis impairment.

**Conclusion:** TCZ appears to be useful in highly refractory BD-related uveitis. However, there are controversial results regarding its efficacy in the treatment of extraocular manifestations of BD.

**Table.**

Case	Sex / Age (years)	Ocular pattern and course	Extraocular manifestations	Manifestations that improved with TCZ therapy
1	Male/27	Bilateral posterior uveitis + unilateral CME  Chronic	Oral ulcers, asymptomatic white matter lesions on MRI, arthritis, folliculitis	Uveitis and CME
	Female/42	Bilateral panuveitis + unilateral CME  Chronic	Oral and genital ulcers, erythema nodosum	Uveitis and CME
3	Male / 50	Bilateral panuveitis/papillitis + unilateral CME  Relapsing	Papillitis, arthritis	All of them (uveitis, papillitis, CME and arthritis)
4	Male / 35	Bilateral panuveitis + retinal vasculitis  Relapsing	Oral ulcers, folliculitis	Uveitis and retinal vasculitis
5	Female/67	Bilateral panuveitis + retinal vasculitis + bilateral CME	Livedo reticularis	Uveitis, retinal vasculitis and CME
6	Male / 31	Unilateral panuveitis + retinal vasculitis + unilateral CME  Relapsing	Oral and genital ulcers, folliculitis	Uveitis, retinal vasculitis and CME
7	Female/22	Bilateral panuveitis + bilateral CME  Chronic	None	Uveitis and CME
8	Male / 75	Bilateral panuveitis + retinal vasculitis + unilateral CME  Relapsing	Oral and genital ulcers, arthritis, folliculitis	Uveitis, retinal vasculitis and arthritis
9	Male / 10	Bilateral anterior uveitis  Relapsing	Oral and genital ulcers, hemorrhagic stroke, erythema nodosum	Uveitis, oral and genital ulcers and erythema nodosum
10	Female/48	Bilateral anterior uveitis  Relapsing	Oral and genital ulcers, arthritis, pseudofolliculitis, erythema nodosum, intestinal involvement	Uveitis
11	Male / 16	Unilateral panuveitis  Chronic	Oral ulcers, arthritis	Uveitis

Abbreviations: CME, cystoid macular edema; MRI, magnetic resonance imaging.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Uveitis is a severe manifestation of Behçet Disease (BD). The treatment is based on corticosteroids and conventional immunosuppressive drugs. In refractory cases, anti-TNF $\alpha$  had demonstrated efficacy. Our aim was to study the efficacy in long-term treatment with Infliximab (IFX) and its optimization.

**Methods:** Multicenter study of 178 patients diagnosed with Uveitis associated with BD refractory to high-dose of corticosteroids and at least one conventional immunosuppressive drug. IFX was used in 103 of these patients. The degree of ocular inflammation was evaluated with “the SUN working Group” (*Am J Ophthalmol* 2005; 140: 509-516) and the macular thickening with the optical coherence tomography (OCT). A comparison between baseline, 1st and 2nd week, 1st, 3rd and 6th month and 1st, 2nd, 3th and 4th year was performed. The statistical analysis was performed with the software STATISTICA Statsoft Inc. Tulsa, Oklahoma, USA). **Results** are expressed in mean $\pm$ SD for variables with a normal distribution, or median [25-75 IQR] when distribution is not normal. The comparison of continuous variables was performed with the Wilcoxon test.

**Results:** We studied 103 patients/185 affected eyes (55 men/48 women), mean age 40.4 $\pm$ 10.1. The ocular pattern was panuveitis (n=64), posterior uveitis (n=28) and anterior (n=11). Before IFX and besides oral corticosteroids, patients received: iv metilprednisolone (n=30), cyclosporine A (CyA) (n=77), azathioprine (AZA) (n=58), metotrexate (MTX) (n=45) and other treatments (n=34). IFX was administrated in monotherapy (n=24) or combined with other drugs (n=78): CyA (n=32), MTX (26), AZA (17), Cyclophosphamide (1), tacrolimus (1) and mycophenolate (1). The maintenance dose of IFX ranged between 3-5 mg/kg every/4 or 8 weeks. The evolution of the main ocular parameters is summarized in **TABLE**. Once achieved the remission we optimized treatment with IFX in 28 patients. **a)** In 23, the interval of dose was increased. **b)** In the other 5 patients the dose was reduced. After a mean follow-up of 32.29 $\pm$ 23.35 months, IFX was stopped in 56 patients for the following reasons: remission (n=20), preference for other way of administration (n=11), inefficacy (n=15), infusional reaction (n=5), TBC (n=1), cutaneous reaction (n=1), oral ulcers (n=1), colon carcinoma (n=1) and desire of pregnancy (n=1).

**Conclusion:** IFX is effective in short and long term treatment of refractory uveitis associated to BD. Optimization and even discontinuation of IFX after remission is possible.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adalimumab (ADA) therapy has been approved by the EMA and the FDA in non-infectious and non-anterior uveitis. After loading, the maintenance dose is 40 mg subcutaneously every other week. However, the duration of ADA therapy is not well established. Our purpose is to assess the long-term follow-up of a large series of patients with refractory uveitis due to Behçet Disease (BD) undergoing ADA therapy who experienced clinical remission and to compare the outcome of BD patients in whom ADA treatment was optimized when clinical remission was achieved with those in whom ADA optimization was not performed (control group).

**Methods:** Multicenter study that included 74 patients with BD uveitis refractory to glucocorticoids and conventional immunosuppressive drugs who required treatment with ADA. BD uveitis remission was defined if there was not apparent anterior and posterior chamber inflammation for at least 3 months. Based on a shared decision between the patient and the physician, once ocular remission was achieved, ADA therapy was optimized. It was performed increasing the interval between ADA doses progressively as follows: Initially every 3 weeks and then every 4, 6, 7 and 8 weeks up to discontinuation. Ocular inflammation was evaluated according to "SUN" (Am J Ophthalmol 2005; 140: 509-516). Macular thickening was evaluated with Optical Coherence Tomography (OCT).

**Results:** Ocular remission was achieved in 65 of 74 (86.6%) patients. ADA was optimized in 23 of these 65 patients (35.3%). In the remaining 42 patients ADA was maintained at standard dose (40 mg/sc/2 weeks). No demographic or ocular differences between the optimized (n=23) and the control group (n=42) were observed at the onset of ADA therapy. At last follow-up BCVA was significantly higher in the optimized group when compared to the control (non-optimized) group. No other significant clinical differences between both groups were seen (TABLE). No relevant

adverse effects were seen in the optimized group. It was not the case in the non-optimized BD patients who had the following complications: 1 lymphoma, 1 pneumonia, 1 severe local reaction at the injection site and 1 bacteremia by *E. coli*. After 34.7±13.3 months follow-up, ADA intervals at last visit in the optimized group (n=23) were as follows: every 3 weeks (n=6), 4 weeks (10), 5 weeks (1), 8 weeks (2), and discontinued (n=4). ADA dose (40 mg/sc/2 weeks) has to be reinitiated at the standard dose (40 mg/sc/2 weeks) due to ocular relapses in only 2 of 23 patients had a, achieving again remission. Results were expressed as mean±SD for normally distributed variables or as median [25-75 IQR] for those that did not follow a normal distribution.

**Conclusion:** Most patients with refractory uveitis due to BD undergoing ADA therapy achieve remission. ADA optimization can be successfully performed.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Behçet's disease (BD) is characterized by recurrent oral and/or genital ulcers accompanied by ocular, cutaneous, articular, gastrointestinal, and/or neurologic manifestations. Oral and/or genital aphthous ulcers are often refractory to conventional treatment. Apremilast is an orally-active small molecule which inhibits phosphodiesterase-4 (PDE-4) that modulates some inflammatory pathways. Our aim was to assess the efficacy of apremilast in BD patients with oral and/or genital ulcers refractory to conventional treatment.

**Methods:** Retrospective national multicenter open-label study on 14 BD patients treated with apremilast at standard dose of 30 mg twice daily. The main outcome was resolution of oral and/or genital ulcers.

**Results:** We included 14 patients (10 women/ 4 men), with a mean age of 44.3±14.4 years. Before apremilast, all patients had also received several systemic conventional drugs: oral corticosteroids (n=13), colchicine (n=14), NSAIDs (n=7), methotrexate (n=7), azathioprine (n=5), cyclosporine (n=4), infliximab (n= 3), adalimumab (n=3), dapsone (n=3), mycophenolate mofetil (n=1), tocilizumab (n= 1), etanercept (n=1), secukinumab (n=1). The main clinical symptoms for starting apremilast were oral aphthous ulcers (n=14) and genital ulcers (n=10). Other manifestations present at apremilast onset were arthralgia/arthritis (n=4), folliculitis (n=4), furunculosis (n=1), erythematous and scaly skin lesions (n=1), psoriasis (n=1), erythema nodosum (n=1), deep venous thrombosis (n=1), ileitis (n=1), asthenia (n=3). Ten patients experienced improvement in the first two weeks after starting apremilast. TABLE shows the evolution of the

patients. After a median follow-up of 3.5 [interquartile range, 3-9] months, most of the patients experienced a total or partial clinical improvement. In this period of time, 7 patients developed side-effects: dyspepsia (n=4), nausea (n=3), diarrhea (n=3), headache (n=1), abdominal pain (n=1), anorexia (n=1), and halitosis (n=1). However, only 2 of 6 patients had to reduce the dose of apremilast to 30 mg/day. In 3 patients (21%) apremilast was withdrawn after 3 months of treatment due to unsatisfactory response.

**Conclusion:** Apremilast leads to a rapid and maintained improvement in many patients with refractory mucocutaneous ulcers of BD. Even in patients refractory to several systemic drugs including biologic therapy.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the case of a complex disease like vasculitis, the patient is often tasked with understanding complicated care plans and managing myriad medications. Without appropriate support for these tasks, however, poor health outcomes may result. Recently, shared decision-making (SDM) has become a strategy for effective disease management, with the focus on the physician's ability to communicate. However, little attention has been paid to the manner in which the abilities and background of the patient interact with the communication and decision-making process. For this project, the following measures were obtained: patient activation (PAM), a measure of patient engagement, objective numeracy (ONS), a measure of objective math skills, subjective numeracy (SNS), a measure of self-reported math skills, health literacy (sTOFHLA), the Brigham Vasculitis Activity Score (BVAS), and the Vasculitis Damage Index (VDI), measures of activity and damage respectively.

**Methods:** Participants (N=43) were recruited from the Ohio State University Lupus, Vasculitis, and Glomerulonephritis (LVG). Subjects completed each of the measures indicated above. Pearson's correlation coefficient (PCC),  $r$ , was calculated for each of the variable pairs shown in Table 1. Some subjects were missing data. All available data for each variable were used.

**Results:** 37 out of the 43 patients had ANCA associated-vasculitis and 3 patients had Takayasu's vasculitis, one patient each had eosinophilic polyangiitis, CNS vasculitis and Behcet's syndrome. The ONS scores were relatively low (mean = 3.85 out of a possible 8 maximum score) while the mean PAM score was high (mean = 3.23 out of a possible 4 maximum score). All but one subject had above normal health literacy scores (sTOFHLA > 23). Table 1 illustrates correlations between variables.

**Conclusion:** Currently, very little evidence exists about the relations between patient activation, numeracy, and disease outcomes in vasculitis patients. Interestingly, although many patients had high patient activation and adequate health literacy scores, they had low math and numerical skills. Subjective and objective numerical ability were correlated, indicating patients who believed they were skilled numerically actually were. Higher activation scores were strongly negatively correlated with both disease damage and activity, indicating that greater engagement in care corresponded to lower disease damage and activity. Surprisingly, higher ONS scores trended with higher disease damage, a relationship that, if it proves robust, merits future investigation.

		Health Literacy	SNS	ONS	Patient Activation

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary angiitis of central nervous system (PACNS) is an isolated vasculitis affecting small-sized cerebral blood vessels. One of the major mimickers of PACNS is reversible cerebral vasoconstriction syndrome (RCVS). Both entities have distinctive pathophysiology, prognosis and therapeutic implications and differentiation between both is prudent. In this study, we aimed to compare the clinical and imaging characteristics of PACNS and RCVS cases at the presentation to better differentiate these entities.

**Methods:** Patients from Cleveland Clinic prospective RCVS-PACNS registry were included in the study. PACNS cases were included if they had a biopsy consistent with vasculitis or positive angiography and inflammatory cerebrospinal fluid pattern. Patients were asked to fill out questionnaires regarding their symptoms at presentation, headache impact test (HIT-6) and migraine disability assesment test (MIDAS). Brain MRI and cerebral angiography performed near the time of presentation were blindly evaluated by one neuroradiologist and two interventional radiologists, respectively.

**Results:** Our study included 28 PACNS and 45 RCVS cases. Main results are summarized in table. Female patients were more commonly affected by RCVS compared to males (3.5:1). RCVS cases more commonly presented with headache than PACNS cases. Headache was often insidious and dull in PACNS, whereas it was sudden and thunderclap in RCVS. Time for headache to peak was reported as seconds and intensity of headache was higher in RCVS cases. Neurologic deficit was more commonly associated with headache in PACNS than RCVS cases.

Appearance of vascular abnormality on cerebral angiogram was sausage-like in most of the RCVS and irregular in most of the PACNS cases. Subarachnoid hemorrhage was more common on MRI of RCVS cases, while nonspecific white matter changes were more common in PACNS cases. Lesions were superficial (involving cortex and subcortical white matter) in RCVS and deep (deep and periventricular white matter) in PACNS cases. Total score of MIDAS was higher in RCVS indicating more disability due to headache in these cases ( $p=0.01$ ). Results of HIT-6 are shown in the figure.

**Conclusion:** PACNS cases experience insidious-onset and dull headache, while RCVS cases often experience sudden, more severe and disabling headache. Radiologic signs such as nonspecific white matter changes, deep location of lesion, and irregular appearance of the vessel on angiogram are more commonly seen in PACNS cases, and can help guide clinicians in differential diagnosis.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IgA Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. IgA Vasculitis is a predominantly pediatric vasculitis. There is limited data for the prognosis of adult IgA Vasculitis, with also no damage assessment. In this study, we aimed to evaluate the clinical characteristics, treatment, outcome and damage of patients with adult IgA Vasculitis.

**Methods:** We assembled a retrospective cohort of patients with adult IgA Vasculitis from tertiary Rheumatology Centers in Turkey. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS), prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.

**Results:** The study included 52 (male/ female: 40/12) patients with adult IgA Vasculitis. The mean age was  $42.2 \pm 17$  years. Infection history within 6 weeks before presentation was present in 22 (42.3%) patients (18 upper respiratory tract, 3 gastrointestinal and one urinary tract). Cutaneous manifestations and arthritis/arthralgia were the most common clinical manifestations (Table 1). All patients were treated with oral glucocorticoids (GC). Pulse GC treatment was also given to 12 (23.1%) patients. As additional immunosuppressive agents, azathiopirine was given to 21 (40.4%) and pulse cyclophosphamide to 11 (21.2%) patients. Twenty-eight patients (53.9%) had follow-up of 28.6 months. Five (17.8%) patients relapsed during follow-up. While 3 relapses were major, 2 of them were minor relapses. At the last visit, disease status was evaluated as active or treatment failure by the treating physician in 6 (21.4%) patients. Mortality was 3.6% (n=1) during follow-up, due to pneumonia. The mean VDI score was 0.6 in the last visit. Nine (32.1%) patients had at least one damage item at the end of follow-up period.

**Conclusion:** Our results showed that approximately one fifth of patients with adult IgA Vasculitis had relapses during follow-up. At the end of follow-up, one third of patients had at least one damage item. Although, 45% of patients had  $\text{FFS} \geq 1$ , the mortality rate was observed to be low in the present study.

## Serum Levels of Interleukin-36 Receptor Antagonist in Behçet's Patients

Pelin Ünsal<sup>1</sup>, Pamir Cerci<sup>2</sup>, Şükrü Alper Açıkgöz<sup>2</sup>, **Göksal Keskin<sup>2</sup>** and Ümit Ölmez<sup>2</sup>, <sup>1</sup>Ankara University School of Medicine, Ankara, Turkey, <sup>2</sup>Immunology and Allergy, Ankara University School of Medicine, Ankara, Turkey

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Behcet's disease (BD) is a systemic vasculitis disorder of unknown etiology with recurrent exacerbations and remissions. The etiopathogenesis of the disease is still unclear. The most investigated cytokine in the pathogenesis of the disease is interleukin (IL) -1 family. A new member of the IL-1 cytokine family, IL-36Ra (Receptor Antagonist), stimulates dendritic cells from the host cells of innate and acquired immunity. In this study we investigated whether the level of serum IL-36Ra increase or not in the etiopathogenesis of Behcet's disease, its effect on disease activity and clinical findings.

## Methods:

Serum IL-36Ra levels were measured by (ELISA) kits following the manufacturer's instructions. All BD patients recruited for this study met the 1990 international criteria for classification of BD.

## Results:

31 of the patients were active disease (51.7%). Demographic and clinical parameters are shown in Table 1.

**Table 1: Demographic and clinical characteristics of Behcet's patients and healthy controls**

Parameter	All BD Patients (n:60)	Active BD Patients (n:31)	Healthy Controls (n:20)
Age (year)	41 ± 11,1 (mean+SD)	38,4 ± 11,3	40,2 ± 13
Sex (M/F)	29/31	14/17	10/10
Oral ulcers	59 (98.3%)	25 (80.6%)	-
Genital ulcers	48 (80%)	23 (74.2%)	-
Thrombophlebitis	14 (23.3%)	7 (22.6%)	-
Arthritis	22 (36.6%)	11 (35.5%)	-
Uveitis	30 (50%)	11 (35.5%)	-
Deep vein thrombosis	18 (30%)	6 (19.4%)	-
CNS involvement	5 (8.3%)	4 (12.9%)	-

Serum IL-36Ra levels were found to be  $15.36 \pm 13.26$  pg / ml in the patient group and  $17.90 \pm 13.03$  pg / ml in the control group ( $p = 0.677$ ). Serum IL-36Ra levels were found to be  $17.80 \pm 10.63$  pg / ml in the active patient group and serum IL-36 Ra level in the inactive patient group was found to be  $12.77 \pm 7.12$  pg / ml. A statistically significant difference was found between IL-36Ra levels in active and inactive patient groups ( **$p = 0.037$** ). There was no statistically significant difference between IL-36Ra levels ( $p = 0.636$  and  $p = 0.207$ , respectively) between active patient and inactive patient group and control group. Serum IL-36Ra levels were significantly higher in patients with Behçet's disease than those without oral ulcers ( $p = 0.018$ ). In addition, serum IL-36Ra levels ( $24.45 \pm 11.58$  pg / ml) were higher in patients with neurological involvement than those without neurological involvement ( $14.45 \pm 8.71$  pg / ml) ( $p = 0.011$ ). No statistically significant difference was found between serum IL-36Ra and other systemic manifestations.

## Conclusion:

According to our results, there was a statistically significant difference between IL-36Ra and oral ulcers, neurological involvement, disease activity and CRP. More study is needed to determine the role of IL-36Ra in the pathogenesis of Behcet's disease.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The mainstay treatment of pulmonary artery involvement (PAI) in Behcet's syndrome (BS) is immunosuppression and corticosteroids (1). The role of surgical intervention in the management of PAI can be questionable in many cases considering the severe outcome of our previous attempts (2-3). For the past few years we observed that there are indeed several conditions associated with PAI which require surgical operations. In this study, we described disease characteristics, management and outcome of a group of BS patients who underwent surgical procedures for complications due to PAI.

**Methods:** There were 9 patients with BS (8 M/1 F) who underwent surgery for PAI from 2003 to 2016 at the Department of Thoracic and Cardiovascular Surgery, Cerrahpasa Medical Faculty. The medical records, outpatient charts, radiological and pathological studies of these patients were reviewed retrospectively.

**Results:** The mean age of the patients was 24.8±7.5 years (range: 12-35). The mean duration of the disease at the time of the surgery was 4.3±3.8 years. The main symptom was haemoptysis. The most common surgery type was lobectomy which was done in 6 patients, followed by decortications in 3. The reason for the surgical procedures were variable as shown in Table. It was giant pulmonary arterial aneurysms refractory to the medical treatment in 4 patients (patients no. 1, 2, 3 and 4), hydropneumothorax due to cavitary lesions in two (patients no. 5 and 6), pleural effusions refractory to the medical treatment in one (patient no. 7), bronchopleural fistula after embolization in one (patient no. 8) and bronchiectasis in another (patient no. 9). All patients received cyclophosphamide treatment with different total doses. Seven patients (patient no. 2, 4, 5, 6, 7, 8 and 9) are still alive and are being followed in our clinic for a median of 7.5 years (IQR:1.5-11). Patient no. 1 had died because of hepatic failure due to Budd-Chiari syndrome after 1 year from the surgery and patient no. 3 had died because of massive haemoptysis within 2 months of lobectomy.

**Conclusion:** We now think that lobectomies in patients with giant aneurysms refractory to medical treatment can be done with successful results. Also, complications such as refractory pleural effusions, bronchiectasies and bronchopleural fistula can be managed with surgical interventions successfully in patients with PAI.

## Clinical Features and Treatment of Central Nervous System Vasculitis Associated with Acute Posterior Multifocal Placoid Pigment Epitheliopathy

**Hiromichi Tamaki**<sup>1</sup> and Rula A Hajj-Ali<sup>2</sup>, <sup>1</sup>Department of Rheumatic and Immunologic Diseases, Cleveland Clinic Foundation, Cleveland, OH, <sup>2</sup>Rheumatic and Immunologic Disease, Cleveland Clinic, Cleveland, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Acute posterior Multifocal Placoid Pigment Epitheliopathy (APMPPE) is a rare inflammatory eye disease and some appear to develop central nervous system vasculitis (CNSV). This entity is poorly described in the medical literature and little is known about treatment and prognostic factors.

## Methods:

We present a case series of 23 patients with CNSV in association with APMPPE; 21 cases have been reported in the literature in addition to our experience with two cases. Patients were identified after a systemic literature search using Pubmed and Scopus for key words including APMPPE, stroke, neurological and CNSV. The cases were classified into definite (confirmed by pathology) or probable (inflammatory cerebrospinal fluid (CSF), imaging evidence of stroke/vasculopathy, and/or steroid response). The clinical features were described.

## Results:

Total 23 articles and 24 articles were found in pubmed and scopus respectively. Total 54 cases were described in these articles. Two cases met the criteria for definitive case and 19 cases met the criteria for probable case. Total 23 cases were analyzed after adding our two cases. The clinical features of these patients were summarized in table 1.

<b>Demographic</b>		
	The total number (No.) of the patients	23
	Age (median [IQR])	23.0 [22.0, 28.0]
	No. of male patients (%)	20 ( 87.0)
<b>Clinical Manifestations</b>		
	No. of patients with bilateral APMPPE eye findings (%)	23 (100.0)
	No. of patients with Headache (%)	15 ( 68.2)
	No. of patients with altered mental status (%)	4 ( 18.2)
	No of patients with lateralized neurological deficit (%)	20 ( 90.9)
	No. of patients with short term memory loss (%)	1 ( 4.5)
	No. of patients with gait disturbance (%)	2 ( 9.1)
	No. of patients with seizure (%)	2 ( 9.1)
	No. of patients with diplopia (%)	1 ( 4.5)
	No. of patients with homonymous hemianopsia (%)	4 ( 19.0)
	No. of patients with speech disturbance (%)	8 ( 36.4)
	No. of weeks from ocular symptoms to onset of CNS disease (median [IQR])	4.0 [2.0, 8.0]
	No. of patients who developed CNS symptom while on glucocorticoids (%)	5 ( 23.8)
<b>CSF analysis (n = 20)</b>		
	No. of patients with CSF pleocytosis or elevated protein (n=20) (%)	19 ( 95.0)
	No. of patients with CSF WBC elevation (n=20) (%)	18 ( 90.0)
	CSF WBC (n= 19) (median [IQR])	18.50[10.75,63.75]
	No. of patients with lymphocytic predominance (n=15) (%)	14 ( 93.3)
	Lymphocyte percentage (n=10) (median [IQR])	93.50 [85.5, 97.5]
	No. of patients with CSF protein elevation (n=18) (%)	9 ( 50.0)
	CSF protein (n=16) (median [IQR])	54.00 [35.25, 66.25]
<b>Imaging study</b>		
	No. of patients with abnormal brain parenchymal imaging (n=21) (%)	21 (100.0)
	No. of patients with abnormal angiography (n = 19) (%)	15 ( 78.9)
<b>Histopathology (n = 2)</b>		
	Granulomatous arteritis	2
<b>Treatment</b>		
	No. of patients treated with glucocorticoids (%)	21 ( 91.3)
	No. of patients treated with azathioprine (%)	5 ( 23.7)
	No. of patients treated with Cyclophosphamide (%)	2 ( 8.7)
	No. of patients treated with mycophenolate mofetil (%)	2 ( 8.7)
	Treatment with pulse glucocorticoids (%)	7 ( 43.8)
	No. of patients treated with pulse steroid for neurologic manifestations (%)	10 ( 52.6)
<b>Outcome</b>		
	No. of patients who died (n=21) (%)	3 ( 14.3)
	No. of patients who had recurrence (n=21) (%)	3 ( 14.3)
	Follow up duration (months) (n=21) (median [IQR])	9 [ 6.0 – 18.0]

Thirteen patients treated only with glucocorticoids (GC) resulted in 2 deaths and 2 relapses. One of these two relapses was treated with cyclophosphamide (CYC) with improvement. One patient received GC and CYC with improvement, however, a relapse occurred after switching to azathioprine (Aza). The other 4 patients who received GC and Aza improved without relapse or death. Two patients were treated with GC and MMF without relapse or death. One patient was treated with GC and mitoxin successfully. Two patients without any treatment resulted in one death. Two patients without any treatment resulted in one death. The prognostic factors were compared (Table 2).

**Table 2. Univariate Analysis of Prognostic Factors**

	Death or relapse 6	No death or relapse 17	P value
No. of the patients who died or relapsed			
age (median [IQR])	26.50 [23.25, 33.50]	23.00 [22.00, 27.00]	0.139
No. of male patients (%)	5 (83.3)	15 (88.2)	0.99
No. of patients with Headache (%)	5 (83.3)	10 (62.5)	0.674
No. of patients with altered mental status (%)	3 (50.0)	1 (6.2)	0.08
No. of patients with lateralized neurological deficit (%)	5 (83.3)	15 (93.8)	0.99
No. of patients with short term memory loss (%)	0 (0.0)	1 (6.2)	0.99
No. of patients with gait disturbance (%)	0 (0.0)	2 (12.5)	0.94
No. of patients with seizure (%)	2 (33.3)	0 (0.0)	0.112
No. of patients with diplopia (%)	0 (0.0)	1 (6.2)	0.99
No. of patients with homonymous hemianopsia (%)	0 (0.0)	4 (25.0)	0.555
No. of patients with Speech disturbance (%)	1 (16.7)	7 (43.8)	0.497
No. of weeks from eye symptoms to CNS symptom onset (median [IQR])	2.00 [0.88, 2.75]	6.00 [3.00, 8.00]	0.053
No. of patients who developed CNS symptom on glucocorticoids (%)	3 (50.0)	2 (13.3)	0.224
CSF WBC (median [IQR])	56.00 [17.00, 60.00]	18.00 [10.00, 65.00]	0.693
No. of patients with CSF WBC elevation (%)	4 (80.0)	14 (93.3)	0.99
No. of patients with Lymphocytic predominance (%)	4 (100.0)	10 (90.9)	0.99
CSF Lymphocyte percentage (median [IQR])	90.00 [87.00, 94.00]	94.00 [83.50, 97.50]	0.732
CSF protein (median [IQR])	57.00 [53.00, 66.00]	44.00 [32.50, 62.00]	0.212
No. of patients with CSF protein elevation (%)	4 (100.0)	5 (35.7)	0.089
No. of patients who had pulse steroid for neurologic manifestation (%)	3 (75.0)	7 (46.7)	0.656

The death and relapse free survival curve of the entire cohort was also drawn (Figure 1).

## Conclusion:

The treatment outcome varies widely among the patients. No clinical variables can predict relapse or death. The longer duration from an onset of eye symptoms to CNS disease may have a better prognosis, although this did not reach statistical significance. We successfully treated CNS vasculitis with MMF and MMF can be used to treat this severe complication of APMPE.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In the clinical approach to CNS vasculitis, exclusion of infection is of major concern as some microbes can cause vasculitis, and infections can complicate immunosuppressive therapy for CNS vasculitis. The yields of conventional microbiologic techniques to detect CNS infections from cerebrospinal fluid (CSF) are suboptimal, particularly for unusual organisms that may not be part of the differential diagnosis. Unbiased metagenomic next-generation sequencing (mNGS) is an emerging technique that offers an alternative, hypothesis-free approach for detecting CNS infections. Here we report on a pilot study to examine the utility of mNGS in the management of patients with CNS vasculitis.

### Methods:

Patients were recruited from our CNS registry at Cleveland Clinic. Total RNA was extracted from 250 uL of CSF, and cDNA sequencing libraries were prepared using random hexamer primers. NGS was performed on an Illumina HiSeq 2500 machine, and the resulting 10-20 million paired-end 150 nucleotide sequences were analyzed by a rapid computational pipeline for identifying all known viruses, bacteria, fungi and parasites. The patients received a regular medical care otherwise. The results of mNGS were compared with regular medical care.

### Results:

The main results are summarized in Table 1.

ID	Clinical scenario	CSF WBC	CSF Protein	CSF Glucose	CSF Cultures	mNGS	Final Diagnosis
1	A 32 year-old man with recurrent transient ischemic stroke, pituitary lesion and multiple intracranial arterial stenosis. A question of neurosarcoidosis vs CNS vasculitis.	343 (63% Lymph)	34	56	negative	Aspergillus	Aspergillus CNS infection
2	A 37 year-old man with relapsing polychondritis and biopsy proven CNS vasculitis developed fever and chronic meningitis while on cyclophosphamide. A question of infection vs worsening CNS vasculitis.	29 (83% neutrophil)	34	47	negative	negative	A flare up of CNS vasculitis
3	A 64 year-old man with cognitive decline and gait disturbance who was presumptively diagnosed with CNS vasculitis (brain biopsy non diagnostic) developed worsening of ischemic lesions on MRI while on cyclophosphamide. A question of infection vs worsening CNS vasculitis.	3 (66% Lymph)	54	130	negative	negative	A flare up of CNS vasculitis
4	A 60 year-old woman with cognitive decline, diffuse white matter lesions on MRI, and retinal vasculitis. A Question of CNS vasculitis vs Susac's syndrome vs retinal vasculopathy with cerebral leukodystrophy (RVCL).	11 (90% Lymph)	61	48	negative	negative	Atypical Susac's syndrome
5	A 49 year-old woman with anti-synthetase syndrome on azathioprine and recent rituximab infusions developed acute ischemic stroke and an angiogram showed symmetrical small vessel vasculopathy. A question of CNS vasculitis in the setting of known systemic autoimmune disease.	1 (88% Lymph)	23	70	negative	negative	Atherosclerotic ischemic stroke

mNGS was useful in the following cases. Patient 1 was presumptively diagnosed with an autoimmune CNS disease based on a negative extensive infectious work-up. The CSF fungal cultures were negative 3 times, but research-based mNGS detected *Aspergillus* spp. This result was confirmed with a clinical 18s rRNA fungal PCR. Two patients (2, 3) with established CNS vasculitis clinically deteriorated while appropriately treated with glucocorticoids and cyclophosphamide. mNGS did not identify an infection. The patients were treated successfully with escalation of immunosuppression. Patient 4 did not have the typical triad for Susac's syndrome, and as a result, a viral etiology was of great concern. To the degree that mNGS can be shown to have good sensitivity, the negative mNGS result in this case, would help exclude any lingering concerns about a potential infectious etiology.

### Conclusion:

While these data are preliminary, mNGS may be useful to detect infectious pathogens that are novel or associated with a low yield with conventional diagnostic techniques in patients with CNS vasculitis. mNGS may be also useful to exclude opportunistic infections in patients with CNS vasculitis arising in those treated with aggressive immunosuppression therapy. This technique is worth exploring in the larger cohort of patients with CNS vasculitis and patient recruitment is ongoing.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

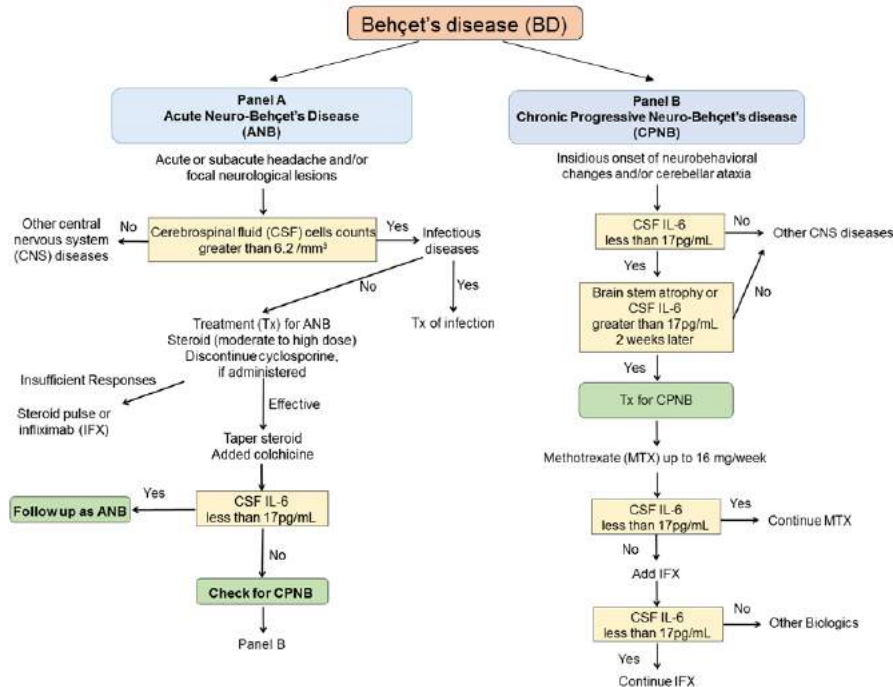

**Background/Purpose:** Central nervous system involvement is one of the most serious complications in Behçet's disease (BD). This condition is referred to as neuro-Behçet's disease (NB) and can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical course and responses to corticosteroid treatment. Diagnostic criteria were generated in 2013 based on a multicenter clinical survey performed by the Behçet's Disease Research Committee of the Ministry of Health, Labor and Welfare of the Japanese Government. Although 'Guidelines for Treatment of NB' was also proposed based on the survey, it is still preliminary. The aim of the current study is to develop evidence-based recommendations for the management of NB supplemented by expert opinions where necessary.

**Methods:** First, clinical questions (CQs) on NB were extracted from a literature search for problem areas and related keywords, and draft CQs and a flow chart were prepared. The expert committee, a task force of the research subcommittee for NB, consisted of 7 board-certified rheumatologists (one was also a board-certified neurologist) and 3 board-certified neurologists. A systematic literature search was performed using Medline and the Japan Medical Abstract Society databases from 1997 to 2016. A total of 15 initial CQs were generated. These yielded the final recommendations developed from 3 blind Delphi rounds, in which the rate of agreement scores on CQs (range 1[strongly disagree]-5[strongly agree]) was determined though voting by the whole committee.

**Results:** Thirteen recommendations were developed for the management of NB (general 1, ANB 7, CPNB 5). The strength of each recommendation was established based on the evidence level as well as rate of agreement. There was excellent concordance between the level of agreement of rheumatologists and that of neurologists. Based on these recommendations, a flow chart was established for the management for ANB and CPNB (Figure).

**Conclusion:** The recommendations generated in this study are mainly based not only on expert opinions but on the results of uncontrolled evidence from open trials and retrospective cohort studies. Nevertheless, such guidelines that can be used for international studies would be needed, for which verification by further properly designed controlled clinical trials is required.

## Clinical Characteristics and Treatment Outcomes of Patients with Behçet's Disease and Vascular Involvement

**In Young Kim**<sup>1</sup>, Yeong Hee Eun<sup>2</sup>, Ji young Chai<sup>3</sup>, Hyungjin Kim<sup>1</sup>, Jaejoon Lee<sup>1</sup>, Eun-Mi Koh<sup>1</sup>, Duk-Kyung Kim<sup>4</sup> and Hoon-Suk Cha<sup>1</sup>, <sup>1</sup>Department of Medicine, Division of Rheumatology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South), <sup>2</sup>Department of Medicine, Division of Rheumatology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, MN, Korea, Republic of (South), <sup>3</sup>Department of Rheumatology, Bundang Jesaeng Hospital, Seongnam, Korea, Republic of (South), <sup>4</sup>Department of Medicine, Division of Cardiology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The international Chapel Hill Consensus Conference (CHCC) categorized Behçet's disease (BD) as variable vessel vasculitis, which was defined as vasculitis that can affect vessels of any size and type. Vascular manifestations have been reported in up to 50% of patients with BD, most commonly as venous thrombosis. The aim of this study is to investigate characteristics and treatment outcomes of patients with vascular BD, particularly with large vessel involvement.

**Methods:** A retrospective review was performed on 2,496 patients with ICD-10 code of Behçet's disease and/or aortic disease who visited Samsung Medical Center between 2004 and 2014. Patients who were suspected to have BD and vascular involvement were enrolled.

**Results:** Eighty-three patients with clinical features of BD and vascular involvement were identified. Although less than half satisfied the classic International Study Group (ISG) criteria, greater proportion fulfilled the International Criteria for BD (ICBD), and all of the patients satisfied at least "suspected BD" according to the Japanese criteria. Fifty patients had arterial lesions including 34 with aorta involvement. Another 33 patients had venous thrombosis without arterial lesions. Patients showed a male predominance (87%) and a predilection of young age with the median of 42 years old. The most prominent type of arterial lesions was aneurysm (80%) with a high frequency of pseudoaneurysms. Among the aorta, the thoracic aorta was most commonly involved and 18 patients had aortic valve regurgitation. Seventy-five (90%) patients received glucocorticoids with a median initial dose of prednisolone of 30 mg per day and 68 (82%) received immunosuppressive treatment. Half of the patients had more than one relapse after stabilization of the first vascular event. During the course, 44 patients underwent surgery and/or endovascular treatment and 60% of these patients had repeated treatment for the relapse. These included 31 aortic valve replacement on 13 patients.

**Conclusion:** Patients with vascular BD showed a predilection of young male and 60% of patients had arterial involvement. The aorta was affected in more than half of the patients who had arterial involvement. Aneurysmal change was frequent finding and relapse rate was high during disease course. Further studies into a practical and specialized diagnostic tool for vascular BD and optimal treatment strategies are required.

## A Comparison of Current Practice to New Vasculitis Treatment Guidelines

Ishrat Gill<sup>1</sup>, Norman Madsen<sup>2</sup>, Imran Hassan<sup>3</sup> and Elaine Yacyshyn<sup>4</sup>, <sup>1</sup>Medicine, University of Alberta, Sherwood Park, AB, Canada, <sup>2</sup>Medicine, Rheumatology, University of Alberta, Edmonton, AB, Canada, <sup>3</sup>EPICORE Centre, University of Alberta, Edmonton, AB, Canada, <sup>4</sup>Medicine, University of Alberta, Edmonton, AB, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Background/Purpose:** Appropriate treatment for Anti-Neutrophilic Cytoplasm Antibodies (ANCA) Associated Vasculitis (AAV) requires induction and maintenance of remission, while balancing side effects from treatment. The CanVasc (Canadian Vasculitis Research Consortium) guidelines (2015) recommend use of corticosteroids and other immunosuppressive therapies for adequate treatment. However, clinical practices may vary significantly under different models of care. We analyzed the current clinical state of practice for treating ANCA related vasculitides within three different subspecialties, to compare differences in prescribing, in contrast to CanVasc guidelines.

**Methods:** This study was a retrospective cohort study; patient information was retrieved from databases of rheumatology, pulmonology and nephrology clinics under Alberta Health Services (AHS) in Edmonton. Diagnosis of patients with ANCA-associated systemic vasculitis was based according to the 2012 Chapel Hill Guidelines and use of corticosteroid therapy at diagnosis was the inclusion criteria. Data on demographics, corticosteroid dosage and time to taper, concurrent therapies, and management of recurrences was recorded. The medical subspecialty most responsible for steroid prescribing was also identified.

**Results:**

Subspecialty	Nephrology	Pulmonology	Rheumatology	P values
# Patients	59	9	20	
% Males	46%	22%	50%	0.426
% Females	54%	78%	50%	0.426
% receiving pulse steroid on initial diagnosis	20.3%	11.1%	25%	0.778
% of patients experiencing flares ( $\geq 1$ )	20.3%	55.6%	45%	0.018
% of patients receiving pulse steroid during a flare	25%	0%	22.2%	0.0006
# receiving any steroid therapy during flare	7	6	9	0.002
Time from start of therapy to taper (days)	32	50	39	0.411

**Conclusion:** Differences in clinical practice persist within subspecialties, when managing AAV patients. Our data highlights a shorter duration on initial dose of prednisone dose after diagnosis in Nephrology patients with taper within 1 month, compared to a longer duration of the initial prednisone dose in Pulmonology patients. CanVasc guidelines recommend glucocorticoids should be gradually tapered to a dose of 5-10 mg/day within 3-6 months of achieving remission. Our data shows that most patients remained on their initial prednisone dose for a much longer period than recommended, although this may be due to remission not being achieved. During recurrences/flares, adjustment to concurrent therapy was preferred over increasing corticosteroid dose instead. Our study highlights that subspecialties have a different approach to managing AAV patients than CanVasc recommendations. Ensuring that patients receive standard best practice for treatment should be a future goal in vasculitis patient management. Further studies are required to assess the effectiveness and knowledge translation of these practice modules, in support of CanVasc guidelines.

## Is There an Association between Adult IgA Vasculitis and Cancer?

**Jaka Ostrovrsnik**<sup>1</sup>, Ziga Rotar<sup>1</sup>, Rok Jese<sup>1</sup>, Matija Tomšič<sup>1,2</sup> and Alojzija Hočevár<sup>1</sup>, <sup>1</sup>Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, <sup>2</sup>University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** An increased incidence rate of cancer has been reported in adult patients with IgA vasculitis (IgAV). These conclusions are mostly based on observations in severely ill, hospitalized subgroup of patients. Most of the studies allowed for a wide time interval between IgAV and cancer appearance, not necessarily reflecting a causative link. The aim of our longitudinal prospective study was to look for the potential association between IgAV and cancer in an unselected adult IgAV population.

**Methods:** We analysed medical records of prospectively followed, histologically proven adult IgAV cases at our secondary/tertiary rheumatology centre **form** a well-defined referral region between 1 January 2010 and 31 May 2016, who were followed until 31 May 2017. Patients with at least 6-month follow up were included in the analysis. We identified cancer as concurrent with IgAV, if the patients had active cancer or a relapse of cancer or newly-diagnosed cancer diagnosed up to 6 months prior or 6 months after IgAV diagnosis. Cancers developing after 6month of follow up were labelled as unrelated to IgAV. We used appropriate descriptive statistical methods, and the Fisher's exact and Mann-Whitney U tests to assess differences of clinical characteristics in acute phase of IgAV, between the cancer and non-cancer groups. The national prevalence and age adjusted incidence rates of cancer from a well-defined referral region were obtained from National cancer registry (NCR).

**Results:** During the 77-month observation **period** we identified 171 new IgAV cases. 2 patients died in the acute disease phase due to vasculitis, and 7 during the first 6 months of follow-up for reasons other than IgAV or cancer. 18 patients were lost to follow-up. The remaining 144 patients (55% male, median (IQR) age 66 (44-77) years) were followed for a median (IQR) of 23 (13-34) months. At the time of IgAV diagnosis, 4/144 (2.8%) had active, previously diagnosed malignant disease. In 2/144 patients (1.4%) a new cancer was diagnosed. One of the patients with an active cancer of urinary bladder, was treated with antibiotics for urinary tract infection prior to IgAV diagnosis, and was also on chemotherapy. The patients with cancer were older (median age (IQR) 82 (80-83) vs. 64 (44-76) years;  $p=0.003$ ) but their presenting features of IgAV, and the initial IgAV treatment did not significantly differ from those without cancer. At the end of the observation period, the prevalence of cancer in our cohort was 4.2%. Compared to the 4.6% prevalence of cancer in our general population and the relative risk of cancer in our IgAV cohort was 0.91 ( $p=0.817$ ; 95% CI 0.42-2.00). The age adjusted incidence rate of cancer was 13.9 per 1000 patient years. The annual age adjusted incidence rate of cancer in our citizens, acquired from NCR, was 31.2 per 1000 patient years and the standardised incidence ratio for our IgAV cohort was 0.89 ( $p=0.781$ ; CI 0.11–3.21).

**Conclusion:** In our cohort of unselected adult IgAV cases, we did not confirm the previous observations of the association of IgAV and cancer.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The aim of the study was to describe the evolution of mortality over recent decades in systemic necrotizing vasculitides, including polyarteritis nodosa (PAN), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA).

### **Methods:**

The date of diagnosis and the cause of death for patients with PAN, GPA, MPA, and EGPA were analyzed from the French Vasculitis Study Group database. Patients were divided into 5 groups: diagnosis before 1980, 1980-1989, 1990-1999, 2000-2010, and after 2010. The causes of death were classified as either vasculitis, infection, cardiovascular, malignancy, miscellaneous, or unknown.

### **Results:**

Among the 2243 included patients (PAN 16%, GPA 42%, EGPA 23%, MPA 19%), 301 (13%) deaths were reported (Table 1). The 5-year overall survival rate increased from 72.2% (95% confidence interval [CI] 59.7-87.2) for patients diagnosed before 1980, to 94.5% (95% CI 90.4-98.8) after 2010 ( $p < 0.001$ ; Figure 1). The incidence of 5-year mortality between 1980-1989 and the last decade ( $>2010$ ) decreased from 2.18 to 0.11 per 100 person-years for vasculitis-related

deaths ( $p=0.004$ ), from 1.09 to 0.11 for cardiovascular-related deaths ( $p=0.03$ ), and from 0.82 to 0.25 ( $p=0.03$ ) for deaths caused by infection. No death by infection occurred in patients diagnosed after 2010. For deaths related to malignancy, the incidence of 5-year mortality was 0.41 per 100 person-years in 1980-1989, 0.17 in 2000-2009 ( $p=0.21$ ), and 0.32 after 2010 ( $p=0.78$ ).

### **Conclusion:**

The results indicate that survival has dramatically improved since the 1980s due to the decrease of vasculitis flares and infections, but that cancer-related mortality remained stable. These results highlight the current targets to improve the overall prognosis.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pulmonary involvement in systemic primary vasculitides is diverse and occurs with variable incidence depending on the type of vasculitis. This study aimed to describe the spectrum and extent of lung manifestations in systemic vasculitides.

**Methods:** A large, cross-sectional study describing, comparing, and contrasting the lung manifestations of adults with Takayasu arteritis (TAK), giant cell arteritis (GCA), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), eosinophilic granulomatosis with polyangiitis (EGPA), polyarteritis nodosa (PAN), and IgA vasculitis (IgAV, Henoch Schönlein) was performed using data from the Diagnostic and Classification Criteria in Vasculitis (DCVAS) study. The DCVAS study is an international, collaborative project that has collected comprehensive clinical data on a large cohort of patients with vasculitis to help in the development of new classification and diagnostic criteria. Data from the baseline and 6-month DCVAS visits were used for analysis.

**Results:** 1952 patients with primary vasculitides were included: 170 TAK, 657 GCA, 555 GPA, 223 MPA, 146 EGPA, 153 IgAV, and 48 PAN. The presence of respiratory symptoms was frequent in GPA (64.5%), MPA (65.9%), and EGPA (89.0%), but less so in TAK (21.8%), GCA (15.8%), PAN (27.1%) and IgAV (5.9%). Hemoptysis occurred mainly in patients with GPA (26.7%), MPA (23.3%), and EGPA (8.2%) and was rare in TAK (n=3), GCA (n=2), and PAN (n=2); no hemoptysis was reported in IgAV. Intubation for respiratory failure was infrequent and only seen in ANCA-associated vasculitis (AAV; 2.7% in GPA, 2.7% in MPA, 3.4% in EGPA).

Abnormal lung imaging was reported in GCA (19.7%), TAK (12.3%), GPA (59%), MPA (73%), EGPA (70%), PAN (36%), and IgAV (11%). Lung nodules were present in 25%, 11.7%, and 13.3% of patients with GPA, MPA, and EGPA, respectively. Lung imaging in PAN and IgAV revealed non-specific inflammation, consolidation, or pleural effusion.

Pulmonary function tests (done in 32% of patients with AAV) revealed a restrictive pattern in GPA (16.6%), MPA (28.3%), and EGPA (4.6%), and an obstructive pattern in 70% of patients with EGPA. Bronchoscopy was done in 23% of patients with AAV, abnormal in 74% of them (mucosal changes, alveolar hemorrhage, hypersecretion). Lung biopsy, performed in 14% of patients with AAV, showed vasculitis in GPA (60.6%), EGPA (63.2%), but not in MPA (0/6).

At 6 months, lung damage items on the Vasculitis Damage Index (VDI) were present in patients with TAK (4.1%), GCA (3.3%), GPA (15.4%), MPA (28.7%), EGPA (52.7%), PAN (6.2%), and IgAV (1.3%). Only 3 patients with lung damage had died by the 6-month follow-up visit, all with MPA. Death was lung- and vasculitis-related in 1 patient only (alveolar hemorrhage). In GPA, lung damage at month 6 was associated with more frequent baseline gastrointestinal (30.6% vs. 16.7%) and neurological (49.4% vs. 30.3%) symptoms.

**Conclusion:** Pulmonary manifestations occur in many primary systemic vasculitides, including PAN and IgAV, but are more frequently severe and the source of permanent damage in AAV.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Prognosis of patients with systemic necrotizing vasculitides has been markedly improved during the last 2 decades. However, infectious complications remain a major cause of morbidity and mortality. In majority of therapeutic studies on systemic vasculitides, number of patients is estimated to assess treatment efficacy and not tolerance. The aim of this study is to describe and analyse infectious complications in patients with systemic necrotizing vasculitides.

### **Methods:**

Data from 5 prospective, randomized, controlled trials conducted by the French Vasculitis Study Group (FVSG) (CHUSPAN 1, CHUSPAN 2, WEGENT, CORTAGE, MAINRITSAN), were pooled and analysed. These studies evaluated therapeutic strategy for the treatment of polyarteritis nodosa (PAN), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA). Primary endpoint of this study was the occurrence of a severe infection, defined by the need of a hospitalization, intravenous treatment or leading to death.

### **Results:**

Seven hundred and thirty-three patients were included between 1993 and 2012, including 398 men (54.3%), with a median age of 60 years old (IQR 47-70). Vasculitis diagnoses were MPA in 231 (31.5%) patients, GPA in 226 (30.8%), EGPA in 186 (25.4%) and PAN in 85 (11.6%). Five Factor Score was greater than or equal to 1 in 289 patients (39.4%), and median Birmingham Vasculitis Activity Score at inclusion was 4.5 (0-14).

After a median follow-up of 5.2 years (IQR 3-9.7), 269 (36.7%) patients experienced 431 infections, among which 148 (20.2%) patients having 174 severe infections, including 84 (48.3%) bronchopulmonary infections, among which 2 aspergillosis and 2 nocardiosis, 28 (16.1%) gastrointestinal infections, 12 (6.9%) urinary infections, 11 (6.3%) septicemias, 11 (6.3%) cutaneous infections, 7 (4%) ENT infections, 6 zoster infections (3.4%), 2 *Candida oesophagitis* (1.1%), 2 endocarditis (1.1%) and 1 malignant anguillulosis (0.6%).

Proportion of patients with severe infection remained stable over time. All patients developing at least one severe infection (n=148) received glucocorticoids, including pulses of methylprednisolone initially in 68 (45.9%) patients. Median glucocorticoid dose at the time of severe infection was 10 mg/day (IQR 5-25.8). Fifty-five percent of patients were also receiving immunosuppressive agents: including cyclophosphamide (16.9%), azathioprine (14.8%), rituximab (10.6%) or methotrexate (8.5%).

Median time from treatment initiation to first severe infection was 14.5 months (IQR 4.1-55.1). Finally, 22 severe infections directly led to death, representing 19.3% of all causes of death.

Statistical analysis of variables associated with severe infections is ongoing in order to identify high-risk patients.

### Conclusion:

Severe infections are a frequent adverse in systemic necrotizing vasculitides, mostly occurring after 12 months, and with a substantial impact on morbidity and mortality. These findings highlight the need for better preventive measures in these immunocompromised patients. Statistical analysis will enable us to identify patients at risk of severe infections.

## Onco-Hematological Malignancies in Systemic Necrotizing Vasculitides: Pooled Analysis of Five Prospective, Randomized, Controlled Trials

**Lafarge Antoine**<sup>1</sup>, Christian Pagnoux<sup>2</sup>, Xavier Puéchal<sup>3</sup>, Maxime Samson<sup>4</sup>, Mohamed Hamidou<sup>5</sup>, Alexandre Karras<sup>6</sup>, Thomas Quémeneur<sup>7</sup>, Matthieu Groh<sup>8</sup>, Luc Mouthon<sup>9</sup>, Loïc Guillevin for the French Vasculitis Study Group<sup>3</sup> and Benjamin Terrier<sup>10</sup>, <sup>1</sup>Medecine Interne, Hôpital Cochin, Paris, France, <sup>2</sup>Mount Sinai Hospital, Toronto, ON, Canada, <sup>3</sup>Service de Médecine Interne, Centre de Référence Maladies Auto-Immunes et Auto-Inflammatoires Systémiques Rares, Hôpital Cochin, Paris, France, <sup>4</sup>Department of Internal Medicine and Clinical Immunology, Hôpital François Mitterrand, CHU de Dijon, Dijon, France, <sup>5</sup>Medecine Interne, CHU Hôtel Dieu, Nantes, France, <sup>6</sup>nephrology, HEGP, Paris, France, <sup>7</sup>Service de néphrologie, médecine interne et vasculaire, Hôpital de Valenciennes, Valenciennes, France, <sup>8</sup>National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP-HP, Université Paris Descartes, Paris, France, <sup>9</sup>Université Paris Descartes Sorbonne Paris, Paris, France, <sup>10</sup>Internal Medicine, Cochin University Hospital, Paris, France

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Background/Purpose:**

The use of long-term immunosuppressive agents in patients with systemic necrotizing vasculitides has dramatically improved the overall prognosis, but expose patients to potential severe adverse events. Also, pro-oncogenic effects of these drugs have been previously showed, but data on onco-hematological malignancies in this patient population are scarce. The aim of this study is to describe and analyse solid cancers and malignant hemopathies in patients with systemic necrotizing vasculitides.

**Methods:**

Data from 5 prospective, randomized, controlled trials conducted by the French Vasculitis Study Group (FVSG) (CHUSPAN 1, CHUSPAN 2, WEGENT, CORTAGE, MAINRITSAN), were pooled and analysed. These studies evaluated therapeutic strategy for the treatment of polyarteritis nodosa (PAN), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA). Primary endpoint of this study was the occurrence of a solid cancer or a malignant hemopathy.

**Results:**

Seven hundred and thirty-three patients were included between 1993 and 2012, including 398 men (54.3%), with a median age of 60 years old (IQR 47-70). Vasculitis diagnoses were MPA in 231 (31.5%) patients, GPA in 226 (30.8%), GEPA in 186 (25.4%) and PAN in 85 (11.6%).

After a median follow-up of 5.2 years (IQR 3-9.7), 39 (5.3%) patients developed an onco-hematological complication, including solid cancer in 34 (4.6%) cases and malignant hemopathy in 5 (0.7%). Solid cancers included gastrointestinal cancers in 9 (26.5%), skin cancers in 8 (23.5%), pulmonary cancers in 6 (17.7%), urinary tract cancers in 5 (14.7%), gynecologic cancers in 4 (11.8%), and cerebral tumor and metastatic cancer of unknown origin in 1 (2.9%) case each. In one-third of patients, synchronous metastases were present at cancer diagnosis. Malignant hemopathies included myelodysplastic syndrome in 2 cases, and multiple myeloma, myeloproliferative syndrome and kidney lymphoma in 1 case each. Proportion of patients experiencing onco-hematological complications decreased over time: 7.7% for patients included between 1993-1999, 6.3% between 2000-2005 and 3% between 2006-2012. Immunosuppressive agents that patients received prior the occurrence of solid cancer or malignant hemopathy were cyclophosphamide in 26 (66.7%), azathioprine in 18 (46.2%), methotrexate in 10 (25.6%), and mycophenolate mofetil and rituximab in 3 (7.7%) cases each.

Median time from treatment initiation to onco-hematological malignancies was 4.1 years (IQR 1.4-7.9). Finally, 19/39 patients died because of their onco-hematological complications, representing 16.7% of all causes of death.

**Conclusion:**

Onco-hematological complications represent a rare complication in systemic necrotizing vasculitides with a decreasing frequency over the last decades. These complications occur lately after vasculitis diagnosis, stressing the importance of thinking about it in patients in remission. Although rare, onco-hematological complications account for almost 20% of causes of deaths. Statistical analysis will enable us to identify patients at risk of such complications.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although cyclophosphamide (CFA) remain the cornerstone for treatment of patients with severe manifestations of systemic autoimmune diseases, the knowledge about the effect of CFA on circulating cell populations in these diseases is limited.

**Objectives:** To investigate the effect of CFA administration on circulating immune cell subpopulations in patients with vasculitis and autoimmune systemic diseases.

**Methods:** We analysed major immune cell populations in peripheral blood (PB) from 13 patients (vasculitis n=7; autoimmune systemic diseases n=6). Paired samples from each patient were analysed before CFA administration, and after one and six months' follow-up. Using 6-colour flow cytometer (BD FACSCanto II) we characterized T lymphocytes (CD3, CD4, CD8, CD25, CD127, HLA-DR), B lymphocytes (CD19, CD20, CD27, HLA-DR), NK cells (CD3, CD16, CD56, CD69), neutrophils (CD15, CD11b, CD16, CD54, CD62L, CD64), and monocytes (CD11b, CD14, CD16, CD64, HLA-DR). Statistics was done by software GraphPad Prism.

**Results:** After single dose of CFA, the percentage of CD69+ NK cells increased and CD4+/CD8+ ratio decreased compared with their percentage before administration ( $P=0.01$ ;  $P=0.03$ , respectively). After six months of CFA administration, decreased percentage of activation marker HLA-DR on CD4+ cells ( $P=0.004$ ), decreased percentage of CD19+ B cells ( $P=0.04$ ) and increased percentage of activation marker CD69 on NK cells ( $P=0.004$ ) was observed comparing with paired samples obtained before CFA therapy. Different patterns were observed in subgroups of patients with vasculitis and autoimmune systemic diseases. Clinical evaluation of treatment response and observed changes in immune cell populations in individual patients is ongoing.

**Conclusion:** In our patients, CFA therapy resulted in changes of activation markers on CD4+, CD8+, B and NK cells, as well as neutrophils. Further investigation of selected markers may lead to identification of new biomarkers for prediction of the treatment effectiveness.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Cryoglobulinemic vasculitis (CV) is an extrahepatic manifestation of chronic HCV infection. It varies in severity from mild to life threatening. Some but not all patients with HCV infection and CV harbor B cell clonal expansions that are somatically hypermutated and show features of an antigen-driven response, with IgM+CD27+ B cell subset overrepresentation of V<sub>H</sub>1-69 and V<sub>κ</sub>3-20 variable genes that encode RFs of the Wa cross-reactive idiotype, Rearrangement of the *bcl-2* gene via a t(14:18) translocation has also been observed.

To begin to determine mechanisms underlying B cell derangement during chronic HCV infection we assessed the variability of decline rate of rheumatoid factor (RF) levels in HCV infected patients treated with interferon free DAA therapy.

### **Methods:**

130 Chronic HCV infected participants undergoing IFN free HCV therapy (Sofosbuvir/ledipasvir for 8 weeks or Sofosbuvir/Ledipasvir/Ribavirin for 12 weeks) were enrolled from the Cleveland VA . They had chronic HCV infection (>6 months seropositive and RNA positive) with absence of serum Hepatitis B surface antigen and HIV antibody, and they were treated with IFN free DAA HCV. Serum IgM RF and soluble CD14 (sCD14) were determined by ELISA.

After identifying 44 RF+ participants, we measured RF levels longitudinally in 44 RF+, 6 RF intermediate, and 3 RF- participants at weeks 0, 4, 8, 12 and 20-24 after initiating curative IFN free DAA HCV therapy, and clinical parameters correlating with RF decline were evaluated.

### **Results:**

All participants achieved a sustained virologic response at week 12 after therapy cessation (SVR12), and all also achieved a SVR24. After DAA therapy initiation, all RF- and RF intermediate participants remained RF- and intermediate respectively. 100%, 73%, 80% and 69% of RF+ participants remained RF+ at weeks 0, 4, 8 and 20-24. 10% of these had no evidence of declining RF level, while RF decline rate appeared similar between those that remained RF positive and those that became RF negative at the completion of the study. Before therapy RF level was associated with albumin level after completion of therapy ( $r=0.417$   $p=0.013$ ), and albumin level after completion of therapy was also associated with RF decline magnitude ( $r=0.504$ ,  $p=0.002$ ). Additionally, baseline sCD14 was correlated with week 4 RF level ( $r=0.654$   $p=0.002$ ), thus factors that induce Kupffer cell production of sCD14 may also participate in hepatic support for RF production.

## Conclusion:

These data indicate wide variability in RF decline rate, and provide support for a model where factors other than HCV itself participate in determining RF level during chronic active HCV infection, as well as RF decline during IFN free DAA therapy. Further definition of factors contributing to persistence of RF may help guide therapeutic approaches for HCV associated cryoglobulinemic vasculitis.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Polyarteritis Nodosa (PAN) is a rare subgroup of the primary vasculitides. There are only two published cohorts describing demographic and clinical features of the disease. Furthermore, various subgroups of PAN have been described, such as hepatitis B virus (HBV)-related, cutaneous and monogenic forms. There is a paucity of information on the current phenotypes and geographic differences of PAN. This study aimed to compare disease characteristics between PAN cohorts from the UK and Turkey (TR).

**Methods:** A retrospective survey of databases from two vasculitis centres between 1990-2016 for PAN patients fulfilling the EMEA Vasculitis Classification algorithm. All paediatric-onset adult patients met the Ankara 2008 (EULAR/PReS endorsed) criteria for childhood PAN. Patients with typical angiographic and/or histopathologic findings consistent with PAN were included. We evaluated demographics, organ involvement, treatment, patient survival and time to first relapse

**Results:** 93 (M/F: 51/42) patients (UK: 47, TR: 46) were included in the study. Median age at disease onset was 36.0 (20.0-49.8) years. Three were HBV-related, 20 (21.5%) had paediatric onset and 16 (16.5%) had cutaneous PAN. TR patients had younger age of disease onset ( $p=0.002$ ). Twelve (26%) of TR patients had a monogenic form of disease (Familial Mediterranean Fever association in seven, deficiency of adenosine deaminase 2, DADA2, in five). Cutaneous PAN was more frequent in the UK (12 vs. four patients,  $p=0.031$ ) whereas renal involvement was higher in the TR group (76.1% vs. 40.4%,  $p<0.001$ ). Further analyses showed female predominance in cutaneous PAN when compared to systemic involvement (68.8% vs. 40.3%  $p=0.037$ ). No difference was found in phenotype between paediatric and adult onset patients except frequency of cutaneous lesions (100% vs. 64.3%,  $p=0.002$ ). In both cohorts, most patients received a combination of glucocorticoids and cyclophosphamide. During a median 67.5 (32-126) months follow up, 13 patients died (12.7% in the UK vs. 15.2% in TR cohorts). No difference was found between the two cohorts in relation to relapse rate, death and vasculitis damage index. Five factor score was significantly related to mortality ( $p=0.019$ ).

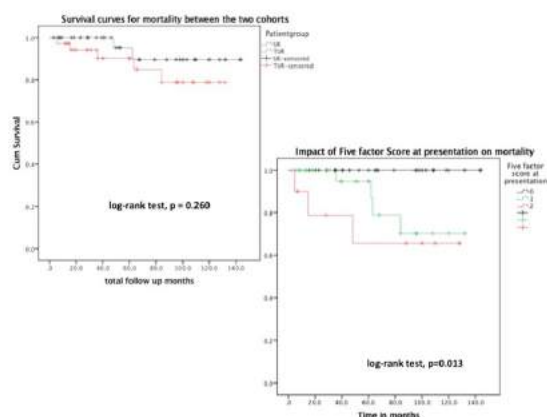

**Conclusion:** This is the largest study defining diagnoses of PAN according to the EMEA algorithm. The TR group had a younger age of disease onset and more cases of monogenic disease; however disease extent, relapse rate, damage index and death rates were similar between groups.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent studies highlight the usefulness and necessity of biologic agents in the treatment of primary vasculitides. Evidence for the use of biologics in PAN is limited. Objective is to study clinical features and treatment responses of PAN patients needing biologic therapy.

**Methods:** A retrospective survey of databases from two vasculitis centres (Addenbrooke's hospital in the UK & Hacettepe University, Turkey) between 1990-2016 for PAN patients fulfilling the EMEA Vasculitis Classification algorithm was done. Hepatitis B related PAN patients were excluded (n=3). Previous therapies including biologics were recorded. Response to therapy was determined according to the documentation by physicians.

**Results:** 90 (M/F: 48/42) patients (UK: 45, TR: 45) were included in the study. 16 patients had cutaneous PAN and 12 of the TR patients had a monogenic form of disease (Familial Mediterranean Fever: 7 patients, deficiency of adenosine deaminase 2, DADA2: 5 patients). During a median follow up of 79 (35.5-128) months, 28 patients (31.1%) (8 from TR, 20 from the UK,  $p = 0.004$ ) were exposed to biologics. Seven of them had more than one biologic. Four of the 16 cutaneous PAN (25%) and 24 of the 74 systemic PAN (32.4%) patients received biologics ( $p=0.684$ ). Except for one patient with cutaneous PAN, all patients had corticosteroids and cyclophosphamide before biologics.

In patients with cutaneous PAN; RTX was used in two patients (one had good response), CAMPATH in two patients (one with no response), Infliximab (IFX) in one patient (with good response).

RTX and IFX were the most commonly used agents in systemic PAN patients. Complete or partial response was observed in more than half of the patients. Etanercept (ETN) was used in 5 patients; of the 4 patients with DADA2 three responded well, one had partial response and one patient did not respond. Adalimumab was used in two patients but was prematurely stopped in both cases due to serious infection. Interferon alpha was used in two patients and resulted in good response in both. TCZ was used in one patient without any benefit. Distribution of biologics used in patients with systemic PAN is shown in Table.

Response could not be evaluated in 6 patients; due to missing data of two patients, and short duration usage in 4 patients (withdrawal due to adverse effects: 3). Biologics were stopped in four of the patients; due to severe infections in three and anaphylactic reaction in one.

**Conclusion:** There is an unmet need to establish evidence for biologics in the treatment of PAN as 30 per cent of the patients in this study needed escalation in therapy to biologics. The experiences of RTX and IFX has been mixed with some very good responses and some not responses. Patients with DADA2 responded well to ETN. This probably reflects the fact that PAN is a more heterogeneous condition in terms of genetic background and clinical course.

**Table.** Distribution of biologics used in patients with systemic PAN

Type of biologics and number of patients	Good response	Partial response	No response	Response not evaluated
Rituximab (n=9)	4	0	3	2
Infliximab (n=9)	3	1	2	1
Etanercept (n=5)	3*	1*	1	
CAMPATH (n=2)			2	
Adalimumab (n=2)				2
Interferon Alpha 2 (n=2)				
Tocilizumab (n=1)			1*	

\*: Patients with DADA2

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Anti-TNF treatment has been shown to be effective in inducing complete remission in many Behcet's disease (BD) patients with eye, large vessel, intestine and central nervous system involvement, but data on patients' outcomes after their discontinuation are currently lacking. We examined whether remission of BD with severe vital organ involvement is maintained after withdrawal of successful anti-TNF treatment.

### Methods:

In this retrospective longitudinal outcome study we examined the records of all patients with BD who have been followed up in our center at least once yearly since 2000. The final follow-up visit and review of flow-charts was conducted during the first trimester of 2017. Patients eligible for the study's analysis were those who, a) achieved complete and sustained remission during long-term anti-TNF treatment given for refractory to conventional immunosuppressive therapy disease, b) discontinued anti-TNF treatment at some point, and, c) were followed-up at least 3 years after discontinuation. The study's endpoint was the proportion of patients achieving complete remission of BD, sustained for at least 3 years after withdrawal of the anti-TNF agent.

**Results:** Of our BD cohort comprising 87 patients, 29 were eligible for analysis (median anti-TNF treatment of 2 years, IQR 1.1-2.0). Of them, 12 (41%) achieved the study's end-point. The remaining patients relapsed within 1 year (median, IQR 0.6-1.5) after discontinuation. Re-treatment with anti-TNF was safe and effective in the long-term in 14/17 (82%); 4 of them have also achieved the study's end-point, so far. Overall, 16/29 patients (55%) remain currently in complete remission lasting for a median of 6.5 years (IQR 5.5-8); 34% are any drug-free, all treated with anti-TNF mainly for sight-threatening disease, and 21% are on low-dose maintenance with azathioprine only, treated initially with anti-TNF for ocular (n=4), intestinal and central nervous system involvement. Notably, patients remaining in drug-free remission were younger ( $p<0.03$ ) and had shorter ( $p<0.03$ ) BD duration at anti-TNF treatment initiation than patients on azathioprine maintenance.

### Conclusion:

Drug-free, long-term remission after withdrawal of successful anti-TNF treatment is feasible in patients with severe BD. Since an anti-TNF-induced 'cure' cannot be differentiated from a spontaneous remission by natural history, prospective studies should examine whether anti-TNF should be used first-line for remission induction in every patient with vital organ involvement.

## Prevalence of Vasculitides As Extraintestinal Manifestation of Inflammatory Bowel Disease (IBD)

**Sarah Iftekar**<sup>1</sup>, Jason Springer<sup>2</sup> and Mehrdad Maz<sup>3</sup>, <sup>1</sup>Department of Medicine, Division of Allergy, Clinical Immunology and Rheumatology, University of Kansas Medical Center, Kansas City, KS, <sup>2</sup>Department of Internal Medicine, Division of Allergy, Clinical Immunology, & Rheumatology, Kansas University Medical Center, Kansas City, KS, <sup>3</sup>Allergy, Clinical Immunology, and Rheumatology, Division of Allergy, Clinical Immunology and Rheumatology, Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The extraintestinal manifestations of Inflammatory Bowel Disease (IBD) are identified in 6%-40% of patients. Systemic vasculitides may present as extraintestinal manifestations of IBD. The purpose of this study was to determine the frequency of vasculitides (large, medium or small vessel) in a cohort of patients with IBD.

**Methods:** This is a retrospective chart review of patients from 12/2006 to 12/2016 at a single tertiary medical center. A cohort of patients with diagnosis codes for inflammatory bowel disease including Crohn's disease (CD), Ulcerative colitis (UC) and Microscopic colitis (MC) was identified. Patients with vasculitides including giant cell arteritis (GCA), Takayasu's arteritis (TA), PAN, aortitis, ANCA associated vasculitis, GPA, MPA, EGPA, CNS vasculitis, cryoglobulinemic vasculitis, cutaneous vasculitis, Leukocytoclastic vasculitis (LCV), Pulmonary vasculitis, Rheumatoid vasculitis, small vessel vasculitis (SVV), and retinal vasculitis were identified. One sided student's t-tests were used for statistical analysis.

**Results:** An EMR query yielded a total of 1686 patients, of whom 913 patients were diagnosed with CD, 695 with UC and 78 with MC. A search for a concomitant diagnosis code for vasculitis yielded 10 patients (10/1687=0.59%). Of the 10 patients, 6 had CD (60%), 3 had UC (30%) and 1 had MC (10%). Both genders had equal representation. The mean age at diagnosis of IBD was 29.4 years with males being diagnosed at a younger age; 26.8 vs 32 years (p=0.28). Vasculitis presented later, at a mean age of 42. The difference in the age at diagnosis of IBD and vasculitis was statistically significant overall (12.6 years; p=0.038). The most common extraintestinal manifestation of vasculitis was LCV (3, 30%) followed by SVV (2, 20%) and CNS vasculitis (2, 20%). Immunological evaluation did not reveal increased incidence of ANCA antibodies (table 1). Only 3 patients (30%) were ANCA positive, 5 were ANCA negative and data was missing for 2 patients. In this cohort of patients with IBD about 0.6% developed vasculitis with an estimated prevalence of extraintestinal manifestations of vasculitis of 590 per 100,000 which is higher compared to reported prevalence rates of vasculitides such as GPA and GCA which have a prevalence of 13.5 and 278 per 100,000 based on population studies in the UK and Minnesota, USA respectively.

**Conclusion:** In this cohort of patients with IBD, a small percentage of patients developed vasculitis. However, in the majority of cases vasculitis was diagnosed after the onset of IBD suggesting that vasculitis may be secondary to IBD or IBD-related treatments.

Table 1: Clinical characteristics of patients with IBD and vasculitis

Gender	IBD	Age at diagnosis of IBD (years)	Biopsy proven IBD	Extra intestinal vasculitic manifestation	Age at diagnosis of vasculitis (years)	Biopsy proven vasculitis	Presence of ANCA Antibody	Medications used for treatment of IBD and vasculitis

### Background/Purpose:

Behcet's disease (BD) is a chronic inflammatory disease of unknown etiology, characterized by recurrent oral and genital ulcers, skin lesions, uveitis, and arthritis. It is regarded as vasculitis and anti-endothelial cell antibodies are found in BD. One of the endothelial cell antibodies was reported to recognize alpha-enolase and serum IgM anti-alpha-enolase antibody (AEA) was associated with involvement of the vascular system in BD in previous study. This study was aimed

to investigate expression of alpha-enolase in the surface of peripheral blood cells and serum IgM or IgG AEA, and their association with clinical manifestations or disease activity of BD.

### Methods:

Cell surface alpha-enolase expression was examined from several cell types of peripheral blood, including lymphocytes, monocytes, and granulocytes using flow cytometry in patients with BD and healthy controls (HCs). Serum AEA levels were measured by enzyme-linked immunosorbent assay (ELISA) in 110 BD patients and age/sex matched 110 HCs. Association of alpha-enolase or AEA with clinical manifestation was analyzed.

### Results:

The frequency of surface alpha-enolase-expressing cells was increased in BD in lymphocytes and monocytes. Serum IgG AEA levels were increased in BD patients (median [IQR], 0.360 [0.268-0.482],  $p < 0.0001$ ), particularly in active patients (BDCAF  $\geq 2$ ) (0.375 [0.274-0.537],  $p < 0.0001$ ) compared to HCs (0.274 [0.231-0.357]). The levels of IgG AEA were correlated with the number of oral ulcer, ESR, and CRP. There was no difference of IgM AEA in sera from BD compared to HCs (0.538 [0.351-0.763] vs. 0.504 [0.344-0.823],  $p = 0.764$ ) and no association of AEA levels and clinical manifestations in patients with BD.

### Conclusion:

Serum IgG AEA was increased in BD patients and correlated with oral ulcer, ESR and CRP.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cyclophosphamide (CYC) remains an important treatment option for Behçet's syndrome (BS) pts with life threatening conditions such as arterial aneurysms. However, several adverse events are associated with CYC

treatment and this has led to increased use of biologic agents such as rituximab in other vasculitides. The aim of this study is to survey the outcome and short and long term adverse events with CYC use among BS pts.

**Methods:** We conducted a retrospective chart review of all BS patients treated with oral or intravenous CYC between 1972 and 2006. Patients were called and a standard form was used for collecting demographic characteristics, indication for CYC use, the reason for the cessation of therapy, cumulative dose of CYC, short and long term adverse events and outcome.

**Results:** We evaluated 99 pts who had an available contact information. After a median follow up of 18 (12-26) yrs after the initiation of CYC therapy, 27 pts had died within a median follow-up of 4 (0-10) yrs, 13 were lost after a median follow-up of 2.5 (0-11) yrs, and 59 were reached. CYC was prescribed for vascular involvement in 62 pts, eye involvement in 24, central nervous system involvement in 2, both vascular and eye involvement in 8 and both vascular and central nervous system involvement in 2. The median duration of CYC use and cumulative dose of CYC were 16 (6-63) gr and 12 (3-26) mo respectively. The reasons for death among the pts were shown in Table.

Twelve pts experienced serious adverse events associated with short term CYC use and 1 of them died due to infection. Among these adverse events, hemorrhagic cystitis occurred in 3 pts, infections in 5, ischemic stroke, acute myocardial infarction, anaphylactic reaction and grand mal epileptic seizure in 1 patient each. CYC treatment was terminated due to refractory disease in 30 pts and adverse events in 13. CYC induction was completed with beneficial results in the remaining 56 pts. During long term follow-up, malignancies and/or cardiovascular disease occurred in 27% of the pts. Overall, 9 malignancies were observed in 8 pts after a median follow up of 20 (12-25) yrs. The malignancies were t-MDS-AML, bladder carcinoma (n=2), lymphoma (n=2), HCC, colon adenocarcinoma, squamous cell carcinoma and prostate adenocarcinoma. Sixteen pts had cardiovascular disease and 3 had stroke.

**Conclusion:** CYC treatment was effective in about half of the pts. Serious adverse events including infections and malignancies occurred in 12% of the pts during CYC treatment and malignancies and cardiovascular events in 27% of the pts during long term follow-up. Other immunosuppressives used by these pts may also have contributed to these results and concomitant use of high dose corticosteroids may be responsible for the cardiovascular events. These results underline the need for safer and effective alternatives to CYC for serious organ involvement in BS, similar to that in other vasculitides.

Table. The reasons for death in 27 of the surveyed 99 BS patients treated with cyclophosphamide

Cause of death	n
Vascular involvement	12
Pulmonary artery aneurysm	7
Abdominal aorta aneurysm	2
Budd-Chiari syndrome	3
Malignancy	3
t-MDS/AML	1
Hepatocellular carcinoma	1
SVCT due to high grade lymphoma	1
Infection	4
Pneumonia	3
Tuberculosis	1
Ischemic stroke	1
Traffic accident	1
Unknown	6

SVCT: superior vena cava thrombosis; t-MDS/AML: therapy related myelodysplastic syndrome-acute myeloid leukemia

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Immunogenicity of anti-TNFs has been recognized as an important problem that may cause loss of response and adverse events such as infusion reactions. We aimed to investigate the prevalence of anti-drug antibodies against infliximab (IFX) in patients with Behçet's syndrome (BS) together with controls.

### **Methods:**

We collected serum samples from 66 consecutive BS patients (51 M, 15 F and mean age 37±9 years) who were receiving IFX. IFX was used for severe eye involvement in 43, vascular involvement in 12, nervous system involvement in 8 and arthritis in 2 patients. Additionally, 53 ankylosing spondylitis (AS), 25 Crohn's disease (CD) and 27 rheumatoid arthritis (RA) patients, and 31 healthy subjects were included as controls. We included patients who had received at least 4 cycles of IFX. Samples were collected just before an infusion, stored at -80° C until analysis, and serum IFX trough levels and anti-IFX antibodies were measured by ELISA at the same time. We reviewed the charts of these patients regarding demographic and clinical characteristics, concomitant DMARDs, the number of IFX treatment cycles, responsiveness to IFX and allergic reactions. We used a cut-off value of 0.5 µg/mL for serum IFX trough level, extrapolating from RA studies. After serum sampling, we continued to follow up patients regarding allergic reactions and treatment efficacy.

### **Results:**

Anti-IFX antibodies were detected in 4 (6%) BS, 5 (18.5%) RA, 3 (12%) CD, and 1 (%2) AS patient, and in none of the healthy subjects. The mean number of IFX cycles was 19±14 in BS, 21±13 in RA, 19±21 in CD, and 33±18 in AS patients. During follow up, 2/4 BS patients with anti-IFX antibodies had flares. Allergic reactions occurred in 9 (14%)

BS, 6 (22%) RA, 5 (20%) CD, and 4 (7.5%) AS patients. 3/5 RA patients and 3/3 CD patients who experienced an allergic reaction had anti-IFX antibodies whereas none of BS and AS patients did.

Concomitant DMARDs were used in 46 (74%) BS, 17 (67%) RA, 22 (84%) CD, and 7 (13%) AS patients. Overall, 6 (46%) patients with anti-IFX antibodies were not on DMARDs. The median serum IFX trough level was significantly lower in patients with anti-IFX antibodies compared to those without antibodies (0.17 (IQR: 0.08-0.28) vs 0.12 (IQR: 0.03-1.18;  $p=0.042$ ). The serum IFX trough level was lower than the cut off value in all of the 13 patients with anti-IFX antibodies and in 89% of patients without anti-IFX antibodies ( $p=0.64$ ).

We were able to get samples before at least 2 consecutive infusions in 27 BS patients and the presence of anti-IFX antibodies was consistent across the samples in all of these patients. We were able to get samples before the infusion and at week 2 in 5 BS patients. Serum IFX level was below 0.5  $\mu\text{g/mL}$  before IFX and above 0.5  $\mu\text{g/mL}$  at week 2 in all of these 5 patients.

### Conclusion:

BS patients had a lower frequency of anti-IFX antibodies compared to RA and CD patients and similar to AS patients. This might be related to the similar comparative low B cell activity in these 2 conditions. Due to the small number of BS patients with anti-IFX antibodies, we could not conclude on the effect of immunogenicity on the treatment response. The low serum IFX levels even in patients without anti-IFX antibodies and good drug response deserves further attention.

## Four-Distinct Phenotypes of Patients with Necrotizing Arteritis of Medium and Small Arteries

Tsuyoshi Shirai<sup>1</sup>, Hiroshi Fujii<sup>1</sup>, Yoko Fujita<sup>2</sup>, Yuko Shirota<sup>1</sup>, Tomonori Ishii<sup>1</sup> and Hideo Harigae<sup>1</sup>, <sup>1</sup>Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, <sup>2</sup>Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Polyarteritis nodosa (PAN) is a necrotizing arteritis of medium and small arteries. PAN is divided into systemic and cutaneous PAN (cPAN). cPAN can be further classified into mild cPAN or severe cPAN in which ulcer, necrosis, or neuritis is observed. However, it is sometimes difficult to set a boundary between severe cPAN and systemic PAN, and their optimal treatments are still unclear. The aim of this study is to evaluate clinical characteristics of patients with necrotizing arteritis of medium and small arteries.

**Methods:** 50 patients who were diagnosed as necrotizing arteritis of medium and small arteries without glomerulonephritis or vasculitis in arterioles, capillaries, or venules during 2008-2016 in our institution were enrolled to this study. Clinical backgrounds, symptoms, laboratory findings including inflammatory markers and antineutrophil

cytoplasmic antibodies (ANCA), affected organs, treatments, and the rates of relapse and death were retrospectively evaluated.

**Results:** Among 50 patients with necrotizing arteritis of medium and small arteries, 39 patients were classified as cPAN (mild, 18; ulcer or necrosis, 8; neuritis, 9; both, 4), and 11 cases manifested systemic vasculitis. One case of cPAN developed renal involvement. Clinical characteristics of mild cPAN included female predominance (94.4%) and younger age (median, 33), while severe cPAN and systemic type had no sex difference. The characteristics of systemic type included older age (median, 69), general symptoms, higher levels of inflammatory markers, lower levels of serum proteins, and organ damages. Severe cPAN manifested intermediate phenotypes. The positivity of autoantibodies in cPAN was about 30 %, while 81.8 % of systemic type possessed some autoantibodies. Particularly, 54.5 % of systemic type possessed myeloperoxidase (MPO)-ANCA though the titers were significantly lower than those of microscopic polyangiitis, suggesting non-specific elevation of MPO-ANCA in Japanese population. The median doses of PSL for mild cPAN, severe cPAN, and systemic type were 20, 40, 40 mg/day, respectively. Immunosuppressants were used in 20% of mild cPAN, 90% of severe cPAN, and 73% of systemic type. Although the mortality rates were indistinguishable, the relapse rates of cPAN with ulcer or necrosis were significantly higher than other types ( $p=0.0032$ , figure 1).

**Conclusion:** 22% of patients with necrotizing arteritis of medium and small arteries presented systemic vasculitis. The clinical characteristics of mild cPAN, cPAN with ulcer or necrosis, cPAN with neuritis, and systemic vasculitis were distinct from each other, suggesting that they should be managed differently. Particularly, cPAN with ulcer or necrosis showed high relapse rates, indicating unmet need to establish adequate treatments such as rituximab.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The diagnosis of Behçet's disease (BD) is mainly based on clinical manifestations and remains a challenge in clinical practice, due to the fact that there are no diagnostic biomarkers available currently. Recently metabolomics has been applied in discovering and validating biomarkers of inflammatory diseases. This study aims to identify serum metabolites associated with BD and to search for the metabolites responsive to treatment using metabolomics approach.

**Methods:** Medical records and serum samples of 24 pre-treated BD patients (15 men and 9 women) and 12 post-treated patients were collected. . Serums from 25 gender- and age-matched healthy volunteers were also collected.

Metabolomics and lipidomics profiling were carried out by using UPLC-QTOFMS and UPLC-QTOFMS<sup>E</sup> respectively. Raw mass spectrometric data were processed using Progenesis QI software. Statistical analysis and putative ion identification on the post-processed data were conducted utilizing MetaboLyzer.

**Results:** Unsupervised principal component analysis (PCA) plots of the lipidomics and metabolomics data showed clear separation of profiles from BD patients and healthy controls. Statistical analysis of the data revealed statistically differential metabolites between BD patients and healthy controls. Identification of selected metabolites was confirmed by comparing MS/MS fragmentation pattern with authentic standards. The serum levels of several phosphatidylcholines (PCs) were found significantly lower in BD patients compared to healthy controls. We also observed a marked increased levels of polyunsaturated fatty acids (PUFAs) including two omega-6 fatty acids, linoleic acid and arachidonic acid, and oleic acid, a n-9 PUFA in BD patients compared with those in the healthy control group. It is of interest to note that treatment recovered two omega-6 fatty acids (linoleic acid and arachidonic acid) but not the other differential metabolites.

**Conclusion:** Our study shows altered serum metabolomics profile in BD patients and suggests that levels of PCs, and PUFAs may be indicative in the diagnosis of BD. Two omega-6 fatty acids, linoleic acid and arachidonic acid, may provide insights for therapeutic effects.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

To report the efficacy and safety of tocilizumab(TCZ) for the treatment of severe and/or refractory Behçet's disease(BD).

### **Methods:**

We retrospectively analyzed the efficacy and safety profile of BD patients with severe and/or refractory BD treated with tocilizumab in our medical center between 2014 and 2017.

### **Results:**

Ten BD patients (9 male and 1 female) were enrolled, with a mean age and median course of  $34.6 \pm 8.6$  year and 80 month (range 35 to 132), respectively. Vascular, cardiac and neurological involvements were presented in 7, 2 and 1 patients, respectively. Of the seven vascular BD patients, pseudoaneurysms were presented in five patients, including one patients with recurrent venous thrombosis and arterial pseudoaneurysms, one patient with internal leakage after the stent placement of abdominal aortic pseudoaneurysm, one patient with coronary sinus rupture and pseudoaneurysm formation, two patients with aortic pseudoaneurysm and multiple artery stenosis or occlusion. Two patients with severe aortic regurgitation developed post-operative paravalvular leakage (PVL) after valve surgery. One neuro-BD patient presented with brainstem, spinal cord and peripheral involvements.

Prior to TCZ therapy, all patients experienced disease progression and elevated serum inflammation markers despite of high-dose glucocorticoids in combination with multiple immunosuppressants. They were then treated with TCZ, 8mg/kg every 4 weeks, in combination with background low- or medium-dose glucocorticoids and immunosuppressants, for a median of 6 (range 3-15) months.

After a median follow-up of 10 month (range 3 to 22), all patients achieved improvement both in clinical symptoms and serum inflammation markers (ESR and hsCRP). Vascular lesions were stable and no recurrent aneurysm was observed. No PVL were observed in both patients with valvular involvement after repeated surgery at 6 and 8 months, respectively. The neuro-BD patient achieved both clinical and imaging improvement. The corticosteroid dose was tapering in most cases, indicating a potential steroid-sparing effect. TCZ was well-tolerated and no serious adverse event was observed.

### **Conclusion:**

Our data suggest that TCZ is safe and effective for the treatment of patients with severe and / or refractory BD. Further controlled studies are warranted to confirm the therapeutic potential of TCZ in BD patients.

## Risk of Hospitalizations for Venous Thromboembolism Among Patients with Selected Systemic Vasculitides: A Nationwide Analysis

Yiming Luo<sup>1</sup>, Jiehui Xu<sup>2</sup>, Yumeng Wen<sup>1</sup>, Alvaro Ramos-Rodriguez<sup>1</sup>, Changchuan Jiang<sup>1</sup>, Shuyang Fang<sup>1</sup>, Mustafa Kagalwalla<sup>1</sup> and Neha Ohri<sup>3</sup>, <sup>1</sup>Department of Medicine, Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY, <sup>2</sup>Department of Biostatistics, Mailman School of Public Health, Columbia University Medical Center, New York, NY, <sup>3</sup>Division of Rheumatology, Department of Medicine, Mount Sinai St Luke's and Mount Sinai West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Vasculitis Poster III: Other Vasculitis Syndromes

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Venous thromboembolism (VTE) contributes significantly to in-hospital morbidity and mortality. Previous studies have suggested that certain vasculitides, including granulomatosis with polyangiitis (GPA) and giant cell arteritis (GCA) are associated with increased risk of VTE. However, there is mixed evidence in the literature about the risk of VTE in patients with polyarteritis nodosa (PAN) and Takayasu's arteritis (TA). Some of these studies were limited by not adjusting for common cofounders, in this case VTE risk factors. We sought to explore the association of VTE as primary reason for hospitalization in patients with GPA, GCA, PAN and TA using a national inpatient database.

### Methods:

We conducted a retrospective cross-sectional study using the National Inpatient Sample (NIS) database for the year 2014. Diagnoses were identified using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. Patients with a principal admission diagnosis of VTE and a secondary diagnosis of GPA, GCA, PAN and TA were included in the study. There were no exclusion criteria. Univariate and multivariate logistic regression models were used to adjust for potential confounders.

In this study, we adjusted for age, gender, race, length of stay and selected common risk factors for VTE such as active smoking, cancer, heart failure, stroke, sepsis, thrombophilia, obesity, nephrotic syndrome, inflammatory bowel disease, pregnancy, postpartum and long bone fracture.

### Results:

A total of 287,790 hospitalizations with a principal diagnosis of VTE were identified. Among this cohort, the number of hospitalizations with a secondary diagnosis of GPA, GCA, PAN and TA were 11,285, 16,480, 4,450 and 1,350, respectively. The unadjusted OR for a principal diagnosis of VTE and a secondary diagnosis of any of these four vasculitis reached statistical significance for GPA (OR 2.76, 95% CI 2.10 - 3.64,  $p < 0.001$ ), GCA (OR 2.45, 95% CI 1.91 - 3.13,  $P < 0.001$ ), PAN (OR 1.81, 95% CI 1.04 - 3.13,  $p = 0.035$ ). There was no difference for TA (OR 2.30, 95% CI 0.95 - 5.56,  $p = 0.065$ ). When adjusting for confounding variables, there was statistical significance for GPA (OR 2.54, 95% CI 1.90 - 3.40,  $p < 0.001$ ), GCA (OR 1.53, 95% CI 1.18 - 1.98,  $p = 0.001$ ) and TA (OR 2.46, 95% CI 1.01 - 5.97,  $p = 0.047$ ), though not for PAN (OR 1.47, 95% CI 0.83 - 2.60,  $p = 0.183$ ).

### Conclusion:

Our study suggests that GPA and GCA are independently associated with increased risk of hospitalizations for VTE, which is consistent with previously published studies in the literature. We found that PAN is associated with increased risk of VTE hospitalizations but is not considered an independent risk factor, which confers a possible explanation for the conflicting results in previous investigations. TA was associated with an increased risk of VTE after adjusting for confounders. Further studies are needed to clarify these relationships further.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Plenary Session III

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

Many rheumatoid arthritis (RA) patients continue to report pain despite excellent control of inflammation with immunotherapy regimes. Variable degrees of co-existing fibromyalgia (FM) may explain this disparity.

Patients diagnosed with FM are characterised by features of pain centralisation. For example they exhibit aberrant inter-regional brain communications, as measured by functional connectivity MRI (fcMRI). We and others have suggested that part of the neural signature for pain centralisation is enhanced connectivity between the insula (a region implicated in the affective processing of pain) and the Default Mode Network (DMN, a network related to self-referential thinking).

We hypothesised that RA patients reporting the highest 2011 ACR FM survey criteria scores - a continuous measure of FM degree also known as fibromyalgians (FMness) – would demonstrate fcMRI features of pain centralisation as observed in FM.

### Methods:

Consecutive clinic attending RA patients fulfilling ACR/EULAR 2012 criteria were recruited and underwent a 9min fcMRI brain scan. In addition, they undertook a clinical evaluation which included a measure of FMness (ACR FM survey criteria) and inflammation (CRP). Images were acquired by a 3 Tesla, 8 channel phased array head coil using a T2\*-weighted gradient-echo echo-planar imaging pulse sequence. FcMRI data were preprocessed and analyzed using SPM8, Conn and GIFT running on MATLAB 7.10. Group independent component analysis selected out the brain networks of interest (DMN, salience, dorsal attention, sensorimotor). Network to whole brain functional connectivity analyses were then conducted for each patient followed by group level multiple linear regression which correlated connectivity of each network to FMness. Finally, corrections for age, sex and CRP were applied. Analyses were significant on the cluster level with a false discovery rate p value <0.05 derived from an uncorrected voxel level p value <0.001.

### Results:

54 patients participated (mean age 54.9years; 75.9% female; mean disease duration 11.5 years; mean FMness score 13.3 [range 1-29]; mean DAS28 3.6 [range 1.5-6.4]). They demonstrated a significant (p=0.002) positive correlation between DMN connectivity to the left mid/posterior insula and FMness (r=0.55). This observation remained significant after adjusting for age, sex and CRP. No other significant functional connections were identified with the DMN or among the other selected networks.

### Conclusion:

Rheumatoid arthritis patients who report high levels of FMness appear to share neurobiological features with 'primary' FM patients. This study is the first to provide neuroimaging evidence that RA is a mixed pain state with a centralised pain component (which demands alternative therapeutic strategies to standard RA immunotherapies). The ACR FM survey appears to be a strong surrogate for neurobiological evidence of centralised pain and, in the future, could be a useful tool to support clinicians' evaluation of pain and subsequent personalised management.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Plenary Session III

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

Once ANCA-associated vasculitis (AAV) remission was obtained, rituximab (RTX) superiority to azathioprine (AZA) to maintain remission was shown.<sup>1</sup> In that study, at month 28, only 5% of RTX recipients vs 29% taking AZA suffered major relapses. However, at present, neither ANCA-positivity and/or titers (status) nor peripheral blood CD19 B-cell–detection are considered reliable AAV-relapse predictors. The MAINRITSAN2 trial (ClinicalTrials.gov, no. NCT01731561) was designed to evaluate RTX infusions individually tailored to ANCA status and/or circulating CD19 B-cell reappearance to maintain AAV remission.

### Methods:

Patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) in complete remission after induction therapy (glucocorticoids and cyclophosphamide, rituximab or methotrexate) were included in an open-label, multicenter, randomized–controlled trial to compare RTX regimens: given according to ANCA status and/or circulating CD19 B-cell reconstitution vs systematically infused (controls). The experimental arm received fixed, 500-mg RTX infusions on day-0 postrandomization, then every 3 months until month 18, when CD19 lymphocytes exceeded 0/mm<sup>3</sup> or ANCA status (reappearance)/titer (higher) differed from the previous determination. Controls received 500 mg of RTX on days 0 and 14 postrandomization, then 6, 12 and 18 months after the first infusion. The primary endpoint was the number of relapses (new or reappearing symptom or worsening disease with BVAS>0) at month 28, as assessed by an independent Adjudication Committee blinded to treatment arms.

**Results:** The 162 patients included [117 (72.2%) GPA and 45 (27.8%) MPA] were equally allocated to the experimental (n=81; 50%) and control (n=81; 50%) groups. Prerandomization induction therapy was cyclophosphamide for 100 (61.7%) patients, RTX for 61 (37.7%) or methotrexate for 1 (0.6%). Median RTX-infusion numbers were: 3 (interquartile range (IQR) 2–4) for the experimental arm and 5 (IQR 5–5) for controls. Twenty-one (13%) patients suffered 22 relapses: 14 (17.3%) in 13 experimental arm patients and 8 (9.9%) in 8 controls (P=0.22). The relapse-free-survival rate was 83.8% (95% confidence interval [CI], 76.1–92.3%) for the experimental arm and 86.4% (95% CI, 79.2–94.2) for controls (P=0.58). Twenty-six (32.1%) experimental arm patients experienced at least 1 severe adverse event vs 31 (38.3%) controls (P=0.51). Four patients died, 1 of an infectious complication. No association between ANCA status and/or circulating CD19 B cells and relapses was observed.

**Conclusion:** AAV-relapse rates for patients given individually tailored or systematic RTX-infusion schedules did not differ significantly. However, ANCA and circulating CD19 B cells could be considered useful tools to decide to reinfuse because they achieved lower RTX total doses (i.e., 3 vs 5 infusions) to prevent relapses in the experimental arm.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Plenary Session III

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Biologic DMARDs have varying mechanisms of action and may be associated with different infection risks. The perioperative time period is a particularly high-risk time for infections, which can carry significant morbidity. This study compared risk of post-operative infections after arthroplasty in patients with RA exposed to different biologic DMARDs or to methotrexate.

**Methods:** A retrospective cohort study using U.S. Medicare data from 2006-2014 evaluated adults with ≥ 2 ICD9 codes for RA undergoing elective inpatient primary or revision total knee or hip arthroplasty. Eligible patients received an infusion of infliximab, abatacept, or tocilizumab or prescription for adalimumab, or etanercept within 8 weeks, or a rituximab infusion within 16 weeks of surgery. Methotrexate treated patients with previous biologic treatment but no biologic within 6 months of surgery were also included. Patients with hip fracture, malignancy, pre-existing infection, or non-elective surgery (admission through the emergency department or as a hospital transfer) were excluded. Multivariable logistic or Cox regression evaluated associations between medication exposure and risk of 1) serious (hospitalized) infection within 30 days using a validated set of discharge diagnoses from inpatient discharge diagnoses and 2) rate of prosthetic joint infection (PJI, ICD9 996.66) within 1 year, adjusting for confounders.

**Results:** Among 8694 surgeries in 7831 patients, serious infection occurred in 844 (9.7%), most commonly urinary infection, skin/soft tissue infection, and pneumonia. Infection incidence ranged from 9.7% to 10.0%, and risk was similar across medication exposure groups after adjustment for confounders (Table). Glucocorticoids were associated with a dose-dependent increase in risk, with

significantly increased risk even at 5-10mg per day (Table). The overall rate of PJI within 12 months was 3.1/100 person-years (n = 228 infections), with crude rates ranging from 1.8 (rituximab) to 6.4 (tocilizumab) per 100 person-years (Figure). After adjustment, risk of PJI remained elevated in tocilizumab vs. TNF inhibitors [HR 2.16 (1.14-4.10), p = 0.02] (Table).

**Conclusion:** Short-term risk of serious post-operative infection after arthroplasty was similar in patients with RA treated with different biologics. Rates of PJI were low, with small variations in PJI risk between biologics possibly related to differences in disease severity. Glucocorticoids showed a strong dose-dependent association with infection, with a larger impact on post-operative infection risk than choice of biologic.

**Table:** Crude incidence of serious infection within 30 days or prosthetic joint infection within 1 year after elective hip and knee arthroplasty and results of multivariable logistic regression and Cox models

	N	30 day Infection n (%)	30 day infection adjusted OR* (95% CI)	PJI n (Incidence/ 100py)	PJI adjusted HR* (95% CI)

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Plenary Session III

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

### **Background/Purpose:**

Synovitis is a common feature in meniscal tear (MT) and osteoarthritis (OA). Synovitis has been associated with progression of cartilage damage in persons with OA, as has arthroscopic partial meniscectomy (APM), a frequent treatment for MT. It is unknown whether the presence or the persistence of effusion-synovitis is associated with changes in cartilage damage in patients with concurrent MT and OA.

### **Methods:**

We used data from the Meniscal Tear in Osteoarthritis Research (MeTeOR) Trial of APM vs. physiotherapy (PT). Subjects were  $\geq 45$  years old, had MT on MRI, OA on MRI or radiograph, and knee symptoms. Subjects crossing-over between treatment groups or without both baseline and 18mo MRI were excluded. MRIs were read using the MRI OA Knee Score (MOAKS). Baseline effusion-synovitis was dichotomized as none/mild (0) and moderate/severe (1). Change in effusion-synovitis over 18mo was categorized as never developed (0 at baseline, 0 at 18mo), intermittent (1 at only 1 time point), and persistent (1 at baseline, 1 at 18mo). Change in cartilage damage over 18mo was examined in 14 subregions and assessed by a) number of subregions with worsening (subregions grade  $\geq 1$  at baseline with increased surface area affected by full thickness loss) and b) number of additional subregions affected (subregions grade 0 at baseline with new full thickness loss). Both outcomes were specified as binary (0 regions vs. 1+). We used logistic regression to investigate the associations between a) baseline effusion and b) change in effusion on both cartilage damage outcomes over 18mo in 4 individual models – with adjustment for differences in treatment (APM vs. PT), sex, BMI, and baseline cartilage damage.

### **Results:**

We analyzed 174 knees (1/person), 102 had APM and 72 PT. Moderate/severe effusion was observed in 48% patients at baseline and 29% at 18mo. Fifty-six percent of subjects had subregions with worsening and 45% had additional subregions affected. Over 18mo, 44% subjects never developed effusion, 35% had intermittent effusion, and 21% had persistent effusion. Overall participants were 59% female, 58 years old, with a BMI of 30 kg/m<sup>2</sup>. Compared to subjects who never developed effusion, those with intermittent effusion had 2.6-fold (95% CI 1.2, 5.5) greater odds of worsening cartilage damage, while those with persistent effusion had 4.5-fold (95% CI 1.6, 12.8) greater odds. Similar results were obtained for analyses of baseline effusion and number of additional subregions affected (Table).

### **Conclusion:**

Effusion-synovitis status at baseline and 18mo was associated with worsening of cartilage damage at 18mo in patients with MT and OA, independent of study treatment. The risk of cartilage damage was greater in those with persistent effusion than in those with intermittent effusion. If confirmed in other studies, these findings would support research on the structural effects of interventions to reduce effusion in this population.

<b>Table:</b> Odds ratios from logistic regression of A) Baseline and B) Change in Effusion-Synovitis on Cartilage Damage over 18 months

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Plenary Session III

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Classification and treatment decisions in lupus nephritis (LN) are largely based on renal histology. Single-cell RNAseq (scRNAseq) analysis may accurately differentiate types of renal involvement at the transcriptomic level, and better inform treatment decisions and prognosis. Through our involvement with the accelerating medicines partnership (AMP) network our objectives were to use scRNAseq profiles of renal constituent cells to distinguish between proliferative and membranous LN subclasses, and explore the use of scRNAseq of skin cells to discover biomarkers in a readily obtainable tissue.

**Methods:** scRNAseq was performed on ~2 mg kidney tissue collected from clinically indicated renal biopsies, and skin biopsies obtained at the time of renal biopsies, in 20 SLE patients. scRNAseq was performed using Fluidigm C1 HT Integrated Fluidic Circuits and cDNA libraries were prepared using the Nextera XT DNA Library Prep Kit followed by NextSeq (Illumina) sequencing.

**Results:** A total of 1616 renal cells and 2392 skin cells were sequenced from LN and healthy control skin and kidney biopsies. Cell-types were determined using principal component analysis and tSNE plotting, resulting in the definitive identification of keratinocytes (N = 2004 cells), tubular cells (N=936 cells), fibroblasts (N=422), endothelial cells (N=154), and leukocytes (N=129). Genes identified by differential expression analysis of tubular cells (Fig. 1) and keratinocytes originating from patients with proliferative (class III or IV) (N=7 patients) and membranous (class V) nephritis (N=6 patients) were subjected to gene ontology pathway analysis. Tubular cells in patients with proliferative nephritis demonstrated upregulated TNF signaling ( $p<.001$ ), including the transcription factor FOS, as compared to patients with membranous nephropathy. Moreover, the VEGF signaling ( $p<.001$ ) pathway was upregulated, as was chemokine activity ( $p<.001$ ) including CCL2 and CXCL3. Interestingly, keratinocytes from non-lesional skin of patients with proliferative nephritis also demonstrated upregulated TNF signaling ( $p<.01$ ) as compared to those with membranous nephritis.

**Conclusion:** scRNAseq from small amounts of renal biopsy tissue in SLE can differentiate between the different classes of LN, and provide important insights into potential pathogenic mechanisms. Further, due to the systemic nature of the disease, transcriptomic changes in the skin of LN patients can provide a useful source of biomarkers and may reflect important information concerning concurrent kidney pathological events.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Plenary Session III

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

## **Background/Purpose:**

Monogenic autoinflammatory interferonopathies, including chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperatures (CANDLE) and STING-associated vasculopathy with onset in infancy (SAVI), present with a prominent interferon (IFN)-response gene signature (IRS) in the blood, systemic inflammation, and organ-specific damage often associated with increased morbidity and mortality in childhood. An Expanded Access Program with baricitinib, a JAK kinase inhibitor with *ex vivo* IFN blocking capacity, was developed to provide baricitinib to patients (pt.) with no comparable or satisfactory treatment options.

## **Methods:**

Potential benefit was assessed by reductions in daily symptom diary to <0.5 (CANDLE and CANDLE-like pt.) and to <1.0 (SAVI pt.) and reductions of steroid doses to <0.15mg/kg/day or by at least 50% from baseline. Quality of life assessments, linear growth, and changes in IRS and IFN-induced biomarkers are also reported. Drug safety was longitudinally followed. Paired t-tests were used to compare daily mean daily symptom diary and prednisone doses at the last clinic visit to baseline data.

## **Results:**

Between October 2011 and October 2016, 18 pt. were enrolled and treated, 10 CANDLE pt., 4 SAVI pt., and 4 CANDLE-like pt. Mean follow-up duration 3.0 years. The median daily symptom diary score decreased from 1.3 (IQR 0.93-1.78) to 0.25 (IQR 0.1-0.63) ( $p<0.001$ ) with responses most significant in CANDLE patients. In 14 patients receiving steroids at baseline, daily prednisone doses decreased from 0.44 mg/kg/day (IQR 0.31-1.9) to 0.11 mg/kg/day (IQR 0.02-0.24) ( $P<0.005$ ); 5 of 10 CANDLE patients achieved lasting clinical remission. All active patients ( $n=16$ ), except two, reported improvement in quality of life. 9 of the 13 patients with growth potential improved their Z-scores from -4.34 to -2.83 ( $p=0.02$ ). DEXA Z-scores also improved from -4.0 to -3.1 ( $p=0.006$ ). IFN scores significantly dropped and durably normalized in 5 CANDLE patients. Treatment-related serious adverse events included infections; 2 patients with genetically undefined interferonopathies discontinued due lack of efficacy, one also had avascular necrosis. One CANDLE patient developed BK viremia and azotemia and was discontinued from the program. The most common adverse events included upper respiratory infections and BK viruria (baseline screening for BK virus in blood and urine was not performed).

## **Conclusion:**

Daily doses of baricitinib significantly improved clinical disease manifestations, laboratory parameters, linear growth, and bone mineral density, and decreased IFN signaling in patients with CANDLE, SAVI and 2 other autoinflammatory interferonopathies. Monitoring safety and efficacy is important in benefit-risk assessment.

**Acknowledgements:** This work was supported by the NIH IRP of NIAID and NIAMS.

**Figure 1.** Least-squares means comparisons between baseline (2 week period), time on effective doses (175 ± 137 days), time on effective doses (890 ± 292 days) and the last 90 days before the last visit.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Antiphospholipid Syndrome

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

The antiphospholipid syndrome (APS) is an autoimmune condition characterized by thrombosis and/or pregnancy morbidity and persistent positivity for antiphospholipid antibodies (aPL). The most common neurological manifestation of APS is ischaemic stroke (1). Identifying patients with APS at high risk for developing any thrombotic event remains a major challenge. In this study, we aimed to identify predictive factors of ischaemic stroke in a cohort of primary APS (PAPS) patients who presented with new onset symptoms suggestive of acute stroke.

## Methods:

This prospective multicenter study included 36 consecutive PAPS patients[mean age 32 years old(SD33·7),female(86%)] who presented with new onset symptoms suggestive of an acute stroke.Data on cardiovascular risk factors and aPL positivity were collected and aGAPSS score was calculated.Patients were prospectively followedup for 12 months. Demographic, clinical and laboratory characteristics are summarized in Table 1 and Table 2.

## Results:

In ten(28%) out of 36 PAPS patients[mean age 41 years old(SD13·4), female(70%)], the suspicion of an acute stroke was confirmed by brainMRI. Sixty percent of these patients were<50years old. Six out of the ten patients had a history of previous venous thrombosis and were receiving vitamin K antagonist(VKA), with INR target 2-3;one patient had a history of a previousarterial event receiving treatment with VKA targetINR2-3 plus low dose aspirin(LDA), and one patient had a history of previous pregnancy morbidity receiving only LDA. Time in therapeutic range for patients receiving VKA was 77·7(S.D.6·6). Hypercholesterolemia was significantly higher in patients with confirmed stroke when compared to those without( $p<0\cdot05$ ). Similarly, we found a significantly higher rate of anti- $\beta$ 2GPI antibodies(IgG/IgM)( $p<0\cdot05$ ) and higher aGAPSS values in patients with a confirmed stroke[mean aGAPSS 8·9 (S.D.4·7)Vs. mean aGAPSS6·4(S.D.2·5); $p:<0\cdot05$ ].

## Conclusion:

Patients with PAPS,including young patients, have a high risk of recurrent thrombosis despite anticoagulation treatment. A careful risk assessment is mandatory to identify patients at risk for recurrence. Modifiable risk factor reduction may be a first step to prevent recurrence.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Antiphospholipid Syndrome

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** APS ACTION Registry was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases. Previously, based on 16 new thrombotic events, we reported the annual recurrent and first thrombosis risk in persistently aPL-positive patients as 2.38 and 1.86%, respectively (*Arthritis Rheumatol.* 2016; 68 [suppl 10]).

**Methods:** A web-based data capture system is used to store patient demographics, history, and medications. Inclusion criteria are positive aPL based on the Updated Sapporo Classification Criteria at least twice within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection; they also receive advice on cardiovascular disease and thrombosis prevention at each visit. In this descriptive analysis, we report additional thrombotic events based on patients who completed one-, two-, three-, and four-year follow-up visits.

**Results:** As of 4/2017, 671 patients were included (aPL/APS without any other autoimmune disease [AIDx]: 436 [no thrombosis: 88; thrombotic APS [TAPS]: 241; obstetric APS [OAPS]: 47; and TAPS+OAPS: 60]; and aPL/APS associated with another AIDx: 235 [no thrombosis: 67; TAPS: 118; OAPS: 18; and TAPS+OAPS: 32]). Of 671 patients, 515 (77%), 391 (58%), 243 (36%), and 52 (8%) completed their one-, two-, three-, and four-year follow-up visits, respectively. Mean follow up were 2.38 years (844 patient-years [pt-y]) and 2.23 years (357 pt-y) for those with and without a history of thrombosis, respectively. Table demonstrates the demographic, clinical, and laboratory characteristics of 13 patients who had new thrombosis since our most recent analysis. Based on a total of 22 recurrent events (10 events during the 1st year; 5 during the 2nd; 6 during the 3rd; and 1 during 4th) and six initial (3 events during the 1st year; 2 during the 2nd; and 1 during the 3rd) since the inception of the registry, the incident thrombosis risk was 2.60 and 1.68 per 100 pt-y in patients with and without history of thrombosis, respectively (annual thrombosis risk 2.63% and 1.68%, respectively). In a subgroup analysis, the incident thrombosis risk was: a) 3.13 and 1.50 per 100 pt-y in patients with and without history of thrombosis, respectively for those with other AIDx and b) 2.38 and 1.79 per 100 pt-y in patients with and without history of thrombosis, respectively for those without other AIDx.

**Conclusion:** The incident thrombosis risk remains relatively low and commonly associated with LA- and/or triple aPL-positivity as well as non-aPL thrombosis risk factors. The risk is similar between aPL- positive patients with and without other AIDx. Annual and risk stratified analysis of APS ACTION registry will better determine the risk of thrombosis in persistently aPL-positive patients based on different risk profiles.

Table

Baseline Data				Follow-up Data

# Adenosine Receptor Agonism Protects Against Antiphospholipid Antibody-Mediated Netosis and Venous Thrombosis

Ramadan A. Ali<sup>1</sup>, He Meng<sup>1</sup>, Srilakshmi Yalavarthi<sup>1</sup>, Yogendra Kanthi<sup>1</sup> and Jason S. Knight<sup>2</sup>, <sup>1</sup>University of Michigan, Ann Arbor, MI, <sup>2</sup>., University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Antiphospholipid Syndrome

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** We have previously reported that antiphospholipid antibodies (aPL) activate neutrophils and thereby exaggerate neutrophil extracellular trap release (NETosis), which potentially contributes to the thrombotic events inherent to antiphospholipid syndrome (APS). Recent evidence suggests that the second messenger cyclic AMP (cAMP) suppresses NETosis. Here, we hypothesized that surface adenosine receptors (which trigger cAMP formation in neutrophils) serve as an endogenous counterpoint to thrombo-inflammatory disease, and that pharmacological agonism of adenosine receptors may therefore mitigate the thrombotic manifestations of APS. In particular, our data led us to investigate the adenosine 2A receptor and its downstream pathways.

**Methods:** For *in vitro* studies, control neutrophils were prepared from healthy volunteers and stimulated with (i) total IgG pooled from primary APS patients, (ii) affinity-purified anti- $\beta_2$ GPI antibodies, or (iii) phorbol 12-myristate 13-acetate (as a positive control). NETs were quantified by chromogenic detection of the enzymatic activity of NET-associated myeloperoxidase, or by SytoxGreen-based fluorescence measurement of extracellular DNA. For *in vivo* studies, thrombosis was triggered by surgical restriction of blood flow through the inferior vena cava, with resulting macroscopic thrombi assessed 48 hours later (a model of thrombosis that our group and others has shown to be accentuated by NETs).

**Results:** We began by assessing the effect of cAMP on aPL-mediated NETosis. 8-Br-cAMP (a cell-permeable, degradation-resistant cAMP derivative) significantly inhibited NETosis in dose-dependent fashion. As extracellular adenosine receptors are key regulators of neutrophil cAMP levels, we assessed agonism of the adenosine 2A, 2B, and 3 receptors. While CGS21680 (A2A agonist) suppressed NETosis with nanomolar potency, BAY60-6583 (A2B agonist) and 2-Cl-IB-MECA (A3 agonist) had minimal effect, even at micromolar concentrations. The antithrombotic agent dipyridamole is known to potentiate adenosine-mediated signaling by (i) increasing extracellular concentrations of adenosine, and (ii) interfering with the breakdown of cAMP. Indeed, dipyridamole suppressed aPL-mediated NETosis in a dose-dependent manner. Finally, in a mouse model of macroscopic venous thrombosis, CGS21680 (A2A agonist) was highly effective in mitigating thrombosis (3-fold reduction in thrombus weight;  $p=0.028$  with 15 mice per group).

**Conclusion:** We demonstrate for the first time that adenosine 2A receptor agonism can attenuate aPL-mediated NETosis *in vitro* and venous thrombosis in mice. Furthermore, dipyridamole (a drug known to potentiate adenosine-mediated signaling) phenocopies adenosine 2A receptor agonism in terms of suppressing *in vitro* NETosis. Studies are underway to fully characterize relevant signaling pathways in neutrophils, and to assess the therapeutic potential of dipyridamole against aPL-accelerated thrombosis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Antiphospholipid Syndrome

**Session Type:** ACR Concurrent Abstract Session

**Background/Purpose:** The antiphospholipid syndrome (APS) is defined by a combination of arterial and/or venous thrombosis, pregnancy morbidity, and persistent antiphospholipid antibodies. There is a real gap in knowledge on intrauterine fetal death (IUFD) in APS patients because there are no large published series. Moreover, heterogeneous gestational ages and varying definitions of APL assays positivity are used in the literature.

**Methods:** We retrospectively analysed the history and clinical data of women followed in 4 French university hospitals for a diagnosis of APS (Sydney criteria) who experienced an IUFD at or after 10 weeks of gestation (WG) between 2000 and 2016. According to the classification criteria, if the IUFD was otherwise explainable by a fetal or obstetrical complication not related to APS, the patient was excluded. The patients were included when at least 2 positive antibodies were found 12 weeks apart or more and within 5 years of the obstetrical event.

**Results:** Sixty patients were included. Their mean age at the IUFD was  $29 \pm 5$  years (Table 1). Prior to the IUFD, 10 patients (17%) had a previous live birth, 8 (13%) had an early miscarriage, 5 (8%) an abortion while 37 (62%) were nulligest. APS was already known in 9 patients (15%) and systemic lupus erythematosus (SLE) in 8 patients (13%). There was a high prevalence of triple positive (38%) and double positive (25%) women.

During the index IUFD, treatment consisted of low dose aspirin (LDA) (n=7), low molecular weight heparin (LMWH) (n=3) or a combination of both (n=5). IUFD occurred at a mean gestational age of  $22.3 \pm 7$  WG. It was associated in 16 cases to obstetrical complications, namely preeclampsia (n=12), HELLP syndrome (n=6) and/or placental abruption (n=5). There was no maternal mortality associated. Placental infarctions were found in 25 out of 34 available histologic examinations.

Regarding the following pregnancy, 34 out of the 43 patients (79%) who received a treatment (LDA and/or LMWH started before 12 WG) had a live birth versus 1 out of 9 patients (11%) who did not receive such treatment.

Overall, including the follow up period of 5 years [IQR: 3-10], 26 patients (43%) experienced one or more thrombosis, among which half before the index IUFD, and 28% were diagnosed with SLE. Ultimately, 51 patients had at least one live birth, including 48 after experiencing the IUFD. The median age at last follow-up of the childless women was 33 years old [IQR: 30-45].

**Conclusion:** The IUFD was mostly inaugural in the APS and unrelated to other obstetrical complications. The strong autoimmune biology, significant occurrence of SLE and thrombosis suggest that these IUFD events happened in patients with a solid APS diagnosis and are not randomly associated with weak autoantibodies. A majority of women succeeded in having at least one live birth when treated.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Antiphospholipid Syndrome

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Anti-phospholipid antibodies (aPL) constitute a diagnostic criterion and source of morbidity, termed anti-phospholipid syndrome (APS), in patients with or without systemic lupus erythematosus (SLE). Oxidization causes the immunogenicity of phospholipid antigens, such as  $\beta_2$ GPI and cardiolipin (Arthritis Rheumatol. **63**, 2774-82). Mitochondrial dysfunction-connected mechanistic target of rapamycin complex 1 (mTORC1) activation has been recently found to trigger aPL in mice (Arthritis Rheumatol. **68**, 2728). Blockade of mTORC1 with rapamycin (Arthritis Rheum. 54:2983-8; J Immunol. 191:2236-46) and the antioxidant, N-acetylcysteine (NAC) has shown clinical efficacy in SLE (Arthritis Rheum. 64:2937-46). Therefore, we measured aPL levels in sera collected during clinical trials with rapamycin and NAC (ClinicalTrials.gov Identifiers: NCT00779194 and NCT00775476).

**Methods:** 40 SLE patients meeting eligibility criteria were started on 2 mg of rapamycin (sirolimus) with the dose adjusted to tolerance and trough levels of 6-15 ng/ml, and sera were collected before 1st rapamycin dose and 1 month, 3 months, 6 months, 9 months, and 12 months after initiation of treatment. 36 patients were enrolled in the NAC trial, and sera were collected before 1st NAC dose and 1 month, 2 months, and 3 months after initiation of treatment. At each study visit, blood samples were obtained from 42 healthy controls (HC) matched for patients' age, gender, and ethnicity for parallel analyses. IgA, IgG, and IgM antibodies to  $\beta_2$ GPI (anti- $\beta_2$ GPI) and cardiolipin (ACLA) were measured by ELISA (Arthritis Rheumatol. **63**, 2774-82). Statistical analyses of drug efficacy was assessed relative to pretreatment samples with paired t-test using GraphPad. Patients and HC were compared with unpaired t-test. For hypothesis testing, differences were considered significant at  $p < 0.05$ .

**Results:** IgG, but not IgM or IgA, anti- $\beta_2$ GPI (unpaired t-test  $p=0.014$ ) and ACLA were elevated in untreated SLE patients relative to HC (unpaired t-test  $p=0.029$ ). With respect to baseline, NAC, but not placebo, reduced IgG and IgM anti- $\beta_2$ GPI levels after 1 month intervention. NAC also reduced IgM, but not IgG or IgA, ACLA after 1 month intervention. Rapamycin reduced IgM and IgA, but not IgG, anti- $\beta_2$ GPI and ACLA production after 1 month, which was sustained after treatment for 12 months.

**Conclusion:** These ancillary studies suggest that rapamycin and NAC limit aPL production which should be included as an efficacy outcome in clinical trials of mTORC1 blockade in patients with SLE and APS.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Antiphospholipid Syndrome

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Monocytes are key players involved in the development of several autoimmune disease due to their capacity to modulate lipid metabolism, secrete inflammatory cytokines, chemokines, tissue factor, proteases and reactive oxygen species. However

their specific molecular profile of activation in the pathogenesis of Antiphospholipid syndrome patients (APS) has not been yet evaluated. Thus, the aim of this study was to characterize the monocytes molecular signature of altered genes and pathways involved in the pathology of APS patients.

**Methods:** Monocytes from peripheral blood of six subject including APS and healthy donors (HDs) were purified by negative immunomagnetic selection (Miltenyi). Total RNA was extract and microarray studies were performed in an Agilent G4112F platform (Whole Human Genome Microarray 44k) using the One-Color gene expression system. Functional categorisation of the altered gene signature and molecular pathways and networks, was carried out by using the Ingenuity Pathway Analysis Software (IPA). The most differentially expressed genes were validated by RT-PCR in monocytes purified from 30 APS and 30 HDs. Correlation and association studies were performed with clinical and analytical variables. The effect of antiphospholipid antibodies (aPL) in the expression of a number of genes were also evaluated by *in vitro* studies on healthy monocytes.

**Results:** Gene expression array identified 518 significantly altered genes in monocytes from APS patients in relation to the control group ( $p < 0.05$  and fold change  $> 2$ ), including 352 up-regulated and 166 down-regulated. IPA analysis showed that the main canonical pathways integrated by these genes were leukocyte adhesion, diapedesis and extravasation signaling (CLDN16, ACTC1, CLDN12, CCL26, CCL23, FPR1 and FPR2), interleukin signaling (IL18, IL12B, IL22RA, NFATC1), IFN, TNF and TGFbeta signaling (IFNAR1, TNFRSF1A, SMAD6), relevant intracellular signaling pathways involved in signal transduction such as p38, Erk, STAT, TLR, JAK and NFkB, and oxidative stress production and antioxidant reponse (GPX8, CYBB, SCLC2A/2,3 and 5). This analysis further identified that the most relevant disease and function in which these altered genes are involved, were leukocyte migration, inflammatory response, cardiovascular disease and free radical scavenging. In addition the alteration of several of these genes was validated by RT-PCR and associated to clinical parameters of all the patients included in the study. *In vitro* studies demonstrated the specific modulation of several genes by direct effect of aPLs.

**Conclusion:** Gene expression profile allows the identification of relevant genes and pathways altered in monocytes of APS patients, which are associated with the pathogenesis of the disease and modulated, at least partially, by aPLs. Thus, the identification of novel biomarkers, might contribute to the development of targeted therapies. Acknowledgements: Supported by FIS (PI01333/2015) and CTS-7940.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Rehabilitation Science

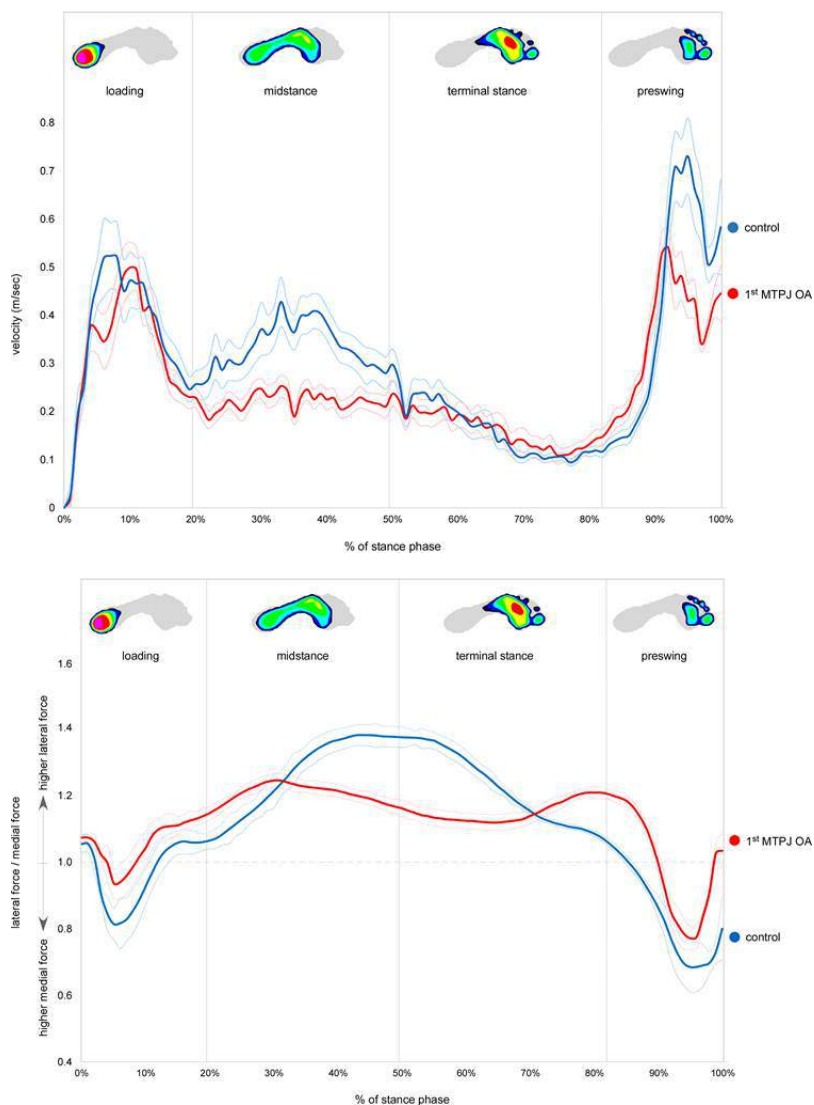

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Osteoarthritis of the first metatarsophalangeal joint (1<sup>st</sup> MTPJ OA) is a common and disabling condition characterised by symptoms of joint pain and stiffness, formation of a dorsal exostosis, and progressive reduction in range of motion of 1<sup>st</sup> MTPJ dorsiflexion. Because the 1<sup>st</sup> MTPJ plays an important role in transferring the body's centre of mass over the foot during the propulsive phase of gait, individuals with 1<sup>st</sup> MTPJ OA frequently adopt an apropulsive walking pattern. The objective of this study was to compare centre of pressure characteristics during walking in individuals with and without 1<sup>st</sup> MTPJ OA, in order to provide insights into alterations in foot function associated with this condition.

**Methods:** Twenty people with 1<sup>st</sup> MTPJ OA and 20 asymptomatic controls matched for age, sex and body mass index underwent gait analysis using the emed<sup>®</sup>-x400 plantar pressure system (Novel GmbH, Germany). Average and maximum centre of pressure velocity and lateral-medial force index during loading, midstance, terminal stance and preswing were compared between the groups, adjusting for contact time.

**Results:** During the preswing phase of gait, maximum centre of pressure velocity was significantly slower in individuals with 1<sup>st</sup> MTPJ OA ( $0.78 \pm 0.19$  vs  $1.13 \pm 0.36$  m/sec;  $p=0.003$ ), and both average and maximum lateral-medial force indices were significantly higher in individuals with 1<sup>st</sup> MTPJ OA ( $0.98 \pm 0.14$  vs  $0.82 \pm 0.13$ ;  $p<0.001$  and  $1.37 \pm 0.29$  vs  $1.15 \pm 0.15$ ;  $p=0.008$ , respectively). See Figures 1 and 2. Non-weightbearing 1<sup>st</sup> MTPJ dorsiflexion range of motion was significantly associated with maximum centre of pressure velocity ( $r=-0.54$ ,  $p<0.001$ ) and average lateral-medial force index ( $r=-0.44$ ,  $p=0.004$ ) during preswing.

**Conclusion:** These findings suggest that individuals with 1<sup>st</sup> MTPJ OA may generate less forward momentum when walking due to a lateral transfer of force during propulsion, possibly due to decreased range of 1<sup>st</sup> MTPJ dorsiflexion.

**Disclosure:** H. Menz, None; M. Auhl, None; J. Tan, None; S. Munteanu, None.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Rehabilitation Science

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The majority of adults with osteoarthritis (OA) are inactive, highlighting the need for continued efforts to promote regular engagement in exercise. Few studies have directly compared different strategies, ranging in intensity of resources required, for improving exercise and related outcomes among patients with OA. The objective of this study was to compare the effectiveness of physical therapy (PT) (with an emphasis on a home exercise program) and internet-based exercise training (IBET) among individuals with knee OA.

**Methods:** This was a randomized controlled trial of 350 participants with symptomatic knee OA, allocated to PT, IBET and a wait list (WL) control group in a 2:2:1 ratio, respectively. The PT group received up to 8 individual visits within 4 months. The IBET program provided tailored exercises, video demonstrations, and guidance on progression. The primary outcome was the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), and four physical performance tests were included as secondary outcomes: unilateral stand test, 30-second chair stand, 2-minute march, and Timed Up-and-Go. Outcomes were assessed at baseline, 4 months and 12 months. General linear mixed effects modeling compared changes in outcomes among study groups, using an intent-to-treat paradigm.

**Results:** At 4-months, both the PT and IBET groups improved in WOMAC score, but mean differences compared to WL were not statistically significant (PT: -3.36, 95% Confidence Interval (CI) = -6.84, 0.12,  $p=0.06$ ; IBET: -2.70, 95%CI = -6.24, 0.85,  $p=0.14$ ). Similarly, at 12-months mean differences compared to WL were not statistically significant for either group (PT: -1.59, 95% Confidence Interval (CI) = -5.26, 2.08,  $p=0.39$ ; IBET: -2.63, 95%CI = -6.37, 1.11,  $p=0.17$ ). Results for WOMAC subscales and physical performance tests are shown in Table 1.

**Conclusion:** Modest improvements in outcomes following both PT and IBET were observed in comparison to a WL control group. Initial gains were better for the PT group, but the IBET group maintained improvements in WOMAC better over time. A combination of these two interventions, with IBET used as a tool to facilitate home exercise following PT, may result in more robust effects and maintenance over time.

## Active Yet Sedentary: The Association of Moderate to Vigorous Physical Activity and Sedentary Behavior with Incident Functional Limitation in Knee OA

**Hiral Master**<sup>1</sup>, Louise Thoma<sup>1</sup>, Meredith Christiansen<sup>1</sup>, Dana Mathews<sup>2</sup> and Daniel White<sup>3</sup>, <sup>1</sup>Physical Therapy and Biomechanics and Movement Science, University of Delaware, Newark, DE, <sup>2</sup>Physical Therapy, Biomechanics and Movement Science, University of Delaware, Newark, DE, <sup>3</sup>Department of Physical Therapy, University of Delaware, Newark, DE

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Rehabilitation Science

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Engaging in adequate levels of moderate to vigorous physical activity (MVPA) reduces the risk of functional limitation in people with knee osteoarthritis (OA). Sedentary behavior (SED) is common in those with either high or low level of MVPA, and is also linked to poor health outcomes in people with knee OA. However, it remains unclear whether being sedentary regardless of MVPA level increases one's risk of developing functional limitation in people with knee OA. The purpose of this study was to examine the association of MVPA and SED with incident functional limitation 4 years later in people with knee OA.

### Methods:

We used publically available data from the Osteoarthritis Initiative (OAI). Our primary exposures were time spent in MVPA and SED that were collected at the 48-month OAI visit (baseline) using an accelerometer (Actigraph GT1M) worn for >10 hours/day for ≥4 days. We classified people as having at least one 10 min bout/week in MVPA defined as ≥2020 counts/min. SED was defined as time spent at <100 counts/minutes standardized to wear time. We classified people as being Active-Low SED (≥1 MVPA bouts and lowest SED tertile i.e. less sedentary), Active-High SED (≥1 MVPA bouts and top two SED tertiles, i.e. more sedentary), Inactive-Low SED (No MVPA bout and lowest SED tertile), and Inactive-High SED (No MVPA bout and top two SED tertiles). We defined our outcome, incident

functional limitation, as >12 sec for the 5 repetition sit-to-stand test (STS) and <1.22 m/sec gait speed during a 20-meter walk at the 96-month OAI visit (4 years later). To examine the association of MVPA and SED with incident function limitation, we calculated risk ratios and 95% confidence intervals [RR (95%CI)] adjusted for potential confounders.

## Results:

We included 1927 people with valid exposure data (55% female, age [mean±(SD)] 65.1±8.8 years, BMI 28.4±4.9 kg/m<sup>2</sup>) at baseline. Of those free of the outcome at baseline and had follow-up data, 15% (n=162/1091) and 21% (n=236/1133) developed functional limitation 4 years later measured by STS and gait speed, respectively. The Active-High SED group had a similar risk of functional limitation compared with the Active-Low SED group. The Inactive-High SED group had 1.5 times the risk of incident functional limitation compared with the Active-Low SED group. The Inactive-Low SED group had 1.5 to 1.6 times the risk of incident functional limitation compared with the Active-Low SED group (Table).

## Conclusion:

For active people, high SED was not associated with incident functional limitation compared to those who were low SED. However, those who were inactive had an increased risk of incident functional limitation regardless of SED compared with people who were Active-Low SED. Thus, being active may potentially offset the functional consequences of SED. Effective clinical interventions to improve MVPA are needed for people with knee OA.

**Table:** Risk Ratios (RR) of the incident functional limitation at the 4-year follow-up as measured by STS and gait speed.

	Baseline Mean (SD)	Incident Function Limitation/total*	%	Unadjusted RR (95% CI)	**Adjusted RR (95% CI)
<b>STS</b>					
Active-Low SED	9.9 (2.7)	31/293	10.6	Reference	Reference
Active-High SED	9.9 (2.6)	49/412	11.9	1.1 (0.7-1.8)	1.0 (0.7-1.6)
Inactive-Low SED	11.1 (3.2)	20/106	18.9	<b>1.9 (1.1-3.2)</b>	1.6 (1.0-2.8)
Inactive-High SED	11.2(2.9)	62/280	22.1	<b>2.2 (1.4-3.3)</b>	1.5 (1.0-2.3)
<b>Gait speed</b>					
Active-Low SED	1.4 (0.2)	45/311	14.4	Reference	Reference
Active-High SED	1.4 (0.2)	75/434	17.3	1.3 (0.9-1.8)	1.2 (0.8-1.7)
Inactive-Low SED	1.3 (0.2)	31/120	25.8	<b>1.9 (1.3-2.9)</b>	1.5 (1.0-2.2)

## Effects of a Home-Based Telephone-Supported Physical Activity Program on Physical Function Among Older Adults with Chronic Low Back Pain

Adam P. Goode<sup>1</sup>, Shannon Taylor<sup>2</sup>, Susan Hastings<sup>3</sup>, Catherine Stanwyck<sup>3</sup>, Cynthia Coffman<sup>3</sup> and Kelli Allen<sup>4</sup>, <sup>1</sup>O, Duke University, Durham, NC, <sup>2</sup>Health Services Research and Development, Durham VA Medical Center, Durham, NC, <sup>3</sup>Durham VA Medical Center, Durham, NC, <sup>4</sup>Rheumatology, University of North Carolina at Chapel Hill and Durham VA Medical Center, Durham, NC

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Rehabilitation Science

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The majority of older adults with chronic low back pain (cLBP) are inactive and have significant functional limitations, highlighting the need for continued efforts to promote regular engagement in exercise and physical activity. Few studies have directly compared different strategies, including behavioral interventions (i.e., cognitive behavioral therapy) for improving physical function-related outcomes among older adults with cLBP. The objective of this trial was to collect preliminary data on the efficacy of physical activity (PA) only and PA + cognitive behavioral therapy for pain (CBT-P) programs for improving functional outcomes among older adult Veterans with cLBP. We hypothesized that home-based telephone-supported PA only and PA + CBT-P program would produce a significant increase in older adults' physical function.

**Methods:** Older adult Veterans with cLBP at the Durham VA HealthCare System were randomized to 12-week telephone-supported PA only or PA + CBT-P interventions or a wait list (WL) control group. A physical therapist conducted the initial evaluation and established the PA and exercise program in person with the participant. Follow up telephone calls were delivered by a physical therapist (n=3) and an exercise counselor (n=10). The PA intervention included stretching, strengthening, and aerobic activities; CBT-P was tailored for older adults with cLBP. Outcomes measured at baseline and 12-weeks were: physical performance (timed up-and-go; TUG), self-report physical function (PROMIS Health Assessment Questionnaire ((HAQ)), self-reported LBP-specific disability (Roland-Morris Low Back Pain and Disability Questionnaire (RMDQ)), the Satisfaction with Physical Function Scale, and pain catastrophizing (from the Coping Strategies Questionnaire). General linear mixed models were used to compare outcomes over 12-weeks of follow-up among groups. Effect sizes were calculated using Cohen's d.

**Results:** Mean age of participants was 70.3 years; 53% were Non-white, 93% Male, and 83% had back pain symptoms lasting longer than 5 years. No significant differences were found for the PA or PA + CBT-P group, compared with the WL group, for primary outcomes of TUG or PROMIS HAQ; however, effect sizes were moderate to large ( $d = -0.64$ ) for improving physical function on the PROMIS HAQ in the PA only group and small for improvements in the TUG for both the PA only ( $d = -0.28$ ) and PA+CBT-P ( $d = -0.31$ ) groups. A significant difference was found for the RMDQ at 12 week follow-up for the PA only group ( $-4.10$  ((95% CI  $-6.85, -1.34$ ;  $p < 0.01$ )) compared to WL, with a moderate to large effect size ( $d = -0.78$ ). Small effect sizes were found for Satisfaction with Physical Function Scale and Coping Strategies Questionnaire Catastrophizing scores in both the PA and PA+CBT-P.

**Conclusion:** Results from this pilot trial suggest that a home-based telephone-supported PA program may be effective for improving some aspects of physical functioning among inactive older adults with cLBP. The addition of CBT-P did not result in a significant additive affect for increasing physical function or changes in behavioral outcomes. Results provide support for a larger trial investigating telephone-supported PA for older adults with cLBP.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Rehabilitation Science

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that is associated with a higher mortality due to higher risk of cardiovascular events. Although physical activity is known to decrease cardiovascular morbidity and mortality, sedentary behavior highly prevails in SLE patients. The purpose of this study was to determine whether leisure-time physical activity level is associated with a better quality of life at one year.

**Methods:** Patients (n=287) in the Health Improvement and Prevention Program in SLE (HIPP) were randomized either into the « now » group (n=144) which received a comprehensive behavioral intervention including a supervised exercise program in the first 12 months or the « later » group (n=143) which received the intervention after 12 months. At baseline, 12 and 24 months, patients were asked to complete questionnaires assessing leisure-time physical activity (LTPA) measured by the Aerobics Centre Longitudinal Study physical activity questionnaire or ACLS, quality of life using the physical (PCS) and mental (MCS) component scales of the Short-Form 36, disease damage (Systemic Lupus International Collaborating Clinics Damage Index or SLICC), disease activity (Systemic Lupus Erythematosus Disease Activity Index or SLEDAI) and coronary heart disease risk factor using the Framingham risk score. LTPA levels were separated on the basis of hour of metabolic equivalent (MET) performed weekly: 1) sedentary group (no LTPA activity), 2) insufficiently active (<7.5 MET-h/week) and 3) active (>7.5 MET-h/week). Logistic and linear regressions were used to assess the effect of LTPA level, study group and their interactions on dichotomous and continuous outcomes respectively. Models were also adjusted for age at baseline.

**Results:** A total of 276 patients were included in this analysis. At baseline, no associations with the LTPA level were found regarding the SLEDAI, SLICC and Framingham scores. However, for the PCS, there was a significant difference for the LTPA levels ( $p<0.001$ ). The active group reported statistically and clinically better physical health ( $43.78\pm0.92$  vs.  $36.97\pm1.30$ ,  $p<0.001$ ) when compared with the insufficiently active group and the sedentary group ( $37.12\pm1.35$ ,  $p=0.0002$ ), while there were no differences between the insufficiently active and the sedentary groups. At one year, those same associations are found between the LTPA levels ( $p=0.003$ ). For the MCS, there was no statistical difference between the study groups but there was a difference between the LTPA level only in the unadjusted analysis, where the active group ( $47.97\pm0.99$ ) had a significantly better score than the insufficiently active ( $43.60\pm1.38$ ,  $p<0.05$ )

**Conclusion:** Our data suggests that the LTPA level is associated with better physical activity at baseline and a good predictor of the physical activity status at one year but is only associated with mental status at baseline. Further research are needed to better understand the LTPA level in SLE patients and to tailor appropriate exercise-based interventions.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Rehabilitation Science

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Knee osteoarthritis (OA) affects approximately 6% of adults and is a leading cause of disability among U.S. adults. Physical activity (PA) is known to improve the health status of those with knee OA. In 2007-2008, 49% of all employed adults failed to meet U.S. PA recommendations. This pilot study examined the feasibility of a scalable worksite PA program for employees with knee OA symptoms working at a large insurance firm.

**Methods:** After exclusion criteria, 61 subjects were randomized to either the MobilWise (MW) lifestyle intervention (n=20), the Fitbit Only (FO) intervention (n= 21), or waitlist control (WC) group (n= 20). Randomization was stratified based on current PA tracker ownership/use and meeting/not meeting PA recommendations of 150 minutes/week of moderate-vigorous PA. MW and FO received an education session including detailed instruction on PA/benefits and the Fitbit Flex monitor. MW group also received weekly individual motivational interviewing-based personalized coaching sessions by phone for 12 weeks. MW and FO groups were asked to synchronize their Fitbit at least twice weekly using the Fitbit App to transfer data to a storage service (Fitabase®), but only MW data were viewed weekly for coaching feedback. WC received the education session and a Fitbit at study's end. Measures at baseline and 3 month follow-up included demographics, PA assessed by triaxial accelerometer (average 7-day vector magnitude counts), and WOMAC pain and function. Feasibility of conducting a larger RCT was assessed by tracking enrollment/retention. Acceptability of MW and FO interventions was assessed by tracking the personal monitor synchronization frequency on Fitabase® and the number of completed coaching encounters.

**Results:** Participants at baseline were primarily obese (59%), female (73%), Caucasian (44%), with mean age 51 years, BMI 33 kg/m<sup>2</sup>. Of 10 participants not completing the study, 6 left the company and 4 dropped. Completing participants were not different (BMI and waist circumference) from non-completers.

Feasibility assessment revealed 63% of those screened via web tool signed consents. Proportion of monitored participants who regularly synchronized Fitbits with Fitabase® was 93%. Retention ranged from 80% (WC), 80% (FO) to 95% (MW), with 100% completing MW coaching calls.

**Conclusion:** MobilWise was moderately successful at improving PA levels and self-reported function in employees with knee OA symptoms, but may not be required to produce change in all those at risk. The Fitbit Only group had equally good/better (improved pain) results at 3 months.

WOMAC Pain and Function Scores at Baseline and 3 Month Follow-up

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Innate Immunity and Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** *NLRP3*-activating mutations cause cryopyrinopathies of which NOMID is the most severe phenotype. *NLRP3* assembles a protein complex, responsible for the maturation of IL-1 $\beta$  and IL-18. NOMID-associated inflammation, not bone phenotype is resolved by IL-1 biologics, but these drugs require parenteral injection and are costly. Engineered mice harboring a mutation found in NOMID patients exhibit several features of the human disease, including excessive IL-1 $\beta$  and IL-18 secretion and low bone mass. Here, we tested the hypothesis that the p38 MAPK/MK2 (p38) axis is central in the biosynthesis of pro-IL-1 $\beta$  and *NLRP3*, and as a result, inhibition of this pathway may provide efficacy in NOMID mice. We used our proprietary p38/MK2 pathway inhibitor, CDD-450 that is predicted to be safer and more efficacious than global p38 inhibitors.

**Methods:** CDD-450 selectivity for the p38/MK2 complex was evaluated by comparing p38 phosphorylation of MK2 vs other substrates including PRAK. CDD-450 efficacy was assessed *in vitro* and *in vivo*. For *in vivo* studies, floxed mice expressing *NLRP3* carrying D301N substitution, ortholog of human D303N, were crossed with Cre-ER for postnatal conditional activation of *NLRP3* upon exposure to tamoxifen, injected for 3 consecutive days over 2 weeks to generate NOMID mice. Mice were fed with normal or 1000 ppm CDD-450-formulated chow beginning 3 days before Tam exposure. This formulation yielded steady-state serum CDD-450 levels, which in pilot studies suppressed LPS-induced cytokine production by >80%. The studies were carried for up to 7 weeks.

**Results:** CDD-450 inhibited p38 phosphorylation of MK2 with low nanomolar potency and was >700-800x less potent at inhibiting p38 phosphorylation of PRAK and ATF2. NOMID mice produced excessive amounts of IL-1 $\beta$ ; approximately 35% of these mice died during the course of the study. However, mice who survived, exhibited severe body weight loss and developed neutrophilia, thrombocytosis, lymphopenia, anemia, and splenomegaly. Remarkably, all CDD-450-treated mice survived and exhibited reduced weight loss as a result of abrogated or at least attenuated disease severity. NOMID mice also exhibited osteopenia, coincident with increased numbers of osteoclasts, responses that were inhibited >95% by CDD-450. Furthermore, *in vitro* osteoclast differentiation of

mouse bone marrow-derived macrophages and IL-1 $\beta$  production by these cells were also blocked by CDD-450. From a translational prospective, human peripheral blood mononuclear cells (PBMC) were isolated from a cryopyrin-associated periodic syndrome (CAPS) patient, in which the disease is triggered upon exposure to low temperatures. CAPS PBMC, but not WT PBMC produced large amounts of IL-1 $\beta$  at 32°C, an event that was inhibited by CDD-450 in a dose-dependent manner. In contrast, WT PBMC cultured at 37°C produced IL-1 $\beta$  only when they were exposed to LPS, a response that was also reduced by CDD-450.

**Conclusion:** CDD-450 is a selective inhibitor of the p38/MK2 axis. Importantly, this compound exhibits sustained efficacy in NOMID mice and human cell systems. These results support ongoing efforts for clinical development of this compound for the treatment of inflammatory disorders.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Innate Immunity and Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Persistently and extremely elevated serum IL-18 has been associated with Macrophage Activation Syndrome (MAS). Chronic IL-18 is hypothesized to contribute to excessive interferon (IFN)- $\gamma$  and MAS-like inflammation. However, NK cells in systemic juvenile idiopathic arthritis (sJIA) fail to increase IFN- $\gamma$  production in response to IL-18. In contrast to IL-18 insensitivity in sJIA, acutely blocking IL-18 successfully treated a patient with NLRC4-MAS.[1] Due to the complex role of IL-18 in MAS and related diseases, we proposed to 1) characterize IL-18 in hyperferritinemic diseases, and 2) characterize NK and other IL-18 responsive cells in murine models of chronic IL-18 exposure.

### **Methods:**

Serum from patients with active sJIA, sJIA-MAS, Infection-Associated Hemophagocytic Lymphohistiocytosis or familial HLH (fHLH) was assayed by ELISA for total IL-18 and related cytokines. Transcriptional and flow cytometric assessment of lymphocytes from WT, Nlr4 mutant (N4-TS), and IL-18 transgenic (Il18tg) mice was also performed.

### **Results:**

Disease activity markers were comparable across the human cohort. Total IL-18 was substantially higher in sJIA-MAS than fHLH. IL-18 Binding Protein (IL-18BP) was not significantly different between hyperferritinemic syndromes, resulting in substantial free IL-18 in sJIA-MAS. By contrast, CXCL9 (a marker of IFN- $\gamma$  activity) was somewhat higher in fHLH. The ratio of total IL-18 to CXCL9 provided a basis for distinguishing sJIA-MAS from fHLH (ROC area under the curve = 0.93). A ratio > 2.3 provided 83% sensitivity and 100% specificity in distinguishing MAS from fHLH. (Figure 1)

Though we have observed increased serum IL-18 in N4-TS mice, we detected free IL-18 only in Il18tg mice. Consistent with this finding, we identified downregulation of the IL-18 receptor (IL-18R) in NK cells of Il18tg but not WT or N4-TS mice. Il18tg NKs had increased transcription of genes encoding perforin, IL-12R, and STAT1 but not IFN- $\gamma$ , suggesting a poised state of activation. The pattern of IL-18R expression in T cells differed from NKs in that we observed cell surface upregulation of IL-18R on activated tissue-resident CD8 $^{+}$  T cells in both N4-TS and Il18tg mice, but not WT.

### Conclusion:

Delays in precise diagnosis in hyperferritinemic syndromes may contribute to increased morbidity and mortality. We found that a diagnostic approach balancing assessment of inflammasome activity (represented by IL-18) with IFN- $\gamma$  activity (represented by CXCL9) impressively distinguished MAS from fHLH in this retrospective cohort. Whereas high IL-18 induces insensitivity in NKs, our data suggest it may promote exuberant responses by CD8 $^{+}$  T cells. Though the downstream effects of increased IL-18 on T cells requires further analysis, our data raise the possibility that the pathogenic effects of IL-18 in MAS are mediated through activated T cells.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Innate Immunity and Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Using whole exome sequencing, we discovered a *de novo* heterozygous germline mutation in *MYD88* (myeloid differentiation primary response 88) (c.666T>G, p.S222R) in a child with destructive small-to-medium joint polyarticular juvenile arthritis (JA) exhibiting persistent neutrophil-predominant synovial infiltrates and rash. MyD88 is a critical adaptor protein that connects Toll-like and IL-1 receptor signaling to activation of NF- $\kappa$ B. Germline loss-of-function mutations in MyD88 cause immunodeficiency, while somatic gain-of-function mutations have been linked to lymphoma. We asked whether the MyD88 S222R mutation causes gain-of-function effects that could contribute to the development of destructive arthritis.

**Methods:** The patient was evaluated for peripheral blood immunophenotype, cytokine and chemokine production, and monocyte osteoclastogenesis, compared to family and other healthy controls. Functional studies in monocytes and dermal fibroblasts included gene/protein expression, quantitation of neutrophil chemotaxis, and siRNA-mediated knockdown of MyD88 and p65. Wild type (WT) or S222R MyD88-AU1 fusion proteins were re-expressed in MyD88-deficient THP-1 cells. NF- $\kappa$ B activity was measured via p65 subunit phosphorylation and using a reporter system. Effects on MyD88 structure were predicted via molecular dynamics modeling, and mechanistic studies were performed to assess the capacity of S222R MyD88 to oligomerize, which is necessary for signaling, using IF microscopy and proximity ligation assay (PLA).

**Results:** MyD88 S222R results in increased NF- $\kappa$ B p65 phosphorylation and NF- $\kappa$ B reporter activity in THP-1 cells compared to WT MyD88. IF microscopy and PLA demonstrated increased MyD88-S222R oligomerization compared to WT MyD88, indicating a behavior similar to MyD88-L265P, which is the most common lymphoma-associated MyD88 gain-of-function mutation. Immunophenotyping showed a persistent absence of CD16 on monocytes, an expansion of CD4<sup>+</sup> Th17 T cells, and the presence of a previously uncharacterized CD123<sup>+</sup>CD11c<sup>+</sup> dendritic cell population, as well as markedly increased basal and stimulated p-STAT3 in monocytes and T and B lymphocytes in the patient. Peripheral monocytes exhibited baseline interferon and chemokine gene expression signatures, while monocyte-derived osteoclasts exhibited enhanced survival and were morphologically larger than those cultured from a control. Fibroblasts exhibited significantly greater baseline expression of CXCL chemokines compared to controls, which abated upon MyD88 or p65 knockdown.

**Conclusion:** This is the first description of a *de novo* germline MyD88 mutation (S222R) associated with severe polyarticular JA. We demonstrate clear gain-of-function effects of the S222R mutation using THP-1 cells which are consistent with biologic effects in hematopoietic and non-hematopoietic cells derived from the patient, and likely to be a consequence of increased oligomerization. These effects offer plausible mechanisms for neutrophil-predominant, destructive arthritis, and support a role for single gene defects contributing to extreme JA phenotypes.

## Activation of a Cytosolic DNA Sensor Pathway in the Etiopathogenesis of Sjögren's Syndrome

Harini Bagavant<sup>1</sup>, Joanna Papinska<sup>1</sup>, Gregorz Gmyrek<sup>1</sup>, Magdalena Sroka<sup>1</sup>, Indranil Biswas<sup>2</sup>, Sai Tummala<sup>2</sup> and Umesh S Deshmukh<sup>1</sup>, <sup>1</sup>Arthritis and Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>2</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Innate Immunity and Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Patients with Sjögren's syndrome (SjS) often present with a heightened type I IFN response. Recognition of DNA within the cytosol by a multitude of cytosolic DNA sensors and downstream activation of the stimulator of interferon gene (STING) protein is a key pathway for the induction of type I IFN. So far, only indirect evidence suggests that this pathway might be involved in the pathophysiology of SjS. Thus, the major objective of this study was to investigate the role of STING activation in the etiopathogenesis of SjS.

**Methods:** Female C57BL/6 mice (10-12 weeks old) were injected with a STING agonist dimethylxanthenone-4-acetic acid (DMXAA) and control mice were treated similarly with the vehicle. Salivary glands were monitored for gene expression by real time PCR and for inflammatory cell infiltration by immunohistochemistry and flow cytometry. Salivary gland function was evaluated by measuring pilocarpine-induced salivation. Sera were analyzed for cytokines and autoantibodies. Cultured primary salivary gland cells were used to study the expression and activation of STING *in vitro*.

**Results:** DMXAA treatment rapidly upregulated the expression of *Irf1* and pro-inflammatory cytokines, both systemically and locally in the salivary glands. In the murine submandibular glands, STING expression was detected only in the acinar, but not in the ductal cells. *In vitro* activation of STING in cultured primary salivary gland cells rapidly phosphorylated TBK1, IRF3 and induced the expression of *Irf1* and *TNFA*. Within 4 weeks of treatment, in comparison with the vehicle group, DMXAA treated mice developed significantly higher incidence of sialoadenitis (1/17 versus 10/21,  $p=0.009$ ). The inflammatory cell infiltrates were mainly composed of CD4<sup>+</sup>T cells and F4/80<sup>+</sup> activated macrophages. At early stages of the disease, significantly increased numbers of Lin<sup>+</sup> NK1.1<sup>+</sup> NK cells (CD49b<sup>+</sup>CD49a<sup>-</sup>), tissue resident type I innate lymphoid cells (ILC1) (CD49a<sup>+</sup>CD49b<sup>-</sup>) and salivary gland ILC1 (CD49a<sup>+</sup>CD49b<sup>+</sup>) were observed in the salivary glands. The mean saliva amount in DMXAA treated group (56±14 mg) was significantly lower ( $p=0.001$ ) than the untreated (80±20 mg) and the vehicle treated groups (78±25). The incidence of high titer ANA (>400) was significantly higher ( $p=0.02$ ) in the DMXAA group (8/16) than in the vehicle treated group (0/8).

**Conclusion:** This study demonstrates that activation of STING protein induces certain features of SjS in mice. Our study also suggests that IFN- $\gamma$  producing ILC1s might be involved in the initial stages of salivary gland disease in SjS. We would like to propose that apart from viral infections, conditions that cause cellular perturbations and accumulation of host DNA within the cytosol should be considered as possible endogenous triggers for SjS.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Innate Immunity and Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Behçet's disease (BD) is a chronic systemic vasculitis characterised by muco-cutaneous, ocular, gastrointestinal, cerebral recurrent lesions. Venous thrombosis, is a frequent and life-threatening complication. The etiology of BD is poorly understood but activated neutrophils have been proposed to contribute to the disease. However, evidence supporting a role for primed neutrophils in BD-associated thrombotic risk is scant. To respond to inflammatory insults, neutrophils release web-like structures, known as neutrophil extracellular traps (NETs), which are prothrombotic.

We aim to evaluate the role of NETs in the thrombotic complications in BD disease.

### **Methods:**

Blood samples were collected from BD patients according to the ACR International Study Group Criteria for Behçet's disease and healthy controls (HC). Cell free DNA (CfDNA), myeloperoxidase (MPO) and DNA complexes were measured in serum using Picogreen assay and ELISA. NETosis was assessed in purified neutrophils from BD patients and HC, and analyzed by microscopy after immunostaining of MPO and DNA. Thrombin generation assay were performed in plasma of patients and HC.

### **Results:**

Active BD patients (n=16) had elevated serum CfDNA levels compared to inactive BD patients (n=23) and to HC (n=8) ( $2105 \pm 249$ ,  $1379 \pm 79$  and  $951 \pm 64$  ng/ml respectively  $p < 0.0001$ ). MPO-DNA complexes were significantly increased in Active BD serum (n=15) compared to inactive BD (n=19) and to HC serum (n=8) ( $2.84 \pm 0.21$ ,  $1.92 \pm 0.26$ , and  $0.32 \pm 0.08$  OD, respectively,  $p < 0.001$ ). In addition, levels of cfDNA and MPO-DNA complexes were significantly higher in Angio BD serum (n=17) compared to non-angio BD serum (n=22) ( $2073 \pm 237$  vs  $1390 \pm 0.83$  ng/ml  $p = 0.008$  and  $2.96 \pm 0.13$  vs  $1.80 \pm 0.26$  OD  $p = 0.004$ , respectively). Purified neutrophils from BD patients exhibited spontaneous NETosis compared to HC ( $31.7 \pm 4.4\%$  vs  $5.4 \pm 1.9\%$  respectively,  $p = 0.004$ ). Consistently, PMA-activated neutrophils from BD patients have increased NET formation compared to neutrophils from HC ( $41.8 \pm 2.7\%$  vs  $18 \pm 3.8\%$  respectively,  $p = 0.002$ ). Thrombin generation in BD plasma was significantly increased and positively correlated with MPO-DNA complexes ( $r^2 = 0.84$ ,  $p = 0.001$  and cfDNA ( $r^2 = 0.9$ ,  $p = 0.002$ ). Importantly, DNase treatment significantly decreased thrombin generation in BD plasma but had no effect in HC plasma suggesting a procoagulant role of NETs.

### **Conclusion:**

Our data show for the first time the critical role of circulating NETs in BD patients. NETs may be involved in thrombi formation. Targeting NETs may represent a potential therapeutic option in BD.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Innate Immunity and Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Fibrosis is the end-result of most inflammatory conditions, but its pathogenesis remains unclear. Studies in patients and animal models suggest a role for T-cells and innate immune cells including dendritic cells (DC) in the development of fibrosis. DCs play a role in T-cell priming and differentiation also infiltrate the lung in response to bleomycin injection in animals. DCs also accumulate in lungs of patients with idiopathic pulmonary fibrosis and in skin of patients with systemic sclerosis (SSc). However, the exact role of DCs in the pathogenesis of fibrotic diseases including SSc is unclear. We investigated the role of plasmacytoid dendritic cells (pDC) in the pathogenesis of systemic fibrosis using the bleomycin model and clinical samples from patients with systemic sclerosis (SSc).

### Methods:

Female C57BL/6 mice were depleted of pDCs using anti-pDCA1 and were compared to mice depleted with isotype control IgG2b. clinical observation and analyses were carried of draining LN, spleen, lungs and skin including flow cytometry, pathology, collagen production and RT PCR array. In our work, we evaluated human data (HRCT and BAL) from SSc Imatinib trial. We also examined pDCs in Peripheral blood, skin and lung in controls as well as SSc patients.

### Results:

pDCs were more profoundly increased than other immune cells in the lung and lung-draining lymph nodes, but not in the spleen, of bleomycin-injected mice compared to control animals. Depletion of pDCs improved the clinical score, lung histopathology score, skin thickness, and collagen content compared to control antibody-treated animals. B-cells, T-cells and natural killer T-cells were reduced in the lungs, but unaffected/increased in the spleen, of pDC-depleted mice as compared to controls. pDC-depleted mice also had a reduced expression of genes involved in chemotaxis, dendritic cell differentiation, inflammation, and fibrosis in the lungs as compared to controls. In humans, while pDCs were reduced in the peripheral blood of patients with SSc compared to healthy donors, their numbers were increased in the lung and skin of patients with SSc. The frequencies of pDCs in the bronchoalveolar lavage (BAL) correlated with SSc-lung disease scores and with IL-4<sup>+</sup> and CD4<sup>+</sup> T-cells in BAL.

### Conclusion:

Taken together, our observations identify the increased trafficking to pDCs to the affected organs as a potential therapeutic target in fibrotic diseases.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Understanding factors associated with the readiness for adopting osteoporosis treatment change may inform the design of behavioral interventions to improve osteoporosis treatment uptake in women at high risk for fracture.

**Methods:** US women in the Global Longitudinal Study of Osteoporosis (GLOW) with prior self-reported fractures and not currently using osteoporosis therapy were eligible to participate in the Activating Patients at Risk for Osteoporosis (APROPOS) Study. Participants' readiness for behavior change was assessed using a modified form of the Weinstein Precaution Adoption Process Model (PAPM). We defined pre-contemplative participants as those who self-classified in the unaware and unengaged stages of PAPM. Contemplative participants were defined by the undecided, decided not to act, and decided to act stages of PAPM. Bivariate tests and stepwise multivariable logistic regression evaluated the following factors associated with these two levels of readiness for behavior change: sociodemographic characteristics, health literacy, self-reported history of depression and dementia, previous treatment for osteoporosis, whether participants had been told they had osteoporosis/osteopenia, and whether they had concerns about osteoporosis.

**Results:** A total of 2,684 women were enrolled in APROPOS. Participants were 95% Caucasian, with a mean(SD) age 74.9(8.0) years and 77% had some college education. Overall, 25% (N=544) self-classified in the contemplative stage of behavior change. Compared to women who self-classified as pre-contemplative, contemplative women were more likely to be concerned about osteoporosis (adjusted OR[aOR]=3.2, 95% CI 2.3-4.4) and to report prior osteoporosis treatment (aOR 4.3, 95% CI 3.1-6.0). Individuals who had been told they had osteoporosis had a 12.4 fold odds to be in the contemplative group (95% CI 8.5-18.1), while those who had been told they had osteopenia had 4.1 fold odds to be in the contemplative group (95% CI 2.9-5.9).

**Conclusion:** Among women with high risk of future fracture, having been told by a health care provider that they had osteoporosis/osteopenia was independently associated with considering taking medications for osteoporosis. Our results suggest that in considering osteoporosis intervention design efficiency and effectiveness, women's recognition of a diagnosis of osteoporosis/osteopenia are critical components to be considered when attempting to influence stage of behavior transitions.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Increasingly, evidence suggests that treatment of people at risk of rheumatoid arthritis (RA) with anti-rheumatic drugs could prevent the onset of disease. Ongoing randomized controlled trials of treatments to prevent RA are starting to report their findings. There will be uncertainty about preventative treatment in practice, arising from the ability to predict who is at risk of RA, uncertain benefits and risks with preventative treatment and the convenience of treatment to the recipient. The aim of this study was to determine the preferences of pre-symptomatic, at risk people, for preventative treatment and the likely uptake of preventative treatment

**Methods:** A discrete choice experiment was administered using a web survey to North American patients and first-degree relatives of patients, asking participants to first choose between sets of 2 hypothetical preventative RA treatments, then choose between their preferred treatment and 'no treatment for now'. Focus groups of RA patients, first-degree relatives of RA patients and rheumatologists identified 5 key attributes of treatment (reduction in risk of RA, how treatment is taken, chance of side effects, certainty in estimates, health care providers opinion). An experimental design using SAS developed 18 choice sets blocked into 4 sets of 11 choices, which included 2 consistency checks. DCE data was analyzed using a conditional logit regression model to estimate the significance and relative importance of attributes in influencing preferences.

**Results:** 597 people (25% of whom reported having RA) started and completed all tasks in the survey. The majority of the sample were from the USA (88%), aged between 25 and 64 years, modal age category was 30 to 39 years (52%), and 59% female. All attributes levels significantly influenced preferences for treatments, but how treatment is taken (oral vs. infusion  $\beta 0.971$ ,  $p < 0.001$ ) was the most influential, followed in similar magnitude by reducing risk of side effects ( $\beta 0.862$ ,  $p < 0.001$ ), matching of patient and health care professional preferences ( $\beta 0.859$ ,  $p < 0.001$ ), and increasing risk reduction ( $\beta 0.839$ ,  $p < 0.001$ ). The strength of preference for reducing uncertainty in evidence was statistically significant but smaller in magnitude (moderate from very little certainty  $\beta 0.487$ ,  $P = 0.005$ ). Respondents would be most willing to trade a reduction in risk of RA for an oral route of administration followed by a treatment preferred by their health care professional. The preferred preventative treatment was chosen over no treatment in 67% of choices.

**Conclusion:** Our survey suggests that the most important feature of preventative strategy for RA will be the convenience of taking treatment, followed by the potential risks and benefits of treatments, but equally the recommendation or preference of their health care provider. The degree of confidence in estimates of risks and benefits of treatments is also important in people's decisions to accept treatment. The uptake of a preventative strategy will depend on these key factors. This evidence will help policy makers understand whether different preventative treatment strategies are likely to be acceptable to people to whom they might be offered.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** biological DMARDs (bDMARDs) are effective in the treatment of RA, but are also associated with side-effects and high costs. Dose reduction of bDMARDs, after low disease activity is reached, is safe and effective<sup>1</sup>. To date, few studies have focused on bDMARD dose reduction from the patient perspective. Therefore, the aim of this study was to identify the factors that play a role for patients when considering dose reduction, and to determine their relative importance.

**Methods:** A mixed methods design was used in which we 1) identified influencing factors by performing qualitative interviews and 2) ranked these factors using a Maximum Difference Scaling questionnaire.

**Phase 1:** We performed semi-structured interviews with RA patients. Interviews were transcribed verbatim and two researchers analyzed the transcriptions by inductive thematic analysis.

**Phase 2:** The influencing factors were derived from the interviews and used in a Maximum Difference Scaling experiment with RA patients from 3 different centers in the Netherlands (an academic hospital, a specialized hospital and a large general hospital). The survey included 18 questions in which patients were asked to choose the most and least important factor from a subset of 5 factors. The mean relative importance score (RIS) for each factor was calculated using hierarchical Bayes modeling.

**Results:** For phase 1 and phase 2, 22 and 195 patients were included respectively (table 1). Thirty factors were identified from the interviews and used in the questionnaire. The 10 factors that were ranked the highest, are shown in table 2. Most respondents had a positive attitude towards bDMARD dose reduction. The results show that patients are concerned that dose reduction will lead to a disease flare that affects their daily life (pain, function). It is important for them to know that it is possible to increase the dose if (further) reduction is not possible and that the bDMARD will be effective again. Patients value the opinion of their rheumatologist, and being involved in the decision to start tapering is highly ranked as well.

<b>Table 1. Patient characteristics</b> (mean (SD) or N (%))		
<b>Characteristic</b>	<b>Phase 1 (n=22)</b>	<b>Phase 2 (n=195)</b>
<b>Female</b>	15 (68%)	126 (65%)

<b>Disease duration (years)</b>	13 (9.4)	16 (10.0)
<b>Number of respondents per center</b>	Specialized hospital: 22 (100%)	Specialized hospital: 69 (35%) Academic hospital: 65 (33%) Large general hospital: 61 (31%)
<b>Experience with bDMARD dose reduction</b>	Yes: 16 (73%) No: 6 (27%)	Yes: 119 (61%) No: 72 (37%) I don't know: 4 (2%)
<b>General attitude towards bDMARD dose reduction</b>	Not applicable	Very positive: 64 (33%) Positive: 79 (41%) Neutral: 28 (14%) Negative: 12 (6%) Very negative: 2 (1%) I don't know: 10 (5%)

<b>Table 2. Top-10 factors from the Maximum Difference Scaling questionnaire</b>	
<b>Nr.</b>	<b>Factor</b>
1	The possibility to increase the dose when disease symptoms worsen
2	The risk that my disease activity will increase
3	My current disease activity
4	The risk that my physical function will deteriorate (e.g. I won't be able to work)
5	The confidence I have in my rheumatologist
6	To what extent I'm involved in the decision on bDMARD dose reduction
7	Whether the bDMARD is (still) necessary for the RA
8	What my rheumatologist advises regarding bDMARD dose reduction
9	The risk that I will experience more pain
10	The effect of the bDMARD after increasing the dose

**Conclusion:** Although preferences will vary between individual patients, the results from this study could facilitate implementation of bDMARD dose reduction by informing care providers on what is important for patients and providing a basis for shared decision making.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Many important treatment decisions for patients with rheumatoid arthritis (RA) are conditional on patient preferences and mandate a shared decision making (SDM) approach. Furthermore, SDM is being increasingly recognized as an important quality measure. One of the most common preference sensitive decisions in RA is how to escalate care when response to

methotrexate monotherapy is inadequate. The objective of this study was to examine whether preference phenotypes can be used to promote SDM at the point-of-care.

**Methods:** 1314 subjects completed a conjoint analysis survey (1048 in English, 266 in Spanish) designed to elicit preferences for triple therapy, FDA-approved biologics and tofacitinib. Five distinct phenotypes were generated using latent class analysis (See Figure). We subsequently created a pamphlet to describe the phenotypes and their implications. To examine the feasibility of using preference phenotypes to promote SDM in the clinic, we performed a pre-post-test study. Consenting RA patients received the pamphlet once roomed by a nurse in the post-phase. Visits in both phases were audiotaped, and those in which there was evidence of active disease were transcribed and analyzed.

**Results:** 50 visits were transcribed in the pre-phase and 46 in the post phase of the study. The mean age of the study population was 59 years; 85% were female, 68% were Caucasian, and 65% were seropositive. The pamphlet was used in 38 of the 46 visits in the post phase. Thirty-six out of the 38 patients were able to identify with one or more of the phenotypes presented in the pamphlet. A greater number of treatment decisions were concordant with patients’ preferences in the post-phase compared to pre-phase (12% vs 35%). Addition of the pamphlet did not increase the time of the visits. The average time of visits in the pre- and post-phases was 29 and 25 minutes respectively.

**Conclusion:** The results of this feasibility study suggest that patients can identify with preference phenotypes representing variability in patient values and that introduction of this tool at the point-of-care may increase the likelihood that treatment decisions are concordant with patients’ values.

Figure 1. Variability in What Matters Most to Patients

Figure 2. Which group most closely matches how you think about RA medications?  
If you don't match up with one group, that's ok. Pick the statements you feel most closely reflect how you feel.

	Orange Group	Tan Group	Blue Group	Yellow Group	Green Group
	"I dread taking my medications because of the stomach problems and diarrhea I get"	"I want it to work fast. I'm in very severe pain; I just barely make it through my day now"	"Anxiety builds up when I have to inject myself or get an IV"	"These serious risks really scare me, even if they are extremely rare"	"The fear of changes to my insurance coverage worries me greatly"
Our TOP priority is to:	Avoid side effects that impact quality of life (stomach problems, headaches, feeling groggy)	Feel the medicine working as fast as possible	Avoid needles	Avoid a very rare chance of a life-threatening infection, permanent eye problems, or a condition like MS	Be able to afford the medicine
Other things that influence our decision:	Affordability Serious infections How fast it starts working	Affordability Serious infections Side effects that impact quality of life How to take the medicine (we prefer infusions)	Affordability Serious infections Side effects that impact quality of life Time on the market	Affordability Serious infections Side effects that impact quality of life	Side effects that impact quality of life How fast it starts working
We pay little attention to:	Time on the market How to take the medicine (but we prefer injections) Very rare life-threatening or disabling side effects	Time on the market Very rare life-threatening or disabling side effects	How fast it starts working Very rare life-threatening or disabling side effects	Time on the market How fast it starts working How to take the medicine (pills or needles)	Time on the market How to take the medicine (pills or needles) Serious infections Very rare life-threatening or disabling side effects

Assessing RA Disease Activity with Promis Measures Using Smartphone Technology

**Huifeng Yun**<sup>1</sup>, Shuo Yang<sup>2</sup>, W. Benjamin Nowell<sup>3</sup>, Cooper Filby<sup>1</sup>, Lang Chen<sup>1</sup> and Jeffrey R. Curtis<sup>4</sup>, <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Global Healthy Living Foundation, Upper Nyack, NY, <sup>4</sup>Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Health information technology has enabled efficient measurement of PROs using Computer Adaptive Testing (CAT) methods, which have been shown to minimize missing data and reduce participant burden. The bridge between PROMIS and traditional patient-reported PROs (e.g. RAPID3) is not clear, and it might be possible that some instruments in PROMIS might proxy for measuring more lengthy PROs.

**Methods:** Four PROMIS CAT instruments: Pain Interference, Physical Function, Sleep Disturbance, Fatigue, and a visual analog scale (Pain Intensity); and the Routine Assessment of Patient Index Data 3 (RAPID3) were administered to participants in the PCORI-funded ArthritisPower patient registry via a mobile application (App) on their smartphone or computer. The RAPID3 was evaluated in terms of multiple correlations (Pearson) with PROMIS and total variance explained using mixed models. Both the RAPID3 score and category was predicted using the selected 4 PROMIS instruments and pain intensity to form a new predicted score ("CAT-PROMIS RAPID3"). Kappa statistics and Bland-Altman 95% limits of agreement (LOA) were used to measure agreement between the measured RAPID3 and the predicted CAT-PROMIS RAPID3.

**Results:** At the time of analysis, 2,376 patients had answered all five PROMIS instruments and the RAPID3 and contributed 3906 observations. Mean  $\pm$  SD age was 51.6  $\pm$  10.5 years; 90% were women. Most (81%) had high RAPID3 scores. The mean assessment time for each of the PROMIS instruments ranged from a low of 16 seconds (sleep disturbance) to a high of 105 seconds (RAPID3). As single pairwise comparisons, the 4 PROMIS CATs examined were only modestly correlated ( $r \sim 0.2-0.4$ ) to one other and the RAPID3. However, in aggregate, the PROMIS instruments explained a very high fraction of total variance ( $R^2=80\%$ ) of the RAPID3. The measured RAPID3 was very highly correlated with the CAT-PROMIS predicted RAPID3 ( $r=0.97$ ). Overall agreement (table) between categories of the RAPID3 vs. CAT-PROMIS RAPID3 also was very high (kappa = 0.81). Bland-Altman 95% limits of agreement shows minimal residual differences and no systematic biases.

**Conclusion:** There was excellent agreement between the measured RAPID3 and a predicted RAPID3 score estimated using several PROMIS instruments. Few if any questions in the RAPID3 may need to be measured if PROMIS scores are available.

Table. Cross Classification of Patient-reported RAPID3 versus predicted PROMIS-CAT RAPID3				
	PREDICTED CAT-PROMIS RAPID3			
RAPID3	Near remission	Low	Moderate	High
Near remission	34	15	1	0
Low	2	66	45	0
Moderate	1	6	423	133
High	0	0	21	3,159

# Patient Beliefs and Preference to Initiate a Proposed Medication in Rheumatoid Arthritis

**Richard W Martin**<sup>1</sup>, Rohit Nallani<sup>2</sup>, Andrew D Head<sup>1</sup>, Aaron T Eggebeen<sup>1</sup>, James D Birmingham<sup>1</sup> and Eric T Slavin<sup>1</sup>, <sup>1</sup>Medicine, Rheumatology, Michigan State University, College of Human Medicine, Grand Rapids, MI, <sup>2</sup>Michigan State University, College of Human Medicine, Grand Rapids, MI

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose :** Normative economic theory assumes that people making decisions have complete information of the options, rationally weigh the opportunity costs, expected outcomes and optimize their net benefit<sup>1</sup>. However, rheumatoid arthritis (RA) patients facing medication decisions during a doctor-patient dialogue often do not have all the information needed to make a rational decision. In addition, patients primed with pharmaceutical industry (pharma) ‘decision guides’ may choose to escalate DMARD therapy based on the social influence of testimonials<sup>2</sup> rather than increased knowledge<sup>2</sup>. In the current study, we evaluate how patient beliefs about antirheumatic medicines influence choice to add or change medications when patients are not primed with pharma decision guides.

**Methods:** We conducted a prospective observational study of doctor-patient discussions about adding or changing medications in consecutive RA patients attending routine rheumatology clinic visits. All patients completed written surveys immediately after medication discussions as well as a 30-day post-visit telephone survey. We evaluated patient beliefs about the proposed medicines from the perspective of the Integrated Model of Behavioral Prediction which included: expected outcomes, as well as perceived social norms and behavioral control<sup>2</sup>.

**Results:** Of 580 RA patients seen during the observation period, 104 (17.9%) patients discussed starting a new medication. 91 (87.5%) completed the follow up survey. Demographics: Mean age 55.4 years, RA duration 7.5 years, CDAI 20 (range 0-50). 65.4% of discussions involved escalating DMARD therapy. Baseline patient belief about medication (0-5) were that they would: Improve symptoms 4.14 (sd .92), Slow progression 3.76 (sd 1.20), Cause serious adverse effect (SAE) 2.43 (sd 0.77), Others like me would choose to start the medication (Social Norm) 3.95 (sd 0.97), and Self-efficacy to take medication 4.68 (sd .53). A linear regression model of these 5 predictor variables on intention to take the proposed medication had an  $R^2 = .143$ . Standardized  $\beta$  were significant for ‘Belief would have SAE’ - .245 (P=.01) and ‘self-efficacy’ .222 (P=.02) but not ‘Improve symptoms’, ‘Slow progression’ or ‘Social Norm’. 30 days after the doctor-patient dialogue patient beliefs the medication would cause improvement and slow progression increased (P<.01), Self-efficacy to take the medication decreased (P<.01) and beliefs would have SAE and Social Norm were stable (NS).

**Conclusion:** Patients making real life decisions had high expectations that anti-rheumatics would improve their symptoms, but their preference to initiate therapy was more dependent on the belief they would have a SAE and beliefs of their behavioral control to take the medication. When not primed with pharma materials, patient perception of social norms did not demonstrate a significant effect on preference.

# Medications Associated with Osteoporotic Fracture Risk in Patients with Rheumatoid Arthritis

Gulsen Ozen<sup>1</sup>, Sofia Pedro<sup>2</sup>, Frederick Wolfe<sup>2</sup> and Kaleb Michaud<sup>1</sup>, <sup>1</sup>Rheumatology, University of Nebraska Medical Center, Omaha, NE, <sup>2</sup>National Data Bank for Rheumatic Diseases, Wichita, KS

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects IV: Medications and Risk

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Osteoporotic (OP) fractures are a major cause of disability, cost, and mortality in RA. Besides increased OP fracture risk, chronic inflammation and pain predispose RA patients to several comorbidities including cardiovascular, mental, and gastrointestinal disorders that lead to the frequent use of multiple medications. Some of these medications have been reported to influence OP fracture risk in the general population, but these associations have not been studied in RA patients. We examined the association of DMARDs, statins, antidepressants, proton pump inhibitors (PPI), opioids, NSAIDs, anticonvulsants, and antipsychotics with OP fracture risk in a US-wide observational RA cohort.

**Methods:** RA patients ( $\geq 40$  years old) without prior OP fracture from 2001 through 2016 in the National Data Bank for Rheumatic Diseases (NDB) were assessed for OP fractures (fractures resulting from any fall from a standing height or less). DMARDs were categorized into 4 mutually exclusive groups: (1) MTX monotherapy-reference (2) TNF inhibitors (TNFi) (3) Non-TNFi biologics (4) Others; along with a separate glucocorticoid (GC) variable. Statins, antidepressants (selective serotonin reuptake inhibitors [SSRI] and others), PPI, opioids (weak and strong opioids), NSAIDs, anticonvulsants, and antipsychotics were evaluated separately as current use vs. nonuse and based on the treatment duration. Cox proportional hazard models were used to adjust for sociodemographics, comorbidities, BMI, fracture risk by FRAX, and RA severity measures.

**Results:** During a median (IQR) 5.4 (2.3-9.7) years of followup in 11,002 RA patients, 863 (7.8%) OP fractures were observed. Patients who developed fractures were significantly older, had higher disease duration and activity, GC use, comorbidity and FRAX scores at baseline than who did not. Crude incidence rates (95% CI) in each medication group are presented in the *Table*. The adjusted models showed a significant OP fracture risk increase with GC use of  $\geq 3$  months of any dose, SSRI (HR 1.35 [1.10-1.64],  $P=0.003$ ), opioids of any strength (weak: HR 1.48 [1.26-1.74]; strong: HR 1.78 [1.41-2.26],  $P<0.001$  for both) (*Table*). OP fracture risk increase started even after 1-30 days of opioid use (HR 1.99 [1.59-2.48],  $P<0.001$ ), whereas SSRI-associated risk increase started after 3 months of use (HR 1.25 [0.99-1.59],  $P=0.061$ ).

**Conclusion:** SSRI and opioids were associated with increased OP fracture risk in RA patients. This risk increase might be associated with increased fall risk caused by these medications. Given the frequent occurrence of chronic pain, mood disorders and polypharmacy in RA patients, the necessity of the medications should regularly be reviewed in RA patients, particularly who have high fracture risk and long-term GC use. When managing pain with opioids, even in the short-term, clinicians should be aware of the fracture risk.

**Table. Crude incidence rates and adjusted hazard ratios associated with mediations in patients with rheumatoid arthritis**

## **Are We over-Testing for Liver Enzyme Abnormalities in Rheumatoid Arthritis Patients Prescribed Methotrexate?**

**Chi Chi Lau**<sup>1</sup>, Syeda Maria Sayeed<sup>1</sup>, Amanda Kennedy<sup>2</sup>, Joan Skelly<sup>3</sup> and Sheldon Cooper<sup>4</sup>, <sup>1</sup>Rheumatology/ Medicine, University of Vermont, Burlington, VT, <sup>2</sup>Internal Medicine, University of Vermont, Burlington, VT, <sup>3</sup>Biostatistics, University of Vermont, Burlington, VT, <sup>4</sup>Department of Medicine/Rheumatology, University of Vermont, Burlington, VT

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects IV: Medications and Risk

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Methotrexate (MTX) is a first line drug for Rheumatoid Arthritis (RA) that is associated with elevated liver function tests (LFTs) in 10- 20% of patients though only 2-3 % of patients stop MTX for this side effect. Current guidelines advise LFT testing every 2 to 3 months with little data to support the utility of such monitoring. Our goal was to describe changes made to MTX dosing in response to elevated aspartate aminotransferase (AST) levels and define any correlation between elevated AST to MTX dose and duration of therapy.

**Methods:** The electronic health records of RA patients on MTX from 7/1/2009 to 12/31/2015 were reviewed for elevated AST values (>46 U/L), which were categorized as mild (>1- < 2x upper limits of normal, ULN) or severe (≥2x ULN). We recorded the MTX dose and duration, and action taken on the dose (continued, decreased, stopped, or stopped for other reason than MTX) at the time of the AST elevation. The last AST observed for each patient while on MTX was used for analysis. Fisher's Exact test was used to compare the proportions of actions taken in each AST category. A Spearman correlation was used to assess the correlation between MTX dose and AST levels; t-tests were used to compare MTX duration between the AST levels.

**Results:** Of 1158 RA patients taking MTX, 235 (20.2%) had at least one elevated AST value. Sixteen (6.8%) patients with elevated AST stopped MTX, because of provider concern for hepatotoxicity from the drug. Most patients (78%) with mild AST elevation continued MTX ( $p < 0.0005$ ), although 18% of patients continued MTX despite severe AST elevation (Figure 1). Providers stopped MTX for other reasons (infection, malignancy, cardiac event, cholelithiasis) in 76% of patients with severe AST elevation. There was no correlation between MTX dose and elevated AST (Spearman correlation = -0.015). Patients with mild AST elevation were on MTX for a mean (SD) of 73.3 (60.7) months which was no different from those with severe AST elevation at 69.5 (47.2) months,  $p = 0.736$  (Figure 2, AST level vs MTX duration).

**Conclusion:** Liver enzyme elevation, as measured by AST level, rarely resulted in MTX cessation for suspected MTX toxicity. The most common reason for stopping MTX was for AST elevation in the presence of an acute illness not related to RA. We advocate less frequent LFT testing for patients on MTX when the patient is clinically stable due to lack of evidence that monitoring leads to meaningful change in provider prescribing practice.

Curtis<sup>3</sup>, Michal Abrahamowicz<sup>4</sup>, Hassan Behloul<sup>1</sup> and **Sasha Bernatsky**<sup>5</sup>, <sup>1</sup>Department of Medicine, McGill University Health Centre, Montreal, QC, Canada, <sup>2</sup>Division of Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada, <sup>3</sup>Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL, <sup>4</sup>Department of Medicine, McGill University Health Centre, Montreal, QC, Canada, <sup>5</sup>Divisions of Rheumatology and Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects IV: Medications and Risk

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Little is known about the real-world safety of tofacitinib, an oral Janus kinase inhibitor. We compared serious infections associated with tofacitinib, disease-modifying antirheumatic drugs (DMARDs), tumor necrosis factor inhibitors (TNFi) and non-TNF biologics in rheumatoid arthritis (RA) patients previously treated with methotrexate (MTX).

**Methods:** We performed a retrospective cohort study using MarketScan® Databases from 2010-2014. We studied adults with RA, previously treated with MTX, and newly prescribed one of the medications under study between January 2011 and December 2014. Cohort entry was the date of first prescription or infusion of drug. We required subjects to be continuously enrolled with medical and pharmacy coverage for 12 months before cohort entry and to have had no use of biologics or tofacitinib at any point prior to cohort entry. We defined serious infection as one associated with a hospitalization. We assessed current drug exposure considering prescription days' supply or infusion intervals in a time-dependent manner, thereby classifying patients into one of the five groups: 1) DMARDs without biologics or tofacitinib; 2) TNFi +/- DMARDs, 3) non-TNF biologics +/- DMARDs; 4) tofacitinib +/- DMARDs, or 5) non-use (time within none of the previous groups). Subjects remained exposed for the most recently presented drug group until 90 days or until the start of a new drug. This classification was independent of whether the patient did or did not continue to use MTX, including the group 5. We estimated the rate of serious infection and hazard ratios (HR) with 95% confidence intervals (CI) to assess the risk of serious infections between the exposure groups, using group 5 as a reference. We adjusted the analysis for covariates such as sex, age, year of cohort entry, current use of MTX, and confounders in the one-year prior to cohort entry: Charlson comorbidity index; use of selective COX-2 inhibitors, nonsteroidal anti-inflammatory drugs, and oral glucocorticoid (none,  $\leq 7.5$ mg/day,  $> 7.5$ mg/day); hospitalization for infection and for all reasons; physician, rheumatology, and emergency department visits. Patients were followed from cohort entry until the earliest date of loss of medical or pharmacy coverage, death, end of the study, or the first hospitalized infection.

**Results:** We included 21,832 RA patients; 0.8% with tofacitinib, 24.7% with other DMARDs, 61.2% with TNFi, and 13.3% with non-TNF biologics. Among all patients, 77.0% were female and the median age was 56 (interquartile interval 48-63) years. The incidence of serious infection with tofacitinib was 3.7 per 100 patient-years. The adjusted HR for hospitalized infection was 1.81 (95% CI 1.08-3.01) for tofacitinib compared to the reference group (Table 1).

Table 1. Crude incidence and adjusted hazard ratio with 95% confidence interval for serious infection.

Exposure groups	Events	Total person-years	Incidence (per 100 patient-year)	Adjusted Hazard Ratio	95% Confidence Interval
Non use	134	6,833.71	1.96	-	-
DMARDs	103	5,157.20	2.00	0.82	0.62; 1.07
TNFi +/- DMARDs	484	22,351.79	2.17	1.13	0.92; 1.38
Non-TNF biologic +/- DMARDs	168	6,648.01	2.53	1.10	0.87; 1.38
Tofacitinib +/- DMARDs	17	464.32	3.66	1.81	1.08; 3.01

## Conclusion:

Tofacitinib was associated with more hospitalized infections, but this could represent channelling. Further analyses are underway.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects IV: Medications and Risk

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Current guidelines recommend holding biologic DMARDs before major surgery, despite limited data. Few studies have examined perioperative timing of individual biologic therapies. This study evaluated whether holding abatacept infusions before elective hip or knee arthroplasty is associated with a decreased risk of serious post-operative infection.

**Methods:** This retrospective cohort study using U.S. Medicare claims data from 2006-2014 evaluated adults with  $\geq 2$  ICD9 codes for RA who received abatacept by infusion (precisely dated in claims data) within 6 months of elective inpatient primary or revision total hip or knee arthroplasty. Patients with hip fracture, malignancy, pre-existing infection, non-elective procedures (admission through the emergency department or as a hospital transfer), or with surgery after hospital day 3 were excluded. Multivariable logistic regression evaluated associations of abatacept stop timing (time between most recent infusion and surgery categorized in 4 week intervals based on dosing interval) with serious (hospitalized) infection within 30 days using a validated set of discharge diagnoses from inpatient hospitalizations, adjusting for potential confounders. Associations of abatacept stop time with rate of prosthetic joint infection (PJI, ICD9 996.66) within 1 year were examined using Kaplan-Meier curves.

**Results:** Among 1476 surgeries in 1358 patients, serious infection within 30 days occurred in 10.1% (n = 149). Urinary infection, skin/soft tissue infection, and pneumonia were the most common infections. In adjusted analyses, stop timing of 4-8 weeks (held for one dosing interval) vs. < 4 weeks was not associated with a significant decrease in the risk of infection [OR 0.91 (0.62-1.33), p = 0.62] (Table). Glucocorticoid dose > 7.5mg/day vs. none was associated with increased risk of infection [OR 2.38 (1.42-3.98), p = 0.001]. Over 12 months, the rate of PJI was 2.7 per 100 person-years (n = 33 infections). Rates of PJI within 1 year were similar in patients with abatacept stop timing < 4 weeks vs. longer stop timing (Figure).

**Conclusion:** Holding abatacept for one dosing interval (i.e. one month) was not associated with a decrease in the risk of post-operative infection. In contrast, glucocorticoid dose > 7.5mg per day was associated with a substantial increase in the risk of post-operative infection. Given the potential risk of flare, holding abatacept prior to elective joint procedures may not be warranted.

**Table 1:** Crude and adjusted risk of serious infection within 30 days and cumulative incidence of prosthetic joint infection within 1 year after elective hip and knee arthroplasty

	N	Crude 30-day Infection n (%)	30-day infection adjusted OR* (95% CI)	Person Years	Crude PJI n (incidence/100py)
Abatacept Stop Timing					
< 4 weeks	589	60 (10.2%)	Reference	492	11 (2.2)
4-8 weeks	633	60 (9.5%)	0.91 (0.62-1.33)	526	16 (3.0)
8-12 weeks	119	13 (10.9%)	0.96 (0.50-1.83)	98	4 (4.1)
≥ 12 weeks	135	16 (11.9%)	1.10 (0.60-2.02)	114	2 (1.8)

\* Adjusted for age, sex, race, disability, surgery type, glucocorticoid dose, Charlson score, obesity, congestive heart failure, hospitalized infection past year, antibiotic use past year, number of previous biologic DMARDs, methotrexate use. Tested as confounders but excluded from the model (all  $p > 0.2$ ): year, region, urban, zip-code based income, diabetes, COPD/asthma, osteonecrosis, extra-articular RA, hospitalization past year, skilled nursing facility stay past year, number of outpatient visits, surgeon volume

**Figure:** Kaplan-Meier curves showing prosthetic joint infection within 1 year of surgery by pre-operative abatacept stop time, censoring at death, end of enrollment, or subsequent hip or knee arthroplasty

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects IV: Medications and Risk

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Baricitinib (bari) is an oral selective Janus kinase (JAK) 1 and JAK2 inhibitor approved in the EU for the treatment (trt) of moderately to severely active rheumatoid arthritis (RA) in adults. Compared to the general population, RA patients (pts) have an increased rate of tuberculosis (TB) and other potential opportunistic infections (OI). This analysis evaluated reported potential OI in RA pts treated with bari across 8 completed studies (4 Phase [Ph] 3, 3 Ph2, 1 Ph1) and 1 ongoing long-term extension (LTE) study, with data up to September 1, 2016.

**Methods:** The All bari RA analysis set included pts exposed to any bari dose, with exposure up to 5.5 years (yrs) (Ph 1-3 and LTE studies); the comparison with placebo (PBO) was based on 6 studies (Ph 2-3) with bari 4 mg QD and PBO up to week (wk) 24 (PBO-bari 4 mg set); dose-response assessment was based on 4 studies (Ph 2-3) with bari 2 and 4 mg QD, including the LTE (bari 2mg-4mg-extended set); the methotrexate (MTX) and adalimumab (ADA) data were based on the individual studies RA-BEGIN and RA-BEAM, respectively, up to wk 52. Reported potential OI were identified using Lilly-defined preferred terms from the Infections and infestations system organ class of the Medical Dictionary for Regulatory Activities (MedDRA) and pre-specified pairings of infecting organism and infection site. Sponsor medical review of these events was conducted to identify potential OI.

**Results:** Forty-five events, including TB, were identified in the All bari RA set (Table). There were 10 reported cases of TB (incidence rate [IR]=0.15/100 pt-yrs [PY]); all occurred in TB-endemic regions and 6 were associated with extra-pulmonary involvement. Bari was associated with an increased risk of trt emergent herpes zoster (HZ) compared to PBO in the PBO-bari 4 mg set (PBO IR=1.0/100PY, bari IR=4.3/100PY). In the All bari RA set, 18 HZ cases had distribution beyond the primary or adjacent dermatomes (considered potential OI), with 194 additional cases (overall IR=3.2/100PY). There were no visceral cases; 4 were associated with facial palsy (3) or other motor nerve palsy (1) and 3 had ocular involvement. Single cases of cytomegalovirus and Epstein-Barr virus infection were reported. Fungal events of candidiasis involving the esophagus (6), lung (1), and soft tissue (1), *Pneumocystis jirovecii* pneumonia (3, all in Japan) and single cases of histoplasmosis, paracoccidioidomycosis, and cryptococcal lung infections, and aspergillosis skin infection were reported. Few events occurred in the randomized, controlled portion of the studies, or with active comparator trt (MTX: none; ADA: 1 TB). Progressive multifocal leukoencephalopathy was not seen in the bari RA program.

**Conclusion:** Trt with bari was associated with an increased risk of HZ. TB and other potential OI, including HZ with distribution of infection beyond the primary or adjacent dermatomes, were uncommon with bari trt.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects IV: Medications and Risk

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** There are relatively clear guidelines for the use of low dose aspirin in the general population for primary cardiovascular (CV) prevention, but the risk-benefit calculation may differ in RA. While RA confers an increased CV risk compared with age and gender matched controls, such patients more likely use NSAIDs and corticosteroids. Since these therapies associate with bleeding, they might counterbalance potential benefits of low dose aspirin. We re-analyzed data from the PRECISION trial, in which all patients received an NSAID, to determine the risk-benefit ratio of low dose aspirin for primary CV prevention in RA.

**Methods:** We conducted a cohort study using data from the PRECISION RCT, including RA patients without a known history of CVD. From this group, we compared the potential risks and benefits for those using low dose aspirin to those not. Patients were censored at the first outcome or loss to follow-up. The primary outcome was major NSAID toxicity, including major adverse CV event (MACE: CV death, non-fatal myocardial infarction, or non-fatal stroke, re-vascularization, hospitalization for unstable angina or transient ischemic attack), clinically significant gastrointestinal events, renal events, and all-cause mortality. We estimated incidence rates and hazard ratios (HR) using Cox regression. Covariates considered for entry into the model included CV risk factors, prior ulcer disease, use of steroids, use of statins, use of DMARDs, HAQ score, serum creatinine, and body mass index (BMI).

**Results:** We found 1852 subjects with RA in PRECISION without known CVD; 540 reported using low dose aspirin for CV prevention and 1312 did not. They had an average age of 60 years, 77% were female and 52% used tobacco. The mean BMI was 31kg/m<sup>2</sup> and CV risk factors were common: 34% had diabetes, 76% had hypertension, and dyslipidemia in 56%. The randomized NSAID treatment assignments were well balanced across the aspirin users and non-users. Any major NSAID toxicity was observed in 79 (6.0%) of non-aspirin users and 37 (6.9%) of aspirin users (p = 0.50) (see **Table**). Aspirin users experienced all components of the primary outcome at a similar rate to non-users (see **Table**). In age and gender adjusted Cox regression models, low dose aspirin did not associate with a reduction in major NSAID toxicity (HR 0.95, 95% CI 0.64 - 1.40) or with MACE (HR 1.23, 95% CI 0.72 - 2.10)(see **Table**). Fully adjusted models yielded very similar results for the primary outcome (HR 1.08, 95% 0.69 – 1.69).

**Conclusion:** RA patients using low dose aspirin had similar risk of major NSAID toxicity and MACE as patients not. Even among this cohort of RA patients with known CV risk factors, the use of low dose aspirin for primary CV prevention appears not to confer clear benefits. A larger cohort will be needed to confirm, but low dose aspirin may not promote primary prevention of CV events in RA despite their increased risk.

**Table: Influence of low-dose aspirin treatment at baseline on adjudicated major NSAID toxicity in RA subjects without known cardiovascular disease in PRECISION**

At baseline	Rates of events			Hazard ratio (95% CI)*	
	Aspirin (N=540)	Non- aspirin (N=1312)	P-value	Age and gender adjusted	Fully adjusted
Major NSAID toxicity	37 (6.9)	79 (6.0)	0.50	0.95 (0.64, 1.40)	1.08 (95% 0.69 – 1.69)
MACE	22 (4.1)	37 (2.8)	0.16	1.23 (0.72, 2.10)	NA
Clinically significant GI events	8 (1.5)	10 (0.8)	0.15	1.72 (0.68, 4.40)	NA
Renal events	3 (0.6)	16 (1.2)	0.20	0.39 (0.11, 1.34)	NA
All-cause mortality	12 (2.2)	31 (2.4)	0.86	0.72 (0.37, 1.40)	NA

NA, not available as there were too few outcomes to include more than age, gender and aspirin status.\* Comparing aspirin users to non-users (reference). Variables included in fully adjusted model: age, gender, treatment assignment (celecoxib, naproxen, ibuprofen), hypertension, diabetes, hyperlipidemia, BMI, statin use, DMARD use, Health Assessment Questionnaire, and LDL.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** *LBH* (Limb-bud and heart development) was recently identified as an RA risk gene that has abnormally methylated loci and a functional enhancer SNP in RA FLS. These genetic and epigenetic marks decrease *LBH* expression, which is associated with increased RA risk. Subsequent studies showed that *LBH* deficiency unexpectedly leads to S phase arrest. The present studies define the mechanism of S-phase arrest and assess the effect of *LBH* deficiency in an animal model of rheumatoid arthritis.

**Methods:** Cultured FLS were derived from RA synovium obtained at the time of arthroplasty. DNA damage was assayed using a comet assay, which is a single cell method that measures diffusion of DNA fragments from the nucleus. Male *Rosa-26-Cre; Lbh<sup>+/+</sup>* (WT) and conditional knockout *Rosa-26-Cre; Lbh<sup>loxP/loxP</sup>* mice (*LBH<sup>-/-</sup>*) were injected i.p. with 80 µl of pooled adult K/BxN mice serum on day 0 and 2. The clinical scores were determined until day 12. Western blots qPCR assays were performed on synovial tissue and cultured FLS extracts to assay protein and mRNA levels. *LBH* deficiency in FLS (*LBH<sup>low</sup>*) was induced using siRNA transfection.

**Results:** Because S-phase arrest is often due to DNA replication damage, we determined whether *LBH* deficiency in FLS increases DNA damage. Comet assays showed that *LBH<sup>low</sup>* cells had comets with significantly longer tails than control cells, indicating increased in DNA strand breaks ( $p = 0.001$ ). DNA damage in *LBH<sup>low</sup>* cells led us to assess the activation status of the checkpoint kinases, CHK1 and CHK2, which are activated in response to DNA damage during S phase and induces growth arrest. Western blot analysis showed that CHK1 phosphorylation increased 4-fold greater in *LBH* deficient cells than control cells, while CHK2 was not activated ( $p=0.03$ ). Three main polymerases are responsible for DNA synthesis in S phase and were assayed in control and *LBH<sup>low</sup>* cells. *LBH* deficiency reduced POLA1 protein by 86% ( $p < 0.01$ ) compared with control. However, *POLD1* and *POLE* were not affected by *LBH* deficiency. To examine the contribution of *LBH* in inflammatory arthritis, passive K/BxN arthritis was studied in WT and *LBH<sup>-/-</sup>* mice. *LBH<sup>-/-</sup>* mice had a significantly increased peak clinical score of arthritis (mean =  $8 \pm 3$ ,  $p = 0.02$ ) compared to WT (mean =  $6 \pm 2$ ), primarily in the later stages of the model. IL-1 $\beta$  gene expression, which plays an essential role in this model, was significantly increased in the joints of the *LBH<sup>-/-</sup>* mice with arthritis ( $2.1 \pm 0.7$ ) compared with arthritic WT mice on day 12 ( $0.7 \pm 0.1$ ,  $p < 0.05$ ). To determine whether checkpoint arrest occurred in the joints of *LBH<sup>-/-</sup>* mice with arthritis, western blot analysis was performed for phospho-CHK1. *LBH*-deficient mice had  $2 \pm 0.5$ -fold higher levels of phospho-CHK1 compared with WT in the arthritis model ( $p < 0.05$ ).

**Conclusion:** These findings indicate that *LBH* regulates the cell cycle *in vitro* and induces cell cycle arrest due to decreased POLA1 expression in response to DNA damage and decreases DNA repair. *LBH* deficiency allows DNA damage to accumulate *in vivo* leading to S phase arrest. Because accumulation of DNA fragments is known to exacerbate murine arthritis, the *LBH* RA risk allele likely contributes to disease severity in RA by suppressing *LBH* expression and increasing DNA damage.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) reside in the synovial intimal lining. They display a unique aggressive phenotype, invading the articular cartilage and promoting inflammation. Elevated mitogen activated protein kinase (MAPK) signaling occurs in RA, but targeting downstream MAPKs like p38 has had minimal success. As an alternative approach, we focused on the upstream MAPK kinase, apoptosis signal regulating kinase-1 (ASK1). ASK1 can regulate p38 and JNK, and aberrant ASK1 signaling has been implicated in cancer, neurodegenerative diseases and inflammatory and cardiovascular disorders. We examine the regulation of ASK1 expression in RA FLS and its role in the collagen-induced arthritis (CIA) model using a novel ASK1 inhibitor.

**Methods:** Synovial tissue was obtained from RA and osteoarthritis (OA) patients during joint replacement surgery or synovectomy. Gene expression was assessed by qPCR. ASK1 promoter activity was measured using minimal promoter luciferase reporter constructs that included a 1.3 kb (Full Length) region, a 994 kb lacking the RelA binding site (Truncated), or a full length region with a mutated upstream RelA-binding site. A novel selective ASK1 inhibitor (ASK1i) was used in the rat collagen induced arthritis (CIA) model, and animals received treatment by oral gavage from day 10 through day 16. Ankle diameters were measured and histology was evaluated for inflammation, pannus formation, cartilage damage, and bone resorption.

**Results:** A strong correlation was found between ASK1 and IL-1 $\beta$  mRNA expression in synovium ( $n = 20$ ,  $r^2 = 0.62$ ,  $p = 0.00003$ ), and to a lesser degree between ASK1 and TNF mRNA ( $r^2 = 0.45$ ,  $p = 0.001$ ). No correlation was found between ASK1 and IL-6 mRNA ( $r^2 = 0.01$ ,  $p = 0.61$ ). Because previous studies showed that IL-1 increases ASK1 expression in FLS, the mechanism behind the increased gene expression was explored using ASK1 reporter constructs. ASK1 promoter activity for the Full Length construct was significantly increased by IL-1 $\beta$  (40-fold  $\pm 10$  increase,  $n = 6$ ,  $p = 0.012$ ) and TNF (15-fold  $\pm 3$ , 6 hr,  $n = 3$ ,  $p = 0.011$ ) compared with control construct. Increased transcription was eliminated in the Truncated construct and in the construct with the mutated RelA binding motif. These results confirm that ASK1 is induced at the transcriptional level after IL-1 $\beta$  and TNF stimulation and identifies the RelA motif as the primary regulatory region. To determine if ASK1 plays a role in inflammatory arthritis, CIA rats were treated with ASK1i. The inhibitor significantly decreased ankle swelling in the CIA rat model in a dose-dependent fashion, resulting in a  $46 \pm 8.8\%$  and  $48 \pm 9.9\%$  decrease at day 16 for animals treated with 3 mg and 10 mg/kg, respectively, compared with vehicle ( $n = 8$  per group,  $p < 0.05$ ). ASK1i decreased histologic severity, with  $36 \pm 12\%$  reduction in total histology score for 10 mg/kg compared with vehicle ( $n = 8$ ,  $p < 0.05$ ).

**Conclusion:** IL-1 $\beta$  and TNF regulate ASK1 through the RelA binding motif in the ASK1 promoter and synovial cytokine expression correlates with synovial ASK1 mRNA. A novel small molecule ASK1 inhibitor significantly decreased disease severity in CIA. The data support advancing an ASK1 inhibitor as a potential therapeutic target for RA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

Previous studies have shown a higher incidence of alveolar bone loss in patients with rheumatoid arthritis (RA) and that patients with periodontitis are at a greater risk for developing RA. Periodontitis, displayed as marginal jawbone loss was analysed in individuals prior to symptom onset of RA and related to plasma levels of receptor activator of nuclear factor kappa-B (RANKL), a cytokine crucial for bone resorption.

## Methods:

A case-control study performed within the Medical Biobank of Northern Sweden included 232 pre-symptomatic individuals with blood samples donated before symptom onset and 194 controls. A questionnaire on self-assessed dental status and smoking status was retrieved. Dental radiographs to evaluate marginal jawbone levels were available from 93 pre-symptomatic individuals (mean age; 56.8 95%CI 55.9, 57.7 years and pre-dating time; -5.3 95%CI -12.2, -0.2, 74.2% females) and 83 controls (mean age; 55.5 95%CI 54.6, 56.5, 73.5% females). Of these individuals 45 had radiograph documentations prior to development of RA symptoms and to whom sex, age and smoking status could be matched among the controls. Plasma were analysed for RANKL (BioVendor, Karasek, Czech Republic), and anti-citrullinated peptide antibodies (ACPA) (anti-CCP2 test, Eurodiagnostics, Sweden) from similar time points.

## Results:

Compared to matched controls, total bone loss was significantly higher in never-smokers who developed RA but not in smokers and increasing levels on total jawbone loss was associated with a significantly higher odds to be diagnosed with RA later (OR=1.06, 95%CI 1.01, 1.11). Regardless of smoking status, the number of unaffected teeth did not differ significantly between those who were subsequently diagnosed with RA and their matched controls. In the pre-symptomatic individuals RANKL positive individuals had significantly higher extent of marginal jawbone loss, which was further increased in ACPA positive individuals. Previously documented association between smoking and ageing and marginal jawbone loss was verified.

## Conclusion:

Marginal jawbone loss preceded onset of symptoms of RA but the difference was only manifested in non-smokers. Moreover, marginal jawbone loss and plasma RANKL levels were related in the pre-symptomatic individuals particularly in ACPA positive individuals.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** CD4<sup>+</sup> T cells can differentiate into functionally distinct subsets and play a pivotal role in rheumatoid arthritis (RA). Th22 cells have been identified as a new subset secreting IL-22. Although elevated levels of IL-22 in the synovial fluids of RA patients were reported, its pathological roles remain unclear. In this study, we examined the function of human Th22 cells, the distribution of Th22 cells in synovial tissues in RA patients, and the influences of Th22 cells on osteoclast differentiation in order to elucidate the role of Th22 cells in RA pathogenesis.

**Methods:** CD3<sup>+</sup> CD4<sup>+</sup> CXCR3<sup>+</sup> CCR6<sup>-</sup> (Th1) cells, CD3<sup>+</sup> CD4<sup>+</sup> CXCR3<sup>-</sup> CCR4<sup>+</sup> CCR6<sup>+</sup> CCR10<sup>-</sup> (Th17) cells, and CD3<sup>+</sup> CD4<sup>+</sup> CXCR3<sup>-</sup> CCR4<sup>+</sup> CCR6<sup>+</sup> CCR10<sup>+</sup> (Th22) cells were sorted from the peripheral blood of healthy individuals and the ability of these subsets to produce cytokines were compared. CD3<sup>+</sup>CD4<sup>+</sup>IL-22<sup>+</sup>IL-17-IFN- $\gamma$ -Th22 cells and chemokine receptor-ligands (CCL17, CCL20, CCL28) in synovial tissues in patients with RA and osteoarthritis (OA) were evaluated by immunohistochemistry. Human monocytes were cultured with IL-22, IL-17 or IFN- $\gamma$  in the presence of M-CSF and RANKL for 12 days. Th1 cells, Th17 cells or Th22 cells were sorted from peripheral blood and co-cultured with monocytes in the presence of M-CSF and RANKL.

**Results:** CD3<sup>+</sup> CD4<sup>+</sup> CCR4<sup>+</sup> CCR6<sup>+</sup> CCR10<sup>+</sup> cells produced neither IFN- $\gamma$  nor IL-17, but characteristically produced IL-22 alone, and that their ability to produce IL-22 exceeded that of other helper T cell subsets. Th22 cells were markedly infiltrated in synovial tissue in patients with active RA, but not in patients with OA. CCL17, CCL20 and CCL28 were abundantly expressed in RA synovial tissue compared to OA. Actually, by in vitro Trans-well migration assay, Th22 cells efficiently migrated towards CCL28. Addition of IL-22 to the in vitro culture of monocytes with M-CSF and RANKL markedly increased numbers of tartrate-resistant acid phosphatase (TRAP)-positive osteoclasts formation. Contrarily, the addition of IFN- $\gamma$  to the culture significantly decreased TRAP-positive osteoclasts number, whereas IL-17 had marginal effects. The gene expression of NFATc1 and cathepsin K was significantly increased by addition of IL-22 to the culture in a dose dependent manner. Co-culture of Th22 cells, which were sorted from peripheral blood, with monocytes in the presence of M-CSF and RANKL induced TRAP-positive osteoclasts formation more efficiently than that of either Th1 cells or Th17 cells. IL-22 neutralizing antibody completely inhibited osteoclast formation in co-culture of Th22 cells with monocytes.

**Conclusion:** Th22 cells, which co-express chemokine receptors CCR4, CCR6 and CCR10, possess strong potency of tissue migration and accumulate into inflamed synovial tissues where the ligands such as CCL28 are highly expressed. The results indicated that Th22 cells have the capacity to promote osteoclast differentiation through production of IL-22. Thus, Th22 cells may play a pivotal role in the pathogenesis of RA by bone resorption in RA synovitis.

## Joint Location-Specific JAK-STAT Signaling in Rheumatoid Arthritis (RA) Fibroblast-like Synoviocytes (FLS)

Deepa Hammaker<sup>1</sup>, Gyrid Nygaard<sup>1</sup>, David L. Boyle<sup>2</sup>, Rizi Ai<sup>3</sup>, Wei Wang<sup>4</sup> and Gary S. Firestein<sup>5</sup>, <sup>1</sup>Medicine, UC San Diego, La Jolla, CA, <sup>2</sup>University of California San Diego, La Jolla, CA, <sup>3</sup>UC San Diego, La Jolla, CA, <sup>4</sup>Chemistry and Biochemistry, UC San Diego, La Jolla, CA, <sup>5</sup>Medicine, University of California San Diego, La Jolla, CA

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

## Background/Purpose:

Aberrant epigenetic marks in RA FLS contribute to disease pathogenesis and aggressive FLS behavior. Computational data also suggest that RA FLS isolated from different joint locations display distinct epigenetic states and transcriptomes that implicate joint-specific pathogenic pathways. For example, IL-6 signaling and JAK-STAT epigenetic marks differ in RA hips and knees. This suggests that hip and knee FLS might have differential responses to IL-6 stimulation and JAK inhibitors like tofacitinib, which could contribute to asynchronous clinical responses between joints in RA patients treated with targeted agents. In this study, the joint-specific biology of IL-6 and JAK in RA hip and knee FLS were explored to biologically validate the computational data using IL-6-induced monocyte chemoattractant protein 1 (MCP1) gene expression as a primary differential function.

## Methods:

FLS lines were established from synovial tissue of RA patients undergoing total hip or knee replacement surgery. The cells were expanded in 10% fetal calf serum/DMEM and used at passages 3 – 7. FLS were plated, serum starved for 18 hours and then stimulated with various concentrations of IL-6 for 2h. In some experiments, the cells were pre-treated with tofacitinib prior to IL-6 stimulation. RNA was isolated and GAPDH-normalized gene transcripts were quantified by qPCR.

## Results:

Under basal conditions, hip FLS expressed significantly less MCP1 than knee FLS ( $1.37 \pm 0.22$  and  $2.5 \pm 0.27$ , respectively;  $n=15/\text{group}$ ,  $p=0.003$ ). At low doses of IL-6 ( $<20\text{ng/ml}$ ), MCP1 expression for hip FLS remained lower than for knee FLS, but the fold increase was greater for hip. For example, at  $7.5\text{ ng/ml}$  of IL-6, MCP1 increased  $2.4 \pm 0.4$  fold for hip FLS and  $1.2 \pm 0.07$  fold for knee FLS). At high concentrations of IL-6 ( $40\text{--}100\text{ng/ml}$ ) hip and knee MCP1 gene expression were similar, suggesting that the differences under basal conditions could be overcome. Because JAK-STAT signaling in RA hips and knee FLS were predicted to be different based on our computational data, we performed dose responses with the JAK inhibitor tofacitinib. Pre-incubation of FLS with various concentrations of tofacitinib prior to IL-6 stimulation reduced IL-6-induced MCP1 expression for both hip and knee FLS, but with greater sensitivity in hip FLS ( $\text{EC}_{50}$  of  $30\text{ nM}$  for hip FLS and  $80\text{ nM}$  for knee FLS). These results suggest that knee FLS required higher concentrations of tofacitinib for the same degree of MCP1 inhibition as hip FLS. Inhibition of basal expression of MCP1 in the absence of exogenous IL-6 was greater for hip compared with knee FLS ( $50\%$  and  $13\%$  inhibition, respectively,  $n=4/\text{group}$ ) suggesting that JAK-STAT-related signaling differs in the joint-specific FLS.

## Conclusion:

These studies biologically validate the prediction that RA hip and knee FLS are imprinted with distinct functions related to IL-6 signaling and the JAK-STAT pathway. Differential sensitivity to JAK inhibition could be related to the unique epigenetic imprinting due to joint location and could contribute to variable clinical responses to tofacitinib. Additional studies that profile the epigenome and transcriptome in individual joints could create opportunities for personalized therapy.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease characterized by synovial inflammation and joint destruction. Monocytes and synovial macrophages are key players in inflammatory process of RA. Enolase-1 (ENO1) is a multifunctional glycolytic enzyme in cytoplasm of cells and it is also found on the cell surface as plasminogen receptor. The majority of cells expressing ENO1 in peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) derived from RA patients were known to be CD14-positive monocytes and macrophages. This study was aimed to discover and investigate a novel ligand of cell surface expressed ENO1 and biological role of the interaction between ENO1 and its novel ligand, apolipoprotein B (apoB).

**Methods:** ENO1 binding protein was identified present in RA synovial fluid (SF) using affinity-base mass spectrometry analysis. The interaction between ENO1 and apoB was evaluated using physical characterization, such as ligand blotting assay, ligand binding assay, surface plasmon resonance (SPR), and confocal microscopy. The production of pro-inflammatory cytokines in PBMCs from RA or healthy control (HC) after stimulation with apoB were evaluated using cytokines ELISA. The pro-inflammatory effect of apoB was evaluated in K/BxN serum transfer arthritis mouse model.

**Results:** Characterization of physical interaction between ENO1 and apoB using various binding assay, ligand blotting assay, ligand binding assay, SPR, and confocal microscopy showed that apoB is a novel ligand of ENO1. Interaction between surface ENO1 and apoB induced higher levels of pro-inflammatory cytokines in RA PBMCs than HC PBMCs. When surface ENO1 expression was down-regulated after transfection with ENO1-specific siRNA, production of inflammatory cytokines by RA PBMCs in response to apoB stimulation decreased. Moreover, in K/BxN serum transfer arthritis model, mice were immunized with K/BxN serum and apoB induced exacerbation of arthritis with increased ankle thickness, arthritis score, and production of pro-inflammatory cytokines. LDLR knockout mice are known to have high levels of serum LDL and apoB. The arthritis score and ankle thickness were markedly higher in low density lipoproteins receptor (LDLR) knockout mice compared to wild type after K/BxN serum transfer.

**Conclusion:** In this study, we discovered apoB as a novel ligand of ENO1. ApoB may enhance chronic inflammation in RA patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars Therapy

**Session Type:** ACR Concurrent Abstract Session

**Background/Purpose:** GP2013, is a biosimilar to European Union (EU) approved reference rituximab (RTX), developed in a stepwise approach that adheres to stringent biosimilar development guidelines. The biosimilarity of GP2013 and RTX has been confirmed preclinically and in patients with RA and follicular lymphoma. Switching patients from a reference product to its biosimilar has to be shown for regulatory approval in some regions. In this study, the safety and immunogenicity of the switch from RTX to GP2013 was compared with the continued RTX in patients with active RA.

**Methods:** This randomized, double-blind, parallel-group study in adult patients with active RA was conducted across the United States (US; 28 centers) and the EU (26 centers), who had received the last treatment with RTX 6-18 months prior to randomization and required RTX re-treatment. Patients were randomized (1:1) to receive 1000 mg intravenous infusions of either GP2013 (switch group) or continue RTX (control group) on days 1 and 15. Methotrexate (7.5-25 mg/week) and folic acid were given in the same stable dose as before randomization. Safety assessments included the incidence of hypersensitivity; infusion-related and anaphylactic reactions; immunogenicity (antidrug antibody [ADA] development); the incidence of adverse events (AE), and other safety parameters (vital signs and laboratory parameters). Patients were followed up for 24 weeks.

**Results:** Of the 107 patients randomized to the switch group (n=53) or control group (n=54), majority of patients completed the study up to 24 weeks (94.3% vs 96.3%). Demographic and baseline characteristics were well balanced between the groups. The incidence of hypersensitivity (9.4% vs 11.1%) and infusion-related reactions (11.3% vs 18.5%) were low and similar in both groups. In the control group, 1 patient developed an anaphylactic reaction within 24 h of infusion. Among the patients, who tested negative for ADA at screening, only 1 patient in the control group tested positive for ADAs in all visits after the first infusion (Table 1). No patient had ADA of neutralizing capacity. The rate of AEs was similar between the groups, serious AE occurred only in the control group (Figure 1). Although more patients in the switch group had AEs in some AE categories, these differences could not be attributed to a cluster of specific events. The majority of patients in both treatment groups did not have newly occurring laboratory abnormalities.

**Conclusion:** The safety profile, in particular hypersensitivity reactions and occurrence of ADAs, of patients who switched from RTX to GP2013 was comparable with the patients who received continued treatment with RTX.

**Table 1. Summary of key safety assessments**

	Switch group (GP2013), N=53 n/N (%)	Control group (RTX), N=54 n/N (%)	Difference (%)	95% CI for difference
Hypersensitivity reactions <sup>1</sup>	5/53 (9.4)	6/54 (11.1)	-1.7	(-20.9, 17.3)
Infusion-related reactions <sup>2</sup>	6/53 (11.3)	10/54 (18.5)	-7.2	(-26.0, 11.4)
Anaphylactic reactions <sup>3</sup>	0/53 (0.0)	1/54 (1.9)	-1.9	(-20.6, 16.9)
ADA <sup>4</sup> positive after screening	0/45 (0.0)	1/48 (2.1)	-2.1	(-22.3, 18.2)

<sup>1</sup>Standardized MedDRA Query (SMQ) was used to identify hypersensitivity reactions in the database of adverse events.

<sup>2</sup>Predefined Query compiling 262 MedDRA Preferred Terms (PT) was used to identify potential infusion-related reactions in the database of Adverse Events occurred on the day of or day after GP2013/RTX infusions.

<sup>3</sup>2006 NIAID/FAAN criteria were used to identify anaphylactic reactions within 24 h of the start of GP2013/RTX infusions.

<sup>4</sup>Patients with negative ADA results at screening and at least an evaluable post-randomization ADA assessment were included in the analysis.

ADA: Anti-drug antibodies; CI: confidence interval; MedDRA: Medical Dictionary for Regulatory Activities; n: number of patients with an event after treatment; N: total number of patients who received respective treatment; NIAID/FAAN: National Institute of Allergy and Infectious Disease and Food Allergy and Anaphylaxis Network; RTX: reference rituximab

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Rituximab (RTX) is a mAb indicated for the treatment of RA in patients with inadequate response to anti-TNF therapy. The current study compares the biosimilar GP2013 with the reference medicine approved in Europe, RTX-EU and in the US, RTX-US.

**Methods:** Eligible patients were randomized to GP2013, RTX-EU or RTX-US. The primary endpoint was the area under the serum concentration–time curve from study drug infusion to infinity ( $AUC_{0-inf}$ ). The read-out for primary and all key secondary analyses were

performed at week 24 (results submitted for publication). Patients were then followed up to week 52.

**Results:** A total of 312 patients (262 female and 50 male) were randomized. Demographics and baseline characteristics were comparable between the groups. The 90% CI of the ratio of the geometric mean were within the predefined range of 80-125% for the primary and key secondary pharmacokinetic and pharmacodynamic (PD) endpoints demonstrating three-way bioequivalence of GP2013, RTX-EU and RTX-US at week 24 (Table 1). Data was pooled for RTX-US and RTX-EU for efficacy assessments. A similar proportion of patients were retreated in both the groups (GP2013: 70% and RTX: 74%). PD responses remained similar up to the end of the observation period at week 52 (Figure 1). Change from baseline in DAS28 (CRP) at week 24 was -2.07 (Standard error [SE] =0.108) and -2.11 (SE=0.095) in the GP2013 and the RTX groups, respectively. The difference of 0.04 (95% CI: -0.241, 0.323) was below the pre-defined non-inferiority margin of 0.6. ACR20 response rate was 72.3% (95% CI: 64.2%, 80.3%) and 67.3% (95% CI: 59.9%, 74.7%) in the GP2013 and RTX groups at week 24, respectively. Efficacy outcome remained similar up to week 52 (Figure 2). The rates of adverse events were similar between the groups. Anti-drug antibodies (ADAs) were detected in 16.5% of GP2013 and in 15.1% of RTX-treated patients up to last visit. The ADAs were transient in the majority of patients and neutralizing ADAs were detected in 5 and 1 patient in GP2013 and RTX group, respectively.

**Conclusion:** The study met its primary objective by demonstrating 3-way PK bioequivalence of GP2013, RTX-EU and RTX-US. Three-way PD equivalence, as measured by the depletion of peripheral B cells was also demonstrated. Furthermore, GP2013 and RTX were similar in terms of efficacy, safety and immunogenicity up to week 52.
