**Methods:** Thirty-four consecutive TA patients with stable disease during the last 6 months were evaluated for serum levels of pro-inflammatory (TNF $\alpha$ , IL-1 $\beta$ , IL-6), anti-inflammatory (IL-2, IL-10), Th1 (IL-12, IFN $\gamma$ ), Th2 (IL-4, IL-5, IL-13), Th9 (IL-9), Th17 (IL-17A, IL-17E, IL-17F, IL-21, IL-23) and Th22 (IL-22) cytokines by the multiplex technique.

**Results:** Serum TNF $\alpha$ , IL-17F, IL-21 and IL-23 were significantly higher in patients with stable disease presenting angiographic type V compared with other angiographic types while serum IL-17E, IL-17F, IL-22 and IL-23 were higher in TA patients with previous ischemic events. Similar levels of cytokines were observed in TA patients with and without aortic aneurysmal disease, and in TA patients with and without therapy with prednisone, immunosuppressive or biological agents. However, by multivariate linear regression analysis, serum IL-4 ( $\beta = 0.064$ ;  $p = 0.004$ ), IL-6 ( $\beta = 14.12$ ;  $p = 0.006$ ), IL-17A ( $\beta = 11.09$ ;  $p = 0.012$ ), IL-17E ( $\beta = 0.064$ ;  $p = 0.003$ ), IL-17F ( $\beta = 0.028$ ;  $p = 0.016$ ), IL-21 ( $\beta = 26.16$ ;  $p = 0.007$ ), IL-22 ( $\beta = 0.062$ ;  $p = 0.012$ ) and IL-23 ( $\beta = 1.86$ ;  $p = 0.002$ ) levels were independently associated with angiographic type V. Moreover, an independent association was also found between ischemic events and serum IL-17E ( $\beta = 0.044$ ;  $p = 0.005$ ), IL-22 ( $\beta = 0.039$ ;  $p = 0.029$ ) and IL-23 ( $\beta = 1.16$ ;  $p = 0.006$ ). Daily prednisone dose was associated with lower serum IL-4 ( $\beta = -0.002$ ;  $p = 0.002$ ), IL-6 ( $\beta = -0.28$ ;  $p = 0.010$ ), IL-17A ( $\beta = -0.22$ ;  $p = 0.021$ ), IL-17E ( $\beta = -0.001$ ;  $p = 0.003$ ), IL-22 ( $\beta = -0.001$ ;  $p = 0.011$ ) and IL-23 levels ( $\beta = -0.03$ ;  $p = 0.005$ ), whereas the use of an immunosuppressive simultaneously with a biological agent led to lower serum IL-4 ( $\beta = -0.044$ ;  $p = 0.024$ ), IL-17E ( $\beta = -0.046$ ;  $p = 0.017$ ) and IL-23 ( $\beta = -0.98$ ;  $p = 0.048$ ) levels.

**Conclusion:** A predominant Th17 response seems to be ongoing in TA patients with extensive arterial involvement (i.e. angiographic type V) or previous ischemic events, despite the remission state. Therapy has a significant impact on serum levels of several cytokines in TA. These findings highlight the potential role of Th17 response in the pathophysiology of TA.

## PET-CT Findings and Clinical Outcomes in Takayasu Arteritis – Does 18F-Fluorodeoxyglucose Uptake in Arteries Predict Relapses?

Anna Larissa Faria Janes<sup>1</sup>, Míriam Fang Castro<sup>1</sup>, Bruna Savioli<sup>1</sup>, Anne Elisabeth Diniz Arraes<sup>1</sup>, Emilia Sato<sup>2</sup> and Alexandre W.S. Souza<sup>3</sup>, <sup>1</sup>Internal Medicine - Rheumatology Division, Universidade Federal de São Paulo - Escola Paulista de Medicina, São Paulo, Brazil, <sup>2</sup>Rheumatology Division, Universidade Federal de São Paulo, São Paulo, Brazil, <sup>3</sup>Rheumatology Div/Dept of Med, Escola Paulista de Medicina - Universidade Federal de São Paulo, São Paulo, Brazil  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** PET-CT scan with 18F-Fluorodeoxyglucose (18F-FDG) has been frequently used as a tool to assess disease activity in Takayasu arteritis (TA) and increased 18F-FDG uptake in arteries is considered a surrogate marker of ongoing arterial inflammation. A previous cross-sectional study showed an association between the maximal standardized uptake value (SUVmax) in TA and disease activity in TA. To date, it is not known whether 18F-FDG uptake in arteries is associated with disease progression in TA with the development of new angiographic lesions. This study aims to evaluate associations between 18F-FDG uptake in arteries from TA and the risk to develop relapses, ischemic events, sustained remission (i.e. absence of disease activity and complete withdrawal of glucocorticoids for at least 6 months), new angiographic lesions and the need to change therapy in TA patients.

**Methods:** TA patients underwent PET-CT scan with 18F-FDG with arterial uptake measured by the SUV and SUVmax in arterial walls to assess disease activity and were longitudinally assessed for disease activity using Kerr's criteria and for the development of new angiographic lesions by magnetic resonance angiography and/or by computerized tomography angiography.

**Results:** Amongst 36 TA patients initially evaluated by 18F-FDG PET-CT scan, 32 were longitudinally followed for a median of 83.5 months. The median SUVmax value in arteries was 1.57 (1.16-2.23). At baseline, 20 TA patients (62.5%) had SUVmax  $\geq 1.3$ , whereas 11 TA patients (34.4%) had active disease by Kerr's criteria. At follow-up, 23 (71.9%) patients had at least one disease relapse at a median of 17.0 months and new arterial lesions were observed in 14 (43.8%) cases. There were no differences regarding the baseline SUV value in arteries that developed and arteries that did not develop new angiographic lesions in TA patients. A higher frequency of disease relapses (85.0% vs. 50.0%,  $p = 0.049$ ) and the need for changing immunosuppressive therapy (85.0% vs. 41.7%,  $p = 0.018$ ) was observed in TA patients with SUVmax  $\geq 1.3$  at baseline compared with those with SUVmax  $< 1.3$ . No differences regarding SUVmax  $\geq 1.3$  in arteries and the development of ischemic events, sustained remission and new angiographic lesions were found in TA patients. Using the Kaplan-Meier curve, a trend for a higher frequency of relapses was observed in TA patients with SUVmax  $\geq 1.3$  ( $p = 0.056$ ) by the log rank test. No independent associations were found between baseline SUVmax  $\geq 1.3$  and the risk of relapses (HR = 1.07; 95CI: 0.39-2.92;  $p = 0.892$ ) or between baseline SUVmax  $\geq 1.3$  and the risk of developing new angiographic lesions in (HR = 0.24; 95CI: 0.02-2.57;  $p = 0.239$ ) by the multivariate Cox's proportional hazard analysis.

**Conclusion:** There is no association between arterial SUV and development of new arterial lesion in TA, but arterial SUVmax in TA patients is marginally associated with a higher frequency of disease relapses and with the need for changing immunosuppressive therapy.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sensorineural hearing loss has been reported to be increased in several chronic autoimmune and non-autoimmune diseases such as systemic lupus erythematosus (SLE), progressive systemic sclerosis, rheumatoid arthritis, small vessel vasculitides, ankylosing spondylitis and Behçet's syndrome. We had sporadically noted several degrees of sensorineural hearing loss among our Takayasu's arteritis (TA) patients. While, some revealed this in their past history, others had relapsing attacks of hearing loss independent of or associated with vascular relapses. We formally investigated the frequency and type of hearing loss among TA patients and suitable controls.

**Methods:** The study was done in two parts. In the first part, consecutive TA and SLE patients seen at outpatient clinic along with apparently healthy controls were administered a standardized questionnaire that assessed hearing loss, tinnitus and episodic vertigo. In the second part previously registered TA and SLE patients for another study (1-2), were called to specifically for otological examination and audiometry tests that included pure-tone air and bone conduction, speech audiometry and acoustic reflex threshold test.

**Results:** In the first part, 73 patients with TA, 107 patients with SLE and 133 healthy controls were studied as shown in Table 1. The frequency of those with hearing deficit/loss, tinnitus and vertigo were significantly more common among both TA and SLE patients (Table 1). While the frequency of those with hearing deficit/loss was similar in TA and SLE, those with tinnitus and vertigo were significantly most common in TA.

Audiometry tests revealed that, several degrees of hearing loss were present in 36.6 % of the patients with TA and 25.0 % of the patients with SLE (Table 2). This was mostly due to sensorineural hearing loss in both groups (TA: 31.7 %; SLE: 20.0 %) and high –frequency type was the most common pattern. Moreover, those TA patients with sensorineural hearing loss did not show any specific vascular pattern.

**Conclusion:** We are unaware of previous surveys of sensorineural hearing loss in TA. Our study shows that audiovestibular system is considerably affected in TA, similar to that observed in SLE. The fact that there was no clear vascular pattern among patients with hearing loss, suggest that small vessel vasculitis was probably the cause of this hearing loss.

## Cardiovascular Risk Factors and Comorbid Diseases in Takayasu's Arteritis

Helin Masyan, **Sinem Nihal Esatoglu**, Ayse Merve Celik, Vedat Hamuryudan, Hasan Yazici and Emire Seyahi, Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In addition to the occlusive vasculitis, hypertension and accelerated atherosclerosis are probably risk factors of the cardiovascular complications in Takayasu arteritis (TA). Although, management of traditional cardiovascular risk factors is recommended to diminish these cardiovascular complications, we still do not know whether traditional risk factors and other comorbid conditions are increased or operative. We looked at the frequency of traditional atherosclerotic risk factors and comorbid conditions among pts with TA.

**Methods:** Between March and December 2016, we studied consecutive 88 TA pts and 81 systemic lupus erythematosus (SLE) pts. In addition, 111 hospital workers were studied as healthy controls. Participants were interviewed with the help of a standardized questionnaire that assesses the presence of traditional atherosclerotic risk factors. The presence of atherosclerosis was not separately assessed. The presence of comorbid conditions was also assessed with the help of the Charlson comorbidity index. Additionally, Framingham coronary heart disease risk score was calculated; however, this was done only for women, because there were only a few male patients in the study cohort and male gender is an independent risk factor in this calculation.

**Results:** As shown in Table 1, among the Framingham components, only hypertension was significantly more frequent in TA. When only females were analyzed, Framingham risk score was more likely to be higher only in TA. Framingham score of SLE pts was found to be similar to that of the healthy controls, despite an increased frequency of hypertension observed among SLE pts. Additionally, familial history of cardiovascular diseases and sudden death were significantly more common among the TA pts compared to the SLE pts and healthy controls. Pericardial/pleural and renal diseases were more frequently observed among the SLE pts, (Table 2). On the other hand, cardiovascular and chronic pulmonary diseases were more common in TA pts. The frequency of inflammatory upper/lower back pain and rheumatologic diseases were increased in both TA and SLE. However, inflammatory bowel diseases (IBD) were only observed among the TA pts.

**Conclusion:** Among the traditional atherosclerotic risk factors, only hypertension appears to be increased among the TA pts. The frequencies of IBD and inflammatory upper/lower back pain are substantially high and deserves further scrutiny. Moreover, the increased incidence of cardiovascular and rheumatologic diseases among the first-degree relatives of TA pts suggest that genetic mechanisms may play role in TA.

**Table 1.** The demographic features and cardiovascular risk factors among females

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Some patients show inadequate responses to initial glucocorticoids (GC) doses or relapses during GC tapering and develop side effects of GCs. The 2015 EULAR/ACR recommendations for the management of PMR has been proposed, in which early introduction of methotrexate (MTX) in addition to GCs was recommended for such GC-resistance or GC-intolerance. A recent trial of tocilizumab (TCZ) in patients with newly diagnosed PMR, conducted in Europe and the United States, has shown its efficacy and safety. To determine the efficacy and safety of TCZ for patients with resistance or intolerance to GCs and/or MTX.

**Methods:** Sixty patients had been diagnosed with having PMR since 2011. The patients are all compatible with the 2012 EULAR/ACR provisional classification criteria for PMR, and had been treated first with GC and then, if they were resistant or intolerant to GC, were added MTX, similarly to the 2015 EULAR/ACR recommendations for the management of PMR. In GCs and MTX resistant patients we assessed the effects of tocilizumab plus GCs and MTX. The disease activity were measured by PMR-AS.

**Results:** There were 16 patients with GC/MTX resistant or intolerant PMR (26.7%). Of them, 8 patients with PMR agreed to the proposal of TCZ addition, and their therapeutic responses to TCZ and its safety were determined. They were at the age of  $69.1 \pm 11.3$ , including two males and six females. Before TCZ addition, the patients were treated with prednisolone (PSL) at  $6.9 \pm 2.4$  mg/day plus MTX at  $6.0 \pm 4.1$  mg/week, and serum CRP were at  $1.0 \pm 1.1$  mg/dL. After  $9.3 \pm 6.6$  months of TCZ treatment, PSL and MTX had been reduced to  $0.9 \pm 1.2$  mg/day and  $2.3 \pm 3.3$  mg/week, respectively, with CRP at  $0.02 \pm 0$  mg/dL. GCs were able to be withdrawn in 5 patients, and MTX were additionally withdrawn in 2 patients. Two patients reached drug-free remission, as judged from MR-AS ( $< 1.5$ ). During TCZ therapy, each one patient showed the worsening of depression and occlusion of the central retinal vein.

**Conclusion:** These results indicate that TCZ may provide a therapeutic option for patients with severe PMR who were resistant or intolerant to GC and additional MTX.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** As published in The Lancet online, March 4, 2016, the first randomized, placebo-controlled trial (RCT) about tocilizumab (TCZ) in giant cell arteritis (GCA) showed clinical efficacy of the anti-IL-6R biologic agent in the induction and maintenance of remission for 52 weeks (ClinicalTrials.gov registration number: NCT01450137). So far nothing is known about the profile of biomarkers in complete remission controlled by TCZ. In this study we compared a large variety of biomarkers in complete remission induced by TCZ plus glucocorticoids (GC; early phase of the study) *versus* complete remission induced by TCZ monotherapy (late phase of the study), and we compared the data with age-matched healthy controls.

**Methods:**

Serum levels of 18 biomarkers were quantified using Multiplex technology (R&D Systems and Invitrogen) at weeks 0, 4, 12 and 52 of the RCT. TCZ concentrations were determined by QPS, Groningen, The Netherlands. Sex and age matched healthy individuals were included as controls (CTRL).

**Results:** TCZ plasma concentrations reached a plateau by week 20. Several molecules did not display a discrete pattern over time (sCD25, adiponectin, resistin, leptin, BAFF, IFN $\alpha$ , YKL-40, TNF-R2, hsCRP, sICAM-1, CD163) or remained undetectable (IL17a, IL28A, IL-11, IL-20, VCAM-1). MMP-3 and Pentraxin-3 showed a decline over time and reached almost normal values at the end of the study. Their concentrations correlated with TCZ plasma levels and inversely with GC dose. None of the parameters predicted flare after study end.

**Conclusion:** The analysis of a wide variety of immune-inflammatory markers documents a persistent subclinical disease activity during co-medication of TCZ and GC, but a near normalization of most values under TCZ monotherapy. In conclusion the results corroborate the advantage of anti-IL-6R therapy over GCs.

## **Epidemiological Study of Giant Cell Arteritis Using a Japanese Administrative Database**

**Eishi Uechi** and Kiyohide Fushimi, Department of Health Policy and Informatics, Tokyo Medical and Dental University Graduate School, Tokyo, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The giant cell arteritis (GCA) management requires the administration of high-dose glucocorticoid (GC) at the introduction remission and the gradual reduction of the dosage. However, the long-term usage of GC can cause several side effects such as diabetes, osteoporosis and infections. Since patients with GCA are mainly elderly, the risk of side effects due to high doses or long-term administration of GC is greater. However, in clinical practice, the protocol of tapering

GC depends on the judgment of an individual clinician. There is no research describing the clinical practice of GCA and GC tapering. Therefore, this study describes the background of patients with GCA and its management using the nationwide clinical database in Japan.

**Methods:** This was a retrospective cohort study using the Diagnosis Procedure Combination (DPC) database, a nationwide inpatient database of Japan. We identified patients who received treatment for GCA (ICD10 code: M316) between 2010 and 2013 and tracked patient data up to 180 days after hospitalization and confirmed the treatment situation of GCA.

**Results:** 875 patients were hospitalized for GCA treatment from 2010 to 2013., 135 patients with age less than 50 years or no GC administration were excluded from the study and 740 patients were analyzed. 354 patients were followed until 90 days after admission and 220 patients were followed until 180 days after admission (Figure 1). The average patient age was 75 years, the mean body weight was 52 kg, and the complications were 27.6% (204/740) of diabetes, 10.4% (77/740) of gastrointestinal ulcers, and 6.8% (50/740) of malignancy. The GC dosage at the start of the treatment was 36.4 mg of prednisolone. The usage of pulse GC and immunosuppressant was 14.2% (105/740) and 11.6% (86/740), respectively. Of all, 69.7% (516/740) were prevented from osteoporosis. Although the mean GC dosage at the beginning was less than the key study protocol average and the recommended guideline, the dosage of GC after 90 days of admission was high (17.6 vs. 7.8 vs. 15 mg; Figure 2). The patientsf age (>74 years) significantly affected the GC dosage reduction after 90 days of admission (P < 0.045)). However, none of the hospital type (university hospital or an educational institution approved by the Japan College of Rheumatology), immunosuppressant combination, patient comorbidity affected the GC tapering at 90 days.

**Conclusion:** Many patients with GCA present with comorbidities. However, the tapering of GC dosage was slower than the main study protocol. Prophylaxis of complications due to GCs was not sufficiently undertaken.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Giant cell arteritis (GCA) is the most common type of systemic vasculitis. Currently, two forms of GCA are described: a cranial(C)-GCA (temporal arteritis) and a systemic, large-vessel (LV)-GCA. Late complications of LV-GCA are aortic aneurysms or aortic rupture. Based on the analysis of temporal artery tissue, GCA is postulated to start at the adventitial site and to be T cell-mediated. In the temporal artery infiltrates, T cells clearly outnumber B cells. However, our report on a disturbed homeostasis of B cells in newly diagnosed C-GCA patients shows evidence for a putative role of B cells in GCA.<sup>1</sup> Recently, the presence of B cells organized in artery tertiary lymphoid organs (ATLOs) has been described in C-GCA.<sup>2</sup> The immunopathological role of B cells in both forms of GCA is underexplored and it is unknown whether B cells are present in the vessel wall of patients with LV-GCA. The objective of this study was to assess the presence and organization of B cells in the aorta of patients with LV-GCA.

**Methods:** Aorta tissue samples of 11 histologically-proven LV-GCA patients who underwent surgery due to an aortic aneurysm were studied by immunohistochemistry. Staining was performed with antibodies against CD20 (B cells), CD3 (T cells), CD21 (follicular dendritic cells (FDC)), PNAd (high endothelial venules (HEV)), bcl6 (germinal centers), and CD138 (plasma cells). None of the patients was receiving immunosuppressive treatment at the time of surgery. For comparison 22 aorta samples from age- and sex-matched atherosclerosis patients with an aortic aneurysm were included.

**Results:** Aorta tissues of LV-GCA patients showed massive infiltration of B cells (see fig. 1). The infiltrating B cells were mainly found in the adventitia and were organized into high density B cell areas. In contrast to the temporal artery, B cells outnumbered T cells in the aorta. Besides the presence of T cells, FDC, germinal centers, plasma cells, and HEV were documented at the areas of B cell infiltrates, which are typical for organized ATLOs.

**Conclusion:** Aorta tissues from patients with histologically-proven LV-GCA showed massive and organized B cell infiltrates mostly located in the adventitia. The mere presence of B cells at the site of inflammation prompts further investigation into the role of B cells in the pathogenesis of GCA.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent studies have suggested that giant cell arteritis (GCA) may be triggered by reactivation of varicella zoster virus (VZV) based on high rates of VZV antigen detected in temporal artery specimens. We attempted to replicate these findings and further validate the possible link between VZV and GCA by assessing clinical and serological markers of acute infection.

**Methods:** 24 patients suspected of having GCA were recruited prior to temporal artery biopsy (TAB) between July 2016 and April 2017. Patients were clinically evaluated for active and past VZV infection and had serum tested for VZV IgM and IgG. All were treated with high dose corticosteroids for at least one week while awaiting TAB and were followed clinically for at least one month. Formalin fixed biopsies were cut into a minimum of four sections and were stained using a mouse derived antibody against VZV antigen and reported by two experienced, blinded immunohistochemistry researchers.

**Results:** Mean age was 68 and 17 (71%) were female. 23 (96%) reported headache, 15 (63%) scalp tenderness and nine (38%) visual disturbance. Inflammatory changes were seen on seven (29%) biopsies; four had mural inflammation and three

had limited periadventitial small vessel vasculitis (SVV). 16 (67%) met ACR criteria for GCA and 11 (46%) were assessed by the treating clinician as having definite or probable ( $\geq 50\%$  chance) GCA at two-week follow-up. No patients had clinical features of herpes zoster (shingles) at the time of enrolment. Six (25%) reported a history of zoster, 22 (92%) chickenpox and none had received the adult zoster vaccine. A single patient developed zoster ophthalmicus one week after commencing corticosteroids with subsequent ipsilateral biopsy showing SVV. All 24 biopsies stained negative for VZV antigen by immunohistochemistry. Of the 23 who had VZV serology, all were IgM negative. 21/23 (91%) were VZV IgG positive consistent with past exposure.

**Conclusion:** VZV antigen was not detected in biopsy specimens. IgM serology was negative in all 23 tested patients. Only one patient developed herpes zoster on follow-up. These interim results do not support a link between VZV and GCA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Positron emission tomography (PET)-CT scan can assess large vessel vasculitis in giant cell arteritis (GCA). It has a reported sensitivity of 80% for biopsy positive disease but the superficial temporal, occipital and vertebral arteries have not previously been assessed due to difficulties with spatial resolution.

**Methods:** 41 patients suspected of having GCA between May 2016 and April 2017 underwent fluorine-18 fluoro-2-deoxyglucose (FDG) time-of-flight PET-CT scan within 72 hours of commencing corticosteroids and before clinically guided temporal artery biopsy (TAB). Patients were imaged from the vertex of the head to the diaphragm with 1mm CT slice

reconstruction. FDG uptake was graded at 16 vascular sites using a semi-quantitative scale defined as zero (less than or equal to blood pool), one (minimally increased), two (clearly increased) or three (very marked uptake) by one of two blinded, experienced nuclear medicine physicians. Arterial calcification, shoulder region FDG uptake, infection and cancer were also reported.

**Results:** Mean age was 70 and 29 (71%) were female. Headache (88%), jaw claudication (34%), PMR (32%) and visual disturbance (29%) were common reported symptoms. Median CRP was 16 mg/L (range 1 – 299) and ESR was 36 mm/hr (range 5 – 130). Eight (20%) patients had mural inflammation on biopsy, four (10%) had limited periadventitial small vessel vasculitis and one had unequivocal thoracic aortitis on CT scan and did not undergo TAB. 28 (68%) had negative biopsies. 30 (73%) met the 1990 ACR criteria for GCA and 18 (44%) were assessed by the treating clinician as having definite or probable ( $\geq 50\%$  chance) GCA at two-week follow-up. 28 (68%) had at least grade one uptake in one or more vascular territory and 14 (34%) had at least grade two uptake. The carotid (44%), vertebral (32%) and superficial temporal (27%) arteries were the most affected. 6 (15%) patients had increased uptake isolated to the vertebral, temporal or occipital arteries. Shoulder region uptake was detected in 23 (56%) of patients, infection in three (two sinusitis, one pneumonia) and lung cancer in three. Vascular calcification did not globally correlate with increased FDG uptake (Spearman's correlation coefficient = 0.05).

**Conclusion:** 68% of patients initially suspected of having GCA had at least mild increased FDG uptake on PET-CT scan. This compared with only 30% with inflammatory changes on biopsy. Increased uptake was commonly seen in the vertebral and temporal arteries which have not previously been assessed in PET-CT studies. Long-term follow-up will determine the clinical role of this protocol in GCA.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Temporal artery biopsy (TAB) is a reference test for establishing a diagnosis of giant cell arteritis (GCA). A subset of patients with a clinical diagnosis of GCA does not show the characteristic histopathological signs, possibly because of technical artifacts or true phenotypic differences. The proportion of TAB-positive GCA cases varies across studies, and the lack of consensus on the sensitivity of TAB hampers comparisons with the performance of non-invasive diagnostic tests. In addition, the patient or study characteristics potentially influencing the sensitivity of TAB are not known. We performed a systematic literature review and meta-analysis to estimate the sensitivity of a positive TAB in GCA and identify factors involved in its variations.

**Methods:** We searched MEDLINE, EMBASE and CENTRAL databases for articles reporting TAB in GCA that were published from 1990 to 2016, with no language restriction. Eligibility criteria included studies with at least 30 GCA cases fulfilling the 1990 ACR criteria. From eligible publications, two independent researchers extracted the main demographic, clinical and study design characteristics and the number of TAB-positive cases among all cases with interpretable results for TAB. By meta-analysis, we computed the pooled proportion of TAB-positive GCA cases by a random-effects model with logit transformation. The extent of variability between studies was assessed by the  $I^2$  statistic. Subgroup and meta-regression analyses were used to examine the effect of covariates (e.g., clinical, geographic, temporal and study descriptors) on TAB positivity.

**Results:** Among 3642 screened publications, 108 met the eligibility criteria. After publications with overlapping patient populations were removed, 43 studies (3836 GCA patients in total) were used for analysis. The pooled proportions of TAB positivity in GCA for all studies combined and within subgroups are shown in the Table. The proportion of TAB-positive GCA did not notably differ by patient or study characteristics on subgroup or meta-regression analysis.

**Conclusion:** The estimated proportion of 70% TAB-positive GCA provides a reference for the sensitivity of TAB in GCA. The unexplained high between-study heterogeneity could result from differences in TAB sampling and processing methods or histopathologic criteria applied or varying propensities to diagnose TAB-negative GCA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Giant cell arteritis (GCA) is a systemic disease with extensive vascular involvement. The mechanisms underlying the diversity of GCA phenotypes are incompletely understood. The purpose of this study was to investigate predictors of large vessel involvement (LVI) in a population based cohort of patients with GCA.

**Methods:** Patients with biopsy-proven GCA were identified using a regional pathology register. Patients with positive temporal artery biopsies (TAB) performed between 1997 and 2010 who were diagnosed with GCA in two defined areas of the region were included. A structured review of histopathology reports and case records through July 2016 of all the identified patients was performed. Reports of all relevant radiological and clinico-physiological studies were reviewed, and cases with LVI were identified according to a pre-specified protocol. LVI was defined as aneurysm, ectasia or stenosis of the aorta or its main branches. Patients were censored at the date of first LVI, death, migration from the area or July 29, 2016. Event free survival was estimated using the Kaplan-Meier method. Potential predictors of LVI were also examined using Cox regression models.

**Results:** A total of 274 patients with biopsy-proven GCA (77 % women) were included. The mean age at GCA onset was 75.7 years (standard deviation (SD) 8.1). Fifty-one patients (19 %) had documented LVI during the follow-up. The median time from diagnosis of GCA to detection of LVI was 4.5 years (interquartile range 0.6-7.4). There were 32 patients with aortic involvement (63% of those with LVI; 12 % of all GCA cases). LVI occurred to a similar extent in women and men (75<sup>th</sup> percentile of LVI-free survival 12.9 and 13.1 years, respectively;  $p=0.96$ ). Survival free of LVI was significantly longer in patients with giant cells present in the TAB (75<sup>th</sup> percentile 13.7 vs 6.7 years;  $p=0.014$ ). There was a trend towards reduced risk of LVI with increasing age at GCA diagnosis (hazard ratio (HR) 0.81 per SD; 95 % confidence interval 0.61-1.08). Other histopathology features, visual symptoms, platelet count, CRP, ESR or symptoms of polymyalgia rheumatica had no significant impact on the risk of LVI. In age-adjusted analysis, the presence of giant cells in the TAB was associated with a reduced risk of LVI (HR 0.48; 95 % CI 0.27-0.86).

#### **Conclusion:**

Clinical features of GCA had no major impact on the risk of LVI. However, the negative association with giant cells in the biopsy suggests that patients with LVI constitute a subset of GCA with particular disease mechanisms.

## **Mortality Risk and Cause-Specific Mortality in Polymyalgia Rheumatica: A Population-Based Cohort Study**

Shafay Raheel<sup>1</sup>, Cynthia S. Crowson<sup>2</sup> and Eric L. Matteson<sup>3</sup>, <sup>1</sup>Rheumatology, Mayo Clinic, Rochester, MN, <sup>2</sup>Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, <sup>3</sup>Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To determine mortality risk in polymyalgia rheumatic (PMR) and compare cause-specific mortality rates among patients with PMR to age- and sex-matched comparators from the same population.

**Methods:** The study cohorts included all incident cases of PMR in a geographically-defined area diagnosed between 1970 and 2014 and non-PMR subjects from the same underlying population with similar age, sex and calendar year of index. Patients were followed until death, migration, last contact or December 31, 2014. Risk factors obtained by retrospective chart review among patients diagnosed in 2000-2014 included: morning stiffness, shoulder, hip and neck ache, anorexia, fatigue, weight loss, fever, erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor positivity, smoking status and education. The underlying cause of death was coded from national mortality statistics and grouped according to ICD 9/10 chapters. Cox models were used for analysis.

**Results:** A total of 760 PMR and 760 non-PMR subjects (66% female; mean age 73.7 years for both) were followed for medians of 9.3 and 7.6 years, respectively, during which 444 PMR and 460 non-PMR subjects died. The overall standardized mortality ratio (SMR) in PMR patients was 0.81 (95% confidence interval [CI]: 0.74-0.89; Figure 1). The SMR remained consistent over the time period (Figure 2). Among patients with PMR there were fewer deaths from cancer (70 vs 88; hazard ratio [HR]: 0.67; 95% CI: 0.49-0.92), and neurological causes (16 vs 38; HR: 0.35; 95% CI: 0.20-0.63) than those without PMR. Risk factor analyses among 377 patients (with 109 deaths) diagnosed in 2000-2014 showed age (HR: 1.14 per 10 year increase; 95% CI: 1.11, 1.18) and male sex (HR: 1.82; 95% CI: 1.23, 2.71) were associated with higher mortality. No other significant risk factors were identified.

**Conclusion:** Survival among patients with PMR is not worse than the general population. Further research needs to be done in order to determine factors associated with improved survival in these patients.

Figure 1. Survival curve for residents from a geographically-defined area with incident polymyalgia rheumatic in 1970-2014 (solid line) compared with expected survival based on state's life tables (dashed line).

Figure 2. Age and sex adjusted mortality rates by calendar year among patients with PMR (solid line), comparators without PMR (dashed line) and expected based on state's life tables (dashed gray line).

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To determine the incidence, time trends and, severity of herpes zoster in a population-based incidence cohort of patients with polymyalgia rheumatic (PMR) compared to individuals without PMR from the same population.

**Methods:** All incident cases of PMR in a geographically-defined area diagnosed between 1990 and 2014 were identified. Patients were followed by retrospective chart review until death, migration, last contact or December 31, 2015. The medical records of all patients with codes for herpes zoster (HZ) were reviewed to confirm the diagnosis, to ascertain the extent of skin disease (single or multidermatomal lesions) and to determine the outcome of HZ infection (extent of organ involvement/ complications and hospitalizations).

**Results:** The study included 541 patients with PMR and 541 subjects without PMR. The average age at PMR incidence (index date for the non-PMR cohort) was 74 years, and 349 (65%) subjects were female in each cohort. The median follow up was 8.5 years in PMR group and 7.3 years in non-PMR groups. During follow-up, 67 patients with PMR and 41 patients without PMR developed HZ. The cumulative incidence of HZ was higher in PMR patients compared to non-PMR subjects ( $14.3\% \pm 1.8$  at 10 years in PMR vs.  $10.4\% \pm 1.8$  at 10 years in non-PMR;  $p < 0.05$ ; Figure 1). Therefore, patients with PMR were more likely to develop HZ than those without PMR (hazard ratio: 1.51; 95 % confidence interval: 1.03 – 2.23). HZ rates by decade among patients with PMR were 1.0, 2.0 and 1.2 per 100 person-years [py] compared to 0.6, 1.6 and 0.9 per 100 py among non-PMR in 1990-1999, 2000-2009 and 2010-2016, respectively. The decline in HZ incidence after year 2006 likely reflects the introduction and use of zoster vaccine in this time period (Figure 2). Complications of HZ occurred at a similar rate in both cohorts. Rate of vision impairment and multidermatomal involvement was higher in PMR group but this did not reach statistical significance.

**Conclusion:** The incidence of HZ in PMR is increased compared to the general population. Patients with PMR should be evaluated for shingles vaccination. Further research needs to be done in order to understand the determinants of increased incidence of HZ in PMR patients.

Figure 1. Cumulative incidence of HZ among patients with PMR (solid line) and without PMR (dashed line)

Figure 2. Trends in rate of HZ over time in PMR (solid line) and non-PMR (dashed line)

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Orbital mass is a rare ophthalmologic manifestation of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) that remains a therapeutic challenge. This study aimed to describe clinical presentation, therapeutic management and outcome of orbital mass in the setting of AAV.

**Methods:** We conducted a nationwide retrospective study including 59 patients with AAV fulfilling the American College of Rheumatology criteria or Chapel Hill Consensus Conference definitions and orbital mass based on clinical and radiological features. Clinical, biological, radiological and histological characteristics, treatment use and efficacy, and outcome, were analyzed.

**Results:** Fifty nine patients (33 women) were included. Fifty-six (95%) patients had granulomatosis with polyangiitis (GPA), two eosinophilic granulomatosis with polyangiitis, and one microscopic polyangiitis, with histological evidence of vasculitis found in 52 (90%) patients. Fifty-one (86%) patients were ANCA-positive, with a specificity against PR3 in 71%. Median age at AAV diagnosis and orbital mass onset were 46 and 49 years, respectively, with 46% patients presenting orbital mass concomitantly to AAV diagnosis, 41% patients during AAV course, and 13% previous to AAV diagnosis. Orbital mass was unilateral in 80% patients. Exophthalmia revealed orbital mass in 54 (93%) patients, while loss of visual acuity was noted in 20 (35%) and diplopia in 21 (36%). Fifty-six (95%) patients had a systemic disease at the time of orbital mass, with a median BVAS at 9. Orbital biopsy was performed in 32 (54%) patients, showing lymphoplasmocytic infiltrate in 65%, extravascular granulomas in 48% and necrotizing vasculitis in 36%. Four patients had histological evidence of IgG4-related disease. All but one patient received corticosteroids as first-line therapy, in combination with immunosuppressive agents in 82%. First-line immunosuppressive agents comprised cyclophosphamide in 24 patients (42%), rituximab in 11 (19%), methotrexate in 5 (9%), mycophenolate mofetil in 4 (7%), azathioprine in 2 (4%), and TNF

antagonist in one (2%). Complete response was noted in 15 (27%) cases, partial response in 27 (48%), stabilization in 10 (18%) cases, and worsening in 4 (7%) cases. Among patients with complete response, seven (47%) were MPO-ANCA positive. Twenty seven patients (47%) required a second line of treatment because of relapse in 16 patients (59%) after a median delay of 13 months and refractory course in 11 cases (41%). Six of these 27 patients (22%) received corticosteroids alone as first line. All patients were treated with corticosteroids and one or combined immunosuppressive agent(s). After a median follow-up of 68 months after orbital mass diagnosis, ophthalmologic sequelae included visual impairment in 28% with blindness in 17%, orbital muscular extension on MRI with diplopia in 36%, and naso-sinusal bone defect on MRI in 22%.

**Conclusion:** Orbital mass represents a therapeutic challenge during AAV, especially during GPA. This rare manifestation is associated with refractory course and high-frequency of sequelae, in particular blindness. Histological findings could help physicians to manage orbital mass.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** there are few studies regarding the incidence of large vessel GCA (LV GCA). **Purpose:** to investigate the incidence in patients diagnosed with large vessel GCA in the Reggio Emilia Area from 2005 through to 2016.

**Methods:** All patients with incident large vessel GCA diagnosed between 1 January 2005 and 31 December 2016 and living in the Reggio Emilia area, were identified by capture and re-capture checking of computerized discharge diagnosis codes (ICD10) and using outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital as well as by examining the Reggio Emilia district database for rare diseases. To be included in the study, patients must satisfy the following 2 criteria: Age at disease onset  $\geq$  50 years; evidence of large-vessel vasculitis by angiography, MRA, CTA, PET/CT and/or ultrasonography; we included in the study also patients associating biopsy proven gca to evidence of LVV at the imaging.

**Results:** There were 81 incident cases of LV GCA (57 women) during the 11-year study period; Mean  $\pm$  SD age at diagnosis was  $70 \pm 9$  years. Incidence per 100,000 persons aged  $\geq 50$  years was 3.38 (95% confidence interval [95% CI 2.69, 4.20]). Incidence was significantly higher in women (4.39 [95% CI 3.25, 5.53]) than in men (2.19 [95% CI 1.31, 3.07]) ( $p < 0.0036$ ). Incidence rates significantly increased by 11.1% every 3 years from 2.86 (2005-2007) to 4.06 (2014-2016). The highest incidence in women and in man was observed in the 70–79 years age group (women 3.55 [95% CI 2.17, 5.48; men 2.48 95% CI 1.24, 4.43]).

**Conclusion:** The incidence of LV GCA in the Reggio Emilia area was 3.38 and it was lower than that of patients with biopsy proven GCA (5.8) (1); the incidence of LV GCA was significantly higher in women as in biopsy proven GCA and increase during the follow-up period.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** GiACTA study is a randomized, phase III controlled clinical trial of tocilizumab (TCZ) in giant cell arteritis (GCA) (1,2). Our aim was to compare GiACTA trial data from those of a national multicenter series of patients with GCA from the clinical practice, focusing on the baseline characteristics of the patients.

**Methods:** Differences between the GiACTA study and clinical practice series were assessed. In the latter, the diagnosis of GCA was established by the ACR-1990 criteria and in the GiACTA trial by the ACR modified criteria. In the clinical practice study TCZ was used at standard IV dose (8 mg/kg/month) while in the GiACTA trial it was given subcutaneously (162 mg every 1 or 2 weeks). Quantitative variables were expressed as mean $\pm$ SD and they were compared by the Student's t-test. Dichotomous variables were expressed as percentages and compared using the chi-square test.

**Results:** At TCZ onset, in the clinical practice series there were a significantly greater (TABLE): **a)** duration of GCA, **b)** polymyalgia rheumatica frequency, **c)** ESR, and **d)** previous conventional immunosuppressants (mainly MTX). There was also a non-statistically significant lower sustained remission. The mean dose of prednisone at the TCZ onset was lower in patients from the clinical practice. In comparing only GiACTA patients with relapsing-GCA versus those of the clinical practice these differences remained unchanged, except for the GCA duration. PET/CT was performed more frequently in the series of the clinical practice.

**Conclusion:** Patients receiving TCZ in the clinical practice study have several baseline clinical and laboratory differences when compared to those included in the GiACTA trial.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Aortitis is characterized by inflammation of the aortic wall. Aortitis may be associated with different conditions.

Our aim was to assess if the different vascular territories affected in aortitis is associated to different underlying diseases or to different clinical subtypes.

## Methods:

Retrospective study of 38 patients with non-infectious aortitis diagnosed by PET/CT. Whole-body FDG-PET uptake was assessed 180 minutes after injection of 7 MBq/Kg of 18F-FDG. Images were visually evaluated according to the intensity of the 18F-FDG uptake by the vessel wall at the supraaortic trunks (ST), thoracic aorta (TA), abdominal aorta (AA), iliac arteries (IA) and arteries of lower limbs (LL).

## Results:

Thirty-eight patients (28 women/10 men) with a mean age of  $68 \pm 11$  years were assessed. The underlying conditions were: giant cell arteritis (n=24), Takayasu arteritis (n=3), spondyloarthropathie (n=3), Sjögren syndrome (n=3), ulcerative colitis (n=2), sarcoidosis (n=1), rheumatoid arthritis (n=1), and polyarteritis nodosa (n=1).

A total of 190 vascular territories were evaluated, observing FDG-uptake in 122 (64.2%): ST (n=28, 22.3%), TA (n=38, 31.1%), AA (n=26, 21.3%), IA (n=13, 10.7%), and LL (n=17, 13.9%).

Four out of 38 patients (10.5%) had FDG-uptake in a single vascular territory (TA), 10 (26.3%) in 2 territories, 6 (15.8%) in 3, 10 (26.3%) in 4, and 8 (21.1%) in the 5 territories. The most common affection was observed in the 5 territories (n=8), ST/AA (n=6), ST/TA/AA/LL (n=5), ST/TA/AA (n=4) and ST/TA/AA/IA (n=4). Significant differences were observed between the extension of the affection ( $\leq 2$  vs  $> 2$  territories) and the number of months from the symptoms onset to the diagnosis ( $79.1 \pm 59.9$  vs  $24.5 \pm 33.4$  months;  $p=0.003$ ). Differences regarding age, sex underlying disease, C-reactive protein, ESR, or treatment were not observed.

## Conclusion:

In patients with secondary non-infectious aortitis, the PET/CT demonstrated a frequent involvement of several vascular territories in addition to aorta, mainly ST. The extension of the vascular affection did not relate to the severity of the clinical syndrome.

## Correlation between the Routine Assessment of Patient Index Data (RAPID3) and Inflammatory Markers in Patients with PMR

Tiffany Kolniak<sup>1</sup>, Joshua Baker<sup>2</sup>, Abhijeet Danve<sup>3</sup> and Shiv Tej Sehra<sup>4</sup>, <sup>1</sup>Internal Medicine, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA, <sup>2</sup>Rheumatology, University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Yale University, New Haven, CT, <sup>4</sup>Rheumatology, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The routine assessment of patient index data (RAPID3) was developed for monitoring and prognosis of patients with Rheumatoid Arthritis and has since been extended for use in other rheumatologic disorders including ankylosing spondylitis, psoriatic arthritis and Sjogren's disease. The purpose of this study was to evaluate the correlation between the RAPID3 and inflammatory markers as well as the physician global assessment of disease (PGA) in patients with polymyalgia rheumatica (PMR).

**Methods:** Twenty-one patients, including four new cases and seventeen previously diagnosed cases of PMR, were enrolled in the study over a one year period. Each patient completed a RAPID3 questionnaire, had a clinical examination by a rheumatologist and had routine laboratory testing for sedimentation rate (ESR) and C-reactive protein (CRP) as part of routine care at each clinical visit. PGA was collected as active v. inactive disease. The rheumatologist was blinded to the results of the RAPID3 at the time of the visit. The independent associations between RAPID3 and other clinical variables were determined by multivariable linear regression models incorporating generalized estimating equations.

**Results:** Data was gathered for a total of 53 visits. The patients included in the study were all Caucasian and majority were female (66.7%). The average age was  $76 \pm 12$ . The average daily prednisone dose over the course of the year was  $5.6 \pm 5.1$  mg. 43.6% of visits were considered in remission according to the scores on the RAPID3. Nineteen percent of visits had normal ESR and CRP and 75% were felt to be inactive by the treating rheumatologist. In univariate analysis, higher scores on the RAPID3 were correlated with higher ESR [B 0.095 (0.026, 0.17)  $p=0.008$ ], female sex [B: 4.03 (0.70, 7.37)  $p=0.02$ ] and physician global scores [B: 7.75 (4.45, 11.1)  $p<0.001$ ]. In multivariable models, only female sex and physician global were independently associated with RAPID3 score. PGA strongly associated with ESR [B: 11.8 (3.21, 20.36)  $p<0.001$ ].

**Conclusion:** The RAPID3 is modestly correlated with inflammatory markers and is strongly associated with physician global assessment of disease activity in PMR. Female sex was also independently associated with higher RAPID3 scores in this population. Further study of the use of RAPID3 in the assessment of disease activity in PMR is of value to determine its potential use as a rapid and easily accessible screening tool for active disease.

Table: Multivariable linear regression model with generalized estimating equations evaluating associations between clinical variables and RAPID3 scores in PMR.

	Association with RAPID3  (N=21, Obs=53)	
	B (95% CI)	P Value
Age	0.024 (-0.19, 0.24)	0.83
Female	3.94 (0.35, 7.53)	0.03
Physician Global	7.47 (3.85, 11.1)	<0.001
ESR	-0.036 (-0.16, 0.087)	0.57

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Corticosteroid related adverse events are a main concern in patients suffering from giant cell arteritis. Conflicting results are reported on this topic, recurrent events are usually not taken into account and direct comparisons with the general population are scarce. We investigated non-cardiovascular corticosteroid related adverse events and cancer risks in an incident GCA patients cohort, the Midi-Pyrénées (southwest France) APOGEE cohort.

### Methods:

APOGEE is an administrative database cohort of 103 incident GCA patients (median age : 77 [51-91] years ) and 606 age- and sex-matched controls included between January 2005 and December 2008. The risk of events was compared between patients and controls during the first 36 months of follow-up using Cox models for single events and a linear negative binomial regression model for multiple events (infections and hospitalizations). Generalized estimating equations were used to compare the risk of occurrence across 6-months time periods.

### Results:

More than 1 Charlson comorbidity was present before diagnosis in 35% and 46,6% of GCA and control patients, respectively ( $p=0,03$ ). The hazard ratios (HR) and incidence rate ratios (IRR) of main events are reported in table 1. The risk of any corticosteroid-related events was increased by 49.6% in GCA patients, but it was significant only during the 24 months following diagnosis of GCA. Recurrent ( $\geq 2$ ) infections occurred in 61.2% of GCA patients versus 46.7% ( $p<0.001$ ). The rate ratio of infections was increased and stable throughout the follow-up. Age over 75 years and sex were not significantly associated with the risk of infection but suffering  $\geq 1$  comorbidity was ( $IRR = 1.187$ ,  $p<0.01$ ). Infection was the main cause of hospitalization in GCA patients. The risk of hospitalization for any cause (excluding the first hospitalization corresponding to GCA diagnosis) was increased (50.5% vs 35,5%,  $p<0,001$ ) and repeated hospitalizations were more frequent ( $p<0.001$ ) in GCA patients. Presence of comorbidities was the sole independent predictor of the risk of hospitalization. The initial prednisone dose ( $<60$  mg prednisone vs  $\geq 60$  mg/d) was not associated with the occurrence of any adverse event.

### Conclusion:

Muskuloskeletal events were rare in the setting of osteoporosis prevention. Overall, the risk of serious (leading to hospitalization) or repeated infections is a concern. The increased risk of cancer was unexpected.

**Table 1 :** risk of new corticosteroid related events and cancer in GCA patients (compared to age and sex matched controls).

<i>De novo</i> events	p-value	HR, IC 95%
Cancer	<0.05	2.33 [1.03-5.22]
Diabetes mellitus	<0.01	2.60 [1.35-5.03]
Glaucoma	<0.001	2.41 [1.45-4.03]
Cataract (after 1 year)	<0.05	2.14 [1.08-4.23]

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While several studies have examined the potential of <sup>18</sup>F-fluorodeoxyglucose (FDG) positron emission tomography (PET) to help establish a diagnosis of large vessel vasculitis (LVV), the role of FDG-PET to monitor disease activity over time and predict clinical outcomes remains unclear. The study objective was to assess the clinical value of FDG-PET in a prospective cohort of patients with large-vessel vasculitis (LVV) and disease comparators.

**Methods:** Patients with Takayasu's arteritis (TAK) and giant cell arteritis (GCA) were studied, along with a comparator group consisting of patients with hyperlipidemia, diseases that mimic LVV, and healthy controls. All participants underwent clinical evaluation and FDG-PET imaging, and patients with LVV underwent serial imaging at six-month intervals. Performance characteristics of FDG-PET interpretation were calculated to differentiate clinically active LVV from disease comparators and from clinical remission. Multivariable logistic regression in a mixed effects model was used to identify clinical factors associated with FDG-PET interpretation. A qualitative summary score based on global arterial FDG uptake in specific arterial territories was developed (the PET Vascular Activity Score – PETVAS). PETVAS was used to study associations between FDG-PET activity and clinical characteristics and to predict relapse.

**Results:** 170 FDG-PET scans were performed in 115 patients (LVV=56; comparators=59). FDG-PET differentiated patients with clinically active LVV and disease comparators with a sensitivity=85% (95%CI: 69-94%) and specificity=83% (95%CI: 71-91%). FDG-PET scans were interpreted as active vasculitis in the majority of patients with LVV in clinical remission (41 of 71, 58%). Clinical disease activity status, disease duration, body mass index, and glucocorticoid use were independently associated with FDG-PET scan activity. Among 39 patients who underwent FDG-PET during remission, clinical relapse requiring a change in medical management was more common in patients with a high versus low PETVAS (45% versus 11%, p=0.03) over a median follow-up of 15 months.

**Conclusion:** FDG-PET provides information about vascular inflammation that is complimentary to, and unique from, clinical assessment in LVV. Use of FDG-PET to detect subclinical vascular inflammation in LVV during remission has prognostic value.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

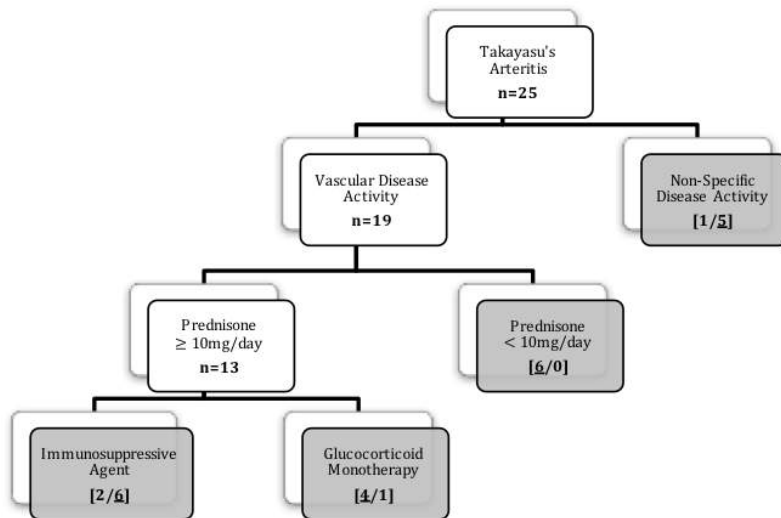

**Background/Purpose:** To study the relationship between clinically-determined disease activity and vascular inflammation assessed by positron emission tomography (PET) in patients with Takayasu's arteritis (TAK).

**Methods:** Patients with new or relapsing TAK were evaluated at 5 centers. Whole body <sup>18</sup>F-fluorodeoxyglucose (FDG) PET-CT imaging was performed during a period of clinical disease activity. Clinical assessments were performed blinded to PET scan findings. A single nuclear medicine physician interpreted all of the PET scans, blinded to clinical data, to determine presence of active vasculitis based on degree of arterial FDG uptake. Classification and regression tree analysis (CART) defined predictors of PET scan activity. Elevated acute phase reactants (ESR > 30 mm/hr, CRP > 10 mg/L), prednisone dose at time of imaging, ongoing use of other immunosuppressive agents for > 1 month at time of clinical assessment, interval between clinical and imaging assessments, and clinical features of disease activity (vascular vs nonspecific) were studied within the CART models. Vascular features included asymptomatic disease progression by angiography. Non-specific features of disease activity were defined as constitutional symptoms accompanied by elevated acute phase reactants in the absence of signs or symptoms of vascular involvement.

**Results:** Clinical assessments were performed in 25 patients with TAK, and PET scans were performed a mean of 7 days later. FDG-PET findings were suggestive of active vasculitis in 13 of 25 patients (52%). Interval increase in glucocorticoid therapy between clinical assessment and imaging occurred in 4/13 (31%) patients with an active scan and 5/12 (42%) patients with an inactive scan (p=0.69). CART analysis predicted FDG-PET scan activity with 84% accuracy based upon 3 variables: clinical features of disease activity, prednisone dose at the time of imaging, and use of a non-glucocorticoid immunosuppressive agent (**Figure**). Acute phase reactants and time interval delay between clinical and imaging assessments were not predictive within the model. Clinical features of disease were the strongest determinant of vascular activity on FDG-PET. Among patients with vascular symptoms of disease activity, use of < 10 mg daily prednisone at the time of imaging assessment and treatment with glucocorticoid monotherapy were associated with increased probability of active vasculitis on FDG-PET.

**Conclusion:** Clinical features of disease and treatment status are associated with different findings on vascular FDG-PET scan in TAK. Clinical studies that incorporate imaging-based assessment of disease activity in TAK should ideally obtain

baseline imaging studies prior to the initiation of glucocorticoid therapy and should consider exclusion of patients with exclusively non-specific symptoms of disease activity.

**Figure. Classification and regression tree analysis (CART) to Determine Predictors of PET Scan Activity in Takayasu's Arteritis.** Clinical nature of disease activity, amount of daily prednisone, and ongoing use of a non-glucocorticoid immunosuppressive agents at the time of initial clinical assessment were predictors of PET scan activity in the cohort. Brackets within terminal nodes (grey boxes) depict the number of patients with [abnormal PET scan / normal PET scan]. CART model predicted PET scan activity with an accuracy of 84% (21 out of 25 patients classified correctly, underlined numbers).

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent studies have indicated a higher incidence of deep vein thrombosis (DVT) and pulmonary embolism (PE) in patients with giant cell arteritis (GCA)<sup>1,2</sup>. Our objective was to determine the incidence rate of concurrent DVT and PE in our prospectively followed GCA patient cohort.

**Methods:** We performed an analysis of our prospectively collected incipient cohort of patients with GCA from December 1<sup>st</sup> 2011 to December 1<sup>st</sup> 2016 at a single secondary/tertiary rheumatology center. The proportion of patients who were

diagnosed with concurrent DVT or PE was determined based on patients' reports and electronic or paper medical records, in addition to clinical and laboratory features of each patient. The DVT and/or PE were defined as concurrent when diagnosed within a time frame extending from 6 months prior until 6 months after the diagnosis of GCA. The cumulative incidence rate of DVT and PE in population aged 50 years and above from the same well defined geographical region in years 2012 to 2015 was acquired from the local electronic DVT/PE registry. Ultimately, standardized incidence ratios (SIR) for DVT and PE with respective 95% confidence intervals (CI) were calculated using Fisher's exact test.

**Results:** During the 5-year observation period, we identified 83 new GCA cases (median age 73.8 (IQR 66.6–78.8) years, 70% female, 47% ever smokers). Sixty-eight (82%) patients fulfilled the 1990 ACR classification criteria for GCA; the remaining 18% had imaging evidence of large vessel vasculitis. We identified a single patient with PE and no patients with DVT within the prespecified one-year time frame. The 79-year-old non-smoking female was diagnosed with PE 1 week after GCA diagnosis and had a history of arterial hypertension, diabetes and hypercholesterolemia. She had no traditional antiphospholipid antibodies, however we detected IgA subtype antibodies against antiprothrombin/phosphatidylserine complex. No patients were diagnosed with DVT or a PE more than 6 months prior to the diagnosis of GCA. The average incidence rate for concurrent DVT/PE in our GCA cohort was 12.0 per 1000 patient-years, whereas the average incidence rate for DVT/PE in the general population aged 50 years and above, residing in the same region, was 2.4 per 1000 patient-years (565 cases/235.800 residents per year). The SIR was 5.0 (95% CI 0.13–27.86;  $p=0.362$ ).

**Conclusion:** Contrary to the recent reports, the incidence rate of DVT and PE was not significantly different in our GCA cohort than in the general population of comparable age and residence. Because of the small patient number and only one thrombotic event in our cohort, further monitoring is warranted to confirm or exclude the association between GCA and DVT/PE.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Most studies looking at seasonal variations in giant cell arteritis (GCA) note a seasonal trend, but show disparity on timing. Concurrent peaks of GCA and polymyalgia rheumatica (PMR) have been described by some studies questioning a common precipitating agent. We aimed to analyze the seasonal variation of GCA and PMR in the US using a large inpatient database.

**Methods:** We used Nationwide Inpatient Sample (NIS) database to identify patients aged  $\geq 18$  years from 2009-11 with a diagnosis of GCA and PMR with ICD-9-CM codes 446.5 and 725 in the first 3 positions. We used the Edwards' recognition and estimation of cyclic trend method to study the seasonal patterns of GCA and PMR hospitalizations stratified by age. Z-test was used to compare seasonal incidences

## Results:

A total of 57728 and 242862 hospitalizations with a diagnosis of GCA and PMR respectively were reported from 2009-11. A significant seasonal variation was observed with highest number of GCA hospitalizations in summer (peak/low ratio 1.092, 95% CI 1.067-1.118,  $p < 0.0001$ ) and most significant peaks seen in age group 65-69 (peak/low ratio 1.092, 95% CI 1.067-1.118,  $p < 0.0001$ ) (Figure 1). No significant seasonal variation was seen with PMR hospitalizations.

## Conclusion:

Our study found peak GCA hospitalizations in summer months which is concurrent with trends seen in Israel and England but differ from other studies showing peaks in late winter and autumn. Interestingly, no similar pattern was observed in closely related disorder, PMR. A better understanding of these patterns could lead to identification and possibly control of potential environmental triggers in the genetically predisposed population.

## Long Term Efficacy and Safety of Intravenous and Subcutaneous Biologics in Large Vessels Vasculitis: 21 Patients Belonging to a Single Italian Center from 2011 to 2017

**Paola Toniati**<sup>1</sup> and Angela Tincani<sup>2</sup>, <sup>1</sup>RHEUMATOLOGY, SPEDALI CIVILI, BRESCIA, Italy, <sup>2</sup>University and Spedali Civili of Brescia, Brescia, Italy

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Large vessels vasculitis (LVV) is the most common form of primary vasculitis comprising giant cell arteritis (GCA) and Takayasu arteritis (TAK) and aortitis.

### Methods:

We collect retrospectively 21 patients affected by LVV, resistant to conventional therapy and treated with intravenous or subcutaneous biologics. Four patients were affected by GCA, with positive temporal artery biopsy; nine patients were affected by TAK according to 1990 ACR criteria and eight patients were affected by aortitis (two with associated retroperitoneal fibrosis), diagnosed with a positive 18F-FDG-PET scan, indicating active LVV with aortic involvement. Data from 18F-FDG PET and CT or MRI associated with improvement of clinical and inflammatory index (ESR and PCR) were used as a criteria of response to treatment. Our aim is to demonstrate the long term efficacy and safety of biologics in LVV.

### Results:

The mean age of 21 patients were 57 year (18-87). Five patients were men with mean age of 65 year (32-79), 16 were women with mean age of 55.3 year (18-87). The mean follow-up time of patients was 29 months (2-79). Eighteen patients out of 21 (86%), suffered an aortic involvement at diagnosis discovered with 18F-FDG-PET scan. These patients were checked yearly with imaging using 18F-FDG-PET with a semiquantitative analysis. 18F-FDG-PET scan follow-up data were available in 12 patients. Tocilizumab (TCZ) was used in 19 patients for a medium period of follow-up period of 25 months (2-60). All patients started with EV TCZ (8 mg/kg/4w), then five patients passed to subcutaneous TCZ reducing the dose to 162 mg/2w. Seventeen patients demonstrated a good response with clinical improvement, reduction of inflammatory index and sparing of steroid dose. Two TAK patients experienced a failure treatment (new stenosis) one after one and the other after 4 year of treatment each. Infliximab was used in 3 patients and suspended in all three patients for infusive reactions, after three (one patient) and six month (2 patients) of treatment. Adalimumab (ADA) was used in 2 patients: one patient responded well with a negative PCR and a negative 18F-FDG-PET scan after one year of treatment and maintain stable remission without steroid, lasting 79 months; the other patient started the treatment three month ago. Golimumab 100 mg/m was used in one TAK patient, resistant to TCZ, with achieving a stable clinical and imaging remission (no new stenosis) during the last year. This patient refused steroid assumption. The side effects were bronchitis affecting two patients with TCZ and one patient with ADA and golimumab each. One patient with aortitis retroperitoneal fibrosis suspended TCZ after two infusions for acute cholecystitis. Mean steroid dose at the beginning of biologics treatment were 30 mg/day (50-0). Mean steroid dose at the last follow-up was 7 mg/day (32-0).

### Conclusion:

In these group of 21 patients biological treatments demonstrated longterm efficacy and acceptable safety profile and important steroid sparing effect.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are no valid followup parameters in the assessment of disease activity in Takayasu arteritis (TA). We investigated the impact of incorporation of vascular imaging into ITAS in the assessment of disease activity in TA

**Methods:** 52 patients who fulfilled the ACR criteria were included. Physician global assessment (PGA), Kerr et al's criteria (K,eC) and ITAS2010/ITAS-A scores were evaluated in all patients (1,2). All the patients were followed using 3-6 monthly USG and 6-12 monthly MR angiography (MRA). Radiological activity (Rad) was defined based on the presence of any of the 3 parameters including new vessel involvement by any imaging technique (5 points), the increase in vessel wall thickness USG (3 points) and vessel wall edema on MRA (3 points). Then we incorporated these scores with ITAS-A to obtain a composite disease activity index (ITAS-A-Rad) (table 1).

**Results:** Total 410 visits of 52 TA patients (mean age 50.7, F:92.3%, mean followup duration:  $6.4 \pm 2.9$  yrs) were evaluated. Radiological assessment was done in 359 visits. Patients were categorized as having active disease in 194 visits (47.4%) according to PGA and 72 visits (17.5%) according to K,eC. The agreement between them was fair (66%,  $\kappa:0.29$ ). Rad parameters were determined in 105 out of 359 visits. The total agreement was found to be 83% ( $\kappa:0.58$ ) between the radiological disease activity and K,eC and 76% ( $\kappa:0.52$ ) between the RAD and PGA. Mean ITAS-A-Rad scores were significantly higher in visits with active disease compared to visits with inactive disease according to both PGA and K,eC (table 2). The ITAS-A-Rad was significantly correlated with all the other activity parameters including ITAS2010, ITAS-A, and APRs. There were 43 visits with new vessel involvement by any of the two imaging techniques; all visits included patients with active disease based on both PGA and Kerr et al criteria. The agreement between ITAS2010 and PGA was fair (69%,  $\kappa:0.38$ ). When acute phase reactant was added (ITAS-A), it did not improve (68%,  $\kappa:0.34$ ). But the agreement between ITAS-A-Rad and PGA (72%,  $\kappa:0.50$ ) and also K,eC (82%,  $\kappa:0.56$ ) was found to be moderate. When only ITAS-A-USG or only ITAS-A-MRA was used, the agreement with PGA remained unchanged (73%,  $\kappa:0.45$  and 76%,  $\kappa:0.52$  respectively). When responsiveness to change of ITAS-A-Rad score was evaluated by serial visits of patients, it was found that the mean value of the score was discriminative for disease activity according to PGA in 9 of 11 visits (Figure 1)

**Conclusion:** This study suggests that ITAS A Rad, a modified ITAS2010 score may be used to be a valuable follow-up parameter in the assessment of disease activity in TA

**Table 1.** The definition of ITAS-A-Rad Score

Definition	Method		Score
ITAS2010	Clinical		≥0
ITAS-A	ITAS2010 + acute phase reactant (ESR or CRP)	ESR	ITAS score plus 0 for ESR<20, 1 for 21-39, 2 for 40-59, 3 for >60 mm/h
		CRP	ITAS score plus 0 for CRP≤5, 1 for 6-10, 2 for 11-20, 3 for >20mg/L
ITAS-A-Rad*	ITAS-A + Rad	New vessel involvement with any imaging method	ITAS-A score plus 5
		Progression of vessel wall thickness on B-mode USG	ITAS-A score plus 3
		Presence of vessel wall edema on MRA	ITAS-A score plus 3

\*Active disease: ITAS-A-Rad > 4

**Table 2.** Response to change. The mean ITAS-A-Rad scores in serial visits

Visit no	ITAS-A-Rad Score (mean±SD)		
	PGA active	PGA inactive	P
1	16.72±6.3	5.25±4.9	<0.001*
2	6.23±4.6	1.92±3.8	<0.001*

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Plenary Session I

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Tissue fibrosis caused by pathological activation of fibroblasts is a major hallmark of systemic sclerosis (SSc). Although fibroblast activation is initially driven by external factors, prolonged activation can render fibroblasts independent of external stimuli. Accumulating evidence suggests that epigenetic alterations play a central role to establish the persistently activated phenotype of fibroblasts. In the present study, we tested the hypothesis that epigenetic silencing of SOCS expression may contribute to the aberrant activation of JAK2 / STAT3 signaling in SSc, and that re-establishment of the endogenous, SOCS-dependent control of JAK / STAT signaling may prevent aberrant fibroblast activation and ameliorate tissue fibrosis.

**Methods:** DNA methylation was evaluated by methylation-specific PCR and MeDIP assays. 5-aza-2'-deoxycytidine (5-aza) was used to inhibit DNA methyltransferases (DNMTs). Knockdown analyses were done by nucleofection of siRNA *in vitro* and by fibroblast-specific knockout mice *in vivo*.

**Results:** SOCS3 was strongly downregulated in skin of SSc patients compared to healthy individuals. Chronically increased levels of TGFβ induced an SSc-like phenotype and reduced the levels of SOCS3 in normal fibroblasts to a level comparable with SSc fibroblasts. These findings suggested that epigenetic mechanisms may account for the reduced expression of SOCS3. Indeed, methylation analyses demonstrated a prominent promoter hypermethylation of SOCS3 in SSc fibroblasts and in normal fibroblasts exposed to persistently high levels of TGFβ. Mechanistically, chronically increased levels of TGFβ promoter hypermethylation of the SOCS3 promoter by induction of DNMT3A. Pharmacological inhibition of DNMTs or selective knockdown of DNMT3A restored the normal expression of SOCS3 and reduced fibroblast activation and collagen release. Knockdown of SOCS3 in normal dermal fibroblasts induced an SSc-like phenotype with increased activation of JAK2-STAT3 signaling, enhanced expression of myofibroblast markers and increased collagen release. Fibroblast-specific knockout of SOCS3 promoted JAK2-STAT3 signaling and aggravated tissue fibrosis in bleomycin- and TGFβRI<sup>act</sup>-induced dermal fibrosis. Vice versa, forced overexpression of SOCS3 inhibited TGFβ-induced JAK2-STAT3 signaling and reduced TGFβ-mediated fibroblast activation. Overexpression of SOCS3 also ameliorated the endogenous activation of SSc fibroblasts. Moreover, treatment with DNMT inhibitors or fibroblast-specific knockdown of DNMT3A re-activated the expression of SOCS3, reduced JAK2-STAT3 signaling and exerted potent antifibrotic effects in bleomycin- and TGFβRI<sup>act</sup>-induced dermal fibrosis.

**Conclusion:** We demonstrate that chronic activation of TGFβ signaling perturbs the epigenetic control of STAT signaling by DNMT3A-induced silencing of SOCS3 expression in SSc. Re-establishment of the endogenous regulation of STAT signaling, either by forced expression of SOCS3 or by pharmacologic inhibition of DNMTs, prevents aberrant STAT3 signaling, inhibits TGFβ-induced fibroblast activation and collagen release and ameliorates experimental fibrosis.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Plenary Session I

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Methotrexate (MTX), a widely used immune-suppressive agent, decreases vaccine response in patients with rheumatoid arthritis (RA). We investigated whether a temporary MTX discontinuation for 2 weeks after vaccination improves the efficacy of seasonal influenza vaccination in RA patients.

**Methods:** In this prospective, multicenter, randomized, parallel-group trial, RA patients taking stable dose of MTX were randomly assigned at a ratio of 1:1 to continue MTX (MTX-continue group) or to suspend MTX for 2 weeks after vaccination (MTX-hold group). All participants were vaccinated with seasonal quadrivalent influenza vaccine containing H1N1, H3N2, B-Yamagata, and B-Victoria. The primary outcome was frequency of satisfactory vaccine response, defined as  $\geq 4$ -fold increase in hemagglutination inhibition (HI) antibody titer at 4 weeks after vaccination against  $\geq 2$  of 4 vaccine strains. Secondary endpoints included seroprotection rate, fold-change in antibody titers relative to baseline in geometric mean titer (GMT).

**Results:** We enrolled 320 patients between Oct 7, 2016 and Jan 9, 2017. The modified intention-to-treat population consisted of 316 patients (156 in the MTX-continue group and 160 in the MTX-hold group). Higher proportion of patients in MTX-hold group achieved satisfactory vaccine response compared to MTX-continue group (75.5% vs. 54.5%,  $p < 0.001$ ) (Figure). Post-vaccination seroprotection rate was higher for all 4 antigens in the MTX-hold group than the MTX-continue group (H1N1: 75.6% vs. 86.3%,  $p=0.016$ ; H3N2: 62.2% vs. 78.1%,  $p=0.002$ ; B-Yamagata: 74.4% vs. 88.1%,  $p=0.002$ ; B-

Victoria: 60.9% vs. 75.6%,  $p=0.005$ ). Similarly, the MTX-hold group achieved higher fold increase of post-vaccination HI antibody titer in GMT [95% CI] for each antigen (H1N1: 4.6 [3.7- 5.7] vs. 6.7 [5.4 - 8.3],  $p=0.017$ ; H3N2: 4.3 [3.5 - 5.3] vs. 8.0 [6.4 - 9.9],  $p<0.001$ ; B-Yamagata: 3.1 [2.6 - 3.8] vs. 5.6 [4.7- 6.6],  $p<0.001$ ; B-Victoria: 2.9 [2.4- 3.4] vs. 5.7 [4.9 - 6.7],  $p<0.001$ ). Vaccine was well tolerated. Disease activity after vaccination did not differ between both groups.

## Conclusion:

Temporary MTX discontinuation for 2 weeks after vaccination improves the immunogenicity of seasonal influenza vaccination in RA patients without increasing RA disease activity.

**Trial registration:** [www.clinicaltrials.gov, protocol number NCT02897011].

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Plenary Session I

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Given FDA warnings, drug holidays (temporary or permanent discontinuation) of bisphosphonates (BPs) after long-term (3-5 years) continuous therapy is becoming increasingly common in the United States (US). However, the benefits and risks of stopping BPs, and the optimal timing to restart, remain unclear. We conducted a population-based cohort study of women on long term BP therapy to evaluate the rate of hip fracture following a drug holiday.

**Methods:** We used Medicare data (2006-2014) to identify all women with medical and pharmacy coverage who initiated a BP and were at least 80% adherent for  $\geq 3$  years ('baseline'), at which follow-up time began. Patients using other bone therapies (e.g. denosumab, estrogen, teriparatide, calcitonin) were excluded or censored if they started after follow-up began. We calculated crude rates of hip fracture for continuing BP therapy and among those who discontinued, for categories of time since discontinuing (i.e., length of drug holiday), extending up to 3 years. We used Cox proportional hazards models to evaluate the risk of discontinuing per the length of the drug holiday, using age as the time axis and controlling for potentially confounding factors, with and without adjusting for death as a competing risk.

**Results:** We identified 156,236 women who were highly adherent, long-term BP users. The mean (SD) age was 78.5 (7.5) years. The most commonly used BPs were alendronate (71.7% ever use, 52% exclusive use) and zoledronic acid (16.2% ever use, 8.9% exclusive use). During a median (IQR) follow up of 2.1 (1.0, 3.3) years, 62,676 (40.1%) of women stopped BP therapy for at least 6 months or more. Among these women, 7,947 (12.7%) subsequently restarted any BP. Overall, 16,904 (10.8 %) died.

A total of 3,745 hip fractures occurred during follow-up. Hip fracture rates were lowest among women who were current users, and gradually increased as the length of the drug holiday increased, achieving their maximum with a drug holiday  $>2$  years (Table).

**Conclusion:** In a large cohort of U.S. women, a BP drug holiday greater than 2 years was associated with a significantly increased risk for hip fracture of up to 39% compared to continued BP use.

**Table: Hip fracture Rate By Duration of BP Drug Holiday, Adjusting for Competing Risk of Death**

Time since Bisphosphonate Discontinuation (yrs)	Number of hip fractures, n	Crude Incidence Rate per 1,000 person-years	Adjusted* Hazard Ratio (95% CI)
0 (i.e. current use)	1958	9.6 (9.2, 10.1)	1.0 (reference)
$>0$ to $\leq 3$ months	530	13.1 (12.0, 14.3)	1.29 (1.17, 1.42)
$>3$ months $\leq 1$ year	539	12.0 (11.0, 13.1)	1.12 (1.02, 1.24)
$>1$ to $\leq 2$ years	422	13.3 (12.0, 14.6)	1.21 (1.09, 1.35)
$>2$ to $\leq 3$ years	235	15.7 (13.7, 17.8)	1.39(1.21, 1.59)

\*adjusted for age, region, race, rural or urban, median income, calendar year, comorbidity(frailty fracture, charlson comorbidity index score), DXA, number of physician visits, care by a rheumatologist or endocrinologist, long term care residence, vitamin D deficiency, glucocorticoids, and proton pump inhibitors

# Unraveling Race and Social Context in Understanding Disparities in Lupus Mortality in the United States

**Titilola Falasinnu**<sup>1</sup>, **Yashaar Chaichian**<sup>2</sup>, **Latha Palaniappan**<sup>3</sup> and **Julia F Simard**<sup>4</sup>, <sup>1</sup>Health Research and Policy, Stanford University, Stanford, CA, <sup>2</sup>Medicine, Immunology & Rheumatology Division, Stanford School of Medicine, Stanford, CA, <sup>3</sup>Stanford University Medical Center, General Medical Disciplines, Stanford, CA, <sup>4</sup>Division of Epidemiology, Health Research and Policy Department, Stanford School of Medicine, Stanford, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Plenary Session I

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that is a source of significantly decreased life expectancy in the United States. Women and racial/ethnic minorities account for an increasingly disproportionate number of cases, with genetic factors regarded as potentially causative. The role of social and environment contexts has received little attention. We examined SLE mortality rates across eight groups of race-county combinations of the US population, developed by Murray et al in 2006, that are referred to as the “Eight Americas”. We examined SLE mortality in the Eight Americas over time to assess whether the impact of race is attenuated when the social and geographic context is also considered. We also examined whether age at death in SLE decedents differs across the Eight Americas, and explicated patterns of disease comorbidities among SLE decedents in the Eight Americas.

**Methods:** Using death certificate data from the National Center for Health Statistics Multiple Cause of Death (MCOB) database, SLE-related deaths were identified via International Classification of Diseases, 10th revision (ICD-10) codes: M32.1, M32.9, and M32.8. Annual SLE-related mortality rates and mortality rate ratios were calculated for each of the Eight Americas using America 3 as the reference category. Average Annual Percent Change (AAPC) in mortality rates summarized trends over a fixed predetermined interval. To examine trends in associated causes of death listed in the death certificates of SLE decedents, we calculated Proportionate Mortality Ratios (PMRs) for the top causes of death (derived from the literature) among SLE patients. Statistical analyses were performed using SAS version 9.4.

**Results:** There were 24,773 SLE-related deaths between 2003 and 2014. Mortality was highest among blacks in three race-geographical contexts (Americas 6, 7, & 8). Age at death was lowest (~48 years) for blacks and Asians, regardless of geographical context, and highest among low-income rural whites (~65 years). Blacks and Asians were also more likely to have infectious diseases listed as associated causes of death, a finding consistent across geographical contexts, while whites were more likely to have cardiovascular diseases and neoplasms reported as associated causes of death.

**Conclusion:** Blacks sharing the same social and geographical contexts as whites were disproportionately more likely to die young and exhibit severe patterns of mortality. Although blacks inhabited three vastly different geographical and social contexts, SLE mortality parameters did not vary among socially advantaged and disadvantaged blacks. Together, these findings suggest that race may transcend social and geographical parameters as a key determinant of SLE mortality.

## Performance on Quality Measures in the RISE Registry and the Merit-Based Incentive Payment System (MIPS)

**Jinoos Yazdany**<sup>1</sup>, Tracy Johansson<sup>2</sup>, Rachel Myslinski<sup>3</sup> and Salahuddin Kazi<sup>4</sup>, <sup>1</sup>Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, <sup>2</sup>Practice, Advocacy & Quality, American College of Rheumatology, Atlanta, GA, <sup>3</sup>Governance & Ethics Specialist, Amer College of Rheumatology, Atlanta, GA, <sup>4</sup>University of Texas Southwestern, Dallas, TX

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Plenary Session I

**Session Type:** ACR Plenary Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Under the new Medicare Access and CHIP Reauthorization Act (MACRA), the quality of care rheumatologists provide will have financial repercussions through the Merit Based Incentive Program (MIPS). MIPS will score providers across four domains: Quality, Clinical Practice Improvement, Advancing Care Information and Cost. In this study, we sought to evaluate performance on quality measures for practices participating in the Rheumatology Informatics System for Effectiveness (RISE) registry in the first quarter of 2017 and to develop a prototype dashboard for RISE to assist clinicians in understanding their MIPS performance.

**Methods:** The RISE informatics platform continuously collects data from the electronic health records (EHRs) of participating practices, allowing centralized aggregation and analysis of quality measures. Measures in the areas of rheumatoid arthritis, drug safety, preventive care and gout were examined. For the first quarter of 2017 (the initial period eligible for MIPS reporting), we calculated performance on quality measures, defined as the percentage of eligible patients receiving recommended care. We also developed a prototype dashboard for RISE that will display scores across the four MIPS domains to help clinicians track their performance over time.

**Results:** Data from 548,990 patients across 491 clinicians and 109 practices was examined. Most rheumatologists were in a group practice (72%); 26% were in solo practice and 2% part of a larger health system. Mean (SD) patient age was 59 (16) years, 75% were female, 21% were racial/ethnic minorities. Performance on measures varied significantly across practices (**Table**). For 2 of 5 measures for which the Medicare program has set national benchmarks, average performance of RISE practices exceeded targets in the first quarter of 2017. Quality measures that make up the MIPS quality domain were combined with simulated information for other MIPS domains to develop a MIPS dashboard prototype for RISE, displayed in the **Figure**.

**Conclusion:** We found significant variation in performance on quality measures in the first quarter of 2017 across RISE practices, with some practices having already achieved a very high level of performance. We anticipate that the MIPS dashboard prototype will go-live on the RISE user interface in late 2017 and will aid rheumatologists in proactively monitoring their MIPS score.

**Table. Performance on Quality Measures in the RISE Registry in 2017.**

Electronic Quality Measure (eCQM)	Measure denominator (N)	Average performance across patients (%)	Practice-level performance (percentile)		CMS benchmark

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is characterized by the production of anti-nuclear antibodies that deposit within tissues leading to organ damage. A central mediator of SLE pathogenesis is interferon-alpha (IFN $\alpha$ ), which is elevated in the serum of SLE patients. IFN $\alpha$  has been shown to enhance B cell signaling and promote the survival of B cells. It also plays a major role in the induction of B cell activating factor (BAFF). While past studies have explored the indirect effects of IFN $\alpha$  through BAFF on B cell tolerance, little work has focused on how IFN $\alpha$  itself directly affects this process. We hypothesize that elevated levels of IFN $\alpha$  directly contribute to the breach of B cell tolerance in SLE. To address this question, we have obtained an adenoviral vector encoding mouse IFN $\alpha$  (mDEF201), which we are using to induce sustained elevations of serum IFN $\alpha$  in several well characterized mouse models of B cell tolerance.

**Methods:** IgHEL/sHEL double transgenic mice, with transgenes encoding anti-hen egg white lysozyme (HEL) Ig and soluble HEL were injected IV with 10<sup>7</sup> PFU of Ad-mIFN $\alpha$  (mDEF201) or Ad-dl70-3 (empty control vector). At 2 weeks post-treatment immune cell populations in the spleen and bone marrow were examined by flow cytometry, and anti-HEL antibody production was measured by ELISA. Serum levels of IFN $\alpha$  were quantified by ELISA and tissue-specific IFN-induced gene expression was assessed by qRT-PCR.

**Results:** 6-8 week old C57BL/6 mice administered with mDEF201, but not Ad-dl70-3, showed robust elevations of serum IFN $\alpha$  from 48h to 2 weeks post infection. At 2 weeks post injection expression of several IFN-inducible genes (2-5' *Oas*, *Pkr*, *Mx1*, *Ifit1*, *Irf7*, *Isg15*), but not *Baff*, was elevated in the liver, bone marrow and spleen of infected mice. B cell homeostasis and activation were altered in IgHEL/sHEL mice following administration of mDEF201. At 2 weeks post

infection mice displayed increased proportions of total splenic B cells (B220<sup>+</sup>CD19<sup>+</sup>). Infected mice also displayed an increase in the proportion of mature B cells (B220<sup>+</sup>CD93<sup>-</sup>) and decreased proportions of immature transitional 1 and 2 B cells (CD24<sup>+</sup>CD21<sup>-int</sup>). Upregulation of the B cell activation marker B7.2 (CD86<sup>+</sup>) and down regulation of surface IgM<sup>a</sup> was observed on mature B cells in infected mice suggestive of enhanced B cell signalling. At 2 weeks post infection mice also displayed increased proportions of germinal center B cells (B220<sup>+</sup>GL7<sup>+</sup>CD95<sup>+</sup>). Upregulation of CD86 and enhanced maturation of the B cell compartment was not seen following infection of mice with Ad-dI70-3. Anti-HEL IgM<sup>a</sup> antibody production was increased 2 weeks post infection signifying a breach of B cell tolerance in IgHEL/sHEL mice. No differences in T cell populations or activation state were seen suggesting that the observed effects on B cells occurred largely from altered B and not T cell function.

**Conclusion:** IFN $\alpha$  may be playing an important role in breaching B cell tolerance in SLE not only through the induction of BAFF but also through its direct actions on B cells. Further research into the effects of IFN $\alpha$  on these processes may prove IFN $\alpha$  to be a more effective therapeutic target than BAFF for SLE patients.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** B cell development involves passage through a formative transitional B cell stage in the spleen. In SLE, self-nucleic acid reactive B cells fail to be deleted at the transitional B cell stage but the factors promoting specific expansion of these autoreactive cells are unknown. Transitional B cells have been shown to exhibit dysregulated type I interferon (IFN) in SLE, and a sub-population of transitional and naïve B cells from SLE patients were recently shown to express high levels of IFN $\alpha$ . The purpose of these studies was to investigate if B cell endogenous type I IFN can act in an autocrine manner to promote survival and development of autoreactive transitional B cells.

**Methods:** Wild type C57BL/6 (B6), B6-CD45.1, CD45.2 B6-*Rag1*<sup>-/-</sup>, and BXD2 were obtained from Jackson Lab. B6-IFN $\beta$ <sup>-/-</sup> mice were provided by Dr. Fish. A 1:1 ratio of bone-marrow cells was used to reconstitution. Type1 interferon- $\alpha$  or

IFN $\beta$  stimulation or blockade was carried out using validated sources. Single-cell QRT-PCR was carried out using a Fluidigm-BioMark system on FACS-sorted T1 B cells. Hierarchical clustering was carried out using ClustVis.

**Results:** Examination of all B cells subsets in B6 and BXD2 mouse spleen revealed that transitional stage 1 (T1) B cells expressed high levels of type I IFN $\alpha$  genes and IFN $\beta$  in both strains. T1 B cells from BXD2 lupus-prone mice overexpressed IFN $\beta$  relative to B6 mice, and intriguingly, T1 B cells expressed IFN $\beta$  at levels comparable to pDCs. T1 B cells from both B6 and BXD2 mice also exhibited higher expression of IFN $\alpha$ R1 and expressed CD86 and CD69 upon IFN $\beta$  stimulation. TLR7 responses following stimulation with CL264 was highly dependent upon this endogenous IFN- $\beta$  in T1 B cells, but not in other B cell subpopulations. Single-cell examination of Ifnb $^{-/-}$  vs. Ifnb $^{+/+}$  T1 B cells revealed heterogeneous expression of IFN $\beta$  in WT T1 B cells and distinct gene expression signatures that required endogenous IFN $\beta$ . IFN $\beta$  $^{-/-}$  T1 B cells exhibited significantly lower expression of CD86, TLR7, and PKR, and type I IFN genes. Single cell analysis of autoimmune BXD2 T1 B cells that overexpressed IFN $\beta$  revealed that IFN $\beta$  is expressed in early T1 B cell development with subsequent upregulation of TLR7 and IFN $\alpha$ s. Functional analysis of Ifnb $^{+/+}$  and Ifnb $^{-/-}$  B cells derived from double chimeric mice revealed that IFN $\beta$  was required for development of germinal center, autoreactive, and IgG class switched anti-DNA, anti-La and anti-Histone autoAb producing B cells.

**Conclusion:** Together, these data highlight the role of IFN $\beta$  in shaping T1 B cell responses in the mouse spleen, including their survival and responses to TLR7. Notably, they indicate that these effects are mediated through the endogenous expression of IFN $\beta$  in T1 B cells. This mechanism suggests that endogenous IFN $\beta$ -expressing T1 B cells are initially autonomous and that their expression of IFN $\beta$  plays a key role in regulating their responsiveness to external factors, including externally-derived type 1 IFNs and TLR7. In lupus, overexpression of IFN $\beta$  in T1 B cells may promote the development of autoreactive mature B cells leading to the generation of polyreactive self-antigen-reactive mature B cells.

**Session Title:** B Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** While the contribution of humoral immunity to SLE is well established, the role it plays in chronic cutaneous lupus erythematosus (CCLE) is less clear. One characteristic of SLE is a breakdown of tolerance in autoreactive VH4.34 antibodies that are recognized by the rat anti-human idiotypic antibody 9G4 (9G4+). 9G4+ antibodies have germ

line encoded autoreactive specificity for glycolipids found on red blood cells and B cells. Despite a high frequency of naive 9G4+ B cells, healthy control donors (HC) have low amounts of serum 9G4+ IgG. In contrast, many SLE patients have high levels of serum 9G4+ IgG that is associated with higher disease activity and highly correlated with anti-dsDNA and a substantial proportion of anti-dsDNA antibodies are 9G4+. The purpose of this study was to compare 9G4+ IgG and associated SLE auto-antibodies between CCLE patients and SLE patients.

**Methods:** We analyzed samples from 36 HC and 52 patients with primary CCLE, 44 SLE with CCLE, and 303 SLE without CCLE. Cases with a validated diagnosis of either discoid, panniculitis, tumidus or chilblain lupus were included as CCLE. The ACR criteria and attending rheumatologist/dermatologist judgement were used to classify CCLE cases as primary or associated with SLE. We used ELISA to measure 9G4 with the rat monoclonal 9G4, and goat anti-human IgG. Anti-dsDNA and anti-chromatin IgG were measured using commercial ELISA kits. B cell binding 9G4+ was evaluated *ex-vivo* by flow cytometry.

## Results:

41% of SLE patients were positive for 9G4 IgG and had significantly higher serum concentration than HC ( $p<0.001$ ). Surprisingly, CCLE patients also had high levels of 9G4+ IgG, 38% were positive and serum concentrations were significantly higher than HC ( $p<0.001$ ) and did not statistically differ from SLE patients. In contrast, while many SLE patients had anti-dsDNA (48%) and anti-chromatin (52%), few CCLE patients were positive for these specificities (12% and 21%) and the concentration was significantly lower for both ( $p<0.001$ ). Consequently, 9G4+ IgG concentration was highly correlated with both anti-dsDNA ( $p<0.001$ ,  $r=0.48$ ) and anti-chromatin ( $p<0.001$ ,  $r=0.45$ ) concentration in SLE patients but not in CCLE patients. CCLE patients, however, did have auto-reactive 9G4+, as B cell binding antibodies were similar between SLE and CCLE patients.

**Conclusion:** Our study confirms the correlation between 9G4+ IgG and anti-dsDNA in SLE and extends this to anti-chromatin. Surprisingly, CCLE patients had high levels of 9G4+ IgG but not anti-dsDNA. This suggests a two-step model of 9G4 tolerance in SLE, the breakdown of general tolerance of germline encoded autoreactive VH4.34 antibodies and a subsequent development of 9G4+ specific for dsDNA. CCLE patients clearly have a defect in the first step and the mechanism of this defect is potentially shared between CCLE and SLE. However, the second step is not shared, as CCLE patients with 9G4+ IgG do not have high levels of anti-dsDNA. Regulation of this step may help determine if otherwise immunologically similar patients may develop SLE or CCLE. Because the specificity of 9G4+ in CCLE is unknown, it remains to be determined whether these antibodies contribute directly to CCLE disease

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Citrulline-modified proteins arising from the post-translational modification of arginine residues are recognized as primary rheumatoid arthritis (RA) autoantigen targets based on the strong association of anti-citrullinated protein antibodies (ACPA) with RA disease development. Nevertheless, the repertoire of citrullinated protein-specific B cell antigen receptors (BCRs) has not previously been directly assessed.

**Methods:** 89 subjects from the IRB-approved University of Minnesota ACPA<sup>+</sup> RA cohort who met the 2010 ACR/EULAR criteria for RA provided blood samples and clinical data for use in this study. Citrullinated filaggrin peptide CFC1 and citrullinated a-enolase peptide CEP-1 were used in the construction of tetramer sets designed to specifically capture and characterize autoreactive citrullinated protein-specific B cells in the unaltered, polyclonal repertoire of RA patients. Citrullinated peptide tetramer-bound B cells were subjected to flow cytometric cell sorting and single cell *IGH*, *IGK*, and *IGL* gene sequencing for B cell lineage determinations. BCR gene sequences were also expressed as recombinant human monoclonal antibodies, and tested for their ability to bind to citrullinated peptides and proteins. Finally, select human V-(D)-J sequences were expressed as recombinant mouse monoclonal antibodies to test their ability to prolong endotoxin-induced arthritis.

**Results:** Tetramer-binding CFC1- and CEP-1-specific IgD<sup>-</sup> CD27<sup>+</sup> switched-memory B cells were found in increased numbers in the blood of RA subjects who also demonstrated high titers of anti-CFC1 and/or -CEP-1 serum antibodies, respectively (5.7-fold increase for CFC1, Pvalue < 0.01; 5.3-fold increase for CEP-1; Pvalue = 0.01). The frequency of CFC1-specific switched-memory B cells was also positively associated with the duration of disease (p = 0.02), the presence of subcutaneous nodules (p = 0.02), and the DAS28-ESR disease activity index (p = 0.01). Citrullinated peptide tetramer-specific BCRs had highly mutated immunoglobulin (Ig) heavy and light chain complementarity determining region (CDR) sequences, biased V-region gene usage, and conserved CDR3 junction lengths. Parsimonious clustering of related *IGH*, *IGK*, and *IGL* nucleotide sequences demonstrated that the clonal expansion of rare individual B cell lineages occurs in association with progressive amino acid sequence divergence. Recombinant human monoclonal antibodies generated from citrullinated peptide tetramer-sorted B cells within extended clades confirmed target peptide antigen-binding for most clones, yet citrulline-dependent cross-reactivity to a broad set of distinct citrullinated peptides and proteins implicated in RA was also observed. Finally, a pair of citrullinated protein-specific recombinant monoclonal antibodies with cross-reactive autoantigen-binding profiles promoted arthritis in mice.

**Conclusion:** Broad anti-citrullinated protein antibody specificities in RA may arise from a restricted repertoire of B cell clades with evolving and divergent citrulline-polyspecific BCRs.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## **Background/Purpose:**

Autoimmunity is a complex, poly-genic disorder that culminates in multi-organ damage. In systemic lupus erythematosus (SLE), the prototypic autoimmune disorder, a breakdown of tolerance leads to erroneous immune cell activation and the production of disease-causing autoantibodies. B cell functional abnormalities appear to be central to this process and many of the lupus susceptibility genes identified by genome wide association studies (GWAS) are predicted to impact B cell selection, differentiation, signaling, and proliferation. However, their precise mechanisms of action in human B cells remain to be defined. A major challenge preventing the application of GWAS data to therapeutic potential is that animal models often do not recapitulate human phenotypes. In fact, a number of identified autoimmune disease-related genes are known to have differential expression in mice and humans. For this reason, it is important to investigate gene function directly in primary human B cells. To date, the methods for investigating gene function in human B cells has been limited by the relative rarity of many susceptibility alleles and ineffective or transient RNA silencing approaches. CRISPR-Cas9 technology, which uses customizable guide RNAs (gRNA) to direct the cutting of DNA by Cas9 enzymes, presents an unexplored opportunity for studying gene function directly in primary human lymphocytes. The aim of this study was to develop a robust CRISPR-Cas9 method for studying gene function directly in peripheral human B cells isolated from PBMCs.

## **Methods:**

Primary human B cells were isolated from healthy donors using Ficoll-Paque gradients followed by negative magnetic sorting of B cells. Isolated B cells were nucleofected with CRISPR-Cas9 ribonuclear protein complexes and cultured on BAFF and CD40L expressing OP9 stroma for 7 days. Function was assessed by calcium flux assays and phosphosignaling using a flow cytometer.

## **Results:**

Taking advantage of recent advances in genome editing technologies, we were able to successfully and robustly knockout CD22 in primary human B cells from healthy donors, achieving an average efficiency of 35% as measured by loss of cell surface expression. Using this highly adaptable system, we show that gRNA selection can have a profound impact on knockout efficiency and that B cell lines are not an effective proxy for this process. Consistent with the literature, knockout of CD22 in primary B cells resulted in the generation of activated/memory B cells with significantly increased expression of CD86. Furthermore, knockout of CD22 resulted in increased basal activation and as a consequence, total B cells had a reduced capacity for pSyk and pPLC $\gamma$  signaling. Supporting this observation, IgD<sup>+</sup> B cells were hyperresponsive to IgM stimulation with an increased capacity for calcium fluxing.

**Conclusion:** These findings demonstrate, for the first time, the ability to robustly knockout genes directly in primary human B cells. Using this approach, the role of CD22 in maintaining naïve B cells was confirmed in healthy donors. This methodology allows for the targeted study of autoimmune-related genes and their impact on B cell function.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

The vast majority (>90%) of anti-citrullinated protein antibodies (ACPA) of the IgG isotype in serum and synovial fluid of patients with rheumatoid arthritis carry *N*-linked glycans in the antibody variable region. This remarkable degree of Fab-glycosylation is absent from ACPA-depleted control IgG and from autoantibodies in other diseases. *N*-glycosylation requires a specific amino acid consensus sequence in the protein backbone (termed an *N*-glycosylation site), which is very rare in germline-encoded variable region genes. Here, we analysed the B cell receptor (BCR) repertoire of ACPA-expressing B cells to understand the molecular basis for this remarkable glycosylation.

### Methods:

We used anchoring reverse transcription of immunoglobulin (Ig) sequences and amplification by nested PCR (ARTISAN) to obtain full-length rearrangements of ACPA-expressing B cells. ACPA-expressing B cells and non citrulline-reactive control B cells were obtained from peripheral blood of patients with established RA by antigen-specific tetramer staining and fluorescence activated cell sorting. Cells were either sorted in pools, or sorted as single cells. Somatic mutations and *N*-glycosylation sites were identified in the sequence reads using IMGT (High)V-QUEST. Paired heavy and light chain sequences (HC/LC) were used to model the spatial positioning of *N*-glycosylation sites.

### Results:

Sequence analysis of pools of cells identified 97 unique ACPA-IgG clones derived from n=8 donors. 87 unique ACPA-IgG clones were retrieved from single cell analysis (n=6 donors). In both datasets, over 80% of ACPA-IgG clones contained *N*-glycosylation sites in both HC and LC. All sites were created by somatic mutations. The mutation rate did not correlate with the number of *N*-glycosylation sites, and their distribution across the variable region and their preference differed from the pattern seen in controls. Structural modelling predicted *N*-glycosylation sites on the exterior of the antibody molecule.

### Conclusion:

ACPA-expressing B cells generate BCRs with a high frequency of *N*-glycosylation sites. Frequency and localization of sites suggest that ACPA-expressing B cells gain a selective survival advantage by acquiring glycans in the variable domain, thereby escaping from putative checkpoints in B cell selection.

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose :** Rheumatoid arthritis (RA) has been associated with increased risk for chronic obstructive pulmonary disease (COPD) and asthma, but these findings may have been confounded by smoking behaviors occurring before and after RA diagnosis. Citrullination of proteins in the airways is important in both RA and COPD etiology so may link these diseases beyond smoking. Marginal structural modeling (MSM) is a statistical method to control for factors, such as smoking, on the causal pathway for an outcome, such as COPD or asthma. We investigated whether RA increases risk for COPD or asthma using MSM to adjust for smoking occurring before RA onset or mediating these respiratory morbidities after RA diagnosis.

**Methods :** Within the prospective Nurses' Health Study (n=121,701 women; 1976-2014), we identified an incident RA cohort and matched each woman with RA to 10 non-RA comparators by age and year of RA diagnosis (index date). All RA cases met the 1987 ACR classification criteria. We excluded women with prevalent COPD or asthma at baseline. Data were obtained through biennial questionnaires and medical records. We used MSM to determine the independent effect of RA on incident self-reported COPD or asthma, adjusting for time-varying covariates by inverse probability weighting. Smoking was categorized as fixed pre-index intensity/duration (0, >0 to 10, 10.1 to 20, or >20 pack-years) and time-varying post-index status (never, past, or current). In subgroup analyses, we separately investigated seropositive RA and seronegative RA for risk of COPD or asthma.

**Results :** We identified 843 women with incident RA during 38 years of follow-up in the NHS, matched to 8,399 comparators without RA. Mean age was 59.8 years and mean follow-up after index date was 18.6 years (SD 9.0) for RA and 18.8 years (SD 9.5) for comparators. During 173,484 person-years of follow-up after index date, we identified 68 (8.1%) incident COPD and 40 (4.7%) asthma cases among women with RA, and 459 (5.5%) COPD and 268 (3.2%) asthma cases among comparators. RA was associated with increased risk of COPD (HR 1.52, 95%CI 1.17-1.97, **Table**) and asthma (HR 1.55, 95%CI 1.11-2.16) compared to comparators matched to age and year at index date. After adjustment for time-varying covariates, including smoking before and after index date, RA was significantly associated with COPD (HR 1.68, 95%CI 1.36-2.07), but not asthma (HR 1.11, 95%CI 0.59-2.09), compared to non-RA. Women with seropositive RA (HR 1.74, 95%CI 1.36-2.23) and seronegative RA (HR 1.62, 95%CI 1.09-2.40) had similar increased risk for COPD compared to comparators.

**Conclusion :** In this large prospective cohort study with time-varying measures throughout long-term follow-up, RA was associated with increased risk for incident COPD, but not asthma, independent of smoking and other lifestyle factors. These results provide rationale to investigate the effect of RA-specific factors beyond smoking on COPD risk.

**Table.** Hazard ratios for COPD and asthma comparing RA serologic phenotypes to matched comparators, adjusted for time-varying confounders and mediators using marginal structural models.

	COPD	Asthma
	HR (95% CI)	HR (95% CI)
<b>All RA (n=843 RA; n=8,399 comparators)</b>		
Age-adjusted <sup>1</sup>	1.52 (1.17-1.97)	1.55 (1.11-2.16)
Smoking-adjusted <sup>2</sup>	1.43 (1.09-1.87)	1.48 (1.05-2.08)
Multivariable adjusted <sup>3</sup>	1.68 (1.36-2.07)	1.15 (0.82-1.61)
<b>Seropositive RA (n=518 RA; n=5,163 comparators)</b>		
Age-adjusted <sup>1</sup>	1.60 (1.17-2.19)	1.38 (0.90-2.13)
Smoking-adjusted <sup>2</sup>	1.44 (1.04-2.00)	1.33 (0.86-2.05)
Multivariable adjusted <sup>3</sup>	1.74 (1.36-2.23)	1.11 (0.75-1.66)
<b>Seronegative RA (n=325 RA; n=3,236 comparators)</b>		
Age-adjusted <sup>1</sup>	1.41 (0.89-2.23)	1.88 (1.10-3.23)
Smoking-adjusted <sup>2</sup>	1.47 (0.91-2.39)	1.72 (0.99-2.98)
Multivariable adjusted <sup>3</sup>	1.62 (1.09-2.40)	1.11 (0.59-2.09)

Comparator status is the reference in all models.

<sup>1</sup>Adjusted for matching factors (age and calendar year) at index date.

<sup>2</sup>Adjusted for matching factors (age and calendar year) at index date, pre-index smoking pack-years (0, >0-10, 10.1-20, >20), and time-varying smoking status (never, past, current) using marginal structural models.

<sup>3</sup>Adjusted for matching factors (age and calendar year) at index date as well as baseline factors of annual family income (<\$40K, >\$40K) and pre-index smoking pack-years (0, >0-10, 10.1-20, >20) as well as time-varying factors of smoking status (never, past, current), body mass index (continuous, kg/m<sup>2</sup>), Alternate Healthy Eating Index (quartiles), menopausal status and PMH use (premenopausal, postmenopausal and never PMH use, postmenopausal and past PMH use, postmenopausal and current PMH use), physical activity (continuous, METs/week), and aspirin use (yes/no) using marginal structural models.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health I: Lung, Bone, and Infection Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Our goal was to examine lung disease and types of pulmonary manifestations observed in patients with SLE. We studied population-based register data from Sweden to determine the incidence of pulmonary diagnoses among incident and prevalent SLE patients compared to the general population.

**Methods:** Using data from a linkage of Swedish registers we identified patients with SLE (at least 2 SLE coded discharge diagnoses and at least 1 SLE-specific discharge diagnosis by a specialist who manages SLE) and matched them to individuals from the general population on age, sex, and county of residence when the SLE index case first presented with SLE. Pulmonary diagnoses were identified using ICD codes from the National Patient Register's (NPR) discharge diagnoses for inpatient and outpatient visit data. Those with a history of pulmonary disease were excluded. Individuals were followed until they had their first pulmonary diagnosis, died, emigrated, or reached the study end. We calculated incidence rates and corresponding 95% confidence intervals (95% CI) overall and by type of pulmonary disease, for incident (2003-2013) and prevalent SLE (2001-2013). To be classified as incident SLE, an individual's first SLE diagnosis code had to occur in 2003

or later. Cox proportional hazards models estimated hazard ratios (HR) and 95% CIs for the association between SLE and pulmonary disease in age and sex adjusted models. Sensitivity analyses assessed the robustness of results using semi-automated approach to quantitative probabilistic bias analysis to account for potential bias due to unmeasured confounding by smoking.

**Results:** 3,209 incident SLE cases were identified using NPR data in Sweden contributing a median 4.8 person-years of follow-up time (vs. 5.1 among non-SLE comparators). We also identified a contemporary cohort of 6,908 individuals with prevalent SLE. The incidence rate for new onset pulmonary disease (about 14 cases per 1000 person-years) was similar in prevalent and incident SLE. Those with incident SLE had a nearly six-times higher rate of new onset pulmonary disease compared to the non-SLE comparator (HR=5.80 (4.84,6.95)) and were comparable in male and female patients. Incident and prevalent SLE was associated with an increased rate of interstitial lung disease (ILD), (HR=19.0 (10.7, 34.0) and 14.3 (10.8-18.8), respectively). Bias due to unmeasured confounding by smoking was unlikely to explain our findings in sensitivity analyses.

**Conclusion:** Lung disease is common among SLE patients, and particularly increased when compared to the general population. Clinicians caring for SLE patients should have a heightened suspicion for lung disease, including ILD, even early within the disease course.

Table. Relative risk of pulmonary disease among SLE compared to non-SLE general population comparators overall and by type of pulmonary disease, presented as age- and sex-adjusted hazard ratios and 95% confidence intervals.

	Prevalent SLE	Incident SLE
	6908 SLE	3209 SLE
	37046 non-SLE	17658 non-SLE
Any pulmonary disease	5.42 (4.90-5.99)	5.80 (4.84-6.95)
By specific pulmonary disease		
Interstitial lung disease	14.27 (10.84-18.78)	19.04 (10.66-34.00)
ARDS and hemorrhage	5.78 (3.94-8.48)	5.34 (2.72-10.49)
Pleural disorders	4.64 (3.92-5.49)	5.91 (4.43-7.89)
Pulmonary hypertension	6.75 (4.74-9.61)	6.14 (3.19-11.82)
Pulmonary embolism	3.77 (3.12-4.55)	3.78 (2.64-5.40)
Diseases of the upper airway	4.19 (3.04-5.79)	3.10 (1.66-5.79)
Pulmonary edema	4.32 (2.80-6.65)	3.30 (1.40-7.80)

## Use of Bisphosphonate and Risk of Incident Atrial Fibrillation in a Population-Based Study

**Shanshan Sheehy**<sup>1</sup>, Christine Peloquin<sup>2</sup> and Tuhina Neogi<sup>3</sup>, <sup>1</sup>Clinical Epidemiology Research & Training Unit, Boston University, Boston, MA, <sup>2</sup>Boston University School of Medicine, Boston, MA, <sup>3</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health I: Lung, Bone, and Infection Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## **Background/Purpose:**

Bisphosphonates remain the first-line agent prescribed medication for the prevention and treatment of osteoporosis. Apart from concern about atypical fractures, another concern about risk of atrial fibrillation has been raised. However, data regarding the relation of specific types of bisphosphonate use to risk of atrial fibrillation has been conflicting, and this has been reflected in contradicting conclusions from different meta-analyses. We sought to evaluate this risk using more contemporary data in a population-based cohort in which data on use of different types of bisphosphonates were available.

## **Methods:**

We conducted a propensity score matched cohort study based on a UK population-based general practitioner database (The Health Improvement Network (THIN) database). From Jan 1, 1998 until Dec 31, 2014, we included 107,282 women who were age 50-89 years, who were free of atrial fibrillation or atrial flutter, and with no prior use of bisphosphonate within 2 years prior to study entry. Incident bisphosphonate users were defined as women with first bisphosphonate prescription. Comparators were women without bisphosphonate use prior to the 1-year cohort accrual block, with the index date randomly assigned within the 1-year accrual block. Incident atrial fibrillation was defined using READ codes. We performed an intent to treat analysis using Cox proportional hazards model, stratified by the 1 year cohort accrual blocks.

## **Results:**

During a median of 4.5 years of follow up, we identified 53,641 pairs of bisphosphonate initiators and PS-matched comparators, whose mean age was 70. The crude incident rate of atrial fibrillation was 8.63 per 1000 person years for bisphosphonate initiators, and 8.7 per 1000 person years for comparators, with an adjusted hazard ratio of 1.01 (95%CI: 0.95-1.08). When restricted only to the commonly used bisphosphonates alendronate, ibandronate, and risedronate, the hazard ratio comparing initiators vs. comparators was 1.05 (95%CI: 0.99-1.11). Results were similar when current vs. past bisphosphonate users were compared, and when further stratified by calendar year to account for secular trends.

## **Conclusion:**

In this large UK general population, use of bisphosphonate was not associated with risk of atrial fibrillation.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health I: Lung, Bone, and Infection Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** In prior work, we found a higher incidence of hip fractures in RA than age and sex matched general population controls (4.1 vs. 2.9 per 1000 PY). To assess burden of disease, we compared age- and sex-adjusted all-cause mortality post hip fracture in RA and general population controls.

**Methods:** We conducted a retrospective study of a population-based incident RA cohort, using administrative health data. Using physician billing data, we identified all people with RA onset between 1997 and 2009 in a Canadian province. Controls (with no diagnosis of RA or other inflammatory arthritis) were randomly selected from the general population, matched 2:1 to RA cases on birth yr, gender and index yr. RA patients and controls with prior hip fractures, pathological fractures or Paget's disease were excluded. Hip fractures were identified using hospitalization data (ICD9-CM codes 820.0, 820.2; ICD10-CA codes S72.0, S72.1, S72.2), from  $\leq 25$  codes defining reason for admission or complications during hospitalization. RA individuals and controls were followed from incident hip fracture to death, last health care use, or study end (Dec. 2014). Mortality data was obtained from Vital Statistics. Cox-proportional hazard models, adjusted for age and sex, compared mortality risk in RA vs. controls with a hip fracture.

**Results:** The cohort included 60,101 incident RA cases and 120,462 controls, of whom 2463 (4.1%) RA individuals and 3566 (3.0%) controls sustained an incident hip fracture and make up the study sample (78% females in RA and 81% in controls; mean (SD) age at time of fracture: 78.9(10.9) yrs for RA and 82.1(9.0) yrs for controls). Crude all-cause mortality rate post hip fracture was 5.9% (n=143) and 8.2% (n=288) at 30 days; and 19.9% (n=481) and 24.5% (n=854) at 1-yr, for RA and controls, respectively. After age and sex adjustment, RA persons with hip fractures had a 17.5% lower risk of death than persons without RA at 30-days and 10.2% lower risk at 1-yr. The mean age at death for 30-day mortality was 83.9 yrs for RA and 86.1 yrs for controls.

Subset	30 Day Mortality		1 Year Mortality		5 Year Mortality

Table 1: Risk of mortality in RA relative to general population controls, adjusted for age and sex.

\*Results not provided for cells with data <6 patients to protect patient confidentiality.

**Conclusion:** Despite a higher incidence of hip fractures in RA, the 30-day and 1-year post hip fracture all-cause mortality was lower in RA than controls, after adjusting for sex and age at time of fracture. Further research is needed to understand

whether mortality differences are related to co-morbidities, differences in post-op care, or other characteristics influencing post-fracture mortality risk.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health I: Lung, Bone, and Infection Outcomes

**Background/Purpose:** Sulfamethoxazole-trimethoprim (SMX/TMP) is a standard drug for the prophylaxis of *Pneumocystis pneumonia* (PCP), but is sometimes discontinued due to adverse events (AEs). We have previously reported the results of this non-blinded, randomized, non-inferiority trial up to week 24 to explore an effective SMX/TMP regimen for PCP with a low drug discontinuation (d/c) rate. We here report the results at week 52.

**Methods:** Adult patients with systemic rheumatic diseases who started prednisolone  $>0.6$  mg/kg/day were randomized into three groups and treated up to week 24: a single-strength group (SS, SMX/TMP of 400/80 mg daily), half-strength group (HS, 200/40 mg daily), and escalation group (ES, started with 40/8 mg daily, raising incrementally to 200/40 mg daily). After week 24, attending physicians determined the use of SMX/TMP including doses, intervals, and treatment duration. The observation period was up to week 52 irrespective of the use of SMX/TMP. The primary endpoint was non-incidence rates (non-IR) of PCP at week 24. Secondary endpoints were PCP non-incidence rate at week 52, treatment d/c rate, and AEs. We estimated the non-incidence rates of PCP using the exact confidence interval as a post-hoc analysis and analyzed treatment d/c rates using the Kaplan-Meier method and log-rank test.

**Results:** Of 183 patients randomly allocated at a 1:1:1 ratio into the three groups, 58 patients in SS, 59 in HS, and 55 in ES started SMX/TMP and were analyzed. Of the 172 patients who started SMX/TMP, 32, 46, and 38 at week 24, and 29, 43, and 34 at week 52 were receiving SMX/TMP as allocated. No cases of PCP were reported up to week 52. Estimated non-IR of PCP in patients who received daily SMX/TMP of 200/40 mg, either starting at this dose or increasing incrementally, was 96.8–100%. From week 0 to 52, the overall d/c rate was significantly lower in HS compared to that in SS (22.7% vs 47.2%,  $p = 0.004$ ) (Figure). The d/c rates due to AEs were significantly lower in HS (19.1%,  $p = 0.007$ ) and ES (20.3%,  $p = 0.007$ ) compared to that in SS (41.8%). The IR of AEs requiring dose reduction of SMX/TMP ( $p = 0.007$ ) and AEs of special interest ( $p = 0.001$ ) at week 52 were different among the three groups with significantly higher IR in SS compared to HS and ES. Almost all AEs requiring dose reduction of SMX/TMP and AEs of special interest were reported by week 24.

**Conclusion:** The combined group of HS and ES had an excellent estimated non-IR of PCP at week 52 and both were superior in safety to SS. From the perspective of feasibility and drug d/c rates, the daily half-strength regimen is suggested to be optimal for prophylaxis of PCP in patients with systemic rheumatic diseases.

### Cumulative rates of treatment discontinuation. Discontinuation of treatment by any reasons.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health I: Lung, Bone, and Infection Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Serious infections (SIs) are a major concern in RA patients, significantly contributing to increased mortality. We examined the SI risk associated with bDMARDs compared to csDMARDs in a US-wide observational RA cohort.

**Methods:** RA patients initiating bDMARDs or csDMARDs from 2001 through 2016 in the National Data Bank for Rheumatic Diseases (NDB) were assessed for SIs (infection + intravenous antibiotics, hospitalization or death). DMARDs were categorized into 3 groups: (1) csDMARDs-reference (bDMARD naive) (2) TNF inhibitors (TNFi) (3) Non-TNFi biologics (abatacept, rituximab, tocilizumab, and anakinra). Each patient contributed to the last DMARD reached. Followup continued until the first SI, DMARD discontinuation, death, or end of study period. SIs were attributed to the corresponding DMARD group when the treatment was ongoing or discontinued  $\leq 3$  months before SI. Propensity scores (PS) reflecting the probability of receiving a specific DMARD were calculated using multinomial logistic regression models with characteristics at treatment initiation. PS was added to the Cox models as a continuous variable along with time-varying confounders (age, disease duration, comorbidities, HAQ, pain and patient global scores, weighted cumulative exposure [WCE] of glucocorticoids [GC], prior sDMARDs and bDMARDs counts) of which changes over time might alter the SI risk.

**Results:** 694 (5.9%) first SIs were identified in 11,623 RA patients during a 27,552 patient-years of follow-up. TNFi and non-TNFi biologics-initiators had significantly higher disease activity, disability, and comorbidity scores than csDMARDs initiators. Crude incidence rate (95% CI) in TNFi group was non-significantly higher than csDMARD and non-TNFi biologic initiators (*Figure*). The PS-only adjusted model showed a non-significant SI risk increase with TNFi (HR 1.11 [0.91-1.34],  $P=0.309$ ) and non-TNFi biologics (HR 1.26 [0.95-1.68],  $P=0.102$ ) whereas further adjustment for time-varying confounders revealed significantly increased risk of SI with both TNFi (HR 1.33 [1.05-1.68],  $P=0.019$ ) and non-TNFi (HR 1.48 [1.02-2.16],  $P=0.041$ ) compared to csDMARDs. Other factors associated with SI are presented in *Table*.

**Conclusion:** TNFi and non-TNFi biologics were associated with an increased SI risk in RA compared to csDMARDs. In addition to DMARDs, older age, comorbidity burden, pulmonary disease, higher disability, disease activity, and cumulative GC exposure were predictive of SI. Assessment and modification of these factors should be completed before and during bDMARD treatment to minimize SI risk.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Psychosocial Impact on Rheumatic Disease

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Previous studies investigating the potential associations between personality and clinical symptoms in fibromyalgia (FM) patients have found mixed results. The purpose of this study was to clarify whether personality dimensions are associated with clinical symptoms, mindfulness, self-efficacy, social support, and outcome expectations among adult patients with FM.

### **Methods:**

We performed a secondary analysis using baseline data from a randomized controlled comparative effectiveness trial between Tai Chi and aerobic exercise for FM. Personality was assessed using the NEO-Five Factor Inventory, a validated measure of 5 basic personality factors: agreeableness, conscientiousness, extraversion, neuroticism, and openness. Fibromyalgia syndrome was evaluated using the validated revised Fibromyalgia Impact Questionnaire (FIQR). Other measures included symptom severity, anxiety, depression, stress, health-related quality of life, social support, self-efficacy, mindfulness, and outcome expectations for exercise. Multivariable linear regression was performed to assess the associations between personality dimensions and measures of health and FM impact, while controlling for age, gender, body mass index (BMI), and living situation.

### **Results:**

The sample consisted of 92 participants, with 95% female, mean age 52 years (SD 12), BMI 30 kg/m<sup>2</sup> (6), 52% white, 94% had a high school degree, and mean duration of body pain 14 years (11). After adjusting for covariates using multivariable linear regression, neuroticism was significantly associated with FIQR and symptom severity (**Table 1**). Higher neuroticism was also associated with higher levels of anxiety, depression, and stress, and worse mental component quality of life, lower self-efficacy, mindfulness, and social support. Higher conscientiousness and extraversion were associated with better mental component quality of life and mindfulness, and lower symptom severity, anxiety, depression, and stress. Higher conscientiousness was associated with better self-efficacy and outcome expectations. Higher extraversion was associated with better social support. More openness was associated with better outcome expectations, mindfulness, and lower levels of depression. Agreeableness was not significantly associated with any outcome. None of the 5 personality dimensions were associated with physical component of quality of life.

### **Conclusion:**

Personality was significantly correlated with FM impact, a variety of health outcomes, and strongly associated with self-efficacy and mindfulness. Higher neuroticism was associated with worse psychosocial factors, suggesting this subset of patients may benefit from individualized treatment that takes personality into consideration. Results further elucidate characteristics of FM patients and highlight the importance of personality in the management of FM.

## Social Support, Stress and Health Outcomes in Systemic Lupus Erythematosus: Georgians Organized Against Lupus (GOAL) Cohort

**Charmayne M. Dunlop-Thomas**, S. Sam Lim, Gaobin Bao and Cristina Drenkard, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Psychosocial Impact on Rheumatic Disease

**Background/Purpose:** Stress can influence immune and neuroendocrine processes, and may lead to poor outcomes in people with systemic lupus erythematosus (SLE). Social support can potentially reduce the negative influences of stress on disease outcomes. We examined the relationships between stress and disease outcomes and whether social support mitigates those relationships in SLE.

**Methods:** We examined cross-sectional data from GOAL, a large population-based cohort of patients with validated SLE from Atlanta, Georgia. Since 2011, participants respond annually to validate self-administered health outcome surveys. Social Support was assessed with the Patient-Reported Outcomes Measurement Information System Social Support Short Form 4a (Emotional, Informational and Instrumental). We used Cohen's Perceived Stress Scale 4 (PSS-4), Systemic Lupus Activity Questionnaire (SLAQ) and the Patient Health Questionnaire-9 (PHQ) for depression severity. Analysis of covariance (ANCOVA) was used to examine the effect of social support (categorical) on the linear relation between perceived stress and disease outcomes.

**Results:** Among 670 participants (93.9% women, 80.0% Black; mean age 48.4), mean(SD) scores were 7.20(2.55) for PSS-4, 15.18(8.66) for SLAQ, and 7.18(5.92) for PHQ-9. Mean(SD) social support scores were 52.03(9.28) for instrumental, 52.80(10.73) for informational, and 55.45(9.33) for emotional support. Stress was significantly associated with disease activity and depression. Instrumental support was the only social support construct that modified the effect of stress on disease activity. Neither emotional, informational nor instrumental support influenced the association between stress and depression. However, at a given stress level, participants with low social support have significantly worse disease activity and depression.

**Conclusion:** In a population-based SLE cohort with large numbers of Blacks, there was an elevated level of perceived stress and moderate to severe disease activity, with 30% endorsing moderate to severe depression. Instrumental social support may buffer the association between disease activity and stress. Recognizing the importance of developing more instrumental resources, such as transportation and home care services may contribute significantly to improving SLE health outcomes.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Psychosocial Impact on Rheumatic Disease

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** There are few studies evaluating the effectiveness of psychotherapy in Systemic Lupus Erythematosus (SLE) patients.

**Objectives:** To evaluate the effectiveness of brief group psychoanalytic psychotherapy (BGPP) in improving quality of life, anxiety and depression levels and coping strategies in SLE. **Methods:** Prospective, randomized clinical trial (number NCT01840709), including 80 SLE patients in a tertiary hospital. Patients were randomized into two groups: therapy (TG n=37) and control (CG n=43). Both groups received standard clinical treatment. TG received BGPP, weekly for 20 consecutive weeks performed by a specialized psychologist. CG remained in the waiting list. Assessments: at baseline (T1), after 20<sup>th</sup> weeks (T2), and 24 months after the end of the study (T3). Damage and disease activity were assessed by SLICC/ACR-DI score and SLEDAI-2k score, respectively. Self-administered questionnaires supervised by a blind evaluator were used to evaluate symptoms (SLE-SSC), quality of life (SLEQOL), anxiety and depression (HAD) and coping strategies (CIS). **Inclusion criteria:** female gender; SLE (ACR-1997 classification criteria), age  $\geq 18$  years, minimum follow-up of six months and signing consent form approved by Institutional Ethic Committee. **Exclusion criteria:** illiterate patients, physical and mental comorbidities that preclude the attendance, and external psychological treatment. **Statistical analysis:** intent to treat analysis. Comparisons of variance between groups over time (ANOVA repeated measures). SPSS version 17.  $p < 0.05$  was considered significant.

**Results:** At baseline, TG and CG were homogeneous in all variables, including medication. In T2, TG showed significant improvement in the majority of domains of SLEQOL (Table 1), all domains of HAD (Table 2) and several domains of CIS (Table 3). Some of benefits were maintained at the 24-month follow-up after the end of the therapy, including the most appropriate coping strategies to face the disease. No significant differences were observed in medication and clinical variables.

**Conclusion:** This study showed effectiveness of BGPP in improving quality of life, depression, anxiety and coping strategies to deal with stress in SLE patients, and some of the benefits were maintained in a long follow-up.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Psychosocial Impact on Rheumatic Disease

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Physical activity (PA) reduces joint symptoms in people with osteoarthritis (PWOA), but most PWOA get insufficient PA. They would benefit from small but sustained increases in PA, but PA interventions usually elicit short-lived increases. Social support is a reliable predictor of PA, and partners (e.g., a spouse) can provide support that helps PWOAs make lasting increases in PA (e.g., by providing encouragement or joining in PA). Yet, partner support may also fail to provide intended resources (i.e., PWOAs may appraise it as “ineffective”—a poor match for their need for a certain quality and quantity of support). Partners may also provide solicitous support that hinders behavior change (e.g., well-intentioned discouragement of activity in favor of rest). The purpose of this dyadic study was to examine these aspects of partner support for PA, as reported by PWOA (“support received”) and their partner (“support provided”).

**Methods:** 173 couples, with PWOAs who had hip or knee OA and were insufficiently active, completed a couples-focused PA intervention with 3-hours of in-person education and 12-weeks of workbook activities. They also completed questionnaires and wore accelerometers at baseline and at 1-week and 3-, 6-, and 12-months post-intervention. We used multilevel modeling to examine support received and provided as predictors of PWOAs’ moderate to vigorous PA (MVPA) and sedentary behavior across these timepoints.

**Results:** Models adjusted for sociodemographic covariates revealed that PWOAs’ MVPA at each timepoint was higher for PWOAs who reported receiving more encouragement for PA from their partner ( $p < .01$ ) and those who reported that their partner joined in their PA ( $p = .02$ ). PWOAs’ MPVA was also higher when partners reported joining in their PA ( $p = .03$ ). PWOAs’ appraised effectiveness of this support did not moderate its association with MVPA, nor were partners’ solicitous behaviors (as reported by PWOAs or partners) associated with MVPA. In addition, an interaction showed a negative association between partner-reported solicitous support and PWOA sedentary behavior when PWOAs appraised this support as relatively ineffective (i.e., a poor match for their needs). This association was attenuated among PWOAs who appraised the effectiveness of their partner’s solicitous support more favorably (i.e., a better match for their needs;  $p = .02$ ). A similar interaction occurred for partner-provided joining in PA ( $p = .048$ ).

**Conclusion:** These findings highlight different pathways by which to change MVPA and sedentary behavior and have implications for designing couples-based PA interventions that elicit lasting behavior change that thus ensure that PWOAs get the health benefits of PA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Psychosocial Impact on Rheumatic Disease

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease affecting multiple organs, leading to a significant impact on health-related quality of life. Theoretical models are critical to understanding the mechanisms behind the relationships between pain and psychosocial variables and can be used to help guide future research and treatment among patients with SLE. Thus, the present study examined whether helplessness is a mediator of the relationship between pain and three types of psychological distress among patients with SLE; specifically anxiety, depression, and perceived stress.

**Methods:** A convenience sample was obtained of patients aged 18 years and above diagnosed with SLE according to ACR 1982 guidelines at a large medical center in Southern California. Assessment included the Lupus Patient-Reported Outcome tool, Arthritis Helplessness Index, Perceived Stress Scale-10, and Hospital Anxiety and Depression Scale. Multiple mediation analysis was completing using an SPSS macro called "PROCESS."

**Results:** The cohort of 136 patients had a mean age of 48.6 years ( $SD = 13.87$ ), and was mostly female (92.6%) and Caucasian (44.9%). The direct effect of pain vitality on anxiety symptoms was  $-0.074$ ,  $p < .001$ ; the relationship between pain vitality and anxiety symptoms was significantly decreased when helplessness was included in our model,  $ab = -.041$ , BCa 95% CI  $[-0.073, -.015]$ . The direct effect of pain vitality on depressive symptoms was  $-0.069$ ,  $p < .001$ ; the relationship between pain vitality and depressive symptoms was significantly decreased when helplessness was included in our model,  $ab = -.035$ , BCa 95% CI  $[-0.502, -.212]$ . The direct effect of pain vitality on stress was  $-0.038$ ,  $p < .01$ ; the relationship between pain vitality and stress was significantly decreased when helplessness was included in our model,  $ab = -.041$ , BCa 95% CI  $[-0.063, -.027]$ .

**Conclusion:** Consistent with studies conducted in other autoimmune populations, findings suggested that helplessness fully mediated the relationship between pain and measures of anxiety, depression, and perceived stress. These results provide a theoretical model to better understand mechanisms that may help explain the relationship between pain and psychological distress in this population. Despite the moderate to low reports of perceived stress, the high reports of perceived helplessness, anxiety and depressive symptoms suggest a need for intervention to improve self-efficacy and reduce psychological distress.

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Psychosocial Impact on Rheumatic Disease

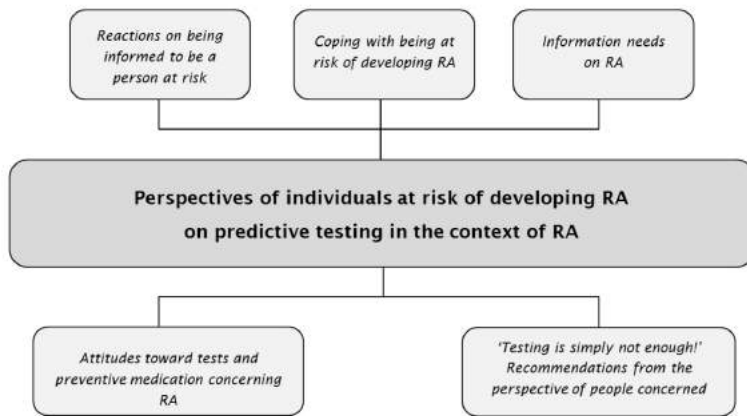

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** People at risk of developing rheumatoid arthritis (RA) may be candidates for interventions aimed at preventing RA development [1]. The identification of such at risk populations includes testing for genetic and other (e.g. autoantibody) biomarkers. However, little is known about the perspectives of at risk individuals on these tests, how they react and cope when identified as having an elevated risk status and what support they need. This study was undertaken to address this gap in the current knowledge.

**Methods:** A qualitative interview study with people who were informed of being at risk of developing RA was conducted. People either took part in a predictive test for RA as part of an extended health examination, or were patients with clinically suspect arthralgia. The interview schedule explored perceptions of RA risk and different types of predictive tests. All interviews were audio-recorded, transcribed verbatim and analyzed using thematic analysis.

**Results:** A total of 34 individuals (rheumatoid factor and/or ACPA positive) from three different European countries, who previously had been informed that they had an elevated risk of developing RA participated in the study. Analysis of the interview data revealed five overarching themes related to predictive testing in the context of RA (Figure).

There were differences between the perceptions of arthralgia patients and asymptomatic individuals. People suffering from pain were much more frightened and worried when informed of being at risk of developing RA. As a consequence, they reported that they modified their lives to a larger extent and had greater knowledge about RA than those without any symptoms who were surprised, but kept calm and did not envisage changing their lifestyle as a consequence of being tested positive. Almost all participants in this study preferred precise predictive tests in the context of RA. However, more than half of them reported that they would refuse synovial biopsy or preventive medication. Recommendations for predictive testing in the field of RA were given, which could promote uptake of preventive strategies.

**Conclusion:** Participants showed a variety of views about predictive testing in the context of RA risk and offered specific suggestions that should be incorporated into service design and delivery in the context of future predictive testing programmes. These findings may also be relevant to prediction and prevention in the context of other diseases where multiple genetic risk factors interact with environmental risk factors to drive disease development.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** To analyze the influence of genetic alterations and differential expression of the TIF1 genes in the pathophysiology of cancer-associated myositis (CAM).

**Methods:** Whole exome sequencing of paired blood and tumor DNA samples from anti-TIF1g positive CAM patients and controls were analyzed for the presence of somatic mutations and copy number changes in the TIF1 genes. To better understand the genesis and maintenance of the autoimmune process we also studied the expression of TIF1g in the different tissues involved in CAM (skin, muscle, and tumor) calculating the immunohistochemical H-score.

**Results:** Six out of 7 tumors from anti-TIF1g positive patients showed somatic mutations or loss of heterozygosity in one or more of the 4 TIF1 genes compared with just one myositis control tumor (86% vs. 17%,  $p=0.03$ ). Compared with control tumors from non-myositis patients, tumors from both anti-TIF1g positive (H-score 255 vs. 196,  $p=0.01$ ) and anti-TIF1g negative CAM patients (H-score 251 vs. 152,  $p=0.03$ ) showed more intense TIF1g staining, without significant differences between anti-TIF1g positive and negative patients. Compared with anti-TIF1g negative patients, TIF1g muscle staining was more intense in anti-TIF1g positive patients (H-score 22 vs. 5,  $p=0.03$ ), while the skin of both myositis and control patients showed intense TIF1g staining.

**Conclusion:** Mutations of TIF1 genes in tumors with high expression of TIFg may trigger myositis. We hypothesize that an intense antineoplastic immune response may cause a rapid depletion of tumor neo-antigen shifting the target of immune cells experiencing affinity maturation towards the wild-type form of the antigen, abundantly expressed in the skin and muscle of these patients.

## Immune Checkpoint Inhibitors and Inflammatory Myopathies: Data from the US Food and Drug Administration Adverse Event Reporting System

**Xerxes Pundole**, Mohsin Shah, Noha Abdel-Wahab and Maria Suarez-Almazor, Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Immune checkpoint inhibitors have become standard of care for many malignancies. Although these therapies are effective, they can activate the immune system resulting in adverse consequences. Inflammatory myopathies are increasingly being appreciated as one of the adverse phenotypes stemming from immune checkpoint inhibitor therapy, but few reports have been described in the literature. We aimed to analyze rates and disproportionality using drugs from the US Food and Drug Administration (FDA) Adverse Events Reporting System (FAERS).

### **Methods:**

We ran a query on AERSMine, an open access web based application designed to mine the FAERS database from the first quarter (Q1) of 2004 to the fourth quarter (Q4) of 2016, in a total of 8,864,346 reports. We ran queries to obtain the number of cases and to calculate the rates and measures of disproportionality; proportional reporting ratios [PRRs] and safety signals [information components (IC)]. Search terms included immune checkpoint inhibitors, namely ipilimumab, nivolumab and pembrolizumab. Inflammatory myopathy terms searched were myositis, dermatomyositis and polymyositis. We used Evans 2001 criteria to detect a signal which includes a PRR of 2 or greater, a  $\chi^2$  of 4 or more and at least 3 reports.

### **Results:**

The FAERS files from 2004 Q1 to 2016 Q 4 contain 42, 94 and 24 inflammatory myopathy reports for ipilimumab, nivolumab and pembrolizumab respectively. Myositis ( $n=28$ ;  $\chi^2=71.4$ ; PRR=4.5; IC=2.2), dermatomyositis ( $n=9$ ;  $\chi^2=33.8$ ; PRR=6.2; IC=2.6) and polymyositis ( $n=5$ ;  $\chi^2=5.5$ ; PRR=3.2; IC=1.7) showed disproportionality signals in relation with ipilimumab. Reports with nivolumab showed similar results with myositis ( $n=78$ ;  $\chi^2=847.2$ ; PRR=13.1; IC=3.7), dermatomyositis ( $n=5$ ;  $\chi^2=6.8$ ; PRR=3.6; IC=1.8) and polymyositis ( $n=11$ ;  $\chi^2=54.1$ ; PRR=7.4; IC=2.9). There were 3 reports of Nivolumab and necrotizing myositis with a  $\chi^2$  of 88.7 and a PRR of 47.3. Pembrolizumab demonstrated a disproportionality signal with myositis ( $n=24$ ;  $\chi^2=177.3$ ; PRR=9.7; IC=3.3). There were 2 reports of necrotizing myositis with pembrolizumab and no reports of dermatomyositis or polymyositis with pembrolizumab.

### **Conclusion:**

Inflammatory myopathies are disproportionally related with immune checkpoint inhibitors. To the best of our knowledge this is the first study to evaluate adverse events in relation with immune checkpoint inhibitors using the FDA FAERS data. All results are hypothesis generating and usual caveats and limitations of pharmacovigilance data mining should be applied while interpreting the results.

## **Autoantibodies Predict Long Term Survival in Myositis Associated Interstitial Lung Disease**

**Silvia Martinez**<sup>1</sup>, Rohit Aggarwal<sup>2,3</sup> and Chester V. Oddis<sup>4</sup>, <sup>1</sup>Internal Medicine, UPMC, pittsburgh, PA, <sup>2</sup>Department of Medicine / Rheumatology, University of Pittsburgh Medical Center, Pittsburgh, PA, <sup>3</sup>Rheumatology, University of Pittsburgh, Pittsburgh, PA, <sup>4</sup>Rheumatology/Clinical Immunology, University of Pittsburgh/University of Pittsburgh Medical Center, Pittsburgh, PA

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

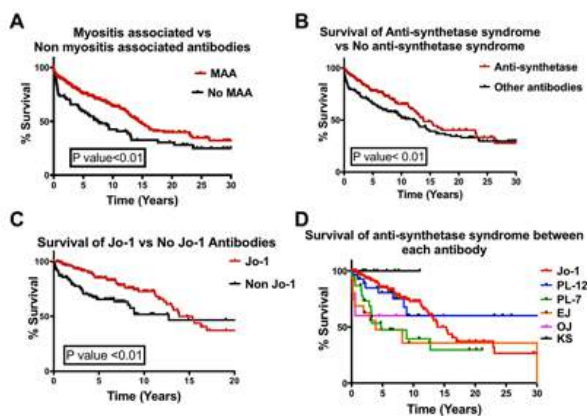

**Background/Purpose:** Interstitial lung disease (ILD) significantly contributes to morbidity and mortality in adult polymyositis (PM) and dermatomyositis (DM). Myositis associated autoantibodies (MAA) are associated with unique clinical phenotypes and patient outcomes. In particular, the anti-tRNA synthetase autoantibodies (anti-synAbs) are associated with high rates of ILD. Our aim was to determine predictors of survival in myositis associated ILD (MA-ILD) and to evaluate differences related to autoantibody (autoAb) subsets.

**Methods:** PM and DM subjects with ILD or with the antisynthetase (anti-syn) syndrome with ILD were consecutively identified from the University of Pittsburgh (UPITT) CTD registry which encompasses more than three decades of prospective data linked to a sample repository collected on outpatients and inpatients with various autoimmune diseases. PM and DM patients met probable or definite Bohan and Peter criteria and the anti-syn patients possessed one of the 8 known anti-syn autoAbs (i.e. anti-Jo-1, PL-7, PL-12, EJ, OJ, KS, Zo and Tyr). ILD was radiographically defined by characteristic xray or high-resolution computerized tomography findings. Death or transplant was determined from the registry or electronic medical record. Kaplan Meier and log rank tests were used to determine survival rates and differences between autoAb groups. Cox proportional hazards model was used to determine survival differences after controlling for co-variables including age at diagnosis, gender, ethnicity and baseline FVC%.

**Results:** 369 patients met criteria for MA-ILD and 306 (83%) had positive autoAbs. Overall, 63% (231/369) had MAAs and 54% (198/369) had a positive the anti-syn autoAb. The most common autoAb subset in the entire autoAb (+) cohort was anti-Jo-1 (124/306; 41%). The overall 5 and 10 year survival of MA-ILD was 80% at 5 years and 72% at 10 years. Patients with an MAA had better survival compared to MAA (-) subjects (5 and 10 year survival 80% vs. 72%; 72% vs. 58%,  $p=0.003$ ). Among MAA (+) patients, those with anti-syn autoAbs had better survival compared to those with non-anti-syn autoAbs (5 and 10 years survival 80% vs. 73%; 73% vs. 61%,  $p=0.004$ ). Among the entire anti-syn autoAb (+) subjects, those with anti-Jo-1 had a better survival than those patients with 1 of the 7 other anti-syn autoAbs (5 and 10 year survival 86% vs. 72%; 77% vs. 65%,  $p=0.04$ ).

**Conclusion:** Myositis patients with MAA, particularly anti-syn autoAbs have better survival rates compared to those without autoAbs. Among anti-syn autoAb (+) patients Jo-1 positivity confers a better survival. Myositis-associated autoAbs predict survival and long-term prognosis in myositis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Children with Juvenile Dermatomyositis (JDM) have variable responses to the available immunosuppressive drugs, with less than optimal outcomes, making it essential to characterize their variable inflammatory response. It is recognized that Myositis Specific Antibodies (MSA) are each associated with different clinical features and disease course, but scarce information is available comparing the differences in genetic regulation among these MSAs. The purpose of this study was to compare RNaseq data from PBMCs obtained from untreated children with new onset JDM positive for p155/150 — the most common MSA — with the RNaseq data from age related controls, as well as JDM who were either positive for MJ or who did not have a recognized MSA. Clinically, children with p155/140 often follow a more variable and recurrent disease course than those patients with other MSA's.

**Methods:** Newly diagnosed, untreated children with JDM were recruited for this IRB approved study (2008-13457), after obtaining age-appropriate informed consent: there were 75% girls, mean age 7.2 ±4.1; Mean DAS=12/20, while the controls had 80% girls, but were slightly older, 16.9±2.9. JDM disease activity was assessed using the Disease Activity Scores (DAS) which range from 0-20. MSA were determined by immunoblot and immunoprecipitation, (Oklahoma Research Laboratory): 4 of the JDM were positive for p155/140, 2 were MJ+, and 2 were negative for MSA, compared with 5 healthy pediatric controls. RNaseq libraries were generated from PBMC RNA using the Clontech stranded high input ribosomal depletion total RNA kits. The samples were sequenced on either an Illumina HiSeq2500 or HiSeq300 in paired-end mode. Serum levels of antibody to specific cytokines were determined by Mesoscale.

**Results:** The untreated JDM had active disease with a mean DAS-total=12.1. The RNaseq data identify 96 genes (adjusted p-value < 0.05) differentially expressed between JDM who were p155/140+ and JDM who either had anti-MJ antibody or were negative for MSA. The overall expression pattern of these genes is also different from the healthy controls. Pathway and gene ontology analysis reveals significant enrichment of this gene list in immune response, especially the interferon signaling (P=2\*10<sup>-15</sup>). We identified among this gene list, OSA1,2,3, TNF, MX1,2, TRIM 14, 22, 25, IFNG, TNFαA1P3, TNFSF-10, TGFBR3, IL-2RB, and others, clearly indicating enhanced immune activation in the children positive for p155/140. Determination of some of the many cytokines involved in the JDM inflammatory pathway showed significant increases in p155/140 sera vs controls: Interferon- γ: p= 0.013, IL-10:p= 0.0056, IL-6: p=0.026; IL-8: p=0.011; TNF-α p=0.003892.

**Conclusion:** We have shown, for the first time, using RNaseq, that the MSA, p155/140 not only identifies children with JDM who will have a difficult diseases course — but that this MSA is also associated with specific enhanced immune activation. **Speculation:** Further definition of the specific differences in gene activation associated with the individual

MSA's may lead to more targeted therapeutic interventions, and may provide a means of assessing the child's response to therapy.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

There is an increased cancer risk associated with the idiopathic inflammatory myopathies (IIM). Studies have identified that positivity for the autoantibody against transcriptional intermediary factor 1 (anti-TIF-1 Ab) confers an even greater cancer risk in the IIMs. Investigating the temporal relationship between anti-TIF-1 Ab positivity and cancer onset in a large longitudinal IIM cohort will be inform future cancer screening practice. This study aimed to characterise the temporal relationship between anti-TIF-1 Ab positivity and cancer onset in a large UK-based adult IIM cohort.

### **Methods:**

Data from adults with a Bohan & Peter-verified diagnosis of IIM from the UKMYONET study were analysed. Anti-TIF-1 Ab (alpha and gamma serosubtype) positive and negative patients were included. Each patient was followed up until they either developed cancer or were censored due to death. UKMYONET recruitment began in 1999, and cancer occurrence linkage was carried out up until December 2016 through the UK Health and Social Care Information Centre. Cancer associated myositis (CAM) was defined as an incident cancer occurring three years either side of the onset of IIM. The cumulative incidence of cancer after IIM onset was estimated according to Kaplan-Meier methods for the anti-TIF-1 Ab positive and negative cohorts. Hazard ratios for the time to cancer diagnosis by anti-TIF-1 Ab positivity were calculated using a Cox-regression model adjusted for age, gender and smoking status.

## Results:

Data from 711 IIM cases were analysed, with a total of 8009 person-years follow up (Table 1); 55 (8%) of the IIM cases were anti-TIF-1 Ab positive, and all had dermatomyositis. A higher proportion of the anti-TIF-1 Ab positive cohort developed CAM, compared to the anti-TIF-1 Ab negative cohort: 38% vs 8%. Even after only one year of follow up, the proportion of the anti-TIF-1 Ab positive patients developing cancer (27%) exceeded the three year proportion of the anti-TIF-1 Ab negative cohort (8%). Cox proportional modelling revealed that anti-TIF-1 Ab positivity was significantly associated with an increased hazard of an associated cancer following IIM onset: HR 3.4 (95% CI 2.2, 5.4). Breast (33%), ovarian (19%) and lymphoma (14%) were the three most common cancers in the anti-TIF-1 Ab positive patients, whereas breast (20%), bowel (14%), lung (6%) and cervix (6%) were the most common sites in anti-TIF-1 Ab negative patients.

## Conclusion:

This study has helped to characterise the temporal relationship between anti-TIF-1 Ab positivity and cancer onset. The findings that earlier cancer onset is associated with anti-TIF-1 Ab positivity, and that associated cancer types differ, are potentially of clinical significance, and appear to suggest a specific cancer screening approach in anti-TIF-1 Ab positive patients.

Table 1 – Baseline demographics and time to cancer confirmation in anti-TIF-1 Ab positive and negative cohorts

	<b>Total cohort n = 711</b>	<b>Anti-TIF-1 Ab positive, n = 55</b>	<b>Anti-TIF-1 negative, n = 656</b>

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Interstitial lung disease (ILD) is one of the leading causes of mortality in patients with polymyositis or dermatomyositis (PM/DM). Since clinical courses and outcomes of ILD are highly variable among PM/DM patients with ILD, disease subsetting is essential in deciding management regimens, by offering opportunity to identify patients who have a greater risk of mortality, especially early in the disease course. In this regard, myositis-specific autoantibodies (MSAs) correlate with unique subsets of PM/DM-associated ILD, but potential utility of other serum biomarkers routinely measured in clinical practice, such as CRP and ferritin, in predicting prognosis is also reported. The aim of this study is to establish predictive modeling of mortality in patients with PM/DM-associated ILD using a large cohort data.

**Methods:** This study was conducted using a database of a multicenter retrospective cohort of patients with PM/DM-ILD (JAMI cohort), which involved 44 institutions across Japan. We enrolled 487 patients based on adult-onset definite or probable PM/DM including clinically amyopathic DM (CADM), ILD confirmed by imaging study, and availability of serum samples at diagnosis. Anti-melanoma differentiation-associated gene 5 (MDA5) and anti-aminoacyl tRNA synthetase (ARS) antibodies were detected by enzyme linked immunosorbent assay and RNA immunoprecipitation, respectively. CRP, ferritin, KL-6 and surfactant protein-D (SP-D) were chosen as serum biomarkers for PM/DM-ILD. Independent risk factors for all-cause mortality were identified by Cox regression analysis using MSAs and serum biomarkers, including CRP, ferritin, KL-6 and surfactant protein-D (SP-D) as explanatory variables. The backward selection method was applied; explanatory variables were eliminated when p value was > 0.10.

**Results:** The overall survival rate was 83% at 1 year. The survival rate was significantly lower in patients with anti-MDA5 than in those without ( $P < 0.0001$ ). The cut-off values of individual serum biomarkers for predicting mortality determined by the receiver operating characteristic curve were CRP  $\geq 1$  mg/dl, ferritin  $\geq 500$  ng/ml, KL-6  $\geq 1000$  ng/ml and SP-D  $< 100$  ng/ml. The presence of anti-MDA5 (hazard ratio [HR] = 3.0, 95% confidence interval 1.6-5.7), CRP  $\geq 1$  mg/dl (HR = 2.4, 1.4-4.0), KL-6  $\geq 1000$  ng/ml (HR = 2.0, 1.3-3.3) and ferritin  $\geq 500$  ng/ml (HR = 1.8, 1.0-3.2) were identified as risk factors for poor prognosis. Our modeling showed that the predicted mortality rates were 1.8%, 8%, 22%, 44% and 54% in patients with zero, one, two, three and all four risk factor score, respectively (Figure 1).

**Conclusion:** We successfully generated predictive modeling of mortality in patients with PM/DM-associated ILD using convenient serum biomarkers. This model is potentially useful in identifying the patients with high mortality risk, which

apparently require intensive treatment

Figure 1. Association between mortality rate and risk factor score in PM/DM-ILD

## Rapid and Sustained Pain Improvement in Rheumatoid Arthritis Patients Treated with Baricitinib Compared to Adalimumab or Placebo

Peter C. Taylor<sup>1</sup>, Roy Fleischmann<sup>2</sup>, Elizabeth Perkins<sup>3</sup>, Jeffrey Lisse<sup>4</sup>, Baojin Zhu<sup>4</sup>, Carol L Gaich<sup>4</sup>, Xiang Zhang<sup>4</sup>, Douglas E. Schlichting<sup>4</sup>, Christina L. Dickson<sup>4</sup> and Tsutomu Takeuchi<sup>5</sup>, <sup>1</sup>NDORMS, University of Oxford, Oxford, United Kingdom, <sup>2</sup>University of Texas Southwestern Medical Center, Dallas, TX, <sup>3</sup>Rheumatology, Rheumatology Care Center, Birmingham, AL, <sup>4</sup>Eli Lilly and Company, Indianapolis, IN, <sup>5</sup>Keio University School of Medicine, Tokyo, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pain – Basic and Clinical Aspects Oral

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Assessment of pain improvement during treatment for rheumatoid arthritis (RA) may help frame patient expectations and may be useful to clinical decision-making and discussions between providers and their patients. Baricitinib (BARI) 4 mg once daily was associated with significant clinical improvements in the Phase 3 study, RA-BEAM, in active RA patients with an inadequate response to methotrexate (MTX) compared with adalimumab (ADA) and placebo (PBO).<sup>1</sup> The objective of this post hoc analysis was to evaluate the time and likelihood of achieving different levels of pain control with BARI relative to ADA and PBO.

### Methods:

1305 patients on stable background MTX were randomized 3:3:2 to PBO, BARI 4 mg, or ADA 40 mg. The patient's assessment of pain was assessed with a 0-100 mm visual analog scale (VAS) at each study visit. The likelihood of achieving  $\geq 30\%$ ,  $\geq 50\%$ , and  $\geq 70\%$  pain VAS improvement through Week 24 and the median time when 50% of patients achieved these pain improvement thresholds were assessed with Cox proportional hazards models and the cumulative incidence estimate.<sup>2</sup> Pain improvement was analyzed by baseline pain VAS subgroup ( $\leq$ median,  $>$ median). Analyses were not adjusted for multiplicity.

**Results:**

BARI-treated patients were more likely to achieve at least 30%, 50%, and 70% pain improvement than PBO and ADA with HR of 1.7, 1.9, and 2.5, respectively ( $p<0.001$ ) compared to PBO, and 1.1 ( $p=0.145$ ), 1.2 ( $p=0.032$ ), and 1.3 ( $p=0.003$ ) compared to ADA. The median time for 50% of patients to achieve at least 30%, 50%, and 70% pain improvement, respectively, was 1.9, 4.0, and 12.4 weeks for BARI, 2.0, 7.9, and 20.0 weeks for ADA, and 4.6, 14.0, and  $>24$  weeks for PBO (Table). The cumulative incidence for achieving 50% pain improvement is presented (Figure). The effects of BARI on pain improvement were consistent regardless of baseline pain severity. In contrast, pain improvement for patients treated with ADA or PBO varied by baseline pain severity (Table).

**Conclusion:**

BARI demonstrated faster and greater pain improvement than ADA or PBO through Week 24. In addition, unlike ADA and PBO, BARI showed consistent improvement regardless of baseline pain severity.

## Trends and Predictors of Chronic Opioid Use in Individuals with RA

Yvonne C. Lee<sup>1</sup>, Joel Kremer<sup>2</sup>, Hongshu Guan<sup>3</sup>, Jeffrey D Greenberg<sup>4</sup> and Daniel H. Solomon<sup>5</sup>, <sup>1</sup>Rheumatology Immunology & Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>2</sup>The Center for Rheumatology, Albany Medical College, Albany, NY, <sup>3</sup>Rheumatology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>4</sup>NYU School of Medicine, New York, NY, <sup>5</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pain – Basic and Clinical Aspects Oral

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The opioid epidemic is a major public health concern, requiring urgent action. However, little is known about chronic opioid use among individuals with RA. We examined trends in chronic opioid use in RA patients from 2002-2015 and identified clinical factors predicting chronic opioid use.

**Methods:** RA patients were identified from a large multicenter US registry. Opioid use was ascertained from surveys obtained at routine clinical visits, as often as once every 3 months. The primary outcome was chronic opioid use, defined as any opioid use reported during at least 2 consecutive study visits. Cox Proportional Hazards regression models were performed to identify associations between patient characteristics and incident chronic opioid use. Subgroup analyses were performed among RA patients with no pain at study entry and RA patients with at least 1 documentation of opioid use from 2002-2015.

**Results:** Among 31,993 individuals with data on opioid use from at least 2 visits, chronic opioid use increased from 7.4% in 2002 to 15.5% in 2014 and decreased to 11.3% in 2015 (**Figure**). Among the 25,054 individuals who were not taking opioids at baseline, longer disease duration, higher RA disease activity, worse disability, more pain, biologic DMARD use, corticosteroid use and antidepressant use were significantly associated with increased risk of chronic opioid use (**Table**). Asian race and a greater number of past DMARDs were associated with lower risk of chronic opioid use. Similar results were observed in a sensitivity analysis with chronic opioid use defined as at least 3 consecutive reports of opioid use. In a subgroup analysis of RA patients with no pain at baseline (N = 6,580), being female (HR 1.37, 95% CI 1.07-1.75) and being on both Medicare and Medicaid (HR 2.03, 95% CI 1.00-4.12) were associated with chronic opioid use, whereas RA disease duration and disability were no longer associated with chronic opioid use. In a subgroup analysis of RA patients with at least 1 report of opioid use during the study period (N = 6,758), the risk of progression to chronic opioid use was most strongly predicted by high disease activity (HR 2.56, 95% CI 2.02-3.24) and high pain (HR 1.36, 95% CI 1.14-1.64).

**Conclusion:** Among individuals with RA, chronic opioid use doubled from 2002 to 2014 but did not increase in 2015. Worse RA disease characteristics predicted increased risk of chronic opioid use, whereas a higher number of past DMARDs was associated with a lower risk of chronic opioid use. Future studies are needed to determine whether aggressive treatment of inflammatory disease leads to a decrease in chronic opioid use.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pain – Basic and Clinical Aspects Oral

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Peripheral and central sensitization (alterations in pain signaling) are related to heightened pain severity and can be present in knee osteoarthritis (OA). Sensory input plays an integral role in motor function, and the pain adaptation theory recognizes the impact of pain on motor function. However, it is unknown if sensitization independently contributes to alterations in physical function beyond the effect of pain severity. We examined the relation of sensitization to low physical function in older individuals with or at risk for knee OA independent of pain severity.

**Methods:** The MOST Study is a NIH-funded cohort of persons with or at risk of knee OA. Two sensitization measures were assessed: 1) *Temporal summation* (a marker of central sensitization) was defined as being present when, after touching the skin of the right wrist with a 60g monofilament repeatedly at 1Hz for 30s, the participant reported new or increased pain at the wrist. 2) *Pressure pain threshold (PPT)* is a marker of peripheral +/- central sensitization at sites of disease/inflammation, or of central sensitization when assessed at an otherwise normal area. PPT was assessed with an algometer (1 centimeter (cm)<sup>2</sup> tip) as the point at which the participants indicated that the pressure first changed to slight pain. Three trials (0.5 kilograms (kg)/s) at each anatomic site were averaged. PPT was assessed at the right wrist and index patella (i.e., knee with the worst knee pain). PPT was divided into sex-specific tertiles. Low physical function was assessed by gait speed and WOMAC function (0-68 scale). Gait speed was calculated from the 20-meter walk test (meters (m)/second(s)). Gait speed and WOMAC function were dichotomized at 1.0 m/s and >28/68, respectively, which are standard definitions of low physical function. Logistic regression models were used to determine the relation of temporal summation and PPT to physical function while adjusting for age, sex, BMI, clinic site, depressive symptoms, catastrophizing, and knee pain severity.

### Results:

2171 participants were included: mean±SD age and BMI were 67.9±7.8 and 30.7±5.9, respectively; 60% were female. Temporal summation was present at the wrist in 42.2% of participants. The mean PPT at the wrist and index patella were 3.4±1.5 and 5.0±2.2 kg/cm<sup>2</sup>, respectively. 53.3% and 10.9% of participants had low physical function as defined by slow walking and WOMAC, respectively. In general, participants with temporal summation at the wrist and low PPTs at the wrist and index patella were more likely to have slow walking (Table). Participants with low PPTs at the patella were more likely to have low WOMAC physical function.

**Conclusion:** Measures of pain sensitization are related to physical function. The relation is independent of knee pain severity and provides support that peripheral and central nervous system alterations may not only affect pain severity, but

also physical function.

Table. Relation of measures of sensitization to physical function

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pain – Basic and Clinical Aspects Oral

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Despite DMARD treatment, many RA patients continue to suffer from pain. Defining distinct pain phenotypes may advance the use of therapies targeted at specific pain mechanisms. This study identified pain profiles among RA patients with active disease, with the goal of informing treatment decisions to improve pain outcomes.

**Methods:** 146 RA patients with active disease were identified from 5 academic medical centers. Trained assessors performed joint and tender point counts. Patient-reported measures of pain, fatigue, sleep and psychological distress were assessed. Quantitative sensory testing was done to evaluate pain sensitivity (pressure pain thresholds), central pain sensitization (temporal summation) and descending pain inhibition (conditioned pain modulation). A principle components analysis (PCA) was performed to identify variables explaining the most variance. These variables were used in a hierarchical cluster analysis to identify pain phenotypes. General linear and logistic regression models were used to identify differences in clinical characteristics.

**Results:** Based on PCA, 20 variables were included in the cluster analysis, which identified 3 pain profiles (**Figure**): 1) low pain and temporal summation with low psychological distress, fatigue, and sleep problems (N = 48, 32.9%); 2) moderate pain and high temporal summation with moderate psychological distress, fatigue, and sleep problems (N = 44, 30.1%) and 3) moderate pain and temporal summation with high psychological distress, fatigue and sleep problems (N = 54, 37.0%). Catastrophizing and patient global differed across groups, with the low pain group (cluster 1) having the lowest levels of both (**Table**). NSAID use differed across groups, with the highest frequency of use in the high temporal summation group (cluster 2). Disease duration, CRP and swollen joint count did not differ across groups.

**Conclusion:** Among RA patients with active disease, 3 pain phenotypes emerged that may inform treatment decisions. Patients with moderate pain and high temporal summation (cluster 2) may benefit from strategies to reduce central sensitization, whereas patients with moderate pain and high psychological distress/fatigue/sleep problems (cluster 3) may benefit from treatments to improve mood and sleep. The finding that NSAID use was highest in the group with high temporal summation is interesting, given a study showing that COX-2 inhibition decreases temporal summation and improves pain (Arendt-Nielsen 2016). Future studies are needed to determine the role of pain phenotypes in directing pain management.

Figure. Radar plot for pain profile 1 (cluster 1, N = 48), pain profile 2 (cluster 2, N = 44), pain profile 3 (cluster 3, N = 54). Each clustering variable is represented by its own spoke with individual axis limits. The shape of the plot represents a map of characteristics for each pain profile.

Table. Clinical characteristics of RA patients with active disease, based on cluster assignment.

	Cluster 1 (N = 48)	Cluster 2 (N = 44)	Cluster 3 (N = 54)	P
Female	72.9%	81.8%	88.9%	0.35

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pain – Basic and Clinical Aspects Oral

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** It is well recognized that factors beyond structural features contribute to the pain experience in people with knee osteoarthritis (OA). Independent of structural pathology, characteristics such as psychological factors, sleep, and sensitization may increase the risk of developing pain. We examined the relation of pain susceptibility phenotypes to incident pain in people free of pain, but with or at risk of knee OA using indicators of psychological and neurophysiological aspects of pain.

**Methods:** We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal prospective cohort of 3026 older adults with or at risk of knee OA. We identified subjects who were free of frequent knee pain (FKP) (pain on most days during the past month) at both the clinic visit and a telephone screen ~1 month before the clinic visit. We excluded subjects who had a total knee replacement or possible peripheral neuropathy. We used latent class analysis to determine groupings (phenotypes) of baseline psychological and neurophysiological characteristics likely to influence pain (widespread pain, sleep, pain catastrophizing, positive affect, depressive symptoms and quantitative sensory testing (pressure pain thresholds (PPT), temporal summation (TS)). We assessed the relation of these phenotypes to incident consistent FKP (CFKP) (i.e., pain at both the clinic visit and telephone screen ~30 days prior) 2 years later using logistic regression, and examined predictors of class membership (age, sex, education, race, BMI, comorbidities, radiographic knee OA).

**Results:** 852 participants met inclusion criteria (mean age; 67.1; mean BMI 29.5 kg/m<sup>2</sup>, 55% women); 87 (11%) developed incident CFKP over 2 years. We identified 3 classes (phenotypes) that we labeled as “low”, “moderate” and “high” risk phenotypes based on prevalence of pain risk factors. PPT was a distinguishing characteristic of the high-risk group, while psychological factors were not (**Figure 1A**). Those in the moderate and low risk groups had significantly lower incidence of CFKP over 2 years OR (95% CI) 0.53 (0.21, 0.86) and OR 0.62 (0.27, 0.96) respectively, compared with the high-risk group. Women were more likely to be in the moderate and high risk groups compared to the low, while those with older age were more likely to be in the high-risk group only (**Figure 1B**).

**Conclusion:** In this cohort free of frequent knee pain with or at risk of knee OA, 3 pain susceptibility phenotypes were identified based on psychological and neurophysiological indicators that were associated with differential risk of developing knee pain, irrespective of structural disease. The high-risk pain susceptibility group was predominated by neurophysiological evidence of sensitization. Women were more likely to have higher risk pain susceptibility phenotypes suggesting that sex specific pain phenotypes may be an avenue for future study.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pain – Basic and Clinical Aspects Oral

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Pain persisting beyond the resolution or control of clinical signs of rheumatoid arthritis (RA) decreases quality of life for millions of people. Unfortunately, this pain does not respond well to typical analgesics, and, while tumor necrosis factor (TNF) is a pivotal cytokine in RA, the persistence of pain in the face of anti-TNF treatment indicates that control of this cytokine alone is insufficient to treat this pain. We have shown that in the K/BxN serum transfer model male C57Bl/6 (WT) mice develop transient inflammation and a corresponding tactile allodynia (TA), which persists beyond the resolution of inflammation. Here, we aimed to understand the role of TLR4 associated spinal cytokines, specifically TNF and interferon (IFN)  $\beta$  in the development of this persistent, post-inflammatory pain state, which is mediated through Toll-like receptor (TLR) 4 signaling.

**Methods:** K/BxN sera (100 $\mu$ l) was injected into male WT, *Tnf*<sup>-/-</sup>, *Tlr4*<sup>-/-</sup>, and *Ifnar1*<sup>-/-</sup> mice on Days 0 and 2. Ankle width and withdrawal thresholds were examined over 28 days. Separate groups of mice were injected intrathecally (IT) with anti-TNF antibody or with IFN $\beta$ .

**Results:** In male mice, there is a pivotal time (~2 weeks) beyond which administration of a TNF inhibitor or a TLR4 antagonist can no longer abrogate the neuropathic pain state in this animal model. Hence, we examined spinal cords from arthritic mice on day 10 for differences in gene expression of key inflammatory cytokines associated with allodynia in male *Tlr4*<sup>-/-</sup> and WT mice, as the WT male mice develop persistent pain, but the *Tlr4*<sup>-/-</sup> do not. We found IFN $\beta$  transcripts decreased in WT mice (average fold change (AFC): 0.41) and were increased in *Tlr4*<sup>-/-</sup> mice (AFC: 18.84). In contrast, TNF transcripts increased in WT mice (AFC 1.33), and remained unchanged in *Tlr4*<sup>-/-</sup> mice (AFC 0.96). The levels of mRNA expression for IL-1 $\beta$  and IL-6 were equivalent between the two strains.

To further understand the roles of TNF and IFN $\beta$  in K/BxN-induced arthritis and pain, we assessed male *Ifnar1*<sup>-/-</sup> and *Tnf*<sup>-/-</sup> mice. The inflammatory phase TA was attenuated in *Ifnar1*<sup>-/-</sup> mice (1.18g relative to 0.5g in WT males,  $p < 0.05$ ); however, these mice developed persistent TA while the late phase TA was reduced in *Tnf*<sup>-/-</sup> mice (1.29g relative to 0.74g in WT males,  $p < 0.05$ ), suggesting neither TNF nor IFN $\beta$  is completely responsible for the persistent pain state. Next, male WT mice were injected IT with anti-TNF antibody or with IFN $\beta$ . Neither pharmacologic treatment alone affected TA ( $p > 0.05$ ). However, when *Tnf*<sup>-/-</sup> male mice were given IT IFN $\beta$ , we saw a persistent reversal in TA. Finally, WT male mice were treated with the combination of both anti-TNF and IFN $\beta$  and showed a reversal in their persistent pain state, with a day 28 threshold of 1.4g relative to 0.27g in vehicle treated controls ( $p < 0.05$ ).

**Conclusion:** These results suggest that the pharmacological co-modulation of TNF and IFN $\beta$  is necessary for the treatment of persistent arthritis-related pain.

### CD11b<sup>+</sup>Gr1<sup>dim</sup> tolerogenic Dendritic Cell-like Cells Suppress the Progression of Interstitial Lung Disease in SKG Mice

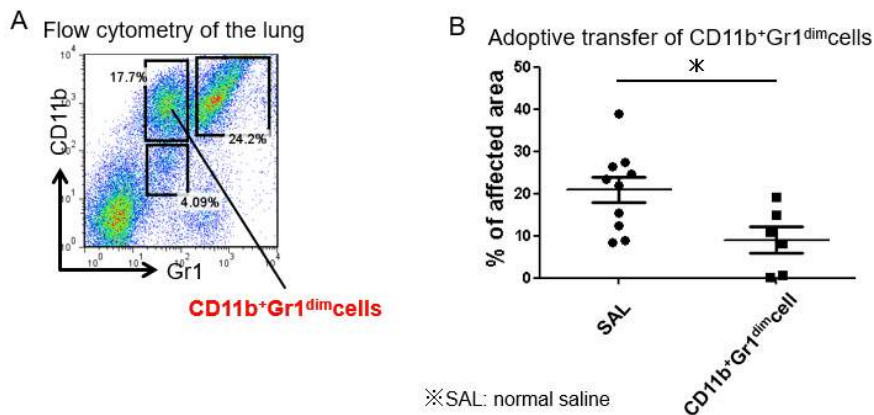

**Background/Purpose:** SKG mice develop interstitial lung disease (ILD) resembling rheumatoid arthritis-associated ILD (RA-ILD) in human. We identified a new cell population, CD11b<sup>+</sup>Gr1<sup>dim</sup> cells, in the lung of zymosan A (ZyA)-treated SKG mice. The purpose of this study is to elucidate the origin and the function of CD11b<sup>+</sup>Gr1<sup>dim</sup> cells, in the pathogenesis of ILD in SKG mice.

**Methods:** We assessed the severity of ZyA-induced ILD in SKG mice histologically, and examined lung-infiltrating cells by flow cytometry. Total lung cells and isolated monocytic myeloid-derived suppressor cells (M-MDSCs) were cultured in vitro with GM-CSF (and IL-4). The proliferation of CFSE-labeled naïve T cells co-cultured with isolated CD11b<sup>+</sup>Gr1<sup>dim</sup> cells and MDSCs was evaluated by flow cytometry. In vitro-generated CD11b<sup>+</sup>Gr1<sup>dim</sup> cells were transferred to ZyA-treated SKG mice.

**Results:** Histological analysis revealed that ZyA-treated mice developed various severity of ILD; HS1: 25%, HS2: 50% and HS3: 25%. MDSCs, Th17 cells, and group 1 and 3 innate lymphoid cells (ILC1s and ILC3s) were increased in the lungs; the proportion of these cells varied with ILD severity. In this process, we found that a unique cell population, CD11b<sup>+</sup>Gr1<sup>dim</sup> cells, was expanded in the lungs with diffusely affected area greater than 60%. About half of the CD11b<sup>+</sup>Gr1<sup>dim</sup> cells expressed CD11c, and the cells were morphologically DC-like. The CD11b<sup>+</sup>Gr1<sup>dim</sup> cells were induced from M-MDSCs with GM-CSF in vitro and were considered tolerogenic because they suppressed T-cell proliferation and expressed high levels of PD-L1. The regulatory function of CD11b<sup>+</sup>Gr1<sup>dim</sup> cells was partially canceled by addition of Anti-TGF- $\beta$  neutralizing antibody when generating them. The CD11b<sup>+</sup>Gr1<sup>dim</sup> cells have never described previously and termed CD11b<sup>+</sup>Gr1<sup>dim</sup> tolerogenic dendritic cell-like cells (CD11b<sup>+</sup>Gr1<sup>dim</sup> tolDC-LCs). Furthermore, adoptive transfer of CD11b<sup>+</sup>Gr1<sup>dim</sup> tolDC-LCs significantly suppressed the progression of ILD in SKG mice.

**Conclusion:** CD11b<sup>+</sup>Gr1<sup>dim</sup> tolDC-LCs were differentiated from M-MDSCs, and could suppress the progression of ILD in SKG mice.

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Invariant Natural Killer T cells (iNKT) express an invariant T cell receptor (TCR) alpha chain and recognize lipid antigens – such as alpha-GalCer (aGC), presented by CD1d. iNKT cells differentiate in the thymus into one of three distinct populations: iNKT1, iNKT2 and iNKT17, which are analogous to Th1, Th2 and Th17. In arthritis iNKT cells have been found to either promote or suppress disease, an effect that could be attributed to involvement of distinct populations of iNKT cells. However, the differentiation and function of iNKT subsets during arthritis have not been explored. We use the Zap70-mutant BALB/c SKG mouse, which develops autoimmune arthritis due to defective thymic selection of CD4 T cells, to explore iNKT cell subsets during arthritis development.

**Methods:** Arthritis induced by mannan injection was evaluated in NKT deficient (CD1d<sup>-/-</sup>) and NKT sufficient (CD1d<sup>+/-</sup>) SKG mice. Also, iNKT cells were depleted in SKG mice by injection of an NKT cell-depleting antibody two days before arthritis onset. CD4 SKG T cells were adoptively transferred into RAG2-KO mice, alone or in combination with thymic iNKT cells. aGC was injected once on the day of arthritis onset in WT and IFN $\gamma$ <sup>-/-</sup> SKG mice. Flow cytometry was used to evaluate iNKT cells in arthritic joints and the development of iNKT cells in the thymus of SKG and WT BALB/c mice.

**Results:** In SKG mice disease severity correlated with a reduced frequency of iNKT1 ( $r=-0.7914$ ,  $P=0.0003$ ) and an expansion of iNKT17 ( $r=0.7938$ ,  $P=0.0003$ ) in arthritic joints. Furthermore, in SKG mice deficient for iNKT cells, either following genetic deletion of CD1d or by antibody mediated depletion, severity of arthritis was exacerbated ( $P=0.009$  and  $P=0.03$  respectively). In line with these results, adoptive transfer of SKG iNKT cells ameliorated development of arthritis in RAG2-KO mice in co-transfer of CD4 SKG T cell ( $P=0.01$ ). SKG mice showed an altered thymic development of iNKT subsets, with an increased frequency of iNKT1 ( $P<0.0001$ ) and reduced frequencies of iNKT2 ( $P=0.0002$ ) and iNKT17 ( $P=0.0016$ ). Activation of iNKT cells in vivo using aGC ameliorated arthritis in SKG mice ( $P=0.05$ ) through an IFN $\gamma$  dependent mechanism.

**Conclusion:** We identify an immune regulatory mechanism by which arthritogenic abnormalities of CD4 T cell selection are associated with enhanced development of arthritis-protective iNKT1 and propose that activation of iNKT1 could be a beneficial therapeutic intervention in rheumatoid arthritis.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Fibroblasts are key effector cells in the persistence of synovial inflammation and joint damage. It is not yet known whether specific subsets of synovial fibroblasts exist, and if so, if they are responsible for the distinct fibroblast mediated features observed in inflammatory arthritis such as invasion of cartilage, bone damage, and persistence of inflammation. Using selective cell deletion strategies and adoptive cellular transfer we demonstrate the presence of functionally distinct subsets of synovial fibroblasts that mediate specific aspects of joint pathology.

**Methods:** Flow cytometry of digested synovial tissue was performed to determine the expression of fibroblast subsets using a cassette of distinct cell surface makers. Bulk transcriptomics was performed using ultra-low input RNAseq. We utilized a transgenic mouse in which FAP expressing cells were conditionally ablated (FAP-DTR) by administration of diphtheria toxin. Poly-arthritis was performed using either the KRN serum transfer model. Mice were scored for clinical signs of arthritis and MicroCT was performed to evaluate inflammatory bone changes.

## Results:

We identified distinct populations of fibroblasts defined by their expression of a cassette of cell surface markers including: podoplanin (PDPN), fibroblast activation protein (FAP), VCAM-1, Cadherin-11 and Thy1.2. Bulk transcriptomic analysis of these targeted subpopulations of cells revealed distinct transcriptional signatures which associated with whether the fibroblast subsets were located in the lining or sub-lining layers of the synovium. Synovial inflammation was associated with activation and selective expansion of these cell subsets with distinct compartments of the synovial membrane. Within the intimal layer of the synovium FAP+ PDPN+ Thy1- fibroblasts highly express MMPs, proteases and were found within pannus tissue invading articular cartilage and bone. In contrast, PDPN+ FAP+ Thy1+, cells rapidly expand within the sub-intimal layer and express pro-inflammatory cytokines, chemokine and survival factors associated with the recruitment and retention of leucocytes.

Utilising their shared expression of FAP we selectively deleted these cells using the FAP-DTR mouse. The deletion of these cells *in vivo* lead to attenuation of synovial inflammation, inhibited leucocyte accumulation and protected against inflammatory bone damage and remodelling. Consistent with these findings the adoptive transfer of FAP+, PDPN+ Thy1+ cells into arthritic mouse joints lead to a more severe and persistent inflammatory arthritis, whereas injection of FAP+ PDPN+ Thy1- cells did not.

**Conclusion:** Synovial inflammation is associated with the expansion, activation and differentiation of fibroblasts into pathogenic distinct functional subsets of cells that regulate those specific aspects of inflammatory joint pathology. Direct targeting of specific pathogenic subsets of synovial fibroblasts may provide a novel, non-immunosuppressive approach to the treatment of inflammatory arthritis.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Transition from acute to chronic inflammation is a key step in the pathogenesis of inflammatory disease but incompletely characterized to date. Similar to the onset phase of inflammation, resolution of inflammation is actively regulated but coordinated by mediators diverse as those that initiate inflammation. Here we identified IL-9-producing Type 2 Innate lymphoid cells (ILC2s) as key regulators in the interaction between innate and adaptive immune responses that orchestrate resolution of inflammation in arthritis.

**Methods:** Wild-type and Il9 deficient mice were analyzed in three different models of arthritis, namely antigen induced arthritis (AIA), serum induced arthritis (SIA) and monosodium urate crystal (MSU) induced arthritis model, followed by histomorphometric analyses of inflammation, cartilage damage, bone damage, and micro-computed tomographies. For synovial tissue analyses (ILC2, IL-9-expressing cells) samples from untreated active RA patients (N=19) and RA patients in remission receiving treatment with DMARDs (methotrexate N=15, TNF inhibitors: N=5) were analyzed (N=19). In addition, a longitudinal biopsy cohort of 10 early (<12 months disease duration) RA patients receiving synovial biopsies at baseline and 6 months after start of anti-rheumatic therapy was analyzed. For the analysis of circulating ILC2s a cohort of 111 RA patients was analyzed. 63 of these 111 patients received a follow-up assessment of circulating ILC2s 6 to 12 months after baseline assessment.

**Results:** In the absence of IL-9, ILC2s did not proliferate and arthritis transformed into a chronic disease with persistent joint swelling, chronic synovial inflammation, excessive cartilage destruction and bone loss. Treatment with recombinant IL-9 led to proliferation and activation of ILC2s and promoted ILC2-dependent activation of regulatory T cells (Treg). This cell/cell contact dependent interaction between ILC2s and Tregs via GITR and ICOS resulted in suppression of Th17 driven inflammation and thereby also crucially influenced tissue damage and bone loss. The course of acute inflammation in response to MSU crystals was not affected by IL-9. IL-9-producing ILC2s increased during resolution of RA both in the synovial membrane as well as in the peripheral blood. IL-9+ ILC2 counts were very low in the synovium of active RA patients, in whom IL-9 production was mostly confined to lineage (Lin) positive cells. In contrast, RA patients in remission (DAS28 < 2.6) showed a strong upregulation of Lin- IL-9+ ILC2s. Also the longitudinal analysis of synovial tissue of RA patients showed a switch of the cellular source of IL-9 from Lin+ IL-9+ cells during active disease to Lin- IL-9+ ILC2s after successful treatment with anti-rheumatic drugs over 6 months.

**Conclusion:** IL-9 driven activation of ILC2s might thus provide a novel therapeutic anchor to induce resolution of chronic inflammatory disease such as arthritis and to restore immune homeostasis. Current cytokine-targeting strategies exclusively suppress the activation pathways rather than fostering resolution of disease, our data provide evidence for a new concept in inflammatory medicine by modifying cytokine pathways relevant for resolution of inflammation.

**Session Title:** Rheumatoid Arthritis – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** In rheumatoid arthritis (RA) the attachment of synovial fibroblasts (SF) to articular cartilage is an important prerequisite in the process of cartilage degradation. The actin-associated protein Lasp-1 is involved in processes of actin organization and polymerization and focal adhesion turnover, respectively. Therefore, we investigated its role in regulating cell-cell contacts and ECM interactions of synovial fibroblasts in RA.

**Methods:** Lasp-1 expression was analysed in tissue from RA patients, in hind paws of arthritic mouse models such as the hTNFtg and G6PI mouse model by using WB and immunohistochemistry. Furthermore, Lasp-1<sup>-/-</sup> mice were interbred with hTNFtg mice and offsprings were analysed for the progression of joint destruction by clinical evaluation and histopathology. Cell spreading as well as migration characteristics of SF derived from wild type (wt), Lasp-1<sup>-/-</sup>, hTNFtg and Lasp1<sup>-/-</sup>hTNFtg mice were analysed by live cell imaging and TEM. Cell-matrix interactions as well as cell-cell contacts of isolated SF from all different genotypes were investigated in an electrical cell/substrate impedance sensing assay (ECIS). Additionally, we used an *in vitro* 3D organ culture system for functional analyses.

**Results:** Lasp-1 expression levels were significantly increased in human and murine RA tissue as well as in arthritic SF in comparison to healthy controls. Evaluation of Lasp-1<sup>-/-</sup>hTNFtg mice revealed a milder arthritis score, less cartilage degradation and reduced SF attachment to articular cartilage compared to hTNFtg mice. Results of cell spreading and migration analyses demonstrated alterations in spreading morphology and cell-cell contacts and a significantly reduced migration rate of Lasp-1<sup>-/-</sup> SF and Lasp-1<sup>-/-</sup>hTNFtg SF compared to healthy controls. Immunofluorescence showed an unstructured and irregular cytoskeleton in cells with Lasp-1 deletion compared to other cells, confirmed by TEM. ECIS analysis demonstrated increased cell-cell contact formation in Lasp-1<sup>-/-</sup> compared to wt SF (+22% vs wt SF) and prolonged cell-cell interactions of Lasp-1<sup>-/-</sup>hTNFtg SF in comparison to hTNFtg SF. Histological sections of the 3D matrices demonstrated that wt SF formed an organised synovial structure comparable with healthy synovial tissue *in vivo* whereas in matrices with hTNFtg SF, this synovial architecture was not seen. Interestingly, Lasp-1 deletion in the hTNFtg background resulted in an organised cellular lining layer comparable with wt SF matrices.

**Conclusion:** Lasp-1 regulates the migratory behaviour of synovial fibroblasts and their invasion into cartilage matrix in rheumatoid arthritis by controlling the dynamics of cell-matrix and cell-cell contacts.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Type I interferons (IFN-I) can be both anti- and pro-inflammatory. Among them, IFN- $\alpha$  inhibits normal Th17 differentiation, whereas it is pathogenic in lupus. The role of IFN-I is controversial in rheumatoid arthritis (RA) and experimental models. An IFN-I signature has been reported in RA patients, the signification of which is unclear. In

mice, IFN- $\alpha$  enhance or inhibit arthritis development according to IFN subtype, arthritis model and kinetics. We have evaluated the therapeutic effect of early IFN- $\alpha$  production in collagen-induced arthritis (CIA).

**Methods:** CIA was induced by 2 immunizations with collagen/CFA. Disease development was studied in conditional transgenic mice over-expressing mouse IFN- $\alpha$ 1 after cessation of doxycycline (Dox) administration (Tet-off system). IFN- $\alpha$ 1-negative littermates were used as controls. All mice express endogenous IFN- $\alpha$ . All mice received Dox. Arthritis was followed by clinical evaluation. Inflammation/bone destruction were estimated by histology. Pain was followed by stance and Von Frey tests. Plasma cytokines/anti-collagen antibodies were measured by Luminex/ELISA. Leukocytes sub-populations and Th1/Th2/Th17 polarization were analyzed by flow cytometry. Bone marrow cells were cultured with M-CSF/RANKL to evaluate osteoclast differentiation and activity. CD4<sup>+</sup>CD25<sup>+</sup> regulatory T cells (Treg) and CD4<sup>+</sup>CD25<sup>-</sup> effector T cells (Teff) were purified by magnetic sorting. Treg ATPase activity was determined in vitro by a luminescent assay. Treg inhibition of Teff activation was measured by flow cytometry/ELISA in co-cultures. The in vivo therapeutic capacity of purified Treg was estimated by adoptive transfer.

**Results:** Induction of mouse IFN- $\alpha$ 1 production before the first or even before the second immunization resulted in CIA protection and lower pain parameters. Anti-collagen antibody production was lower in IFN- $\alpha$ 1<sup>+</sup> mice. Likewise, IFN- $\alpha$ 1<sup>+</sup> mice produced less IL-6 but more IL-5. Protection was associated with decreased polarization to Th17 and lower IL-17 secretion capacity and increased polarization to Th2 and IFN- $\gamma$ -positive Th1 and NK cells. On the contrary, osteoclastogenesis and osteoclast activity were decreased in IFN- $\alpha$ 1<sup>+</sup> mice. CIA protection in IFN- $\alpha$ 1-overexpressing mice was associated with impaired B cells while increased CD86<sup>+</sup> PMN in the bone marrow and particularly with an expansion of Treg with a higher CD39/CTLA-4 expression, higher ATPase activity and a higher capacity to inhibit Teff proliferation and cytokine secretion. Most importantly, adoptive transfer of those highly suppressive Treg purified from CIA IFN- $\alpha$ 1<sup>+</sup> mice impaired CIA development in recipients in comparison to adoptive transfer of Treg purified from CIA IFN- $\alpha$ 1<sup>-</sup> mice.

**Conclusion:** This is the first study analyzing the impact of IFN- $\alpha$  on CIA development. Early induction of IFN- $\alpha$ 1 production and even after the first immunization (i.e., seropositive mice) nearly completely protects against arthritis, highlighting a therapeutic window. Protection is associated with an expansion of more suppressive Treg able to confer protection upon adoptive transfer. This work better defines the role of IFN- $\alpha$  and shows its potent modulatory effect in inflammatory arthritis.

## Highly Sensitive Cardiac Troponin-I in Peripheral Blood Predicts Cardiovascular Events in Patients with Rheumatoid Arthritis

**George Karpouzas**<sup>1</sup>, Joel Estis<sup>2</sup>, Long Pham<sup>3</sup>, John Todd<sup>2</sup> and Matthew Budoff<sup>4</sup>, <sup>1</sup>Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, <sup>2</sup>Singulex, Alameda, California, Alameda, CA, <sup>3</sup>Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, <sup>4</sup>Cardiology, Harbor-UCLA Medical Center, Torrance, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Cardiac troponins (cTn) are specific biomarkers of myocardial injury; their measurement with highly-sensitive assays and at subthreshold levels for myocardial infarction (MI) diagnosis, predicts greater risk of both fatal and non-fatal coronary heart disease, heart failure hospitalization, and overall mortality in the general population. We previously reported that highly-sensitive cardiac troponin-I (cTnI>1.5pg/ml), independently predicted occult coronary plaque burden and composition on coronary computed tomography angiography (CTA) in patients with established rheumatoid arthritis (RA). We now explore whether high cTnI predicts cardiovascular events in the same cohort after five years of follow-up.

**Methods:** One hundred and fifty RA patients without prior diagnosis of cardiovascular disease (CVD) underwent a baseline 64-slice CTA for plaque evaluation between 3/2010-3/2011. Blood was collected for cTnI and other biomarker assessments at the time of the CTA. Subjects were followed for a mean of 60±26 months for incident CV events. Composite rates of ischemic [cardiac death, non-fatal MI, ischemic stroke, peripheral arterial ischemia] as well as non-ischemic [new onset heart failure hospitalization] CV events were the study end-points. Cox regression analysis evaluated the association between high cTnI (>1.5pg/ml) and CV events in raw and several adjusted models; hazards ratios (HR) were calculated as an estimate of CV event risk associated with high cTnI.

**Results:** Eleven patients suffered incident events (1.54/100PY): 8 were ischemic, including 1 cardiac death, 3 MI, 2 strokes, and 2 peripheral arterial ischemic events requiring emergent revascularizations; the 3 non-ischemic events were new onset, hospitalized, systolic heart failure. cTnI was higher in patients with events compared to those without [2.6 (2.1-4.4) vs. 1.5 (1.0-2.4) pg/ml, p=0.006]. High cTnI predicted risk of incident CV events (Figure 1, p=0.03) independently of demographic and traditional cardiac risk factors (Table 1). Additionally, patients with low cTnI (≤1.5pg/ml) were 82% less likely to suffer a CV event. No events occurred in patients with both low cTnI and low interleukin-6 (≤2.85pg/ml).

**Conclusion:** Highly-sensitive cTnI may provide prognostic information on long-term CV event risk assessment in RA patients without symptoms or known history of CV disease.

**Figure 1.** Kaplan-Meier curves in RA patients with high and low cTnI

**Table 1.** cTnI>1.5pg/ml portends higher risk of cardiovascular events

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Serum troponin is used in clinical practice in the diagnosis of acute myocardial infarction. Recent studies have found that high sensitivity assays can predict cardiovascular (CV) events in the general population. We sought to evaluate the association of troponin and mortality in a cohort of inflammatory polyarthritis (IP) patients.

**Methods:** Patients recruited between 2000 and 2009 to the Norfolk Arthritis Register, an IP inception cohort (inclusion criteria: 2 or more swollen joint for 4 or more weeks, aged over 16 years) had CV risk factors and IP characteristics recorded at inclusion and blood samples stored. High sensitivity troponin I (Tn-I) was measured on baseline samples, using an automated clinical assay (Abbott, UK). Patients were flagged with the national death register and cause of death classified using ICD10 codes. Patients were followed until death or December 2016. Tn-I was log transformed for analysis. Association with all-cause and CV mortality was tested using Cox regression. Further Cox regression models were performed for CV mortality, with adjustment for CV then IP factors. Subgroup analyses were performed in those with no prior CV events and in those who met ACR/EULAR 2010 criteria for rheumatoid arthritis. The cohort was split into tertiles based on Tn-I levels and Kaplan Meier curves were used to explore differences in CV mortality.

**Results:** 1022 patients were evaluated. Baseline characteristics are seen in Table 1. 158 deaths occurred during 11,237 person years follow up, 37 were CV deaths. Tn-I levels were associated with all-cause and CV mortality (HR[95%CI]: 1.71[1.46, 2.00] and 2.03[1.58, 2.61] per 1 unit increase in log Tn-I ). Results from adjusted regression models are seen in Table 2. The association with CV mortality remained on adjustment for CV and IP factors. In both subgroup analyses, a significant association between Tn-I and CV mortality was found. Survival curves are seen in Figure 1. Patients in the highest tertile had a 7.7 fold increased risk of CV death compared to those in the lower tertiles (HR [CI 95%]: 7.78[3.56, 17.0]).

**Conclusion:** Tn-I levels are associated with CV mortality in IP, independent of CV risk factors and the association is not explained by baseline IP disease characteristics or inflammation. The role of Tn-I in CV risk prediction warrants further investigation.

Table 1. Baseline characteristics (median(IQR) or frequency(%) where*)	
Age (years)	56 (44, 66)
Female*	697(66.4%)
Symptom duration (months)	10.6(5.6, 26.5)
Seropositive (RF and/or ACPA)*	512(50.5%)
3 component disease activity 28 score (DAS28)	3.73 (2.86, 4.69)
Health Assessment Questionnaire (HAQ) score	1 (0.375, 1.625)
ACR/EULAR 2010 criteria for rheumatoid arthritis (RA)*	628 (61.4%)
Prior CV event*	39 (3.9%)
Diabetes*	72 (7%)
Current smoker*	214 (20.8%)
Hypertension*	180 (17.6%)
Total cholesterol to HDL ratio (TC:HDL)	4.31(3.37, 5.38)
CRP (mg/l)	11.6 (6.1, 21)
Creatinine (mmol/l)	66 (41, 77)
Troponin I (pg/ml)	6.3(4.6, 8.7)
Detectable Tn-I levels*	1022 (100%)

**Table 2. Association of baseline Tn-I levels with subsequent CV mortality (per 1 unit increase in log Tn-I)**

	Whole cohort (n=1022) HR (95% CI)	Subjects no prior CVD (n=984) HR (95% CI)	RA patients (n=628) HR (95% CI)
Model 1:Unadjusted model	2.03 (1.58, 2.61)	1.98 (1.49, 2.63)	1.91 (1.41, 2.60)
Model 2: Age and gender adjusted	1.74 (1.19, 2.56)	2.37 (1.10, 2.59)	1.74 (1.13, 2.67)
Model 3: CV risk factors adjusted	1.71 (1.14, 2.59)	1.58 (0.99, 2.50)	1.61 (0.99, 2.63)
Model 4: IP factors	1.64 (1.09, 2.49)	1.50 (0.93, 2.43)	1.73 (1.09, 2.72)
Model 5: Full adjusted	1.61 (1.04, 2.52)	1.59 (0.91, 2.42)	1.61 (0.96, 2.70)

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Rheumatoid arthritis (RA) patients have a greater risk of cardiovascular (CV) mortality compared to general population. Traditional CV risk factors may be less accurate in predicting CV mortality in RA patients. We examined the performance of the CV risk factors compared to carotid ultrasound measures of intima-media thickness (IMT) in predicting CV mortality in a RA cohort.

**Methods:** We recruited patients who met the 1987 ACR criteria for RA from private, public and military rheumatology practices. We measured carotid IMT using high resolution ultrasound. Baseline data on traditional CV risk factors which included systolic blood pressure, diabetes, smoking, high density lipoprotein and total cholesterol were collected. For Framingham CV risk, we used published tables to calculate the predicted 10-year risk of coronary heart disease, based on

the above risk factors. We then divided Framingham risk score into three categories defined as low (<10%), intermediate (10-20%) and high (>20%) risk of CV mortality. We also divided IMT into risk groups of low (IMT < 1.0 mm), intermediate (IMT 1.0-1.5 mm) and high (IMT > 1.5 mm). Patients were followed prospectively until they either died or reached the censoring date of Nov 12, 2015. Certificates were obtained for all deaths, and cause of death classified as CV according to established criteria. We then plotted area receiver operator characteristic (ROC) curves, calculated the area under the curve (AUC) and compared curves using Stata 8.2. We also computed the Net Reclassification Index (NRI).

**Results:** We followed 1,194 RA patients for 7,062 patient years. During this time, 113 CV related deaths occurred, for a CV mortality rate of 1.6 per 100 patient-years. Both the Framingham risk score and the carotid IMT were significantly associated with CV mortality. Patients in the high Framingham risk group had a CV mortality rate of 5.7 per 100 patient years, while those in the lower risk group had a CV mortality rate of 0.8 per 100 patient years. Patients in high IMT category had a CV mortality rate of 5.8 per 100 patient years, while those in the low IMT category had a CV mortality rate of 0.6 per 100 patient years. The ROC area for the Framingham risk score was 0.7695 and while that of carotid IMT was 0.7760 (P=ns). When combined the Framingham risk score with the carotid IMT, the ROC curve area increased to 0.8096 (P < 0.0001, Figure). The carotid IMT added to the Framingham risk score, correctly reclassified 12.6% of the patients (NRI of 0.126, p=0.01).

**Conclusion:** Our findings suggest that carotid ultrasound measures of IMT significantly increase accuracy of CV mortality predictions in RA patients over Framingham risk score.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Cardiac involvements cause of morbidity and mortality globally in rheumatoid arthritis (RA). Myocardial disease is typically clinically silent, only manifesting as myocardial dysfunction after an extended preclinical phase. Feature tracking (FT) cardiac magnetic resonance (CMR) imaging could reliably be used to assess myocardial function in patients with early dysfunction. Left ventricular (LV) global longitudinal peak systolic strain (GLS) is prognostic of adverse cardiovascular outcomes in various patient populations. Global circumferential peak systolic strain (GCS) is a predictor of congestive heart failure. We sought to measure GLS and GCS by using FT-CMR approach in RA patients without cardiac symptoms. Furthermore, we aimed to evaluate the association of GLS and GCS with RA status and severity.

**Methods:** RA patients and controls without cardiac symptoms were enrolled. RA patients and control subjects with no history and/or clinical findings of systemic and pulmonary hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia underwent a non-contrast CMR. Patients with RA were administered non-biologic disease-modifying antirheumatic drugs (nbDMARDs) or biologic DMARDs (bDMARDs). All subjects underwent evaluation of LV regional function, as measured by FT-CMR. GLS and GCS were calculated in the sixteen segments of the whole LV. Group comparisons were made using the Wilcoxon rank sum test, Fisher's exact test and Steel test where appropriate.

**Results:** We compared 90 patients with RA (95% women; mean age, 59.5±9.0 years) with 30 healthy controls (100% women; mean age, 55.7±4.5 years). No statistically significant differences were observed in the characteristics between the patients and the healthy controls in cardiovascular risk (CV) factors. GCS was significantly reduced by 31% in the RA group compared to controls ( $p=0.011$ ). Furthermore, GCS was significantly lower in the nbDMARD than in the bDMARD group ( $p=0.04$ ). GCS in the RA group was associated with the Simplified Disease Activity Index (SDAI) and levels of matrix metalloproteinase 3 (MMP3) ( $p=0.03$ ,  $p=0.02$ , respectively). GCS in the RA group was not associated with CV risk factors or other RA status. GLS in the RA group was significantly reduced by 21% compared to the control group ( $p=0.05$ ). GCS in the RA group was not associated with CV risk factors or RA status. GLS tended to be lower in the bDMARD group than in the nbDMARD group. GLS tended to be associated with only the SDAI.

**Conclusion:** This prospective study is among the largest studies of LV regional dysfunction in RA, assessed by FT-CMR, and the only study to explore the multivariable associations of RA characteristics with CMR-assessed GCS and GLS. Subclinical LV regional dysfunction was prominent in the RA patients without cardiac symptoms. We demonstrated the association of GCS with disease activity and MMP3. Longitudinal studies are required to track whether the regional dysfunction we observed predict those destined to develop clinical cardiac involvements.

**Session Title:** Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Patients with DM have increased coronary microvascular dysfunction (CMD) compared to the general population, leading to higher rates of cardiac death despite normal perfusion scans. While CMD is also thought to play a role in excess cardiovascular (CV) risk in RA, studies are limited. CMD can be detected using coronary flow reserve (CFR), calculated using data from clinically available stress myocardial perfusion PET scans. A pathognomonic sign of CMD is a patient with normal perfusion on a stress test, but impaired CFR. The objective of this study was to compare the frequency of CMD in RA compared to DM among subjects with normal perfusion scans.

### **Methods:**

We performed a retrospective study within a tertiary care hospital registry of patients who received stress myocardial perfusion PET scans as part of routine clinical care between 1/1/2006-1/1/2016. The registry contains data on demographics, CV risk factors, stress test results (normal vs abnormal perfusion), CFR, and adjudicated mortality outcomes. RA patients were identified using a validated algorithm and their medical records were reviewed to confirm prevalent RA at the time of the stress test. We created a DM comparison group, matching to RA by age, gender, race, and year of stress test. Among patients with normal perfusion scans, we compared the distribution of CFR in RA compared to DM, and their mean CFRs using the student's t-test. We performed chi-square tests to determine whether an impaired CFR (CFR<2) was associated with a higher proportion of all-cause mortality in the RA and DM groups.

### **Results:**

We studied 49 RA and 163 DM patients with normal perfusion scans. The RA patients had a mean age of 64.4 years at the time of their scan, 59.2% white, 51% seropositive. There was no significant difference between the age, gender, hypertension, dyslipidemia, family history of CVD, or smoking status between the RA and DM groups. The mean CFR was 2.02 for RA and DM, with a similar distribution of CFR between the two groups (p=0.98) (Figure). During a median follow-up of 5.4 years, DM with impaired CFR had a significantly higher all-cause mortality than those with normal CFR (p=0.02); a similar trend was observed in RA (p=0.29) (Table).

### **Conclusion:**

In patients undergoing clinically indicated stress tests with normal perfusion scans, we observed a similar distribution of CMD in RA compared to DM. These data suggest that CMD may contribute to the excess CV risk in RA as in DM. CFR, calculated from clinically available stress myocardial perfusion PET scans is a promising imaging biomarker to guide CV risk assessment in RA.

**Figure.** Distribution of CFR in RA compared to DM among subjects with a normal perfusion scan.

**Table.** All-cause mortality in RA compared to DM among patients with a normal perfusion scan stratified by coronary flow reserve (CFR)\*.

Coronary Flow Reserve (CFR)	RA, mortality (%), n=49	DM, mortality (%), n=163
CFR≥2, normal	13.6	2.9
CFR<2, coronary microvascular dysfunction	25.9	13.7
p-value	0.29	0.02

\*Median follow-up time: 5.2 years

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:**

Patients with RA are prone to develop myocardial dysfunction, in which chronic inflammation is suggested to play an important role. We have previously shown myocardial abnormalities on cardiac MRI (cMRI) in active RA.

## Methods:

We collected 2 RA groups: a) patients with untreated active early RA (ERA; n=30) starting conventional synthetic DMARDs (csDMARDs, n=28) or biological DMARDs (bDMARDs, n=2) and b) patients with CRA (n=28) with active RA and were candidates for bDMARDs. Patients with coronary artery disease, diabetes or smoking, and aged >70 years were excluded. Before and after one-year DMARD therapy, the patients (n=58) underwent cMRI. Sex and age-matched 22 FM patients and 35 healthy volunteers underwent cMRI once. cMRI (1.5T or 3T) included analyses of T1 relaxation times, late gadolinium enhancement (LGE), and cardiac functions.

## Results:

Of ERA patients, 77% used csDMARDs combinations (60% used MTX-SSZ-HCQ combination). Of CRA patients, 86% used anti-TNF therapy. In RA patients, LGE was detected as frequently at baseline as at follow-up (67%). None of FM patients had LGE. Over time, DAS28-crp (mean+SD) declined in ERA (3.7+1.0 vs 2.0+1.0;  $p<0.001$ ) and in CRA (3.3+1.1 vs 2.6+0.9;  $p=0.002$ ). At baseline, cardiac function was impaired in RA patients compared with FM patients or healthy volunteers. In RA patients, cardiac function improved over study-period (Table 1). ERA patients experienced improvement in LV TPFR (496+96 mms vs 445+126;  $p=0.010$ ) and in RV ESV (36+8 ml/m<sup>2</sup> vs 34+7;  $p=0.043$ ). In CRA, no significant improvement was observed in cardiac functions. T1 time did not improve in ERA patients, but it improved in nine CRA patients who underwent 3.0 T cMRI (1168+21 ms vs 1125+67;  $p=0.044$ ).

Table1. Cardiac MRI in RA patients (n=58) over study-period

	Baseline	Follow-up	p-value
	mean+SD	mean+SD	
LV EF%	59+4	59+5	0.477
LV ESV, ml/m <sup>2</sup>	34+6	33+8	0.449
LV EDV, ml/m <sup>2</sup>	82+11	81+11	0.645
LV TPFR, ms	472+99	445+106	0.035
LV mass (mg/m <sup>2</sup> )	52+11	54+17	0.568
SV index, ml/ m <sup>2</sup>	48+6	48+6	0.929
RV EF%	59+6	60+6	0.065
RV ESV, ml/m <sup>2</sup>	34+9	32+8	0.006
RV EDV, ml/m <sup>2</sup>	81+12	78+11	0.022
T1 relaxation time (1.5T cMRI)	1038+90	1047+76	0.274
(n=22)			
T1 relaxation time (3.0T cMRI)	1122+81	1113+81	0.395
(n=28)			

LV= left ventricle, RV=right ventricle, ESV = end-systolic volume, EDV=end-diastolic volume, SV=stroke volume, EF = ejection fraction, TPFR = time to peak filling rate

## Conclusion:

Patients with active RA show myocardial abnormality on cMRI at baseline: prolonged myocardial T1 relaxation times suggesting diffuse inflammation or fibrosis, LGE indicating local myocardial scars, and impairments of myocardial functions. After 1-year treatment, targeting to remission, myocardial functions improved in early RA patients in parallel with decreasing RA activity. In some CRA patients, T1 time improved. Active rheumatological inflammation seems to be deleterious to the myocardium.

**Session Title:** Sjögren's Syndrome I: Clinical Assessment and Trial Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

The type I interferon (IFN) signature is a hallmark of the pathogenesis of primary Sjögren's syndrome (pSS). However, little is known regarding the clinical utility of assessing this signature in a large cohort of patients prospectively followed up.

### Methods:

395 patients with pSS were enrolled in the « ASSEssment and Evolution of Systemic complications in primary Sjögren's syndrome ». Patients have been followed up every year ever since and completed their 5-year follow-up. At baseline, along evaluation of clinical disease activity using international scores, ESSDAI and ESSPRI, serum B-cell activation biomarkers, and whole blood RNA were collected in all enrolled patients. The type I IFN signature was evaluated using the gene expression of IFI27, IFI44 et OAS3 (ref1).

### Results:

IFN-high signature is associated with an earlier onset of the disease and a higher systemic disease activity at enrollment

The type I interferon signature was assessed in 366 patients at enrollment. 187 patients (51.1%) had a high IFN signature and 179 had a low IFN signature (49.9%). Patients with a high IFN signature had a significantly earlier onset of symptoms (median age at first symptoms: 44 [34 ;54] years versus 50 [42 ;58] years in patients with low IFN signature,  $p < 0.0001$ ). ESSDAI was significantly higher in high-IFN patients (4 [2 ;8] versus 2 [1 ;7] in low-IFN patients,  $p = 0.01$ ). ESSPRI tended to be lower in high IFN patients (5.3 [3.3 ; 6.7] vs 5.7 [4.2 ;7.3],  $p = 0.07$ ). IFN-high patients had significantly more frequently active hematological and biological domains of ESSDAI (71.9% and 72.1%, respectively) than IFN-low patients (47.6 and 34.5%, respectively,  $p < 0.0001$  for both comparisons) and tended to have more frequently active lymphadenopathy (80 vs 52.8%,  $p = 0.1$ ), glandular (66.7 vs 50%,  $p = 0.2$ ) and muscle (80 vs 53%,  $p = 0.37$ ) domains of ESSDAI.

IFN high signature is associated with a higher systemic disease activity during the prospective follow-up

Median ESSDAI during the 5-year follow-up was significantly higher in IFN-high than IFN-low patients (3.6 [2 ;7.33] vs 2.8 [1 ;6],  $p = 0.003$ ).

Among the 5 patients who developed a lymphoma during the prospective follow-up , 4 out of 5 (80%) were IFN-high at enrollment (versus 50.6% in patients without lymphoma and 43.8% in patients with a history of lymphoma).

Immunological correlates

High IFN signature was highly associated with anti-SSA and anti-SSB antibodies (9.4% in anti-SSA/SSB negative patients, 66.7% in anti-SSA-positive only patients and 87.5% in anti-SSA and anti-SSB-positive patients,  $p < 0.0001$ ).

IFN score was inversely correlated with components of the hematological domain and C3, C4 and was significantly correlated with IgG ( $r = 0.53$ ,  $p < 0.0001$ ), kappa and lambda free light chains of Ig ( $r = 0.46$  and  $0.48$ ,  $p < 0.0001$  for both), RF ( $r = 0.45$ ,  $p < 0.0001$ ), beta-2 microglobulin ( $r = 0.61$ ,  $p < 0.0001$ ), and BAFF ( $r = 0.36$ ,  $p < 0.0001$ ).

## Conclusion:

IFN gene signature is associated with a more active and systemic disease in a 5-year multicenter prospective cohort and with increased serum markers of B-cell activation. This reinforces the rationale to target type I IFN in pSS-related systemic complications.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome I: Clinical Assessment and Trial Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** B lymphocytes are important in the pathogenesis of primary Sjögren's syndrome (PSS), but two phase III trials (TEARS and TRACTISS) of the B cell depleting agent rituximab (RTX) failed to show an effect on their primary endpoints in PSS. It is possible that RTX may lack efficacy in a non-stratified PSS population, but other explanations for these negative results include the choice and timing of primary outcome. In a small single-site salivary gland ultrasound (SGUS) substudy in TEARS, more subjects in the RTX arm demonstrated improvement in parotid gland echostucture. Importantly, SGUS is an operator-dependent technique and we sought to compare the effects of RTX versus placebo on SGUS in PSS, in a multicentre, multiobserver randomised double-blind substudy of TRACTISS.

**Methods:** All subjects fulfilled 2002 American-European Consensus Group Criteria for PSS, were anti-Ro antibody positive, had symptomatic oral dryness and fatigue, some residual salivary flow, and evidence of systemic disease if disease duration was greater than 10 years. Subjects also consenting to SGUS were randomised to 1000mg RTX or placebo given at weeks 0, 2, 24 and 26, and scanned at baseline and weeks 16 and 48. Sonographers completed a 0-11 total ultrasound score (TUS) comprising domains of echogenicity, homogeneity, glandular definition, glands involved, and size of hypoechoic foci. Baseline-adjusted values of TUS were analysed over time, modelling change from baseline at each time point. For each TUS domain we fitted a repeated measures logistic regression model to model the odds of a response in the RTX arm (defined as a 1 point improvement) as a function of the baseline score, age category, disease duration and time point.

**Results:** 66 patients (49.6% of the total study population) consented to SGUS, and 52 (39.1%; n=26 RTX and n=26 placebo) completed the baseline and at least one follow-up visit. Estimated baseline-adjusted TUS at week 16 was 6.2 (95% CI 5.4-7.0) for placebo and 5.0 (95% CI 4.4-5.6) for RTX, and at week 48, 6.1 (95% CI 5.5-6.6) and 4.8 (95% CI 4.2-5.4) respectively. Estimated between group differences (RTX-placebo) in baseline adjusted TUS were -1.2 (95% CI -2.1 to -0.3; p=0.0099) and -1.2 (95% CI -2.0 to -0.5; p=0.0023) at weeks 16 and 48. Glandular definition was the only domain to show statistically significant improvement with an OR of 6.8 (95% CI 1.1-43.0; p=0.043) at week 16 and 10.3 (95% CI 1.0-105.9; p=0.050) at week 48. Improvement of  $\geq 1$  point in TUS was associated with improvement in oral dryness VAS at week 16 (diff=15.9; CI 1.5 to 30.3; p=0.030) but not week 48.

**Conclusion:** TUS differed between study arms, favouring RTX. This encourages further research into both B cell depletion therapies in PSS and SGUS as an imaging biomarker in PSS clinical trials.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjogren's Syndrome I: Clinical Assessment and Trial Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Overexpression of B cell activating factor (BAFF) in salivary glands contributes to the pathogenesis of primary Sjögren's syndrome (pSS) by promoting autoantibody (AAB) production. Treatment of pSS patients with VAY736, an anti-BAFF receptor mAb, appears promising and was associated with a depletion of circulating B cells and a positive therapeutic effect [1]. In addition to the classical anti-SS-A/Ro and anti-SS-B/La, a broader set of AABs may reflect B cell disturbances in pSS and could serve as markers during clinical development of novel pSS therapeutics. In this study, we explored novel AABs in pSS patients and healthy controls (HCs) and we tested their associations with the disease, disease activity, and clinical response to VAY736.

**Methods:** Reactivity of AABs to 1,596 antigens was measured in serum samples from 27 pSS patients from a placebo-controlled trial at baseline and post-treatment week 12 and from 50 age and gender-matched HCs. Patients were treated at baseline with a single dose of VAY736 at 10 mg/kg (n=12), 3 mg/kg (n=6), or placebo (n=9). First, to identify AABs associated with pSS, 3 different methods compared AAB levels at baseline between pSS patients and HCs: Wilcoxon rank sum test, significance analysis of microarrays, and comparison of the 90<sup>th</sup> quantiles between groups. Second, to identify AABs associated with pSS activity, Pearson correlation of AABs with EULAR Sjögren's Syndrome Disease Activity Index, secondary outcomes, and salivary and serum BAFF were tested, using baseline and week 12 levels as well as relative changes. Third, VAY736 treatment-specific changes in AAB levels were investigated using linear mixed-effects models adjusting for dosage, age, and gender effects.

### **Results:**

Of 1,596 antigens, 36 were significantly different between pSS patients and HCs for at least one of the 3 tests, including the known SS-A/Ro and SS-B/La (significant for all 3 tests) as well as novel antigens. SS-A/Ro and SS-B/La AABs were not associated with disease activity or response to treatment. However, 48 AABs were significantly correlated with pSS activity combining all treatment arms, and 12 AABs had baseline values that correlated with change in pSS activity upon VAY736 treatment (unadjusted  $p < 0.05$ ). Interestingly, 51 serum AABs correlated with BAFF saliva levels ( $|r| > 0.55$ ), but not with

BAFF serum levels. The genes encoding novel antigens are involved in apoptotic, anti-viral, metabolic, inflammatory, blood coagulation and B-cell processes, suggesting a possible link to the disease pathology. Finally, there was no reduction in AABs levels in response to VAY736.

**Conclusion:** In conclusion, we identified new AABs in pSS patients that have the potential to serve as markers of diagnosis, pSS activity, or as predictors of clinical outcome measures. Further large-scale studies are needed to confirm the value of these markers.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome I: Clinical Assessment and Trial Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** To analyse whether epidemiologic factors (such as gender or age at diagnosis of the disease) are associated with particular disease expressions and define some specific subsets in patients with primary Sjögren syndrome (SS).

**Methods:** The Big Data Sjögren project is an international, multicentre registry formed in 2014 to take a "high-definition" picture of the main features of primary SS at diagnosis by merging international SS databases using a Data-Sharing methodological approach. By January 2017, the database included 9302 consecutive patients recruited from 21 countries of the five continents. The main features at diagnosis (time of criteria fulfilment) or at recruitment were collected and analysed.

**Results:** Of the 9032 patients, 8680 (93%) were women and 622 (7%) were men with a mean age at diagnosis of primary SS of 50 years; 76% were Caucasian. The frequency of fulfilment of the 2002 criteria was: 92% for dry eye, 93% for dry mouth, 88% for positive salivary gland biopsy, 93% for positive ocular tests, 85% for positive oral tests and 71% for positive Ro/La autoantibodies. Other immunological tests included positive ANA (81%), RF (49%), low C4 levels (13%), low C3 levels (14%) and cryoglobulins (7%). Men with primary SS presented a higher frequency of White ethnicity (83% vs 76% in women,  $p < 0.001$ ) and rheumatoid factor (54% vs 49%,  $p = 0.017$ ), and a lower frequency of dry eyes (89% vs 92%,  $p = 0.011$ ) and dry mouth (90% vs 94%,  $p = 0.026$ ) in the multivariate model analysis. Patients with a younger onset ( $< 35$  years) showed a lower frequency of White ethnicity (69% vs 77% in aged  $> 35$  yrs,  $p < 0.001$ ), dry eyes (86% vs 93%,  $p <$

0.001) and positive ocular tests (81% vs 85%,  $p = 0.001$ ), and a higher frequency of anti-Ro/La autoantibodies (84% vs 70%,  $p < 0.001$ ), ANA (89% vs 80%,  $p < 0.001$ ), RF (62% vs 47%,  $p < 0.001$ ) and low C3 levels (19% vs 13%,  $p < 0.001$ ) in the multivariate model analysis. Patients with an elderly onset ( $> 70$  years) showed a higher frequency of White ethnicity (85% vs 75% in aged  $< 70$  yrs,  $p < 0.001$ ), positive oral tests (82% vs 76%,  $p = 0.003$ ) and a lower frequency of anti-Ro/La autoantibodies (62% vs 72%,  $p < 0.001$ ) and low C3 levels (9% vs 14%,  $p < 0.001$ ) in the multivariate model analysis.

**Conclusion:** In the largest reported cohort of primary SS patients diagnosed homogeneously around the world according to the 2002 AE criteria, we found that primary SS is a disease that can be presented heterogeneously at diagnosis, depending on specific epidemiologic features such as gender, age and ethnicity.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome I: Clinical Assessment and Trial Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

The common classification criteria sets of primary Sjogren syndrome, did not considered the ultrasonography (US) of the major salivary glands as a useful item. However, it is well known that US can increase the performance of these two sets.

UTOPIA study (ultrasonography to diagnose and classify pSS) was an international vignette survey undertaken to determine the accuracy of salivary gland ultrasonography (SGUS) and to add it as a new item in the AECG-2002 and new ACR/EULAR-2017 classification criteria.

**Methods:** Twenty four experts in primary Sjogren, from 20 countries participated in the study (22 Europeans from 13 countries, two North Americans and two Japanese). They evaluated on an internet-secure relational database, 512 realistic vignettes, randomly assigned, abstracted from 150 patients of an Italian cohort (CB). Each vignettes contained items of the classification criteria and sections on 'history' (duration of the symptoms, gender, age), clinical symptoms (dry mouth or eyes and systemic manifestations) and results of the SGUS evaluation. Each expert has to consider the diagnosis of pSS as absent, unlikely, likely or present for 64 vignettes. Each vignette was evaluated by 3 experts. The diagnosis of pSS (the gold standard) was obtained when 2/3 considered it as likely or present. Univariate and multivariate analysis were performed to evaluate the association of US to the diagnosis of pSS. Data were secondly verified on an independent French cohort (DiapSS cohort).

**Results:** The univariate and multivariate analysis confirmed that both classification criteria and SGUS were independently associated with the diagnosis of pSS ( $p < 0.001$ ). Disease duration, OSS and ocular dryness were not associated with the diagnosis of pSS. When adding US to the AECG-2002 criteria, the sensitivity (Se) and specificity (Sp) were respectively of 91 % and 83 % and of 98% and 80% if we add US. For the ACR/EULAR 2017 criteria, (with a global score of 4), the Se and Sp were respectively of 90 % and 84 % and of 95% and 82% if we add US. Results were quite similar in the independent French DiapSS. The SE and Sp of the ACR/EULAR 2017 were 87.5 and 84.5% and of 92.5 and 82 % with US. If we considered each items of the vignettes separately to build a new weighted score, only 6 variables were selected by logistic regression analysis: presence of anti-SSA (weight:4), focus score (weight:4), SGUS (weight:2), Schirmer's test (weight:1), dry eye (weight:1) and salivary flow rate (weight:1). According to ROC curve analysis, a score of  $\geq 5$  had 96% Se and 84% Sp, compared with 90% Se and 84% Sp for the ACR/EULAR 2017 Criteria. The corrected C statistic (AUC) for the new weighted score was 0.98.

### Conclusion:

Adding US item to both AECG and ACR/EULAR 2017 classification criteria increased Se but did not change Sp. The modified scores are easy to use especially the ACR/EULAR 2017.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome I: Clinical Assessment and Trial Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

Ultrasound (US)-guided core needle biopsy (CNB) with or without concomitant fine needle aspiration (FNA) is a standard method for pre-operative evaluation of salivary gland tumors. Its application to the diagnosis of salivary gland lymphoma in patients with Sjogren's syndrome (SS) has not been evaluated extensively. We sought to review our experience with these diagnostic techniques in SS patients with suspected salivary gland lymphoma.

### **Methods:**

All patients of the Hopkins Sjogren's Syndrome Center who underwent an US-guided CNB of a major salivary gland between 7/1/2009 and 5/30/2017 were identified through a computer database search. Twenty-six such patients had documented SS at the time of the biopsy and 25 underwent the procedure for evaluation of possible salivary gland lymphoma. All US-guided procedures were performed by radiologists with extensive experience in these techniques. CNB and FNA were done under real-time US guidance, using an 18 or 12 MHz linear transducer. The procedures included FNA at the discretion of the radiologist. FNA was generally done first with cellular material assessed for adequacy by a cytotechnologist present in the procedure room. The CNBs were obtained with an 18 gauge InRad needle. Patients were contacted one day after the procedure to assess for complications.

### **Results:**

The indications for CNB included bilateral parotid gland enlargement (n=15), unilateral parotid (n=1) or submandibular gland (n=1) enlargement, discrete masses in the parotid (n=5) or submandibular (n=2) glands, and a sonographically abnormal intraparotid lymph node (n=1). The US-guided procedures included CNB in all 25 patients [mean number of CNB per gland = 2.15 (range, 1-4)], and FNA in 20 patients. Samples were sent for flow cytometry in 24 patients, using material obtained from CNB alone in 4, CNB and FNA in 18, and FNA alone in 2. Immunohistochemistry (IHC) was performed on 9 CNB samples with a prominent lymphocytic infiltrate. Final pathologic diagnoses were marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT; n=8), benign lymphocytic infiltrate (n=10), salivary gland tissue without an inflammatory infiltrate (n=6), and lymphoepithelial cyst (n=1). Flow cytometry revealed a clonally restricted cell population in 10/24 patients (B cell in 9, plasma cell in 1), of whom 7 were diagnosed with MALT lymphoma based on histopathology, IHC, and IgH gene rearrangement phenotyping of the B-cells. Flow cytometric samples were comprised of largely debris

and thus without diagnostic utility in 4 patients (despite inclusion of tissue cores in 3); none of these 4 had MALT lymphoma on final diagnosis. No complications ensued from the procedures.

## **Conclusion:**

US-guided CNB, coupled with flow cytometric analysis from one of the CNB samples and/or FNA, is a safe and effective method for differentiating benign from malignant lymphoid proliferation of the salivary gland in patients with SS. A clonally restricted B cell population on flow cytometry is not always indicative of lymphoma and must be corroborated by IHC and routine histopathologic analysis of CNB samples.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Venous thromboembolism (VTE) encompassing deep venous thrombosis (DVT) and pulmonary embolism (PE) is the third most common cause of death related to cardiovascular disease following stroke and heart attack. Studies in the past have shown an increased association with the common inflammatory rheumatological disorders, however they still remain under-recognized as risk factors for VTE. We examined the risk of VTE among hospitalized spondyloarthritis patients in a large inpatient US database.

**Methods:** Using the National Inpatient Sample (NIS) data from 2006-2011, we identified VTE related hospitalizations (DVT or PE as primary diagnosis) and selected patients with spondyloarthritis, malignancy and osteoarthritis based ICD-9 codes. NIS is the largest publicly available all-payer inpatient care database in US. Discrete cohorts of patients with spondyloarthropathies (SpA), osteoarthritis (OA), malignancy and control group were created after excluding all hospitalizations with other common rheumatological diseases such as (RA, SLE, myositis, APS, vasculitis). Univariate and multivariate logistic regressions (adjusted for age, sex, race, obesity, from nursing home, long bone fractures, prior malignancy, post-surgery status, DM, CHF, respiratory failure, spinal cord injury, prior VTE, hypercoagulability, smoking, length of stay  $\geq 3$  days, calendar year, venous catheterizations and infections) were used to derive odds ratio for measures of association. SVY function was used in STATA version 13.0 to make weighted estimation for the whole US population.

### **Results:**

Our study included 29,116 hospitalizations (weighted N= 143,650) with spondyloarthritis from 2006-2011. The rates of VTE related hospitalizations was comparable between SpA and malignancy (1.50 % vs 1.54 %). Adjusted OR of VTE among

patients with SpA was close to that of malignancy ( 1.30 (1.17-1.4) vs 1.31 (1.29-1.33)), while that of osteoarthritis was 0.81 (0.79-0.83) (Table 1).

## Conclusion:

It has been shown that inflammation drives thrombosis with imbalance between innate pro-coagulants, anti-coagulants and fibrinolysis. Alarming elevated risk of VTE among inflammatory rheumatological diseases are reported and our study is in line with the same. We found a relatively high risk of VTE among patients hospitalized with SpA, which was comparable with that of malignancy (Table 1). This raises an argument as to whether an inflammatory rheumatological disease like SpA should be considered as an independent risk factor for VTE among hospitalized patients. Given the large, rising burden of rheumatological diseases and its proven associations with VTE, it appears prudent to include these in the pre-test probability calculators such as Well's or other validated scores for VTE. The weightage or score to be given should be guided by future large, prospective trials.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). Here, we evaluate radiographic progression in PsA patients (pts) treated with tofacitinib, using data from a global, 12-month, placebo- and active-controlled, parallel-group Phase 3 study. Pts had an inadequate response to  $\geq 1$  conventional synthetic disease-modifying antirheumatic drug, and were tumor necrosis factor inhibitor-naïve (OPAL Broaden; NCT01877668).

**Methods:** Pts were randomized to receive oral tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, adalimumab (ADA) 40 mg subcutaneous once every 2 weeks, or placebo (PBO). Pts who initially received PBO advanced to tofacitinib 5 or 10 mg BID at Month (M)3. Radiographs of the hands and feet at baseline (BL) and M12 were scored independently by 2 assessors using the van der Heijde-modified Total Sharp Score for PsA (mTSS; range 0–528);<sup>1</sup> average scores were used. For radiographs missing at M12, mTSS was calculated by linear extrapolation from an earlier mTSS. Change from BL in mTSS, erosion and joint space narrowing (JSN) was reported for all pts and pts grouped by BL C-reactive protein (CRP)  $>2.87$  mg/L or  $\leq 2.87$  mg/L. The proportion of pts with radiographic non-progression (defined as either an increase from BL in mTSS  $\leq 0.5$  or  $\leq 0$  and less than the smallest detectable change [SDC;  $\leq 0.66$  derived from this trial]) at M12 are reported for all pts.

**Results:** Treatment groups were comparable for demographics and BL characteristics (Table 1). Pts in all groups demonstrated minimal changes from BL in mTSS, erosion, and JSN at M12 (Table 2). Change from BL was similar in pts with CRP  $>2.87$  mg/L or  $\leq 2.87$  mg/L. Radiographic non-progression at M12 using any threshold was observed in  $>90\%$  of pts in all groups. At M12, 95.9%, 94.9%, and 97.9% of pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, and ADA, respectively, were non-progressors based on radiographic changes less than the SDC in mTSS.

**Conclusion:** Pts with PsA receiving tofacitinib showed minimal mean changes in mTSS at M12, regardless of whether BL CRP level was  $>2.87$  mg/L or  $\leq 2.87$  mg/L. At M12,  $>90\%$  of pts who received tofacitinib or ADA met all radiographic non-progression criteria.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** IL-23 is considered to play an important role in the development of enthesitis. Ustekinumab (UST), a combined inhibitor of IL-12/IL-23 shows efficacy in psoriatic arthritis (PsA), while it has no therapeutic role in diseases driven by synovitis only such as rheumatoid arthritis. We therefore speculated that inhibition of IL-23 is particularly effective in enthesitis-driven PsA patients. To compare the efficacy of UST with tumor necrosis factor inhibitor (TNFi) treatment in clearing enthesitis in PsA patients.

**Methods:** ECLIPSA is a prospective, observational, open study. Patients with PsA with active enthesitis (at least one painful enthesis on SPARCC or MASES sites), were consecutively enrolled 1:1, receiving either standard doses of UST (arm 1) or TNFi (arm 2). At baseline the following parameters were assessed: age, gender, BMI, disease duration, previous DMARDs, use of corticosteroids, use of non-steroidal anti-inflammatories (NSAIDs), swollen and tender joint count, VAS-pain, VAS-global, NPSI, PASI, MASES, SPARCC, LDI, BASDAI, BASFI, HAQ-DI, SF-36, FACIT-F, ESR and CRP. Primary endpoint was a SPARCC of 0 after 6 months. Patients were seen every 3 months and followed for a total of 6 months. In order to investigate the effects of study treatment over time we used 2x3 mixed design ANOVA models for both physician's and patient's reported outcomes. Furthermore, exploratory logistic regression was used to predict a SPARCC of 0 at month 6 from baseline PASI, tender joint count, swollen joint count, and FACIT while additionally accounting for age, gender, PsA duration and study treatment.

**Results:** 51 patients (UST=25; TNFi= 26) were screened and 47 patients (UST=23; TNFi= 24) were enrolled with 4 patients not presenting with active enthesitis at baseline. Mean  $\pm$  SD age was  $59.11 \pm 12.16$  years and mean  $\pm$  SD disease duration was  $6.4 \pm 7.79$  years. Mean  $\pm$  SD SPARCC at baseline was  $4.9 \pm 2.7$  in the UST group and  $3.8 \pm 2.5$  in the TNFi group. Other baseline characteristics were similar between both groups with exception of gender and mental component of the SF-36. In regards to the effect of study treatment (TNFi vs. UST) and time, the corresponding ANOVAs suggested an important interaction of both factors for measures of enthesitis (MASES and SPARCC), patient-reported disease activity (HAQ-DI), and skin activity (PASI), all  $p \leq 0.03$  with superiority of UST. After 6 months, 17 out of 24 UST patients (70.8%) and 10 out of 26 TNFi patients (38.4%) reached the primary endpoint defined as clearance of enthesitis (SPARCC=0). Logistic regression predicting enthesitis-free state of disease according to SPARCC was significantly related to study treatment, with patients receiving UST being more likely to show no signs of enthesitis at month 6 (OR=0.034;  $p=0.005$ ). Higher FACIT scores at baseline were also predictive of an enthesitis free-state (OR=0.864;  $p=0.024$ ).

**Conclusion:** These results show that UST is superior to TNFi in resolving the enthesitis component of disease in a population of PsA patients characterized by active enthesial disease. Based on these data more stratified treatment approaches can be designed in PsA patients, where enthesitis-driven patients are targeted by IL-23/IL-17 pathway inhibitors.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The prevalence of undiagnosed psoriatic arthritis (PsA) in psoriasis patients is high, with delays in diagnosis contributing to poor patient outcomes. We aimed to describe a novel model of care involving a self-referral system and central triage clinic for psoriasis patients with musculoskeletal (MSK) symptoms and to compare the efficacy of several triage methods for PsA.

**Methods:** Patients with psoriasis were identified by searching the institutional electronic medical records. These patients received a letter inviting them to contact the research team if they were experiencing any MSK symptoms. Participants were assessed in a central triage clinic to determine their likelihood of having PsA. The following triage methods were used: 1) three PsA screening questionnaires (TOPAS-2, PEST, PASE); 2) MSK ultrasound assessment of symptomatic joints and entheses; 3) clinical assessment by an advanced practice physiotherapist and 4) levels of CRP and ESR. Each patient was then assessed by a rheumatologist to determine whether they have PsA. Patients were classified by the rheumatologist to “Not PsA”, “Possible PsA” or “PsA”. The rheumatologist was blinded to the results of the triage methods. The performance of each triage method to identify PsA was assessed by calculating its sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and area under the ROC curve (AUC).

**Results:** Of the 1159 patients invited to participate, 300 responded (26%) and 152 (13%) agreed to participate. Of the 94 patients assessed thus far in the clinic, 69 (73%) did not have PsA, 17 (18%) had possible PsA, and 8 (9%) had PsA. The performance of triage methods is presented in Table 1. The advanced practice physiotherapist's assessment in detecting clinical PsA was highly sensitive (100%) with good specificity (71%). The screening questionnaires varied by their sensitivity and specificity with TOPAS-2 showing highest sensitivity (88%) and PASE with highest specificity (87%). The prevalence of positive MSK inflammation by ultrasound (at least 1 joint or enthesis with positive power Doppler signal) was 39.4%. The sensitivity of positive MSK ultrasound was high (88%) but its specificity was moderate (65%). 22% of the study participants who had positive MSK ultrasound findings were not classified by the rheumatologist as having PsA. The performance of CRP and ESR as triage methods was poor.

**Conclusion:** MSK ultrasound, advanced practice physiotherapist and TOPAS-2 were highly sensitive in identifying patients with PsA among psoriasis patients with MSK symptoms. A significant proportion of patients with positive MSK inflammation by ultrasound were not identified as having PsA by the clinician.

<b>Table 1 – Properties of various triage methods in detecting clinical PsA among patients with psoriasis and musculoskeletal symptoms</b>					
<b>Triage Method</b>	<b>Sensitivity</b>	<b>Specificity</b>	<b>PPV</b>	<b>NPV</b>	<b>AUC</b>
<b>Positive MSK ultrasound (Definition 1)</b> at least 1 joint or enthesal sites with positive power Doppler signal	88%	65%	19%	98%	0.76
<b>Positive MSK ultrasound (Definition 2)</b> at least 2 joint or enthesal sites with positive power Doppler signal	75%	78%	24%	97%	0.77
<b>Advanced Practice Physiotherapist: Positive assessment</b>	100%	71%	24.2%	100%	0.86

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:**

Venous thromboembolism (VTE)(pulmonary embolism [PE] and deep vein thrombosis[DVT]) is a potentially life threatening disease. Previous hospital-based studies have shown an increased risk of VTE in patients with ankylosing spondylitis (AS) but limited population-based data are available. We estimated the population-based risk of **newly recorded PE and DVT** among **incident cases with AS** compared with controls from the general population using physician-billing and hospitalization databases that cover the entire population of the province of British Columbia, Canada (~5 million)

**Methods:**

Our data includes all visits to health professionals and all hospital admissions from Jan 1, 1996 to Dec 31, 2012 and all dispensed medications from Sept 1, 1996 to Dec 31, 2012 for all individuals. We conducted a retrospective matched cohort study of all patients >18 years of age satisfying the following criteria: 1) two ICD-9 or 10 codes (720.0 or M45) for AS at least two months apart and within a 2-year period by any physician or hospitalization; 2) all AS cases had at least a 7-year run-in period before the 1st ICD code for AS in order to consider the case as incident. Each AS patient was matched with up to 10 controls by birth year, sex, and entry cohort time. We excluded cases that were diagnosed with other inflammatory conditions such as rheumatoid arthritis, vasculitis, myositis, and systemic lupus erythematosus on at least two visits. Ten non-AS controls matched by birth year, sex, and calendar year of follow-up were selected from the general population for each case.

Our outcomes were incident PE and DVT events that were recorded from outpatient visits, hospitalizations, or death certificates. For non-fatal events, we required the use of anticoagulation medications within six-months as part of all outcome definitions. We estimated relative risks (RRs) by comparing those with AS to age, sex, and entry time matched comparison cohorts, adjusting for potential known risk factors for VTE.

**Results:**

Among 7,190 incident cases of AS (51% male, mean age of 46yrs [SD 15.6]), 35, 47, and 69 developed PE, DVT, or both, respectively (incidence rates= 0.79, 1.06, and 1.56 per 1000 person years, respective) (see table). Compared with age, sex, and entry time matched controls, the RRs were 1.95 (95% CI; 1.36-2.81), 2.19 (95% CI; 1.60-3.00), and 2.06 (95% CI; 1.59-2.68) for PE, DVT, and both, respectively. After adjusting for covariates, the results remained similar (see table 1).

**Conclusion:**

This large population-based study indicates an increased risk of PE and DVT in patients with AS. Our results support the increased need for awareness and potential monitoring of these complications in AS patients.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Cardiovascular (CV) disease and cardiometabolic syndrome are common comorbidities/causes of mortality in patients (pts) with psoriatic arthritis (PsA). Tofacitinib is an oral Janus kinase inhibitor under investigation for PsA. We investigated changes in lipid levels and incidence of CV events in pts with PsA treated with tofacitinib in Phase (P) 3 and long-term extension (LTE) studies.

**Methods:** Data were analyzed for pts who received  $\geq 1$  dose of tofacitinib 5 or 10 mg BID or placebo (PBO), integrated across 2 P3 studies (OPAL Broaden [12 months (mo); NCT01877668, including adalimumab control]; OPAL Beyond [6 mo; NCT01882439]) and 1 LTE study (OPAL Balance [data cut-off May 2016; ongoing, database not locked; NCT01976364]). Lipid levels were assessed throughout P3 and LTE studies; this analysis included data from the PBO-controlled period (Mo 0–3) of P3 studies. Blood pressure, hypertension events (standardized MedDRA query [narrow]), and adjudicated (independent/blinded to treatment) major adverse cardiovascular events (MACE) are reported for all pts who received  $\geq 1$  dose of tofacitinib, pooled across doses. Incidence rates (IR; pts with events/100 pt-years [PY]) and 95% CI are reported.

**Results:** Overall, 783 pts (776 PY of tofacitinib exposure) were included in P3 and LTE studies; treatment duration was 1–927 days. After 3 mo of tofacitinib treatment in P3 studies, dose-dependent increases in lipid levels were observed with tofacitinib; minimal changes were observed with PBO, except for triglycerides (Fig). Concurrent increases in high-density and low-density lipoprotein (HDL/LDL) and no change in the total cholesterol/HDL ratio were shown. Across P3 and LTE studies, no clinically significant changes in systolic or diastolic blood pressure were seen to 24 mo. Hypertension events were reported in 38 (4.9%) pts: IR 4.93 (95% CI 3.49, 6.77). Of these events, 4 led to pt discontinuation, and 2 were serious adverse events. MACE were reported for 3 (0.4%) pts receiving tofacitinib (IR 0.38; 95% CI 0.08, 1.11), and included sudden cardiac death (57 days of exposure at time of event), myocardial infarction (197 days), and ischemic stroke (80 days). This is within the range reported in tofacitinib studies in pts with psoriasis (IR 0.24 [0.15, 0.37]; 8,759 PY of exposure) and rheumatoid arthritis (RA) (IR 0.38 [0.30, 0.47]; 21,886 PY of exposure). No dose-dependent effects on blood pressure, hypertension, or MACE were apparent.

**Conclusion:** In pts with PsA, the magnitude and dose dependency of increases in lipid levels to Mo 3 were consistent with findings in tofacitinib studies in pts with psoriasis and RA. In P3 and LTE studies, no clinically significant changes were seen in blood pressure or incidence of hypertension. Incidence of MACE was within the range reported in prior tofacitinib studies in psoriasis and RA; however, the long latency of MACE requires longer-term observation.

Figure. Mean % change from baseline in lipid levels to Month 3 integrated across Phase 3 studies

BID, twice daily

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:**

Voclosporin (VCS) is a novel CNI with a favorable metabolic profile, no observed effect on electrolytes, and a predictable dose response potentially eliminating the need for therapeutic drug monitoring.

VCS has completed testing in a global phase II trial, AURA, in patients with active lupus nephritis (LN). In AURA, two doses of VCS (23.7mg BID, 39.5mg BID) were evaluated vs placebo in a double blind RCT when added on top of MMF (2g/ day) and a stringent steroid taper.

## Methods:

The primary endpoint was 24-week complete remission (CR). However, blinding and randomization were maintained through 48 weeks permitting further efficacy assessments at 48 weeks. CR required a confirmed UPCR of <0.5 mg/mg, eGFR >60 ml/min without a decrease of >20% from baseline, low-dose steroids for at least 8 weeks prior to the endpoint assessment and no administration of rescue medications.

## Results:

Previously reported 24-week data showed a statistically significant CR improvement in patients receiving low dose VCS vs control (32.6% vs. 19.3%; OR: 2.03, p=0.045) and 27.3% in high dose VCS (p=NS). Furthermore, at 24 weeks both doses of VCS demonstrated statistical superiority over control in partial response (PR, 50% reduction in proteinuria from baseline) time to CR and time to PR. VCS treatment effect increased at 48 weeks with 49.4% low-dose (OR 3.21, p<.001) and 39.8 % high dose (OR 2.1, p= .026) VCS patients achieving CR vs 29.6% of control patients. Additionally, all low dose VCS patients in CR at 24 weeks remained in CR at 48 weeks. More AEs (84% control, 96% high, 91% low) and SAEs (19% control, 25% high, 28% low) were observed in both VCS arms compared to control. There were 13 deaths (low dose 10, high dose 2, control 1). All deaths were considered unrelated to VCS treatment by investigators and were consistent with cause seen in other LN studies. Eleven of thirteen deaths were clustered in sites with compromised access to standard of care and which disproportionately recruited to the low dose VCS arm. Following completion of study treatment, 3 control arm patients died while one developed a malignancy. No additional deaths were reported in the low dose VCS arm following 24 weeks.

We now present a 48-week CR subgroup analysis based on ethnicity, sex and age.

**Table 1: 48-week complete remission ethnic, sex and age subgroups**

Subgroup	Low dose CR%, (OR)	High dose CR% (OR)	Control CR %	N
White	56.7 (3.64)	50 (2.82)	26.2	108
Asian Indian subcontinent	59.1 (2.95)	40 (1.35)	33.3	60
Asian other	40 (2.43)	29.2 (1.47)	22.2	72
Other	28.6 (>99)	25 (>99)	0	25
Female	51.3 (3.87)	38.3 (2.2)	21.9	230
Male	38.5 (1.19)	57.1 (2.63)	33.3	35
Age ≤30	44.2 (2.17)	39.2 (1.7)	27	140
Age ≥30	56.8 (4.82)	40.5 (2.5)	21.6	125

## Conclusion:

48-week subgroup analysis demonstrates sustained VCS treatment effect that was consistent across subgroups. AURA was not powered to show statistical significance in these subgroups; however, odds ratios strongly favored low and high dose VCS across these 8 subgroups. Further data regarding VCS treatment effect in subgroups of patients with active LN will be currently being generated in the phase III AURORA trial.

## **CC-220 Decreases B-Cell Subsets and Plasmacytoid Dendritic Cells in Systemic Lupus Erythematosus (SLE) Patients and Is Associated with Skin Improvement: Pharmacodynamic Results from a Phase IIa Proof of Concept Study**

**Victoria P Werth**<sup>1</sup>, Richard Furie<sup>2</sup>, Allison Gaudy<sup>3</sup>, Ying Ye<sup>3</sup>, Shimon Korish<sup>3</sup>, Nikolay Delev<sup>3</sup>, Douglas Hough<sup>3</sup>, Michael Weiswasser<sup>3</sup>, Suktae Choi<sup>3</sup> and Peter Schafer<sup>3</sup>, <sup>1</sup>University of Pennsylvania and the VA Medical Center, Philadelphia, PA, <sup>2</sup>Northwell Health, Great Neck, NY, <sup>3</sup>Celgene Corporation, Summit, NJ

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### **Background/Purpose:**

CC-220 is a high affinity ligand for cereblon with immunomodulatory properties, currently in development for the treatment of Systemic Lupus Erythematosus as well as other autoimmune conditions and multiple myeloma. CC-220 administration results in significant reductions in ikaros (IKZF1) and aiolos (IKZF3), transcription factors which are genetically linked to SLE risk, and are overexpressed in the peripheral blood of SLE patients compared to healthy controls.

### **Methods:**

CC-220-SLE-001 is a randomized, double-blinded, placebo-controlled, phase 2a dose escalation study to investigate the safety, PK, PD, and efficacy of CC-220 in patients with SLE. Forty-two (42) adult SLE subjects fulfilling SLE ACR criteria, having a history of SLE for  $\geq 6$  months and a baseline Safety of Estrogens in Lupus Erythematosus National Assessment–Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) score  $\geq 4$ . Subjects were randomized to placebo or 1 of 4 escalating doses of CC-220 (0.3 mg QOD, 0.3 mg QD, 0.6/0.3 mg alternating QD, or 0.6 mg QD). Efficacy endpoints were exploratory and included Cutaneous Lupus Area and Severity Index (CLASI) skin scores.

### **Results:**

CC-220 significantly reduced total CD20+ B cells, immature B cells, unswitched memory B cells, switched memory B cells, BAFFR+ B cells, and plasmacytoid dendritic cells (pDC) by as much as 96%, 91.2%, 59%, 81.4%, 67.5%, and 86.5% (Day 85 median percent change from baseline), respectively. CD4+ and CD8+ T cell counts were not significantly affected, but trended upward, paralleling an increase in plasma cells in those subjects who received the highest dose (0.6 mg). Mean CLASI activity score at baseline was 9.8 with mean reductions in the CLASI activity score at day 85 ranging from 4.3 to 7.8 in the CC-220 treatment groups compared to an increase of 0.4 in the placebo group. The reductions in CLASI activity score were even more significant among subjects who had moderate-to-severe skin involvement (CLASI score  $\geq 10$  at baseline). Strong correlations between CLASI improvement and pDC reductions, rather than B cell depletion, were observed in the overall population and in subjects with a baseline CLASI score  $\geq 10$ .

### **Conclusion:**

CC-220 reduces B-Cell subset populations and pDCs in SLE subjects. Treatment with CC-220 resulted in improvement on CLASI score in all treatment groups compared to placebo with strong correlation with pDC depletion. These results support further development of CC-220 in SLE patient population with skin involvement.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** CC-220 is a CUL4CRBN E3 ubiquitin ligase modulator that binds to cereblon and leads to potent and deep reduction of the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3), which are overexpressed in the peripheral blood of Systemic Lupus Erythematosus (SLE) subjects. CC-220 is currently in development for the treatment of SLE as well as other autoimmune conditions and multiple myeloma. This study evaluated the safety, tolerability and pharmacokinetics of CC-220 in subjects with SLE. Exploratory efficacy assessments were included.

**Methods:** Subjects with history of SLE  $\geq 6$  months and a baseline of hybrid SELENA-SLEDAI (hSS) score  $\geq 4$  were randomized to 1 of 4 escalating doses of CC-220 or matching placebo (PBO). The 4 active treatments were CC-220 0.3 mg QOD, 0.3 mg QD, 0.3 mg alternating with 0.6 mg QD, and 0.6 mg QD; subjects were randomized 4:1 active to PBO in each group for 12 weeks of treatment, followed by 12 weeks of observational follow-up and/or long-term extension. Stable doses of corticosteroids ( $\leq 10$  mg prednisone or equivalent daily), non-steroidal anti-inflammatory drugs, and antimalarials were permitted. Safety assessments included clinical evaluation of adverse events (AEs), laboratory parameters, electrocardiograms, physical examinations, and overall tolerability. Exploratory efficacy assessments included hSS, Cutaneous Lupus Area and Severity Index (CLASI) skin scores, Physician Global Assessment (PGA), swollen joint counts (SJC), and tender joint counts (TJC).

**Results:** A total of 42 adult subjects were randomized; 39 subjects were female (93%); Mean age was 47.2 years; 64% were White and 31% were Black or African-American. Mean SLE duration was 9.4 years, with a mean baseline hSS score of 6.6, CLASI activity score of 9.8, and PGA score of 1.3. Seventy-nine percent of subjects completed the study; 9 of 42 subjects discontinued, of which 6 subjects discontinued due to an adverse event (AE): 1 in the placebo group and 5 in the 2 highest CC-220 groups combined. No discontinuations were due to lack of efficacy. Four subjects had serious AEs (highest CC-220 doses: n=2 [pneumonia]; PBO: n=2). Three subjects had neutropenia (grade 3: n=2; grade 1: n=1); 2 subjects in the highest CC-220 dose group had dermatitis, and 1 subject in the 0.3 mg QD and 1 in the 0.6 mg QD dose groups had urticaria. Pharmacokinetic evaluation demonstrated dose proportional exposure between cohorts, with moderate accumulation in the

non-alternating dose cohort. An exposure-response analysis demonstrated decreasing B cells, pDCs with increased exposure to CC-220.

**Conclusion:** CC-220 was generally well tolerated in this SLE population over 12 weeks of treatment, with neutropenia and dermatitis observed at the highest doses studied. Treatment with CC-220 resulted in a trend toward greater improvement in multiple measures of SLE disease activity compared with PBO. These results support further development of CC-220 in SLE patient population.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The Phase 3 CHABLIS-SC1 trial (NCT01395745) evaluated blisibimod, an inhibitor of B-cell activating factor (BAFF), in SLE. Prior SLE trials suggested that treatments are better distinguished from placebo in patients with higher disease activity, greater corticosteroid use, anti-double-stranded DNA (dsDNA), low complement<sup>1</sup>. The population in this study was enriched for these factors.

**Methods:** 442 SLE patients on corticosteroids ( $\leq 0.5$  mg/kg or 40 mg) with anti-nuclear antibodies and/or anti-dsDNA and SELENA-SLEDAI score  $\geq 10$  on standard of care medications were randomized to weekly subcutaneous blisibimod (200 mg) or placebo. Patients with renal activity were eligible unless proteinuria exceeded 6 g/24hour or disease severity required escalation of immunosuppressive therapy. Corticosteroid taper was encouraged from Week 8 with the goal to reach  $\leq 7.5$  mg prednisone/day. The primary endpoint was the Week 52 SLE Responder Index-6 (SRI-6) in the absence of new/increased immunosuppressives or antimalarials:  $\geq 6$ -point improvement in SELENA-SLEDAI, no new BILAG 1A or 2B domain scores, and  $<0.3$ -point increase in Physician's Global Assessment.

**Results:** At enrollment, the mean SELENA-SLEDAI score and corticosteroid dose was  $13.5 \pm 4.2$  and  $15.6 \pm 9.1$ mg, respectively. The SRI-6 primary endpoint at Week 52 was not met (Figure), and placebo response was greater than reported in previous studies. More blisibimod-treated subjects achieved corticosteroid taper to prednisone  $\leq 7.5$  mg/day during Weeks 40-52 and better blisibimod effect was observed under the secondary endpoint which, in addition to meeting SRI-6 criteria at Week 52, required corticosteroid dose in Weeks 40-52 to be lower than baseline (Figure). Reductions in anti-dsDNA,

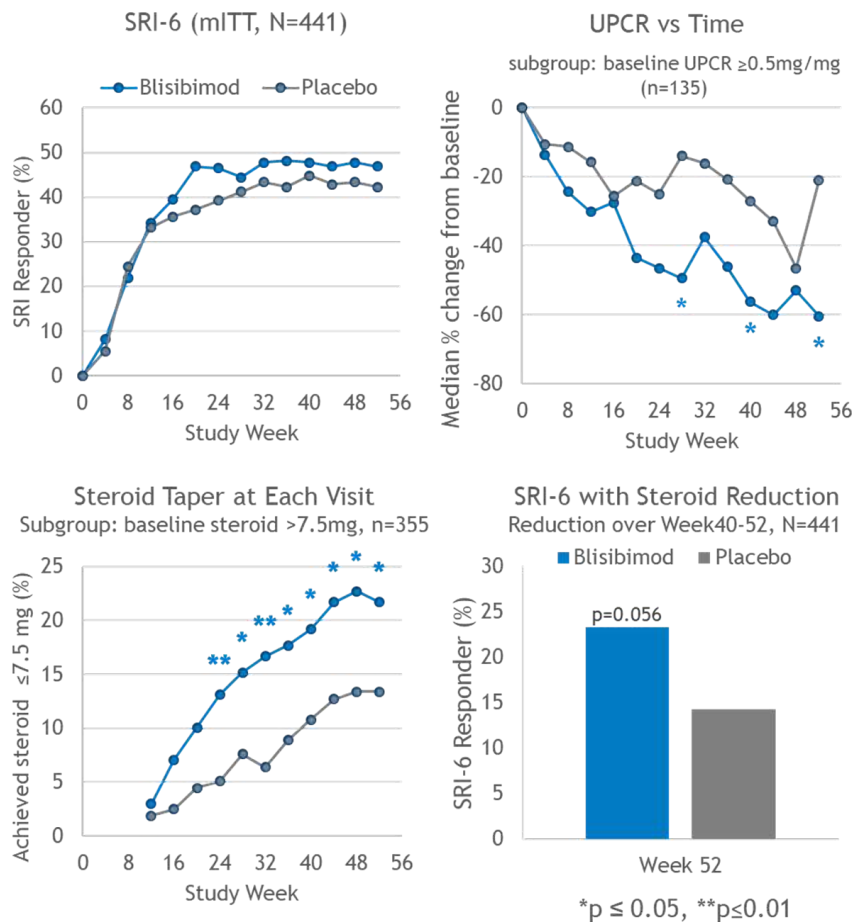

significant reductions in peripheral B cell lineages, anti-phospholipid antibodies, and immunoglobulins, and significant increases in complement C3 and C4 were observed with blisibimod.

In a subgroup of subjects with baseline urinary protein:creatinine ratio (UPCR)  $\geq 0.5$  mg/mg, greater decreases in UPCR from baseline were observed in the blisibimod arm (Figure). At week 52, significantly more subjects who received blisibimod achieved  $>50\%$  reduction in UPCR from baseline (59.7 vs 30.8%,  $p=0.006$ ), and/or UPCR  $<0.5$  (53.2 vs 30.8%,  $p=0.02$ ).

Adverse events were balanced between treatment arms except injection/application site reactions which were more common with blisibimod. None were serious or severe.

**Conclusion:** This study did not meet its primary endpoint. Blisibimod treatment was associated with successful steroid reduction, decreased UPCR, and biomarker responses.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Low disease activity (LDA) in lupus patients is increasingly a goal of treatment. For instance, Lupus Low Disease Activity State (LLDAS) attainment is associated with reduced damage accrual in patients with SLE (Franklyn et al Ann Rheum Dis 2016). Atacicept targets the B-cell stimulating factors, BLYS and APRIL, and was associated with reduction of disease activity in SLE patients (pts) starting with high disease activity (HDA; SLEDAI-2K  $\geq 10$  at Screening) in the Phase IIb ADDRESS II study. We present a post-hoc analysis of LDA attainment by ADDRESS II pts who started with HDA.

**Methods:** In ADDRESS II (NCT01972568), pts received weekly atacicept (75 or 150 mg SC injection) or placebo (PBO) for 24 weeks (1:1:1 randomization). 3 LDA definitions were used: LDA-1 (SLEDAI-2K  $\leq 2$ ); LDA-2 (SLEDAI-2K  $\leq 2$  and prednisone-equivalent  $\leq 7.5$  mg/day); and LLDAS (SLEDAI-2K  $\leq 4$  without major organ activity, no new disease activity vs previous visit, Physician's Global Assessment  $\leq 1$ , prednisone-equivalent  $\leq 7.5$  mg/day, and stable maintenance doses of immunosuppressants). Each LDA definition was assessed at each post-baseline study visit. The association of LDA attainment with SLE responder index (SRI)-6 was explored using descriptive statistics, and differences in LDA attainment between HDA pts treated with atacicept vs PBO at Week 24 were analyzed using odds ratio (OR) of LDA attainment estimated from logistic regression.

**Results:** Of the 306 pts in ADDRESS II, 158 (52%) had HDA at Screening (52 PBO; 55 atacicept 75 mg; 51 atacicept 150 mg). Fig 1 shows the attainment of LDA and SRI-6 response at Week 24: 37 pts (23.4%) achieved LDA-1, 19 (12.0%) LDA-2, 25 (15.8%) LLDAS and 67 (42.4%) SRI-6 response, irrespective of treatment. Each LDA definition identified a similar subset of pts, with LDA-2 the most stringent. Of the SRI-6 responders, 64.2% also attained LDA; all except 2 pts who attained LDA were SRI-6 responders. LDA attainment increased with atacicept dose. Pts who received atacicept 150 mg were more likely to attain LDA at Week 24 vs those who received PBO (LDA-1: OR 3.82 [95% CI 1.44, 10.15],  $p=0.007$ ; LDA-2: OR 3.30 [95% CI 0.98, 11.17],  $p=0.055$ ; LLDAS: OR 5.03 [95% CI 1.32, 19.06],  $p=0.018$ ; Fig 2).

**Conclusion:** For pts in the ADDRESS II study starting with high disease activity, LDA attainment was associated with SRI-6 response. Treatment with atacicept 150 mg vs PBO was associated with a 3- to 5-fold relative increase in the odds of LDA attainment. These results warrant further evaluation of atacicept in SLE, and suggest that LDA endpoints, including LLDAS, which has been validated against damage accrual, can be robust outcome measures in future SLE clinical trials.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Neutrophil extracellular traps (NETs) are auto-antigenic DNA strands and potentially give rise to SLE-specific autoantibodies that can deposit in glomeruli. It has been shown that autoantibodies can induce NETs, contributing to the vicious circle of immune activation in SLE. We hypothesized that eliminating autoantibodies can lead to decreased NET induction and thereby ameliorating disease in SLE. Therefore, we designed a proof-of-concept study to eliminate autoantibodies and NET formation through synergetic B-cell immunomodulation (SynBiose) with rituximab and belimumab (RTX+BLM) in severe, refractory SLE.

### Methods:

We treated patients with severe, refractory SLE in a phase 2 study with RTX+BLM. The primary endpoint assessed reduction of pathogenic autoantibodies and NET induction at 24 weeks. Anti-dsDNA autoantibodies were measured and high sensitivity FACS was performed to assess B-cell subsets. NET induction was measured with 3D confocal immunofluorescence microscopy.

### Results:

We included 14 patients with severe, refractory SLE of whom 11 had a renal flare. At 24 weeks we observed significant reductions in anti-dsDNA autoantibodies ( $p=0.0015$ ). CD19+ B-cells were depleted throughout the study ( $p=0.0005$ ) while plasma cells (PCs) temporarily decreased but returned at week 24 despite persistent depletion of transitional B-cells. Taken together with the observed reductions of autoantibodies and stable total IgG, there is no reconstitution of autoreactive PCs. We also observed significant decrease in NET reduction ( $p=0.0017$ ). In vitro studies elucidated this resulted in reduction of immune complexes by RTX+BLM. Importantly, the beneficial immunological effects translated to amelioration of clinical disease activity: SLEDAI decreased from a median of 18 to 2 ( $p=0.0002$ ). Ten out of 11 LN patients showed a response (4 complete renal responders). The response was achieved while tapering immunosuppressive medication. Treatment was generally well-tolerated.

### Conclusion:

The SynBiose study is the first to demonstrate that RTX+BLM ameliorated disease in severe SLE in association with the reduction of pathogenic autoantibodies and immune complex-mediated NET induction. Therefore, RTX+BLM represents a novel treatment concept in SLE.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis I: Clinical Trials and Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Tocilizumab (TCZ), a humanized anti-IL-6 receptor antibody, showed a favorable trend toward relapse suppression in patients (pts) with refractory Takayasu arteritis (TAK) in a randomized, double-blind (DB), placebo-controlled, multicenter trial in Japan (TAKT Study; *Arthritis Rheumatol.* 2016;68:suppl 10). However, little is known about the long-term efficacy and safety of TCZ in pts with TAK. Here we present the efficacy and safety of TCZ treatment over 52 weeks (wks) in the DB period and open-label extension (OLE) of the ongoing TAKT Study.

**Methods:** Pts  $\geq 12$  years old with TAK diagnosed according to the Japanese Circulation Society guideline (*Circ J.* 2011;75:474-503), who had relapsed while receiving oral glucocorticoid (GC;  $\geq 0.2$  mg/kg/day prednisolone equivalent) within the prior 12 wks, were randomly assigned 1:1 to weekly subcutaneous TCZ 162 mg or placebo (PBO) after achieving remission with oral GC therapy. During the DB period, background GC was tapered by 10%/wk from Wk 4 to a minimum of 0.1 mg/kg/day. Pts who experienced protocol-defined relapse during the DB period could enter the OLE period to receive weekly TCZ 162 mg. The DB period ended when relapse of TAK occurred in 19 pts and all pts were eligible to move on to the OLE period. During the OLE period, background GC doses were adjusted at the investigator's discretion. All pts were evaluated for reduction of GC dose and protocol-defined relapse of TAK in long-term treatment of TCZ.

**Results:** Thirty-six pts were randomized to receive study treatment (18 pts received TCZ and 18 pts received PBO) in the DB period and all pts entered the OLE period. As of the November 2016 data cut-off, 7 pts had withdrawn from the study during the OLE period. The median (min-max) total duration of TCZ treatment was 70.4 (8.1-108.0) wks and 31 pts were treated with TCZ over 52 wks. The median GC dose decreased from 0.22 mg/kg/day at relapse before participation in the study to 0.13 mg/kg/day at Wk 52 (Figure). Twelve of the 31 pts achieved at least 50% reduction of GC dose and 2 pts were weaned off GC at Wk 52. Protocol-defined relapse was observed in 8 pts during the OLE period. The exposure-adjusted relapse rate was 23.6 events per 100 patient-years (PYs) in the OLE period while they were 203.1 events per 100 PYs in the PBO group and 101.1 events per 100 PYs in the TCZ group in the DB period. In total, 34 (94.4%) pts experienced at least 1 adverse event (AE) while receiving TCZ. The exposure-adjusted AE rate did not increase after the DB period. Serious AEs

were reported in 6 pts (16.7%). Infections were the most frequent AEs (31 pts; 86.1%) and SAEs (2 pts; 5.6%). No new safety concerns were observed with TCZ throughout the study. No pts died in this study.

**Conclusion:** Over 52 wks, TCZ exhibited sustained, clinically meaningful, steroid-sparing effects in pts with refractory TAK. TCZ continued to show a safety profile consistent with that observed with RA/JIA.

## Health-Related Quality of Life in Patients with Giant Cell Arteritis Treated with Tocilizumab in a Randomized Controlled Phase 3 Trial

Vibeke Strand<sup>1</sup>, Sophie Dimonaco<sup>2</sup>, Katie Tuckwell<sup>2</sup>, Micki Klearman<sup>3</sup>, Neil Collinson<sup>2</sup> and John H. Stone<sup>4</sup>, <sup>1</sup>Division of Immunology/Rheumatology, Stanford University, Stanford, CA, <sup>2</sup>Roche Products, Ltd., Welwyn Garden City, United Kingdom, <sup>3</sup>Genentech, South San Francisco, CA, <sup>4</sup>Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis I: Clinical Trials and Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Superior rates of sustained glucocorticoid (GC)-free remission were shown in patients with giant cell arteritis (GCA) treated with weekly (QW) or every-other-week (Q2W) subcutaneous (SC) tocilizumab (TCZ) 162 mg + 26-week GC taper (TCZ+26) for 52 weeks compared with placebo + 26-week or 52-week GC taper (PBO+26 or PBO+52) in a phase 3 randomized controlled trial (GiACTA). Improvements in patient-reported SF-36 Physical Component Summary (PCS) score and Patient Global Assessment (PtGA) of disease activity were also reported for TCZ vs PBO+52 (Stone JH et al, *N Engl J Med*, in press). QW TCZ was recently approved for the treatment of patients with GCA.

**Methods:** Exploratory analysis of patient-reported outcomes (PROs) was performed in patients treated with QW TCZ+26 (n = 100) vs PBO+52 (n = 51) for 52 weeks based on observed data. Analyses included mean PROs based on a repeated-measures model that included all patients and post-escape data. Post hoc exploratory analyses were based on proportions of patients, and those who withdrew were classified as nonresponders at week 52.

**Results:** Improvements in SF-36 Physical Component Summary (PCS) and Mental Component Summary (MCS) scores, 6 of 8 domains, and Functional Assessment of Chronic Illness Therapy (FACIT)–Fatigue at week 52 were statistically greater with QW TCZ+26 than PBO+52 (descriptive  $p < 0.01$ ; Table, Figure); similar trends were observed vs PBO+26 (not shown). At week 52, mean scores exceeded age and gender (A/G)–matched normative scores with QW TCZ+26; higher proportions of patients reported scores  $\geq$  A/G norms in SF-36, PCS, MCS, all domains, and FACIT–Fatigue scores (Table). The median cumulative prednisone dose over 52 weeks was lower with QW TCZ+26 (1862.0 mg) than with PBO+52 (3817.5 mg) ( $p < 0.0001$ ).

**Conclusion:** Patients with GCA treated with weekly TCZ 162 mg and a 26-week taper reported greater improvements in health-related quality of life and fatigue than those treated with a 52-week prednisone taper alone, in part ascribed to lower prednisone doses.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis I: Clinical Trials and Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** GPA (Wegener's) and MPA are organ- and life-threatening systemic vasculitides characterized by the presence of ANCA-associated vasculitis (AAV), implicating B cells in disease pathogenesis. This study investigated the efficacy and safety of belimumab (BEL), a monoclonal antibody that inhibits B lymphocyte stimulator, in addition to standard of care, for the maintenance of remission in AAV following a standard induction regimen.

**Methods:** This multicenter, double-blind study (BEL115466/NCT01663623) randomized (1:1) patients ( $\geq 18$  years) with GPA or MPA in remission (Birmingham Vasculitis Activity Score [BVASv3] = 0 plus prednisolone  $\leq 10$  mg/day or equivalent) following prior induction with CYC or RTX for new or relapsing disease. Patients received azathioprine (AZA) 2 mg/kg/day, and oral glucocorticoids, plus either intravenous BEL 10 mg/kg or placebo (PBO) (Days 0, 14, 28, and every 28 days thereafter until study completion [12 months after last patient randomized]). The primary endpoint was time to first relapse, defined as  $\geq 1$  major BVAS item, total BVAS score  $\geq 6$ , or receipt of prohibited medications resulting in treatment failure. Adverse events (AE) were monitored. The study was truncated from 300 to 105 patients due to changes in conventional treatment practice.

**Results:** When the study stopped, of 105 patients in the intent-to-treat population, 76 continued for  $\geq 1$  year, 21 for  $\geq 2$  years, and 2 for  $\geq 3$  years. Baseline data:

**Table 1. Baseline demographics and disease characteristics**

		Belimumab (n=53)	Placebo (n=52)
Age, years	Mean (SD)	56.2 (13.59)	53.5 (13.56)
Sex: female	n (%)	26 (49)	25 (48)
Disease duration, years	Median (range)	1.3 (0.01–20.6)	2.3 (0.3–14.9)
Disease stage pre-induction	n (%)		
Initial diagnosis		19 (36)	24 (46)
Relapsing disease		34 (64)	28 (54)
GPA	n (%)	42 (79)	41 (79)
MPA	n (%)	11 (21)	11 (21)
ANCA type (historical diagnosis)	n (%)		
Anti-PR3		41 (77)	40 (77)
Anti-MPO		12 (23)	12 (23)
Induction regimen	n (%)		
Intravenous CYC		21 (40)	24 (46)
Oral CYC		18 (34)	15 (29)
Rituximab		14 (26)	13 (25)

ANCA, anti-neutrophil cytoplasm antibodies; CYC, cyclophosphamide; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; MPO, myeloperoxidase; PR3, proteinase 3; RTX, rituximab

There was no significant difference in time to first relapse between treatment groups: adjusted hazard ratio (95% confidence interval), 1.07 [0.44, 2.59];  $p=0.884$ . Among patients who relapsed (BEL, 10 [19%]; PBO, 11 [21%]), median (range) time to first relapse was 162 (1–371) days for BEL and 95 (15–789) days for PBO. For patients induced with RTX there were 0/1 relapses classified as vasculitis related in the BEL group versus 3/4 in the PBO group. In CYC-induced patients there were 6/9 versus 5/7 vasculitis relapses, respectively. At the final visit (double-blind) most patients were in remission (BEL, 40 [82%]; PBO, 40 [87%]).

AEs were reported in 49 (93%) BEL and 43 (83%) PBO patients post baseline. The most common AE category was infection (BEL, 30 [57%]; PBO, 30 [58%]). Serious AEs (SAEs) occurred in 18 (34%) BEL and 16 (31%) PBO patients; the most common category was infection (BEL, 4 [8%]; PBO, 4 [8%]).

**Conclusion:** In patients with AAV who were in remission, the addition of BEL to maintenance therapy with AZA and oral glucocorticoids did not reduce risk of relapse. RTX-induced patients exhibited numerically fewer relapses of vasculitis with

treatment with belimumab compared with placebo, warranting further investigation. Overall relapse rate was low (21/105 [20%]). No new safety signals were identified for BEL in the overall population.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis I: Clinical Trials and Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Interferon (IFN) containing regimens used for hepatitis C virus (HCV)-cryoglobulinemia vasculitis (CryoVas) are poorly effective and associated with important side effects. In small-size and short term studies, direct antiviral agents (DAAs) have been reported to have a better response rate and tolerance. To evaluate effectiveness and

tolerance of all oral IFN-free regimen in a real life - long term follow up - large cohort of symptomatic HCV-CryoVas patients.

**Methods:** 145 patients (57 years, 55% F) presenting symptomatic HCV-CryoVas who received DAAs, i.e. Sofosbuvir (SOF) plus Ribavirin (n=50), SOF plus Daclatasvir (n=49), SOF plus Ledipasvir (n=23), SOF plus Simeprevir (n=18), or other DAAs (n=5), for 12 or 24 weeks. Primary efficacy end point was a complete clinical response of CryoVas 12 weeks after stopping antivirals. Secondary endpoints: (i) sustained virological response (SVR12), (ii) tolerance of antivirals, and (iii) complete clinical response of CryoVas at the end of follow up.

**Results:** Baseline HCV-CryoVas features included arthralgia (64%), purpura (57%), neuropathy (58%), and glomerulonephritis (17%). Forty six (36%) patients had cirrhosis and 70 (48.3%) were naïve of antivirals. At 12 weeks post-DAAs, 103 (72%) showed a complete clinical response, 33 (23.1%) a partial response and 7 (4.9%) no response of CryoVas symptoms. Cryoglobulinemia disappeared in 53.1%. SVR12 was obtained in 97.1%. Premature DAAs withdrawal due to side effects was noted in 6 (4.1%). Main differences between patients with a complete response of the vasculitis (n=103) vs. partial/no response (n=40) were a severe form of CryoVas (65.1% vs 85%), arterial hypertension (22.3% vs. 45%), type 3 mixed cryoglobulinemia (31.3% vs. 9.1%), and use of immunosuppressant/plasma exchange (36.1% vs. 13.7%). The only factor that remained independently associated with a poor response was a severe form of CryoVas [OR 0.26, CI95% 0.07-0.98; P=0.04]. After a median follow-up of 15.3 months, 4 (2.8%) patients died. The 12-months survival rate was 97% [CI95% 94,100]. At the end of follow up, rates of CryoVas manifestations clearance were skin ulcers (98%), purpura (98%), renal involvement (92%), arthralgia (87%), neuropathy (78%) and cryoglobulinemia (54%). Rates of CryoVas complete remission at week12 post-treatment and at the end of follow up were for SOF plus Ribavirin 62% and 70%, SOF plus Simeprevir 67% and 72%, SOF plus Daclatasvir 78% and 88%, and SOF plus Ledipasvir 87% and 87%, respectively.

**Conclusion:** Sofosbuvir-based IFN-free DAAs combinations are highly effective in HCV-CryoVas patients in short term and long term, with a very good tolerance profile.

# Temporal Trends in Incidence and Outcomes of End-Stage Renal Disease due to Granulomatosis with Polyangiitis in the US from 1995-2014

## Background/Purpose:

Granulomatosis with polyangiitis (GPA) often affects the kidneys, frequently leading to end-stage renal disease (ESRD). The national trends in the frequency and outcomes of ESRD due to GPA are largely unknown, although these data would provide important benchmarks in assessing GPA disease burden and care. Our objective was to examine temporal trends in the incidence and outcomes of ESRD due to GPA.

## Methods:

We identified ESRD due to GPA in the US Renal Data System (USRDS) between 1995 and 2014, using nephrologists' ICD-9 coding (446.4) for the ESRD etiology. The cohort was divided into four five-year subcohorts based on year of ESRD onset. Overall and sociodemographic group trends in incidence rates (IRs) were assessed. Changes in rates for mortality, waitlisting, and transplantation were assessed using Cox-proportional hazards models. We conducted analyses taking into account the competing risk of death in analyses for the outcomes of waitlisting and transplantation

## Results:

Between 1995 and 2014, there were 5,929 incident cases. The annual incidence rate increased over the study period (P-for-trend <0.0001). The incidence rate of death (per 1,000 patient-years) declined from 19.0 (17.2-21.1) to 15.3 (14.0-16.7, P<0.0001) with a corresponding adjusted HR of 0.77 (95% CI, 0.67-0.89). The log-rank test also showed significant improvement in survival during the study period (P=0.03) (**Figure 1**). Adjusted HRs for death were 1.0, 0.90, 0.82, and 0.77 for the 1995-1999, 2000-2004, 2005-2009, and 2010-2014 sub-cohorts, respectively (P-for-trend = 0.005). Accounting for competing risk, there was a 70% increase in the risk of being waitlisted for transplant (adjusted HR for 2010-2014, vs 1995-1999 = 1.7, 95% CI, 1.38-2.11), whereas the risk for transplantation decreased by 30% (corresponding adjusted HR = 0.70, 95% CI, 0.53-0.93).

## Conclusion:

The burden of ESRD due to GPA has increased in the US over the past two decades, which is likely related to overall improvements in GPA survival. During the same period, survival of patients with GPA ESRD has improved, although the likelihood for being waitlisted for a transplant is rising with access to renal transplantation becoming more limited. With 5,929 GPA ESRD patients included, this is the largest AAV study to date in the literature.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis I: Clinical Trials and Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Relapses of ANCA-associated vasculitis (AAV) are associated with death, decreased renal function, and end-stage renal disease. Whether longer-term treatment with glucocorticoids (GC) reduces the risk of relapse is unclear. The objective of this study was to determine the association between dosages of GC and relapse in patients with AAV and update a previous meta-analysis with long-term follow-up and trials with rituximab.

**Methods:** MEDLINE, EMBASE, Cochrane Clinical Trials, and the Grey Literature were searched from January 1, 2008 until May 26, 2016 without language restriction for studies with patients with AAV. Studies were included if duration of GC use was specified *a priori* and patients were followed for a minimum of 18 months. Both randomized controlled trials (RCT) and prospective cohort studies were included. Quality of evidence was assessed using modified Newcastle-Ottawa criteria. Meta-analysis was completed using a random-effects model of DerSimonian and Laird.

**Results:** Twenty-four studies met inclusion criteria consisting of 2272 patients. Thirteen (54%) discontinued GC in less than one year. All patients received additional non-GC immunotherapy for induction of remission and 3 studies (<10% of patients) included patients receiving only GC as maintenance therapy. The pooled relapse rate was 14.3 per 100 patient years (95% CI 4.5, 24.0). Relapse was more frequent when discontinuation of GC at any time was compared to long-term, low-dose GC (20.7 per 100 patient years, 95% CI 6.8,34.5 as compared to 8.0 per 100 patient years, 95% CI 5.7,21.7). Multivariable linear meta-regression confirmed that long-term, low-dose GC was associated with lower relapse rates ( $b = -0.16$ , 95% CI  $-0.26, 0.07$ ,  $P = 0.001$ ) and overall follow up time was associated with increased relapse rates ( $b = 0.003$ , 95% CI  $0.001, 0.006$ ,  $P = 0.002$ ). Time to discontinuation of non-GC immunotherapy, time to GC discontinuation, study type, renal function, presence of relapsing disease at baseline, and immunotherapy that included oral cyclophosphamide did not demonstrate any significant association with relapse rates.

**Conclusion:** Long-term, low-dose GC is associated with decreased relapse rates in patients with AAV. The clinical severity and consequences of the excess relapses are not well studied. Characterization and reporting of adverse events limited analysis. These data have implications for both clinical care and trial design. RCTs are needed to determine optimal GC administration in patients with AAV.

**Figure Legend:** Random effects meta-analysis of long-term, low dose GC as compared to GC discontinuation on relapse per patient year. CYC = cyclophosphamide, MTX = methotrexate, IV = intravenous, PO = oral, MMF = mycophenolate mofetil, AZA = azathioprine, LEF = leflunomide, RTX = rituximab, PLEX = plasma exchange, C = continuation arm, WD = withdrawal arm.

**Session Title:** 2017 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lecture

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Cutaneous inflammation is a common and disfiguring manifestation for 70% of patients with systemic lupus erythematosus, yet our understanding of the pathogenesis of cutaneous lupus erythematosus (CLE) has lagged. Type I IFN signatures are elevated in CLE lesions and contribute to pathology. However, the source of type I IFN production and the function of type I IFNs in CLE has not been examined. We thus investigated the sources of type I IFN in CLE and examined the role of keratinocyte-produced IFN kappa to prime for type I IFN responses in keratinocytes.

**Methods:** 90 biopsy-proven CLE patients were examined for type I IFN expression using Affymetrix ST2.1 microarray. Tissue expression of IFNs was confirmed with immunofluorescence microscopy. Primary keratinocytes were grown from biopsies of non-lesional, non-sun exposed skin from healthy controls and patients meeting >4 ACR SLE criteria with a history of documented CLE. IFN activation was examined using real-time PCR and Western blot. IFN kappa knockout keratinocyte lines were made using CRISPR/cas9-mediated deletion.

**Results:** Analysis of CLE lesions confirmed heightened type I IFN responses and demonstrated IFNK as one of only two increased type I IFN transcripts in CLE lesions vs. control skin. IFN kappa was expressed predominantly in the basal keratinocyte layer in both healthy skin and lesional CLE, but its expression was increased in CLE lesions and in non-lesional SLE keratinocytes. Importantly, IFN kappa was required for basal type I IFN responses in keratinocytes. Indeed, absence of IFNK resulted in minimal type I IFN gene expression and a delayed response to exogenous type I IFN stimulation. In contrast, IFN kappa overexpression accelerated and amplified responses to exogenous IFN alpha in a IFN kappa dependent manner.

**Conclusion:** IFN kappa is a key regulator of IFN responses in keratinocytes. In SLE and CLE, keratinocytes are primed by an abundance of IFN kappa to generate robust responses to exogenous type I IFNs, setting up a feed forward loop which promotes exaggerated IFN responses and subsequent activation of the immune system. Thus, IFN kappa may serve as an excellent and specific target for treatment and prevention of cutaneous inflammation in SLE patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** 2017 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lecture

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Toll-like receptor (TLR) signaling is a central to lupus pathogenesis. GWAS studies have repeatedly identified components of TLR signaling pathway in SLE patients. Furthermore, the endosomal TLRs, 7 and 9, have been implicated in numerous murine models of SLE. Despite being a “pro-inflammatory” innate immune receptor, TLR9 deficiency in lupus prone MRL.Fas<sup>lpr</sup> mice exacerbates clinical manifestations including reduced lifespan and more severe nephritis, despite lacking anti-nucleosome (anti-DNA) antibodies; while TLR7 deficiency dominantly ameliorates disease. Similar regulatory roles for TLR9 have been identified in multiple other lupus models. The mechanisms by which TLR9 suppresses rather than promotes autoimmunity are unclear. We hypothesized that TLR9 has cell-specific functions.

### Methods:

We created two novel murine strains: a conditional TLR9 knock-out (*Tlr9<sup>flox</sup>*) and a conditional TLR9 overexpression allele (*rosa26-flox-stop-Tlr9*). These strains were both fully backcrossed onto lupus prone backgrounds MRL.Fas<sup>lpr</sup> (MRL/lpr) and B6.Yaa.Fcgr2b<sup>-/-</sup>. The *Tlr9<sup>flox</sup>* allele was crossed several different cre alleles; including CD19-cre (B cell specific), CD11c-cre (DC specific), MRP8-cre (neutrophil specific), and LysM-cre (macrophage and neutrophil targeting) to assess for cell specific roles of TLR9. Cell specific deletion was assessed using cell sorting and qPCR of genomic DNA. These cohorts were analyzed for disease pathology including proteinuria, renal histology, dermatitis, ANA, and immune cell activation.

### Results:

Strikingly, of all the strains tested only B-cell specific deletion of TLR9 exacerbated disease, similar to what was observed in the complete knockout, exhibiting increased proteinuria (p<0.05) and nephritis (p<0.05) with loss of anti-DNA antibodies (p<0.001). DC, macrophage and neutrophil cell specific deletion of TLR9 did not result in alteration of pathology. Given the positive results in the B cell specific deletion. We then performed the reciprocal experiment using the TLR9 overexpression allele which results in a 2 fold overexpression of TLR9 in B cells with a concomitant increase in function. When TLR9 was overexpressed only in B cells, we found that disease was ameliorated in two models of SLE, MRL.Fas<sup>lpr</sup> and B6.Fcgr2b<sup>-/-</sup>.Yaa,. In both models, there was reduced renal disease including proteinuria (p<0.05) and glomerulonephritis (p<0.05); however, there were minimal alterations in tested anti-RNA and anti-DNA autoantibodies.

### Conclusion:

These data, in which we manipulate TLR9 expression in both directions, indicate B cell expression of TLR9 accounts for a substantial proportion of the known TLR9 regulatory effect. Additionally we have effectively ruled out a role for TLR9 in numerous other hematopoietic cell types. The data further suggests that anti-DNA antibodies either play no role or are

protective in SLE pathogenesis in these murine models, thus going against the conventional wisdom in the field. To our knowledge this is the first data to show that TLR9 overexpression can be protective, and given its significant ameliorative effect, TLR9 overexpression in B cells alone may represent a potential therapeutic strategy.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** 2017 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lecture

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) increases a young woman's risk of myocardial infarction by up to 50-fold. This marked increase in cardiovascular disease (CVD) risk is not explained by Framingham risk and is not well understood. It has been suggested that innate immune responses associated with aberrant neutrophils, known as low density granulocytes (LDGs), enhance CVD risk by promoting vascular damage due to their proinflammatory properties. LDGs may represent a heterogeneous population of neutrophils and the pathogenicity of various LDG subsets has not been characterized. In this study, we sought to explore the association of these cells with subclinical vascular disease.

**Methods:** SLE patients fulfilling ACR criteria and healthy controls underwent FDG-PET/CT scans to assess vascular inflammation as target-to-background ratio (TBR) and coronary CT angiogram for coronary plaque characterization. Total and non-calcified plaque burden were quantified using QAngio. Circulating LDGs and cholesterol efflux were measured by previously validated methods. RNA sequencing of whole blood was used to analyze the transcriptional profile of both patients and controls. A neutrophil gene signature was created by calculating a z-score for the most upregulated primary granule neutrophil genes (*AZU1*, *MPO*, *CTSG*, *PRTN3*, *ELANE*, *DEFA3*) found in patients with cardiovascular involvement.

**Results:** Compared to controls, SLE patients had significantly elevated aortic TBR ( $1.68 \pm 0.16$  vs.  $1.59 \pm 0.14$ ,  $p=0.007$ ) and coronary non-calcified plaque burden (NCB) ( $0.86 \pm 0.33$  vs.  $0.76 \pm 0.19$ ,  $p=0.022$ ). We identified diverse subsets of LDGs based on maturation. The percentage of an immature subset of LDGs was significantly elevated in peripheral blood mononuclear cells in patients compared to controls ( $1.6$  ( $3.2-0.47$ ) vs.  $0.35$  ( $0.96-0.13$ ),  $p<0.001$ ). This immature subset associated with the primary granule neutrophil gene signature ( $\beta=0.844$ ,  $p<0.001$ ), TBR ( $\beta=0.34$   $p=0.015$ ), and with NCB ( $\beta=0.31$ ,  $p=0.001$ ) in unadjusted analyses. The neutrophil gene signature also associated with NCB ( $\beta=0.44$ ,  $p<0.001$ ). In addition, a mature subset of LDGs was present in SLE, which associated with TBR ( $\beta=0.23$ ,  $p=0.02$ ), NCB ( $\beta=0.31$ ,  $p=0.002$ ), and HDL efflux ( $\beta=-0.29$ ,  $p=0.024$ ), supporting previous work that suggests the enhanced neutrophil extracellular

trap formation in mature LDGs impairs HDL efflux. These associations persisted after adjusting for traditional risk factors in multivariate analyses.

**Conclusion:** Patients with SLE have an increase in both aortic vascular inflammation and coronary plaque burden compared to controls. The associations of aberrant neutrophil subsets with this atherosclerotic phenotype support studies suggesting a pathogenic role for these cells in assaulting the vasculature and that targeting responses triggered by these cells may have potential therapeutic benefits.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** 2017 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lecture

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The central nervous system (CNS) manifestations of SLE remain poorly understood. Although potentially neuropathic autoantibodies have been identified in the serum, lupus patients show inconsistent correlations between these and neuropsychiatric SLE (NPSLE). This is likely due to the highly restrictive nature of the blood brain barrier and the variability between patients in barrier dysfunction and humoral immune transmission into the CNS.

**Methods:** We used the MRL/MpJ-*Fas*<sup>lpr/lpr</sup> mouse, a well-established model of lupus associated neuropsychiatric deficits, to evaluate the immune effectors responsible for CNS disease. We performed RNA sequencing, immunofluorescent phenotyping, and light and electron microscopy of brain tissue to identify signaling pathways and cellular contributors to NPSLE.

**Results:** We found extensive cellular infiltrates in the MRL/MpJ-*Fas*<sup>lpr/lpr</sup> choroid plexus by 16 weeks of age, when these mice display profound cognitive deficits and depression like behavior (Figure 1). Transcriptome analysis of the choroid plexus revealed an expression signature driving tertiary lymphoid structure (TLS) formation, including elevated *Cxcl13*, *Lta/b* (lymphotoxin  $\alpha/\beta$ ), *Ccl19*, and a host of other cytokines and chemokines related to lymphoid organization. Additionally, gene ontology assessment revealed transcriptional profiles closely related to various stages of lymphocyte activation and germinal center formation. Immunofluorescent evaluation of the choroid plexus defined the cellular infiltrate in NPSLE mice to include locally proliferating B and T cells, extensive T-cell activation, and evidence of *in-situ* somatic hypermutation and class switch recombination and IgG<sup>+</sup> plasma cells. Finally, the choroid plexus was found to be important

in trafficking lymphocytes into the CNS, as evidenced by the routine presence of intra-epithelial lymphocytes on transmission electron microscopy. Evaluation of human lupus choroid plexus tissue is in progress.

**Conclusion:** Collectively, we not only determined a potential new pathway underlying neuropsychiatric lupus, we identified TLS formation in the choroid plexus as a novel mechanism through which the immune system may bypass the blood brain barrier.

Figure 1: Representative H&E staining and scanning electronic microscopy of the choroid plexus in 16 week old female mice reveals extensive cellular infiltration with dramatically expanded stroma in the choroid plexus in MRL/lpr mice, whereas control MRL/+ mice appear normal. Arrows= choroid plexus epithelium; asterisks= mixed cellular infiltrate.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** 2017 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lecture

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease characterized by autoantibody production and periods of elevated and suppressed disease activity. Various genetic and environmental factors likely contribute to disease pathogenesis. Epstein Barr Virus (EBV) is an environmental factor consistently associated with SLE. EBV maintains latency in B cells and shows frequent reactivation, which can be measured indirectly in terms of antibodies to EBV antigens. In this study we determined whether antibody measures of viral reactivation and single nucleotide polymorphisms (SNPs) in EBV associated genes were associated with transitioning to SLE in at risk individuals.

**Methods:** Blood relatives (n=436) of SLE patients who did not meet ACR SLE classification criteria at baseline were evaluated an average of 6.3 ( $\pm$  3.9) years later. At both baseline and follow-up, detailed demographic, environmental, clinical information, and blood samples were obtained. 56 individuals (13%) transitioned to SLE ( $> 4$  cumulative ACR criteria) as verified by protocolled medical record review. Healthy, matched, unrelated individuals (n=122) were recruited at local health fairs. To assess evidence of viral exposure/reactivation, antibody responses against the EBV antigens Viral Capsid Antigen (VCA) and early antigen (EA) and Cytomegalovirus (CMV) were measured by ELISA. 5 SNPs in IL10, 1 in complement receptor 2 (CR2) and 3 in CD40 gene were typed by ImmunoChip. Generalized estimating equations (GEE), accounting for correlation within families, were used to test associations between the viral antibody variables and the categorical outcome of transitioning to SLE. Associations between SNPs, seroconversion and disease transition were examined in an additive model. Interactions between SNPs and antibody titers were examined.

**Results:** Higher proportion of individuals who transitioned to SLE were positive for anti EA IgG at baseline compared to healthy controls (37.5% vs 12.7%,  $p=0.0005$ ). Mean baseline anti VCA and EA IgG levels were significantly different between those family members who transitioned to SLE and those who did not ( $4.88\pm1.80$  vs  $4.18\pm2.83$ ;  $p=0.007$ ;  $1.19\pm1.11$  vs  $0.88\pm0.76$ ;  $p=0.008$  respectively). Increased levels of VCA IgG and EA IgG were associated with transitioning to SLE when compared to healthy controls (OR 1.05, 95%CI 1.01-1.10; OR 1.18, 95%CI 1.09-1.26 respectively). VCA IgG, EA IgG and CMV IgG positively correlated with number of autoantibody specificities and ACR scores at both baseline and follow-up visits. Significant interaction was observed between SNPs in CD40 and VCA IgG and between SNPs in IL10 and VCA IgA in transitioning to SLE.

**Conclusion:** Elevated EA IgG and VCA IgG were associated with transitioning to SLE in unaffected SLE relatives, suggesting that viral reactivation may contribute to development or worsening of SLE autoimmune responses. To our knowledge, this is the first prospective study examining the pre-clinical association between serologic measures of EBV reactivation and SLE disease transition.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Exacerbated differentiation of monocytes into osteoclasts (OC) contributes to the pathogenesis of rheumatoid arthritis (RA) resulting in severe bone erosion and functional damage. Osteoclastogenesis is initiated by M-CSF and RANKL signalization through their respective receptor CSF-1R and RANK. *In vitro*, it has been demonstrated that Human Cytomegalovirus (HCMV) infection inhibits macrophage differentiation through a down regulation of numerous receptor, including CSF-1R [Frascaroli *et al.*, *J. Immunol.*, (2009)]. As CSF-1R signaling is essential to induce RANK expression, the key receptor for osteoclast differentiation, we studied the effect of HCMV infection on osteoclastogenesis and evaluated the consequences of HCMV seropositivity on bone erosion evolution in a RA cohort.

**Methods:** Blood monocytes from healthy donors were purified by adherence selection and differentiated in osteoclast by recombinant M-CSF and RANKL (both at 50 ng/mL) during 12 days. After 24 hours of differentiation, pre-osteoclasts were infected with a HCMV clinical strain (VHL/E) at the m.o.i. of 3. Expression of cellular proteins CSF-1R, RANK, and “X-protein” (patent being filed) and viral protein (IE) expressions were studied by RT-qPCR, Western Blot, Flow Cytometry and fluorescence microscopy. OC differentiation was evaluated by manual counting after TRAP staining. Lentiviral transduction and Amaxa transfections were performed to over-express or inhibit the expression of “X-protein” and confirm its role.

We then analyzed patients from the French « ESPOIR » cohort, fulfilling the 2010 ACR/EULAR criteria for RA. We evaluated the correlation between HCMV serology status and structural involvement assessed by the modified Sharp score, at baseline and 1 year.

**Results:** We demonstrated for the first time that HCMV infection inhibits osteoclastogenesis. No osteoclast was observed in HCMV infected wells *in vitro*. We observed that HCMV infection inhibits CSF-1R and RANK mRNA and proteins expression in a viral replication dependent manner. We found that viral IE protein expression was followed by an increase of expression of the cellular “X-protein”. To confirm these observations, we over-expressed the “X protein” in monocytes and observed that CSF-1R, RANK and, as a result, osteoclastogenesis were completely inhibited. Knock-down experiment of “X protein” with shRNA lentiviral vectors blocked the inhibitory effect of HCMV on CSF-1R and RANK expression.

Analysis of the ESPOIR cohort, including 273 HCMV+ and 214 HCMV- RA patients, demonstrated that, although there was no difference at inclusion, HCMV seropositive patients displayed less severe bone erosion score in comparison with HCMV negative ones after one year (**p=0.0151**), thus providing a pathophysiological counterpart of our *in vitro* observations.

**Conclusion:** HCMV infection inhibits osteoclastogenesis through a mechanism involving “X-protein” and results in a protective effect on bone erosion during RA. Over expression of this “X-protein” inhibited OC differentiation and could be a new therapeutic target to limit bone erosion during chronic inflammatory disease such as RA and in osteoporosis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Previously, we described increased expression of Wnt-1-induced signaling protein 1 (*Wisp1*) in murine synovium and cartilage after induction of experimental osteoarthritis (OA) models. *WISP1* is a downstream target of canonical Wnt signaling, which has been shown to play a pivotal role in the etiopathology of OA. In agreement with this, we have observed increased breakdown of the articular cartilage after overexpression of *Wisp1* in naïve mouse knee joints, whereas *Wisp1*<sup>-/-</sup> mice revealed decreased cartilage degeneration in three independent experimental OA models compared to wild type controls. Together, these data indicate a direct correlation between *Wisp1* and OA in mice. In the current study we set out to characterize the relation between expression of *WISP1* and human OA.

**Methods:** Articular cartilage from preserved and degenerated OA areas was collected from 39 Caucasian end-stage OA patients. Cartilage from non-OA-diagnosed individuals was collected after femoral neck fractures. Cartilage degeneration was classified according to the Mankin scoring system. DNA was isolated to determine correlation between *WISP1* expression and methylation profiles using Generalized Linear Mixed Model (GLMM). RNA expression levels were determined with microarray analysis and RNA sequencing. Immunohistochemical staining was used to determine *WISP1* protein expression. Recombinant *WISP1* was added to human chondrocyte microparticles, and cartilage extracellular matrix deposition was determined by measuring cartilage microparticle size and Safranin O/Fast Green staining.

## Results:

We observed increased *WISP1* expression in cartilage of OA patients compared to non-OA-diagnosed controls. Moreover, within OA patients, both *WISP1* mRNA and protein expression were significantly increased in OA-affected cartilage compared to preserved regions of the same joint, and *WISP1* expression significantly correlated with Mankin score. Interestingly, we found that positional CpG dinucleotides were hypomethylated in cartilage of OA-affected areas as compared to unaffected areas from the same joint, which correlated with increased RNA expression as determined with both microarray analysis and RNA sequencing analysis. Of note, methylation levels of a CpG affecting *WISP1* transcription were found to highly significantly correlate to a single nucleotide polymorphism (SNP) at the *WISP1* locus. Next, to investigate effects of increased *WISP1* levels on chondrocyte microparticles, we added human recombinant *WISP1*. This resulted in a significantly decreased deposition of cartilage extracellular matrix as reflected by decreased microparticle circumference, and a strongly decreased proteoglycan content, suggesting that increased *WISP1* levels are detrimental to cartilage.

## Conclusion:

The expression of *WISP1* is increased in OA-affected as compared to preserved articular cartilage. This increased expression is inversely correlated with methylation levels of a positional CpG, which was found to be under the influence of a SNP at the *WISP1* locus. Together, our results suggest that tight regulation of *WISP1* expression via methylation is essential to maintain cartilage homeostasis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Autophagy, an essential chondrocyte homeostasis mechanism, is defective in Aging and Osteoarthritis (OA). However, the targets regulating this mechanism are still unknown. *Here, we aimed to identify targets regulating autophagy in human chondrocytes.*

**Methods:** We performed quantitative proteomic analysis of Atg5 knockdown primary human chondrocytes using iTRAQ (isobaric tags for relative and absolute quantitation) labeling coupled with on-line 2D LC/MS/MS. Protein identification and quantification were performed using Protein Pilot Software v 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for *Homo sapiens*. Human chondrocytes and human cartilage from healthy, aged and OA patients were employed to confirm the role of the identified target by Western Blot (WB), Immunofluorescence (IF) and Immunohistochemistry (IHC). Importantly, CRISPR/Cas9 genome editing technology and mutant mice were used for mechanism of action studies.

**Results:** 24 out of 487 proteins were significantly altered ( $p < 0.05$ ) in response to defective autophagy. Cytoskeleton organization, collagen catabolism, oxidative stress, and aging pathways were affected. Interestingly, Lamin A/C, a nuclear protein implicated in cell senescence, was found upregulated under defective autophagy. Increased Lamin A/C expression was found in human chondrocytes with reduced autophagy. Furthermore, aging and OA human cartilage showed increased Lamin A/C expression. Induction of chondrocyte aging by genetic deletion of Zinc Metalloproteinase STE24 (Zmpste24) via CRISPR-Cas9, lead to Lamin A/C accumulation, accompanied by a reduction of LC3 and increased chondrocyte death and mitochondrial dysfunction. Importantly, Zmpste24 KO mice showed bone damage and intervertebral disc degeneration (IDD), suggesting that deficient autophagy is correlated with aging and OA phenotype.

**Conclusion:** Lamin A/C, a nuclear protein contributing to structural integrity to the nucleus and matrix was identified as candidate target for regulating cartilage function under defective autophagy, such as aging and OA. These results support the hypothesis that autophagy is decreased with aging. Therefore, targeting autophagy might be a promising strategy to find novel therapeutics for cartilage aging and OA.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** We have recently reported that endogenously produced adenosine, interacting with A2AR, is a critical autocrine factor for maintenance of chondrocyte and cartilage homeostasis and intra-articular injections of liposomal preparations of adenosine inhibit progression of OA in a post-traumatic OA (PTOA) model in rats. We therefore determined whether intra-articular injection of a more selective A2AR agonist could also prevent progression and possibly reverse OA in this model and in the obesity related OA model in mice.

### Methods:

PTOA was induced in SD rats following rupture of the anterior cruciate ligament (ACL) by application of external force to the knee. Starting 4 weeks after injury, when OA has already progressed, knees were injected with 100ul of saline, empty liposomes (LIPO) or liposomes containing CGS21680 (LIPO-CGS) every 10 days (6 injections) before sacrifice. The cartilage volume in OA and normal knees was measured by microCT after staining with hexabrix (40%). Chondrocytes were isolated from neonatal mice and cultured, only first passage chondrocytes were studied.

For the obesity-OA model, C57Bl6 mice (3/group, 12 weeks old) were fed a 60% fat diet (HFF mice). After 3 months, when OA was present, mice received intrarticular knee injection (10 µl) of LIPO, LIPO-CGS or liposomal adenosine (LIPO-Ado) every 10 days for 4 injections before sacrifice.

**Results:** Injection of LIPO-CGS but not saline or LIPO, significantly reduced swelling of affected rat knees ( $p < 0.001$ ). Surprisingly, there was an increase in tibial and femoral cartilage volume in normal knees treated with intra-articular injections of LIPO-CGS but not LIPO or saline (47% increase in tibia and 22% in femur). More importantly, intra-articular injections of LIPO-CGS, but not LIPO or saline, increased tibial and femoral cartilage volume in OA knees, as compared to normal knees and completely abrogated the histologic evidence of OA as well (OARSI score for CGS21680  $0.66 \pm 0.33$  vs  $4.55 \pm 0.82$  in the vehicle group and  $3.90 \pm 0.89$  in the saline group). There was marked chondrocyte proliferation in the deep cartilage of knees of rats treated with LIPO-CGS (Ki67 immunofluorescence).

Similarly, LIPO-CGS reversed the OA changes in the obesity related OA model. HFF mice had an OARSI score of  $4.7 \pm 1.2$ . Treatments with LIPO-Ado and lipo-CGS decreased OA severity (OARSI score  $1.3 \pm 0.3$  and  $0.7 \pm 0.6$ , respectively,  $p < 0.001$  vs untreated). A2AR stimulation increased TGF- $\beta$  immunostaining in LIPO-CGS-injected joints and increased TGF- $\beta$  production by cultured neonatal murine chondrocytes with increased SMAD2/3 phosphorylation and diminished RUNX2 expression.

**Conclusion:** These results demonstrate that intra-articular injection of a long-acting A2AR agonist stimulates chondrocyte and cartilage regeneration, likely by a TGF- $\beta$ -dependent mechanism. More importantly, these results indicate that treatment with an A2AR agonist can reverse OA in both traumatic and obesity-related OA.

## Anp32a Is a Critical Regulator of Oxidative Stress in Cartilage and Protects Against Osteoarthritis

Frederique Cornelis<sup>1</sup>, Silvia Monteagudo<sup>1</sup>, Wouter den Hollander<sup>2</sup>, Tine Peeters<sup>3</sup>, Laura-An Guns<sup>1</sup>, Lies Storms<sup>1</sup>, Ingrid Meulenbelt<sup>2</sup> and Rik Lories<sup>1</sup>, <sup>1</sup>Skeletal Biology and Engineering Research Center, KU Leuven, Leuven, Belgium, <sup>2</sup>Department of Molecular Epidemiology, Leiden University Medical Center, Leiden, Netherlands, <sup>3</sup>Skeletal Biology and Engineering Research Center, KU Leuven, 3000, Belgium

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** We described an association between polymorphisms in the *ANP32a* gene and osteoarthritis. Osteoarthritis is one of the most common chronic musculoskeletal disorders and a cause of serious morbidity and disablement, particularly in the elderly population. Progressive damage to the articular cartilage and bone leads to pain and loss of joint function. The development of osteoarthritis is very complex and is influenced by both genetic and acquired or environmental risk factors. *Anp32a* (acidic leucine-rich nuclear phosphoprotein 32 family member a) functions as a tumor suppressor gene and as a regulator of gene transcription, stabilization of RNA, intracellular transport and apoptosis. Moreover, Anp32a associates with Axin-1 and Phosphatase 2A, molecules that exert a regulating role in the Wntless-type signaling (Wnt) pathway, a signaling cascade with important roles in skeletal development, homeostasis and disease, including in osteoarthritis. But it remains unknown how Anp32a affects cartilage health and osteoarthritis.

**Methods:** *ANP32A* expression levels were determined in preserved and damaged areas of articular cartilage of patients with osteoarthritis (OA) by RNA sequencing. Different established mouse models for OA were induced in *Anp32a*<sup>-/-</sup> mice. Genome-wide transcriptome analysis of the articular cartilage, comparing *Anp32a*<sup>-/-</sup> mice to C57Bl/6 wild-type (WT) mice, was performed to understand how loss of *Anp32a* affects cartilage homeostasis at the molecular level. Chromatin immunoprecipitation-quantitative PCR (CHIP-qPCR) and siRNA-mediated silencing were performed in primary human articular chondrocytes. Detection of Atm and ROS was performed using immunohistochemical staining on mice knee sections of *Anp32a*<sup>-/-</sup> and C57Bl/6 WT mice.

**Results:** We observed a significant decrease in *ANP32A* expression, in damaged areas of the cartilage of patients with OA, compared to non-damaged areas in the same patients. In the different OA mouse models, absence of *Anp32a* resulted in increased cartilage damage as compared to control animals. Transcriptome analysis identified *Ataxia-telangiectasia-mutated* (*Atm*) as a potential Anp32a effector gene. Indeed, *Atm* was highly downregulated in *Anp32a*<sup>-/-</sup> mice. *Atm* is a suppressor of reactive oxygen species (ROS), which are known to induce chondrocyte hypertrophy during endochondral ossification and in the onset of osteoarthritis. It is reported that the detrimental effects of *Atm* depletion on cartilage homeostasis can be reversed by inhibiting ROS with N-acetyl-cysteine (NAC). We treated our *Anp32a*<sup>-/-</sup> mice in the DMM-induced OA model with NAC, via the drinking water. Effectively, this treatment ameliorated the cartilage damage observed in our *Anp32a*<sup>-/-</sup> mice. CHIP-qPCR demonstrated that Anp32a binds to the *Atm* gene promoter and influences the recruitment of the RNA polymerase II transcription machinery.

**Conclusion:** We have demonstrated that Anp32a plays a relevant role in osteoarthritis, and identified Anp32a as an essential regulator of *Atm* and oxidative stress in cartilage. Our insights have therapeutic implications, as pharmacological blockade of ROS ameliorates osteoarthritis induced in *Anp32a*<sup>-/-</sup> mice.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** In 2011, the Veterans Affairs (VA) Office of Academic Affiliations funded the creation of the Center of Excellence (COE) in Musculoskeletal (MSK) Care and Education at the Salt Lake City (SLC) VA. This report reviews the growth of the COE from a local training program to a national resource supporting multicenter projects in health professions education and scholarship.

**Methods:** Data was collected from program faculty on activities of the COE over the last five years.

**Results:** Four educational programs, two clinical experiences and 44 scholarly projects were identified.

Educational programs (offerings and participants listed in Figure 1):

1. MSK Education Week—an intensive week-long rotation for students and trainees
2. SLC Mini-Residency—a 3-day accredited continuing professional education (CPE) program for primary care providers (PCPs)
3. National Mini-Residency—an accredited CPE program presented jointly as an educational partnership between faculty from the SLC VA and 12 VA medical centers
4. National Simulation, Learning, Education, and Research Network (SimLEARN)—two programs: MSK Master Educator (designed for educational leaders) and MSK Clinician (for PCPs seeking to expand their MSK skills)

Clinical experiences offering hands-on application of skills following educational programs (Figure 2):

1. A new-model MSK clinic embedded in primary care (PC MSK) and staffed by rheumatologists and a physician assistant with orthopedic experience
2. A multidisciplinary MSK clinic (MD MSK), with rheumatology, endocrinology, orthopedics, physiatry and primary care

Scholarship (summarized in Figure 3) has included published descriptions of educational programs, evidence of validity of novel assessment tools, impact on learners' clinical behaviors, and the durability of change.

**Conclusion:** The COE in MSK Care and Education has evolved from a local experience for students and trainees to a national repository for a range of programs serving the continuum of health professions education that fulfils the three-fold mission of academic health centers: clinical care, education, and scholarship. In addition to creating resources for educators, the COE is now developing a shared database to support collaborative projects initiated by leaders at other sites participating in this program through dissemination of their own innovations.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

The US Department of Veterans Affairs (VA) has developed a national continuing professional development program to train primary care providers (PCPs) in the care of patients with common musculoskeletal (MSK) conditions. Utilization of advanced imaging technology (e.g., magnetic resonance imaging (MRI)) in evaluating knee pain is an important concern because inappropriate ordering of MRI adds to costs in health care systems without increasing benefits, and limits access to this technology for other patients who may have greater need. Several recent reports suggest that PCPs overuse MRI in evaluating knee pain, and have called for the creation of educational programs and establishment of performance measures to address this issue. The aim of this study was to investigate the impact of this educational program on providers' utilization of MRI in the evaluation of knee pain.

### Methods:

Two hundred twenty seven providers from 13 VA medical centers participated in the MSK Mini-Residency between April 2012 and October 2014. All orders for knee MRIs submitted by these providers over the 12-months prior to their participation in the mini-residency (pre-training) were reviewed, as well as all orders submitted over the 12-months following their participation (post-training). MRIs were categorized as follows:

• Inappropriate: No prior weight-bearing x-rays done within the 12 months preceding the MRI order

• Probably Inappropriate: Findings of osteoarthritis (OA) described on x-ray report

• Possibly Appropriate: No findings of OA described on x-ray report.

The number of MRIs in each category was recorded for the pre-training and post-training period specific to each provider, and the number of MRIs in each category was tallied. Differences in the numbers of MRIs that were ordered post-training as compared to pre-training for each of the three categories were evaluated using paired Student's t-test (2-tailed).

### Results:

Numbers of MRIs ordered in the 12 months preceding training and following training for each of the categories described above are presented in the Table:

Category	Completed MRIs n (% of total)		Change n (% of change, p)
	12 Months Pre- training	12 Months Post- training	
Inappropriate	255 (76%)	180 (73%)	-75 (-29%, <0.005)
Probably Inappropriate	59 (18%)	34 (14%)	-25 (-42%, 0.09)
Possibly Appropriate	22 (7%)	31 (13%)	9 (41%, 0.23)
<b>Total</b>	<b>336 (100%)</b>	<b>245 (100%)</b>	<b>-91 (-27%, &lt;0.005)</b>

### **Conclusion:**

Following the MSK Mini-Residency program, the total number of MRIs ordered by participants decreased by 27%. This reduction was greatest in the number of studies classified as inappropriate. The total number of knee MRI orders that were categorized as either inappropriate or probably inappropriate decreased by 100 (32%), while the number of those that were possibly appropriate were not significantly changed. These findings provide further evidence that the VA MSK Mini-Residency program is effective in changing provider behavior and improving access to appropriate care for patients, though the high percentage of MRI scans classified as inappropriate indicate that additional work is needed in this area.

## **Two-Year Impact of a Continuing Professional Education Program to Train Primary Care Providers to Perform Arthrocentesis**

**Michael J. Battistone**<sup>1</sup>, Andrea Barker<sup>1</sup>, J. Peter Beck<sup>2</sup>, Phillip Lawrence<sup>3</sup> and Grant Cannon<sup>4</sup>, <sup>1</sup>Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, <sup>2</sup>Orthopaedics, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, <sup>3</sup>Salt Lake City VA Medical Center and Roseman University of Health Sciences, Salt Lake City, UT, <sup>4</sup>Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Initial reports of a local continuing professional education (CPE) program designed for primary care providers (PCPs) described an increase in the number of joint injections performed by those who had participated in the training.<sup>(1)</sup> The aim of this study was to examine the magnitude and durability of this behavioral change in a larger, geographically diverse impact of cohort of primary care providers. **Methods:** Thirty-eight primary care providers (PCPs) from 28 VA clinics representing 15 states participated in the week-long MSK “Mini-Residency” which was held at the Salt Lake City VA periodically between April 2012 and October 2013. The number of de-identified procedure codes performed by participants over the 24-months prior to their matriculation in the mini-residency (pre-training) were reviewed, and

compared to those performed 24-months following their participation (post-training). Differences in the numbers of procedure codes that were documented post-training as compared to pre-training were evaluated using paired Student's t-test (2-tailed). **Results:** Thirty-four PCPs (25 MDs/Dos, 9 PAs/NPs—89% of the total number of trainees) were clinically active in primary care following the program. The mean number of injection codes per provider, as well as the ranges and standard deviations for the physician and non-physician provider groups at 2-years and 1-year prior to the training, as well as at 1- and 2-years post-training are presented in the Table below. Differences in these numbers, as well as the percent change from the preceding period of observation, are also shown:

		Mean Injections/yr (% 1-year change; p) [Range, s.d]			
	N	2 Years Pre- Training Mean Injections/yr [Range, s.d.]	1 Year Pre- Training	1 Year Post- Training	2 Years Post- Training
MD/DO	25	12 [0-75, 20]	12 (0%; 0.92) [0-75, 18]	34 (183%; 0.02) [0-248, 54]	43 (26%; 0.26) [0-309, 81]
ARNP/PA	9	3 [0-12, 4]	3 (0%; 0.86) [0-12; 4]	16 (464%; 0.07) [2-54, 16]	43 (40%; 0.18) [2-74, 35]
Overall	34	10 [0-75, 17]	10 (0%; 0.96) [0-75, 16]	29 (205%; 0.004) [0-248, 48]	37 (28%; 0.17) [0-309, 71]

**Conclusion:** Results from the pilot program are confirmed at 2 years, showing sustained changes in clinical behavior, for both physician and non-physician provider groups. Substantial variance in the number of joint injections was observed across the participants, suggesting that after the training some providers expanded their clinical repertoire more than did others. These findings should inform decisions made by clinic managers and clinical leadership in selecting participants for a training opportunity designed to increase proficiency in joint injections. Additional investigation of the sources of variance in provider behavior following the mini-residency program is needed to better understand these results.

## Training Adult Rheumatology Fellows in Young Adult Transition and Transfer Skills

**Rebecca Sadun**<sup>1</sup>, Gary Maslow<sup>2</sup>, Richard Chung<sup>3</sup> and Lisa Criscione-Schreiber<sup>4</sup>, <sup>1</sup>Rheumatology Adult and Pediatric, Duke University Medical Center, Durham, NC, <sup>2</sup>Psychiatry and Pediatrics, Duke University Medical Center, Durham, NC, <sup>3</sup>Internal Medicine and Pediatrics, Duke University Medical Center, Durham, NC, <sup>4</sup>Internal Medicine, Duke University Medical Center, Durham, NC

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The transition from pediatric to adult healthcare is a vulnerable time for adolescents and young adults (AYA) with chronic conditions. EULAR and the Pediatric Rheumatology European Society jointly published expert opinions regarding transition care of AYA with juvenile-onset rheumatic diseases, and the ACR recently developed a transition toolkit. However, there are no published curricula for teaching transition guidelines, skills, or utilization of existing tools. We therefore designed and evaluated a workshop to help adult rheumatology fellows learn key skills for providing effective transition care to transferring young adult patients.

**Methods:** A 1-hour skills-based workshop on transition and transfer best practices was developed alongside an objective standardized clinical examination (OSCE) station in which trainees welcomed a young adult with lupus – and her parent – to a first visit in an adult clinic. Adult rheumatology fellows (n=19) from 5 institutions were asked to self-assess their ability to perform 10 transition/transfer skills pre- and post-workshop on a Likert scale from 1-4, with 1 being “not at all prepared” and 5 being “completely prepared.” The OSCE evaluation rubric assessed 5 transition/transfer skills on a Likert scale of 1-5, with 5 being the best performance. Twelve fellows were tested with the OSCE de novo, whereas 7 were tested with the OSCE after participating in the workshop. Aggregated pre- and post-workshop survey responses were compared using Fisher’s exact test, and OSCE scores were compared using an unpaired *t*-test.

**Results:** After participating in the workshop, fellows felt significantly more prepared with regards to 8 of the 10 transition/transfer skills (table 1). In addition, OSCE performance (table 2) was significantly better among the fellows who participated in the OSCE after the workshop than among those who took the OSCE de novo ( $p=0.01$ ).

**Conclusion:** This brief educational intervention successfully increased adult rheumatology fellows’ confidence with many transition/transfer skills as well as increasing fellows’ ability to employ transition best practices in an OSCE setting. Making this curriculum available to all rheumatologists-in-training would likely improve the care young adult rheumatology patients receive when transferring from pediatric to adult rheumatology. Further exploration is needed to determine optimal teaching strategies to enhance communication between pediatric and adult rheumatologist and to equip adult rheumatologists with rapport-building skills for working with young adults.

**Table 1**

Self-Assessed Preparedness Increased	Self-Assessed Preparedness Not Increased
Orient young adult to adult rheumatology care ( $p<0.01$ )	Establish rapport and trust with young adult patients ( $p=0.13$ )
Provide expectations of the young adult patient ( $p<0.01$ )	Speak w/ pediatric providers re transferring patients ( $p=0.07$ )
Explain differences between pediatric & adult care ( $p<0.01$ )	
Assess young adult self-management skills ( $p<0.0001$ )	
Assure young adult of confidentiality ( $p<0.001$ )	
Ask parent to leave the room for social history ( $p=0.01$ )	
Take a transition-focused adolescent social history ( $p<0.01$ )	
Identify barriers to transition and adherence ( $p<0.05$ )	

**Table 2**

	Explaining differences between pediatric and adult care	Placing the AYA patient in the primary role (parent for corroboration)	Assessing self-management skills	Performing a confidential adolescent social history	Assessing barriers to transition & adherence	Total score / Average score

## How Well Do Rheumatology Fellows Manage Acute Infusion Reactions? a Pilot Curricular Intervention

**Jason Weiner**<sup>1</sup>, Amanda M. Eudy<sup>2</sup> and Lisa Criscione-Schreiber<sup>3</sup>, <sup>1</sup>Department of Medicine, Division of Rheumatology and Immunology, Duke University Medical Center, Durham, NC, <sup>2</sup>Duke University Medical Center, Chapel Hill, NC, <sup>3</sup>Internal Medicine, Duke University Medical Center, Durham, NC

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Infusible DMARDs are commonly prescribed in rheumatology and other fields. There are no published formal educational curricula rheumatology fellowship programs can use to teach infusion reaction management skills to fellows. We aimed to better understand this educational gap, and implement and assess the effectiveness of an experiential curriculum on acute infusion reaction management.

### Methods:

We included current rheumatology fellows and recent graduates from five fellowship programs. Using a novel behavioral checklist, we assessed fellows' performance managing an infusion reaction in a simulation, followed by a didactic focused on infusion reactions. Pre and post-surveys assessed experiences to determine relevance, as well as attitudes and knowledge.

### Results:

Despite ubiquitous prescribing of infusible biologic DMARDs, >50% of fellows were uncomfortable managing infusion reactions and 11% preferred prescribing injections because of these concerns. Only 11% of fellows reported infusion reaction training during fellowship, but 56% reported managing actual patient infusion reactions. Graduates reported similar experiences with 67% currently utilizing infusion services within their immediate clinic areas and 50% having managed

actual patient infusion reactions. Furthermore, all graduates reported no specific training requirements prior to prescribing infusible DMARDs in their current practice. In the simulated infusion reaction, fellows managed grade 1 reactions appropriately, but grade 4 reactions poorly, meeting <50% of objectives. All fellows discontinued the infusion in the setting of anaphylaxis, but only 56% administered epinephrine. There was no difference in performance or written knowledge by training year. All fellows felt more prepared to manage infusion reactions post-curriculum and were satisfied with the experience. All graduates recommended fellows receive education on this topic.

## Conclusion:

We confirmed an education gap in rheumatology fellowship training regarding infusion reactions, both in knowledge and performance. We developed and implemented a brief experiential curriculum including simulation of a high-risk patient care scenario. This curriculum was well received and is easily exportable to other programs and fields of medicine.

## Has the Attractiveness of a Career in Rheumatology Changed for the Better? Comparison of Trends in the Rheumatology Fellowship Match from 2014 to 2017 with 2008 to 2013

Huynh Tran<sup>1</sup> and Richard Panush<sup>2, 1</sup>Special Project Manager, University of Southern California, Los Angeles, CA,  
<sup>2</sup>Rheumatology, Program Director, University of Southern California, Los Angeles, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:**

Rheumatology has been a less attractive career choice than most other medical subspecialties for many years. The 2015 American College of Rheumatology (ACR) workforce study, derived largely from rheumatology fellowship matching data from 2008 to 2013, projected a shortage of up to 4,729 full-time equivalent rheumatologists by 2030. However the attractiveness of rheumatology seems to have changed since 2014.

**◇Goals/Objectives:**

We therefore compared more recent trends in application and match rates in rheumatology with other popular medical subspecialties.

**Methods:**

We reviewed data from the National Resident Matching Program from 2008 to 2017, the ACR Rheumatology workforce study of 2015, and Medscape physician salaries from 2008 to 2017. We examined the numbers of applicants, numbers of fellowship positions, ratios of applicants-to-fellowship positions, percentages of offered positions filled, percentages of applicants who matched, percentages of US graduates in fellowships, and salary trends in rheumatology. We compared data for rheumatology with that for non-procedure-oriented medical subspecialties (endocrinology, hematology/oncology, infectious disease, and nephrology) and procedure-oriented medical subspecialties (cardiology, gastroenterology, and pulmonology/critical care medicine) and trends for 2008-2013 with those from 2014-2017.

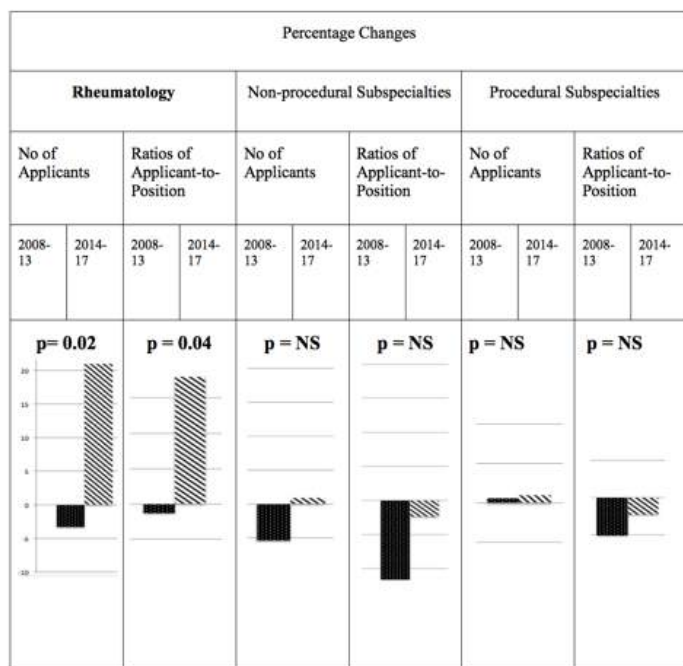

**◇Results:**

◇For rheumatology, the total number of applicants from 2008 to 2013 decreased from 251 to 230 (-8%) with an average annual percentage change of  $-3.32 \pm 2.8\%$  (mean  $\pm$  SEM) but from 2014 to 2017 increased from 230 to 332 (+44%) with an average annual percentage change of  $21 \pm 10.5\%$  ( $p = 0.02$ ) (Figure). For non-procedural medical subspecialties the total number of applicants from 2008 to 2013 decreased from 1,940 to 1,594 applicants (-18%) with an average annual percentage change of  $-5.42 \pm 3.4\%$  but from 2014 to 2017 increased from 1,594 to 1,714, (+8%) with an average annual percentage change of  $0.9 \pm 2.3\%$ . For procedural medical subspecialties the total number of applicants from 2008 to 2013, increased from 2,455 to 2,562 (+4%) with an average annual percentage change of  $0.6 \pm 1.4\%$  while from 2014 to 2017 the number of total applicants continued to increase from 2,562 to 2,631 (+3%) with an average annual percentage of  $1 \pm 1.1\%$ . The increase for rheumatology from 2014-2017 was significantly greater than changes in non-procedural specialties ( $p < 0.05$ ) (Figure). Trends for the other parameters examined generally supported the increased attractiveness and competitiveness of rheumatology.

**◇Conclusion:**

◇Our observations complement and extend the 2015 ACR workforce report. While a few years and perhaps relatively small quantitative changes may not constitute a lasting tendency, analysis of recent trends suggests that rheumatology has become a more attractive career choice since 2014.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Long-chain n-3 (also known as omega-3) polyunsaturated fatty acids (PUFA), especially eicosapentaenoic acid (EPA; 20:5n-3) and docosahexaenoic acid (DHA; 22:6n-3), have long-been considered to have anti-inflammatory and immunomodulatory actions. Both n-3 and n-6 series PUFA (determined by the number of carbon atoms between the methyl end of the fatty acyl chain and the first double-bond) cannot be synthesized *de novo* by animals. Findings relating to the dietary intake of n-3 PUFA and risk of rheumatoid arthritis (RA) are mixed. We compared erythrocyte membrane PUFA, as an accurate biomarker of PUFA status, between pre-RA individuals and matched controls from a population-based sample.

## Methods:

EPIC is a multicentre, pan-European prospective cohort study of apparently healthy populations. We undertook a nested case-control study, by identifying RA cases with onset after enrolment (pre-RA) in four EPIC cohorts: Naples, Turin and Ragusa in Italy, and Murcia in Spain. Identification and case validation has been previously described [1]. Confirmed pre-RA cases were matched with controls by age, sex, centre, and date, time and fasting status at blood collection. Total erythrocyte lipids were extracted and dissolved in toluene. Fatty acid methyl esters were synthesised and resolved in a BPX-70 fused silica capillary column using an Agilent 6890 gas chromatograph equipped with flame ionisation detection. We also measured the following serum cytokines: TNF $\alpha$ , IL-1 $\beta$ , IL-2, IL-4, IL-5, IL-6, IL-10, IL-12p70, IL-13 and IFN $\gamma$  (Meso Scale Diagnostics). Conditional logistic regression (CLR) analysis of data was adjusted for potential confounders including body mass index (BMI), waist circumference, education level, physical activity, smoking status, and alcohol intake. Negative binomial regression was used to test the relationship between PUFA and serum cytokine level, stratified by incident RA, and adjusting for age, sex, country of origin, BMI, and smoking status.

## Results:

The study analysed pre-symptomatic samples from 354 individuals of which 96 individuals went on to subsequently develop RA. In this analysis, time to diagnosis (defined as time between date of blood sample and date of diagnosis), was 6.71 years (SD 3.43).

No association was observed for any individual n-3 PUFA, or with total n-3 PUFA or total long chain n-3 PUFA, or with total n-3/n-6 ratio, and risk of RA. However a significant inverse association was observed with the n-6 PUFA linoleic acid (LA) level and pre-RA in the fully adjusted model (highest tertile : OR 0.29; 95% CI 0.12 to 0.75; p for trend 0.01).

Among the controls, LA was positively associated with serum levels of TNF $\alpha$  and IL-6 and negatively with IL-4, IL-5, IL-10, IL-12, IL-13 and IFN $\gamma$  in fully adjusted models. In the pre-RA population, LA was positively associated with TNF $\alpha$  and IL-1, and negatively with IL-6, IL-5, IL-12 and IL-13 levels.

## Conclusion:

In this nested case-control study within southern European prospective cohorts, high erythrocyte levels of the n-6 PUFA LA are associated with lower levels of T cell related cytokines and with lower risk of subsequent RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Studies have suggested a potential association between traffic pollutants and rheumatoid arthritis (RA), but findings have been inconclusive. We therefore assessed the risk of RA from occupational exposure to combustion products in a large population-based case-control study.

## Methods:

We included participants living in Sweden from 2006 to 2013. Incident cases of RA were enrolled from the Swedish Rheumatology Quality Register. Ten controls per case, matched on sex, age and county, were enrolled from the total population register. Work histories were available through population and housing censuses. We estimated exposure to asphalt fumes, diesel engine exhaust and polycyclic aromatic hydrocarbons from 1955 to 1995 with job-exposure matrices. Conditional logistic regression was used to estimate the risks of two histological subtypes of RA (seropositive or seronegative RA) from exposure to either of the combustion products taken separately or all of them combined. All main exposures were adjusted for potential confounding from each other as well as from respirable crystalline silica dust and household disposable income. The results are presented for men and women separately.

## Results:

We analyzed 9 180 cases and 81 367 controls. Ever exposure to diesel engine exhaust in men was associated with a marginally higher risk of seropositive RA (OR: 1.11, 95 % CI: 1.00-1.23), which was slightly higher among workers with at least 20 years of exposure (OR: 1.22, 95 % CI: 1.00-1.49). More than 20 years of asphalt fumes exposure was also associated with a higher risk estimate for seropositive RA among men (OR: 1.87, 95 % CI: 1.05-3.31). Being exposed to asphalt fumes, diesel engine exhaust or polycyclic aromatic hydrocarbons combined for more than 20 years resulted in an OR of 1.22 (95 % CI: 1.03-1.45) among men for seropositive RA and 0.98 (95 % CI: 0.77-1.23) for seronegative RA.

Women were less likely than men to have been exposed to combustion products during work and few female workers had been exposed for a longer period of time. Ever exposure to polycyclic aromatic hydrocarbons in women was associated with a potentially higher risk of seropositive RA (OR: 1.22, 95 % CI: 1.00-1.48). Women exposed to asphalt fumes, diesel engine exhaust or polycyclic aromatic hydrocarbons combined for more than 20 years had an OR of 0.91 (95 % CI: 0.36-2.29) for RA overall.

## Conclusion:

Long-term exposure to combustion products may increase the risk of seropositive RA among men after adjustments for potential confounders.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

Several studies have reported an association between exposure to pesticides and the risk of systemic lupus erythematosus (SLE). However, this association has not yet been examined in an urban population, where residential pesticide exposure is more common than agricultural exposure. The purpose of this study was to assess the risk of SLE associated with residential exposure to pesticides in an urban population of predominantly African-American females.

### **Methods:**

Female patients with SLE were identified via 6 hospital databases and community screening in 3 predominantly African-American neighborhoods in Boston, Massachusetts. Each SLE patient was reviewed by a rheumatologist and confirmed to have  $\geq 4$  ACR criteria for SLE. Subjects without SLE were female volunteers from the same neighborhoods, screened for the absence of connective tissue disease by questionnaire and finger stick anti-nuclear antibody. In-person interviews from April 2002 to August 2003 determined type and frequency of pesticide exposure prior to SLE diagnosis or corresponding reference age in subjects without SLE. Subjects were considered exposed to pesticides if they had ever required an exterminator for an ant, cockroach, or termite problem. The risks associated with exposure to pesticides were analyzed using multivariable logistic regression models, adjusted for age, race, parity, employment status, educational attainment, smoking status, and place of birth.

### **Results:**

93 SLE patients and 170 subjects without SLE were matched by age and race, with similar baseline characteristics (see table). Patients with SLE were more likely to have had exposure to pesticides than subjects without SLE (65% vs. 51%,  $p=0.03$ ). Pesticide exposure was associated with SLE, even after controlling for potential confounders (OR 2.24, 95% CI 1.28-3.93). A dose-response effect for increased frequency of exterminator service use was not statistically significant ( $p$  for trend=0.21).

### **Conclusion:**

Residential exposure to pesticides in an urban community of predominantly African-American women was associated with an increased risk of SLE, even after controlling for potential confounders. Our findings demonstrate that previous reports of

an association between pesticide exposure and SLE may be applicable to urban African-American women, a population at increased risk for SLE. As our results may be limited by recall bias and/or residual confounding, additional research is needed to determine whether pesticide exposure is implicated in SLE pathogenesis, or is instead serving as a surrogate for a related exposure such as pest burden or poor living conditions.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

The thymus is the site of T cell maturation and selection and thus of vital importance for the development of immunological tolerance. Early thymectomy is routinely performed in infants undergoing surgical correction of congenital heart defects. Various immunological changes have been described after early thymectomy but the long-term clinical consequences are unknown. The aim of this study was to investigate the association between early thymectomy and risks of autoimmune disease, cancer, infectious and atopic diseases.

### **Methods:**

The study is a nationwide population-based cohort study using the Medical Birth, Cause of Death and National Patient Registers in Sweden. We identified 5664 individuals born in 1973-2009 thymectomized before five years of age. For each individual, ten age and sex matched general population controls as well as 2276 surgery controls who had undergone early cardiac surgery, not involving thymectomy, were included. The main outcomes were incidence rates and hazard ratios for selected autoimmune diseases, cancer, infectious and atopic diseases.

### **Results:**

Compared to the surgery controls, thymectomized individuals were at increased risk for hypothyroidism (HR 3.03; 95%CI 1.17-7.83), type 1 diabetes (HR 3.16; 95%CI 1.08-9.21) and both viral (HR 1.40; 95%CI 1.30-1.50) and bacterial (HR 1.26; 95%CI 1.11-1.43) infections. The HR for asthma was reduced (HR 0.69; 95%CI 0.58-0.83). Compared to the general population, increased risks were detected for hypothyroidism (HR 4.94; 95%CI 3.27-7.46), juvenile idiopathic arthritis (HR 1.85; 95%CI 1.11-3.09), rheumatic diseases (HR 1.89; 95%CI 1.00-3.57), celiac disease (HR 1.96; 95%CI 1.42-2.72), cancer (HR 1.61; 95%CI 1.07-2.43), infections (HR 3.18; 95%CI 3.07-3.30) and asthma (HR 1.84; 95%CI 1.64-2.07) in thymectomized individuals.

### **Conclusion:**

In conclusion, early thymectomy is associated with increased risks of autoimmune disease, cancer as well as infectious disease. The study implicates important roles for the post-natal human thymus for the preservation of immunological tolerance as well as for immune effector functions. The results also indicate that avoidance of total thymectomy during early cardiac surgery may be advisable.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Symptomatic Hand Osteoarthritis (SxHOA) is a painful, destructive and deforming polyarticular disorder that is highly prevalent. The epidemiology of incident SxHOA and its association with metabolic processes is unclear with limited studies and conflicting results. We aimed to characterize individuals who develop symptomatic interphalangeal, thumb-based and erosive hand osteoarthritis and compare them to those who did not.

**Methods:** We evaluated 3604 participants in the Osteoarthritis Initiative (OAI) with complete data for baseline and 48-month radiographic hand OA. We defined interphalangeal OA as a hand with at least two joints with KL grade  $\geq 2$  on at least two fingers (digits 2 to 5), thumb-base OA using same KL criteria of either the CMC or STT joints, and erosive hand OA if one erosion was also present on any interphalangeal joint.

SxHOA required both presence of radiographic OA and symptoms (pain, aching, stiffness) on most days for the past 30 days. A metabolic syndrome score (MetS) was defined by summing presence of abdominal obesity (defined by gender-specific waist circumference), hypertension, diabetes, and dyslipidemia (range 0-4). Logistic regression was performed adjusting for age, sex and race for all models and other confounders (knee OA, smoking) depending on the outcome examined using a backward selection process to define the most parsimonious model.

**Results:** The overall 4-year incidence of symptomatic interphalangeal OA (SxIPOA), thumb-based OA (SxTBOA) and erosive hand OA (SxeHOA) were: SxIPOA n=536 (14.9%) ; SxTBOA n=551 (15.3%); SxeHOA n=150 (4.2%). Older age, female sex, and knee OA were associated with SxIPOA, SxTBOA, while SxeHOA was not associated with knee OA. Black race compared to whites was inversely associated with all three symptomatic hand OA sub-types. (Table 1) A monotonically increasing risk of SxIPOA was found related to MetS compared to no metabolic risk factors (1 component OR=1.36; 2 components OR=1.50; 3 or 4 components OR=1.59, P for trend <0.01). Of the MetS risk factors dyslipidemia was significantly associated an increased risk of SxIPOA (OR=1.34, 95% CI 1.09,1.65 and SxTBOA (OR=1.34, 95% CI 1.09,1.64) while hypertension was associated with incident SxeHOA (OR=1.52, 95% CI 1.06,2.18). MetS was not associated with SxTBOA or SxeHOA nor with incident radiographic defined IPOA, TBOA and eHOA unrelated to symptoms.

**Conclusion:** Metabolic syndrome risk factors demonstrate a monotonically increased risk for SxIPOA but not with radiographically defined IPOA. Further research into the metabolic pathways, sex and race differences in the progression of symptomatic hand OA appear warranted.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Early treatment of rheumatoid arthritis requires the early detection of arthritis. This is generally done by joint examination and difficult for general practitioners (GPs). To promote early recognition of arthritis, the Leiden Early Arthritis Recognition Clinic (EARC) was initiated, where GPs can send patients if in doubt about arthritis (instead of 'wait-and-see'). Although the EARC importantly improved the early identification, this approach may not be easily implemented at other places. This study determined the discriminative value of a combination of symptoms and other signs for clinical arthritis.

### Methods:

1,288 patients visited the EARC between 2010 and 2015. Symptoms and signs were studied with the presence of synovitis (joint examination by experienced rheumatologist) as outcome. Parameters were identified using multivariable logistic regression in 644 patients and validated in another 644 patients. A simplified rule was derived to facilitate application in clinical practice.

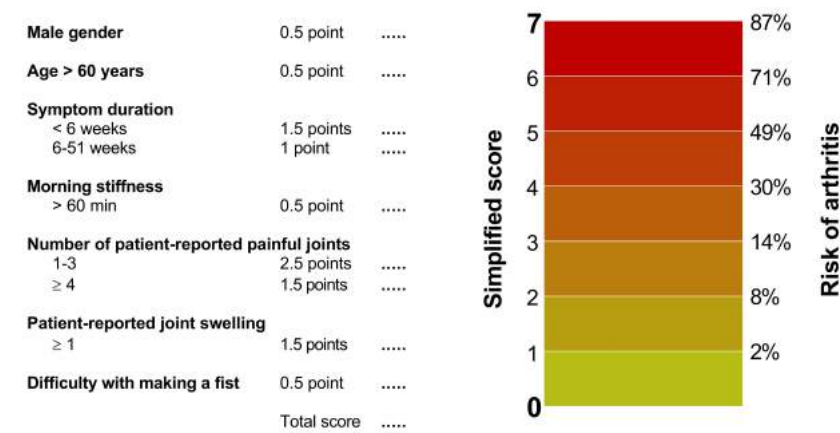

**Results:**

41% had arthritis at examination. Male sex, age  $\geq 60$  years, a short symptom duration, morning stiffness  $>60$  minutes, a low number of tender joints, the presence patient-reported swollen swelling and difficulties with making a fist were significantly associated with the presence of arthritis in the derivation cohort. A simplified rule, consisting of these 7 items, was generated (Figure); it had an AUC of 0.74 (95%CI 0.78-0.70). When a sensitive rule is preferred, a cut-off of  $\geq 4$  yields a sensitivity of 94%; when a specific rule is preferred the cut-off  $\geq 6$  has a specificity of 92%. Risks of arthritis were determined, and also estimated for a setting in which the prevalence of clinical arthritis in patients with suspected arthritis was half of that observed here.

**Conclusion:**

A rule composed of clinical parameters had a reasonable discriminative ability for clinical arthritis. Ultimately this could assist GPs in decision-making in patients with suspected inflammatory arthritis.

**Figure. The Clinical Arthritis Rule (CARE) and corresponding risks of the presence of inflammatory arthritis per score.**

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The Genome Research in African American Scleroderma Patients (GRASP) consortium was created to obtain a collection of African American (AA) scleroderma patients to facilitate genomic studies to identify novel genetic variants that could account for the increased scleroderma prevalence and severity in African Americans compared with individuals of European ancestry. In a companion abstract we report a genome-wide association study establishing significant genetic associations for AA scleroderma in the MHC and for *TGFB3*. Here we used MHC region genotypes to impute classical HLA types and analyzed their associations with scleroderma in the GRASP cohort.

**Methods:** SNP genotyping of 934 scleroderma cases and 946 controls was performed on the Illumina Multi-Ethnic Global array. We extracted the genotypes of 25,256 markers from 20 Mb encompassing the greater MHC region and used the Michigan Imputation Server with 1000G Phase 3 v5 reference and Eagle phasing algorithm to obtain input data for submission to the HLA\*IMP:03 web server. HLA types were converted to presence or absence genotypes (PP/PA/AA) for each typed allele and disease association was determined using a dominant model. Regression and conditional analyses were performed after recoding the genotype data to 0 or 1 using a dominant model and the top 10 principal components were included as covariates.

**Results:** The most significantly scleroderma-associated HLA type was a predominantly African allele, *HLA-DRB1\*08:04*, with odds ratio 2.95, 95%CI 2.26-3.85 (Figure 1). Regression analysis conditioning on the disease-associated alleles identified another African DRB1 allele, *\*11:02*, as well as *HLA-DPBI\*13:01*, and *HLA-DRB4\*01:01* as independent contributors to disease risk, but no association was found for MHC class I alleles (Figure 1). 34.6% of GRASP cases carry either *DRB1\*08:04* or *\*11:02* compared with 16.3% of controls. Analysis of 246 anti-topoisomerase antibody positive cases revealed a strong disease risk conferred by *HLA-DPBI\*13:01* ( $P=4.93 \times 10^{-17}$ , OR=4.10, 2.90-5.79). Remarkably, 30.49% of anti-topoisomerase antibody-positive cases carry *HLA-DPBI\*13:01*, compared with 9.7% of controls.

**Conclusion:** The scleroderma risk-associated *HLA-DRB1* types identified in the GRASP cohort differ from those reported in individuals of European ancestry. These HLA types are found at a higher population frequency than the European scleroderma risk types and therefore could contribute to the increased disease incidence or severity observed in African

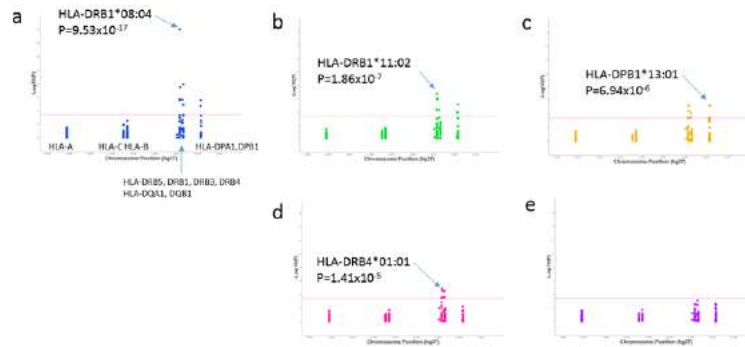

Figure 1: Conditional regression analysis in 934 cases and 946 controls identifies four HLA class II types that independently contribute to scleroderma in African Americans. a) Regression analysis, dominant model. b) Conditioned on *HLA-DRB1\*08:04*. c) Conditioned on *HLA-DRB1\*08:04* and *HLA-DRB1\*11:02*. d) Conditioned on *HLA-DRB1\*08:04*, *HLA-DRB1\*11:02*, and *HLA-DPB1\*13:01*. e) Conditioned on *HLA-DRB1\*08:04*, *HLA-DRB1\*11:02*, *HLA-DPB1\*13:01*, and *HLA-DRB4\*01:01*. ### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Among lupus patients, adherence to hydroxychloroquine (HCQ), the backbone of therapy, remains suboptimal. Individual-level factors, including younger age, poverty, and black race, have been associated with HCQ nonadherence. However contextual factors including neighborhood poverty and concentration of healthcare resources have not been examined. We constructed multilevel models to investigate whether zip code, county and state-level characteristics were associated with HCQ nonadherence.

**Methods:** We identified individuals with SLE enrolled in Medicaid (2000-2010) from 28 U.S. states using a previously defined algorithm. We included new users of HCQ (no use in  $\geq 6$  months) with  $\geq 12$  months of continuous enrollment with complete drug dispensing data following HCQ initiation. Adherence was measured over this 12-month period using the proportion of days covered (PDC) and defined as  $\geq 80\%$ . We identified individual-level characteristics (demographics, medications, comorbidities) from Medicaid data. We obtained zip code, county and state-level characteristics (percent of the population below the Federal poverty level (FPL), educational attainment and percent black population) from the American Community Survey. Health resource data (per capita hospitals, physicians, pharmacies and health professional shortage areas) were obtained from Area Health Resources Files. We used four-level hierarchical multivariable logistic regression models with Markov Chain Monte Carlo procedures to examine odds (OR [95% credible interval]) of adherence vs. nonadherence.

**Results:** Among 10,268 HCQ initiators with SLE residing within 4,930 zip codes in 1,414 counties in 28 states, 15% were adherent. After adjusting for individual-level characteristics, we observed lower odds of adherence across zip codes with higher percentages of black residents (highest tertile OR 0.81 [0.68-0.96] vs. lowest) (**Table**). The association remained after controlling for zip code percent below FPL and educational attainment. Odds of adherence were higher in counties with the greatest number of hospitals vs. the fewest (OR 1.32 [1.08-1.60]), and lower in health professional shortage areas (OR 0.86 [0.75-1.00]). There was no association with county-level per capita number of physicians or pharmacists. There was minimal variation in adherence by geographic area; the greatest was between states (1.4%).

**Conclusion:** Among Medicaid beneficiaries with lupus, after accounting for individual-level factors, we observed reduced odds of HCQ adherence in areas with higher percentages of black residents, fewer hospitals, and shortages of health professionals. Further studies are needed to assess whether racial residential segregation and poorer availability of high-quality medical care may contribute to racial differences in HCQ nonadherence and in turn, to disparities in lupus outcomes.

**Table:** Multilevel hierarchical logistic regression models examining the odds (OR with 95% credible interval) of adherence (PDC $\geq$ 80%) vs. nonadherence among 10,268 individuals with lupus within 4,930 zip codes in 1,414 counties in 28 states

Tertile 3					1.15 (0.87-1.47)

In all models, tertile 1 is the reference. All models are adjusted for individual-level age, sex, race/ethnicity, SLE risk-adjustment index, lupus nephritis, diabetes mellitus, antidepressant use, corticosteroid use, immunosuppressive medication use, number of lupus-related lab tests, number of medications, healthcare utilization, obesity, smoking and calendar year. All models account for zip code, county and state-level random effects. County and state-level models are adjusted for all individual-level characteristics as well as zip code-level percent black (Model 1). Model 1 was chosen from Models 1-2, and an additional model including educational attainment, because it had the lowest deviance information criterion (DIC). Models 3-5 included healthcare resource variables separately due to collinearity.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology

**Session Type:** ACR Concurrent Abstract Session

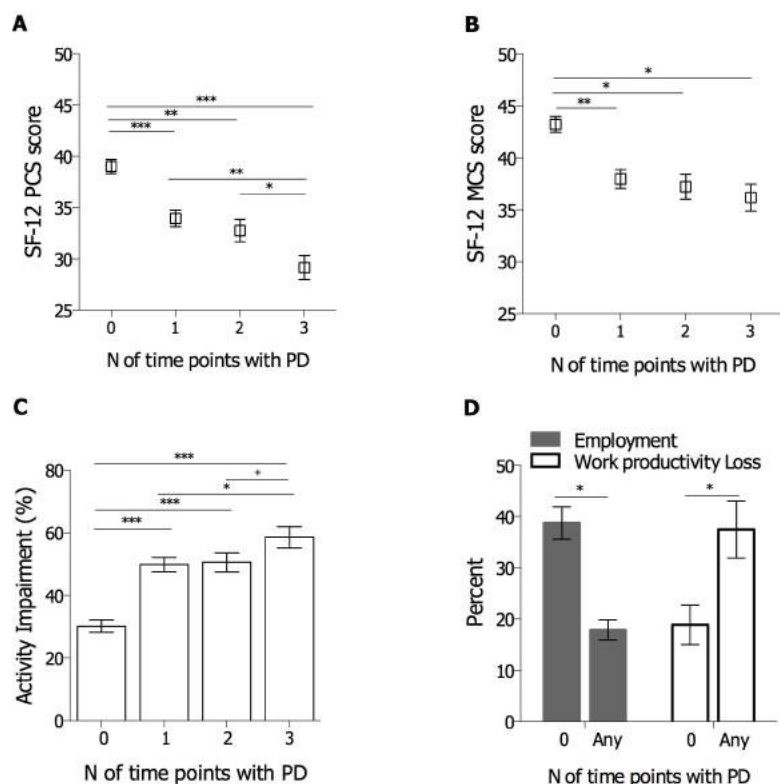

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The impact of discordant patient-physician assessments of rheumatoid arthritis (RA) activity on quality of life is largely unknown. We examined the prevalence and stability of discordance on serial visits, over two years, in a large cohort of Hispanics from a single center in the US; we further explored the influence of discordance -at any point- and its persistence on health-related quality of life (HRQoL) and work productivity upon final visit.

**Methods:** We evaluated 308 patients with established RA. Patient (PGA) and physician/ evaluator (EGA) global assessments were measured annually on 10-cm visual analogue scales; discordance was defined as a difference  $\geq 3$  cm between them. HRQoL was quantified using the SF-12 physical (PCS) and mental (MCS) component summary scores (higher scores indicate better HRQoL). Activity impairment, work productivity loss, presenteeism and absenteeism were calculated based on the Work Productivity and Activity Impairment Questionnaire. The impact of discordance and its persistence on HRQoL, activity impairment and employment-related outcomes at two years was assessed using analysis of covariance, adjusting for baseline values of those outcomes.

**Results:** Positive discordance (PD, or higher patient ratings) was more prevalent and stable over time ( $k$  range 0.32-0.36); 85 (27.6%) subjects had PD once, 49 (15.9%) twice, and 45 (14.6%) at all three time points. Negative discordance (ND, or lower patient ratings) was less common and unstable; 45 (14.6%) patients had ND once, 10 (3.3%) twice, and 1 (0.3%) at all three time points. Any PD throughout the study adversely impacted HRQoL upon last visit; persistence of PD yielded progressively lower SF-12 PCS (Fig 1A,  $p<0.001$ ), and SF-12 MCS was lower among patients with any PD compared to those without (Fig 1B,  $p<0.001$ ). Presence and persistence of PD yielded progressively greater activity impairment at final visit (Fig 1C,  $p<0.001$ ). PD was negatively associated with employment ( $p<0.025$ ); moreover, higher presenteeism ( $p=0.001$ ) and work productivity loss ( $p=0.014$ ) were seen with any PD (Fig 1D). PD appeared to be a patient-specific rather than a visit-specific feature; those with baseline PD had higher prevalence of fibromyalgia and irreversible articular damage (both  $p<0.01$ ), and were 5-times more likely to have future PD.

**Conclusion:** Positive discordance is common and generally stable over time. Its presence at any time- and persistence adversely and incrementally impact clinical outcomes, including health related quality of life, work productivity, and activity impairment upon final visit.

**Figure 1.** Impact of positive discordance and its persistence on final visit outcomes. Effect of number of time points with positive discordance over time on (A) SF-12 PCS, (B) SF-12 MCS, (C) activity impairment, and (D) predicted probability of employment and percentage work productivity loss upon final visit (two-year follow-up). ANCOVA models are adjusted for relevant covariates and baseline values of respective outcomes, with Benjamini-Hochberg corrected pairwise comparisons. SF-12 PCS, Short Form Health Survey physical component summary; SF-12 MCS, Short Form Health Survey mental component summary; ANCOVA, analysis of covariance. <sup>+</sup>  $p < 0.1$ , \*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$

## Biologic DMARD Prescribing Patterns in Elderly Patients with Rheumatoid Arthritis

Britney Jones<sup>1</sup>, Imran Hassan<sup>2</sup>, Walter P. Maksymowych<sup>3</sup> and Elaine Yacyshyn<sup>4</sup>, <sup>1</sup>University of Alberta, Edmonton, AB, Canada, <sup>2</sup>EPICORE Centre, University of Alberta, Edmonton, AB, Canada, <sup>3</sup>Department of Rheumatology, University of Alberta, Edmonton, AB, Canada, <sup>4</sup>Medicine, University of Alberta, Edmonton, AB, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Rheumatoid arthritis is a chronic inflammatory process involving progressive destruction of joints.

Currently, 30% of rheumatoid arthritis (RA) patients are over the age of 65. As the population ages, shifts in epidemiology and disease patterns will require an appropriate response from the healthcare system. Elderly patients frequently have more active disease; however, inequalities in prescribing patterns may favor more aggressive treatment in younger patients. There are myriad different reasons why this may be the case; elderly patients tend to have a higher number of comorbidities, more medications, and a greater degree of frailty.

Elderly patients with RA benefit from tight disease control and use of biologic Disease Modifying Anti-rheumatic Drugs (boDMARDs) minimizes the need for other medications. There is a growing body of evidence suggesting that patient outcomes do not significantly decline with age. The reluctance to use boDMARDs in the elderly from concerns around side effects paradoxically means these patients may be exposed to much more deleterious drugs such as glucocorticoids, narcotics, and NSAIDs that may be less desirable in the elderly population.

This study identified differences in biologic prescribing patterns between young (<65 years old) and elderly (> 65 years old) patients with RA. Secondary outcomes examined demographic variation and disease activity between patient age groups.

### Methods:

A retrospective cohort study of 1581 patients was conducted using information collected from the Rheumatoid Arthritis Pharmacovigilance Program and Outcomes Research in Therapeutics (RAPPORT) Database. This database encompasses an inception cohort of all RA patients in Northern Alberta starting treatment with biologics.

Fisher's exact test was used to determine the age of RA patients at first boDMARD prescription using the cutoff of young (<65 years old) and elderly (> 65 years old).

Wilcoxon-Mann-Whitney test was used to stratify disease activity in different age groups using the Health Assessment Questionnaire (HAQ) and Disease Activity Score (DAS28).

### Results:

A significantly larger proportion of young RA patients were prescribed boDMARDs compared with elderly RA patients (96.8% vs 90.0%;  $p = 0.006$ ). Elderly patients prescribed boDMARDs had significantly higher HAQ (mean 1.69 +/- 0.66;  $p = 0.001$ ) and DAS28 (mean 6.0 +/- 1.68;  $p = 0.002$ ) scores compared to younger patients (mean 1.41 +/- 0.72 and mean 5.29 +/- 1.7, respectively).

There was no statistically significant difference in other demographic information including sex, ethnicity, and years of schooling.

### Conclusion:

Despite current guidelines recommending early, aggressive disease control including the timely introduction of boDMARDs, this study suggests that a prescribing bias remains. Younger patients with lower levels of disease activity are more likely to receive biologic therapies than their elderly counterparts. While there was no statistically significant difference between the basic demographics of each cohort, patient's level of frailty and comorbid conditions were not accounted for in this study.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Health outcomes after total knee replacement (TKR) are generally worse for patients from high poverty neighborhoods. Whether education mitigates the effect of poverty is not known. We assessed the interaction between education and poverty on pain and function 2 years after TKR.

**Methods:** Patient-level variables - demographics, baseline and 2-year WOMAC pain and function scores, and geocodable US addresses - were obtained from an institutional TKR registry (5/07 - 2/11). Individual patient data were linked to US Census Bureau data at the census tract level. Statistical models including both patient-level and census tract-level variables were constructed within multilevel frameworks. Linear mixed effects models with separate random intercepts for each census tract were used to assess the effect of the interaction between education at the individual and census tract level and census tract poverty level on WOMAC scores at 2 years.

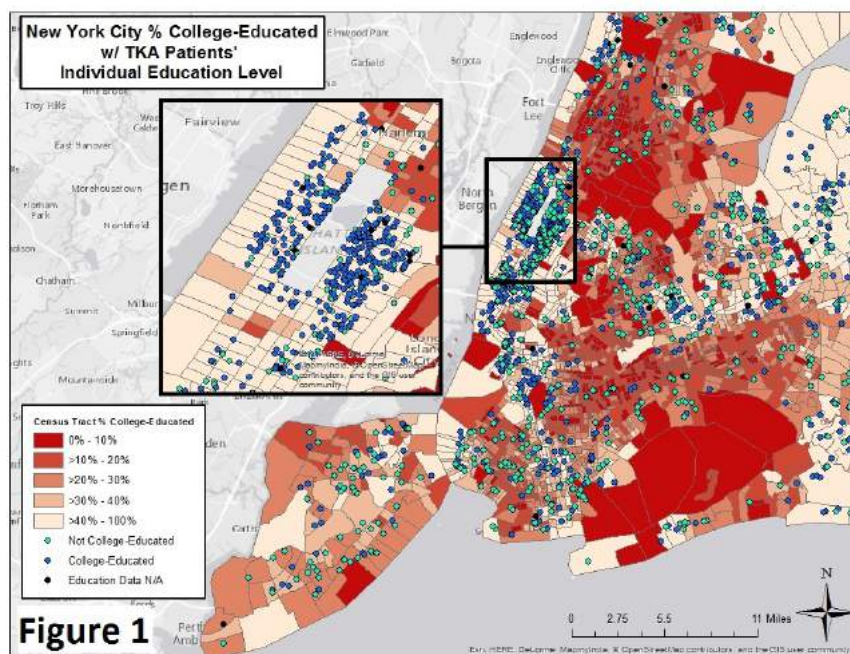

**Results:** Of 3970 TKR cases, 2438 (61%) were college-educated or above (**Table 1, Figure 1**). In the univariable analysis, race, sex, BMI, baseline WOMAC, and Medicaid were significantly associated with worse WOMAC scores at 2 years. In a linear mixed effects model, living in neighborhoods where <15% are college-educated and living in neighborhoods where ≥15% are below poverty were significantly associated with worse WOMAC pain ( $p=0.02$ ) and function ( $p=0.006$ ) at 2 years. There was little interaction between individual education and census tract education in our models, but when we assessed the interaction between individual education and community poverty, we found a significant interaction between them and WOMAC pain or function at 2 years. Comparing patients without college in high vs low poverty communities, WOMAC pain at 2 years was predicted to be 10 points lower (83.36 versus 72.75) and decreased in a linear fashion as community poverty increased, whereas patients with college had a difference in predicted WOMAC pain scores of only 1 point (87.10 vs. 86.09) (**Figure 2**); results for WOMAC function were similar.

**Conclusion:** In poorer communities, those without college education attain WOMAC scores 10 points lower than those with college education, a clinically meaningful difference. Education has no effect in wealthier communities. The reason education appears protective in poorer communities needs further study.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** High rates of rheumatoid arthritis and systemic lupus erythematosus have been described in indigenous North American (INA) populations. Few studies have investigated the prevalence or clinical patterns of juvenile idiopathic arthritis (JIA) in INA populations, but two studies have suggested high rates in specific regions of the US and Canada. The purpose of this project was to determine the prevalence of JIA overall and its subtypes in Alaska Native children statewide and to describe the clinical characteristics and treatment patterns of JIA in this population.

**Methods:** Potential cases of JIA were identified by a query of administrative data from the electronic health record of the Alaska Native Medical Center for codes possibly identifying JIA and from adult and pediatric rheumatology clinic databases. Cases were required to be under age 18 as of 9/30/2015 and to have a diagnosis of JIA confirmed by medical record abstraction. The denominator for prevalence was the 2015 Alaska Area Indian Health Service user population under the age of 18. Medical record abstraction was used to confirm the criteria met for JIA, subtype diagnosed, demographic features, other clinical characteristics, and medications ever used for treatment.

## Results:

The unadjusted prevalence of JIA in Alaska Native children was 67.5 per 100,000 (age-adjusted 71.7 per 100,000). JIA was more common in females than males (unadjusted prevalence 91.2 vs. 45.5 per 100,000). Oligoarthritis was the most common subtype (32% of cases), but enthesitis-related arthritis was also common (26.3% of cases). The mean age at diagnosis was 9 years and the prevalence was highest in children aged 16-18. During the one year study period, cases had a mean of 2.2 visits to a rheumatologist. Of the combined cohort, 53% had a positive ANA, 26% had positive rheumatoid factor, 24% had positive anti-CCP antibody, and 26% had the presence of HLA B27. Uveitis had been diagnosed in 26% of cases. Methotrexate was the most commonly prescribed non-biologic DMARD (ever prescribed in 66% of cases) and adalimumab was the most commonly prescribed biologic (in 32%).

**Conclusion:** The prevalence of JIA in Alaska Native children may be slightly higher than the general US population. Enthesitis-related arthritis makes up a higher proportion of cases than in other populations described, likely because of the high prevalence of HLA B27 in this population.

## Open-Source Consensus-Based Models to Improve the Cost-Effectiveness of Rheumatology Care

Devin Incerti<sup>1</sup>, Jeffrey R. Curtis<sup>2</sup>, Maria Lorenzi<sup>1</sup> and Jeroen Jansen<sup>1</sup>, <sup>1</sup>Innovation and Value Initiative, Oakland, CA, <sup>2</sup>Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Clinical Practice/Patient Care/Health Services Research

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The treatment and prognosis of moderate to severe rheumatoid arthritis has improved considerably due to the advent of biological therapies. But at the same time, the high costs of treatment are a threat to affordability and access to patients, and highlight the need for cost-effectiveness models that can help align prices with value. Unfortunately, there is no consensus in the literature on the proper mathematical structure for these models and estimates of value vary widely. Moreover, new evidence on the efficacy of biologics is rapidly evolving, so estimates of value must be updated as the evidence base evolves. Transparent, flexible, and accessible cost-effectiveness models that shed light on the implications of different modeling approaches are needed.

**Methods:** We developed an open-source “family” of cost-effectiveness models that reflects a number of scientifically defensible approaches and variation in the perspectives of decision makers. The code is publically available on GitHub, a version control repository, and the model has been released as an R package. We also created a user-friendly web application where users can modify parameter values or structural assumptions and run the model online. We used the models to compare the cost-effectiveness of a standard sequence of 6 biologics treatments to conventional disease-modifying antirheumatic drugs (cDMARDs) using a number of different modeling assumptions.

**Results:** Under various plausible assumptions, incremental cost-effectiveness ratios (ICERs) ranged from less than \$100,000 to around \$300,000. Biologics were predicted to be more cost-effective when they had a larger effect on the Health Assessment Questionnaire (HAQ) Disability Index score at 6 months, increases in the HAQ score were assumed to lead to larger increases in mortality, the drop in clinical efficacy after each treatment failure was smaller, the HAQ score on cDMARDs progressed more quickly over time, biologics were assumed to be discounted more from their wholesale acquisition cost, and productivity losses were larger. For example, under our baseline assumptions, the ICER was approximately \$120,000 when the effect of treatment on HAQ did not decline after the first treatment failure and over \$200,000 when we assumed no clinical efficacy after 1st line treatment. In addition, subgroup analyses conducted using our baseline assumptions indicated that biologics were more cost-effectiveness in younger patients, with ICERs ranging from \$100,00 at age 35 to \$165,000 at age 70.

**Conclusion:** Estimates of value vary considerably across different modeling assumptions, suggesting that steps must be taken to shrink diversity in modeling approaches and evidence considered to the greatest extent possible. These include new research studies and processes to encourage collaboration.

## Relationship of Traumatic Knee Injuries to Early-Onset Knee Osteoarthritis in Young Military Officers

**Yvonne M. Golightly**<sup>1</sup>, Maryalice Nocera<sup>2</sup>, John Cantrell<sup>2</sup>, Jordan B. Renner<sup>3</sup> and Stephen W. Marshall<sup>4</sup>, <sup>1</sup>Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Injury Prevention Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>UNC School of Medicine, University of North Carolina, Chapel Hill, NC, <sup>4</sup>Epidemiology, University of North Carolina, Chapel Hill, NC

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Clinical Practice/Patient Care/Health Services Research

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Traumatic knee injuries, such as tears and ruptures of the anterior cruciate ligament (ACL) and/or menisci, are associated with osteoarthritis (OA). Surprisingly little is known, however, about the etiology and pathology underlying this association. Large epidemiologic studies of populations with high rates of knee injury are needed to enhance our understanding of the onset and progression of injury-mediated OA. We investigated radiographic OA, symptoms, and patient-reported outcomes in military officers with and without a history of traumatic knee injury.

#### **Methods:**

Participants were 439 military officers who either had a history of ACL and/or meniscal injuries (knee injury group) or were injury-free (uninjured group). Participants were recruited from an existing cohort of 6452 military officers originally enrolled between 2004 and 2008 as matriculating cadets at the U.S. Air Force Academy, U.S. Military Academy, or U.S. Naval Academy. The knee injury group (n=167) experienced ACL/meniscal injuries prior to, during, or after their 4-year academy career. The uninjured group (n=272) was site-matched from the same source cohort but had no history of ACL/meniscal injuries. Injury status was established using a self-reported injury history questionnaire, confirmed by clinical record review. Knee OA was assessed using 1) a single-item measure of knee pain, aching, or stiffness in the past 30 days, 2) a patient-reported knee outcome measure (Knee injury and OA Outcome Score [KOOS]; 0 [extreme] - 100 [no problems]), and 3) standardized weight-bearing posteroanterior radiographs of the tibiofemoral joint obtained using a fixed-flexion knee positioning frame. Radiographic knee OA was defined as Kellgren-Lawrence grade  $\geq 2$ . Knee-injured and non-injured groups were compared using descriptive statistics and prevalence ratios (PR) with 95% confidence intervals (95%CI).

**Results:** Enrollment was completed on March 31, 2017, and collection of survey and radiographic data is on-going. Currently available data are presented. Among 403 participants with survey data, mean age was 28 years and mean body mass index was 25 kg/m<sup>2</sup>. Per the parent cohort, 40% were women. Mean time from first ACL/meniscal injury to follow-up assessment was 8.6 years. Among participants with available knee radiographic data, 19.0% (16/84) of knee-injured had radiographic knee OA, compared to 0% (0/104) of the uninjured (PR=40,  $p<0.001$ ). Nearly 38% (51/136) of participants with knee injury reported moderate-severe symptoms vs. 13% (20/156) of the uninjured (PR=2.9, 95%CI: 1.8, 4.7,  $p<0.001$ ). Among 292 participants with available KOOS data, the knee-injured had clinically-relevant deficits on KOOS symptoms, sports/recreation, and quality of life scales (mean differences: -7.7, -8.1 and -11.0, respectively vs. non-injured, all  $p<0.001$ ).

**Conclusion:** Traumatic knee injuries are strongly linked to early-onset knee OA, which greatly impacts quality of life and knee function during physically-vigorous activities. At a mean age of <30 years, young officers with a history of knee trauma experience substantial limitations from OA that impede their military performance.

## **Do Familiarity with Centers for Disease Control Guidelines, Continuing Education, and Provider Characteristics Influence Adherence to Chronic Pain Management Practices and Opioid Prescribing?**

**Kim Jones**<sup>1</sup>, Ronald Friend<sup>2</sup>, Robert M. Bennett<sup>1</sup> and Jean McCalmont<sup>3</sup>, <sup>1</sup>Schools of Nursing and Medicine, Oregon Health & Science University, Portland, OR, <sup>2</sup>School of Nursing, Oregon Health & Science University, Portland, OR, <sup>3</sup>Nursing, Oregon Health & Science University, Portland, OR

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Clinical Practice/Patient Care/Health Services Research

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** 1) To evaluate providers' experience and knowledge with chronic pain management and opioid use with actual utilization of the Centers for Disease Control's 2016 *Guidelines for Prescribing Opioids for Chronic Pain*. 2) To evaluate the specific influence of continuing education (CME), familiarity with CDC guidelines, and provider profession and region on confidence and best practice adherence in chronic pain management.

### Methods:

A cross-sectional, web-based survey conducted between January and April of 2017 with a convenience sample of 417 Oregon prescribing providers consisting of 210 MD and 207 NP participants (Urban/Rural= 64/36%; Age= 49.7 sd=12.2, Female=32%, Years of Practice= 15.7, sd=12.3). Measures included CME hours in past 2 years (minimal, 0-3; moderate, 4-10; high, 11 or more) and CDC familiarity (not read or read not applied vs. read and applied). Primary outcome variables included provider confidence in pain management (0-9), opioid conversion confidence (0-9), and adherence to best practices (opioid risk tool, urine drug screening, opioid treatment agreement, Oregon Prescription Drug Monitoring Program; all Likert, 0-5). Multivariate analysis of variance (MANOVA) and Chi-Square were used to analyze the influence of CME, CDC familiarity, provider profession and regional medical setting on provider best practices and confidence ratings.

**Results:** CME hours was significantly associated with increased use of opioid best practices (2.6, 3.2, 3.8;  $p < .001$ ; scale 0-5), opioid conversion confidence (5.5, 6.5, 7.4;  $p < .001$ ; scale 0-9) and confidence in pain management (5.5, 5.9, 6.9;  $p < .001$ , scale 0-9). Providers familiar with CDC guidelines were only slightly more likely to apply best practices than were not (57% vs 43%), while increases in CME were more strongly associated with CDC best practices use (42% vs 57% vs 72%;  $p < .001$ ). Neither providers professional status (MD vs NP) nor regional setting (urban vs. rural) showed differences in opioid best practices or general confidence in pain management with the exception of opioid conversion confidence where NPs reported slightly less than MDs (5.9 vs. 6.9;  $p < .001$ , scale 0-9) and rural slightly *more* than urban providers (6.8 vs 6.2;  $p < .05$ ; scale 0-9).

**Conclusion:** Results demonstrate that recent CME in chronic non-cancer pain positively benefits provider confidence in pain management and application of best practices, as defined by the CDC guidelines. Nurse Practitioners and rural providers were found to provide equivalent adherence to best practices and confidence levels to their MD and urban counterparts, with minor exceptions.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Clinical Practice/Patient Care/Health Services Research

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** China doesn't have efficient primary medical care and referral system. Patients can choose any hospitals or any doctors they like to seek medical care. As a result, most patients with rheumatic diseases rushed to a few large cities. Surveys showed that more than 40% of the rheumatic disease patients were unnecessary to go to hospital and they only need advices from specialist. Smart System of Disease Management (SSDM) is a series of applications for chronic diseases management, which strengthens the interaction between doctors and patients based on valuable clinical data. Our previous study showed that rheumatoid arthritis (RA) patients can master the SSDM and perform self-management after training, including disease activity score with 28 joints (DAS28) and health assessment questionnaire (HAQ) evaluations, as well as medication and lab test data entries. The purpose of this study is to evaluate the feasibility and benefit of the medical economics of online consultation based on SSDM by rheumatologist.

**Methods:** The rheumatologists implemented the education and training programs on patients in using SSDM and assist the patients in downloading SSDM mobile application. The SSDM includes doctors' and patients' interfaces. The patient's terminal system includes self-assessment (DAS28, HAQ), medication management, adverse events management and laboratory records. After data entry, patients can synchronize data to the authorized doctor. On the basis of these data, the rheumatologists can accept the request from their follow-up patients and practice consultation through SSDM in the form of text or voice.

**Results:** From February 2015 to June 2017, 403 rheumatologists supplied 4,002 patients (RA 42%, systemic lupus erythematosus 21%, ankylosing spondylitis 11%, gout 10%, osteoarthritis 5%, Sjogren syndrome 3% and other rheumatic diseases 7%) with 293 free and 3,709 paid consultations. Paid consulting included 3,983 times text Q&A and 19 voice consultations. The consulting fee ranged from RMB 10 to 500 yuan (USD: RMB =1: 6.81) each in average of  $96.06 \pm 38.61$  yuan, which match the registration fee in hospital. The total collection of fee for consultations was 477,960 yuan RMB. 35.3% patients receiving online consultation lived in different city with the rheumatologists. If patients seek medical care in hospital, in addition to the registration fees and medical expenses, the mean cost of transportation, accommodation, meals and lost wages was  $565.17 \pm 510.49$  (200 - 2,800) yuan. The total of cost for all patients would have been 3,157,220 yuan RMB, which is 6.61 times higher compared with the cost of online. Online consultations through the SSDM can save 84.86% of the cost for patients. Survey shows that all patients were satisfied and 66.35% of them were "very satisfied" with the consultations.

**Conclusion:** Through online consultations using SSDM system, Chinese patients with rheumatic diseases can enjoy reduced cost with high satisfaction. In the era lack of primary care system in China, SSDM may serve as a complimentary platform to control medical care cost, as well as develop a new partnership between physicians and patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Clinical Practice/Patient Care/Health Services Research

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** We have previously shown that 24% of the patients in a SLE-cohort study (n=84) reported high levels of SLE-related pain (VAS $\geq$ 40 mm), and also impaired HRQoL, more fatigue, higher levels of symptoms regarding anxiety and depression. In contrast, the patients reporting  $\leq$ 39 mm on VAS did not differ from the controls regarding patient reported outcomes. We have now investigated the variation in SLE-related pain and its association with chronic widespread pain (CWP) and patient-related outcomes after seven years of follow-up.

**Methods:** 64 of 84 patients agreed to participate in the 7-year follow-up and answered questionnaires on pain (VAS/mm), fatigue (MAF), HRQoL (SF-36), anxiety and depression (HADS) and, in case of remaining pain > three months, marked painful body regions on a pain-drawing. Disease activity and damage (SLAM, SLEDAI, SLICC) were also captured. Nonparametric statistics were used, and difference in measures (diff) between inclusion and follow-up was calculated.

**Results:** For the patients with low levels of SLE-related pain the previous week ( $\leq$ 39 mm on VAS) at inclusion, n=50, there were no significant difference at 7 years follow-up in pain, fatigue, anxiety, depression and most dimensions of SF-36. Of these patients with low level of pain, 26% indicated chronic widespread pain on the pain drawing.

Among patients with high degree of pain ( $\geq$ 40 mm VAS) at inclusion, n=14, half of the patients reported significantly decreased pain, diff (IQR) 45 (35 to 65), p=0.021, fatigue, 8 (8 to 17), p=0.018, anxiety, 4 (1 to 4), p=0.035 and depression, 4 (2 to 5), p=0.018 and improvements in most dimensions of SF-36.

However, half of the patients with high degree of pain at inclusion reported no significant changes at follow up regarding pain, median diff (IQR) -13 (-20 to 28), fatigue, 5 (-0.3 to 6), anxiety, 2 (-1 to 3) and depression, 0 (-3 to 2). These patients reported significant deterioration in vitality in SF-36 but no significant changes in the other dimensions of SF-36. All patients with high remaining pain indicated chronic widespread pain on the pain drawing. These patients with remaining pain had significantly higher SLAM at follow-up compared to the patients with decreased pain at follow-up, p=0.017 and the patients with low levels of pain at inclusion, p=0.006. No significant differences were found in SLEDAI and disease damage

**Conclusion:** For most patients, pain and other patient reported outcomes remained low or improved after seven years. However, a minority of the patients reported remaining high levels of pain after seven years, and were characterized by a heavy symptom burden with widespread pain more than three months, high levels of pain-related problems, impaired health-related quality of life and remaining high levels of fatigue. The results highlight the heterogeneous nature of SLE and stresses the needs of special attention to vulnerable sub-groups of patients with SLE.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Clinical Practice/Patient Care/Health Services Research

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) can affect young women and pregnancy still represents a challenge. Prednisone is safely used, at low doses (<7.5 mg daily), during pregnancy. Modified-release prednisone (MRP) optimize corticosteroid treatment strategy in rheumatic diseases, thanks to its capability of respecting the physiological cortisol circadian secretion. MRP has been approved from FDA in SLE treatment, but no data are available regarding its administration during pregnancy.

We aimed to investigate whether this drug is safe and effective as the immediate release prednisone (IRP) in SLE pregnant patients.

**Methods:** We retrospectively evaluated 9 female patients, fulfilling the ACR criteria for SLE, consulting our centers in a 4-years observational range. All of them, thanks to a stable disease (not requiring treatment regimen modifications within 12 months), experienced a successful pregnancy during the observation. All the cases were taking low-dose MRP (5 to 7.5 mg/daily) as a baseline treatment, from at least 6 months. They were matched to 9 controls, defined as SLE patients with the same age and duration of disease, taking the same prednisone dose, from at least 6 months, in the IR formulation. Age of patients and disease duration (months); overall pregnancy outcome features; SLE disease activity (calculated at least once during pregnancy, SLEPDAI) and at baseline/post-partum (SLEDAI) score; patient's global assessment (VAS) at baseline, during pregnancy and in postpartum (mm); need of treatment changes throughout pregnancy and at postpartum (%) were assessed. Homogeneity tests, percentages and scores comparison were run out by non-parametric statistical analysis.

**Results:** Mean MRP age group was 312±52 months; disease duration, 48±96 months; IR one, respectively, 336±43 and 36±108 (both, p=ns). SLEDAI at baseline was 1±0.1 among MRP and 1±0.3 among IR women; SLEPDAI, 1±0.9 and 2±0.2 (both, p=ns). No major perinatal complications were detected. Preterm births, caesarean section rates, newborn's weight and APGAR scores, assessed 5 minutes after delivery, did not differ between the two subpopulations (all, p=ns). SLEDAI assessed at postpartum was 2.8±0.6 in MRP subjects and 3.4±0.4 in IR (p<0.05). Patients VAS (MRP vs IR) was 3±0.4 and 2±0.9 at baseline (p=ns); 2±0.6 and 4±0.7 during pregnancy (p<0.05) and 3±0.3 and 4±0.9 at postpartum (p<0.05). Regarding treatment regimen changes (add-on strategy), the observed rates involved 1/9 (MRP) and 5/9 (IR) women during the observational gap (pregnancy+postpartum) (p<0.001).

**Conclusion:** Activity (SLEDAI) score was significantly higher at postpartum and treatment had to be increased in IR patients, in comparison to the MRP, to manage SLE. VAS, conversely, was significantly higher among IR, both during pregnancy and postpartum. No major perinatal side effects were observed during the study; minor and expected complications rates did not differ between the two subpopulations. Despite the limited number of subjects, MRP treatment seems to be as safe, but more effective, in comparison to the standard IR one, during pregnancy of SLE-affected women.

## Dose-Response Effects of Tai Chi and Physical Therapy Exercise Interventions in Symptomatic Knee Osteoarthritis

Augustine Lee<sup>1</sup>, William F. Harvey<sup>2</sup>, Lori Lyn Price<sup>3,4</sup>, Xingyi Han<sup>1</sup>, Jeffrey B. Driban<sup>1</sup>, Maura D. Iversen<sup>5,6</sup>, **Raveendhara R. Bannuru**<sup>1</sup> and Chenchen Wang<sup>2</sup>, <sup>1</sup>Rheumatology, Tufts Medical Center, Boston, MA, <sup>2</sup>Rheumatology, Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA, Boston, MA, <sup>3</sup>Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA, <sup>4</sup>Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, <sup>5</sup>Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>6</sup>Department of Physical Therapy, Movement & Rehabilitation Sciences, Northeastern University, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

**Session Type:** ACR Concurrent Abstract Session

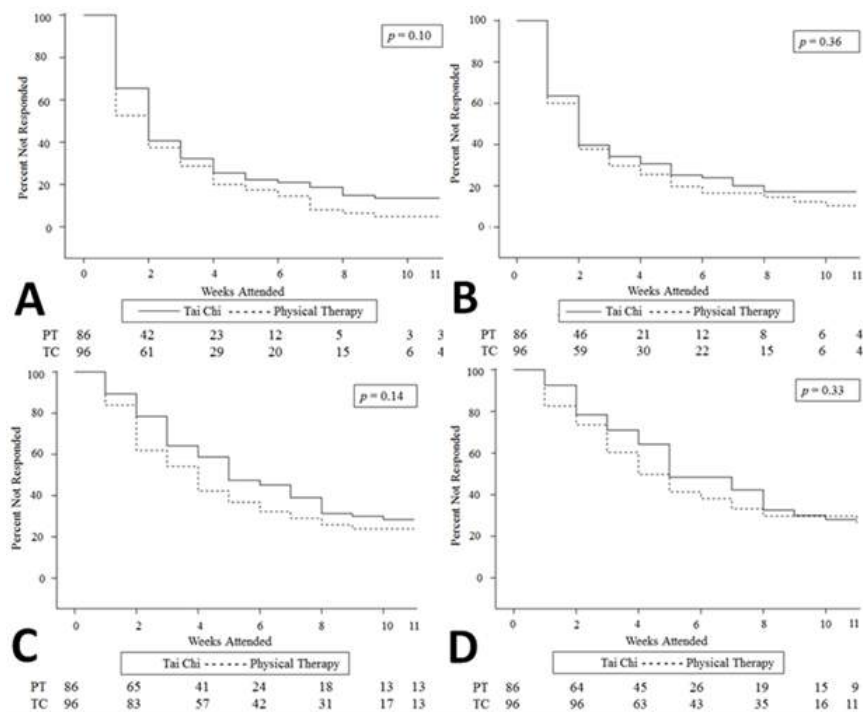

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Therapeutic exercise is the recommended non-pharmacological treatment for knee osteoarthritis (OA). However, the optimal treatment dose and clinically meaningful treatment durations remain unclear. Our purpose was to examine dose-response relationships, the minimum effective dose, and baseline factors associated with the timing of response from two exercise interventions among adults with symptomatic knee OA.

**Methods:** Secondary analysis of a single-blind, randomized trial comparing 12-week Tai Chi and Physical Therapy exercise programs among adults with symptomatic knee OA (ACR Criteria). WOMAC pain (0-500) and function (0-1700) scores were completed each week of intervention. We defined dose as attendance-weeks (i.e. total treatment weeks attended), and treatment response as  $\geq 20\%$  and  $\geq 50\%$  improvement in pain and function. Using log-rank tests, we compared time-to-response between interventions, and used Cox regression to examine baseline factors associated with the timing of response ( $\geq 50\%$  improvement only).

**Results:** We examined 182 participants (mean age 61 years, BMI 32 kg/m<sup>2</sup>, 70% female, 55% white). Both interventions had linear dose-response effect resulting in a 9 to 11-point reduction in WOMAC pain and a 32 to 41-point improvement in function per week. There was no significant difference in overall time-to-response for pain and function between treatment groups (**Figure**). Median time-to-response for  $\geq 20\%$  improvement in pain and function was 2 attendance-weeks and 4 to 5 attendance-weeks for  $\geq 50\%$  improvement. On unadjusted models, we found a general pattern wherein physical health factors, self-efficacy, and outcome expectations tended to be significantly associated with treatment response rather than psychosocial or biomechanical factors (**Table**). On multivariable models, outcome expectations were independently associated with incident function response (Hazard Ratio: 1.47; 95% CI: 1.004 to 2.14).

**Conclusion:** Both interventions had linear dose-dependent effects on pain and function, their minimum effective doses ranged from 2 ( $\geq 20\%$  improvement) to 5 weeks ( $\geq 50\%$  improvement), and patient-perceived benefits of exercise independently influenced the timing of response among adults with symptomatic knee OA. These results may help clinicians optimize patient-centered exercise treatments and better manage patient expectations.

**Figure (A-D). Time-to-Response from Tai Chi and Physical Therapy Interventions in Knee OA:** PT= Physical Therapy; TC= Tai Chi. Kaplan-Meier curves for  $\geq 20\%$  improvement in pain (**Panel A**) and physical function (**Panel B**); and for  $\geq 50\%$  improvement in pain (**Panel C**) and physical function (**Panel D**) by attendance-week.  $P$ -values refer to log-rank tests comparing overall time-to-response between interventions. The number "at risk" (i.e. participants not responded) is listed at each cumulative attendance-week by treatment group.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Varus knee thrust is an abrupt change in frontal plane tibiofemoral alignment observed during gait. Thrust has been linked to radiographic knee OA progression and worsening cartilage and bone marrow lesions. In addition, thrust has been cross-sectionally linked to knee pain presence during weight-bearing. *Our objective was to determine the longitudinal effect of knee thrust on worsening knee pain over 2 years in older adults with or at risk for OA.*

**Methods:** The Multicenter Osteoarthritis Study (MOST) is a prospective cohort study of older Americans with or at risk for knee OA. At the 60-month clinic exam, 60 Hz frontal plane videos recorded participants completing two self-paced walking trials over a 4.9 meter walkway. A trained reader, blinded to disease status, assessed the presence of varus thrust on a majority of steps (intra-rater  $\kappa = 0.73$ ). Pain in each knee while walking, using stairs, standing upright, sitting, and in bed was assessed using the WOMAC questionnaire at 60 and 84 months. Among knees with submaximal WOMAC scores at 60 months, worsening pain at 84 months was defined as any increase in WOMAC score, and clinically important worsening was defined as an increase of  $\geq 1.28$  in WOMAC score. To assess the relation of thrust to worsening knee pain, we used logistic regression with generalized estimating equations to account for non-independent limbs from a subject, adjusting for age, sex, race, BMI, and gait speed. We repeated the analysis on a subset of knees with baseline WOMAC scores of 0 to assess the relation of thrust to incident WOMAC knee pain. We also assessed the relation of thrust to worsening knee pain in a subset of knees without baseline radiographic OA (Kellgren-Lawrence (KL) Grade  $< 2$ ).

**Results:** 1623 participants (mean age  $67.2 \pm 7.6$  years, mean BMI  $30.4 \pm 5.9$ , 59.9% female, 88.7% White) contributed 3204 knees. Varus thrust was observed in 31.5% of knees. At baseline, mean total WOMAC pain was 2.40, and 41% of knees had radiographic knee OA (KL  $\geq 2$ ). Knees with a varus thrust had 1.45 (95% CI: 1.22, 1.72) and 1.46 (95% CI: 1.20, 1.77) times the odds of any worsening and clinically important worsening total WOMAC pain, respectively, compared to knees

without thrust; this increased pain was consistent across all WOMAC listed activities (see Table) and among the subset of knees without radiographic knee OA at baseline (OR = 1.39; 95% CI: 1.06, 1.82). Among knees with no WOMAC pain at baseline, knees with thrust had 1.81 times the odds (95% CI: 1.35, 2.41) of incident pain at two years compared to knees without thrust.

**Conclusion:** Varus knee thrust observed during walking is associated with increased odds of worsening knee pain during both weight-bearing and non-weight-bearing activities in older adults with or at risk for OA. Given that thrust is potentially modifiable using non-invasive therapies, detecting thrust provides an opportunity to prevent worsening knee pain in these populations.

Felson<sup>3</sup>, <sup>1</sup>Boston University School of Medicine, Boston, MA, <sup>2</sup>Boston University School of Public Health, Boston, MA, <sup>3</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Sleep and pain have been shown to be reciprocally related. Studies have suggested a stronger effect of sleep impairment on chronic pain such as fibromyalgia and widespread pain than pain effects on sleep quality. In this study, we attempted to disentangle the longitudinal association of sleep quality with knee pain development and worsening related to knee OA from chronic widespread pain.

**Methods:** In the Multicenter Osteoarthritis Study of participants with or at risk of knee OA, sleep quality was assessed at the 60-month study visit (baseline) using a single questionnaire item on a four-point Likert scale from the Pittsburgh Sleep Quality Index, i.e. the overall quality of sleep in the past 7 days and 2) in the Center for Epidemiologic Studies Depression Scale Revised (CESD) for frequency of restless sleep. We categorized sleep quality as ‘fairly good’ and ‘very good’ for the upper two category responses, and ‘bad’ (referent group) for the lower two category responses combined together. Chronic widespread pain (WSP) was defined as having pain above and below the waist, on both sides of the body, and in the axial region. We defined our outcomes as follows: 1) knee pain worsening as relative change  $\geq 14\%$  or absolute change  $\geq 2$  in WOMAC pain score; and 2) incident consistent frequent knee pain (CFKP, knee pain on most days in past month at both the clinic visit and telephone screen ~30 days prior to the clinic visit and not present at baseline). We examined the relation of sleep quality to each knee pain outcome over a 2-year period stratified by baseline WSP status using logistic regression with Generalized Estimating Equations to account for correlations between two knees within an individual, and adjusted for potential confounders (see Table).

**Results:** We included 2329 participants (4658 knees) with valid values for sleep quality [mean (SD) age: 62.1 (7.9), BMI: 30.9 (6.1), 60.5% female, 84.3% White, 41% with WSP]. The spearman correlation for sleep quality and restless sleep was 0.69 ( $p < 0.001$ ). There was a significant interaction between sleep quality and baseline WSP for both outcome measures ( $p < 0.01$ ). In those who had knee pain at baseline, better sleep quality was associated with a lower risk of knee pain worsening regardless of baseline WSP ( $p$  for trend  $< 0.04$ ), with an effect that appeared to be stronger among those with WSP. No significant association was found for risk of incident CFKP in either stratum of WSP (see Table). Similar results were observed using restless sleep in CESD.

**Conclusion:** Although better sleep quality was associated with a lower risk of worsening knee pain regardless of chronic widespread pain, sleep quality did not affect the risk of developing new knee pain. Objective measures of sleep quality and knee pain are warranted to study the role of sleep in knee pain in OA. Nonetheless, these data suggest that for those with knee pain, sleep quality improvement should be considered for knee pain management.

**Table** Odds ratio (OR) [95% confidence interval (CI)] for relation of sleep quality from the Pittsburgh Sleep Quality Index to knee pain worsening and joint pain stratified by baseline widespread pain status in the Multicenter Osteoarthritis Study

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Inflammation is a key contributor to osteoarthritis (OA).<sup>1</sup> OA pain is mediated by interactions between inflammatory cytokines and other features including local tissue damage, synovitis and cellular response mechanisms.<sup>1</sup> Synovitis is integral to OA, and is associated with symptom severity, joint dysfunction and cartilage loss.<sup>2</sup> FX006, an extended-release formulation of triamcinolone acetonide (TA) for intra-articular (IA) injection, provided statistically and clinically significant, sustained improvements in pain/stiffness/function of knee OA vs placebo in clinical trials.<sup>3</sup> We compared FX006 efficacy in patients with and without baseline inflammation determined by clinical assessment.

**Methods:** A pooled subgroup analysis of 3 double-blind, randomized, placebo-controlled trials (NCT01487161/NCT02116972/NCT02357459) was conducted. Patients with Kellgren-Lawrence grade 2/3 knee OA and Average Daily Pain (ADP)-intensity score  $\geq 5$ – $\leq 9$  (0–10 Numerical Rating Scale) received a single IA injection of FX006 40 mg or saline-placebo. Investigators assessed index knees for clinical indicators of inflammation (effusion, Baker's cyst, tenderness, swelling, and/or redness/heat). ADP-intensity was assessed daily for 24 weeks. Western Ontario and McMaster University Arthritis Index for OA (WOMAC; 0–4 Likert scale) pain (A), stiffness (B), and physical function (C) were assessed at baseline and Weeks 4/8/12.

**Results:** 349/586 patients (60%) had baseline clinical inflammation (**Table**). Changes from baseline in weekly mean ADP-intensity and WOMAC-A, B, C consistently favored FX006 vs saline-placebo (**Figure**). FX006 effect was enhanced, generally >2-fold, in patients with vs without baseline clinical inflammation: least squares mean differences for ADP and WOMAC-A, B, C, respectively, was -1.84 vs -0.74, -0.71 vs -0.27, -0.82 vs -0.41, and -0.69 vs -0.26 at Week 8, and -1.35 vs -0.37, -0.44 vs -0.16, -0.50 vs -0.27, and -0.44 vs -0.16 at Week 12.

**Conclusion:** FX006 provided sustained clinical improvement in knee OA vs saline-placebo irrespective of baseline clinical inflammation. Enhanced FX006 effect in patients with baseline clinical inflammation is consistent with the role of inflammation in OA pathogenesis and known anti-inflammatory action of TA. A drawback of this study is the lack of standardized measures of inflammation. Longer-term evaluations with objective inflammation measures (e.g., ultrasound, biomarkers) are needed.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Knee osteoarthritis (OA) is characterized by pain, disability and joint deformity due to articular cartilage degradation and bone remodeling. Wnt signaling is involved in these cellular processes and inflammation.

SM04690, a small molecule Wnt pathway inhibitor, is in development as a potential disease modifying drug for knee OA.

A phase 2, multicenter, 52-week, randomized, double-blind, placebo-controlled (PBO) trial was conducted to determine the safety and efficacy of SM04690.

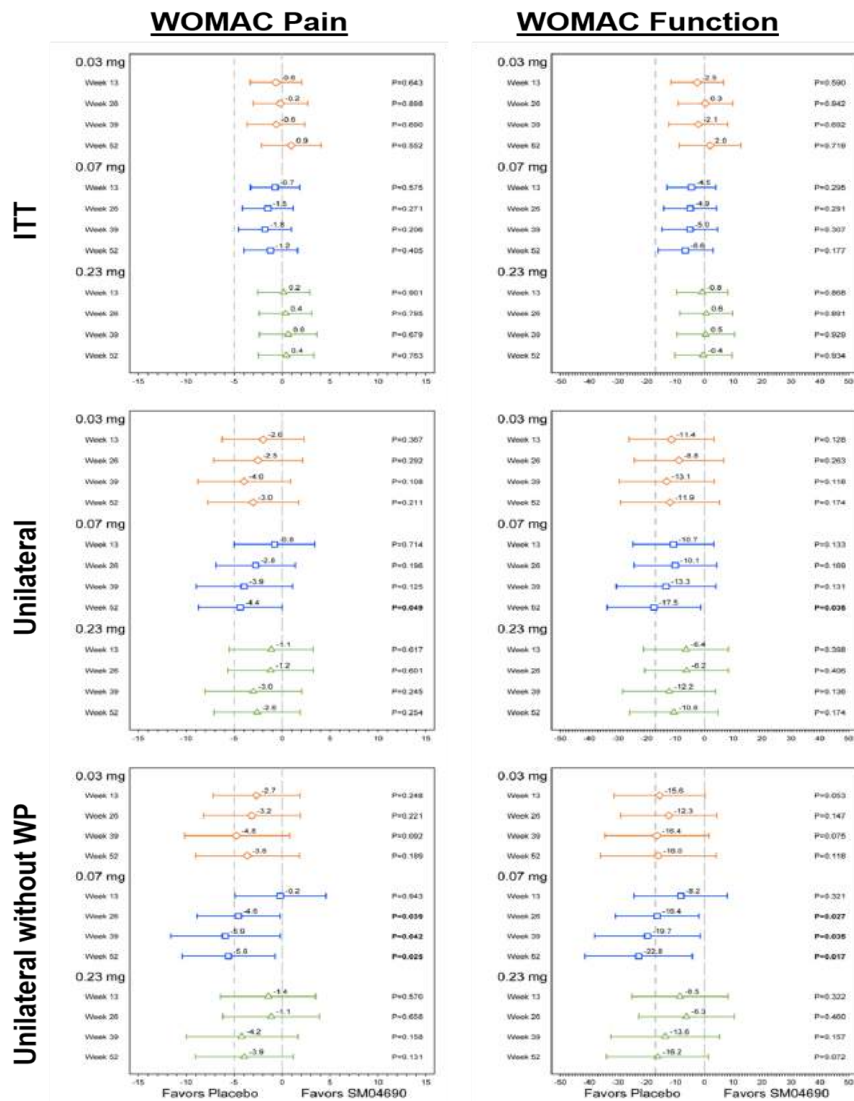

**Methods:** Knee OA subjects with Kellgren-Lawrence (KL) grades 2-3, received a single 2 mL injection of 0.03 mg, 0.07 mg, 0.23 mg SM04690 or PBO in target (most painful) knees. Western Ontario and McMaster Universities Arthritis Index Outcome (WOMAC) Pain [0-50] and Function [0-170] were assessed at Weeks 0, 4, 13, 26, 39 and 52, and radiographs were taken at Weeks 0, 26 and 52 for medial joint space width (mJSW). Analysis of covariance adjusted for baseline in the intention-to-treat (ITT) population was conducted with multiple imputation. Two subgroups were explored: 1) unilateral symptomatic knee OA subjects as determined by investigator through history and examination (pre-specified), and 2) unilateral symptomatic knee OA subjects without widespread pain (Widespread Pain Index ≤4 and Symptom Severity ≤2 [WP], post-hoc).

**Results:** 455 subjects (mean age 60.3 [±8.7], BMI 29.9 [±4.6] kg/m<sup>2</sup>, female 58.9%, KL 3 [64.4%], unilateral symptomatic OA [36.0%]) were enrolled. Serious adverse events, all deemed unrelated to SM04690, were reported in 17 (3.7%) subjects (4.5% [0.03 mg], 3.5% [0.07 mg], 3.8% [0.23 mg], 2.8% [PBO]).

In the ITT population, clinically meaningful outcomes improvements (>10% full range) compared to baseline were seen in all groups at all timepoints. Unilateral symptomatic subjects treated with 0.07 mg SM04690 had significant improvements in

WOMAC Pain with clinically meaningful and significant improvements in WOMAC Function compared to PBO at Week 52. Unilateral symptomatic subjects without WP treated with 0.07 mg SM04690 had clinically meaningful and significant improvements in WOMAC Pain and Function compared to PBO at Weeks 26, 39, and 52 (**Figure**). At Week 52 in the ITT population, mean changes in mJSW were -0.14 mm in PBO, 0.10 mm in 0.03 mg (*NS*), 0.06 mm in 0.07 mg (*NS*), and -0.02 mm 0.23 mg (*NS*).

**Conclusion:** In this phase 2 study, improvements compared to PBO in WOMAC Pain and Function were seen in study subgroups of unilateral symptomatic and unilateral symptomatic without WP subjects. SM04690 maintained or improved mJSW over 52 weeks. Radiographic and clinical outcomes suggested SM04690 has potential as a DMOAD for knee OA treatment.

**Figure.** Ladder plots depicting change from baseline in WOMAC Pain and Function between treatment groups to placebo adjusting for baseline. The x-axis represents change in WOMAC score of treatment vs. PBO, where 0 equals no effect. Error bars represent 95% confidence interval.

## **Knee Confidence Trajectories over 8 Years and Factors Associated with Poor Trajectories: Data from the Osteoarthritis Initiative**

**Alison H. Chang**, Julia (Jungwha) Lee, Orit Almagor, Joan S. Chmiel, Kirsten C. Moio, Karen W. Hayes, Julie Szymaszek and Leena Sharma, Northwestern University, Chicago, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Lack of knee confidence, a frequent complaint, has been associated with function decline in knee OA. Given its key role in weight-bearing activities, a better understanding of how confidence changes over time and modifiable factors associated with poor trajectories will inform strategies to help to prevent function decline. Our objectives were to identify, in persons with or at higher risk for knee OA, distinct trajectories of knee confidence over 8 years and baseline factors associated with poor trajectories.

**Methods:** The OAI is a prospective longitudinal cohort study of persons with or at higher risk for knee OA aged 45-79 yrs. Knee confidence was self-reported annually from baseline to 96m in the KOOS (Knee Injury and Osteoarthritis Score), as how much an individual is troubled by lack of confidence in their knees: 0, not at all; 1, mildly, 2, moderately, 3, severely, and 4, extremely. Confidence trajectories for % with score 2-4 were modeled using 4515 OAI participants who had  $\geq 3$  time points for confidence. Latent class models identified groups with a similar underlying trajectory, and, in 4105 persons with complete baseline data, logistic regression was used to model associations of baseline predictors with poor (vs. good) trajectories.

**Results:** We identified 4 distinct knee confidence trajectories (Figure), persistently good, declining, improving, and persistently poor, with estimated probabilities to each trajectory of 62.9%, 11.0%, 14.7%, and 11.3%, respectively. The 4105 persons had a mean age 61.4 years (SD 9.2), BMI 28.6 kg/m<sup>2</sup> (4.8), and 2381 (58.0%) were women. As shown in the Table, baseline factors associated with both persistently poor and declining confidence were BMI, depressive symptoms, disease severity, and worse function; with persistently poor only were younger age, male sex, extensor weakness, injury, and knee and ankle pain; with declining only were comorbidity, falls, and hip pain.

**Conclusion:** Four distinct 8-year knee confidence trajectories were identified in persons with or at higher risk for knee OA. Targeting BMI, depressive symptoms, function, extensor weakness, and knee, ankle, and hip pain may help to prevent poor or declining confidence trajectories.

**Figure. Knee Confidence Trajectories over 96 Months.** Actual (dot) and estimated (solid line) proportion of persons moderately-extremely troubled by lack of knee confidence and 95% confidence intervals (dotted line) by knee confidence trajectory classes (1=persistently good, 2=declining, 3=improving, 4=persistently poor) are shown.

Baseline predictors	Persistently poor knee confidence vs. persistently good	Declining knee confidence vs. persistently good

## Treatment Response in Polyarticular JIA Is Associated with Transcriptional Changes and Chromatin Reorganization in CD4+ T Cells

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** To identify transcriptional changes in CD4+ T cells as children with polyarticular JIA transition from active disease to remission, and to identify underlying changes in chromatin architecture that account for these changes.

**Methods:** We isolated RNA from CD4+ T cells of children with 3 phenotypes: active, treated polyarticular JIA (ADT, n=12), children on medication who fit criteria for clinical remission (CRM, n=10), and 10 healthy children (HC). RNA sequencing was performed using the Illumina HiSeq 2500 platform. We used the assay for transposase-accessible chromatin-sequencing (ATACseq) to survey open chromatin in a subset of these same patients (6 HC, and 5 ADT and CRM). We investigated whether regions of open chromatin that were unique to any of the 3 phenotypes (ADT, CRM, or HC) might show enrichment for specific transcriptional regulators, using standard computational approaches to determine whether unique peaks were associated with up-regulated genes, as determined by phenotype-to-phenotype comparisons of RNAseq data. We divided peaks into central and flanking regions then calculated the best match to each of 700+ motifs for each sub-region within each peak, and calculated enrichment by comparing the score of the best central match to the score of the best flanking matches.

**Results:** Each of the 3 phenotypes was associated with its own its own chromatin accessibility signature as identified by ATACseq and its own transcriptional signature. We identified 16,039 accessible sites that were unique to HC, 38,451 that were unique to ADT, and 58,289 sites that were unique to CRM. Further analyses of the open regions unique to the HC cells showed that these regions were highly enriched (compared to genome background) for CCCTC-binding factor (CTCF) binding sites. These CTCF binding sites were absent in JIA CD4+ T cells. Differential CTCF accessibility was identified within 2 of the known JIA risk haplotypes, those identified by the SNPs rs147992 (upstream of the IL2 gene) and rs2266959, an intronic region of the UBE2LR gene that also features H3K27ac+ enhancer marks in CD4+ T cells. This finding suggests that aberrant 3D chromatin architecture (which is regulated by CTCF) may be a primary driver of the transcriptional aberrations observed in JIA. Analysis of the combined RNAseq and ATACseq using BETA software demonstrated that the differences in chromatin accessibility had high regulatory potential for the differentially expressed genes, providing strong evidence that the chromatin changes and gene expression changes are causally linked. The CRM state was not associated with normalization of either the chromatin or transcriptional signatures of CD4+ T cells in children with JIA.

**Conclusion:** Treatment response in JIA is associated with significant re-organization of chromatin and is accompanied by significant changes in transcription that can be attributed to the chromatin re-organization. Patterns of chromatin accessibility suggest important roles for chromatin regulators (e.g., CTCF) in JIA and possible genetic determinants governing CTCF accessibility. The achievement of CRM does not result in a normalization of either the transcriptome or the epigenome of CD4+ T cells.

## SESSION INFORMATION

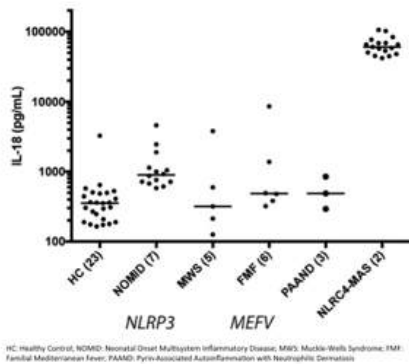

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Patients prone to the development of Macrophage Activation Syndrome (MAS) can have extreme and often chronic elevation in the pro-inflammatory cytokine interleukin-18 (IL-18). In particular, those with gain-of-function mutations in the inflammasome-nucleating protein NLRC4 provided the first mechanistic link between the inflammasome, IL-18, and MAS. Other inflammasome-associated disorders lack such extreme and persistent IL-18 elevation (Fig. 1). In order to dissect the mechanisms associated with NLRC4 hyperactivity, we generated a mouse with an MAS-associated germline missense mutation (T337S) in *Nlrc4* (N4-TS mice).

**Methods:** N4-TS mice were generated by Crispr-Cas9 genome engineering and bred to WT for at least four generations. IL-18 was measured by bead-based immunoassay (Luminex or BD Cytometric Bead Array). RNA-sequencing was performed on duodenal epithelial mucosal tissue scrapings placed into Trizol. MHC-II upregulation was assessed by flow cytometry.

**Results:** N4-TS mice overproduced IL-18 in an allele-dependent manner. We found that IL-18 elevation was present as early as 3 weeks of age, and was unaffected by co-housing or antibiotic treatment. Using bone-marrow chimeras, we determined that IL-18 elevation in N4-TS mice was non-hematopoietic. Upon review of publicly available transcriptional datasets, we discovered that barrier epithelia, and in particular intestinal epithelial cells (IECs), are a rich source of colonization-independent *Il18* and expressed high levels of *Nlrc4* compared to other inflammasome nucleators. RNA-seq of duodenal epithelium showed upregulation of pathways associated with antigen presentation and epithelial turnover in N4-TS mice. Though we saw no increase in Dextran Sodium Sulfate-Induced colitis in N4-TS mice, increased baseline IEC proliferation was confirmed by EdU incorporation. MHC-II was upregulated in N4-TS intestinal epithelial cells as well intraepithelial and  $\alpha\beta$ - and  $\gamma\delta$ -T-cells, but not in splenic or liver lymphocytes. By contrast, mice with transgenic expression of *Il18* (Il18tg) had MHC-II upregulation in intestines, liver, and spleen. (Fig. 2)

**Conclusion:** Like NLRC4-MAS patients, N4-TS mice spontaneously overproduce IL-18. Barrier epithelia may be an important site for NLRC4-dependent IL-18 maturation. MHC-II upregulation is tissue-specific in *Nlrc4*-T337S mice and

may be an anti-inflammatory response. These data suggest a role for barrier epithelial dysfunction as a contributor to systemic inflammatory diseases, particularly those associated with chronic IL-18 elevation and MAS.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Pulmonary fibrosis, is a life-threatening complication of the monogenic autoinflammatory interferonopathy, *STING*-Associated Vasculopathy with onset in Infancy (SAVI) that is caused by gain-of-function mutations in the viral sensor/adaptor TMEM173/*STING*. Pathogenic mechanisms causing fibrosis and factors modifying the onset and severity of lung fibrosis in SAVI patients (pts.) are unknown. Here we show that *STING*-mediated endothelial cell activation induces an endothelial-mesenchymal transition (EndMT)-like differentiation program that causes lung fibrosis in SAVI pts.

**Methods:** To understand the role of *STING* signaling in pulmonary fibrosis, we assessed chest computed tomography (CT), pulmonary function tests (PFTs) in 13 SAVI patients (pts.), and lung histopathology was available from 4 pts. We conducted pts. and control fibroblast, human lung and umbilical vein endothelial cell (EC) lines (HMVEC-L and HUVECs, respectively) and pts. and control induced pluripotent stem cell (iPSC)-derived EC stimulations with endogenous and microbial cGAMP plus/minus IFN $\beta$ . Gene expression (q-RT-PCR, RNA-seq), cytokine production, and EndMT (by cell

morphology and gene expression studies), were assessed. Pts. were genotyped for a common *STING* SNP (R232H, rs1131769) and the modifying effect of the variant was examined in transfection studies in HEK293T cells.

**Results:** Of 13 SAVI pts., 10 had severe lung disease, 4 succumbed to pulmonary complications. Pulmonary findings included hilar lymphadenopathy, diffuse ground glass opacities and cystic emphysematous changes on chest CT, and reduced diffusing lung capacity for carbon monoxide (DLCO) and abnormal 6-minute walk test on PFTs. In contrast to control lung biopsies (n=5), pts.' biopsies (n=4) displayed perivascular fibrosis on Masson's trichrome-stain around medium-sized and small alveolar vessels. In pts., endothelial lining co-expressed mesenchymal ( $\alpha$ -SMA) and stromal fibroblast (FSP-1) markers within the subendothelial compartment. cGAMP stimulation in pt. and control fibroblasts showed no expression of myofibroblast and extracellular matrix (ECM) markers by RNA-seq and q-RT-PCR. *Endogenous* cGAMP stimulation on HMVEC-L induced morphologic transition to fibroblasts with a decreased expression of EC markers CDH5 (V-cadherin), VWF and PECAM1 (CD31), and an increased expression of the mesenchymal markers ACTA2 ( $\alpha$ -SMA) and FAP and of the stromal fibroblast marker S100A4 (FSP-1). IFN $\beta$  and cGAMP stimulation synergize and addition of a JAK inhibitor attenuated the mesenchymal transformation. iPSC-derived EC (iEC) from 4 SAVI pts. but not HCs spontaneously differentiated into myofibroblasts in culture. Differentiation was attenuated by JAK inhibition and in shRNA *STING* knock down iEC. Homozygosity for R232/R232, a *STING* SNP associated with increased IFN $\beta$  production, in addition to the SAVI *STING* mutation led to a more severe clinical lung phenotype in SAVI patients.

**Conclusion:** We suggest a novel pathway of *STING*-mediated ECs activation to induce EndMT-like mesenchymal transformation as cause for lung fibrosis in SAVI pts.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic juvenile idiopathic arthritis (sJIA) is a childhood inflammatory disease whose pathophysiology is poorly understood. sJIA is phenotypically heterogeneous with variable manifestations and responses to treatment. Until recently genetic investigations of sJIA have consisted of candidate gene studies in small patient collections. These studies found only modest associations, yet these associations are regularly included in discussions of sJIA

pathophysiology. Therefore, we examined the 11 reported sJIA candidate susceptibility loci (*IL1A/B*, *GLI2*, *IL1RN/PSD4*, *IL1R2*, *IL10/20*, *IL6*, *MVK*, *CCR5*, *MIF*, *SLC26A2* and *TAPBP*) in the largest sJIA study population assembled to date.

**Methods:** Single nucleotide polymorphism (SNP) genotypes were extracted from the INCHARGE dataset, (771 sJIA, 6947 controls). Logistic regression was performed in each case-control stratum and association results were meta-analyzed. The effect of sJIA associated SNPs on gene expression was evaluated *in silico* in paired whole genome (WGS) and RNA sequencing (RNAseq) data from lymphoblastoid cell lines (LCL) of 373 European 1000 Genomes Project subjects. The relationship between sJIA associated SNPs and response to recombinant interleukin-1 (IL-1) receptor antagonist (anakinra) treatment was evaluated in 38 US patients for whom treatment response data were available.

**Results:** None of the 26 SNPs with previously reported sJIA associations demonstrated even nominal ( $p < 0.05$ ) association with sJIA in our study. We expanded the analysis to determine whether the 11 loci containing the 26 SNPs harbored any sJIA risk SNPs. We examined 5479 SNPs from the 11 candidate regions, among which 500 SNPs were independent ( $r^2 < 0.5$ ), defining the study's significance threshold as  $p < 1E-4$ . Association meta-analysis revealed only one significant association among the 11 candidate loci, the promoter region of *IL1RN*, where 3 SNPs in strong linkage disequilibrium showed a significant association with sJIA. Analysis of LCL data showed that the sJIA associated SNPs correlated with *IL1RN* expression, with an inverse correlation between sJIA risk and *IL1RN* expression. Importantly, the presence of homozygous *IL1RN* high expression alleles correlated strongly with non-response to anakinra ( $p = 9.8E-4$ , OR 17.3 [2.8, 108.1]).

**Conclusion:** *IL1RN* was the only candidate locus associated with sJIA in our study. The sJIA associated SNPs are among the strongest known determinants of *IL1RN* and *IL1RA* levels, linking low expression with increased sJIA risk. Although high expression alleles were protective against sJIA, patients with 2 high expression alleles were significantly less likely to respond to anakinra treatment than those with 1 or 2 low expression alleles. Even though anakinra is well known to ameliorate or reduce inflammation in some sJIA patients, this is the first report to link sJIA risk and response to anakinra treatment with genetically determined capacity to produce *IL1RN* or *IL1RA*. These SNPs are the first potential biomarker(s) capable of prospectively guiding therapeutic decision making in sJIA.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Congenital heart block (CHB) may develop in the fetus of women with Ro/SSA autoantibodies. The mothers are commonly diagnosed with Sjögren's syndrome or SLE. During pregnancy, the antibodies are transported across placenta and bind to the fetal heart where inflammation develops, leading to the fibrosis and calcification that cause the permanent disruption of impulse propagation. The mechanism by which the antibodies initiate inflammation is however not understood. In the mother, Ro/SSA antibodies may induce type I IFN production, and we recently described an upregulation of type I IFN-regulated genes in PBMC as well as an increase in circulating IFN-alpha also in the Ro/SSA exposed newborns. IFN-alpha is known to influence leukocytes, expand and activate NK cells, and in this study, we, therefore, analyzed the immune cell populations in cord blood of anti-Ro/SSA exposed neonates and evaluated the influence of IFN-alpha on fetal cardiac cells.

**Methods:** Maternal and cord blood was sampled at birth from healthy controls (HC) (n=9) and Ro/SSA positive pregnancies (n=13). PBMC were prepared and used for microarray analysis and for flow cytometry to define CD19<sup>+</sup> B cell (CD27<sup>-</sup>IgD<sup>+</sup> naïve, CD27<sup>+</sup>IgD<sup>-</sup> memory, CD27<sup>+</sup>IgD<sup>+</sup> marginal zone), CD3<sup>+</sup> T cell (CD8<sup>+</sup>, CD4<sup>+</sup>) subpopulations and CD16<sup>+</sup>CD56<sup>+</sup> NK cells. Cardiomyocyte cultures were established from human fetal tissues (n=5) and stimulated by medium with or without IFN-alpha for 6 hours before mRNA preparation and microarray analysis.

**Results:** In the Ro/SSA positive mothers, an increase in naïve B cells, but decrease in memory and marginal zone cells was observed, confirming previous reports for non-pregnant Sjögren's syndrome and SLE. Surprisingly, Ro/SSA exposed neonates presented an expanded population of NK cells (p=0.02), the presence of which was influenced by immunomodulatory treatment of the mother (neonates of non-treated mothers p=0.002, neonates of treated mothers p=ns compared to HC). No other differences in the T or B cell subsets analyzed were observed. Microarray analysis of PBMC revealed a type II IFN signature with high IFN $\gamma$ , the prototype cytokine produced by activated NK cells, in Ro/SSA exposed neonates compared to HC. Finally, stimulation of fetal cardiomyocytes with IFN-alpha induced upregulation of MICA and MICB (major histocompatibility complex (MHC) class I chain related sequence A and B), which are ligands for activating NK cell receptors.

**Conclusion:** Our data demonstrate an expansion of NK cells and their activity markers in Ro/SSA exposed neonates, as well as an upregulation of activating NK cell receptors in fetal cardiac cells after IFN-alpha exposure, indicating that NK cell related effector mechanisms such as antibody-dependent cell cytotoxicity (ADCC) may be a central mechanism by which the inflammation is initiated in CHB. The expansion of NK cells in neonates at risk for CHB is a novel observation, and implicates fetal innate immune mechanisms in the pathogenesis.

## **Role of the Pyrin Inflammasome in Resistance to Yersinia Pestis: A Possible Selective Advantage for Carriers of MEFV Mutations**

Yong Hwan Park<sup>1</sup>, Wonyong Lee<sup>1</sup>, Lawton Chung<sup>2</sup>, James Bliska<sup>2</sup>, Daniel L. Kastner<sup>1</sup> and **Jae Jin Chae**<sup>3</sup>, <sup>1</sup>Inflammatory Disease Section, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, <sup>2</sup>Department of Molecular Genetics and Microbiology, School of Medicine, Stony Brook University, Stony Brook, NY, <sup>3</sup>Inflammatory disease section, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics

**Session Type:** ACR Concurrent Abstract Session

**Background/Purpose:** Mutations in *MEFV*, encoding pyrin, cause the prototypic autoinflammatory disease, familial Mediterranean fever (FMF). The carrier frequency of FMF-associated *MEFV* mutations is extraordinarily high in Mediterranean and Middle Eastern populations, suggesting that heterozygous FMF mutations may confer a selective advantage against some pathogenic microbes. Inactivation of the RhoA GTPase is a common bacterial virulence mechanism, because RhoA activation is required for actin polymerization and leukocyte migration, phagocytosis, and degranulation. The pyrin inflammasome senses RhoA inactivation and activates IL-1 $\beta$  as part of the host defense against these bacteria. Pathogenic *Yersinia*, including *Y. pestis*, the agent of plague in humans, deliver virulence effectors, termed *Yersinia* outer proteins (Yops), into host cells; some of these Yops are known to inactivate RhoA. In the current study, we utilized pyrin knockin (KI) and knockout (KO) mice to examine the role of pyrin in host defense against *Yersinia* infection.

**Methods:** Pyrin-KO and FMF-KI mice harboring the FMF-associated M680I or V726A mutations were examined for susceptibility to *Y. pestis* by infection studies. We measured IL-1 $\beta$  production by ELISA in immune cells from wild type and from FMF-KI mouse strains, in response to wild type (WT) *Y. pseudotuberculosis* or *Y. pestis*, or to mutant *Yersinia* strains with deletions of specific Yops. Protein interactions were studied by immunoprecipitation.

**Results:** In *Yersinia*-infected macrophages, the pyrin inflammasome was activated by the RhoA-inactivating enzymatic activities of YopE and YopT. On the other hand, YopM specifically inhibited pyrin to promote virulence by activating the host protein kinases (PKN1 and PKN2) that phosphorylate pyrin to block pyrin inflammasome activation. Pyrin-KO mice were highly susceptible to *Yersinia* yopM mutant infection, while WT mice were not susceptible. However, bone marrow-derived macrophages (BMDMs) from both homozygous and heterozygous FMF-KI mice released significantly higher levels of IL-1 $\beta$  in comparison with WT BMDMs in response to *Yersinia* infection. These results suggest that the FMF-associated mutant pyrin is not suppressed by YopM, thereby providing survival advantage of FMF-KI mice against *Yersinia* infection. Indeed, FMF-KI mice, both homozygotes and heterozygotes, showed significant resistance to *Y. pestis* infection in comparison with WT mice.

**Conclusion:** These findings, taken together with the historical record of high-mortality epidemics throughout human history, suggest that *Yersinia pestis* played an important role in selecting for the high frequency of FMF-associated *MEFV* mutations in Mediterranean and Middle Eastern populations.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

**Background/Purpose:** While prior observational studies have identified predictors of mortality in systemic sclerosis-interstitial lung disease (SSc-ILD), no studies have evaluated predictors of long-term mortality in a clinical trial, in which all patients receive standard care. The objective of this study was to identify predictors of mortality in patients who participated in the Scleroderma Lung Study (SLS) I<sup>1</sup> and II<sup>2</sup>.

**Methods:** SLS I randomized 158 SSc-ILD patients to 1 year of oral cyclophosphamide (CYC) versus placebo. SLS II randomized 142 patients to 1 year of oral CYC followed by 1 year of placebo versus 2 years of mycophenolate (MMF). The FVC%-predicted and DLCO%-predicted were measured every 3 months for 2 years in both trials. 12 years after SLS I commenced, each study center contacted enrolled patients/designated surrogates to assess morbidity and mortality outcomes. Counting process cox proportional hazard modeling identified variables associated with mortality. A joint model of longitudinal FVC and survival data was used to internally validate the model. We externally validated the model using long-term mortality data from SLS II (up to 5 years of follow-up).

**Results:** Among SLS I patients, 43% died during the follow-up period (median follow-up: 8 years), and only 24% remained alive without organ failure. Where known, the cause of death was attributable most often to SSc. The most common type of organ failure was respiratory failure (N=31 of 33 organ failures) defined as the need for supplemental oxygen therapy (N=29) and/or lung transplantation (N=3). There was no significant difference in the time to death between patients randomized to CYC versus placebo (Figure 1). The Cox model identified the following mortality predictor variables: baseline skin score (HR 1.03;  $P=0.004$ ), age (HR 1.06;  $P<0.0001$ ), and the course of the FVC from baseline to 24 months (HR 0.98;  $P=0.022$ ). The course of the FVC was a better predictor than the baseline FVC. The joint model identified the same variables associated with mortality. Using the SLS II data, the Cox model identified the same mortality predictor variables: baseline skin score (HR 2.08;  $P=0.021$ ), age at randomization (HR 1.08;  $P=0.011$ ), and the course of the FVC from baseline to 24 months (HR 0.79;  $P=0.020$ ).

**Conclusion:** Treatment with 1-year of oral CYC for SSc-ILD did not significantly decrease long-term mortality compared with placebo. In addition to identifying traditional mortality risk factors in SSc (i.e. increased skin score and advanced age), this study found that a decline in FVC over 2 years was a better predictor of mortality than the baseline FVC. These findings suggest that early changes in surrogate measures of SSc-ILD progression may have important effects on long-term outcomes.

## **Long-Term Survival and Follow-up of Anti-Th/to Antibody Positive Systemic Sclerosis Patients**

**Devon Charlton**<sup>1</sup>, Maureen Laffoon<sup>2</sup>, Thomas A. Medsger Jr.<sup>3</sup> and Robyn T. Domsic<sup>4</sup>, <sup>1</sup>Division of Rheumatology and Clinical Immunology, University of Pittsburgh Medical Center, Pittsburgh, PA, <sup>2</sup>Rheumatology, University of Pittsburgh Medical Center, Pittsburgh, PA, <sup>3</sup>Department of Medicine/Rheumatology, University of Pittsburgh, Pittsburgh, PA, <sup>4</sup>Medicine - Rheumatology, University of Pittsburgh, Pittsburgh, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

Anti-Th/To antibody is an autoantibody associated with systemic sclerosis (SSc), occurring in 5-10% of patients. To date, only relatively small case series have described the clinical associations of this autoantibody, as commercial testing has not been readily available. Thus, the long-term clinical features and outcomes of patients with anti-Th/To antibody is not known. The objective of this study was to further characterize the clinical associations and mortality risk of SSc patients who are anti-Th/To positive.

### **Methods:**

We performed a case-control study. Eligible patients were identified from consecutive new SSc patients seen at a large US SSc Center between 1980-2015. Cases were found to be anti-Th/To antibody positive by immunoprecipitation. Each case was matched to the next two consecutive SSc patients seen in clinic (2:1 match). Descriptive statistics, Kaplan-Meier and Cox proportional hazards was performed using SAS 9.4.

### **Results:**

199 Th/To-positive SSc patients were identified and matched to 398 controls. The mean age of the entire population was  $51.6 \pm 14.1$  years, 78% female and 92% Caucasian. Th/To positive patients were more frequently Caucasian, had long disease duration at evaluation and more often presented with SSc sine scleroderma (see Table 1). At baseline Th/To patients were more frequently found to have pulmonary hypertension, but less frequent joint involvement. There was no difference in rate of interstitial lung disease (ILD) found on radiographic imaging (Table 1).

As of last follow-up 41 (21%) of Th/To positive patients had developed PAH compared to 43 (11%;  $p=0.001$ ). Twenty-five (13%) Th/To positive patients had developed PH secondary to ILD compared to 33 (8%) controls ( $p=0.10$ ), with no difference in frequency of ILD. Despite the greater frequency of PH in cases, 5-year cumulative survival was not any different between Th/To positive patients (29%) and controls (28%;  $p=0.90$ ), even after adjustment for age and gender.

### **Conclusion:**

This is the largest cohort of Th/To antibody positive SSc patients for which there is long-term follow-up for clinical features and survival data available. Compared to other SSc patients, anti-Th/To patients develop higher rates of PAH. Cumulative 5-year survival is not reduced in Th/To patients, likely reflecting advances in PAH management. SSc patients should be routinely screened for the Th/To antibody, with consideration of appropriate screening for PAH.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The clinical associations of anti-Th/To antibodies (Abs) are not fully established, and until recently immunoprecipitation (IP) was the only reliable assay. Using IP, anti-Th/To Abs are mostly detected in SSc but other reported associations include ILD. Our objective was to examine clinical correlates of anti-Th/To Abs targeted against three different proteins associated with the Th/To autoantigen complex in SSc. We used a commercially available hPOP1 immunoblot and a recently described Rpp25 and Rpp38 chemiluminescence assay in a multinational cohort of SSc.

**Methods:** Cross sectional retrospective study including 1312 patients from the Australian Scleroderma Cohort study (ASCS), Canadian Scleroderma Research Group (CSRG) and the Genetics versus Environment in Scleroderma Outcome Study (GENISOS). Demographic and clinical variables were harmonized and sera tested for anti-Th/To Abs using hPOP1 (EUROLINE, Eurimmun, Lubeck, Germany) and Rpp25/38 (QUANTA Flash Assay, Inova Diagnostics Inc, San Diego, CA). Rpp25/38 was defined as positive if either one or both autoantibodies were present. ILD was determined by high resolution CT chest (HRCT) or a published algorithm [1] which allows diagnosis of ILD by chest X-ray showing increased interstitial markings or fibrosis and/or physician reported “velcro-like crackles” when HRCT is not available. Descriptive statistics summarise baseline demographic and clinical variables and Kaplan Meier analyses were used to assess survival

## Results:

Patients had median (interquartile range) age at disease onset 46.3y (18.6) and disease duration 5.1y (11.4) at recruitment. hPOP1 was positive in 2.4% and Rpp25/38 was positive in 4.5% patients. Notably hPOP1 and Rpp25/38 identified overlapping patient populations ( $p < 0.001$ ). Median age of disease onset for hPOP1 patients was 48.9y (23.3) and for Rpp25/38 patients was 48.8y (17.3).

hPOP1 was associated with ILD on HRCT chest (OR:5.16;  $p = 0.02$ ) but not ILD by algorithm (OR:1.19;  $p = 0.642$ ). hPOP1 was negatively associated with centromere Abs (CENP) (OR:0.24,  $p = 0.018$ ) and positively associated with PM75/100 (OR:

3.07,  $p=0.01$ ), and Ro52/TRIM21 (OR: 3.18,  $p=0.002$ ). hPOP1 was not associated with Scl-70 ( $p=0.089$ ).

Fifty patients (4.0%) were Rpp25 positive and 14 patients (1.1%) Rpp38 positive with strong correlation between the two ( $p<0.001$ ;  $\rho=0.72$ ). Rpp25/38 was associated with ILD detected by HRCT (OR:3.04;  $p=0.009$ ) and by algorithm (OR: 2.01  $p=0.01$ ). Rpp25/38 was negatively associated with CENP (OR: 0.08,  $p<0.001$ ) and Scl-70 (OR: 0.19,  $p=0.020$ ).

Survival was reduced in hPOP1 positive patients ( $p<0.001$ ), especially when ILD was present. Rpp25/38 and hPOP1 positivity was not associated with pulmonary hypertension nor other disease manifestations.

## Conclusion:

In a large multinational SSc cohort autoantibodies to the hPOP1 and Rpp25/38 components of Th/To were found infrequently and appeared to identify two ILD populations. hPOP1 positivity was associated with ILD on HRCT chest and reduced survival while Rpp25/38 positivity was associated with ILD on HRCT and by clinical algorithm and testing may therefore identify those with differing lung involvement.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## **Background/Purpose:**

Racial differences exist in the severity of systemic sclerosis (SSc). To enhance our knowledge about SSc in African Americans, we established a comprehensive clinical database from the largest multicenter cohort of African American SSc patients assembled to date (the Genome Research in African American Scleroderma Patients (GRASP) cohort). We compared the phenotypic manifestations of SSc in the GRASP cohort to that reported in the European League Against Rheumatism Scleroderma Trials and Research (EUSTAR) cohort<sup>1</sup>.

## **Methods:**

African American SSc patients were enrolled retrospectively and prospectively over a 30-year period (1987 to 2016), from 18 academic centers throughout the United States. 945 (94%) patients met the 2013 ACR/EULAR classification criteria for SSc, with the remaining 64 (6%) meeting the 1980 ACR or CREST criteria. The cross-sectional prevalence of sociodemographic, clinical and serological features was evaluated using data obtained at the time of study enrollment. Factors associated with clinically significant manifestations of SSc were assessed using multivariate logistic regression analyses.

## **Results:**

The study population included a total of 1009 African American SSc patients comprised of 84% women. While 43% were actively employed, 33% required disability support. The majority (57%) had the more severe diffuse subtype and a young age at symptom onset (39.1±13.7 years), in marked contrast to that reported in the EUSTAR cohort. 11% of patients had a severe Medsger cardiac score<sup>2</sup> of 4 (Figure 1). Pulmonary fibrosis evident on computed tomography (CT) chest was present in 43% of patients, and was significantly associated with anti-topoisomerase I positivity (Table 1). 38% of patients with CT evidence of pulmonary fibrosis had a severe restrictive ventilator defect with forced vital capacity (FVC) ≤50% predicted. 16% of patients in the GRASP cohort required oxygen therapy compared to 3% in the EUSTAR cohort. A significant association was noted between longer disease duration and higher odds of pulmonary hypertension (Table 1). The prevalence of potentially fatal scleroderma renal crisis was 7%, 3.5 times higher than that reported in the EUSTAR cohort.

## **Conclusion:**

Our study emphasizes the unique and severe disease burden of SSc in African Americans compared to those of European ancestry.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** To fully understand the impact of Systemic sclerosis (SSc) there is a need to complement existing multi-center registry data with novel, unbiased, high resolution results from large population based cohorts, such as complete, nationwide cohorts. The Norwegian health system is organized so that all SSc patients are followed by specialists at public hospitals; making it possible to identify every single patient resident in the country within a defined time period. Here, we took advantage of this possibility; and aimed to determine incidence, prevalence, mortality and organ involvement of SSc in Norway (denominator population 5.0 million).

**Methods:** The Norwegian, nationwide SSc (Nor-SSc) study cohort included all adult patients in Norway who were; (A) resident in Norway from 2000-12, (B) first time registered with an ICD-10 code M34 (SSc) in a public hospital database, (C) had a clinical SSc diagnosis verified by rheumatologist and (D) met the 1980 ACR and/or 2013 ACR/EULAR classification criteria for SSc. Detailed electronic patient journal review was performed in all cohort patients to assess disease features from SSc onset and to the end of the defined observation period (January 2013).

**Results:** The Nor-SSc cohort included 885 patients, of whom 666 (75.3%) were alive by January 2013. Point prevalence of SSc in Norway was estimated to 13/100.000. Number of new SSc cases per year is shown in Figure 1. Mean age at onset was 49 years, 70% were female and 70% had limited cutaneous SSc (Figure 2). Preliminary analyses of echocardiography data (available in 705 patients; 80%), lung HRCT (from 637 pts; 72%) and right heart catheterization (performed in 290 pts; 33%) indicate frequencies of cardiopulmonary involvement that are comparable to multi-centre registry data (Figure 3).

Upper GI involvement appears to be highly prevalent (Figure 3).

**Conclusion:** In this population based, nationwide study, we found a comparable SSc prevalence to regional studies from other northern European countries. We found that a large proportion of the patients had severe organ involvement; reinforcing the view that SSc truly has a very high burden of disease.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:**

Muscle involvement in systemic sclerosis (SSc) is under-recognised and poorly understood. Reported prevalence varies up to 15%, reflecting lack of consistent definition, the heterogeneous spectrum of muscle involvement, ranging from non-specific myopathic changes to idiopathic inflammatory myopathies such as polymyositis, but also lack of a standardised approach to detection. Early diagnosis of inflammatory myopathy by muscle biopsy is important to guide immunosuppressive therapy to minimise irreversible loss of muscle power and function. We sought to determine the prevalence of inflammatory myopathy in patients with SSc assessed annually for features of muscle involvement according to a standardised algorithm.

**Methods:**

Consecutive patients with SSc, according to the 1980 ACR or LeRoy and Medsger criteria, enrolled in the Australian Scleroderma Cohort Study (ASCS) since 2007, are assessed annually for features of myopathy: proximal muscle weakness based on the Medical Research Centre scale and elevated creatine kinase (CK) > 150 U/L. No specific guidelines for further investigation are followed. In a subset of patients from a single ASCS centre, if proximal weakness and/or elevated CK were present, myositis immunoblot for myositis specific antibodies (MSA) and/or MRI of upper or lower limbs for increased T2 signal or fatty infiltration and atrophy were performed; positive findings prompted a muscle biopsy. Features of patients with and without histopathological features of inflammation on biopsy were compared.

**Results:**

Among 1197 patients enrolled in the ASCS, 176 (14.7%) had elevated CK with or without weakness at any time during follow up, 128 (10.7%) had weakness with a normal CK, and 18 (1.5%) patients had biopsy-proven inflammatory myopathy. In a separate ASCS cohort of 333 patients in South Australia, 89 of 323 (27.6%) had elevated CK, 83 of 326 (25.5%) had proximal weakness and 34 (10.2%) were selected for muscle biopsy. Abnormalities were present in all 34 biopsies, with inflammatory myopathy (polymyositis, 10; dermatomyositis, 4; inclusion body myositis, 3; necrotising, 1; other, 2) confirmed in 20 (58.8%) and nonspecific features of myopathy reported in 14.

Among the biopsied patients, incidence of diffuse cutaneous subtype and levels of CK were significantly higher in those with inflammatory compared with non-inflammatory myopathy (Table 1). Immunosuppressive use at time of biopsy was similar in the two groups.

**Table 1: Characteristics of SSc patients selected for muscle biopsy**

	Inflammatory myopathy  n = 20	Non-inflammatory myopathy  n = 14	P value <sup>1</sup>
Diffuse SSc	6	0	0.031
SSc antibodies:	10/20	9/14	0.500

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** It has been proposed that immunological triggers at mucosal sites, such as the gut microbiota, may promote autoimmunity affecting joints in patients with rheumatoid arthritis (RA). We recently reported evidence for immune relevance of *Prevotella copri*, a gut microbe, in a subgroup of new-onset and chronic RA patients. However, it has been unclear how immune responses to gut microbes may be linked to autoimmune joint pathology.

**Methods:** To identify disease-relevant microbial and self antigens involved in the pathogenesis of RA, we used a novel proteomic approach to identify HLA-DR-presented peptides (T cell epitopes) in patients' samples by tandem mass spectrometry. Immunoreactive peptides or their source proteins were then tested for T cell reactivity by IFN- $\gamma$  ELISpot assay and for antibody responses by ELISA in our large cohort of RA patients or control subjects. Serum samples were also analyzed for innate, Th1, and Th17 mediators by Luminex. Immunoreactive epitopes were searched for microbial sequence homology using BLASTp, and homologous peptides were tested for T cell reactivity. All RA patients met the 2010 ACR/EULAR criteria for RA.

**Results:** From proteomic analyses, we identified two novel autoantigens, *N*-acetylglucosamine-6-sulfatase (GNS) and filamin A (FLNA), as targets of T and B cell responses in about half of RA patients. These autoantibody responses were found primarily in patients with antibodies to *P. copri*, and both IgG and IgA responses to *P. copri* correlated with the autoantibody levels. These microbial and self immune responses occurred specifically in RA patients, and not in those with other rheumatic diseases or in healthy subjects. Both self proteins were highly expressed in synovia. GNS (but not FLNA) appeared to be citrullinated, and antibody to the citrullinated GNS correlated with anti-citrullinated-protein antibody levels. Anti-GNS and anti-FLNA autoantibodies also correlated with inflammatory cytokines IFN- $\gamma$ , IL-12, IL17-F, and IL-22, indicative of Th1 and Th17 adaptive immune responses. In a search for T cell epitope mimicry, the HLA-DR-presented GNS peptide was found to have marked sequence homology with epitopes from sulfatase proteins of the gut microbes of the *Prevotella* and *Parabacteroides* *sp.*, whereas the HLA-DR-presented FLNA peptide had homology with epitopes from proteins of *Prevotella* and *Butyrivimonas* *sp.*, another gut commensal. Patients with T cell reactivity with each self-peptide had responses to the corresponding microbial peptides, and the levels correlated directly. These responses were more common in patients with shared-epitope alleles.

**Conclusion:** These findings provide evidence for immune relevance of a related order of gut commensals in a subgroup of RA patients, and suggest that gut dysbiosis may compromise the mucosal barrier resulting in leakage of microbes. Moreover, the identification of T cell epitope mimicry between microbial and self epitopes as well as significant correlations

in patients' immune responses to these antigens provide a mechanism linking mucosal immunity and joint autoimmunity in these patients. Finally, the specificity of these responses may advance diagnostic testing in RA.

## **Identification of Naturally Processed Immunodominant Topoisomerase I Epitopes in Patients with Systemic Sclerosis**

Eleni Tiniakou<sup>1</sup>, Andrea Fava<sup>2</sup>, Tara Guhr<sup>3</sup>, Francesco Boin<sup>4</sup> and Erika Darrah<sup>5</sup>, <sup>1</sup>Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Johns Hopkins University, Baltimore, MD, <sup>3</sup>University of North Carolina, Chapel Hill, NC, <sup>4</sup>Rheumatology, University California, San Francisco, San Francisco, CA, <sup>5</sup>Department of Medicine/Division of Rheumatology, The Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

Identification of immunodominant T cell epitopes of autoantigens is crucial to understanding the pathogenesis of autoimmune diseases and developing disease-specific diagnostic and therapeutic tools. A subset of patients with systemic sclerosis (SSc) exhibit autoantibodies and CD4<sup>+</sup> T cells specific for topoisomerase-I (Topo-I), which are quantitatively associated with the presence and severity of lung fibrosis. Mapping of immunodominant Topo-I T cell epitopes has been difficult due to poor sensitivity, high cost of current protocols, and has mainly been based on in silico prediction or overlapping peptide libraries. Existing data are limited by the low precision of these approaches and the poor sensitivity of detection assays. We present a new method for mapping immunodominant Topo-I T cell epitopes using the natural processing and presentation of HLA-DR-restricted Topo-I peptides by monocyte derived dendritic cells (MoDCs) from SSc patients.

### **Methods:**

MoDCs from 6 anti-Topo-I positive SSc patients were pulsed with whole Topo-I protein. Following overnight exposure, immunoprecipitation was performed to isolate HLA-DR/peptide complexes. Peptides were identified by mass spectrometry, and matched to the Topo-I sequence. The peptides were then synthesized and used to stimulate peripheral blood mononuclear cells (PBMCs) from these patients in the presence of anti-CD40 antibody. Topo-I-reactive CD4<sup>+</sup> T cells were identified by flow cytometry based on activation status (CD40L/CD154 upregulation). PBMCs from 8 additional randomly selected anti-Topo-I + patients and 6 anti-Topo-I negative controls (anti-centromere or anti-RNA-Polymerase-III) were stimulated using the same protocol.

### **Results:**

Ten different naturally processed Topo-I peptides were identified. The peptides detected were located mainly in the core region of the molecule. The median number of distinct peptides presented by each individual patient was 4 (range 1-8). Peptide overlap among patients existed despite differences in their HLA-DR haplotype, with 8 out of 10 epitopes being

presented by two or more subjects. All Topo-I peptides were able to stimulate CD154 upregulation by CD4+ T cells from at least one of the 14 anti-Topo-I positive patients tested. These T cell responses were significantly higher than that of 6 randomly selected anti-Topo-I negative SSc controls ( $p < 0.001$ ).

## **Conclusion:**

Through characterization of naturally processed peptides, we have identified immunodominant Topo-I epitopes capable of stimulating CD4+ T cells from anti-Topo-I positive patients with SSc. Additionally, our approach showed that a restricted set of immunodominant Topo-I epitopes is presented by SSc patients carrying diverse HLA-DR alleles. This method represents a cost-effective and dependable way to identify immunodominant epitopes and can provide novel targets for disease monitoring and eventually, designing peptide-targeted immunotherapy.

**Session Date:** Sunday, November 5, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## **Background/Purpose:**

The presence of ACPA in RA indicates that an immune response directed toward citrullinated synovial antigens participates in disease development or persistence. Research from our group have identified T cell targets derived from the auto-antigens aggrecan, vimentin, fibrinogen, alpha-enolase, and cartilage intermediate layer protein (CILP). In this study, we visualized peripheral antigen-specific CD4+ T cells using a multiplexed flow-cytometry based HLA class II tetramer assay in a cross-sectional cohort of 80 RA and 30 matched healthy control subjects to understand their relevance to RA disease progression and response to therapy.

## **Methods:**

All subjects were DRB1\*04:01. RA subjects were CCP positive and represented a range of characteristics including time from diagnosis, disease activity and treatment at the time of blood draw. Antigen-specific T cells were visualized by directly staining peripheral blood mononuclear cells (PBMC) with multiple tetramers corresponding to different antigens. Frequencies and phenotypic features of antigen-specific CD4+ T cells were assessed for correlation with clinical characteristics.

## **Results:**

*Ex-vivo* analysis of PBMC revealed an increase in synovial targeted CD4 T cells when compared to matched healthy DRB1\*04:01 subjects. When analyzed by individual antigen CD4 T cells, aggrecan, vimentin and fibrinogen were increased in RA, and by contrast cartilage-intermediate-layer-protein (CILP) and enolase specific T cells were reduced in comparison to healthy subjects, suggesting that the characteristics of the CD4+ T cells response to synovial epitopes may be unique to antigen specificity.

Within this patient cohort we found a lower frequency of synovial specific T cells in individuals on TNF therapies sampled within 5 years of diagnosis. These differences were most pronounced in the CD4 T cells specific for aggrecan, vimentin and fibrinogen, and showed alterations in chemokine receptor and activation marker expression in the treated group.

Ongoing studies will determine if frequency, phenotype and specificity of synovial specific CD4 T cells correlate directly with disease duration, therapeutic duration, and clinical diagnostic values such as level of RF, CCP, CRP, and disease severity.

#### **Conclusion:**

We have shown that a multiplexed tetramer assay can define the breadth and character of the T cell response to synovial antigens. Characterizing a relatively large cohort of subjects, we demonstrate differences in the phenotype and frequency of the T cells that respond to a diverse set of synovial antigens thought to be important targets in RA. In particular, we show that synovial specific T cell frequency is influenced by therapeutic interventions. Better understanding the interplay of antigen specificities and phenotypes in RA is vital to understanding disease pathogenesis, response to therapy and ultimately developing antigen specific therapies.

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Lymphopenia is a common clinical feature in patients with systemic lupus erythematosus (SLE), and associates with high disease activity and comorbidities including infections. However, the mechanisms of lymphopenia in SLE patients are not fully understood. SLE T cells exhibit increased susceptibility to apoptosis and display altered expression of apoptosis/survival related genes such as the Bcl-2 family genes, many of which have pro- and anti-apoptotic isoforms. Using discovery approaches we previously identified the serine arginine-rich splicing factor 1 (SRSF1) in human T cells, and showed that it regulates normal expression of the CD3zeta chain and is required for IL-2 production. We showed that SRSF1 expression levels are decreased in T cells from SLE patients, and this decrease associates with severe disease.

Because it is reported that SRSF1 regulates alternative splicing of the apoptosis-related gene Bcl-x to promote the anti-apoptotic long (L) isoform over the pro-apoptotic short (s) isoform, we hypothesized that SRSF1 is important for T lymphocyte homeostasis, and its deficiency leads to apoptosis and lymphopenia in mice and in SLE patients.

**Methods:** 42 SLE patients, and age-, race- and gender-matched healthy individuals were enrolled, and clinical and laboratory parameters recorded. Peripheral blood T cells were isolated by negative selection and SRSF1 protein levels assessed by western blot. SLE patients were divided into lymphopenic (<1000/ $\mu$ L) and non-lymphopenic groups, and correlations were assessed with relative SRSF1 expression levels, and compared to gender- and age-matched healthy controls. To generate T cell-specific *Srsf1* conditional knockout (*Srsf1*-cko) mice, *Srsf1*-flox mice were crossed with *d.Lck*.Cre transgenic mice. Mice were euthanized at 10-20 weeks of age or aged to >1 year, and lymphoid tissues (spleen and lymph nodes) were analyzed. Immune cell phenotype was assessed by flow cytometry. Apoptosis was assessed in splenocytes ex vivo or after induction by anti-CD95 (Fas) crosslinking, by flow cytometry staining for 7AAD and Annexin V.

**Results:** SLE patients with lymphopenia presented significantly lower expression levels of SRSF1 (0.65 vs. 1.05,  $p=0.0074$ ), whereas there was no correlation of SRSF1 with hemoglobin, platelet counts, or serum complement levels. In parallel, peripheral T cell lymphopenia was observed in *Srsf1*-cko mice. Lymphopenia was more evident in younger mice, and was more profound in the CD8 than CD4 T cells. Crosslinking with anti-CD95 (Fas) antibody led to increased apoptosis in T cells from *Srsf1*-cko mice. The expression levels of anti-apoptotic gene Bcl-xL were decreased in spleen cells from the *Srsf1*-cko mice both ex vivo and after anti-CD95 (Fas) crosslinking. These results indicate that a deficiency of SRSF1 induces apoptosis in T cells through decreased expression of Bcl-xL.

**Conclusion:** SRSF1 controls the expression of the anti-apoptotic gene Bcl-xL and is an important regulator of T lymphocyte homeostasis in vivo and its reduced expression levels associate with lymphopenia in SLE patients. Therefore, deficiency of SRSF1 may represent a molecular defect that contributes to the pathophysiology of systemic autoimmune disease.

**Session Title:** T Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Treatment of polyarticular JIA with anti-TNFA biologics has experienced significant success, with up to 80% of patients demonstrating clinically meaningful efficacy. Yet concerns regarding medium/long term toxicities and costs, have driven the clinical need to locate predictors for successful drug discontinuation. Compelling evidence indicate that T cells play a paramount role in disease progression. Identification of these pathogenic subsets within the T cell immunome will likely help stratify patients in terms of clinical fate. JIA patients previously treated with anti-TNFA were recruited through the Understanding TNFA trial and segregated into flare, active and inactive arms after drug discontinuation. Utilising a high dimensional platform, CyToF, that is capable of phenotyping up to 41 markers at single cell resolution, we aim to identify the pathogenic subsets responsible for clinical relapse and signatures capable of distinguishing therapeutic outcomes.

**Methods:** Patients treated with anti-TNF-alpha were recruited into the study (Improved Understanding of the Biology and Use of TNF inhibition in Children with JIA Trial) with clinically inactive disease on treatment (Wallace criteria) and initiated with therapy discontinuation. The patients were followed and evaluated as flare, inactive and active based on 6 JIA core set parameters; number of joints with active arthritis and/or loss of motion, MD global assessment of current disease activity, patient/parent global assessment of overall disease severity in prior week, a validated measure of physical function and ESR.

**Results:** PBMCs from 47 JIA patients (Flare= 18, Active= 11, Inactive= 18) and 10 healthy controls were stained and interrogated with CyToF. Patients destined to flare (vs inactive/healthy) prior to therapy withdrawal, displayed significant dysregulation in the CD4 Memory compartment ( $p < 0.05$ ), enriched particularly in (a) CD4 CD45RA<sup>-</sup> TNFA<sup>+</sup>, (b) CD4 CD45RA<sup>-</sup> CXCR5<sup>+</sup>, and were skewed towards (c) CD152<sup>-</sup> / PD1<sup>-</sup>. When contrasting against healthy controls, patients destined to flare additionally upregulated CD4 CD45RA<sup>-</sup> TNFA<sup>+</sup> IL-6<sup>+</sup>, possibly a sub-clinical disease subset. Intriguingly we noted a migratory subset, CD4 CD45RA<sup>-</sup> CXCR3<sup>+</sup> CCR6<sup>+</sup> that was present in patients destined to develop active disease (vs inactive/healthy). Upon flaring, the sub-clinical subset CD4 CD45RA<sup>-</sup> TNFA<sup>+</sup> IL-6<sup>+</sup> surfaces and CD4 memory subsets are now upregulating expression of CD152/PD1 (vs inactive) in response to ongoing inflammation, but when compared to healthy controls are still inadequate. Parallel pathogenic subsets were also detected in the synovial microenvironment, reflecting targeting towards the joints.

**Conclusion:** For some patients (Flare), anti-TNFA therapy is merely suppressing disease activity and not curative. The persistence of CD4 memory cells are likely to play a pivotal role in disease relapse, that may be partially explained by a weaker control through immune checkpoints (CD152/PD1). These results suggest that clinical fate is immunologically predetermined and patients who will develop different clinical fates can be identified from prior biologic sampling.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** T Cell Biology and Targets in Autoimmune Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

Systemic lupus erythematosus (SLE) is a prototypical autoimmune disease that causes mortality and morbidity worldwide. Recent studies suggest proinflammatory TH17 cells are key pathogenic factors that contribute to lupus nephritis. Our group previously demonstrate that microRNA-21 was highly upregulated in effector CD4<sup>+</sup> T cells from both lupus patients and lupus-prone mice. However, the role of microRNA-21 in pathogenic TH17 cells and TH17 cell-mediated autoimmune diseases is still unclear. In this study, we systemically dissect the role of microRNA-21 in the differentiation and effector function of pathogenic TH17 cells and they-mediated autoimmune diseases.

### **Methods:**

MicroRNA-21 knockout and conditional knockout mice (CD11c-cre, Lyz2-cre, and CD4-cre) were generated for studying the role of microRNA-21 in the differentiation and effector function of TH17 cells. Experimental autoimmune encephalomyelitis (EAE) was induced to study the role of microRNA-21 in pathogenic TH17 cell-mediated autoimmune diseases. RNA-seq and DAVID bioinformatic analysis were conducted to find key microRNA-21 regulated pathway and molecular targets in pathogenic TH17 cells. Metabolomics study and metabolic assays were done to study the glycolytic activity of microRNA-21-deficient pathogenic TH17 cells.

### **Results:**

In this study, we demonstrate that microRNA-21 induced by IL-6-STAT3 signaling targets the E3 ubiquitin ligase Peli1-c-Rel axis to promote effector and metabolic function of pathogenic TH17 cells. We demonstrate that microRNA-21 is not required for the development of intestinal homeostatic TH17 cells, but is essential for the maintenance of pathogenic TH17 cells in vivo. MicroRNA-21-deficient TH17 cells express less pathogenic TH17 signature genes and show less glycolytic activity. Many of the genes involved in glycolytic and related metabolic pathways are significantly downregulated in microRNA-21-deficient pathogenic TH17 cells, which include key transporters for glucose intake, *Slc2a1/3* (*Glut1/3*), and rate-limiting enzymes, *Hk1/2*, *Pfkl*, *Pgm2*, *Ldha* and *Pdk1*. Interestingly, we find that non-pathogenic and pathogenic TH17 cells have greatly distinct metabolic states, with pathogenic TH17 cells highly glycolytic. We further show that conditional deletion of microRNA-21 in CD4<sup>+</sup> T cells protects mice from EAE while loss of microRNA-21 expression by dendritic cells and myeloid cells do not.

### **Conclusion:**

To our knowledge, our study identifies the first evidence that by targeting the E3 ubiquitin ligase Peli1 microRNA-21 promotes the effector and metabolic function of pathogenic TH17 cells. Furthermore, the selective dependence of pathogenic TH17 cells on microRNA-21-mediated metabolic reprogramming has provided novel targets for therapeutic intervention of autoimmune and inflammatory diseases elicited by pathogenic TH17 cells.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CR6086 is a selective EP4 receptor antagonist immunomodulator in clinical development for rheumatoid arthritis (RA). In animal models of RA, it demonstrated a superior efficacy vs. conventional, biologic, or targeted synthetic DMARDs in both early and late disease paradigms. In vitro on human immunocompetent cells, we previously showed that CR6086 counteracts the immunological unbalance characteristic of RA. This partly explains its efficacy in vivo, but does not completely account for its superior efficacy vs. DMARDs. Bone erosion contributes even to very early phases of RA and EP4 receptors have a key role in bone resorption. Acting on this receptor, PGE2 stimulates different cell types (including macrophages, chondrocytes, and osteoblasts) to release mediators causing bone erosion. Among them, IL-6, RANK ligand (RANKL), the major inducer of osteoclastogenesis, and VEGF that has angiogenic, pro-inflammatory and bone destructive roles in RA. Aim of this study was to assess the effects of CR6086 on the expression and release of these mediators by human macrophagic cells, chondrocytes and osteoblasts.

**Methods:** Human THP-1 cells were differentiated to macrophages with PMA. Chondrocytes and osteoblasts were purified from material obtained from patients undergoing knee replacement. Gene expression and release of IL-6, RANKL with its endogenous inhibitor osteoprotegerin (OPG), and VEGF were analysed by Real Time PCR and ELISA assay.

**Results:** CR6086 dose-dependently inhibited gene expression of IL-6, RANKL and VEGF in human macrophages and/or chondrocytes. Conversely, it had no effect on gene expression of OPG, maintaining the balance RANKL/OPG in favor of a reduction of bone erosion. In particular, in macrophages stimulated with LPS 10ng/ml + PGE2 10nM, CR6086 dose dependently inhibited gene expression of VEGF (fig. 1), reduced IL-6 gene expression (up to 44%) and IL-6 release (up to 53%).

Figure 1: CR6086 inhibition of VEGF gene expression induced by LPS+PGE2 in human THP-1 cells differentiated to macrophages with PMA.

In chondrocytes stimulated with PGE2 or IL-1 $\beta$  + PGE2, CR6086 dose-dependently suppressed RANKL and IL-6 gene expression (Table 1). Similar results were obtained in osteoblasts.

Table 1: CR6086 inhibition of RANKL and IL-6 gene expression in human chondrocytes

Stimulation	% decrease in RANKL expression		% decrease in IL-6 expression
	PGE2 10nM	IL1 $\beta$ 2ng/ml + PGE2 10nM	PGE2 10nM
CR6086 0,1 $\mu$ M	82	23	81
1 $\mu$ M	88	58	81
10 $\mu$ M	104	98	98

**Conclusion:** The new potent EP4 receptor antagonist immunomodulator CR6086 directly affects bone resorption by inhibiting the expression of different mediators that induce bone erosions in RA (RANKL, IL-6 and VEGF). These results support the *in vivo* findings and confirm that CR6086 may potentially act as a novel DMARD. CR6086 is in Phase II clinical development in DMARD-naïve early RA patients.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Glycosylation has been reported to associate with tumor invasion and metastasis. Fucosylation is involved the biological functions of adhesion molecules and growth factor receptors. In regards to arthritis, we have previously reported that fucosylated proteins were expressed on rheumatoid arthritis (RA) synovial tissues. Here, we examined the expression of fucosylated proteins in RA and mediates angiogenesis.

**Methods:** Total glycans were determined in serum from normal (NL) subjects and RA patients using mass spectrometry. To determine whether fcosylated proteins involved with RA inflammation, the correlation with disease activity score (DAS) 28 (ESR) was measured. 2-deoxy-D-galactose (2-dGal) is an analog of hexose that inhibits fucosylation. In order to confirm the role of fucosylation in RA angiogenesis, we did Matrigel assays *in vitro*. To block the expression of fcosylated proteins, human umbilical vein endothelial cells (HUVECs) were treated with 2-dGal (15 mM) for 5 days. After treatment with 2-dGal, HUVECs were plated on Matrigel and were incubated with phosphate buffered saline (PBS) or RA synovial fluids. Finally, expression of proangiogenic cytokines such as fractalkine/CX3CL1, CXCL16, interleukin (IL)-8/CXCL8, monocyte chemotactic protein 1 (MCP-1)/CCL2, epithelial neutrophil-activating protein 78 (ENA-78)/CXCL5 and vascular endothelial growth factor (VEGF) in 2-dGal treated HUVEC conditioned medium were measured by ELISA.

**Results:** Total glycans in RA serum were significantly higher than in NL serum [mean  $\pm$  SEM; 477  $\pm$  24 pmol/ $\mu$ l (n=10) and 339  $\pm$  14 pmol/ $\mu$ l (n=10),  $p < 0.05$ , respectively]. In addition, total glycans in RA serum were significantly decreased with tocilizumab treatment at 24 weeks. Total glycans in RA serum were also correlated with DAS28 (ESR). Percent of fucosylated proteins in total glycans were decreased with TCZ treatment at 24 weeks. 2-d Gal treated HUVEC tube formed

towards RA synovial fluids (n=6 patients) were decreased compared with nontreated HUVEC tube formed (number of tube formed;  $7 \pm 1$  and  $25 \pm 2$ ,  $p < 0.05$ , respectively). Fractalkine/CX3CL1, CXCL16, or IL-8/CXCL8 in 2-d Gal treated HUVEC conditioned medium were decreased compared with in non-treated HUVEC conditioned medium but not MCP-1/CCL2, ENA-78, or VEGF.

**Conclusion:** These data indicate that glycoproteins are involved with RA, and play a role in angiogenesis in RA and suggest that targeting glycosylation especially fucosylation may provide a method by which to decrease inflammation and potentially treat other inflammatory diseases.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A disintegrin and metalloproteases (ADAMs) are reported that membrane-anchored glycoproteins composed of multiple distinct protein modules. ADAM-15 is one of them and is reported in several malignancies such as breast cancer and prostate cancer. However, the role of ADAM-15 in autoimmune diseases is unclear. Here, we have shown the role of ADAM-15 in rheumatoid arthritis (RA) angiogenesis.

**Methods:** RA and osteoarthritis (OA) synovial fluids (SFs) were obtained from patients. RA and normal (NL) serum were also obtained. ADAM-15 expression was measured in serum and SFs using enzyme-linked immuno sorbent assay (ELISA). To clarify the differences of ADAM-15 in RA treatment, the level of ADAM-15 at pre, 12, 24 and 54 weeks with tocilizumab treatment was measured. To determine ADAM-15 expression on RA synovial tissues, immunohistochemistry was performed. In order to examine the role of ADAM-15 in RA angiogenesis, we used human umbilical vein endothelial cells (HUVECs). To examine whether ADAM-15 was expressed on HUVECs, immunohistochemistry was also performed. To block the expression of ADAM-15, HUVECs were transfected with small interfering (si) RNA against ADAM-15. In order to confirm the role of angiogenesis, we did Matrigel assays *in vitro*. Finally, proangiogenic cytokines in ADAM-15 siRNA transfected HUVEC conditioned medium were measured.

**Results:** ADAM-15 in RA serum was significantly higher compared with NL ( $500 \pm 21$  pg/ml and  $390 \pm 29$  pg/ml, respectively,  $p < 0.05$ ). The levels of ADAM-15 in RA SFs were also higher compared with OA SFs ( $619 \pm 53$  pg/ml and  $328 \pm 39$  pg/ml, respectively,  $p < 0.05$ ). After treatment with tocilizumab, ADAM-15 in serum was significantly decreased between pre and 24 weeks ( $500 \pm 21$  pg/ml and  $432 \pm 21$  pg/ml, respectively,  $p < 0.05$ ), pre and 54 weeks ( $500 \pm 21$  pg/ml and  $434 \pm 22$  pg/ml, respectively,  $p < 0.05$ ). We found that ADAM-15 was expressed on RA synovial tissue ECs and HUVECs. ADAM-15 siRNA treated HUVECs had decreased EC line and tube formed in Matrigel in response to RA SFs compared with non-treated HUVECs (number of EC lines  $14 \pm 2$  and  $7 \pm 1$ , respectively,  $p < 0.05$ ) (number of EC tube formed  $4 \pm 1$  and  $1 \pm 0$ , respectively,  $p < 0.05$ ). Epithelial neutrophil-activating protein 78 (ENA-78)/CXCL5 and intercellular adhesion

molecule (ICAM) -1 in tumor necrosis factor (TNF) - $\alpha$  stimulated ADAM-15 siRNA transfected HUVEC conditioned medium were decreased compared with in TNF- $\alpha$  stimulated control siRNA transfected HUVEC conditioned medium.

**Conclusion:** These data show that ADAM-15 is expressed on RA synovial tissue ECs and may play a role in RA angiogenesis. ADAM-15 may be a potential target in inflammatory disease such as RA.

## **Tumor Necrosis Factor- $\alpha$ Induces Production of Eotaxin-1/CCL11 from Fibroblast-like Synoviocyte in Rheumatoid Arthritis**

**Kuninobu Wakabayashi**, Takeo Isozaki, Airi Nishimi, Shinichiro Nishimi, Sho Ishii, Takahiro Tokunaga, Hidekazu Furuya and Tsuyoshi Kasama, Div of Rheumatology, Showa University School of Med, Shinagawa-ku Tokyo, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chemokine C-C motif ligand 11 (CCL11) also known as eotaxin-1 is a member of the CC chemokine family, which acts as a major chemoattractant of eosinophils and a stimulator of basophils. Eotaxin-1/CCL11 is produced by lymphocytes, eosinophils and monocytes/macrophages and interacts with C-C chemokine receptor 3 (CCR3). CCR3 is associated with numerous inflammatory conditions and a recent study has also suggested expression of CCR3 on fibroblast-like synoviocyte (FLS) in rheumatoid arthritis (RA). In this study, we investigate the expression and the role of eotaxin-1/CCL11 and CCR3 in RA.

**Methods:** The levels of eotaxin-1/CCL11 were determined in serum from healthy control (HC) and the patients with RA using enzyme-linked immunosorbent assay (ELISA). We also measured the levels of eotaxin-1/CCL11 and tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) in synovial fluids (SFs) from the patients with RA and osteoarthritis (OA) using ELISA. To investigate the expression of eotaxin-1/CCL11 on RA FLS, cells were left unstimulated or were stimulated for 12-, 24- and 48-hours with 50 ng/mL of TNF- $\alpha$ . After stimulation, the protein expression levels of eotaxin-1/CCL11 in TNF- $\alpha$  treated RA FLS conditioned medium were measured by ELISA and the messenger RNA (mRNA) expression of eotaxin-1/CCL11 and CCR3 in RA FLS were measured by quantitative polymerase chain reaction (qPCR) analysis. The expression of eotaxin-1/CCL11 on RA FLS was demonstrated by immunohistochemistry.

**Results:** The levels of eotaxin-1/CCL11 in the serum from RA were higher than those in the serum from HC [mean  $\pm$  SEM; 76  $\pm$  6 pg/mL (n=48) and 52  $\pm$  9 pg/mL (n=31), p<0.05, respectively]. The levels of eotaxin-1/CCL11 in SFs from the patients with RA were higher than those in SFs from the patients with OA [mean  $\pm$  SEM; 61  $\pm$  24 pg/mL (n=43) and 9  $\pm$  2 pg/mL (n=20), p<0.05, respectively] and were positively correlated with the levels of TNF- $\alpha$  (r=0.35, p<0.05). The expression of eotaxin-1/CCL11 mRNA and the secretion of eotaxin-1/CCL11 in RA FLS were time-dependently increased by TNF- $\alpha$  stimulation following 12-, 24- and 48-hours (p<0.05). The expression of CCR3 mRNA was also induced time-dependently by TNF- $\alpha$  stimulation (p<0.05). Furthermore, it was observed that the eotaxin-1/CCL11 mRNA expression was positively correlated with the CCR3 mRNA expression (r=0.89, p<0.01). In addition, we confirmed that the expression of eotaxin-1/CCL11 on RA FLS was increased with TNF- $\alpha$  stimulation using immunohistochemistry.

**Conclusion:** These data indicate that TNF- $\alpha$  induced production of eotaxin-1/CCL11 from RA FLS, suggesting that eotaxin-1/CCL11 and CCR3 may play an important role of inflammation in RA.

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A disintegrin and metalloprotease family proteins (ADAMs) have been reported to be involved in a number of inflammatory conditions. We have previously reported a disintegrin and metalloprotease- 17 (ADAM-17) is expressed in rheumatoid arthritis (RA) synovial fluids and synovial tissues, and is increased compared to osteoarthritis (OA) synovial fluids. Cells involved in bone formation express a variety of cytokines and osteoblasts appear to be major regulators of bone remodeling in RA. The association between ADAM-17 expression and osteoblasts is unclear. Here, we examine the expression of ADAM-17 in RA osteoblasts.

**Methods:** RA human osteoblasts (HOB) isolated from femora of RA patients were incubated. RA-HOB were stimulated with 25ng/ml tumor necrosis factor (TNF)- $\alpha$  at 4 hours, and messenger RNA (mRNA) was collected. ADAM-17 mRNA expression was examined using quantitative polymerase chain reaction (qPCR). To examine the expression of ADAM-17 in TNF- $\alpha$  stimulated RA-HOB conditioned medium, RA-HOB were stimulated with 0.25 ng/ml, 2.5 ng/ml and 25 ng/ml TNF- $\alpha$  at 24 hours and measured using enzyme linked immunosorbent assay (ELISA). To determine ADAM-17 expression in RA-HOB lysate, western blotting (WB) was also performed. Finally, to confirm the presence of ADAM-17 on RA osteoblasts, immunostaining was performed.

**Results:** ADAM-17 was expressed in TNF- $\alpha$  stimulated RA-HOB conditioned medium which was significantly higher compared to non-stimulated (NS) RA-HOB conditioned medium (mean  $\pm$  SEM;  $171 \pm 4$  pg/ml and  $310 \pm 21$  pg/ml, respectively,  $p < 0.05$ ). Furthermore TNF- $\alpha$  was induced dose-dependent secretion of ADAM-17 levels from RA-HOB (mean  $\pm$  SEM; NS:  $171 \pm 4$  pg/ml, TNF- $\alpha$  0.25 ng/ml:  $255 \pm 15$  pg/ml, TNF- $\alpha$  2.5ng/ml:  $234 \pm 7$  pg/ml, TNF- $\alpha$  25 ng/ml:  $310 \pm 21$  pg/ml,  $p < 0.05$ ). We found that ADAM-17 mRNA in TNF- $\alpha$  stimulated RA-HOB was 70 times elevated compared with in non-stimulated RA-HOB ( $p < 0.05$ ). Additionally, we also found that ADAM-17 expression on RA-HOB was inducible by TNF- $\alpha$  by using immunostaining and WB.

**Conclusion:** We have reported that ADAM-17 is involved in angiogenesis in synovial tissue of RA. In this study, we showed the expression of ADAM-17 in RA osteoblasts, suggesting the possibility that it plays an important role in bone destruction in inflammatory disease such as RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A disintegrin and metalloproteinase 17 (ADAM-17), also known as tumor necrosis factor- $\alpha$  converting enzyme (TACE), have been reported to be involved in a number of inflammatory conditions. We examined the expression of ADAM-17 in rheumatoid arthritis (RA) biological fluids and the role it plays in monocyte migration and adhesion to RA synovial fibroblasts.

**Methods:** ADAM-17 expression was measured by enzyme-linked immunosorbent assay in serum and synovial fluids from normal (NL) subjects, osteoarthritis (OA) patients and RA patients. We also analyzed relativity with ADAM-17 and disease activity score 28 (DAS28) in RA. To determine expression of ADAM-17 on RA synovial tissues (STs) and RA fibroblast like synoviocyte (FLS), immunofluorescence was performed. To determine the role of ADAM-17 in RA, RA FLSs or THP-1 (human acute monocytic leukemia cell line) were transfected with small interfering RNA (siRNA) against of ADAM-17. THP-1 adhesion to ADAM-17 siRNA transfected RA FLSs was measured. THP-1 chemotaxis assay was performed towards RA synovial fluids or monocyte chemotactic protein-1 (MCP-1)/CCL2.

**Results:** The levels of ADAM-17 in RA serum was significantly higher compared with NL serum [mean  $\pm$  SE;  $2093 \pm 539$  pg/ml (n=23) and  $0 \pm 0$  pg/ml (n=7), respectively,  $p < 0.05$ ]. ADAM-17 in RA synovial fluids was higher compared with OA synovial fluids [ $1644 \pm 952$  pg/ml (n=10) and  $4.6 \pm 4.3$  pg/ml (n=7), respectively,  $p < 0.05$ ]. The level of ADAM-17 in RA serum was also correlated with DAS28 (n=58,  $r = 0.64$ ,  $p < 0.05$ ). ADAM-17 was expressed on RA ST lining cells. On the other hand, ADAM-17 was not expressed on OA STs. ADAM-17 was also expressed on RA FLS. THP-1 adhesion to ADAM-17 siRNA transfected RA FLS had decreased compared with that to control siRNA transfected RA FLS [adhesion index;  $0.61 \pm 0.10$  (n=12) and  $0.93 \pm 0.05$  (n=12), respectively,  $p < 0.05$ ]. We found ADAM-17 siRNA transfected THP-1 cells had decreased migration compared with control siRNA transfected THP-1 cells towards RA synovial fluids [number of THP-1 migrated  $6 \pm 2$  (n=6) and  $33 \pm 12$  (n=6), respectively,  $p < 0.05$ ]. Furthermore, ADAM-17 siRNA transfected THP-1 cells also had decreased migration compared with control siRNA transfected THP-1 cells towards MCP-1/CCL2 [number of THP-1 migrated  $27 \pm 4$  (n=3) and  $146 \pm 18$  (n=3), respectively,  $p < 0.05$ ].

**Conclusion:** These data indicate that ADAM-17 may play a role in RA inflammation by regulating monocyte migration and adhesion to RA synovial fibroblasts. ADAM-17 may be a potential target in inflammatory disease like RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The CXCL12/CXCR4 chemokine axis has been implicated in the pathogenesis of RA. The expression of this chemokine and receptor has been shown to be increased in RA synovium, and moreover, CXCR4 levels in synovium have been correlated with joint destruction in RA patients. Given that high levels of CXCR4 are associated with RA pathogenesis, we sought to determine whether CXCR4 levels are altered by adalimumab (ADA) both *in vivo* in RA patients and in the human TNF transgenic mouse model (huTNF Tg197) of arthritis, as well as *in vitro* with RA fibroblast-like synoviocytes (RA-FLS) and human osteoclast precursors (OCP) following TNF exposure. In addition, we investigated the role of CXCR4 in human osteoclastogenesis (OCgenesis) under chronic TNF exposure.

**Methods:** Public DNA microarray data of synovial tissue from ADA treated RA patients was analyzed for changes in the expression level of various chemokines and their cognate receptors. PBMC populations from ADA treated RA patients taken at baseline, wks. 4 & 12 were assessed by CyTOF for CXCR4. IHC staining was performed on formalin paw sections from wk. 13 placebo control and ADA treated (1 mg/kg i.p.) huTNF Tg197 mice to evaluate CXCR4 expression in various pannus-associated cells. To assess the role of TNF and concomitant ADA treatment on human cultures *in vitro*, CXCR4 RNA expression was evaluated in RA-FLS treated with conditioned media from PBMCs +/-ADA for 6 hrs., and CXCR4 protein on OCP by flow cytometry in response to 72 hr. M-CSF+RANKL+/-TNF+/-ADA. To demonstrate the role of CXCR4 in OCgenesis, OCP were cultured for 6 d. in M-CSF+RANKL+/-TNF following 30 min. pretreatment with CXCR4 neutralizing antibody. OC maturation and activity were assessed by measuring TRAcP 5b activity and CTX-I release, respectively.

**Results:** Preliminary microarray data analysis of RA synovial tissue demonstrated that active RA patients over-expressed CXCR4 while CXCR4 was significantly normalized (two-fold reduction) in the responders to Ada therapy. In addition, CyTOF analysis of PBMC from ADA treated RA patients indicated a significant reduction from baseline in CXCR4 expression on B cells and CD4+ T cells by wk. 4. In huTNF Tg197 mice, CXCR4 expression in the inflamed pannus (most notably in FLS, lymphocytes and OC) was also decreased by ADA therapy. *In vitro* human cultures of similar cell types including RA-FLS and OCP were subjected to conditioned media or TNF, respectively, and found to express higher levels of CXCR4 that was reduced with concomitant ADA treatment. Finally, antibody-mediated blockade of CXCR4 on human OCP decreased both TNF-enhanced OC maturation and activity.

**Conclusion:** Our findings demonstrate that ADA therapy reduces CXCR4 expression *in vivo* both in RA patient PBMCs and in the pannus of huTNF Tg mice with inflammatory arthritis especially in lymphocytes, FLS and OC. Similar results were also observed with our *in vitro* human cultures of equivalent cell types. More importantly, we've shown that inhibition of CXCR4 can reduce TNF-enhanced OCgenesis *in vitro*, suggesting that CXCR4 may be a contributing factor to TNF-mediated osteolysis in RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Syndecans (SDCs) are type-I transmembrane proteoglycans that prominently interact with heparan sulfate, extracellular matrix (ECM) components and glycoproteins. The present study was carried out to determine the role of syndecans in promoting tissue destruction mediated using human rheumatoid arthritis synovial fibroblasts (RASFs) and a rat adjuvant-induced arthritis (AIA) model of RA

**Methods:** Human RASFs and healthy (NL) SFs were isolated from de-identified RA and NL synovial tissues, respectively, under an IRB approved protocol. RASF and NLSF lysates were prepared to study the expression of SDC-1, SDC-2, SDC-3, and SDC-4 using qRT-PCR and Western immunoblotting. Knockdown of SDCs using siRNA approach was conducted to study its effect on IL-1 $\beta$  (10 ng/ml) or TNF- $\alpha$  (20 ng/ml) induced signaling pathways and downstream inflammatory mediators in RASFs. Ankle, heart, spleen and liver homogenates from naïve and AIA rats were analyzed for differences in the expression levels of SDCs. Serum levels of SDC-2 and SDC-4 were also analyzed in RA patients and in AIA rats.  $p < 0.05$  was considered significant.

**Results:** Our qRT-PCR results showed that the expression of SDC-2 (~320%) and SDC-4 (~80%) was significantly higher in RASFs when compared to NLSFs, which was also confirmed in protein levels using Western blotting method. No significant changes were observed in SDC-1 and SDC-3 expression in RASFs compared to NLSFs. Stimulation of RASFs with IL-1 $\beta$  or TNF- $\alpha$  induced SDC-2 and SDC-4, but not SDC-1 or SDC-3, expression compared to the un-stimulated controls. Knockdown of SDC-2 and SDC-4 significantly inhibited IL-1 $\beta$ -induced matrix metalloproteinase-1 (MMP-1) and MMP-13 production, which could partly be due to the decrease in ERK and PKC $\delta$  activation in RASFs. In addition, we also observed a statistically significant decrease in IL-1 $\beta$ -induced IL-6 production with the knockdown of SDC-2 or SDC-4. Evaluation of the tissue homogenates from naïve and early (day 8) and established (day 18) AIA in rats for SDC expression showed a marked increase in SDC-2 and -4 expression in serum, ankles, liver, and spleen in AIA group at day 8 and at day 18 compared with naïve group. Treatment of methotrexate (MTX) significantly decreased both SDC-2 and -4 expression compared to the AIA alone group. However, human RA serum samples showed a consistent increase only in SDC-4 expression compared to the serum from healthy donors.

**Conclusion:** These findings suggest SDC-4 may be a potential therapeutic target in regulating the role of cytokines and MMPs in mediating tissue destruction in RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

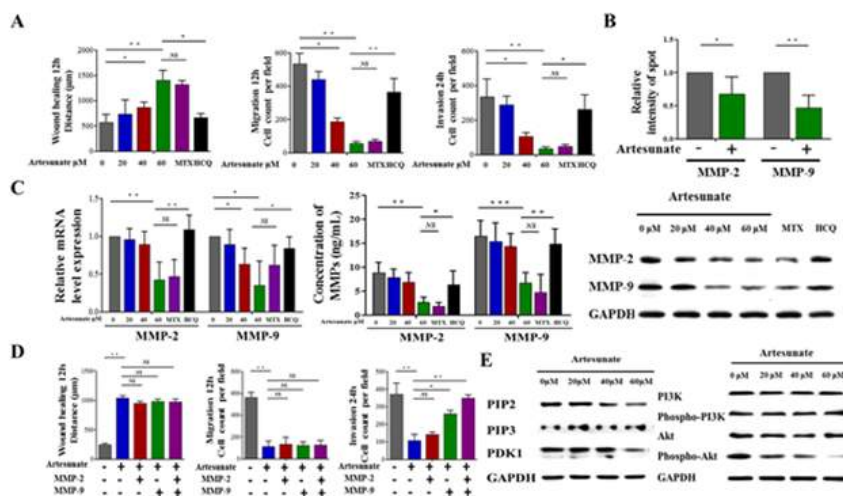

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibroblast-like synoviocytes (FLS) play major roles on joint destruction in rheumatoid arthritis (RA) through migrating and invading cartilage and bone by secreting proteases such as matrix metalloproteinases (MMPs). Recent studies show that artesunate, an important artemisinin derivative, may inhibit proinflammatory cytokines secretion of RA-FLS. We aim to investigate the effect of artesunate on migration and invasion of RA-FLS and its underlying mechanism

**Methods:** FLS isolated from knee synovium of active RA patients were cultured in vitro. The effects of artesunate, methotrexate (MTX) or hydroxychloroquine (HCQ) on cell viability and anti-proliferation were measured by CCK-8 assay. Effects on migration and invasion capacity were detected by wound healing and transwell assays. Differential expression of MMPs were analyzed by Proteome profiler human protease array (R&D Systems) and furtherly verified by quantitative real-time PCR, western blot (WB) and ELISA. The expression of PI3K, PIP2, PIP3, PDK1 and Akt in PI3K/Akt signal pathway was measured by WB.

**Results:** The IC<sub>50</sub> value of artesunate, MTX and HCQ on RA-FLS were 6891μM, 181.4nM and 5433μM respectively. Compared with untreated group, IC<sub>1</sub>-20μM, IC<sub>3</sub>-40μM, IC<sub>5</sub>-60μM of artesunate, IC<sub>5</sub>-10nM of MTX and IC<sub>5</sub>-20μM of HCQ showed no significant change in proliferation even after 72h. Wound healing and migration assays for 12h and invasion assay for 24h showed artesunate inhibits the migration and invasion of RA-FLS in a dose-dependent manner. MTX also has inhibition effect on the migration and invasion of RA-FLS, but HCQ not (Fig. A). Proteome profiler human protease array of culture supernatant showed that 60μM artesunate markedly inhibited MMP-2/9 expression (Fig. B). Further verification showed that RA-FLS pretreated with 60μM artesunate attenuated MMP-2/9 mRNA and protein expression, and ELISA results showed 60μM artesunate decreased MMP-2 and MMP-9 concentration of 5.82±0.45 and 11.74±1.30ng/mL respectively (Fig. C). Further pre-treatment with recombinant human MMP-2 (6 ng/ml) or MMP-9 (12 ng/ml) for 24h could reverse inhibitory effect of 60μM artesunate on invasion, but not migration (Fig. D). Quantitative real-time PCR and WB analysis showed that PDK1 expression and Akt activity (phospho-Akt/Akt) in 60μM artesunate treatment group was significantly lower than that in untreated group which indicated that artesunate suppressed generation of PDK1-induced activation of Akt (Fig. E).

**Conclusion:** Artesunate could inhibit migration and invasion of RA-FLS and MMP-2/9 expression through suppressing PDK1-induced activation of Akt.

**Figure: Artesunate inhibits migration and invasion of fibroblast-like synoviocytes and matrix metalloproteinases expression via suppression of PI3K/Akt pathway in RA.** A: Artesunate inhibits the migration and invasion of RA-FLS in a dose-dependent manner. B: Proteomic profiler human protease array displayed different MMPs expression profiles. C: Quantitative real-time PCR, Western blot and ELISA showed that MMP-2/9 expression of RA-FLS were markedly inhibited by 60μM artesunate. D: Pretreatment of recombinant human MMP-2/9 reversed the inhibitory effect of artesunate on invasion, but not migration. E: Representative blots showed that artesunate suppressed the expression of PDK1 and phospho-Akt. All bars are representative as means  $\pm$  SD, \* $P$ <0.05, \*\* $P$ <0.01, \*\*\* $P$ <0.001. NS: not significant.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Although the risk of atherosclerotic cardiovascular disease and abnormalities in cholesterol transport have been demonstrated in rheumatoid arthritis (RA), lupus (SLE) and, to a lesser extent, in psoriatic arthritis (PsA), the degree of cholesterol transport abnormalities is not known. This study examines the effect of RA, PsA, and SLE versus healthy control (HC) plasma on cholesterol transport genes. Particular genes affect atherosclerotic processes by modulating cholesterol influx, catabolism, and efflux. Dysfunctional cholesterol handling underlies mechanisms that promote atherosclerosis.

## Methods:

THP-1 human macrophages ( $10^6/\text{ml}$ ) were incubated (18h-24h, RPMI1640 media) in the presence of 10% plasma from patients diagnosed as follows: 8 RA females; 12 SLE (9 female, 3 male), 22 PsA (7 female, 15 male); 21 HC (21 female). Cholesterol transport mRNA was quantified by real-time RT-PCR using specific primers for each gene. Statistical analysis was performed using Graphpad Prism. All data were analyzed by one-way analysis of variance, and pairwise multiple comparisons were made between control and treatment conditions using Bonferroni correction. RA patients fulfilled the 2010 revised criteria of the American College of Rheumatology for classification of RA. SLE patients fulfilled the Systemic Lupus International Collaborating Clinics Classification Criteria of 2012. PsA patients fulfilled the Classification Criteria for Psoriatic Arthritis of 2006. Patients with previous documentation of a diagnosis of a connective tissue disorder other than RA, PsA or SLE were excluded.

## Results:

**SLE:** 10% SLE plasma increased cholesterol influx gene expression. CD36 mRNA increased by  $220 \pm 56\%$  ( $P < 0.001$ ), LOX-1 by  $202 \pm 22\%$  ( $P < 0.001$ ), and SR-A1 increased to  $122.0 \pm 45.0\%$  versus HC plasma (set at 100%). Efflux genes were suppressed. ABCA1 mRNA decreased to  $77.0 \pm 47.0\%$ , ABCG1 to  $89.0 \pm 33.0\%$ , and 27-hydroxylase (27-OH) mRNA to  $20.0 \pm 48.0\%$  versus HC.

**RA:** 10% RA plasma increased CD36 by  $157.4 \pm 111.0\%$ , SR-A1 to  $124 \pm 19.0\%$ , and LOX-1 to  $102.0 \pm 53.0\%$  versus HC. Mean ABCA1 mRNA decreased to  $65.7 \pm 28.4$  ( $P < 0.001$ ), ABCG1 to  $65.0 \pm 47.0\%$  ( $P < 0.05$ ), and 27-OH to  $32.5 \pm 14.2\%$  ( $P < 0.01$ ) in RA treated plasma versus HC plasma.

**PsA:** 10 % PsA plasma didn't alter message level of influx nor efflux genes. However, levels of SR-A1 decreased to  $80.0 \pm 30.0\%$ .

## Conclusion:

Consistent with clinic evidence, cholesterol transport abnormalities are most deranged in SLE. RA and SLE plasma induced a consistent pro-atherogenic profile of cholesterol flux genes. PsA plasma was less atherogenic, reflecting their lesser disease-related cardiovascular risk. These results identify cholesterol transport genes as a potential new therapeutic target for atherosclerosis prevention in the setting of autoimmunity.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Decoy receptor 3 (DcR3) is a secreted decoy tumor necrosis factor receptor and competitively binds and inhibits the TNF family including Fas-ligand, LIGHT, and TL1A. We previously reported that DcR3 overexpressed in rheumatoid synovial fibroblasts (RA-FLS) stimulated by TNF $\alpha$  protects the cells from Fas-induced apoptosis [1]. We recently reported that DcR3 binds to TL1A expressed on RA-FLS resulting in the negative regulation of cell proliferation induced by inflammatory cytokines [2]. Further, we newly revealed the gene expression profiles in RA-FLS regulated by DcR3 by using microarray data analysis [3] and the possible involvement of tryptophan hydroxylase 1 down-regulated [4], interleukin 12B up-regulated by DcR3 [5] and centrosomal protein 70kDa [6] in the pathogenesis of RA. The profiles indicated that Cadherin 2/type 1/N-cadherin (CDH2) was up-regulated by DcR3 (fold change 1.93) [3]. CDH2 has been reported to be associated with cell attachment and migration [7], osteoblast differentiation [8], and the proliferation of RA-FLS [9]. The hemophilic interaction of CDH2 suppresses the proliferation of RA-FLS through increasing the P27<sup>Kip1</sup> that inhibit cell-cycle progression [9]. In this study, we investigated the significance of DcR3 regulation of CDH2 for RA-FLS.

**Methods:** Before the quantification of relative expression levels of CDH2 mRNA by real-time polymerase chain reaction (real-time PCR), RA-FLS were stimulated with various concentration of DcR3-Fc or 1,000 ng/ml IgG1 as a control, or left untreated in serum-free Opti-MEM® for 12 h. Anti-CDH2 antibody was applied to frozen sections of synovial tissues from patients with RA or OA for overnight. After that, the expression of CDH2 protein was evaluated by immunohistochemical analysis.

**Results:** Real-time PCR demonstrated that DcR3-Fc significantly increased the expression of CDH2 mRNA in RA-FLS. Immunohistochemistry revealed that CDH2 was expressed more in the sublining layer of rheumatoid synovium than OA synovium.

**Conclusion:** In the gene expression profiles, we focused on CDH2 as the gene was highly up-regulated and belonged to major functional clustering categories; protein complex assembly, cell motility, regulation of transcription, cell membrane and glycosylation. In this study, we showed that the expression of CDH2 mRNA in RA-FLS was induced by DcR3 and that CDH2 was increased in the sublining layer of rheumatoid synovium. Considering the fact that CDH2 inhibits RA-FLS proliferation, the induction in CDH2 expression by DcR3 signaling may control the hyperplasia of RA synovium.

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The synovium is primarily built by fibroblast-like-synoviocytes (FLS). These cells form a complex tissue network via long-distance connections (nanotubes) and wide intercellular matrix spaces. FLS coordinate and transfer information between each other to carry out tissue functions that are critical to joint homeostasis. For this, they exchange cargo, i.e. organelles like mitochondria either via transfer through interconnecting nanotubes or vesicles. Here we search for the underlying mechanisms of cell-to-cell cargo transfer. As targets, we selected actin and tubulin, both part of the cytoskeleton of nanotube structures, as well as the clathrin pathway for endocytosis.

**Methods:** Human FLS were taken from joint synovectomies. Passaged FLS were used to generate micromass cell cultures using Matrigel (BD®). Within just a few days these cells build a 3D structure that strongly resembles the in-vivo situation of the synovium. Cells were dyed with Celltracker and Mitotracker dyes (TF®) and challenged with various blocking agents. Analyses of the 3D confocal and multiphoton imaging data were done with Imaris Bitplane® software.

**Results:** By extracting the actin skeleton from the cells body, we show the triangular arrangement of actin filaments connected by the Arp2/3 complex at the basis of nanotubes as well as their linear arrangement in building nanotubes using electron microscopy. To block actin filament construction via the Arp2/3 complex we used CK666. This not only changed the architecture of the tissue but also significantly lowered the mitochondrial transfer rate between cells.

While thin nanotubes only consist of actin filaments, thick nanotubes may also contain microtubules. Additionally, kinesins use microtubules to shuttle cargo through the cytoplasm. To block tubulin synthesis, we used nocodazole. This treatment changed the structure of FLS micromasses, however, did not significantly lower the mitochondrial transfer rate. Moreover, we determined the mitochondrial travelling speed through nanotubes at 45,4 µm/h. This contrasts kinesin-mediated shuttling which amounts to 0,005 µm/h.

Clathrin mediated endocytosis, and thus the transfer of vesicles between cells, can be blocked by sucrose. Intriguingly, this treatment does not only affect vesicle transfer but also the formation of nanotubes, as it hinders the cell to build curvatures into its membrane. Sucrose treatment resulted in both a change in tissue architecture and significantly lowered the mitochondrial transfer rate.

**Conclusion:** Since the mitochondrial transfer rate was not affected by blocking the synthesis of microtubules and the traveling speed of mitochondria in our experiments was very different from that of kinesin shuttling, we conclude that microtubules are not involved in cell-to-cell cargo transfer. However, by blocking actin synthesis as well as clathrin mediated endocytosis, mitochondrial transfer was significantly lowered. Thus, cell-to-cell cargo transfer is likely an important feature of synovial tissue function that operates using distinct cellular pathways. Further studies will demonstrate its significance in the normal as well as the diseased synovium.

---

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sites of chronic inflammation, such as rheumatoid arthritis synovial tissue, are characterized by neovascularization and often contain tertiary lymphoid structures with characteristic features of lymphoid organs such as endothelial venules (HEV), and sometimes true germinal centers. Ligation of the lymphotoxin- $\beta$  receptor (LT $\beta$ R) results in activation of both canonical and NF- $\kappa$ B-Inducing Kinase (NIK)-dependent non-canonical NF- $\kappa$ B signaling in endothelial cells (ECs) and plays a crucial role in lymphoid neogenesis. Non-canonical NF- $\kappa$ B signaling in ECs promotes inflammation-induced angiogenesis and triggers the development of the cuboidal HEV appearance. However, the relative contribution of the individual pathways to the acquisition of leukocyte traffic-regulating properties by ECs is less well understood.

Goal of the current study is to identify molecular pathways by which LT $\beta$ R drives inflammatory activation of ECs to promote interactions with leukocytes.

**Methods:** Primary human ECs were treated with LT $\beta$  or LIGHT to activate LT $\beta$ R. Induction of downstream signaling pathways was assessed by western blot and NF- $\kappa$ B transcription factor ELISA. The expression of adhesion molecules, inflammatory cytokines and chemokines in ECs was measured by RT-qPCR and cytokine antibody arrays. EC interactions with leukocytes were determined by adhesion assay, and EC barrier integrity was assessed by permeability assay. To repress canonical NF- $\kappa$ B signaling pathway, a small molecule inhibitor of IKK $\beta$  was used, and inactivation of non-canonical NF- $\kappa$ B

signaling was achieved with siRNAs targeting NFκB2. The role of NIK in LTβR signaling was investigated using small molecule inhibitors of NIK, siRNAs targeting NIK and adenoviral vectors encoding wild type and kinase-deficient NIK.

**Results:** LTβR triggering in ECs resulted in activation of both canonical and non-canonical NF-κB signaling pathways and induced the expression of inflammatory cytokines and chemokines (CXCL1, CXCL5, CXCL8, MCP-1, GM-CSF, CCL5). Consistent with inflammatory activation of ECs, LTβR ligation also induced adhesion of immune cells to activated endothelium and increased permeability across EC monolayers. IKKβ inhibition completely repressed LTβR-induced inflammatory activation of ECs, indicating that this process was mediated through canonical NF-κB signaling. Interestingly, inactivation of NIK with small molecule inhibitors and siRNAs significantly decreased LTβR-induced expression of inflammatory cytokines and adhesion of immune cells to endothelium, whereas silencing of NFκB2 had no effect. This suggests that the non-canonical pathway is dispensable for NIK-dependent activation of endothelial cells through the canonical NF-κB pathway. Further analyses, including silencing of NIK and NIK overexpression, demonstrated a role for NIK in activation of the canonical NF-κB pathway by amplifying IKK complex activity.

**Conclusion:** These findings suggest that in addition to its pivotal role in the non-canonical pathway, NIK can serve as an amplifier of the canonical NF-κB pathway and associated inflammatory responses in ECs mediated by LTβR ligation, which may play a role in development and maintenance of chronic inflammation.

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Cardiovascular comorbidity is significant in patients with systemic autoimmune diseases including rheumatoid arthritis and systemic lupus erythematosus. T cell receptor transgenic K/B.g7 mice develop autoimmune arthritis and concomitant inflammatory and fibrotic valvular heart disease (VHD) with complete penetrance. This model allows dissection of the molecular and cellular pathways that drive accelerated cardiovascular disease in the setting of systemic autoimmunity. We have previously demonstrated that VHD in K/B.g7 mice is orchestrated by discrete mononuclear phagocyte populations with CD301b<sup>+</sup> tissue-reparative macrophages comprising the dominant valve-infiltrating population. We have also demonstrated

that a TNF/IL6-VCAM1-VLA4 axis drives disease. Here we sought to assess the specific contribution of mononuclear phagocytes (MNP) in this disease process, using a conditional gene knockout approach.

## Methods:

To test the hypothesis that MNPs responding to circulating autoantibodies provide the source of TNF and IL6 during mitral valve disease (MVD) initiation, we first generated a *Cx3cr1-Cre:Syk<sup>fl/fl</sup>* K/B.g7 line to prevent FcγR-mediated MNP activation. Histological assessment of valve disease severity and flow-cytometric assessment of TNF and IL6 production from valve-infiltrating and lymphoid MNPs were employed. Secondly, to test the hypothesis that recruitment of circulating MNPs drives MVD progression through VLA4-VCAM1 interactions, we generated a *Cx3cr1-Cre:Itga4<sup>fl/fl</sup>* K/B.g7 line to disrupt this interaction. Valve inflammation and fibrosis were quantified histologically. *Cre*-negative littermates were employed as controls in all cases.

## Results:

Deletion of *Syk* in from MNPs ameliorated MVD severity and was accompanied by impaired TNF and IL6 production by valve infiltrating macrophages. Interestingly, lymphoid-resident MNP cytokine production was unaffected. Impairing MNP recruitment through deletion of VLA4 (*Itga4*) significantly attenuated the severity of K/B.g7 cardiac valve inflammation and fibrosis.

## Conclusion:

These studies define the critical molecular pathways used by MNPs to promote cardiovascular pathology in the setting of systemic autoimmunity. We have defined multiple therapeutic targets (TNF, IL6, Syk, VLA4, VCAM1) that could be exploited for the treatment of the cardiovascular comorbidity that accompanies human rheumatic diseases. Ongoing studies are aimed at clarifying the molecular pathways governing MNP-mediated matrix production following their infiltration to the valve stroma.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Background/Purpose:**

Several inflammatory cytokines and intracellular signaling pathways have been targeted in drug development with varying clinical results. Improved understanding of the intracellular signaling's modulation of the extracellular matrix turnover could aid in selecting novel anti-inflammatory treatments for inflammatory arthritis. The aim of this study was to investigate the effect of small molecule inhibitors targeting 4 main pro-inflammatory signaling pathways (p38, Syk, I $\kappa$ B $\alpha$ , and STAT) on Oncostatin M (OSM) and Tumor Necrosis Factor  $\alpha$  (TNF $\alpha$ ) stimulated cartilage.

**Methods:**

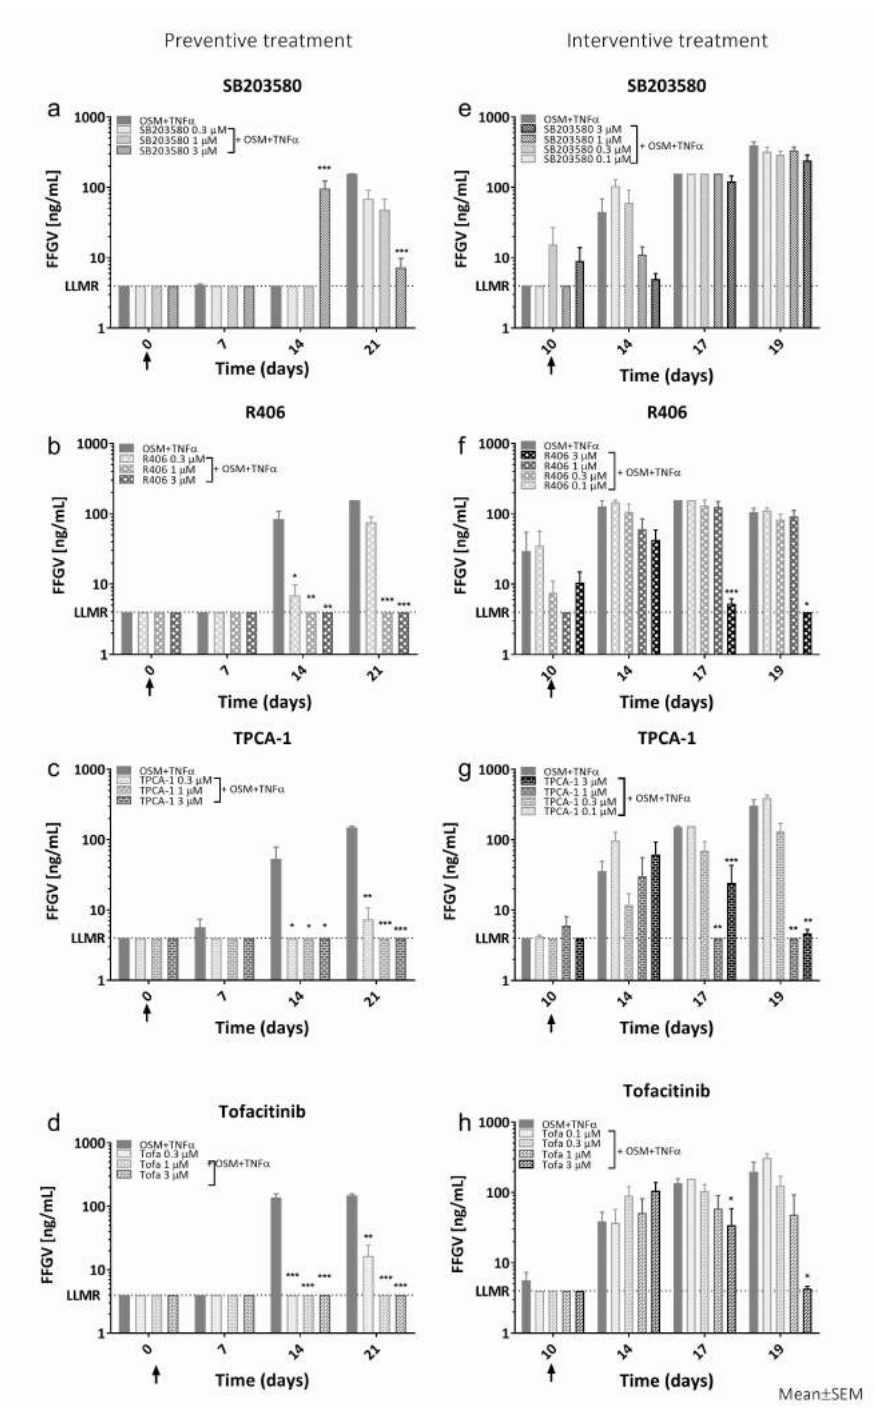

Full depth cartilage explants (FDC) were isolated from bovine knees. The FDCs were cultured for 21 days without (WO) treatment, OSM [10ng/mL]+TNF $\alpha$  [2ng/mL] or OSM+TNF $\alpha$  together with SB203580, R406, TPCA-1 or Tofacitinib (Tofa) at 3  $\mu$ M, 1  $\mu$ M, 0.3  $\mu$ M, or 0.1 $\mu$ M. DMSO was included in WO and OSM+TNF $\alpha$ . The inhibitors were given at start of the experiment (preventive) or after 10 days of OSM+TNF $\alpha$  stimuli (interventive). Activation of the p38, JNK, ERK, I $\kappa$ B $\alpha$ , and STAT3 signaling pathways were assessed at time 0, 15', 30', 1h, 2h, 4h, 8h, and 24h of OSM+TNF $\alpha$  stimuli by western blot. The effect of the OSM+TNF $\alpha$  induced cartilage turnover was assessed by the biomarkers AGNx1, C2M, and FFGV by ELISA in the conditioned medium.

**Results:**

Western blot verified activation of p38, JNK, ERK, I $\kappa$ B $\alpha$ , and STAT3 signaling within 24h of OSM+TNF $\alpha$  stimuli. OSM+TNF $\alpha$  significantly increased the biomarkers AGNx1 ( $P<0.001$ ), FFGV ( $P<0.001$ ) (Fig. 1), and C2M ( $P<0.001$ ). Preventive SB203580 treatment had no effect on OSM+TNF $\alpha$  induced AGNx1 release, while R406 (3 $\mu$ M:  $P=0.034$ ), TPCA-1 (3 $\mu$ M:  $P<0.001$ ) and Tofa (3 $\mu$ M:  $P<0.001$ ) significantly decreased AGNx1 in a dose-dependent manner. All inhibitors given preventive inhibited the release of C2M and FFGV (Fig. 1a-d). SB203580 in a dose-dependent manner (3 $\mu$ M:  $P=0.001$ ), while all concentrations of R406, TPCA-1, and Tofa significantly inhibited the release ( $P<0.05$ ). Interventive treatment with SB203580 tended to decrease C2M and FFGV (Fig. 1e) release 4 days after addition. R406, TPCA-1, and Tofa had no effect on C2M or FFGV after 4 days of interventive treatment, but tended to decrease C2M and significantly decreased FFGV (Fig. 1f-h) release after seven days of treatment in a dose-dependent manner (C2M: 3  $\mu$ M,  $P\leq 0.055$ , FFGV).

**Conclusion:**

In summary, we verified that OSM+TNF $\alpha$  stimulation activates a series of signaling pathways in our FDC culture. Using small molecule inhibitors targeting these individual pathways we found that they modulate the release of extracellular matrix degradation fragments in a spatial and temporal manner. This is both dependent on the target signaling pathway and whether the treatment is preventive or interventive.

## **Background/Purpose:**

Anti-citrullinated proteins antibodies (ACPAs) injected in mice induce IL-8 dependent bone loss and arthralgia, but no synovial changes. We hypothesized that additional stimulus, sensitizing the synovial compartment to ACPA effects, is needed for the transition from bone to synovial pathology.

## **Methods:**

Synovial biopsies were obtained from healthy volunteers and RA patients by arthroscopy. Synovial fibroblasts (SFs) were isolated from synovial tissue of RA patients by enzymatic digestion. Polyclonal ACPA and other non-ACPA IgGs were separated from peripheral blood of RA patients by affinity purification on a cyclic citrullinated peptide (CCP)-2 column. Monoclonal ACPAs were generated from synovial fluid single B-cells. SFs migration capacity was tested by scratch-assays in starved and non-starved cultures treated with ACPAs, with or without presence of IL-8. The results were evaluated by NIH ImageJ software. SF adhesion was analyzed by xCELLigence System Real-Time Cell Analyzer (ACEA bioscience). Peptidylarginine deiminases (PAD) expression and protein citrullination were evaluated by immunohistochemistry and immunofluorescence on SFs. Citrullination level of synovial biopsies were evaluated by biotinylated monoclonal ACPAs. The role of signaling pathways in the ACPA-mediated SF modulation was analyzed by using specific signal inhibitors and by monitoring protein phosphorylation using western blot.

## **Results:**

Serum starvation of SFs increased citrullinated proteins and PAD expression. Starved but not non-starved SFs showed an increased mobility index following polyclonal ACPA stimulation to a mean±SD fold increase of 2.6±0.5. Similar effects were observed with monoclonal B09 but not C03, with a fold increase of the migration index of 1.8±0.4 for B09 antibody and 1.0±0.5 for C03 antibody. This effect was abolished by PAD inhibition as well as ACPA blocking with citrullinated but not native fibrinogen. Exogenous pro-inflammatory cytokines IL-8 and TNF induced PAD expression in SF and synergistically increased their mobility when added together with ACPA. Phosphorylation and inhibition studies of intracellular signaling pathways in starved SFs indicated an important role for PI3K-mediated signals in the ACPA-induced increase of SF mobility. Neither B09 nor C03 were binding to the non-inflamed healthy synovial tissues, while both B09 and C03 showed various degrees of binding to the inflamed RA synovial biopsies, with only B09 binding the fibroblast cell population.

## **Conclusion:**

We demonstrated that some but not all ACPAs fail to activate SFs in basal conditions but have a pronounced effect on cellular stressed SF. Our findings offer a novel scenario on how a synovial insult (in this case the in vitro induced cellular stress) that will normally resolve unobserved, might be essential for the transition towards chronic synovial changes in the presence of ACPA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CD6 is an important marker and regulator of T cells and interacts with its known ligand, CD166. Our group has previously shown that interferon gamma (IFN $\gamma$ )-inducible antigen recognized by monoclonal antibody 3A11 is a new CD6 ligand distinct from CD166. And, it has recently been discovered that CD318 is the new CD6 ligand recognized by 3A11. CD318 is a cell surface protein widely expressed on epithelial tissues and tumor cells as an important regulator of cell adhesion through phosphorylation of its intracellular tyrosine domain. We currently examined CD318 expression on synovial tissues (STs) and soluble CD318 concentrations in synovial fluids (SFs) of rheumatoid arthritis (RA) patients. In addition, we investigated its potential roles in recruitment and retention of T cells in the RA joints. We hypothesize that CD6 on T cells interacts with CD318 on synovial fibroblasts and may lead to activation of either or both cellular subsets to induce proinflammatory responses in RA.

**Methods:** To determine the localization of CD318 in the RA joints, normal (NL), RA, and osteoarthritis (OA) ST sections were stained via both chromogenic and fluorescent immunohistochemistry using 3A11. To quantify the CD318 levels, STs were homogenized and measured for CD318 using ELISA. Additionally, to examine whether CD318 is shed in a soluble form, NL and RA peripheral blood sera and RA, OA, and juvenile idiopathic arthritis (JIA) SFs were measured for CD318 using ELISA. To confirm the expression of CD318 *in vitro*, synovial fibroblasts were treated with or without IFN $\gamma$  and stained for CD318 for flow cytometric analysis. To investigate the role of CD318 in the interaction between synovial fibroblasts and T cells, adhesion assays were performed on synovial fibroblasts stimulated with or without IFN $\gamma$  in the presence or absence of neutralizing antibodies to CD318 and/or CD166. To further characterize the function of CD318, T cell migration assay was performed in a modified 48-well Boyden chamber system.

**Results:** Immunohistochemistry revealed robust staining in the RA STs, specifically on the synovial fibroblasts and endothelial cells, greater in RA than in NL and OA STs. ELISA showed elevated levels of CD318 in the RA ST homogenates compared to that of NL and OA ST homogenates. ELISA for SFs also showed that soluble CD318 is selectively and significantly elevated in the SF from patients with RA and JIA. Flow cytometry showed upregulation of CD318 on synovial fibroblast lines upon IFN $\gamma$  treatment. In adhesion assays, without IFN $\gamma$  treatment, only CD166 was functionally involved, consistent with low expression of CD318 on these cells. In contrast, with IFN $\gamma$  treatment, both CD318 and CD166 were functionally involved, and adhesion was substantially diminished only by antibodies to both CD166 and CD318. T cell migration assay confirmed CD318 as a chemoattractant at concentrations corresponding to the levels seen in RA sera and SFs.

**Conclusion:** CD318 is highly elevated in the RA joints and involved in T cell adhesion to synovial fibroblasts. Soluble CD318 is a T cell chemoattractant and its levels are similarly elevated in the SFs of RA and JIA patients. CD318 is a potential new biomarker or target for the diagnosis and treatment of RA and other inflammatory arthritides.

## **JAK/STAT Mediated Inhibition of Mir-23a~24-2~27a Cluster Potentiates Activation of CD14+ Monocytes in Treatment-Resistant RA**

**Marina Frleta-Gilchrist**, Donna McIntyre, Aziza Elmesmari, Lynn Stewart, Derek Baxter, Mariola Kurowska-Stolarska, Derek Gilchrist and Iain B. McInnes, Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

While emerging and existing treatments of RA allow better options and clinical outcomes for patients, studies informing drug resistant states and further clinical therapeutic choices are lagging. We sought herein to compare a cross-sectional cohort of patients with maintained low disease activity on conventional DMARDs (cDMARDs) and patients failing multiple modes of both conventional or biologic treatments. A broad insight into the treatment resistant state was obtained by selecting blood derived CD14+ cells as precursors of many pathogenic cell types in RA. From these, we profiled the expression of microRNAs (miR), which as post-transcriptional regulators have the ability to control entire pathways giving an informative 'snapshot' of cell state. The resulting data identified regulatory miRs and associated pro-inflammatory pathways underpinning treatment resistance in RA, highlighting how they could be utilized to inform future treatment choices.

### **Methods:**

RA patients meeting ACR 2010 diagnostic criteria were selected for this study. Two control groups included 21 healthy matched controls and 16 patients with established disease, well controlled by conventional DMARDs (cDMARDs); while treatment resistant groups contained 22 patients with high disease activity with cDMARDs and 41 patients with active disease after multiple biologic agents. Peripheral blood CD14+ cells were isolated using Miltenyi isolation kit. MiR expression was determined using the Affymetrix 3.0 miR Array. Predicted miR targets were identified using TargetScan. Direct miR-target interactions were confirmed by luciferase reporter assay. CD14+ cells isolated from buffy coats were stimulated with IL-6, IFN $\gamma$  or GM-CSF. THP-1 cell lines lacking the activities of miR-23a, miR-27a singly or together were created by the stable introduction of miR sponge transgenes.

### **Results:**

Microarray profiling of CD14+ cells from patient cohort showed that the expression of miR-23a~24-2~27a cluster was significantly repressed in both treatment resistant RA groups. Specifically, miR-23a and miR-27a were found to mediate a

novel regulatory feedback loop of the IL-6 pathway. IL-6 stimulation of primary monocytes suppressed the expression of these miRs. In turn, this alleviated the repression of their direct targets, both soluble and membrane bound IL-6R, further sensitizing the cells to IL-6 signaling. Additionally, miR-23a and miR-27a expression was repressed by other cytokines utilizing JAK/STAT signaling cascade, such as viral mediator IFN $\gamma$ , but also monocyte maturation factor GM-CSF, suggesting a potential mechanism for their activation upon migration into tissues. Moreover, cells lacking miR-23a and miR-27a expressed higher levels of the pro-inflammatory cytokines TNF $\alpha$  and IL-6 upon LPS stimulation.

## Conclusion:

Collectively, these data provide evidence of how the multifactorial induction of intracellular JAK/STAT signaling inhibits miR-23a cluster expression leading to increased production of IL-6R, further potentiating the role of this novel pro-inflammatory circuit in treatment resistant RA.

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

IL-6 and TNF- $\alpha$  play an important role in the pathogenesis of RA, and the proliferation of RA-synoviocytes (FLS) is controlled by cell cycle regulators including Cyclins, Cyclin dependent kinases (CDK), CDK inhibitors (CKDIs) and retinoblastoma protein (RB). To reveal actions of proinflammatory cytokines on the cell cycle of RA-FLS, we examined the expressions of the cell cycle regulators and the cellular viability under stimulations of IL-6 and TNF- $\alpha$ .

## Methods:

RA-FLS were cultured with or without IL-6/soluble IL-6 receptor (sIL-6R) (100ng/ml) or TNF- $\alpha$  (10ng/ml). The expressions of CDKs (*p16<sup>INK4a</sup>*, *p21<sup>Cip1</sup>*, *p27<sup>Kip1</sup>*) and *Cyclin E1/2* mRNA were measured by Real-time PCR, CYCLIN D and CYCLIN E protein were measured by Western blot, the expression of CYCLIN D and the phosphorylation of RB were observed by immunofluorescence, and the cellular viabilities were measured by WST-8. In addition, siRNA/p27<sup>Kip1</sup> was

introduced into RA-FLS to analyze the expression of *Cyclin E1* mRNA by Real-time PCR, under stimulations with or without IL-6/sIL-6R or TNF- $\alpha$ .

## Results:

IL-6/sIL-6R decreased the expression of *p16<sup>INK4a</sup>*, whereas increased CYCLIN D and the phosphorylation of RB. TNF- $\alpha$  increased the expressions of *p27<sup>Kip1</sup>*, *Cyclin E1/2* mRNA, CYCLIN D, and the phosphorylation of RB. The expression of CYCLIN D and the phosphorylation of RB were synergistically increased by IL-6 and TNF- $\alpha$ . The expression of *Cyclin E1* mRNA was decreased by siRNA/*p27<sup>Kip1</sup>*.

## Conclusion:

Results clearly indicate that IL-6 and TNF- $\alpha$  interact with each other in regulating the cell cycle of RA-FLS.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung disease (ILD) is one of the most common extraarticular manifestation of rheumatoid arthritis. ILD is characterized by progressive fibrosis of the lung parenchyma and is associated with increased morbidity and mortality. Since TGF- $\beta$  is thought to play an important role in tissue fibrosis, understanding the molecular details of TGF- $\beta$  signaling will provide us a novel therapeutic target for fibrotic disorders. Recently, leucine-rich  $\alpha$ -2 glycoprotein (LRG) was reported to function as a modulator of TGF- $\beta$  signaling in angiogenesis in retinal disease and cardiac remodeling. However, the role of LRG in fibrotic diseases including lung fibrosis has not yet been investigated. In this study, we aimed to investigate the involvement of LRG in lung fibrosis using an animal model of lung fibrosis.

**Methods:** Bleomycin was intratracheally administered to C57BL/6 (WT) mice and LRG knockout (KO) mice, and lung fibrosis was evaluated by Masson's trichrome staining and hydroxyproline quantification in the lung. TGF- $\beta$  signaling in the lung was examined by analyzing phosphorylation of Smad proteins and expression of TGF- $\beta$  downstream genes. Furthermore, *in vitro* analysis using L929 mouse fibroblast cell line was performed to assess the effect of LRG on TGF- $\beta$  signaling in fibroblasts.

**Results:** The amount of LRG in BALF of WT mice was increased after bleomycin treatment. Immunohistochemistry of the lung section showed that LRG was expressed in alveolar epithelial cells, bronchial epithelial cells and infiltrated immune cells in bleomycin-treated WT mouse lung. In LRG KO mice, fibrosis in the lung was less severe as indicated by attenuated

Masson's trichrome staining and lower collagen content in the lung compared with WT mice. In addition, expression of  $\alpha$ -SMA was decreased and phosphorylation of Smad2 was reduced in the lung of LRG KO mice compared with WT mice, suggesting that fibroblast activation was inhibited in the absence of LRG. *In vitro* experiments indicated that LRG enhanced TGF- $\beta$ -induced phosphorylation of Smad2 and expression of PAI-1 and  $\alpha$ -SMA in fibroblasts. On the other hand, Smad1/5/8 signaling was not enhanced by LRG. Although endoglin, an accessory TGF- $\beta$  receptor, is known to be essential for LRG to modulate TGF- $\beta$  signaling in endothelial cells, we found that endoglin was not involved in the process of enhancing Smad2 phosphorylation in fibroblasts.

**Conclusion:** LRG promotes lung fibrosis by enhancing TGF- $\beta$ -induced phosphorylation of Smad2 in fibroblasts and by accelerating fibroblast differentiation into myofibroblasts.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autophagy is generally thought of as a survival mechanism, although its deregulation has been linked to non-apoptotic cell death. Fibroblast-like synoviocytes (FLS) resistance to apoptosis is a major characteristic of rheumatoid arthritis (RA). We hypothesized that interleukin (IL)-17A might have an impact on autophagic flux and that modulation of autophagy might be involved in migration and proliferation of synovial fibroblasts in the patients with RA under inflammatory condition.

**Methods:** Synovial tissue was obtained from clinically involved knee joints of patients with RA or osteoarthritis (OA) patients. The autophagosome of FLS isolated from RA and OA patients displayed different morphological and physiological features by using transmission electron microscopy. The effects of IL-17 on the relationship between autophagy and cell migration were evaluated with co-treatment of autophagy inhibitor using bafilomycin A1 and transfection of si-Atg5.

**Results:** IL-17 induced autophagosome formation and autolysosome accumulation in RA FLS, suggesting that they were resistant to apoptosis. IL-17A increased autophagy of RA FLS by causing up-regulation of LC3II, Atg5 and Beclin1. Migration and proliferation of FLS stimulated by IL-17A was suppressed by bafilomycin A1 and si-Atg5 which knocked

down of autophagy. And, autophagy inhibitor regulated signaling pathway which decreased IL-17A-induced expression of phosphorylation-Akt and increased mTOR signaling pathway.

**Conclusion:** Taken together, our findings demonstrated that IL-17A could induce activate autophagy, induce inflammatory response, and eventually lead to proliferation of synoviocytes. We suggest that autophagy can be one of the therapeutic target for the RA management.

## **Cannabinoid Receptor 2 Agonist (JWH-015) Inhibits Interleukin-1 $\beta$ -Induced Inflammation in Rheumatoid Arthritis Synovial Fibroblasts**

**Sabrina Fechtner** and Salahuddin Ahmed, Department of Pharmaceutical Sciences, Washington State University, College of Pharmacy, Spokane, WA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster II: Mesenchymal Cells Do React - But How?

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by activated synovial fibroblasts in which pro-inflammatory cytokine interleukin-1 $\beta$  (IL-1 $\beta$ ) mediates inflammation. The endocannabinoid system (ECS) is comprised of two evolutionarily conserved cannabinoid receptors 1 and 2 (CB1 and CB2) which elicit their effects through G $\alpha_{i/o}$  mediated signaling. However, the mechanism through which ECS activation can modulate inflammatory signaling in RA is poorly understood.

**Methods:** Human RASFs were obtained from patients diagnosed with RA according to the ACR guidelines (7 female, 2 male, average age 50  $\pm$  43 years). RASFs were pre-treated with 10 or 20  $\mu$ M of JWH-015 for 10 minutes prior to the addition of IL-1 $\beta$  (10 ng/mL). Stimulation duration was for 30 minutes for signaling studies or 24 hours to evaluate the production of IL-6, IL-8, PGE $_2$ , and cyclooxygenase (Cox) enzymes. Conditioned media was used for the quantification of IL-6, IL-8, and PGE $_2$  by ELISA and cell lysates were prepared for the analysis of IL-1 $\beta$  signaling proteins like p-P38, p-JNK, p-ERK, and p-TAK-1<sup>Thr184/187</sup> using Western immunoblotting. To understand the role of CB2, knockdown studies were performed using CB2 siRNA for 48 hours prior to the addition of JWH-015 and IL-1 $\beta$ .

**Results:** Pretreatment of JWH-015 inhibited IL-1 $\beta$ -induced IL-6 (39 and 50% at 10 and 20  $\mu$ M, respectively) and IL-8 (20 and 47% at 10 and 20  $\mu$ M, respectively) production in human RASFs ( $p < 0.05$ ;  $n = 3$ ). Evaluation of the signaling pathways using Western immunoblotting showed JWH-015 reduced the expression of phosphorylated TAK-1<sup>Thr184/187</sup> by 12% and 27% at 10 and 20  $\mu$ M concentration, respectively. Phosphorylated JNK1 was also inhibited by 11% and 22% at 10 and 20  $\mu$ M and JNK2 by 18% and 64% at 10 and 20  $\mu$ M, respectively ( $p < 0.05$ ;  $n = 3$ ). Knockdown of CB2 expression using siRNA approach showed almost 40% reduction in the production of IL- $\beta$ -induced IL-6 and IL-8 and also abrogated the protective effect of JWH-015 ( $p < 0.05$ ;  $n = 3$ ), suggesting CB2 as a receptor central to JWH-015's anti-inflammatory action. We also observed CB2 knockdown resulted in a significant decrease of IL-1 $\beta$ -induced Cox-2 expression by  $\sim$ 58%, which resulted in a marked inhibition of PGE $_2$  production by  $\sim$ 80% ( $p < 0.05$ ;  $n = 3$ ).

**Conclusion:** Our study provides novel evidence that CB2 activation is anti-inflammatory in response to IL-1 $\beta$  stimulation in RASFs, and JWH-015 elicits anti-inflammatory effects through CB2, not CB1, in human RASFs. These findings suggest that JWH-015 may be tested as an adjunct therapy option to reduce inflammation and the perception of local pain through the ECS.

## **Association of Leisure-Time Physical Activity with Late-Life Mobility Limitation Among Women with Total Joint Replacement for Hip or Knee Osteoarthritis**

Aladdin Shadyab<sup>1</sup>, Wenjun Li<sup>2</sup>, Charles Eaton<sup>3</sup> and Andrea LaCroix<sup>4</sup>, <sup>1</sup>Family Medicine and Public Health, University of California, San Diego, La Jolla, CA, <sup>2</sup>Medicine, University of Massachusetts Medical School, Worcester, MA, <sup>3</sup>Family Medicine and Epidemiology, Warren Alpert Medical School, School of Public Health, Brown University, Providence, RI, <sup>4</sup>Family Medicine and Public Health, University of California, San Diego School of Medicine, La Jolla, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Maintaining mobility in old age is an important public health goal for patients with hip or knee osteoarthritis (OA), who are vulnerable to functional decline and disability. Previous studies have observed that physical activity (PA) may improve physical function among OA patients and before undergoing total joint replacement (TJR) surgery for hip or knee OA. However, the association of PA with long-term functional outcomes after total hip (THR) or total knee (TKR) replacement for OA is less clear. We examined associations of leisure-time PA with late-life mobility limitation and death among women who underwent THR or TKR for OA.

**Methods:** The Women's Health Initiative recruited women aged 65-79 years from 1993-1998 and followed them through 2012. Medicare claims data were used to determine THR (n=904) and TKR (n=1867) for OA. Women were followed for up to 18 years after receiving a TJR to determine mobility status at age 85. If women reported that their health limited their ability to walk one block or climb one flight of stairs in annual follow-up, they were classified as having mobility limitation. Women completed a questionnaire at baseline to determine engagement in activities of light, moderate, and vigorous intensities. PA variables were analyzed in metabolic equivalent-hours/week (MET-h/wk). Multinomial logistic regression analyses were performed to determine associations of PA variables with mobility limitation at age 85 and death before age 85 (reference category=mobility intact at age 85). Total PA, moderate-to-vigorous physical activity (MVPA), walking, and walking speed were analyzed in separate regression models adjusted for demographic, lifestyle, and health-related characteristics.

**Results:** Relative to women with the highest level of total PA (>17.42 MET-h/wk), women with THR (odds ratio [OR]=2.41; 95% confidence interval [CI]=1.29-4.51) or TKR (OR=1.56; 95% CI=1.04-2.34) who reported no PA had the highest risk of developing mobility limitation at age 85. Compared with women with the highest amount of MVPA ( $\geq 15$  MET-h/wk), women with THR (OR=1.96; 95% CI=1.18-3.24) or TKR (OR=1.48; 95% CI=1.05-2.07) who reported no MVPA had increased risk of mobility limitation; the risk was also increased among women who did not meet federal guidelines of  $\geq 7.5$  MET-h/wk of MVPA. Women with THR (OR=2.03; 95% CI=1.16-3.58) or TKR (OR=1.54; 95% CI=1.05-2.27) who reported casual compared with fast walking speed were more likely to experience mobility limitation.

Among women with THR, there were significant dose-response associations of total PA, MVPA, walking, and walking speed with mobility limitation and death. Among women with TKR, there were significant dose-response associations of total PA, MVPA, and walking speed with mobility limitation and death.

**Conclusion:** Among older women with hip or knee OA, higher levels of total PA and MVPA, as well as faster walking speed, before TJR were associated with better mobility in late life and decreased risk of death. Further studies are needed to determine whether physical activity before TJR is associated with better mobility later in life among women with hip or knee OA.

## **Dietary Patterns and Risk of Developing Knee Osteoarthritis: Data from the Osteoarthritis Initiative**

**Bing Lu**<sup>1</sup>, Jeffrey B. Driban<sup>2</sup>, Timothy E. McAlindon<sup>3</sup> and Charles Eaton<sup>4</sup>, <sup>1</sup>Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>2</sup>Rheumatology, Tufts Medical Center, Boston, MA, <sup>3</sup>Division of Rheumatology, Tufts Medical Center, Boston, MA, <sup>4</sup>Family Medicine and Epidemiology, Warren Alpert Medical School, School of Public Health, Brown University, Providence, RI

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Few studies have examined the effect of diet on future risk of knee OA development. The association between overall dietary patterns and risk of OA is unknown. We aimed to examine the prospective association of major dietary patterns by principal component analysis (PCA) with risk of developing radiographic knee OA.

**Methods:** In the Osteoarthritis Initiative (OAI), 2835 participants (4570 knees) without knee OA in at least one knee [Kellgren and Lawrence (KL) grade of 0 or 1] who had dietary data at baseline were followed up to 48 months. We defined knee OA incidence as KL grade  $\geq 2$ . Dietary intake was assessed with a Block Brief Food Frequency Questionnaire completed at baseline. We identified two major underlying patterns of food consumption by PCA: "Western" pattern, characterized by high intakes of red / processed meats, refined grains, french fries, desserts, and sweets, and the "Prudent" pattern characterized by high intakes of fruit/ vegetables, legumes, poultry, and fish. Each subject receives a score for each dietary pattern, with a higher score indicating a higher adherence to the respective pattern. The derived patterns are statistically uncorrelated with each other. We grouped the dietary pattern scores using quartiles. We developed a Cox proportional hazards model (with discrete time) to assess the association between dietary patterns and incident knee OA. The robust covariance estimates were used to account for intra-subject correction.

**Results:** Among our sample, 414 knees developed knee OA within 48 months. In multivariable models after controlling for age, sex, race, injury/surgery, and other covariates, adherence to the Western pattern was associated with an increased risk of knee OA (HR<sub>Q4 vs Q1</sub>: 1.60, 95% CI: 1.03 to 2.51, p trend: 0.03), while adherence to the Prudent pattern tended to be associated with a reduced risk of knee OA (HR<sub>Q4 vs Q1</sub>: 0.72, 95% CI: 0.52 to 1.00, p trend: 0.11) (Table). The observed associations were attenuated after additionally adjusting for body mass index (BMI).

**Conclusion:** Following a Western diet may increase the future risk of knee OA, whereas following a Prudent pattern may be associated with a reduced risk of knee OA. The associations may be partially mediated through BMI. Replication of these novel findings in other prospective studies demonstrating that improvement of dietary quality leads to delay in knee OA development are needed.

**Key words:** Western dietary pattern, Prudent dietary pattern, osteoarthritis.

Table. Dietary patterns and risk of knee OA (Hazard ratio, 95% CI)

## What Have We Learned from Trajectory Analysis of Clinical Outcomes in Osteoarthritis?

Maud Wiecezorek<sup>1</sup>, Anne-Christine Rat<sup>1,2,3</sup>, Francis Guillemin<sup>1,2</sup> and Christine Rotonda<sup>1</sup>, <sup>1</sup>Université de Lorraine, EA4360, APEMAC, Nancy, France, <sup>2</sup>Inserm, CIC-1433 Epidémiologie Clinique, Vandoeuvre-lès-Nancy, France, <sup>3</sup>Rheumatology Department, CHRU Nancy, Vandoeuvre-lès-Nancy, France

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

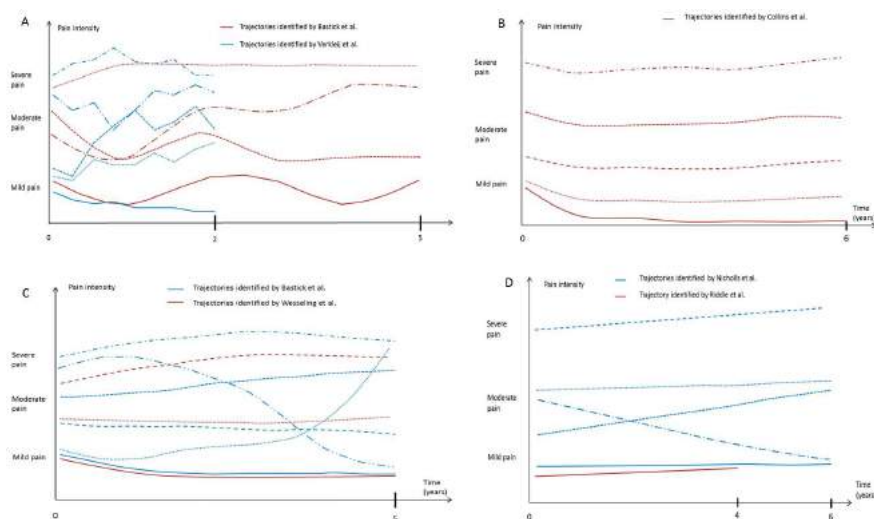

**Background/Purpose:** The aims of this review were to summarize the literature on the trajectories of clinical outcomes in knee and hip OA, to describe the distinct trajectories for each outcome and to collect the predictive factors associated with these trajectories.

**Methods:** The Medline database was searched for relevant studies. Selection criteria were: i) patients  $\geq 18$  years old, ii) patients at high risk of, or diagnosed with, knee or hip OA, iii) studies aiming to identify homogeneous subgroups with distinct trajectories of clinical outcomes, iv) methodology and analysis designed to identify trajectories (longitudinal design

and repeated measures). Articles selection was made independently and in duplicate by two reviewers while the final selection was made independently by three reviewers based on the full text.

**Results:** Of the 3867 abstracts retrieved, 37 studies met inclusion criteria among which 15 other studies analyzed trajectories before surgery. The other 22 studies focused specifically on the course of clinical outcomes after hip or knee arthroplasty. The most frequent outcome reported in the papers was pain (28 studies) while 19 studies reported results on function, 5 on mental health, 1 on stiffness, 3 on social participation and 1 on activity limitation. In the cohort studies without surgery, hip pain trajectories were divided in stable mild, moderate and severe pain. 3 additional subgroups included patients who underwent a moderate pain regression, oscillated between moderate and severe pain levels or highly progressed over time (Fig). A low educational level, high body mass index (BMI), an impaired physical function WOMAC score, high Kellgren (KL) grade for the hip, a limited flexion and internal rotation of the hip and concurrent back and trochanteric pain were associated with the membership in the severe pain trajectory. For the knee joint, the number of trajectories identified in the literature was between 1 and 6. A “no pain”, a mild pain, a moderate pain and a severe pain trajectories were identified as well as pain progression (moderate or severe worsening) or regression (major or moderate improvement) trajectories. Patients belonging to the severe pain trajectory were more likely to be male, have a younger age, a low educational level, a low social class, a high BMI, a high number of comorbidities, a high WOMAC physical function score, a high KL grade, higher levels of anxiety and depression, and a poorer general health.

**Conclusion:** This review highlighted the high heterogeneity across studies in terms of numbers of trajectories retrieved, especially for the pain outcomes. Nonetheless, some predictive factors of membership in a severe pain trajectory have been identified and these findings could be an aid to an early identification of patients with a high risk of clinical worsening.

A) Pain trajectories in patients with hip OA; B) Pain trajectories in patients with radiographic knee OA; C) Pain trajectories in patients with early symptomatic knee OA; D) Pain trajectories in patients at high risk of knee OA or with suspected or confirmed knee OA

**Disclosure:** M. Wiczorek, None; A. C. Rat, None; F. Guillemin, None; C. Rotonda, None.

## Is Intra-Articular Injection of Synvisc Associated with a Delay to Knee Arthroplasty in Knee OA Patients?

Kevin Ong<sup>1</sup>, Maria Runa<sup>1</sup>, Edmund Lau<sup>2</sup> and Roy Altman<sup>3</sup>, <sup>1</sup>Exponent, Inc., Philadelphia, PA, <sup>2</sup>Exponent, Inc., Menlo Park, CA, <sup>3</sup>UCLA Medical Center, Los Angeles, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Knee OA patients may undergo intra-articular (IA) hyaluronic acid (HA) injection treatment, but there is debate about its effectiveness. We asked: (1) What is the epidemiology of IA HA use in knee arthroplasty (KA) patients? (2) Is hylan G-F 20 associated with a delay to KA? (3) Is there a difference in the delay to KA with the number of HA courses?

**Methods:** A retrospective, observational dataset (Optum Clinformatics; 2006 to June 2016) was used to identify knee OA patients. Three different cohorts were identified: (1) No HA cohort who did not receive any IA HA; (2) Non-hylan G-F 20 cohort who received multiple HA types or only one type of non-hylan G-F 20 HA; and (3) hylan G-F 20 cohort who received only hylan G-F 20. Patients who subsequently received a KA were further identified. A quantile regression model was used, adjusting for clinical confounding factors and with propensity score weighting, to evaluate the effect of the covariates on the median duration from knee OA to KA. The trend in time to KA with each additional course of HA was also evaluated.

**Results:** From the initial cohort of 4,027,848 knee OA patients, 141,305 KA patients were identified. Overall median time from knee OA diagnosis to KA was 1.2 years (average:  $1.9 \pm 1.9$  years) with a corresponding interquartile range of 0.4 to 2.8 years. After propensity score adjustment, HA patients had significantly longer median time to KA by at least 5 months ( $p < 0.001$ ; Table 1). When the HA cohort was compared after adjusting for the time to HA and number of injections, no significant differences in the time to KA between multiple-shot hylan G-F 20 and non-hylan G-F 20 HA patients were observed ( $p \geq 0.620$ ), but a longer time was observed for one-shot hylan G-F 20 patients by about 3 months and patients who received both one- and multiple- shot hylan G-F 20 (“One+multiple-shot hylan G-F 20”) by about 15 to 16 months. There was a trend toward longer time to KA the more HA courses the patient underwent (Figure 1). For example, the average time to KA increased from 2.3 years to 5.1 years as the hylan G-F 20 patients increased their treatment courses from one to five or more. There was disparity between states in terms of KA patients who used HA. The three states with the lowest percent of KA patients who used HA were HI (14.5%), IN (16.3%), and AK (16.7%), while the three states with the highest percent of KA patients who used HA were NJ (39.1%), LA (33.9%), and MS (31.8%).

**Conclusion:** Most KA patients did not use HA (73.7%) and the ones who received it were associated with a longer median time to KA by 5 to 22 months, depending on the HA cohort. The time to KA was shown to increase with more HA courses.

Figure 1. Average time to KA by the number of HA courses

**Table 1: Differences in median time to KA**

Reference group	Treatment type	Quantile (median; in months)	
		Without Propensity Score	With Propensity Score
No HA	Non-hylan G-F 20 HA	7.67 (7.33 to 8.01), <0.001	7.73 (7.26 to 8.20), <0.001
	multiple-shot hylan G-F 20	4.70 (4.24 to 5.16), <0.001	4.94 (4.41 to 5.47), <0.001
	one-shot hylan G-F 20	9.46 (8.97 to 9.95), <0.001	9.04 (8.48 to 9.59), <0.001
	One+multiple-shot hylan G-F 20	23.34 (20.88 to 25.80), <0.001	22.37 (20.35 to 24.38), <0.001
Non-hylan G-F 20 HA	multiple-shot hylan G-F 20	-4.86 (-5.50 to -4.21), <0.001	-3.06 (-3.69 to -2.43), <0.001
	one-shot hylan G-F 20	*-0.03 (-0.29 to 0.23), 0.835	*0.09 (-0.26 to 0.43), 0.620
	one+multiple-shot hylan G-F 20	3.42 (2.84 to 4.00), <0.001	1.77 (1.22 to 2.33), <0.001
	one+multiple-shot hylan G-F 20	*3.00 (2.74 to 3.26), <0.001	*2.64 (2.34 to 2.94), <0.001
	multiple-shot hylan G-F 20	12.87 (10.93 to 14.81), <0.001	14.44 (12.11 to 16.78), <0.001
	one-shot hylan G-F 20	*15.99 (14.18 to 17.81), <0.001	*14.83 (12.27 to 17.39), <0.001
	one+multiple-shot hylan G-F 20	12.87 (10.93 to 14.81), <0.001	14.44 (12.11 to 16.78), <0.001
	one+multiple-shot hylan G-F 20	*15.99 (14.18 to 17.81), <0.001	*14.83 (12.27 to 17.39), <0.001

## The Common Risk Factors for Hyperuricemia and Gout Do Not Predict Incident Gout Once Hyperuricemia Is Established

**Richard J. Reynolds**<sup>1</sup> and Jasvinder A. Singh<sup>2</sup>, <sup>1</sup>Medicine, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Rheumatology, University of Alabama at Birmingham, Birmingham, AL

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Metabolic syndrome, chronic kidney disease and hypertension are known to be associated with hyperuricemia and gout. Hypertension is associated with incident gout. The Normative Aging Study indicates five times the number of people with gout have asymptomatic hyperuricemia, and it is not understood what factors can explain this difference. Using data from two prospective cohorts, the Framingham Heart Study (FHS) and the Atherosclerosis Risk in Communities Study (ARIC), we tested the hypothesis that traits representing the comorbid conditions of hyperuricemia and gout, given hyperuricemia at baseline, could discriminate those that subsequently develop gout from those that do not during the follow-up period.

**Methods:** A total of 3,415 and 1,040 participants from ARIC and FHS, respectively met the inclusion criterion in which serum urate concentration was greater than 7.0 mg/dL at the 1<sup>st</sup> exam in ARIC or exam 1, 2, or 8 of the offspring cohort in FHS. Prevalent gout cases were excluded. With ARIC, incident gout was defined only if self report gout was reported at the fourth exam (ARIC). With FHS, incident gout was defined only if clinical diagnostic impression of gout was reported at any exam subsequent to the exam with serum urate concentration greater than 7.0. We extracted the following variables at the exam where hyperuricemia was recorded: Age, sex, race (ARIC), systolic blood pressure, glomerular filtration rate (ARIC),

BMI, triglycerides, low-density lipoprotein-LDL, WaistHipRatio (ARIC), glucose and serum urate level (7-8, > 8 mg/dL). Logistic regression was used to model incident gout with a linear predictor comprising the explanatory variables.

**Results:** A total (proportion) of 167 (0.05) and 99 (0.095) incident gout cases occurred during follow-up. The mean (SD) age at baseline was 55 (5.8) and 39.5 (11.5) with 10 and 16 years of follow-up for ARIC and FHS, respectively. Age at first exam (P-value=0.047-ARIC; 0.033-FHS), with odds ratio-OR (95% confidence interval [CI]), 0.97 (0.94, 1.0)-ARIC, 0.98 (0.96, 0.999)-FHS, and serum urate level (P-value=<0.0001-ARIC, 0.056-FHS), with OR 3.42 (2.38, 4.93)-ARIC, 1.53 (0.985, 2.38)-FHS, were the only consistent explanatory variables for incident gout between the two data sets. Increased LDL was associated with incident gout in FHS (P-value=0.02, mean (SD) in gout vs no gout 145.2 (33.9) vs 138.2 (36.1), with OR = 1.01 (1.001,1.014)). The model R<sup>2</sup> was 6.3% and 2.8% for the ARIC and FHS datasets respectively.

**Conclusion:** The traditional risk factors for hyperuricemia and gout do not differentiate people with hyperuricemia that develop incident gout from those that do not during the follow-up period. A possible explanation is that most of the risk factors predict the development of hyperuricemia but not gout. Individuals presenting with serum urate levels > 8 mg/dL had the highest risk for developing gout in the future. The low explanatory ability of these models indicates that additional features, possibly molecular (e.g., genomic, metabolomic), behavioral (e.g. exercise, smoking, alcohol use) and use of medications (diuretics, aspirin, ACE inhibitors), may be important predictors of gout given the state of hyperuricemia.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterized by small vessel vasculopathy, autoantibody production, and excessive collagen deposition in the skin and internal organs. Its clinical manifestations and progressions are chronic and diverse. Studies on epidemiology and mortality of systemic sclerosis (SSc) at the national level are scarce. To investigate incidence, prevalence, mortality, and causes of death in SSc patients using nationwide population based data in Korea.

### **Methods:**

We used data from the Rare Intractable Disease (RID) registry and Health Insurance Review and Assessment (HIRA) service, which include information on all SSc patients diagnosed based on uniform criteria between 2008 and 2013. The RID<sub>1</sub>'s diagnostic criteria for SSc adopt the 1980 criteria of American College of Rheumatology. We linked the data from Statistics Korea to the HIRA-RID database to confirm the causes of death.

## Results:

The mean annual incidence of SSc in Korea was 8.0 per 10<sup>6</sup> population, with a female-to-male ratio of 3.9:1. The prevalence in 2013 was 77.7 per 10<sup>6</sup> population. The average annual mortality was 1.40 per 10<sup>6</sup> people, and the standardized mortality ratio was 4.34. The 5-year survival rates were 88.5%, which was significantly lower than the age-gender matched general population. SSc was the most common cause of death (36.5% of total death), followed by malignancy (18.2%), cardiovascular diseases and respiratory diseases (10.7%, each).

## Conclusion:

Incidence and prevalence of SSc in East Asian countries is considered to be lower than in North America and Australia, but higher than in Northern European countries. The higher mortality of SSc patients compared to the general population is attributable to SSc related diseases, lung cancer and respiratory diseases. Post-diagnosis survival of SSc patients was better than previous studies, which may represents a recent improvement in patient management.

**Figure 1.** Incidence of Systemic sclerosis by sex and age in Korea, 2008–2013. The vertical axis shows incidence rates per 10<sup>5</sup> population; the horizontal axis shows age in 5-year increments until the age of 80.

## Identifying Exposures to Chemicals in Patients with SLE – a Non-Targeted Exposome Approach Reveals Enrichment for Phthalates

**Cristina Lanata**<sup>1</sup>, Thomas Lin<sup>2</sup>, Maria Dall'Era<sup>1</sup>, Jinoos Yazdany<sup>3</sup>, Patricia P. Katz<sup>1</sup>, Laura Trupin<sup>3</sup>, Charles G. Helmick<sup>4</sup>, Roy Gerona<sup>5</sup> and Lindsey A. Criswell<sup>1</sup>, <sup>1</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Univeristy of California, San Francisco, SAN FRANCISCO, CA, <sup>3</sup>Medicine/Rheumatology, University of California

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017  
**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis  
**Session Type:** ACR Poster Session B  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Environmental exposures may play a substantial role in the pathogenesis of SLE. The goal of this study is to characterize the serum levels of multiple chemicals in a cohort of SLE patients and controls.

**Methods:**

Patients from the California Lupus Epidemiology Study and healthy controls were studied. Banked serum was analyzed by Liquid Chromatography Quadruple Time-of-Flight Mass Spectrometry (LC-QTOF/MS). The results of the LC-QTOF/MS analysis were matched into a database of 740 potentially detected environmental organic chemicals. Detection frequencies of chemicals were calculated. Univariate and multivariate analyses were performed, adjusting for potential confounders. Association testing between chemical classes, chemicals and specific lupus phenotypes and disease activity was performed.

**Results:**

58 females with SLE and 78 healthy females were studied. The number of unique chemicals detected was 309, with an average of 60 chemical-hit matches per subject (range 32-150). SLE patients had a higher detection frequency of phthalates whereas healthy controls had a higher detection frequency of pesticides and phenols (table 1). A higher phthalate detection frequency was associated lupus nephritis, but did not correlate with disease activity (SLEDAI score), hypocomplementemia or anti ds-DNA status. In patients with SLE, a per count increase in detection frequency of a phthalate was associated with an OR of 1.4 for history of lupus nephritis, adjusting for age, disease duration, race, education and income (p=0.002, CI[1.1-1.7]). Chemicals detected at a higher frequency in SLE were enriched for specific phthalates such as metabolites of DHEP (table 2). Among SLE patients, 2 specific phthalates, mono2ethyl5oxohexylphthalate (p=0.00002) and mono2ethyl5oxohexylphthalate (p=0.00015) were associated with lupus nephritis.

**Conclusion:**

LC-QTOF/MS can identify a wider range of potential chemical exposures in SLE, and may aid in prioritizing chemicals for further research and intervention. We found that patients with SLE had significantly increased exposure to phthalates compared to healthy controls, with further enrichment among patients with lupus nephritis. Exposure to Mono-(2-carboxymethylhexyl) phthalate has been associated with dsDNA production and lupus nephritis in NZB/W F1 mice.

Table 1. Detection Frequency by Chemical Class

Chemical class (frequency count)*	SLE n=58				LN Positive N=28				LN Negative n=30				Healthy n=78				pvalue**

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A prospective study of preclinical SLE disease evolution is needed to help elucidate critical aspects of disease etiology and early pathogenesis, and to identify early directed therapeutic targets. However, designing the most informative study of this complex heterogeneous disease is unclear without better definition of high-risk populations. Our objective was to determine screening characteristics to identify individuals for follow-up in a prospective study.

**Methods:** We sent letters to 3823 individuals who reported having a family member with SLE and who did not meet  $\geq 4$  ACR criteria for SLE at their baseline visit to enroll in a follow-up study to gather information regarding interim development of signs and symptoms consistent with SLE; 436 enrolled. Fifty-six individuals had transitioned to SLE ( $> 4$  cumulative ACR criteria, verified by medical record review) by the time of follow-up. Generalized estimating equations, accounting for correlation within families, assessed associations between our dichotomous outcome of transitioning to SLE with baseline characteristics, including age, sex, race, ANA positivity (ANA+), Connective Tissue Disease Screening Questionnaire (CSQ) SLE score, and number of ACR criteria. Predictive accuracy of characteristics on transitioning were analyzed using positive predictive value (PPV), negative predictive value (NPV), sensitivity, and specificity. Characteristics

were separated by the amount of effort required to collect the data: questionnaire alone; questionnaire and a blood test; and a blood draw and medical records for ACR criteria confirmation.

**Results:** Age (47.2 vs 47.2 years), sex (87.5% vs 83.2%), and race (76.8% vs 73.4% European American (EA)) were similar between those who transitioned and those who did not transition. Sisters of a SLE proband were just as likely to transition as other first-degree relatives (OR=1.5, 95% CI 0.8-2.8), as were those <30 years of versus those ≥ 30 years old (OR=1.3, 95% Ci 0.5-3.2), and non-EAs versus EA (OR=1.3, 95% 0.5-3.5). ANA+, CSQ classification of possible or probable SLE (CSQ-SLE+), and greater number of ACR criteria were each associated with transitioning to SLE. Being ANA+ and having photosensitivity by confirmed ACR criteria had the highest PPV and specificity for transitioning to SLE (Table 1). CSQ-SLE+ had a better PPV, NPV, sensitivity and specificity than ANA+ alone. Combining ANA+ and CSQ-SLE+ increased the PPV and specificity of transitioning to SLE; additionally limiting to females did not increase the predictive accuracy.

**Conclusion:** Limiting follow-up to females or to a specific race/ethnic group does not appear to be needed. Confirmed ACR criteria provided the best predictive accuracy. Given limited resources, identifying subjects based on the SLE portion of the CSQ questionnaire could be most efficient for follow-up.

Table 1. Predictive Accuracy of Baseline Characteristics for Transitioning to SLE.

Baseline Characteristics	N (%) with Characteristic(s)	Positive Predictive Value	Negative Predictive Value	Sensitivity	Specificity
Using Questionnaire Data alone					
CSQ-SLE+*	183 (42.0%)	27.9%	98.0%	91.1%	65.3%
Female	365 (83.7%)	13.4%	90.1%	87.5%	16.8%
CSQ-SLE+* and Female	166 (38.1%)	27.7%	96.3%	82.1%	68.4%
Using Questionnaire Data and Blood Draw for Measurement of ANA					
ANA+	226 (51.8%)	19.0%	93.8%	76.8%	51.8%
ANA+ and CSQ-SLE+*	122 (28.0%)	32.8%	94.9%	71.4%	78.4%
ANA+ and Female	200 (45.9%)	19.5%	92.8%	69.6%	57.6%
ANA+, CSQ-SLE+*, and Female	113 (25.9%)	32.7%	94.1%	66.1%	80.0%
ANA+ and Positive Photosensitivity from CSQ	80 (18.4%)	33.8%	91.9%	48.2%	86.1%
ANA+ and Positive Raynaud from CSQ	112 (25.7%)	28.6%	92.6%	57.1%	78.9%
Using Blood Draw for Measurement of ANA and Medical Records to confirm ACR Criteria					
ANA+ and Immunologic Disorder by Confirmed ACR Criteria	21 (4.8%)	52.4%	89.2%	19.6%	97.4%
ANA+ and Positive Photosensitivity by Confirmed ACR Criteria	24 (5.5%)	62.5%	90.0%	26.8%	97.6%
ANA+ and Positive Clinical <sup>†</sup> ACR Criteria	60 (13.8%)	58.3%	94.4%	62.5%	93.4%

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular disease (CVD) risk is increased in SLE patients, compared to the general population and age- and sex-matched diabetes mellitus (DM) patients. Heart failure (HF) is the leading cause of hospitalizations in the U.S., and HF risk is elevated among DM patients compared to those without DM. Given the elevated CVD risk in SLE patients, we investigated rates and risks of HF hospitalization among SLE patients and age- and sex-matched DM and general Medicaid patients.

**Methods:** We used Medicaid Analytic eXtract (MAX) data, containing billing claims for Medicaid patients from the 29 most populated US states, 2007-2010. We identified both SLE and DM patients, ages 18-65, using >3 ICD-9 codes for SLE or DM, each separated by >30 days. Index date was the date of the 3<sup>rd</sup> diagnosis code. We matched each SLE patient at index date to 2 DM patients and 4 general Medicaid patients without SLE or DM, by age at index date and sex. (The general Medicaid cohort had non-SLE, non-DM ICD-9 codes on date of SLE index date.) We required a baseline period of 6 months of continuous Medicaid enrollment prior to the index date for all patients. Subjects were followed from index date until death, disenrollment or end of follow-up. We used ICD-9 codes to identify HF as primary or secondary hospital discharge diagnosis and calculated rates of first HF hospitalization event per 1,000 person-years for each cohort. We used Cox proportional hazard models to calculate hazard ratios (HR) for first HF hospitalization events. In a secondary analysis, we excluded those with baseline HF.

**Results:** 40,212 SLE patients were matched to 80,424 DM and 160,848 general patients. In all cohorts, 92% were female, and mean age was 40.3 (+12.1) years. Mean follow up was 1.8 (+1.1) years for SLE, 1.8 (+1.1) years for DM, and 1.6 (+1.2) years for general patients. Baseline CVD was prevalent in 18% of SLE, 13% of DM and 1% of non-SLE, non-DM cohorts, and baseline HF was prevalent in 6% of SLE, 5% of DM and <1% of non-SLE, non-DM patients. HF hospitalization rates per 1,000-person years were similar in SLE and DM, but lower in the general population (**Table**). Adjusted HRs for first HF hospitalizations were higher among DM (HR 4.0, 95% CI 3.6-4.3) and SLE (HR 2.4, 95% CI 2.2-2.7) patients compared to non-SLE, non-DM patients. When patients with baseline HF were excluded, the HR for first HF hospitalizations were similar between SLE (HR 2.5, 95% CI 2.3-2.8) and DM (HR 2.7, 95% CI 2.4-2.9).

**Conclusion:** SLE and age- and sex-matched DM patients had significantly higher rates of HF hospitalization than age- and sex-matched general (non-SLE, non-DM) Medicaid patients. The adjusted risk of first HF hospitalization was also over twice as high in both SLE and DM patients than in patients without either condition, which has important implications for improving clinical care for SLE patients.

**Table. Rates and Multivariable Hazard Ratios for Hospitalizations for HF\* among SLE Patients and Age- and Sex-Matched DM Patients, compared to the General (non-SLE, non-DM) Medicaid population, 2007-2010**

Cohort†	Events	Person-years	Rate‡ (95% CI)	HR§ (95% CI)	
				Including all patients	Excluding patients with baseline HF
<b>General Medicaid</b>	620	250,281	2.5 (2.3-2.7)	1.0 (ref)	1.0 (ref)
<b>SLE</b>	837	73,299	11.4 (10.7-12.2)	<b>2.4 (2.2-2.7)</b>	<b>2.5 (2.3-2.8)</b>
<b>Diabetes Mellitus</b>	1,675	145,692	11.5 (11.0-12.1)	<b>4.0 (3.6-4.3)</b>	<b>2.7 (2.4-2.9)</b>

\*HF: Heart failure events by hospitalization ICD-9 diagnosis codes 402.01, 402.11, 402.91, 404.01, 404.11, 404.91, 404.03, 404.13, 404.93, and 428.xx, but excluding 398.91 rheumatic heart disease (Chen J, Circulation, 2013).

†Cohort: SLE cohort defined as >3 SLE ICD-9 codes (710.0), each separated by >30 days; DM cohort defined as >3 ICD-9 codes (249.XX, 250.XX, 357.2, 362.01-362.06, 366.41), 1:2 matched by age, sex to SLE cohort; General Medicaid cohort defined as any non-SLE, non-DM ICD-9 code on same date as SLE index date, 1:4 matched by age, and sex to SLE cohort

‡Rate: Rate of first HF hospitalization events per 1000 person-years of follow up

§HR: Hazard ratio for first HF hospitalization event adjusted for age, sex, race/ethnicity, US region of residence, zip-code level socioeconomic status, Charlson comorbidity index; Two separate Cox proportional hazard models: 1) including all patients, 2) excluding patients who had baseline HF diagnosis

## **Do Death Certificates Underestimate the Burden of Rare Diseases: The Example of Systemic Lupus Erythematosus Mortality in Sweden**

Titilola Falasinnu<sup>1</sup>, Marios Rossides<sup>2</sup>, Yashaar Chaichian<sup>3</sup> and Julia F Simard<sup>4</sup>, <sup>1</sup>Health Research and Policy, Stanford University, Stanford, CA, <sup>2</sup>Medicine Solna, Clinical Epidemiology Unit, Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Medicine, Immunology & Rheumatology Division, Stanford School of Medicine, Stanford, CA, <sup>4</sup>Division of Epidemiology, Health Research and Policy Department, Stanford School of Medicine, Stanford, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Routine data sources such as death certificates are used to estimate the burden or cost of disease in a population. However, mortality due to rare diseases, e.g., systemic lupus erythematosus (SLE), that are significant sources of

premature mortality, is often ignored in mortality reports. The objective of this study was to determine the completeness of SLE mention in the death register in Sweden and patterns of completeness by demographic factors.

**Methods:** A Swedish population-based cohort of individuals with prevalent SLE (the Swedish Lupus Linkage [SLINK]; 2001-2013) was linked to the Cause of Death Register. All death records from subjects known to be deceased in the cohort were reviewed and information regarding patient demographics (i.e., sex, age, region, place, and year of death) and causes of death were extracted. Odds ratios (OR) and 95% confidence intervals (95% CI) for the absence of SLE on death certificates were estimated using a multivariable-adjusted logistic model. We also estimated the degree of over- or underestimated SLE mortality using the comparability ratio.

**Results:** Approximately 59% of decedents with SLE had SLE absent from their death certificates (n=1,802). The majority of deceased individuals were aged 60-79 years at death (52%), female (81%), and born in Nordic countries (96%). In the adjusted model, increasing age was associated with SLE being absent from death certificates among those in the established cohort. Decedents 60-79 years old at death were approximately 2.5 times as likely to have SLE missing from their death certificates compared with those <40 years (OR: 2.48, 95% CI: 1.34-4.58). Having renal failure listed on the death certificate decreased the likelihood of SLE being absent (OR: 0.55, 95% CI: 0.41-0.73), while cancer increased this likelihood (OR: 2.35, 95% CI: 1.83-3.02). Death certificate data underestimated SLE mortality by 59% (comparability ratio 0.41 [95% 0.38-0.43]).

**Conclusion:** SLE is greatly underreported as a cause of death on death certificates thereby underestimating the burden of this disease. This may be due to ambiguity and disparate practices concerning the recording of comorbidities in death certificates. Inadequate attention may be devoted to the contribution of lupus to cancer secondary to systemic inflammation compared to lupus mortality related to direct organ involvement.

## Death Certificates Do Not Accurately Identify SLE Patients

Kelly Kaysen, Cristina Drenkard, Gaobin Bao and S. Sam Lim, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mortality rates are higher in SLE patients compared to the general population, and research on SLE mortality is ongoing. The majority of mortality studies have relied on death certificates to identify SLE patients. However, this approach may misclassify cases and include both false positives and negatives. The rate of misclassification on death certificates is unclear. Using a large population-based registry of validated SLE patients, we sought to ascertain the accuracy of death certificates in identifying SLE patients.

**Methods:** The Georgia Lupus Registry (GLR) is a population-based registry of validated SLE patients living in Atlanta, GA from 2002-04. The state HIPAA exemption for surveillance allowed health care providers and facilities to provide access to protected health information without written patient consent. Patients were validated by meeting  $\geq 4$  ACR criteria or 3 ACR criteria with a final diagnosis of SLE by a board-certified rheumatologist. These patients were matched to the Georgia Office of Vital Records death certificates through 2013. The primary, secondary, tertiary, and contributing causes of death were identified on the death certificates using ICD-10 codes.

**Results:** State death certificates matched with 321 SLE patients from the GLR through 2013. Only 24.6% (79/321) of patients had SLE listed on the death certificate. Characteristics of the deceased SLE patients are listed in the below table. While there were no significant differences with race and sex, SLE patients captured in death certificates were much younger at SLE diagnosis and died at a younger age.

**Conclusion:** In a population-based registry with many high-risk black SLE patients, SLE was recorded on the death certificates of only 24.6% of deaths. SLE was listed more often on the death certificates of those who were younger at SLE diagnosis and death, perhaps indicating more severe disease or increased awareness by the caring providers. Death certificates do not accurately capture the full spectrum of SLE patients. Reliance on death certificates to obtain SLE mortality data will underestimate the burden of the disease.

Characteristics of deceased SLE patients and identification of SLE on death certificates					
Characteristic	Category	Overall (n=321)	SLE captured in death certificate		
			No (n=242)	Yes (n=79)	P Value

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ultraviolet-B radiation (UV-B) exposure may lead to worsened photosensitivity, rashes, and systemic flares among SLE patients. Although UV-B radiation damages keratinocytes and may result in production of novel forms of autoantigens, it remains unknown whether UV-B exposure increases the risk of developing SLE. We aimed to examine the association of UV-B exposure with risk of incident SLE in a large prospective cohort of women, examining SLE risk overall and by subtypes defined by presence of anti-Ro/La antibodies (+anti-Ro/La) and/or cutaneous manifestations most associated with UV exposure in SLE patients.

**Methods:** The Nurses' Health Study (NHS) enrolled 121,701 U.S. female nurses in 1976; NHSII enrolled 116,430 in 1989. Biennial questionnaires collected lifestyle, environmental, and medical data. Residential addresses were geocoded. Incident SLE was confirmed by medical record review. National Aeronautics and Space Administration Total Ozone Mapping Spectrometer and Ozone Monitoring Instrument gridded remote sensing images scaled to a 1 km spatial resolution predicted average July noon-time erythemal UV-B ( $\text{mW/m}^2$ ) annually starting in 1980. Participants without UV-B data at baseline were excluded. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated using Cox regression models across tertiles of cohort-specific, time-varying cumulative average UV-B through one cycle prior to SLE onset. We examined SLE risk overall and stratified by presence of anti-Ro/La or cutaneous manifestations (malar rash and/or photosensitivity) at diagnosis through 2014 (NHS) or 2013 (NHSII), controlling for potential confounders. We also conducted a 'lagged' analysis by ending the exposure window two cycles prior to SLE diagnosis, as SLE symptoms may develop insidiously pre-diagnosis.

**Results:** Mean age at SLE diagnosis was 49.3 (10.4) years among 286 SLE cases in NHS/NHSII. At SLE diagnosis, 13% of women had +anti-Ro/La whereas 80% had either +anti-Ro/La or at least one cutaneous manifestation. Compared to the lowest tertile of UV-B exposure, risk of overall SLE, SLE with +anti-Ro/La, or SLE with photosensitivity in the highest UV-B tertile were increased, but not statistically significant in the main analysis (**Table**) or in lagged analyses. However, women in the highest UV-B tertile had statistically significantly increased risks of SLE with malar rash (HR 1.68 [95% CI 1.08-2.62]) (**Table**), but this was no longer significant in the lagged analysis (HR 1.41 [95% CI 0.88-2.25]).

**Conclusion:** Increasing cumulative UV-B exposure was not associated with risk of developing overall SLE. However, among women at risk for SLE, living in areas with higher UV-B exposure was associated with increased risk of developing SLE presenting with malar rash. Further studies are warranted to determine whether high UV-B exposure may play a role in triggering SLE onset with malar rash.

**Table. Association between Cumulative Average Ultraviolet-B Radiation and Risk of Incident SLE, Overall and by Subtypes Characterized by Anti-Ro/La Antibodies (+Anti-Ro/La) and Cutaneous Manifestations, among Participants in Nurses' Health Study and Nurses' Health Study II (1976-2014)**

## Impact of DMARD Treatment on Risk of Repeat Cardiovascular Events Among Patients with Rheumatoid Arthritis, Psoriatic Arthritis, or Psoriasis

**Jeffrey A. Sparks**<sup>1</sup>, Tamara Lesperance<sup>2</sup>, Neil A. Accortt<sup>3</sup> and Daniel H. Solomon<sup>4</sup>, <sup>1</sup>Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>2</sup>DOCS Global, Inc., North Wales, PA, <sup>3</sup>Center for Observational Research, Amgen, Inc., Thousand Oaks, CA, <sup>4</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chronic inflammatory diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO) increase the risk of cardiovascular (CV) disease. However, it is unclear what factors, including DMARD treatment, after a first CV event may affect risk of subsequent CV events. We estimated and compared the incidence of subsequent CV events among patients with RA, PsA, or PsO who were being treated with DMARDs prior to the initial CV event.

**Methods:** Patients with RA, PsA, or PsO, who experienced a major non-fatal CV event (acute myocardial infarction, stroke, or cardiac revascularization) between 1/1/2006 and 6/30/2015 were identified in an administrative claims database. Index date was defined as the hospital discharge date for the first non-fatal CV event during the study period. Eligible patients were: continuously enrolled for 12 months prior to index date; had ≥1 DMARD claim (categorized as TNF inhibitor (TNFi), conventional synthetic [csDMARD], or a non-TNFi biologic DMARD including tofacitinib) within 12 months prior to the index date; and had ≥30 days of follow-up after index date. The primary outcome was the occurrence of any CV event

during the follow-up period. Incidence rates (IR) per 1,000 person-years with 95% confidence intervals (CI) were calculated and age and sex standardized to the general population. The hazard ratio (HR) and 95% CI for a subsequent CV event was estimated using Cox proportional hazard models. Patients who were not treated with any DMARD after initial CV event were not included in the analyses.

**Results:** We identified 8,610 patients with RA, PsA, or PsO eligible for study. After the index date, 2,924 (34.0%) patients used a TNFi, 4,813 (55.9%) used a csDMARD as monotherapy or combination, and 873 (10.1%) used a non-TNFi biologic DMARD. Median follow-up time after initial CV event was 1.6 years. Patients using non-TNFi biologic DMARDs had higher crude incidence rates of repeat CV events than those who used TNFi or csDMARDs (Table 1). The multivariate adjusted hazard ratios for subsequent CV events were 0.98 (95% CI, 0.82-1.17) for csDMARDs, and 1.16 (0.86-1.57) for other biologic DMARDs compared to TNFi (Table 2). RA diagnosis (as compared to PsO diagnosis) and heart failure diagnosis in baseline were risk factors independently associated with increased risk of subsequent CV event.

**Conclusion:** In this large nationwide database reflecting typical clinical care, we found that type of DMARD use after initial non-fatal CV event was not associated with risk for subsequent CV event among RA, PsA, and PsO patients. Predictors of subsequent CV event included having RA and heart failure prior to initial CV event.

<b>Table 1. Incidence of Subsequent CV Events among RA, PsA, PsO Patients (n=9,529)</b>			
	<b>TNF Inhibitors (n=2,924)</b>	<b>csDMARDs (n=4,813)</b>	<b>Other (non-TNFi) Biologics (n=873)</b>

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We previously found that lower levels of omega-3 fatty acids (n-3 FA) were associated with the presence of inflammatory arthritis (IA) as well as risk of developing incident IA in ACPA+ individuals without IA at baseline. Omega-6 fatty acids (n-6 FA) compete with n-3 FA for elongation and desaturation enzymes in the body that help determine the pro- and anti-inflammatory potential of these FA and their derivatives. Western diets tend to have a high n-6 to n-3 ratio that may promote the pathogenesis of inflammatory and autoimmune diseases. We examined the association between n-6 FA levels and the presence of IA/rheumatoid arthritis (RA) in ACPA+ individuals.

**Methods:** At Colorado-based health fairs from 2008-2014, 47 subjects without a previous diagnosis of RA tested positive for the ACPA, anti-cyclic citrullinated peptide (CCP3, Inova), and were recruited into a follow-up research study. At their immediate post-health fair research visit (baseline), 10 of these ACPA+ subjects were identified as having disease-modifying anti-rheumatic drug (DMARD)-naïve IA. Of the 10 ACPA+ subjects with prevalent IA at baseline, 8 were classified as RA by 2010 ACR/EULAR Criteria. Findings in those subjects with IA were compared to those without IA. Specifically, n-3 and n-6 as percent of total lipids in red blood cell membranes (RBC) were measured. Logistic regression assessed the associations between baseline IA and RBC n-6 FA%, as well as the n-6 to n-3 ratio.

**Results:** Subjects with IA at baseline were more likely to be ever smokers and test positive for rheumatoid factor and C-reactive protein than those without IA (Table 1). In addition, we found that subjects with higher n-6 FA and linoleic acid levels had higher odds of IA (Table 2). Furthermore, analysis of the n-6 to n-3 ratio demonstrated that higher total n-6 FA % relative to total n-3 FA % in RBCs significantly increased the odds of IA by almost 3-fold (Table 2).

**Conclusion:** We found that a higher n-6 to n-3 ratio was associated with prevalent IA in this ACPA+ population. Building off our previous work, this suggests a potential beneficial role of n-3 FAs in decreasing the risk of transitioning from ACPA positivity to IA. Specifically, our findings herein suggest that decreasing the n-6 to n-3 FA ratio in the body, perhaps either via n-3 FA supplementation or diet may play a role in decreasing the transition from an ACPA+ state to IA, findings that warrant further investigation.

<b>Table 1: Descriptive Characteristics by IA status at Baseline, Colorado Health Fair Population, 2008-2014</b>			
<b>Variable</b>	<b>Prevalent IA at Baseline (n=10)</b>	<b>No IA at Baseline (n=37)</b>	<b>p-value</b>
Age, yrs (mean ± SD)	55.9 (10.3)	55.9 (10.4)	0.996
Age ≥ 50 yrs	8 (80.0)	26 (70.3)	0.703
Sex: Female	8 (80.0)	21 (56.8)	0.277
Race/Ethnicity: non-Hispanic White	7 (70.0)	29 (78.4)	0.679
Education: > High school	8 (80.0)	32 (86.5)	0.630
Income: > \$40,000	7 (77.8)	25 (71.4)	1
Smoking: Ever	9 (90.0)	16 (43.2)	0.012
Shared Epitope (SE)+	7 (70.0)	16 (43.2)	0.168
Omega 3 supplement use	8 (80.0)	19 (51.3)	0.154
Rheumatoid Factor (RF)+	6 (60.0)	5 (13.5)	0.006
C-Reactive Protein (CRP)+	6 (60.0)	7 (18.9)	0.017
n-6 : n-3 ratio (mean ± SD)	4.00 (1.41)	3.14 (0.81)	0.093
All values reported as n(%) unless otherwise stated. Fisher Exact p-values presented for categorical variables. Satterthwaite p-values reported for continuous variables.			

<b>Table 2: Adjusted analyses evaluating the relationship between omega-6 fatty acid % and IA at Baseline (N=47)</b>		
<b>FA% in RBC</b>	<b>OR (95% CI)</b>	<b>p-value</b>
n-6 : n-3 FA ratio	2.99 (1.11, 8.05)	0.030
Total n-6 FA	2.96 (1.12, 7.79)	0.028
Linoleic acid	2.63 (1.10, 6.29)	0.030
Gamma linolenic acid	4.91 (0.85, 28.35)	0.075
Arachidonic acid	0.81 (0.21, 3.22)	0.768
The n-6:n-3 FA ratio model adjusted for ever smoking status, SE, RF+, and CRP+; and the OR represents the odds of IA for each unit difference in the n-6:n-3 ratio. The n-6 models adjusted for ever smoking status, n-3 FA supplement use, SE+, RF+, and CRP+; and the ORs represent the odds of IA for a one standard deviation (SD) difference in the n-6 FA% in RBC. The SD for these variables are as follows: Linoleic acid: 1.72, Gamma linolenic acid: 0.06, Arachidonic acid: 1.37, Total n-6: 1.97.

## Publication Timeliness of the Randomized Controlled Trials of Drug Therapy for Inflammatory Arthritis

Vyjayanthi Ganga<sup>1</sup>, Mohan Edupuganti<sup>2</sup> and Nasim A. Khan<sup>3</sup>, <sup>1</sup>St. Vincent Healthcare System, Little Rock, AR, <sup>2</sup>Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, <sup>3</sup>Rheumatology, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Timely publication of randomized controlled trials (RCTs) is crucial for their potential impact on patient care. We assessed the publication timeliness of drug therapy RCTs of inflammatory arthritis.

**Methods:** The print issues (or online issues for online-only journal) of the 10 highest impact factor (IF) rheumatology journals publishing original research and 5 highest IF internal medicine journals for the years 2013-2014 were searched using Medline. Original parallel-design, non-phase-1 RCTs reports of drug therapy for inflammatory arthritis with clinical primary outcome(s) were eligible. RCT completion dates were retrieved either from the manuscript or the respective trial registry information in the manuscript. The dates of manuscript submission, acceptance, first online publication, and publication in a print issue were used to calculate the intervals in the publication process of study RCTs. RCT characteristics associated of with the time from trial completion to first (online or print) and final (typically print) available version were assessed.

**Results:** Eligibility criteria were met by 67 RCTs. The study conditions were rheumatoid arthritis (68.7%), spondyloarthropathy (20.9%), gout (6%) and others (4.5%). Experimental drug manufacturer fully or partially funded 56 (83.6%) RCTs. All RCTs had trial registry information (ClinicalTrials.gov for (58[86.6%]) RCTs). The experimental interventions included biologics (73.1%), small molecule (14.9%), traditional disease modifying agent ([10.4%), and other (1.5%). Most trials were multicenter (92.5%) and multinational (56.7%). RCT completion date was obtained from the manuscript for 16 (23.8%) and trial registry record for 49 (73.1%) RCTs. Some dates such as manuscript submission and acceptance were unreported for nearly 45% RCTs. Table shows the different time intervals in the publication process. The first available version was published within a year of completion for 8 (12%) and within 2 years for 39 (58%) RCTs. Final available version of RCTs with positive results (statistically significant result favoring the experimental intervention) was available earlier [median (IQR): 25.5 (21.7-35) months for positive vs 32.5 (26.6-44.5) months,  $p = 0.04$ ]. No significant differences were noted in the time from RCT completion to first or final publication according to study condition, funding source, experimental intervention type, and whether the RCT was multicenter or multinational.

**Conclusion:** There is a considerable time lag between the completion and publication of RCTs. Several crucial dates needed to assess the publication timeliness were unavailable in the manuscripts. Clinical trial registries enabled publication timeliness assessment. Advance online publication helps in early availability of trial results.

Table. Different intervals from RCT completion to final publication.

Time interval	N*	Median (IQR)**	Range**
RCT completion to manuscript submission	35	20 (13-30)	14-100
Manuscript submission to acceptance	36	4 (3.5-6)	1.5-12
Manuscript acceptance to first published version	56	1 (0.7-1.4)	0-3.5
First version to final published version	67	4.6 (1.5-9)	0-15
RCT completion to first version	65	21.7 (18-32.9)	4.6-98.5
RCT completion to final version	65	27.5 (22.5-39.6)	13.8-99.5

## **The Effect of Anti-TNF Therapy on Work Productivity and Activity Impairment in Patients with Rheumatoid Arthritis, Ankylosing Spondylitis and Psoriatic Arthritis over One Year – Real Life Data from the Czech Biologics Registry Attra**

**Jakub Zavada**<sup>1</sup>, Lenka Szczukova<sup>2</sup>, Karel Pavelka<sup>3</sup> and Jiri Vencovsky<sup>3</sup>, <sup>1</sup>Institute of Rheumatology, Prague, Czech Republic, <sup>2</sup>Institute of Biostatistics and Analyses. Faculty of Medicine, Masaryk University, Brno, Czech Republic, <sup>3</sup>Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The ATTRA registry captures more than 95% of patients with RA, PSA or AS treated with biologics in the Czech Republic (CZ). In CZ, anti-TNF-therapy is reimbursed for RA if DAS28>5.1 despite therapy with csDMARDs, for PSA if disease is not adequately controlled with csDMARDs and for AS if BASDAI>4 and CRP/ESR elevated above normal. To assess the effect of anti-TNF therapy on work productivity using the Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP) questionnaire in patients with RA, PSA and AS in the real life setting using the data from ATTRA.

**Methods:** WPAI-SHP scores were collected for all patients enrolled in ATTRA since 2012 at baseline and after 12 months of anti-TNF exposure. Bionšive patients with RA (n=352), AS (n=442) and PSA (n=133) starting anti-TNF therapy with available baseline data on demography, disease duration and physical function, and WPAI-SHP at baseline and at 12 months were included in this analysis. Patients older than 60 years, on maternity leave or students were excluded. Only patients working for pay at baseline were assessed for WPAI-SHP summary scores: absenteeism (mean % work time missed), presenteeism (mean % productivity loss at work), overall work impairment (mean % overall work productivity loss), and activity impairment (mean % productivity loss in regular activities). Regression analyses were performed to analyse the predictors of improvement in WD overall work impairment one year.

**Results:** Baseline characteristics were significantly different between diagnoses (Table 1). Working status changed significantly only in patients with RA (employed 69→64%, p=0.013), but not in AS (77→78%) or PSA (77→73%). In patients employed for pay both at baseline and after 12 months, all WPAI-SHP scores improved significantly over one year of anti-TNF therapy (Table 2). Patients with AS, younger age and more pronounced functional impairment (HAQ) at start of anti-TNF therapy had most profit in terms of improvement in overall work impairment over one year (table 3).

**Conclusion:** In the real life setting of the CZ, anti-TNF therapy effectively reduced absenteeism, presenteeism, activity impairment and work impairment over one year in employed patients with RA, AS and PSA.

**Acknowledgements:** Supported by project 00023728 of Ministry of Health, CZ.

## Increase in Prevalence of Psoriasis Arthritis over Time: Analysis of Claims Data from 65 Million People in Germany from 2009 to 2012

**Philipp Sewerin**<sup>1</sup>, Matthias Schneider<sup>2</sup>, Benedikt Ostendorf<sup>1</sup> and Ralph Brinks<sup>3</sup>, <sup>1</sup>Department and Hiller-Research-Unit for Rheumatology, Heinrich-Heine University, Düsseldorf, Germany, <sup>2</sup>Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, <sup>3</sup>Department and Hiller-Research-Unit for Rheumatology, Heinrich-Heine University, Duesseldorf, Germany

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Epidemiological studies are important contributors for our understanding of psoriatic arthritis (PsA). Currently, there are no data about temporal trends of prevalence of PsA on the population level. The aim of this study is to estimate the annual age- and sex-specific prevalence of diagnosed PsA in Germany during 2009 to 2012.

**Methods:** Complete diagnosis data from about 80% of the overall German population from 2009 to 2012 were screened for physician diagnosed and ascertained PsA. Diagnoses are based on claims data from all insurances of the German statutory health insurance (SHI) system. Quality checked claims data were provided by a governmental data trustee. After determining the age- and sex-specific prevalence of PsA for each of the years from 2009 to 2012, trend tests for age-standardized and age-specific prevalence in men and women were applied.

**Results:** In 2009, a total of 127 thousand patients with diagnosed and ascertained PsA were identified in 64.6 million people from the German SHI. In the following years 2010 to 2012, 138, 146, and 156 thousand people with diagnosed PsA have been observed, respectively. The age-standardized prevalence increases from 1.8 to 2.1 per mil in men (p-trend = 0.009), and from 2.1 to 2.5 per mil in women (p-trend = 0.01). The age-specific prevalence of PsA for men and women increases linearly from age group <20 to a peak of about 60 years of age. After age 60, the age-specific prevalence is steeply decreasing. In virtually all age groups, there is evidence for an increase of the age-specific prevalence with time in men and women. The highest increases are in the age groups 60+.

**Conclusion:** These data from about 65 million people insured in the German SHI for the first time indicate that there is an increasing prevalence of PsA on the population level. A selection bias is likely to be present, because the roughly 20% of the overall German population not included in our analysis is known to have other health risks (mainly privately insured people). However, our results refer to the vast majority of the German population and the 127 to 156 thousand people with diagnosed PsA. The analysis cannot be adjusted for potential confounders other than age and sex (e.g., socio-economic position or presence of co-morbidities).

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is limited information on the epidemiology of psoriasis and psoriatic arthritis (PsA) in North America. The aims of this study were to estimate the prevalence and incidence rates of psoriasis and PsA and their temporal trends in Ontario, Canada.

**Methods:** A retrospective cohort analysis was performed in Ontario health administrative databases. The following validated algorithms were used for case definition: 1) Psoriasis: diagnosis in hospitalization records or at least 2 psoriasis

diagnostic codes assigned by any physician (specificity 99%, sensitivity 52%, PPV 62%); 2) PsA: diagnosis in hospitalization records or a combination of: [1 psoriasis code by any physician or 1 prescription of topical anti-psoriatic treatment] and 2 diagnostic codes of spondyloarthritis at least 1 by a rheumatologist (specificity 100%, sensitivity 52%, PPV 66%). The crude and age and sex-standardized prevalence and incidence rates of psoriasis were calculated from 2000 to 2015 in the general population. For PsA, results are reported from 2008 onwards due to a change in billing code in 2006.

**Results:** Among the 10,757,627 individuals aged 20 years and older living in Ontario in 2015, we identified 263,586 and 16,144 patients with psoriasis, and PsA, respectively, resulting in overall crude psoriasis and PsA cumulative prevalence of 2.25% and 0.14%, respectively. For psoriasis, the age and sex-standardized prevalence increased from 1.43% in 2000 to 2.24% in 2015 (Figure 1). For PsA, the age and sex-standardized prevalence increased from 0.07% in 2008 to 0.13% in 2015 (Figure 2). In contrast, the incidence rates of both diseases remained relatively stable.

**Conclusion:** These findings enhance our understanding of the Canadian epidemiology of psoriatic disease and burden for healthcare resources planning. Although our previous validation work showed that administrative data under captures psoriatic disease the prevalence and incidence rates of psoriasis and PsA in Ontario were comparable to European populations. The steady increase in the prevalence of psoriasis and PsA over the past decade may be attributable to population growth, an aging demographic, and increase in patients seeking medical care.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is limited information on the epidemiology of Psoriatic Arthritis (PsA) in general and in Middle Eastern populations in particular. The aims of this study were to estimate the prevalence and incidence rates of PsA and their temporal trends in the general population in Israel.

**Methods:** In this study, we derived a cohort of adult patients with PsA from the database of Clalit Health Services (CHS), Israel's largest health fund, with over 4.4 million members (52% of Israel's population). PsA cases were identified if they fulfilled one of the following conditions: 1) PsA diagnosis assigned at least once by a rheumatologist; 2) permanent diagnosis code assigned by a family physician combined with use of synthetic or biologic disease modifying antirheumatic drugs; 3) PsA code listed in a hospitalization discharge summary. This algorithm had positive predictive value, sensitivity and specificity of 90.5%, 88.7% and 88.1%, respectively.

We calculated crude and age- and sex-standardized prevalence and incidence rates of PsA from 2006 to 2015 in the general population. The variation in PsA prevalence was assessed in relation to several demographic factors.

**Results:** Among the 2,931,199 individuals aged 18 years and older registered in the CHS database in 2015, 4490 patients had a diagnosis of PsA (322 incident cases), resulting in overall crude prevalence and incidence rates of 0.153% (95% CI 0.149%, 0.158%) and 10.9 (95% CI% 9.8, 12.3) per 100,000 population, respectively. The prevalence of PsA in Israel doubled between 2006 and 2015 (0.073% to 0.153%). In contrast, the global incidence rate remained stable, with a gradual increase in the incidence among individuals aged 51 to 70 years (Figure 1). PsA is associated with Jewish ethnicity, high socioeconomic status, rural residency and higher body mass index (Table 1).

**Conclusion:** The prevalence and incidence of PsA in Israel are within the range of previous estimates from Southern European populations. An increase in the prevalence of PsA was observed over the past decade in the general population in Israel.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We assessed the accuracy of algorithms to identify patients with psoriasis and psoriatic arthritis (PsA) in administrative health data in a validation set derived from primary care electronic medical records (EMRs), and contrasted the effect of different algorithms on the population-based prevalence of psoriasis and PsA in Ontario, Canada.

**Methods:** We developed a validation set using a sample of 2210 adult patients with suspected psoriasis and PsA. This sample was identified through a targeted search for psoriatic disease-related terms in the EMRs of a random sample of 30,424 patients in the primary care Electronic Administrative data Linked Database (EMRALD) in Ontario, Canada. The reference standard for classifying patients with physician-recorded psoriasis or PsA, was confirmed using a retrospective chart abstraction. All patients were then linked to health administrative data to assess the performance of the different algorithms combining physician billing and hospitalization diagnostic codes, medications and procedures for identification of patients with psoriatic disease. The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each algorithm were computed. Estimated population prevalence of psoriasis and PsA were then calculated for each algorithm.

**Results:** Based on our reference standard we identified 1028 patients with psoriasis and 90 patients with PsA which resulted in overall psoriasis and PsA prevalence of 3.4% and 0.29%, respectively. The majority of the patients with PsA (67%) had a documented diagnosis by a rheumatologist, while only 29% of the psoriasis patients had a documented diagnosis by a dermatologist. The accuracy of selected psoriasis and PsA case definition algorithms are presented in Table 1. All algorithms had excellent specificity (97-100%). However, the sensitivity and PPV of the algorithms were low to modest, ranging from 28% to 72% for sensitivity and 43% to 72% for PPV. The population prevalence of psoriasis (1.07-2.4%) and PsA (0.12-0.14%) ranged depending on the algorithm used for case definition.

**Conclusion:** The accuracy of identifying patients with psoriasis and PsA in Ontario health administrative databases varies widely, however when we applied these algorithms to the entire Ontario population, we observed similar patterns and a steady increase in prevalence, irrespective of the algorithm used. We recommend that PsA receives a distinct outpatient diagnostic code to improve case ascertainment.

**Table 1 – The accuracy of selected psoriasis case definition algorithms**

Algorithm	Prevalence				
	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	(per 100 population)
1 H or 1 P ever	71%	97%	43%	99%	2.40%
1 H or 1 P ever by a specialist	50%	98%	48%	98%	1.69%

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Tuberculosis (TB) is a major concern in patients receiving TNF inhibitors (TNFi).

**Objectives:** To assess the incidence of active TB and the efficacy of TB prevention measures in a large, single-center cohort of patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) receiving TNFi.

### **Methods:**

Data of all patients in whom treatment with TNFi was initiated in our rheumatology clinic from January 1st 2002 until December 31st 2015 have been retrospectively analysed. The cohort was divided into 2 groups per the mandatory latent TB infection (LTBI) screening method at baseline: tuberculin skin test (group TST), and QuantiFERON®-TB Gold test (group QFT). The incidence of active TB was analysed for each group and compared to TB incidence data in general population.

### **Results:**

653 patients were included (344 RA, 52 PsA, 257 AS); 324 patients belonged to the TST and 329 to the QFT group. The number of active TB cases/ time of exposure to TNFi (person-years, PY) was 17/2002.6 and 7/1041.2 respectively, accounting for an incidence of 848.9 and 672.3 cases per 105 PY, about 8 times higher (8.3 and 8.8 for TST, respectively QFT group) than the average TB during the period of exposure to TNFi. LTBI reactivations per total TB cases were only

4/17 and 2/7, respectively, too few to identify statistically significant differences between the 2 LTBI screening protocols. Only 10 patients had pulmonary TB, whereas the rest were disseminated TB (8 cases), TB pleurisy and/or pericarditis (4 cases), one mediastinal lymph node TB and one isolated hepatic TB. Using Pearson chi-square test, we found no significant differences between LTBI group and active TB (Table 1).

## Conclusion:

In our cohort, new infection TB exceeds reactivation TB, suggesting the necessity of periodical LTBI re-screening.

**Table 1. LTBI screening results and TB occurrence in the 653 TNFi-treated patients. (Pearson  $\chi^2$  test)**

	TST	QFT	All	p value
	(n=324)	(n=329)	(n=653)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** This study's aim was to assess the association between sociodemographic characteristics, disease progression, and mental health comorbidity with risk of mental disorders (RMD).

**Methods:** In 2016 a sample of 680 axSpA patients was interviewed as part of the Spanish Atlas. To quantify the RMD, Goldberg's General Health Questionnaire (GHQ-12) scale was employed. Possible RMD predictors analysed were: sociodemographic characteristics (age, gender, being part of a couple, patient association membership, job status); disease characteristics (BASDAI, spinal stiffness ranging from 0-3, functional limitation in 18 daily activities ranging from 0-3); and mental health comorbidities (depression and anxiety). All clinical variables showed a Cronbach's alpha coefficient guaranteeing the reliability of the scales used. First, a descriptive analysis was employed to describe the sample and study variables. Second, we performed univariate correlation and homogeneity analyses between each predictor (independent variable) and RMD (GHQ-12). Third, selection of variables that showed statistical significance in the univariate analyses in order to conduct a multiple hierarchical and stepwise regression analysis.

**Results:** All variables except educational level and thoracic stiffness showed significant univariant correlation with RMD. BASDAI, functional limitation and age showed higher coefficient ( $R = 0.543$ ,  $R = 0.378$ ,  $R = -0.174$ , respectively). Multiple Hierarchical regression analysis showed as sociodemographic variables explained in great detail the RMD ( $R^2 = 83.2\%$ ). By contrast, having established sociodemographic as a control variable, the inclusion of depression and anxiety to the model increase the  $R^2$  value to just  $0.6\%$  ( $p = 0.001$ ), while the inclusion of variables related to the disease characteristics add  $5.5\%$  ( $p = 0.000$ ) to the GHQ-12 punctuation variability. The only variables presenting a significant coefficient different from 0 were BASDAI ( $0.52$ ,  $p = 0.000$ ) and functional limitation ( $0.14$ ,  $p = 0.004$ ). This suggests that once the sociodemographic and mental commorbidity variables are established, a change to BASDAI levels or functional limitation impacts the GHQ-12 score. In the stepwise regression analysis, four variables (BASDAI, functional limitation, association membership, cervical stiffness) showed a significant relation to GHQ-12 and explained the majority of RMD variability. BASDAI displayed the highest explanatory degree ( $R^2 = 0.875$ ).

Table 1. Sample characteristics (n = 474, unless other specified).

Variables	Values (means $\pm$ SD or percentage)
<i>Age, mean <math>\pm</math> SD</i>	45.43 $\pm$ 10.78
<i>Sex, No. of men</i>	233 (49.16%)
<i>Having a couple, No. of participants (N=444)</i>	386 (86.94%)
<i>Education level, No. of university studies</i>	185 (39.30%)
<i>Job status, No. of unemployed</i>	68 (14.35%)
<i>Association Membership</i>	227 (47.89%)
<i>BASDAI, mean <math>\pm</math> SD (N=442)</i>	5.49 $\pm$ 2.17
<i>Cervical stiffness, No. (N=447)</i>	201 (44.97%)
<i>Thoracic stiffness No. (N=435)</i>	186 (42.76%)
<i>Lumbar stiffness No. (N=458)</i>	288 (62.88%)
<i>Functional Limitation, mean <math>\pm</math> SD (N=473)</i>	27.54 $\pm$ 12.78
<i>Depression, No. (%) (N=474)</i>	99 (20.89)
<i>Anxiety, No. (%) (N=474)</i>	134 (28.27)
<i>GHQ-12, mean <math>\pm</math> SD</i>	18.30 $\pm$ 8.01

**Conclusion:** Patients at certain sociodemographic levels are more prone to present a higher BASDAI. Taking these conditions for granted, the degree of disease progression measured by BASDAI is a good indicator of RMD. Therefore, in those with higher disease activity, psychiatric evaluation and intervention should be considered within the medical treatment.

## Association between Smoking with Spinal Level of Stiffness and Functional Limitation in Patients with Axial Spondyloarthritis: Results from the Spanish Atlas

**Marco Garrido-Cumbrera**<sup>1</sup>, Victoria Navarro-Compán<sup>2</sup>, Jorge Chacon-Garcia<sup>1</sup>, Jordi Gratacos-Masmitja<sup>3</sup>, David Galvez-Ruiz<sup>1</sup>, Eduardo Collantes Estevez<sup>4</sup>, Pedro Zarco<sup>5</sup> and Olta Brace<sup>1</sup>, <sup>1</sup>Universidad de Sevilla, Seville, Spain, <sup>2</sup>Rheumatology, Hospital Universitario La Paz, Madrid, Spain, <sup>3</sup>Rheumatology, Hospital Parc Taulí, Sabadell - Barcelona, Spain, <sup>4</sup>Universidad de Cordoba, Cordova, Spain, <sup>5</sup>H Fundación Alcorcón, Alcorcón, Spain

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smoking has been associated with greater disease activity and radiographic progression in patients with Axial Spondyloarthritis (ax-SpA). In addition, radiographic damage has been linked to greater functional limitation. However, clarification is still being sought as to whether or not this association exists. To investigate the association between smoking and both the area of spinal stiffness and functional limitation in patients with ax-SpA.

**Methods:** A sample of 680 patients diagnosed with ax-SpA was interviewed during 2016 as part of the Spanish Atlas, which aims to promote early referral and improve healthcare and the use of effective treatments in patients with ax-SpA. Tobacco consumption was recorded as: Smoker (62.4%), Occasional Smoker (8.9%) and Non-Smoker (28.7%). Spinal stiffness was assessed in the three different vertebral areas: cervical, dorsal and lumbar. To determine the degree of functional limitation we used a composed index which includes the sum of the degree of limitation in the 18 daily activities well established (dressing, grooming, bathing, tying shoelaces, moving around the home, stairs, getting to/out of bed, toilet, shopping, preparing meals, eating, cleaning, walking, using public transportation, going to the doctor, driving, physical exercise, sexual relations) using an ordinal variable (0=none, 1=little, 2=some and 3=moderate). A descriptive analysis was used to compare the level of stiffness (chi-squared test) and the mean degree of limitation (Kruskal-Wallis test) in the different groups of smokers consumptions. Regression analysis was also used to assess the relation between smoking and degree of limitation (0-54).

**Results:** 53% were females, mean age 46 years and 77.1% were HLA-B27+. The percentage of patients with stiffness in the lumbar region was significantly higher in habitual/occasional smokers than in non-smokers (89.0%, 93.8%, 83.5% respectively;  $p < 0.01$ ) (Table). The mean degree of functional limitation increased with tobacco consumption, although this difference was not statistically significant ( $47.9 \pm 12.1$  vs.  $45.1 \pm 11.5$  vs.  $44.8 \pm 13.7$  respectively;  $p = 0.2$ ). However, regression analysis showed a statistically significant correlation between smoking and functional limitation ( $r = 0.096$ ;  $p = 0.02$ ).

Table 1. Relationship between tobacco consumption and spinal stiffness levels in patients with ax-SpA

	Smoker	Occasional smoker	Non smoker	<i>P</i>	$\chi^2$
Cervical stiffness	84.2%	77.1%	73.1%	0.171	9.044
Thoracic stiffness	76.0%	76.6%	72.4%	0.408	6.141
Lumbar stiffness	89.0%	93.8%	83.5%	0.002	20.518

**Conclusion:** Smoking in patients with ax SpA is associated to greater stiffness in the lumbar region, but is not related to stiffness in the cervical or dorsal regions. Additionally, smoking is associated to the degree of functional limitation in these patients.

## Use of Mutual Information Theory in Development and Refinement of a Predictive Model for Early Identification of Ankylosing Spondylitis

Atul A. Deodhar<sup>1</sup>, Cody Garges<sup>2</sup>, Oodaye Shukla<sup>2</sup>, Theresa Arndt<sup>2</sup>, Tara Grabowsky<sup>2</sup> and Yujin Park<sup>3</sup>, <sup>1</sup>Oregon Health & Science University, Portland, OR, <sup>2</sup>HVH Precision Analytics, LLC, King of Prussia, PA, <sup>3</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Background/Purpose:** Delayed diagnosis and treatment of ankylosing spondylitis (AS) contribute to the economic, physical and psychological burden on patients and their caregivers. The objective of this analysis was to refine a previously developed predictive mathematical model for AS<sup>1</sup> based on features observed in the medical histories of patients with and without a diagnosis of AS to aid in the earlier identification of AS.

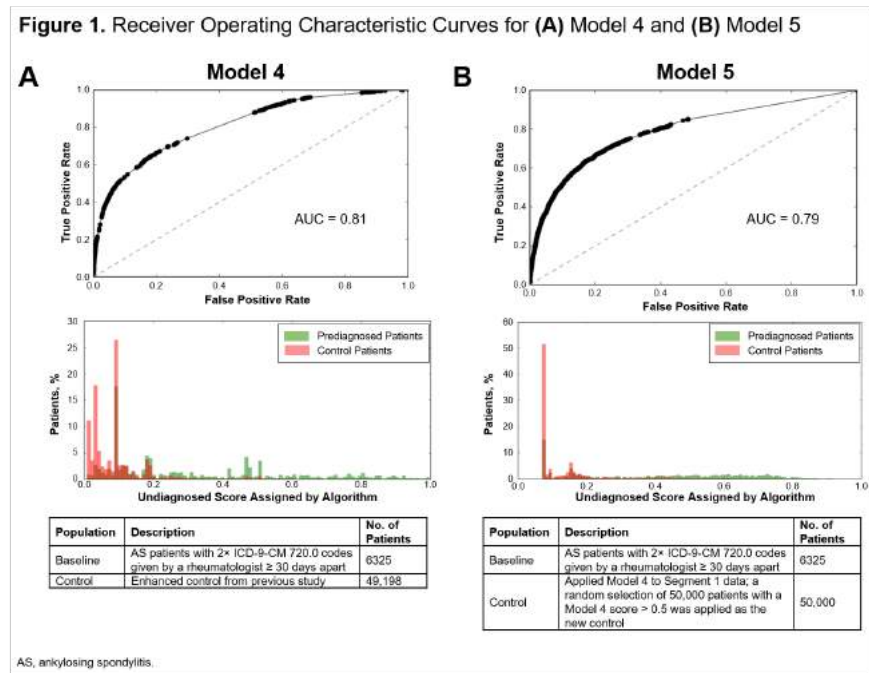

**Methods:** This retrospective cohort study used administrative claims data from > 182 million patients in the Truven Health MarketScan® Commercial and Medicare Supplemental Databases from January 2006 to September 2015 (Segment 1) and October 2015 to November 2016 (Segment 2). The AS population in Segment 1 included all patients with ≥ 2 diagnoses of AS (ICD-9-CM 720.0) by rheumatologists ≥ 30 days apart who had ≥ 12 months of continuous enrollment prior to first AS diagnosis. Control patients were matched by age, sex, enrollment period and geographic location and were randomly selected from the same database. Mutual information was used to identify features that differentiated AS from the control population; select features were then used as inputs in development of a suite of predictive models using data from Segment 1.<sup>1</sup> The optimized predictive model was then tested by observing whether patients predicted to have AS in Segment 1 subsequently received an ICD-10-CM AS diagnosis code (M45.x or M08.1) in Segment 2.

**Results:** In the initial study, 3 iterations of the predictive risk model (Models 1, 2 and 3a/3b) were developed using data from patients with ≥ 1 ICD-9-CM AS diagnosis during Segment 1, with each subsequent model iteration using additional AS-specific queries to reflect a more real-world situation.<sup>1</sup> A 2-stage model (Models 4 and 5) was built using patients with ≥ 2 ICD-9-CM AS diagnoses during Segment 1 to improve performance. Model 4 identified patients with AS from the general control population in the database (**Figure 1A**). To further improve precision, Model 5 was built using 50,000 random patients in Segment 1 who scored above a 0.5 in Model 4 (i.e., were more like patients with AS) as a new control population (**Figure 1B**). Models 4 and 5 were then combined to identify new patients with AS in Segment 2; of the ≈ 20 million patients who tracked across Segment 1 and Segment 2, 742 patients had an ICD-10-CM AS diagnosis in Segment 2 who did not have an ICD-9-CM diagnosis in Segment 1.

**Conclusion:** Predictive models for AS diagnosis were developed and refined in this US administrative claims database. Work is ongoing to compare the sensitivity and positive predictive value of these predictive models versus more traditional linear regression models, and future research will validate the model in a separate, commercially insured population database.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The primary goals of treating Ankylosing Spondylitis (AS) patients are to maximize long-term health-related quality of life through control of symptoms and inflammation, prevention of progressive structural damage, and preservation of function. With two classes of biologic disease modifying agent (bDMARD) currently available, providers have more options to offer to their patients, especially after failing a first biologic. The objective of this study was to describe treatment patterns (persistence, discontinuations, and switch to a 2nd or 3rd line biologic) in the 2 years following the initiation of biologic therapy in AS patients.

**Methods:** Adult patients with  $\geq 2$  AS diagnoses were included in this retrospective analysis of medical and pharmacy claims data from the Truven MarketScan Commercial Claims database. AS patients who newly initiated a biologic agent (etanercept, adalimumab, golimumab, infliximab, or certolizumab pegol) during the period from January 1, 2009, to December 31, 2013 were selected and indexed on their first biologic during the time period. All patients were required to have a 1-year pre-index clean period of all biologic therapy and continuous enrollment (medical and prescription) 1-year pre-index and 2-years post-index. Patients were excluded if they had  $\geq 2$  diagnostic codes for any of the following conditions: Rheumatoid Arthritis, Juvenile Idiopathic Arthritis, Psoriatic Arthritis, Crohn's Disease, Ulcerative Colitis, Plaque Psoriasis, Hidradenitis Suppurativa, or Uveitis. Demographic, clinical, and treatment patterns were analyzed. Treatment patterns included switching to a new biologic (2 and 3+ lines), discontinuation ( $\geq 90$ -day gap in therapy), or persistence (no gaps in therapy  $\geq 90$ -days) during the 2-year follow-up period.

**Results:** A total of 1,372 AS patients met the inclusion criteria for this study. The majority of patients (61.7%) were male and the overall mean age of patients was 43.8 years. Adalimumab was the index biologic for 44.1% of patients, followed by etanercept (40.9%), infliximab (10.6%), golimumab (4.3%), and certolizumab pegol (0.1%). During the follow-up period, 33.1% of patients (n=454) were persistent on their index biologic, while 66.9% (n=918) either discontinued their index biologic therapy or switched to a 2<sup>nd</sup> line biologic. Among the patients who discontinued their first index biologic, 39.1% (n=359) switched to a 2<sup>nd</sup> line biologic. Of those with a 2<sup>nd</sup> line biologic, 20.1% (n=72) had 3 or more different biologics prescribed during the follow-up period. From 2009 to 2013, the proportion of new biologic users initiating 2<sup>nd</sup> line biologic increased over time from 25.2% to 28.8% (average for all four years = 26.2%).

**Conclusion:** This study suggests that approximately two-thirds of AS patients newly initiating on a biologic do not remain on the index therapy 2 years post initiation. More work is needed to understand the reasons for non-persistence and the increasing trend of second line biologic use in this population.

## Survival and Years of Potential Life Lost in Connective Tissue Disease and Vasculitis; Data from the Norwegian Connective Tissue Diseases and Vasculitis Registry (NOSVAR)

Torhild Garen<sup>1</sup>, **Karoline Lerang**<sup>1</sup>, Anna Maria Hoffmann-Vold<sup>2</sup>, Helena Andersson<sup>1</sup>, Øyvind Midtvedt<sup>1</sup>, Karin Kilian<sup>1</sup>, Ragnar Gunnarsson<sup>1</sup>, Birgir Gudbrandsson<sup>1</sup>, Gudrun Norby<sup>1</sup>, Øyvind Molberg<sup>2</sup> and Øyvind Palm<sup>1</sup>, <sup>1</sup>Department of Rheumatology, Oslo University Hospital, Oslo, Norway, OSLO, Norway, <sup>2</sup>Department of Rheumatology, Oslo University Hospital, Oslo, Norway, Oslo, Norway

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Epidemiology and Public Health Poster II: Rheumatic Diseases Other than Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Survival is decreased in patients with connective tissue diseases (CTDs) and vasculitis, however few studies have compared the mortality between the specific diseases prospectively by similar methods for patient's selection. Here, we aimed to compare survival, standard mortality rates (SMR) and premature mortality between diagnoses of CTDs and vasculitis.

### Methods:

All patients included in NOSVAR diagnosed from January 1, 1999 to December 31, 2016, in total 2148 patients were followed up until death or study end. Fifteen controls matched for each individual patient for year of birth, sex and residence area was randomly selected from the Norwegian Central Public Population Register. All controls were alive at time of patients diagnosis. Kaplan-Meier survival probabilities and curves were used to determine survival, and the difference between patients and controls was estimated by the log-rank test (Mantel Cox). In the Standardized mortality ratio (SMR) the number of deaths was divided by number of years of observation for each diagnosis and calculated as the ratio between the observed and expected numbers of death. The years of potential life lost (YPLL) was defined as the years a person would have lived if he or she had not died prematurely (here defined as 60 years of age). The YPLL for each death in patients are summed to represent the total years of potential life lost for all patients in each patient-group. The YPLL (60) rate is found by dividing YPLL by years of observation under the age of 60 in each group.

### Results:

During a mean (SD) follow-up time of 9,2 years (4,7), 280/2148 (13%) patients deceased compared to 2885/32186 (9%) of the controls ( $p<0.001$ ). Patient's characteristics and demographics are shown in Table 1. Compared to controls, the lowest 5-and 10 years survival was seen in diffuse cutaneous systemic sclerosis (dcSSc) (79 % and 60%), ( $p<0.001$ ), Antisynthetase syndrome (86% and 73%), ( $p<0.001$ ), and limited systemic sclerosis, (89% and 75%), ( $p<0.001$ ) Figure 1). For ANCA vasculitis and controls 5 years survival was 91% vs 95% and 10 years survival was 80 % vs 87%, ( $p=0.030$ ). Highest SMR was observed for dSSc (5,8) and Antisynthetase syndrome (4,1)(Figure 2) The sum of YPLL60 among patients was 493 years and in matched controls 115 years, indicating a four-fold increase in premature deaths among the patients. The mean YPLL60 was highest in SLE and Takayasu with 19 and 15 years lost, respectively. Both lcSSc and dcSSc had a mean of 7 years lost YPLL60. The ranking of annual rate of YPLL60 for each disease is shown in (Figure 3)

### Conclusion:

We show that there is a difference in survival, mortality and YPLL60 among the different CTDs and vasculitis. Methods used supplement each other and highlights the different aspects of outcome among the diagnoses. Systemic sclerosis and Antisynthetase syndrome had the lowest 5 and 10 years survival and the highest rate of premature mortality, but the mean loss of years before 60 years of age were higher in individuals with Takayasu and SLE.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Epidemiology and Public Health Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Hair dye exposure has been reported as a risk factor for systemic lupus erythematosus (SLE) and connective tissue diseases, though conflicting results exist. We performed a population-based case-control study based on the MILES Program to determine whether hair dyes, rinses and permanents were associated with SLE risk.

### Methods:

The MILES Program includes a population-based cohort of SLE cases and controls from southeast Michigan. Detailed data on history of hair treatment exposures prior to SLE diagnosis (i.e., hair dyes, rinses and permanents to curl/straighten hair) were collected, including details regarding frequency, duration, colors used and timing in relation to SLE diagnosis. For controls, we generated a reference date in lieu of a diagnosis date using multiple imputation (SAS PROC MI). Multivariable logistic regression, adjusted for covariates (race, ethnicity, age, county of residence, family income, and history of beauty salon occupation), was used to assess association between hair product use and case/control status.

### Results:

In this study population of 654 participants (462 SLE cases, 192 controls), 584 (89.3%) were female, 288 (44%) black, and mean age at baseline visit was 53 years. Primary analyses were restricted to females, due to small numbers in males. In female cases vs controls, hair dye use was reported in 35.1% of cases/38.8% of controls; hair permanents in 55.8%/56.7%; hair rinses in 19.7%/19.6%; and history of beauty salon occupation in 9.1%/6.5%. Odds ratios (95% CIs) adjusted for covariates were: hair dye [0.94 (0.63, 1.40)]; hair rinse [0.91 (0.57, 1.46)]; hair permanent [0.86 (0.57, 1.30)]. Likewise, duration of use, dark color hair dyes, and history of beauty salon occupation were not found to be associated with SLE. Results from analyses stratified by race were similar.

### Conclusion:

This population-based case-control study is one of the largest studies to examine the relationship between hair product use and lupus. We found no evidence of an association between any of the treatment types – hair dye, hair rinse, or hair permanents – and risk of lupus.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Epidemiology and Public Health Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Arthritis, a leading cause of disability, affects 54.4 million US adults. By knowing the state and county level arthritis impact, state-level public health professionals can determine appropriate resource allocation, understand existing disparities, and target dissemination of evidence-based interventions that can reduce arthritis impact.

**Methods:** To summarize the arthritis burden at the state and county-level, we used data from the 2015 Behavioral Risk Factor Surveillance System, an annual, random-digit-dialed landline and cellphone survey that is representative of the noninstitutionalized adult population aged ≥18 years in the 50 states and territories. Arthritis was defined as a "yes" to "Has a doctor or other health professional ever told you that have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" For each state, we calculated arthritis prevalence overall and among those with specific comorbidities; among adults with arthritis, we estimated the prevalence of arthritis-attributable activity limitation (AAAL), social participation restriction (SPR), severe joint pain (SJP), physical inactivity (PIA), leisure walking (LW), and arthritis management behaviors; the latter category on management was calculated for the 13 states that collected this information. Age-adjusted (standardized to the projected 2000 U.S. population) percentages were calculated for all prevalence estimates shown below.

**Results:** For the 50 states and DC in 2015, the median prevalence of arthritis was 23.0% (range: 17.2-33.6%). For arthritis-attributable impact measures among adults with arthritis, median (range) prevalence for AAAL was 49.7% (40.4-59.4%); SPR was 19.7% (12.6-30.4%); and SJP was 29.7% (20.3-46.0%). Median (range) prevalence of arthritis among adults with obesity, heart disease, and diabetes was 30.9% (24.6-41.2%), 44.5% (25.6-72.6%), and 37.3% (27.1-53.7%), respectively. Median (range) prevalence of PIA and LW among adults with arthritis was 35.0% (23.1-47.9%) and 48.0% (38.5-59.5%), respectively. For arthritis management, median (range) prevalence of being told to exercise for their arthritis and lose weight if overweight/obese to manage arthritis symptoms was 58.5% (52.3-61.9%) and 44.5% (35.1-53.2%), respectively; median prevalence of attending a self-management education (SME) course was 14.5% (range=9.1-19.0%). Arthritis prevalence varied considerably by county (range: 13.5%-34.8%).

**Conclusion:** Arthritis was common -- particularly among those with comorbid conditions -- and varied substantially at both the state and county level. Adults with arthritis have a high prevalence of characteristics that impact quality of life (e.g., AAAL, SPR, and SJP), and a large percentage are PIA and do not participate in LW. Participation in a SME course among adults with arthritis remains low; approximately half of health care providers recommended self-management behaviors. Greater use of evidence-based physical activity and SME interventions could reduce pain and improve function and quality of life for all adults with arthritis including those with comorbidities.

## The Prevalence of Patellofemoral Osteoarthritis in China: A Multi-Center Population-Based Cross-Sectional Study

**Zhanglai Li**<sup>1</sup>, Qiang Liu<sup>1</sup>, Changsheng Zhao<sup>2</sup>, Yuqing Zhang<sup>3</sup>, Xiaowei Li<sup>1</sup> and Jianhao Lin<sup>1</sup>, <sup>1</sup>Arthritis Clinic and Research Center, Peking University People's Hospital, Peking University, Beijing, China, <sup>2</sup>Peking University International Hospital, Peking University International Hospital, Beijing, China, <sup>3</sup>School Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017  
**Session Title:** ARHP Epidemiology and Public Health Poster  
**Session Type:** ACR Poster Session B  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To describe the prevalence and risk factors of patellofemoral osteoarthritis (OA) in a Chinese population.

**Methods:** A multi-center population-based cross-sectional survey was conducted in 2015 in Beijing, Henan and Ningxia, China. 4138 residents aged  $\geq 50$  years were recruited using a cluster sampling method. Subjects completed a home interview (including socio-demographic factors, history of knee injury, joint symptoms, job-related physical activity and work history) and had weight-bearing posterior-anterior semi-flexed view of radiographs at tibiofemoral joints and skyline view of radiographs at patellofemoral joints (PF). Height was measured twice for each subject, using a wall-mounted studio meter and weight was assessed using a balance beam scale with a precision to 0.1 kg. BMI was calculated as weight in kilograms divided by height in meters squared. Radiographs were read by two orthopedic surgeons. Each knee was evaluated for the presence of osteophytes (OST), joint space narrowing (JSN) on a 0-3 scale based on OARSI atlas. If two readers disagreed on a patient's OA status, adjudication session was held with third orthopedic surgeon present. Radiographic OA (ROA) at PF joint was defined if OST score was  $\geq 2$  or if JSN score was  $\geq 2$  with concurrent grade 1 OST in the PF joint. The kappa for inter-rater reliability was 0.71-0.85 and the intra-rater reliability was 0.85-0.91 prior to adjudication. Knee pain symptoms were asked for each participant using the following questions &Prime Did knee pain occur when going up and down stairs on most days in the past month? &Prime PF symptomatic OA (SxOA) was recorded if both pain and ROA were present at the same knee. We examined the relations of a set of risk factors to the prevalence of PF ROA and SxOA using logistic regression model.

**Results:** Of 4138 subjects recruited, 533 (12.9%) subjects were excluded from the analysis due to missing knee radiographs. Of the remaining (n=3605) 35.6% (n=1283) were men, mean age was  $62.89 \pm 7.58$  years, and mean BMI was  $25.05 \pm 3.60$  kg/m<sup>2</sup>; 64.4% (n=2322) were women, mean age was  $60.86 \pm 7.50$  years, and mean BMI was  $26.26 \pm 3.81$  kg/m<sup>2</sup>. The prevalence of PF ROA and SxOA was 23.7% and 14.1%, respectively. As shown in Table 1, women, older age, higher BMI, history of knee injury and bicycling  $\geq 2$  hours per day lasted less than 30 years were significantly associated with both PF ROA and SxOA. Few years of education was associated with high prevalence of PF ROA, whereas standing  $\geq 2$  hours per day lasted less than 30 years was associated with PF SxOA. No statistical significant difference was observed between job-related physical activity and PF ROA/SxOA.

**Conclusion:** Our study suggests that prevalence of PF ROA and SxOA was high in China. Several potential risk factors for prevalent PF OA were identified and need to be verified in the future prospective cohort studies.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Epidemiology and Public Health Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Knee osteoarthritis (OA) is characterized by structural changes in subchondral bone and degradation of articular cartilage, but the pathology does not necessarily lead to pain and functional limitations. Latent and modifiable factors, such as depression, may contribute to or worsen knee OA symptoms. However, depression is clinically heterogeneous and presentation may manifest differently by subtypes and by sex. The objectives were to identify depressive symptom subtypes, examine sex differences across subtypes, and evaluate clinical correlates. **Methods:** Eligible participants (n=4490) were enrolled in the Osteoarthritis Initiative (OAI) and had or were at risk for symptomatic knee OA. Latent class analysis was applied to symptomology measured by the 20-Item

Center for Epidemiological Studies Depression Scale to identify homogenous subtypes with similar patterns of depressive symptoms at study enrollment. Subtype prevalence and item-response probabilities, an indicator of severity within subtype, were estimated separately in men and women. Posterior probability estimates were used to assign each participant to the subgroup for which he or she had the highest probability of membership. Clinical characteristics, including body mass index (BMI), Charlson comorbidity, gait speed, analgesic use, pain severity, and radiographic evidence of knee OA (Kellgren-Lawrence grade  $\geq 2$ ), were compared across subtypes by sex. **Results:** Four depressive symptom subtypes were identified: “No Symptoms,” “Moderate,” “Moderate-Melancholic,” and “Severe.” Item-response probabilities and prevalence estimates significantly differed by sex ( $P = <0.001$ ). “No Symptoms” was more common in men (79.8%) than women (77.5%) and had low item-response probabilities across all symptoms. “Moderate” was characterized by sadness and anhedonia and occurred more frequently in men (12.2%) than women (11.2%); however, item-response probabilities were higher in women, indicating greater severity. “Moderate-Melancholic” and “Severe” were differentiated from other subtypes by fatigue, loss of appetite, and insomnia and were more common in women (7.0% and 4.2%, respectively) than men (6.4% and 1.7%, respectively); yet, item-response probabilities were higher in men, suggesting greater severity. Comorbidity scores, gait speed, pain scores, and analgesic use were significantly associated with subtype membership among both sexes; radiographic evidence of knee OA was only significant in men, while BMI was only significant in women (Table 1). **Conclusion:** Study findings indicate the presence of four distinct depressive symptom subtypes that differ in prevalence and clinical presentation by sex among persons who have or are at risk for symptomatic knee OA. Understanding variation in concurrent depressive symptoms among knee OA patients will help inform tailored treatment strategies.

**Table 1. Baseline clinical characteristics among men and women enrolled in the Osteoarthritis Initiative by depressive symptom subtype (N=4490).**

	Men (n=1881)								
Variable (n % or mean sd)	No Symptoms (n=1540)		Moderate (n=208)		Moderate-Melancholic (n=103)		Severe (n=30)		P Value

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Epidemiology and Public Health Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The introduction of biological agents has been an important advance in the treatment of RA. However, they are not exempt from adverse events and their high cost limits access and maintenance of treatment in many circumstances. Our aim was to evaluate the biological treatment patterns in RA patients and their accumulated survival and long-term efficacy using the LUNDEX index.

**Methods:** Patients  $\geq 18$  years of age who met ACR/EULAR 2010 criteria for RA and who had started their first biological disease modifying drugs (b-DMARD) between 01/2006 and 12/2017 were included. Socio-demographic variables such as age, sex, employment status, marital status, health coverage, education and number of cohabitants, as well as comorbidities, smoking status (current, past), date of onset of symptoms, disease characteristics and previous DMARDs treatment were recorded. Disease activity and functional capacity were assessed before and after biologic treatment using CDAI and HAQ, respectively. Cumulative drug survival was assessed by Kaplan Meier curves and comparisons using log Rank. LUNDEX was calculated as the product of efficacy (CDAI remission or low disease activity) and percentage of patients who continued to receive biological treatment at different cut-off times

**Results:** 347 patients were included, 89.6% were female, median age was 57.80 years (IQR 48-65), 96.5% had positive rheumatoid factor and 60.8% had positive anti-CCP. 70.6% of patients had health insurance, 79.8% were smokers and 47% of them had comorbidities. The first bDMARD was etanercept in 46.8%, adalimumab (ADA) 28.9, certolizumab 7.2%, abatacept 6.4%, golimumab 4.3, tocilizumab 2.6%, rituximab 2.3% and infliximab 1.4%. Only 5.6% of patients received monotherapy, 53.9% of patients discontinued treatment with bDMARD, and the causes of discontinuation were: lack of provision (33.5%), inefficacy (33%), adverse events (20.3%). Out of the available data the most frequent adverse event was infection. The median survival of the first biological was 31 months (95%CI: 21.8-40.1), without differences between different drugs. CDAI significantly improved over time. Lundex was 45.5% at 6 months and 41.1% at one year. CDAI at 6 months was significantly lower in non smokers vs smokers ( $11.37 \pm 9.6$  vs  $17.71 \pm 14$ ,  $p=0.03$ ). In Cox regression analysis, smoking status (HR 1.8, 95%CI: 1.2-2.8) and younger age (HR: 0.98, 95%CI: 0.96-0.99) were independently associated with lower bDMARD survival rates.

**Conclusion:** Socioeconomic factors impact on biological survival in our region. Smoking significantly reduces the effectiveness of biological treatment, as well as it reduces drug survival.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies have showed that chondrocytes from OA patients had mitochondrial alteration in comparison with healthy. However the role of mitochondria in the biological dysfunction of chondrocytes is not totally know. Cybrids are optimal cellular models to study mitochondrial biology and function implications in the cellular behavior, since they carry different mitochondrial variants with the same nuclear background, excluding the variations because of nuclear genome. **Purpose:** To test the real role of mitochondrial function in OA pathogenesis using mtDNA cybrids.

**Methods:** mtDNA Cybrids were developed using the cell line 143B.TK<sup>-</sup> Rho-0 as the nuclear donor, and platelets from patients without and with knee osteoarthritis respectively as mitochondrial donors (N vs OA). The stress response was evaluated analyzed O<sub>2</sub><sup>-</sup> production; percentage of cell survival in presence of H<sub>2</sub>O<sub>2</sub> and the level of apoptotic cells were studied using flow cytometry. The OXPHOS function and glycolytic activity was evaluated by SeaHorse XFp. The metabolic status was evaluated by glucose consumption and lactic acid production.

**Results:** Cybrids carrying the platelets from OA patients showed significant higher levels O<sub>2</sub><sup>-</sup> than N (36.61% vs 17.79%). Percentage of not viable cell in presence of H<sub>2</sub>O<sub>2</sub> was higher in OA than in N cybrids (40.1 % vs 27.15 %). The percentage of cell in inducing apoptosis condition was higher in OA than in N cybrids (15.68% vs 6.41%). OA cybrids had lower basal respiration (92.07 and 155.5), and maximal respiratory capacity (114.7 and 160.6) than N. The analysis of ATP production was lower in OA than in N cybrids (66.69 vs 101.5). The % spare respiratory capacity for the N was significantly lower than in OA cybrids (107 vs 124.7). Cybrids carrying the mtDNA from OA patients showed higher glucose consumption than N cybrids (43.77 mg/ml vs 31.91 mg/ml) however in the lactic acid production did not exit differences. The glycolytic showed that OA cybrids had lower glycolysis (71.05 vs 85.43) but higher glycolytic reserve than N cybrids (56.60 vs 39.73).

**Conclusion:** These results showed that the mitochondria obtained from healthy and OA donors had a different behaviour and offer a real rationale for why mitochondria alterations play an important role in OA pathogenesis.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

### Background/Purpose:

Rheumatoid arthritis (RA) is a complex genetics disease driven by multiple genetic contributors as evidenced by association with over 100 risk SNPs by GWAS. However, the majority of risk SNPs are not causal and explain only a small proportion of heritability in RA. Novel approaches for the analysis and interpretation of large-scale genomics data are needed to detect the missing heritability of and gain further insight into RA. Additionally, risk gene and SNP associations differ in European and Asian RA populations (1). Regulatory genetic elements, such as non-coding micro RNAs (miRNA), are thought to play an important role in RA and have been identified by gene-based testing in Europeans with RA (2). Our aim was to identify non-coding genetic elements in Asians with RA with gene-based association testing.

### Methods:

Our dataset consisted of 4,873 RA cases and 17,642 controls from GWAS meta-analysis in Asians (1). All RA cases fulfilled the 1987 ACR criteria or were diagnosed by a rheumatologist. We used the Knowledge-based mining system for Genome-wide Genetic studies (KGG v.4) for gene-based association testing using extended Simes procedure (GATES) with SNPs outside the extended MHC [Chr. 6, 25.7-33.3 Mb] (3). Genes were defined as  $\pm$  5kb. Genomic control was calculated by median of Chi-square statistic. We accounted for linkage disequilibrium (LD) between SNPs with 1000 Genomes Phase 1 for Asians. Benjamini & Hochberg false discovery rate (FDR) was used to correct for multiple testing. UCSC Genome Browser was used for visualization of findings.

### Results:

Our genome analysis build used 6,581,301 million SNPs and a total of 25,550 genes (including 5189 non-coding RNAs); 51.66% of SNPs were located inside genes. A total of 108 genes were found to be significant by GATES (FDR <0.05). Amongst the top genes by GATES, we identified several non-coding RNAs associated with RA in Asians. The significant long non-coding RNAs were *TNFRSF14-AS1* (Chr.1 at RA risk locus *TNFRSF14-MMEL1*), *LINC01843* (Chr. 5 near *JADE2*), *LINC00336* (Chr.6 near *GGNBP1-BAK1*) and *LINC01016* (Chr.6 near *MLN*). The significant miRNAs were *MIR3934* (Chr.6 near *UQCC2-ITPR3*), *MIR7159* (Chr. 6 near *MLN*), *MIR4647* (Chr.6 at RA risk locus *NFKBIE*), *MIR3939* (Chr.6 at RA risk locus *CCR6*), *MIR4658* (Chr.7 near *C7orf43*) and *MIR4308* (Chr. 14 near *GCHI*). There was no overlap of these non-coding RNAs identified in Asians with RA compared with RA in Europeans.

### Conclusion:

Through large-scale gene-based association testing, we identified novel non-coding RNA associations specific for RA in Asians. These novel regulatory genetic elements, in addition to established RA risk loci, may improve our understanding of the complex genetics of RA. Non-coding RNAs could also play a role as potential biomarkers and novel drug targets in RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Targeted proteomics, which involves quantitative analysis of targeted proteins using selected reaction monitoring (SRM) mass spectrometry, has emerged as a new methodology for discovery of clinical biomarkers. The aim of this study was to identify circulating biomarkers for prediction of disease activity and organ involvement in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) by using targeted serum proteomics.

**Methods:** We selected the targeted candidates by an experiment-based approach in which we conducted MS-based serum proteomic profiling of AAV patients before and after treatment. We further selected 87 endothelium-related proteins, which were expected to be present in blood, based on information from publicly available databases. A large-scale SRM assay targeting 135 biomarker candidates was established using a triple quadrupole mass spectrometer coupled with nano-flow liquid chromatography. Target proteins in serum samples from patients in the active and remission (6 months after treatment) stages were quantified using the established assays. Identified marker candidates were further validated by ELISA using serum samples (n=169) collected in a large-cohort Japanese study (RemIT-JAV-RPGN study).

**Results:** The following proteins were identified as biomarkers for discriminating patients with highly active AAV from those in remission or healthy controls: tenascin C (TNC), C-reactive protein (CRP), tissue inhibitor of metalloproteinase 1 (TIMP1), leucine-rich alpha-2-glycoprotein 1, S100A8/A9, CD93, matrix metalloproteinase 9, and transketolase (TKT). Of these, TIMP1 was the best-performing marker of disease activity, allowing distinction between non-remission (mildly active AAV) and remission. The serum levels of TKT and CD93 were higher in patients with renal involvement than in those without, and predicted renal outcome. The serum level of TNC was elevated significantly in patients with lung infiltration. AAV severity was associated with markers reflecting organ involvement (TKT, CD93 and TNC) rather than inflammation.

**Conclusion:** We have identified promising biomarkers of disease activity and severity and organ involvement in AAV with targeted proteomics approach using serum samples collected in a large-cohort Japanese study. Especially, our analysis demonstrated the effectiveness of TIMP1 as a marker of AAV activity. In addition, we identified TKT and CD93 as novel markers for evaluation of renal involvement and renal outcome in AAV.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Recent studies revealed that haplogroup J associates with a decreased rate of incident knee Osteoarthritis. Among the functional characteristics of this haplogroup, lower rates of apoptosis stand out. In this study we aimed to evaluate if this process is epigenetically regulated.

## Methods:

DNA methylation profiling from a previous study performed in knee articular cartilage was obtained from Gene Expression Omnibus database (accession GSE-43191). In that study, cartilage DNA was isolated from 13 samples carrying the haplogroup J and 20 samples carrying the haplogroup H. The differential methylation between J and H haplogroups was obtained using *Lumi* and *Methylumi* packages (R bioconductor).

A subsequent validation by RNA-seq was performed in 7 haplogroup J cartilage samples and 9 haplogroup H cartilage samples. Differential expression data between haplogroups were analyzed using *Kallisto* package (R bioconductor). Gene ontology analyses from methylation and expression approaches were performed using DAVID (<https://david.ncifcrf.gov/>).

## Results:

Gene ontology analysis of the 538 differentially methylated regions between haplogroups J and H revealed that genes involved in the negative regulation of apoptosis ( $p=0,021$ ) and catalytic activity ( $p=0,036$ ) were hypomethylated in haplogroup J cartilages. On the contrary, haplogroup H cartilages showed an enrichment of hypomethylated genes involved in the positive regulation of apoptosis ( $p=0,008$ ); an enrichment of hypomethylated genes involved in the negative regulation of the metabolic processes of nitrogen compounds ( $p=0,03$ ) and macromolecules ( $p=0,026$ ) was detected in haplogroup H cartilages.

Subsequent validation by RNA-seq revealed 416 differentially expressed genes between haplogroups H and J, considering an adjusted  $p\text{-value}\leq 0,005$  as well as a  $\log_2\text{Fc}\geq \pm 4$  (Figure 1). Of these genes, 362 were up-regulated in haplogroup J cartilages and 54 up-regulated in haplogroup H. Among the most differentially altered biological processes, an enrichment of over-expressed genes involved in the positive regulation of apoptosis ( $p=0,047$ ) and cellular adhesion ( $p=0,0018$ ) was detected in haplogroup H cartilages. On the contrary, an enrichment of up-regulated genes involved in lipid synthesis ( $p=0,044$ ), Calcium homeostasis ( $p=0,047$ ), cell signaling ( $p=0,00031$ ) and immune system development ( $p=0,0092$ ) was detected in haplogroup J cartilages.

## Conclusion:

Mitochondrial haplogroups J and H induce specific methylation and expression profiles in cartilage samples that lead to an epigenetic regulation of apoptosis, being more repressed in cartilages with J haplogroup and more active in cartilages with H haplogroup.

**Figure 1.** Volcano plot showing differentially expressed genes between haplogroups H and J. Blue dots represent significantly over-expressed genes in H and red dots represent significantly over-expressed genes in J. Significance declared at  $\text{adj-p-value} \leq 0.005$  and  $\log_2 \text{Fc} \geq \pm 4$

## Analysis of microRNAs in Familial Mediterranean Fever

Gil Amarilyo<sup>1</sup>, Nir Pillar<sup>2</sup>, Ilan Ben-Zvi<sup>3</sup>, Daphna Weissglas-Volkov<sup>2</sup>, Jonatan Zalcman<sup>2</sup>, Liora Harel<sup>4</sup>, Avi Livneh<sup>3</sup> and Noam Shomron<sup>2</sup>, <sup>1</sup>Schneider Children's Medical Center of Israel, Sackler School of Medicine, Tel Aviv University, Petach Tikva, Israel, <sup>2</sup>Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, <sup>3</sup>Chaim Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, <sup>4</sup>Schneider Children's Medical Center of Israel, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Familial Mediterranean fever (FMF) is thought to be inherited as an autosomal recessive trait. However, there are frequent deviations from this model. The aim of this study was to explore epigenetic modifications in patients with FMF.

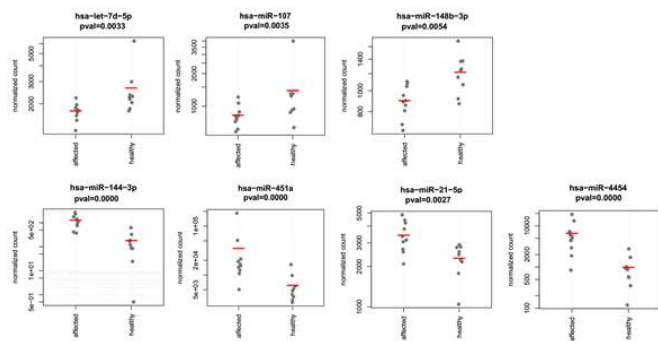

**Methods:** Ten patients diagnosed with FMF according to the Tel-Hashomer criteria were recruited from the rheumatology outpatient clinic of Sheba Medical Center, Tel Hashomer, Israel. All patients were homozygous for the M694V mutation, the most common mutation in FMF, and all had the most severe phenotype of the disease. All were in the quiescent phase at the time of the study. Total RNA was drawn from peripheral blood and profiled for microRNA expression using NanoString nCounter technology. Findings were compared to 10 healthy age- and sex-matched control subjects. Statistical analyses were conducted using R software, version 3.2. Data

preprocessing and normalization followed by differential expression analysis were performed using the R package DESeq2 (25516281) and in house scripts. A priori *P* values were adjusted for false discovery rate (FDR).

**Results:** Of the 798 mature human miRNAs probed, 103 exhibited reasonable expression levels in these cells. Seven were found to be significantly deregulated in the patients with FMF: three were significantly downregulated compared to control samples (miR-107, let-7d-5p, and miR-148b-3p), and four were significantly upregulated (miR-144-3p, miR-21-5p, miR-4454 and miR-451a), all with an adjusted *P* value of <0.01 (Figure 1).

To ensure that the observed changes were true biological effects and not technical artifacts, we performed Taqman quantitative real time polymerase chain reaction (qRT-PCR) analysis of two of the differentially expressed miRNAs between the patients and controls. Each miRNA was quantified in each sample, and its expression level was normalized to the reference RNA, U6-snRNA. In both groups, the direction of effect and the miRNA expression patterns in the NanoString analysis were consistent with the Taqman measurements ( $R^2=0.93$ )

**Conclusion:** We identified significant epigenetic changes in patients with clinically quiescent FMF. Further research is warranted in order to elucidate critical FMF manifestation such as susceptibility to early disease, disease severity, risk of the development of amyloidosis, and resistance to colchicine. All these factors might be ultimately explained, at least in part, by epigenetic modifications.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** *HLA-class II* region harbors the strongest genetic factors for ANCA-associated vasculitis (AAV), and differences in the genetic background of *HLA-class II* may partly explain the epidemiologic differences in AAV between European and Asian populations. *HLA-DPB1\*04:01*, highly prevalent in the European populations, is associated with granulomatosis with polyangiitis (GPA)/PR3-AAV prevalent in the European populations, whereas *DRB1\*09:01*, almost exclusively distributed in Asian populations, is associated with microscopic polyangiitis (MPA)/MPO-AAV, which account for the majority of AAV in Japan. Of interest, although *DRB1\*09:01* is very rare in the European populations, genome-wide association study (GWAS) detected significant association of a single nucleotide polymorphism (SNP) rs5000634 between *DQB1* and *DQA2* loci with MPA/MPO-AAV. Whether this association is independent from *HLA* alleles has not been reported. Another unique feature in Japanese AAV is that only half of the patients with GPA are positive for PR3-ANCA, and the other half are positive for MPO-ANCA. This provides a valuable opportunity to distinguish whether the genetic factors are associated with clinical classification of GPA or ANCA specificity. In the present study, we addressed these two issues in Japanese patients with AAV.

**Methods:** *HLA-DRB1* and *DPB1* were genotyped using high-resolution allele typing, and rs5000634 using TaqMan SNP assay. Association was tested in 467 Japanese AAV patients (clinical classification: MPA [285], GPA [92], eosinophilic GPA [56], unclassifiable [34], ANCA specificity: MPO-AAV [376], PR3-AAV [62]) and 596 healthy controls. Among GPA, 36 were single positive for PR3-ANCA (PR3-GPA) and 35 were single positive for MPO-ANCA (MPO-GPA).

**Results:** As shown in Table 1, rs5000634A was slightly decreased in MPO-AAV and MPA. However, when conditioned on *DRB1\*09:01* or *DRB1\*13:02*, the association was no longer significant, while the association of *DRB1* alleles remained significant after conditioned on rs5000634. When the associations of *DRB1* and *DPB1* were examined in MPO-GPA and PR3-GPA (Table 2), *DPB1\*04:01* was associated with PR3-GPA, but slightly decreased in MPO-GPA. In contrast, association of *DRB1\*08:02* was observed in MPO-GPA, but not in PR3-GPA.

**Conclusion:** In Japanese AAV, the genetic contribution of *HLA-DQ* region GWAS SNP was the secondary one caused by linkage disequilibrium with *HLA-DRB1* alleles. Striking differences in *HLA-DRB1* and *DPB1* associations were observed between MPO-GPA and PR3-GPA, suggesting that *HLA* may be more strongly associated with ANCA specificity than with clinical classification of GPA.

Table 1. The association of European GWAS SNP rs5000634 with MPA/MPO-AAV was secondary to *DRB1* association in the Japanese population.

## **The Rheumatic Disease Data Refinery: A Case Study in Integrative Genomics Reveals Complex IFN Signatures in Therapeutic Studies in SLE**

**Jaclyn N Taroni** and Casey S. Greene, Systems Pharmacology and Translational Therapeutics, University of Pennsylvania, Philadelphia, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Over the past 15 years, more than 10,000 whole tissue biopsies from patients with rheumatic diseases have been deposited into publicly available gene expression databases. Often rheumatic diseases are studied in isolation, but these data can be harnessed to characterize the full catalog of shared molecular patterns perturbed in these disease states. We present plans for a rheumatic disease transcriptomic compendium (**Fig 1**) and demonstrate feasibility through a case study in SLE whole blood gene expression data.

**Methods:** We curated experiments from studies of rheumatic diseases from ArrayExpress. For our SLE whole blood case study, we selected 8 experiments from multiple platforms, including data from 2 clinical trials examining the effects of treatments modulating IFN (Lauwerys, et al. *Arthritis Rheumatol.* 2013; Welcher, et al. *Arthritis Rheumatol.* 2015.). Cross-platform normalization using quantile normalization was performed. Interferon module gene sets from Chiche, et al. *Arthritis Rheumatol.* 2014. and unsupervised machine learning algorithms were used to examine the change in IFN signatures during treatment and the overall data structure during the integration process. This is, to our knowledge, the first application of the Chiche, et al. whole blood modular framework to these trials.

**Results:** We demonstrate that it is possible to integrate SLE whole blood data from multiple platforms and studies and retain underlying biology. We find that expression of Type I IFN module genes are altered following the treatment with the therapeutic vaccine IFN-alpha-kinoid in patients with high baseline Type I signatures, consistent with the therapeutics mechanism of action and the original study (**Fig 2**). We also find that only putative Type II modules are altered during blockade of IFN-gamma.

**Conclusion:** We have established the feasibility of a rheumatic disease gene expression compendium that is an order of magnitude larger than any single publicly available experiment. Our results further support the utility of data-driven cross-disease modules and suggest that unsupervised approaches can yield insight into complex molecular patterns altered in rheumatic diseases (**Fig 1**).

**Fig 1.** Overview of the Rheumatic Disease Data Refinery.

**Fig 2.** Summarized expression values (change from baseline) of IFN

**modules during treatment with IFN- $\gamma$ -kinoid** (data from Lauwerys, et al. *Arthritis Rheumatol.* 2013.). Patients were stratified into the following groups: placebo, those with a low Type I (M1.2) signature at base (IFN-negative), and those with a high M1.2 signature at baseline.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) and Osteoarthritis (OA) are two most common types of joint diseases with lots of similar symptoms, and their pathological mechanisms remain largely unknown. Although some key genes and diagnostic markers have been identified by microarray, these biomarkers still cannot reveal the complicated pathogenesis of RA and OA entirely. We conducted a novel integrative analysis of identification the key biomarkers of synovial tissue from RA and OA patients to better understand their difference.

**Methods:** After screening NCBI GEO database, 3 new expression profiling datasets (GSE 55235, GSE 55584, GSE 55457) met the eligibility criteria (from synovial tissue of RA and OA patients diagnosed according to American Rheumatism Association 1987 revised criteria, detected by the same platform, and sample size >15). A global normalization was performed to minimize the data inconsistency and heterogeneity. Differentially expressed genes (DEGs,  $p < 0.05$ ,  $FDR < 0.05$ ,  $Fold\ Change > 2$ ) between RA and OA from the 3 datasets were explored by R v3.4.0 software. Gene Ontology and KEGG pathway analysis of the DEGs were conducted by Cytoscape 3.4.0. Protein-protein interaction (PPI) network of the DEGs was obtained from STRING database v9.05.

**Results:** 375, 242 and 264 DEGs from GSE 55235, GSE 55584 and GSE 55457 datasets were obtained, respectively. Among them, 81 DEGs presented identical expression trends in the 3 datasets, including 50 up-regulated genes (*IGHG1*, *GUSBP11*, *STAT1*, et al) and 31 down-regulated genes (*SCRGI*, *MAB21L2*, *GHR*, et al). The DEGs mainly involved in *negative regulation of I-kappa B kinase/NF-kappa B signaling*, *cellular response to vitamin D pathway*, et al (Fig. 1). *STAT1* and *GHR* were the cores of PPI networks of 50 up-regulated proteins and 31 down-regulated proteins, respectively (Fig. 2).

**Conclusion:** Several apoptosis and vitamin D related pathways were more closely related to RA than OA, which suggested that anti-oxidative stress therapy and vitamin D might be more effective for RA. *STAT1* and *GHR* (both relate to bone metabolism) are the key genes presenting statistical significant difference between RA and OA. This study provides novel insights into the molecular mechanisms underlying RA and OA, thereby aiding the diagnosis and treatment of the diseases. Well-designed, well-controlled and dependent experiments are needed in future to validate the findings of the present study.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although pharmacogenetic studies of TNF inhibitors (TNFi) response presented the estimates of high heritability, only few loci with suggestive weak association as biomarkers for TNFi response have been identified. We aimed to identify optimal phenotype for drug response using heritability estimates ( $h^2$ ) and new predictive biomarkers of response to TNFi using genome-wide association studies (GWAS) in the Korean population.

**Methods:** Disease Activity Scores based on 28 joint counts (DAS28) and Clinical Disease Activity Index (CDAI) were assessed at baseline, and after 6 months in 370 Korean RA patients who started TNFi due to moderate or high disease activity from Hanyang university hospital. Genotypes were generated on the Illumina HumanOmni2.5Exome array (2.5 million variants). Quality control (QC) procedures were applied using the PLINK 1.9 and R 3.2.2 software. We estimated heritability by a linear mixed effect modeling approach (GCTA) for TNFi response using changes ( $\Delta$ ) in DAS28 and CDAI. To identify clinical and genetic variables that influence response to TNFi, a multivariate generalized linear model (GLM) analysis was performed. We also conducted a gene-based analysis [optimal sequence kernel association test (SKAT-O)] of rare variants.

**Results:** We identified that clinical factors seem to influence the therapeutic good response of TNFi including male, high disease activity score at baseline, BMI. The heritability estimates were found for  $\Delta$ DAS28  $h^2=0.44$ ,  $\Delta$ CDAI  $h^2=0.62$ ,  $\Delta$ provider global assessment of disease activity (PrGA)  $h^2=0.66$ ,  $\Delta$ swollen joint count (SJC)  $h^2=0.66$ ,  $\Delta$ tender joint count (TJC)  $h^2=0.59$ ,  $\Delta$ patient global assessment of disease activity (PtGA)  $h^2=0.58$ , and  $\Delta$ ESR  $h^2=0.49$ . We identified two novel significant functional SNPs [rs117811759 (UTR3 of SAP18), rs17279819 (exon of SKA3)] associated with response to TNFi, surpassing genome-wide significant threshold ( $P < 5.0 \times 10^{-8}$ ). Using a gene-based approach, we also identified two genes (SAP18 and SKA3) with significant burden signals after correction for multiple comparisons.

**Conclusion:** The optimal phenotype based on heritability suggests the use of changes in clinical disease activity index (CDAI) including provider global assessment than DAS28 in pharmacogenetic study. Our study suggests that SAP18 and SKA3 associated with response to TNFi therapy may serve as the useful genetic biomarker in RA patients of Koreans.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is the first-line disease modifying anti-rheumatic drug for the treatment of rheumatoid arthritis (RA). However, many patients do not respond adequately or experience adverse effects, therefore identifying blood-based biomarkers that predict treatment response is a clinical priority. DNA methylation is an epigenetic marker that modifies, but does not alter, DNA sequence, and it is thought that MTX may act, at least in part, by inhibiting intracellular methyl donor status leading to DNA hypomethylation. We aimed to identify differential DNA methylation signatures in whole blood, which may be predictive of response to MTX in patients with RA.

**Methods:** DNA methylation was measured using the HumanMethylation450 BeadChip in DNA samples from individuals recruited to the Rheumatoid Arthritis Medication Study (RAMS), a one year observational study in the UK including patients with RA starting MTX for the first time. In RAMS, demographic and clinical data are collected prior MTX start (baseline) and at 6 months after commencing MTX. DNA was extracted from whole blood samples collected baseline and at 4 weeks from patients who, at 6 months, had a EULAR good response (n=36) or EULAR poor response (n=36) to MTX (test cohort). Differentially methylated positions (DMPs) between the baseline and 4 weeks, and between good and poor response were identified using linear regression, adjusting for gender, age, cell composition, baseline disease activity score (DAS28), and smoking status. Analyses also compared methylation with changes in DAS28 and the individual DAS28 components over 6 months. DMPs that showed significant differences in the test cohort

were selected for replication by pyrosequencing in an independent group of 100 patients with both baseline and 4 week samples (replication cohort).

**Results:** In the test cohort, differential methylation at 2 CpG sites in samples taken at 4 weeks was associated with response status determined at 6 months ( $p$ -value  $<10^{-5}$ ). Three additional DMPs were associated with change in tender joint count, whilst three other DMPs were associated with change in swollen joint count, and a further four DMPs associated with change in C-reactive protein. One of the 4 DMPs associated with change in CRP, cg04334751, showed a trend to association in the independent replication cohort (Spearman's Rho  $p$ -value = 0.058). This CpG site is located close to microRNA, mir182.

**Conclusion:** These preliminary results suggest DNA methylation may provide a biomarker of MTX response but requires additional replication in other cohorts and testing in a prospective study of patients starting MTX for the first time.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The etiology and reasons underlying the ethnic disparities in systemic sclerosis (SSc) remain unknown. African-Americans are disproportionately affected by SSc, yet dramatically underrepresented in research. The role of DNA methylation in disease risk remains unclear. This analysis was conducted to comprehensively identify differentially methylated loci associated with SSc in AA.

**Methods:** Genomic DNA was isolated from cultured dermal fibroblasts isolated from 15 AA SSc cases and 15 AA controls. All patients met the 2013 ACR/EULAR classification criteria for SSc, most (93%) presenting with diffuse cutaneous SSc. DNA methylation patterns were profiled through reduced representation bisulfite sequencing (RRBS). Alignment and methylation calling were performed using Bismarck v0.16.3 and the GRCh37/hg19 reference genome. Data was filtered, normalized, and analyzed with RnBeads v1.6.1. Differential methylation analysis was conducted on CpG, promoter, gene and system level.

**Results:** We generated DNA methylation data for over 5 million CpGs in each sample with at least 40x coverage in promoter and CpG islands. Using the Combined Score approach implemented in RnBeads, a total of 97 CpG islands, 197 genes and 112 promoters showed significant differential enrichment in methylation levels between cases and controls. The top differentially methylated loci include, among others, the promoter of SERPINA1 (a protease inhibitor of elastase, plasmin, thrombin and trypsin) and SERPINA3, SERPINA4, SERPINA5, SERPINA11 and SERPINA13P. The SERPIN superfamily is characterized by its function as chaperone proteins and its roles in inflammation and immune function. Enrichment analysis revealed that both hypo- and hypermethylated genes and their promoter regions were enriched for differentiation and immune-related gene ontology terms (hypomethylated regions: IL2-mediated signaling pathway,  $P=5E-3$ ; and mesenchymal cell differentiation,  $P=3E-4$ ; hypermethylated regions: type I IFN signaling pathway,  $P=8E-4$ ; and positive regulation of cell differentiation,  $P=1E-3$ ).

**Conclusion:** We observed dramatic DNA methylation differences between cases and controls. Interestingly, most of the dysregulated genes can be placed in immune pathways, supporting the role of immune dysregulation in triggering the fibrosis characteristic of SSc.

These add to previous reports of mostly European-Americans that report an enrichment of extracellular matrix-receptor interaction and focal adhesion genes. These data support a role for DNA methylation differences in mediating susceptibility to SSc in AA, and a potentially stronger immune-driven etiology in AA.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Despite the success of anti-TNF therapies in RA, ~ 30 % of patients are non-responders. Several studies have focused on understanding the biology underlying non-response in these patients, and this remains an area of active investigation. We conducted a comprehensive molecular profiling of biologic naïve RA patients being treated with anti-TNF therapy in combination with MTX, prior to initiating (baseline) and following 3 months of treatment. The aim of the study was to understand the molecular mechanisms (other than drug neutralization), that affect clinical response to anti-TNF and to identify potential predictive markers that could allow us to differentiate responders and non-responders at baseline.

### **Methods:**

Two independent cohorts of 52 and 41 RA patients were selected from the Corrona CERTAIN registry. Clinical response at three months was defined according to EULAR criteria. Patients were included in each cohort only if a minimum level of anti-TNF was detected in the 3 month plasma sample to assure drug exposure.

Whole-blood RNA (PAXgene) and plasma samples from baseline and after 3 months of treatment were profiled using a broad array of technologies including RNAseq (Illumina HiSeq2500), shotgun and targeted proteomics, and glycan / glycopeptide analysis. A cell-specific transcriptional data analysis methodology was developed and applied to results of RNAseq analysis to enable characterization of the most common immune cell sub-populations.

### **Results:**

Results from each cohort show a strong treatment-related molecular signature between 3 months and baseline, and also a high level of correlation ( $\rho=0.7$ ; permutation  $p<10^{-3}$ ), between cohorts. Interestingly, no significant difference could be established between responders and non-responders in terms of treatment signature. Cell-specific transcriptional profiling analysis indicated a decrease in neutrophil markers at 3 months (permutation  $p<0.01$ ), which is concordant with observed changes in neutrophil counts. Shotgun proteomics in plasma showed a significant reduction of acute phase proteins, including CRP. Results at baseline, comparing responders to non-responders, demonstrated a lower concordance across the two cohorts, however, cell-specific analysis indicated increased representation of innate cell type signatures in responders and, conversely, increased expression of adaptive cell type signatures in non-responders. These results were not only conserved between the two cohorts, but were also observed when this analysis was applied to other independent publicly available RA datasets assessing response to anti-TNF treatment.

## Conclusion:

Results from this comprehensive molecular profiling study identified that differences in innate / adaptive immune cell signatures at baseline may be a major contributor to response to anti-TNF treatment within the first 3 months of therapy. These observations were supported by analysis of independent, publicly available RA datasets, and could potentially lead to an approach to patient selection, resulting in improved treatment outcomes.

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lyme arthritis (LA) is initially triggered by *Borrelia burgdorferi* infection, but in some patients, the synovitis persists despite 2-3 months of antibiotic therapy and spirochetal killing, called post-infectious LA. As in rheumatoid arthritis (RA), post-infectious LA is characterized by autoimmune inflammation and synovial hyperplasia. Our recent microRNA analysis revealed that antibacterial responses characterized the infectious phase of LA, and impaired wound healing may contribute to inflammatory and proliferative synovitis following resolution of infection. In mice, impaired wound repair and elevated interferon (IFN) responses during *B. burgdorferi* infection are associated with severe murine LA, but the role of impaired wound healing has not been explored in post-infectious LA or RA.

**Methods:** High-throughput RNA sequencing was performed using synovial tissue from patients with post-infectious LA (n=14), RA (n=5), and osteoarthritis (OA, n=5), and analyzed using in-house and online bioinformatics tools. Cells expressing IFN $\gamma$  were identified by intracellular cytokine staining and flow cytometry of cells collected from fresh synovial tissue and synovial fluid. Immunofluorescent (IF) microscopy was used to identify IFN $\gamma$ -responsive cells from patient synovial biopsies.

**Results:** 1001 genes were differentially expressed (DE) in post-infectious LA synovial tissue compared with OA tissue, of which 517 (43%) were interferon-regulated genes. In addition, 85/190 (45%) of genes in the response to wounding gene ontology (GO) set were DE in post-infectious LA patients compared with OA patients. Of these, ~1/3 were involved in coagulation, cell proliferation/differentiation, and extracellular matrix (ECM) formation, and were down-regulated in post-infectious LA, but less consistently in RA, compared with OA; whereas ~2/3 were involved in immune activation, IFN responses, and ECM degradation, and were up-regulated in both post-infectious LA and RA, compared with OA. Cytotoxic CD8<sup>+</sup> T cells were a major source IFN $\gamma$  in post-infectious LA and RA synovial tissue, and fibroblasts within foci of active synovitis expressed high levels of IFN $\gamma$ -inducible HLA-DR molecules.

**Conclusion:** These data show that impaired wound healing is a previously unrecognized component of the inflammatory-proliferative synovial pathology of post-infectious LA and RA. We propose that dysregulated wound healing in inflamed tissue may potentiate break in immune tolerance during the early stages of autoimmune development. Thus, post-infectious LA provides a natural human model of infection-induced autoimmunity, in which impaired wound healing leads to autoimmune synovial pathology of the chronic inflammatory arthritides, including RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Virtually all gout patients have high levels of uric acid in the blood (hyperuricemia, HU), but approximately 80% of patients with HU will never develop gout. There are a numbers of GWAS that identified risk alleles for hyperuricemia and/or gout using general population as comparison. This study examines genes that might influence the risk of gout among subjects with HU.

**Methods:** Subjects with HU (uric acid  $\geq 6.5$  mg/dl from lab data) and available GWAS data were requested from Partners HealthCare Biobank, a collaborative database that contains linked electronic medical records (EMR), survey data and genomic data for 15,000+ subjects. Gout was defined using a validated EMR algorithm with positive predict value of 0.95. Samples were genotyped from three Illumina MEGA chips. We performed standard quality control (QC) procedures for each file, merged them into one analysis dataset, and applied standard QC again. We restricted our genome-wide association study (GWAS) analysis to the Caucasian population.

Principal component analysis (PCA) was performed. Among subjects with HU, association between SNPs and gout was tested using logistic regression assuming a genetic additive model. The first 10 PCAs were utilized as covariates to control for any potential population stratification. We also looked at potential gout and HU SNPs with genome-wide significance among European ancestry from the GWAS Catalog (<https://www.ebi.ac.uk/gwas/>).

**Results:** 3146 self-reported Caucasian subjects with HU were identified from the Biobank, with 467 (14.8%) were identified as having gout. The gout group was slightly older (mean  $\pm$ SD, 72 $\pm$ 11 vs 66 $\pm$ 14,  $p < 0.0001$ ), more likely to be male (79% vs 56%,  $p < 0.0001$ ) compared to non-gout HU group. 793,514 SNPs passed QC and were utilized in the GWAS. The most significant SNP was rs1481012 in *ABCG2* gene with p value of  $1.8 \times 10^{-6}$ , which is a known risk factor for gout. We identified 14 SNPs at  $p \sim 10^{-6}$  (see Table); 12 were new SNPs and 2 had been previously identified as gout/HU risk SNPs from the GWAS catalog. 53 SNPs were identified at  $p \sim 10^{-5}$ ; only 1 is a previously identified gout/HU risk SNP. 623 SNPs were identified at  $p \sim 10^{-4}$ ; with only 1 as a known gout/HU SNP.

**Conclusion:** We carried out a GWAS of gout in patients with HU, and found that some of the risk alleles for gout in the general population are also associated with gout in a population with HU. But, we found many possible new SNPs and some previously identified SNPs were null in the HU population. The null findings may be because of limited power, confounding, or true non associations.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Azathioprine (AZA) is used to treat rheumatic diseases and to prevent transplant rejection. There is marked variability in toxicity to azathioprine; one such toxicity is thiopurine-induced acute pancreatitis (TIAP). The cause of TIAP is not known, but a HLA-DRB1\*07:01-HLA-DQA1\*02:01 haplotype was recently identified as a risk factor, suggesting that pancreatic injury may be immunologically mediated and modified by genetic factors. We aimed to build a cohort of patients who had pancreatic injury while taking AZA to perform pharmacogenetic studies. Here we present preliminary data.

**Methods:** We used the Vanderbilt University Medical Center BioVU resource that contains de-identified medical records linked to a biobank containing DNA samples from 225,000 patients. A validated bioinformatic algorithm was used to assemble a cohort of European American patients taking AZA. Those AZA users with amylase or lipase values that exceeded twice the upper limit of normal or with ICD-9/ICD-10 codes for acute pancreatitis were identified. Each record was reviewed to confirm AZA use at the time and to further classify patients into three not mutually exclusive categories: pancreatic injury (enzyme abnormalities alone), acute pancreatitis

(defined by American College of Gastroenterology Guidelines), or TIAP (Figure 1). The remaining patients served as controls. Age, sex, race, and BMI were compared between groups. All available genotypes from Infinium MEGA<sup>EX</sup>, a platform for genome wide analysis (GWA), were retrieved. After standard quality control measures with removal of variants with minor allele frequency <0.01, we performed an exploratory GWA with 849,934 variants adjusted for age and sex.

**Results:** We identified 3,212 AZA users. Evidence of pancreatic injury based on enzyme abnormalities occurred in 109 patients, of whom 22 and 7 met criteria for pancreatitis and TIAP, respectively. The remaining 3,103 were controls (Figure 1). Patients with pancreatic injury were more likely to be male ( $p=0.002$ ). MEGA<sup>EX</sup> genotypes were available in 34 cases and 449 controls. Although the results did not reach GWAS statistical significance, variants in two snps, rs4859716 ( $p=3.01 \times 10^{-6}$ ) and rs4843192 ( $p=7.13 \times 10^{-6}$ ), differed in patients with pancreatic injury.

**Conclusion:** These preliminary findings suggest that AZA users with pancreatic injury are more likely to be male and that variants in rs4859716 or rs4843192 may be associated with pancreatic injury. The rs4859716 variant is an intergenic variant near the SHROOM3 gene, necessary for epithelial morphogenesis of the gut, and rs4843192 is an intergenic variant near the FOXL1 gene, a tumor suppressor gene whose activity predicts tumor aggressiveness in pancreatic cancer. Further investigation is warranted into clinical and genetic determinants of pancreatic toxicity with azathioprine.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Current serological tests are not sufficiently accurate in differentiating between HC and those with autoimmune rheumatic diseases. We developed the iCHIP antigen microarray to provide extensive autoantibody profiling in human serum. We previously described the SLE-Key Rule-Out test, which distinguishes SLE patients from HC with 94% sensitivity, 75% specificity, and a negative predictive value (NPV) of 93%<sup>1,2,3</sup>. Here, we report the use of the autoimmune discovery iCHIP to distinguish between HC and subjects with SLE, RA, SSc, SS, and the APS.

## Methods:

We examined IgM and IgG autoantibodies binding to 519 antigens (1038 features) in the sera of HC subjects (N=136), and in patients with SLE (N=30), RA (N=30), SSc (N=40), SS (N=20), and APS (N=16). FDR-adjusted p-values were calculated for each univariate test. Three independent multivariate classification methods were applied: Support Vector Machine (SVM), Quadratic Discriminant Analysis (QDA) and Naive Bayesian classifier (NB). Classifier training and testing were performed based on 10-fold cross validation on all samples, and the performance of each classifier was determined.

## Results:

Univariate analysis revealed multiple statistically significant separating reactivities. We found that IgG autoantibody reactivity to the connective tissue antigen receptor leukocyte-associated immunoglobulin-like receptor 1 (LAIR-1) differentiated HC subjects with all of the 5 diseases with a p value of 2.8E-63. Other highly significant autoantigen reactivities included connective tissue proteins such as collagen III (p = 6.5E-26 (IgM)) and collagen II (p = 5E-22 (IgG)). Figure 1 shows anti-LAIR-1 data comparing HC subjects to each of the 5 diseases; each of the three classification methods differentiated between HC and subjects with autoimmune diseases. The typical mean classifier performance was 93% sensitivity, 96% specificity, and 95% accuracy. Interestingly, LAIR-1 appears to function as a "checkpoint" down-regulator of immune reactivity<sup>4</sup>; thus, it is possible that anti-LAIR-1 represent a target for therapeutic discovery and also may be pathogenic, and predispose to a variety of autoimmune conditions.

## Conclusion:

Autoantibody specificities detected by the autoimmune discovery iCHIP successfully distinguished between HC individuals and individuals with several autoimmune rheumatic diseases, including SLE, RA, SSc, SS, and APS. These preliminary results are based on relatively small numbers of serum samples, but are very promising and warrant additional validation in larger cohorts of autoimmune and HC subjects.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neonatal-onset multisystem inflammatory disease (NOMID) is an IL-1 mediated autoinflammatory disease caused by a gain-of-function mutations in *NLRP3* that results in constitutive activation of IL-1b and specific organ/tissue inflammation and damage. To date no reliable serum biomarkers that identify IL-1 mediated systemic inflammation or inflammatory organ damage particularly CNS inflammation exist. We explore high-throughput proteomic profiling to screen for potential biomarkers.

**Methods:** Serum samples were obtained from healthy age-matched children (HC), n=8 and 12 NOMID patients (pts.) before and after a median of 42 months (range 3-96mo) after starting IL-1 blocking treatment with anakinra. All patients were in inflammatory remission at the time of blood draw. Using an aptamer-based proteomic assay (SOMAscan) we screened 1129 proteins. To identify biomarkers of exaggerated systemic and tissue specific IL-1-mediated inflammation, we selected proteins that significantly changed with anakinra treatment many were significantly increased or decreased in untreated NOMID vs HC. Mann-Whitney U test and Wilcoxon rank-sum analyses with FDR correction were used for statistical comparison. We determined RNA transcript levels (RNAseq) of the protein targets in whole blood. RPKMs < 1 characterized low expression in blood cells and suggested that the protein origin might be from non-hematopoietic cells. We also determined protein function.

**Results:** In the SOMAscan Assay we identified 70 proteins that changed in the serum of NOMID pts. before and after treatment (n=12; q<0.05). Of these 15 (21%) were also significantly increased or decreased compared to controls at baseline. Protein levels of 30 proteins decreased and protein levels of 40 increased with treatment. Of these, 63% and 82% respectively had low or no gene expression in whole blood. Protein targets of the IL-1 pathway (IL-1 $\beta$ , soluble IL-1RI, IL-1 RAcP) significantly decreased. Of markers that decreased were those indicating systemic inflammation including complements (i.e CRP, SAA1, C3, C9, CFI) and markers that have been associated with tissue damage including CNS manifestations (CFI TNFSD11A) and hypercoagulability (F9) as well as vascular endothelial markers associated with atherosclerosis (PLAUR, CST3). Of the markers that increase, most are associated with growth and tissue regeneration (including growth hormone receptor: GHR, IGFBP3 and -5, NOTCH3, TGF $\beta$ ), p<0.05 for all.

**Conclusion:** Protein changes with anakinra treatment reveal markers of IL-1 pathway that are not reliably detectable in ELISA assays and transcription assays. These markers need to be validated in other presumed IL-1 mediated diseases. Furthermore, markers of tissue inflammation particularly of CNS inflammation need to be validated in treatment studies to determine their utility in assessing appropriate treatment with IL-1 blocking therapies.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early diagnosis of rheumatoid arthritis (RA) is hampered by suboptimal accuracy of currently available serological biomarkers. Recent advancements in metabolomic profiling include dansylation liquid chromatography mass spectrometry (LC-MS), resulting in 1000-fold increase in detection sensitivity of amine/phenol-containing metabolites, and universal metabolome-standard (UMS) methodology in conjunction with differential chemical isotope labeling (CIL LC-MS), to provide long-term analytical reproducibility and facilitate metabolome comparisons among different data sets. CIL LC-MS uses different labeling reagents to target chemical group-based submetabolomes to provide in-depth metabolomic analysis. We aimed to identify a metabolite signature with high accuracy for RA.

**Methods:** 12C-dansylation and acid labeling of individual serological samples and 13C-dansylation and acid labeling of pooled samples from 47 age/gender matched healthy control subjects, 52 age/gender matched RA patients, and 46 patients with seropositive myasthenia gravis was undertaken. A total of 7,458 amine/phenol and 9954 organic acid metabolites were combined into a single data set for analysis. Metabolite concentrations were natural-log transformed. Model accuracy estimation was performed using 5-fold cross-validation, and metabolites were selected using within-fold feature selection. Metabolites were ranked using Spearman correlation coefficient, and the top *n* were selected, with a varying *n*. Training of the predictive model was done using a linear Support Vector Machine (SVM). After cross-validation, the final model formula was calculated on the entire data set using the same methodology as was evaluated using cross-validation. Cross-validation accuracy was further analyzed using randomly selected metabolites. Data processing and analysis was performed entirely in R (version 3.2.3). SVM was trained using the e1071 package (version 1.6-7) and cross-validation was done using the caret package (version 6.0-64).

**Results:** A total of 5711 metabolites were identified in all samples with orthogonal partial least squares discriminant analysis showing a clear separation of the 3 groups (R<sup>2</sup>=0.98, Q<sup>2</sup>=0.80). 34 serum metabolites were identified as potential RA biomarkers with correlation

coefficients  $\geq 0.80$ . Cross-validation accuracy of top-ranked metabolites, according to Spearman's correlation, and using a varying number of metabolites shows that 99.1% accuracy for RA versus controls is achieved using only 4 metabolites.

**Conclusion:** CIL LC-MS metabolomic profiling and UMS methodology reveals that serum metabolomes of RA patients differ considerably from healthy and autoimmune disease.

Figure. Cross-validation accuracy using a varying number of metabolites. 99% accuracy is achieved using 4 metabolites.

**Session Date:** Monday, November 6, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Lupus is a prototypic autoimmune disease characterized by B cell hyperactivity, autoantibody formation and resultant tissue damage. The mechanisms underlying tissue pathology in lupus are not completely understood. Analysis of gene expression in various tissues has been employed in an attempt to develop a better understanding of disease pathogenesis and tissue injury. The current experiments were undertaken to develop a more comprehensive understanding of molecular pathways involved in lupus organ pathogenesis by assessing gene expression profiles so that novel treatment candidates targeting commonly dysregulated cellular functions could be identified.

### Methods:

Publicly available gene expression profiles were identified in GEO from lupus affected skin, synovium, and kidney. The raw data were downloaded, normalized, curated and assessed for differentially expressed (DE) genes. Correlation with clinical or histologic features was carried out by Weighted Gene Correlation Network Analysis (WGCNA) and variation in pathway activity was determined in individual samples and groups of samples by Gene Set Variation Analysis (GSVA).

### Results:

More than 300 gene expression profiles from lupus patients and controls were analyzed to determine DE genes (8279 discoid lupus skin, 5465 synovium, 6381 kidney glomerulus WHO class 3/4, 5587 kidney tubulointerstitium WHO class 3/4). Notably, 45% of lupus tissue DE genes were detected in more than one tissue and 439 were differentially expressed in all tissues. Curated STRING-based protein-protein interaction analysis carried out using MCODE in Cytoscape of these 439 DE genes identified a number of gene clusters that

were functionally characterized by both Biologically Informed Gene Cluster Analysis (BIG-C) and IPA. BIG-C identified 13 pathways that were abnormally expressed in all lupus tissues, whereas IPA identified 65 dysregulated pathways shared among these tissues. Using the the 45 BIG-C functional categories, GSVA separated lupus tissues from control tissues, identified commonly dysregulated functional pathways, documented individual tissue variation and also largely identified the same functional pathways that emerged from pathway construction generated from DE genes. WGCA identified a number of gene modules that correlated with clinical of histologic features. These modules contained nearly 85% of the DE genes. A number of approaches were employed to connect the dysregulated lupus organ pathways to potential drug candidates, including cross referencing to the Library of Integrated Network Based Cellular Signatures (LINCS). More than 75 potential drug candidates were identified.

#### **Conclusion:**

These results indicate that common cellular and molecular pathways can be identified in all of the affected lupus tissues, implying that related processes might be involved in the pathology of multiple organs in this autoimmune disease. Connectivity between lupus organ gene expression abnormalities and candidate drug induced changes in gene expression identified a number of potential novel treatments that could target the commonly dysregulated molecular pathways underlying lupus organ pathology.

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Auto-inflammatory syndromes are inherited conditions characterized by recurrent inflammation (fever, abdominal pain, dermatitis, arthritis). Diagnosis and treatments are challenging as detection rate of mutations in patients with high suspicions for auto-inflammatory syndromes is low, symptoms are reminiscent of other autoimmune diseases, especially Systemic Autoimmune Rheumatic Diseases (SARD), and the cytokines abnormally secreted are unknown. As a consequence, patients can be misdiagnosed, leading to inappropriate treatment, severe complications and substantial socio-economic costs. We hypothesized that the secretion of cytokines by peripheral blood mononuclear cells (PBMC) is an indicator of the disease and could guide the treatment to the most suitable anti-cytokine.

**Methods:** Plasma and peripheral blood mononuclear cells (PBMCs) were obtained from healthy controls, suspected auto-inflammatory patients, and rheumatoid arthritis and systemic lupus erythematosus patients from the CHU de Québec SARD Biobank Repository Database (SBRD). PBMC were stimulated with inflammatory and immune stimuli, and cytokines in the supernatant were analyzed by multiplex assays.

**Results:** The cytokines found in the plasma were similar between healthy donors, SARD patients and suspected auto-inflammatory patients. In contrast, PBMC had a distinct profile of cytokine secretion. Stimulation of PBMCs with IL-15 or anti-Ig (Figure 1) led to differential secretion of members of IL-1 cytokine family, IL-12 and IFN $\gamma$  in autoimmune, but not auto-inflammatory patients. In

contrast, stimulation with inflammasome activators or pro-inflammatory cytokines led to selective secretion of IL-1 $\alpha$ , IL-1 $\beta$ , IL-1RA, IL-18 (Figure 2), IFN $\gamma$  or IL-12 in suspected auto-inflammatory patients, but not in autoimmune patients.

**Conclusion:** This study demonstrates that analysis of leukocytes' secretome is reliably more sensitive than serum to reveal cytokine signatures and to predict treatment options in patients with suspected chronic auto-inflammatory syndromes.

**Acknowledgement:** This work was partly funded by the Fondation du Grand défi Pierre Lavoie. We thank Pfizer, Amgen, BMS, Abbvie, Roche, Sanofi-Genzyme and Merck & Co. for their unrestricted financial support of the SBRD.

**Figure 1:** Stimulation of PBMCs with anti-immunoglobulins to activate B cells reveals different cytokine signatures between autoimmune and auto-inflammatory patients

**Figure 2:** Stimulation of PBMCs with inflammasome activators or pro-inflammatory cytokines uncovers abnormal over-secretion of the IL-1 cytokine family member IL-18 by auto-inflammatory patients

**Session Title:** Genetics, Genomics and Proteomics Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The functional capacity of individuals with rheumatoid arthritis (RA) is related to the severity of damage to bone and cartilage within joints. This is a highly variable trait that is known to have a significant genetic component. A loss-of-function non-synonymous variant (rs2066844, Arg702Trp) in nucleotide-binding oligomerization domain containing 2 (NOD2) gene, results in lower activation of NF- $\kappa$ B-mediated inflammation and tissue damage in RA. Our hypothesis was that the 702Trp variant is, as a result of reduced inflammatory load, be associated with lower radiological damage in RA.

### Methods:

The initial study was performed in the British Genetics of RA (GORA) cross-sectional population (N=914), radiological damage was assessed by the Modified Larsen Score (MLS). Genotyping was performed using either the Illumina HumanCoreExome array (N=568) or the Illumina HumanCNV370 Quad v3 array (N=346). Genotypes for rs2066844 were imputed for individuals typed on latter platform using IMPUTE v2. Replication was performed in the Leiden EAC (N=597), with damage assessed at baseline and yearly thereafter using the Sharp-van der Heijde score (SHS) and samples were genotyped on the Illumina iScan platform (ImmunoChip). RF and ACPA status was available for both populations. Analyses were conducted in R v3.4.0 and SPSS v20. For the combined meta-analysis, we used the most recent measurement on each patient in a zero-inflated negative binomial model adjusted for sex and age at assessment, followed by a fixed-effects meta-analysis of the two summary statistics.

### Results:

In the discovery GORA population the minor rs2066844 (702Trp) frequency was 5%, similar to the 1000 genomes European frequency (5.1%), genotypes fitted Hardy-Weinberg equilibrium. The minor allele carriage was associated with lower MLS: incidence ratio risk 0.75 (95% CI: 0.60-0.93),  $p=0.009$ . The association was only significant in RF+ ( $p=0.008$ ) or ACPA+ ( $p=0.013$ ) subgroups. The proportion of variance explained by rs2066844 was 0.007. In the replication Leiden cohort we observed a similar lower yearly progression of SHS score for each minor allele, by 0.95 SHS (95% CI: 0.92-0.99,  $p=0.006$ ) in all patient and in ACPA positive patients (0.92, 95% CI: 0.87-0.97,  $p=0.004$ ). Meta-analysis of the two cohorts revealed a significant pooled effect with an IRR of 0.76 (95% CI: 0.64-0.91,  $p=0.003$ ).

**Conclusion:** These data reveal a protective effect of rs2066844 minor allele with severity of sero-positive RA that is likely a consequence of the lower inflammatory activity associated with this genotype. Although the overall influence on the variance of tissue damage is modest, in combination with established prognostic biomarkers, it may contribute to the development of prognostic algorithm for RA.

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Outcomes Measures in Rheumatology Trials (OMERACT) TJR Working Group has proposed six core domains that would constitute a standardized measurement set that can be used as a tool to compare outcomes among TJR clinical trials. The specific aim was to query two different groups of stakeholders, patients and surgeons, to establish a consensus regarding the domains.

**Methods:** We e-mailed a survey to 3810 hip/knee TJR patients and 49 hip/knee arthroplasty surgeons at a high-volume orthopedic center of excellence to rate the importance of the six core domains and two additional domains for consideration. Ratings were on a 1 to 9 scale: 1-3 indicating limited or no importance for patients, 4-6 being important, but not critical, and 7-9 being critical. Scores were summarized with median [interquartile range]. Comparisons between the sexes, age groups (< 55 years vs. ≥ 55 years), and participant types (surgeons vs. patients) were made using the Wilcoxon rank-sum test.

**Results:** 1295 patients (34%) and 21 (43%) surgeons completed the questionnaire. Patient non-responders were similar in age (≥ 55 years, 86%) and gender (57.5% female) to responders. All core domains were confirmed as “critical” by both patients and surgeons. This consensus rating persisted even when compared between the sexes as well as the age groups. The only exception was cost, while “critical” overall, when compared to patients and females respectively, which both surgeons and males scored cost as only “important”, not “critical”. Cost was also rated differently between those < 55 years vs. participants ≥ 55 years: 6 [5, 8] vs. 7 [5, 8], p=0.015.

**Conclusion:** Our study confirmed that both orthopedic surgeons and TJR patients agree that the OMERACT TJR core domains were critical for patients. These results support a broad endorsement and encourage the identification of candidate outcome instruments to further develop a TJR standardized measurement set.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Prior retrospective claims analyses examining rheumatoid arthritis (RA) treatment costs have shown infliximab (IFX) to be costlier than certolizumab pegol (CZP) across all sites of care (physician office, home, outpatient [OP]), primarily due to lower CZP drug costs.<sup>1</sup> The present study assessed one-year (yr) healthcare resource utilization (HRU) and costs incurred by RA patients (pts) treated with CZP vs IFX.

**Methods:** Medical and pharmacy claims data (2008–2015) were derived from the Truven MarketScan<sup>®</sup> database of insured pts matching the inclusion criteria: RA diagnosis, treatment initiation (index date) with CZP or IFX (July/1/2008–December/31/2014), continuous eligibility  $\pm 12$  months around index date, and age  $\geq 18$  yrs. Mean, unadjusted one-yr visits (OP, inpatient [IP], emergency room [ER], and physician office) and costs (pharmacy, medical, and total healthcare) were calculated and compared between groups via Mann-Whitney U tests. These were also assessed using multivariate (MV) regression models and adjusted for treatment (CZP/IFX), prior biologic use (yes/no), gender, age, baseline health, and baseline HRU and costs.

**Results:** 1,398 RA pts were treated with CZP and 3,592 with IFX. CZP pts were more likely to have prior biologic use than IFX pts (74.0% vs 40.8%,  $p < 0.001$ ; Table 1). In the unadjusted analyses, CZP pts demonstrated increased pharmacy usage (68.7 vs 56.1 fills per pt per yr,  $p < 0.001$ ), but reduced physician office visits (19.8 vs 21.9,  $p < 0.001$ ) and OP hospital-based services (4.4 vs 4.9,  $p = 0.221$ ) compared to IFX pts, resulting in greater overall pharmacy costs but lower medical expenditure than IFX patients ( $p$  values  $< 0.001$ ; Figure 1A). In adjusted analyses, MV models controlling for patient and treatment characteristics revealed that prior biologic use was associated with more office visits ( $p < 0.001$ ), OP visits ( $p < 0.001$ ), ER utilization ( $p < 0.001$ ), and elevated total medical costs ( $p < 0.001$ ). Despite the CZP cohort having more biologic-experienced pts, CZP treatment was associated with fewer physician office ( $p < 0.001$ ; Table 2) and OP ( $p < 0.001$ ; Table 2) services compared to IFX pts, but a greater pharmacy spend ( $p < 0.001$ ; Figure 1B). However, CZP treatment was associated with reduced total healthcare costs ( $p < 0.001$ ), with IFX pts incurring over \$4,000 per pt per yr more than CZP pts (\$46,908 vs \$42,867,  $p < 0.001$ ; Figure 1B).

**Conclusion:** Despite the CZP-treated RA population having a higher rate of prior biologic use, which has been correlated with more severe disease,<sup>2</sup> annual total healthcare costs were higher for IFX-treated RA pts. MV models controlling for demographics and baseline HRU revealed that treatment with CZP was associated with a \$4,000 saving per pt per yr compared to treatment with IFX.

HRU, mean (SE)	CZP	IFX
Office Visits	18.1 (0.12)	20.4 (0.09)
Outpatient Hospital Visits	3.7 (0.05)	4.3 (0.04)
ER Visits	0.3 (0.01)	0.3 (0.01)
IP Admissions	0.2 (0.01)	0.2 (0.01)
Prescription Fills	57.2 (0.83)	49.2 (0.48)

Variables in bold indicate a statistically significant difference between CZP and IFX groups. Poisson log-linear models were fitted for physician office and OP visits. Logistic regression was used for IP and ER utilization (any/none). Total prescription fills were estimated using gamma models with a log link. SE: standard error.

## Developing a Multi-Phase Claims-Based Algorithm to Facilitate the Study of Drug Exposure during Pregnancy

S Phillips<sup>1</sup>, KE Johnson<sup>1</sup>, SW Shen<sup>2</sup>, KJ Woodcroft<sup>3</sup>, SA Oliveria<sup>4</sup> and TA Simon<sup>5</sup>, <sup>1</sup>QuintilesIMS, Seattle, WA, <sup>2</sup>Bristol-Myers Squibb, Hopewell, NJ, <sup>3</sup>Henry Ford Health System, Detroit, MI, <sup>4</sup>QuintilesIMS, New York, NY, <sup>5</sup>Bristol-Myers Squibb, Princeton, NJ

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The use of antirheumatic medications during pregnancy may lead to birth defects or other complications. Safety studies are critical, with registries being common but often yielding a small number of cases after years of follow-up. Medical administrative claims data can be used to study large numbers of women and infants more quickly and efficiently, if these claims data

accurately identify: pregnancy outcomes, gestational age, drug exposure by trimester and mother/infant links. No *single* existing algorithm uses only administrative claims data to measure *all* of these variables. The objective is to develop a multi-phase algorithm for use in administrative medical claims data to identify live/non-live pregnancy outcomes (phase 1), estimate gestational age (phase 2), estimate drug exposure by trimester (phase 3) and link claims data for mothers and infants (phase 4).

**Methods:** A multi-phase algorithm is being developed in a phased manner among women aged  $\geq 15$  and  $\leq 50$  years with  $\geq 1$  International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) end of pregnancy code. Women were enrolled and had prescription coverage 340 days prior to the end of pregnancy in the Henry Ford Health System between 1/1/2013 and 9/30/2015. In all phases, algorithms will be developed, applied to claims data and compared to electronic medical records for validation. Positive predictive value (PPV), sensitivity and 95% CI will be calculated. The best performing algorithm developed in each phase will be used to move to the next phase.

**Results:** A total of 698 women met inclusion criteria. Three algorithms were developed and tested for phase 1. Algorithm 1 ( $\geq 1$  definitive ICD-9-CM end of pregnancy code) performed best (Table 1). Two algorithms for phase 2 were developed and tested. Algorithm 2 (adjusted delivery date based on selected procedure codes and assigned 245 days to preterm, 273 days to term, and 294 days to post-term) performed best for preterm and term births (Table 2).

**Conclusion:** End of pregnancy outcomes can be identified in claims data with high PPV and sensitivity. Gestational age can be estimated with reasonable PPV and sensitivity for preterm and term live births. Further analyses are underway for phases 3 and 4.

Table 1. Phase 1: End of Pregnancy Algorithm Summary and Performance Characteristics

	PPV (%)	95% CI	Sensitivity (%)	95% CI
<b>Algorithm 1: <math>\geq 1</math> definitive ICD-9-CM code (e.g. single, live born) for end of pregnancy</b>				
Overall	94.21	92.18–95.85	98.91	97.76–99.57
Live births*	98.49	97.04–99.35	97.38	95.64–98.56
Non-live births*	78.62	71.04–84.99	99.13	95.24–99.98
<b>Algorithm 2: <math>\geq 1</math> ICD-9-CM code for end of pregnancy in the primary position</b>				
Overall	90.58	88.08–92.71	96.75	95.02–98.01
Live births*	91.70	89.05–93.89	98.22	96.64–99.19
Non-live births*	72.06	63.72–79.41	85.22	77.39–91.15
<b>Algorithm 3: <math>\geq 1</math> ICD-9-CM code for end of pregnancy in the primary position —and— <math>\geq 1</math> procedure code (ICD-9-CM, CPT-4 or HCPCS) related to pregnancy within 0–7 days after the end of pregnancy code in the primary position</b>				
Overall	92.70	90.29–94.67	86.94	84.05–89.48
Live births*	92.71	90.16–94.77	97.64	95.91–98.78
Non-live births*	72.46	60.38–82.54	41.32	32.44–50.63

\*Live birth and non-live birth data are not necessarily mutually exclusive, as in the case where there is a multiple birth and there is at least one live birth and at least one non-live birth  
CPT-4=Current Procedural Terminology, 4th Edition; HCPCS=Healthcare Common Procedure Coding System; ICD-9-CM=International Classification of Diseases, Ninth Revision, Clinical Modification; PPV=positive predictive value

Table 2. Phase 2: Estimated Gestational Age Assignment Algorithm Summary and Performance Characteristics

	PPV (%)	95% CI	Sensitivity (%)	95% CI
<b>Algorithm 1:</b>				
1. Checked for delivery procedure codes after the end of pregnancy code from phase 1. If a delivery procedure code was 1–60 days after the end of pregnancy, then delivery date was adjusted to that procedure code. If not, then the date was not adjusted				
2. Assigned gestational age based on ICD-9-CM codes 0–60 days after the phase 1 end of pregnancy date:				
a. Assigned preterm (245 days) if codes 644.x or 765.x were present				
b. Assigned post-term (294 days) if codes 645.11, 645.21, 766.21 or 766.22 were present				
c. All other pregnancies = term				
Preterm	93.5	78.6–99.2	67.4	51.5–80.9
Term	94.2	91.2–96.4	80.6	76.4–84.4
Post-term	40.2	31.6–49.2	89.5	78.5–96.0
<b>Algorithm 2:</b>				
1. Checked for delivery procedure codes after the end of pregnancy code from phase 1. If a <i>definitive</i> delivery procedure code (e.g. cesarean section) was 1–60 days after the end of pregnancy, then delivery date was adjusted to that procedure code. If not, then the date was not adjusted				
2. Assigned gestational age as in Algorithm 1:				
a. Assigned preterm (245 days) if codes 644.x or 765.x were present				
b. Assigned post-term (294 days) if codes 645.11, 645.21, 766.21 or 766.22 were present				
c. All other pregnancies = term				
Preterm	93.8	79.2–99.2	68.2	52.4–81.4
Term	94.2	91.2–96.4	80.6	76.4–84.4
Post-term	40.2	31.6–49.2	89.5	78.5–96.0

ICD-9-CM=International Classification of Diseases, Ninth Revision, Clinical Modification; PPV=positive predictive value

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The rising prevalence of heart failure (HF) in the general population and associated increased hospitalization costs is a major public health problem. There is a 2-fold increased risk of HF in rheumatoid arthritis (RA) compared to the general population. Little is known about hospitalization rates in patients with RA and HF. We aimed to compare the frequency of and trends in hospitalizations following HF diagnosis in patients with and without RA during 1987-2015.

**Methods:** The study included a retrospectively identified population-based cohort of patients with incident HF and prior RA (age $\geq$ 18 years, 1987 ACR criteria) and a comparison cohort of incident HF patients without RA matched 3:1 on age, sex, and year of HF diagnosis. Hospitalizations at the time of HF diagnosis were excluded from analyses. All subjects were followed until death, migration, or 1/1/2015. Person-years methods and rate ratios (RR) from Poisson regression models were used to compare hospitalization rates between the groups. Generalized linear models were used to analyze the length of stay (LOS).

**Results:** The study included 212 patients with RA (mean age at HF diagnosis 78.3 years; 68% female) and 636 non-RA patients (mean age at HF diagnosis 78.6 years; 68% female). The hospitalization rate following HF diagnosis was higher in RA vs non-RA patients (RR 1.16; 95%CI 1.08-1.25). This difference may be decreasing after 2010 (Figure). The magnitude of the increase was similar in both sexes and across all ages. In patients with available echocardiography, HF with preserved ejection fraction (HFpEF) was not different in RA (57%) vs non-RA (51%;  $p=0.3$ ). Patients with RA and HF with reduced ejection fraction (HFrEF, RR 1.65; 95%CI 1.29-2.09) but not those with HFpEF (RR 0.80; 95%CI 0.63-1.01) had significantly more hospitalizations than non-RA patients. Following HF diagnosis, RA patients were more likely to be hospitalized for non-cardiovascular causes (RR 1.26; 95%CI 1.14-1.39), but not for HF (RR 0.96; 95%CI 0.76-1.21) or other cardiovascular causes (RR 0.99; 95%CI 0.81-1.20) compared to the non-RA patients. There was no overall difference in hospital LOS in RA vs non-RA patients after HF diagnosis (mean of 5.6 vs 5.3 days, respectively,  $p=0.31$ ). LOS was higher in earlier years in RA than non-RA and declined faster in RA than non-RA over time, with similar LOS in both groups in recent years (interaction  $p=0.019$ ). Readmission rates within 30 days of prior discharge were similar in RA and non-RA ( $p=0.14$ ).

**Conclusion:** Hospitalization rate following HF diagnosis was 16% higher in RA than in non-RA patients regardless of sex and age. This increased hospitalization risk was mostly among patients with RA who had HFrEF rather than HFpEF, and was predominantly due to non-cardiovascular causes. Increased complexity of management of patients with comorbid RA may play a role in more frequent hospitalizations in the RA cohort.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** RA is often treated with a biologic DMARD (bDMARD), such as abatacept (ABA) or a TNF inhibitor (TNFi). Real-world data on how economic outcomes vary by bDMARD therapy in patients (pts) with seropositivity to anti-cyclic citrullinated peptide (anti-CCP) are sparse. The objective of this study was to compare healthcare resource utilization (HCRU) and costs among pts with RA and anti-CCP positivity who initiated a new bDMARD therapy. **Methods:** A retrospective study was conducted using claims data from a large US health plan, linked with laboratory results. Pts were aged  $\geq 18$  years with  $\geq 1$  diagnosis code for RA (ICD-9-CM 714.x) and  $\geq 1$  claim for ABA (identified first) or a TNFi (adalimumab, certolizumab pegol, etanercept, golimumab or infliximab) during Jan 1, 2007–Jul 31, 2015. Cohort assignment was based on index therapy (ABA or first observed TNFi). Pts were required to have  $\geq 18$  months of continuous health plan enrollment ( $\geq 6$  months pre-index [pre-initiation], 12 months post-index [post-initiation]), no pre-index claims for index therapy and anti-CCP positivity ( $\geq 20$  IU/mL). Per-pt-per-month HCRU and costs (total and RA-related) were calculated separately for the pre- and post-index periods. Independent sample *t*-tests were used to examine differences by cohort.

**Results:** Analyses included 203 ABA users and 1066 TNFi users (etanercept=487, adalimumab=331, infliximab=144, certolizumab=60, golimumab=44) with anti-CCP positivity (median age 55 & 52 years, female 88 & 75%, Medicare Advantage 17 & 15%; mean Charlson Comorbidity Index score 1.6 & 1.4, pre-index bDMARD use 48 &  $<1\%$ ). Compared with TNFi users, ABA users experienced greater mean ambulatory visits in pre-index (2.6 vs 2.0,  $p<0.01$ ) and post-index periods (2.6 vs 1.7,  $p<0.01$ ). No statistically significant differences ( $p<0.05$ ) in mean emergency room visits or inpatient days for the pre- or post-index periods were observed between cohorts. Compared with TNFi users, ABA users experienced higher mean costs in pre-index (\$2543 vs \$932,  $p<0.01$ ) and post-index periods (\$3632 vs \$2957,  $p<0.01$ ). Analyses of RA-related costs and utilization were similar, with the exception that a statistically significant difference was not observed in post-index RA-related costs between ABA and TNFi users (\$2660 vs \$2306,  $p=0.06$ ).

**Conclusion:** Among pts with RA and anti-CCP positivity, unadjusted differences in pre-index ambulatory care and healthcare costs were observed between abatacept and TNFi users, which carried over to post-index cost and HCRU comparisons. These differences appeared to be driven, in part, by greater ambulatory care among abatacept users. Further research is needed to understand additional factors driving pre-index costs among pts initiating bDMARDs to treat RA, to inform multivariable adjusted analyses and ensure comparability of cohorts, as abatacept is likely to be their second line of therapy due to formulary availability.

**Table 1. Per-Patient-Per-Month Costs and Healthcare Resource Utilization by Biologic DMARD Group**

	6 months pre-index		12 months post-index	
	Abatacept	TNFi	Abatacept	TNFi
<b>Healthcare costs, USD, mean (SD)</b>				
Total healthcare costs	2543 (3283)	932 (1668)*	3632 (3480)	2957 (2457)*
RA-related healthcare costs	1379 (1660)	310 (1168)*	2660 (2567)	2306 (1785)
<b>Healthcare resource utilization, mean (SD)</b>				
Total ambulatory visits	2.62 (1.86)	1.96 (1.42)*	2.56 (1.73)	1.68 (1.35)*
Total ER visits	0.11 (0.29)	0.07 (0.28)	0.10 (0.29)	0.06 (0.19)
Total inpatient days	0.12 (0.72)	0.06 (0.67)	0.12 (0.58)	0.09 (0.47)
RA-related ambulatory visits	1.02 (0.75)	0.74 (0.48)*	1.15 (0.66)	0.61 (0.46)*
RA-related ER visits	0.03 (0.09)	0.01 (0.07)	0.02 (0.04)	0.01 (0.06)
RA-related inpatient days	0.10 (0.69)	0.05 (0.66)	0.11 (0.54)	0.08 (0.43)

Costs and healthcare resource utilization were reported as per-patient-per-month  
 \*p<0.05; statistically significant differences were computed between abatacept and TNFi groups ER=emergency room; TNFi=TNF inhibitor; USD=United States dollars, adjusted to 2016 dollars

## Presence of Anti-Cyclic Citrullinated Peptide Antibodies Is Associated with Better Treatment Response to Abatacept but Not to TNF Inhibitors in Patients with RA: A Meta-Analysis

E Alemao<sup>1</sup>, R Postema<sup>2</sup>, Y Elbez<sup>3</sup>, C Mamane<sup>4</sup> and Axel Finckh<sup>5</sup>, <sup>1</sup>Bristol-Myers Squibb, Princeton, NJ, <sup>2</sup>Bristol-Myers Squibb, Uxbridge, United Kingdom, <sup>3</sup>Excelya, Boulogne-Billancourt, France, <sup>4</sup>Mapi, London, United Kingdom, <sup>5</sup>University Hospital of Geneva, Geneva, Switzerland

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The association between anti-citrullinated protein antibody (ACPA) status and erosions, as well as response to TNF inhibitor (TNFi) treatment, has been explored.<sup>1,2</sup> **Results** based on a large US RA registry study have suggested that anti-cyclic citrullinated peptide (anti-CPP; a surrogate for ACPA) positivity predicts better clinical responses to abatacept, but not to TNFi.<sup>3</sup> The objective of this study was to investigate whether ACPA status is associated with clinical responses to abatacept or to TNFi in RA, in the published literature **Methods:** A systematic literature review (SLR) was performed to identify published studies and conference abstracts estimating biologic DMARD response according to ACPA status. The SLR was supplemented by additional studies that were identified through expert input. Mantel-Haenszel meta-analysis methods were used to pool risk ratios (RRs) based on ACPA status. In the base-case, response to therapy was assessed using the EULAR response as the primary outcome, while a scenario analysis assessed response by combining various definitions including ACR20 and EULAR for abatacept, and ACR20, DAS28 and EULAR for TNFi therapy. **Results:** Nineteen studies were included in the meta-analysis: 4 for abatacept, 14 for TNFi and 1 for both treatments. The base-case analysis included 4 of the abatacept and 6 of the TNFi studies and showed a statistically significant positive association between

ACPA positivity and EULAR response for patients treated with abatacept (RR 1.13 [95% CI 1.00, 1.26]; Figure 1), while ACPA positivity was associated with lower EULAR responses to TNFi therapy (RR 0.92 [95% CI 0.86, 0.98]; Figure 2). For the scenario analyses, in which all definitions of response were pooled, the results were consistent with base-case for abatacept (RR 1.18 [95% CI 1.30, 1.35]), while for TNFi therapy, no significant difference by ACPA status was observed (RR 0.97 [95% CI 0.86, 1.10]).

**Conclusion:** This meta-analysis confirms that ACPA-positive RA patients are more likely to achieve response to abatacept treatment compared to ACPA-negative patients. Additionally, the analysis demonstrates that there is no association between ACPA status and response to TNFi therapy, consistent with the findings of previously published studies.<sup>1,3</sup> 1. ## Risk of Hospitalization Among RA Patients with Multiple Autoimmune Co-Morbidities Differs By DMARD Treatment

E Alemao, Z Guo and L Burns, Bristol-Myers Squibb, Princeton, NJ

First publication: September 18, 2017

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Patients (pts) with autoimmune (AI) disorders are at higher risk of developing another AI disorder; co-occurrence of some AI conditions is reported more frequently than others in RA pts.<sup>1</sup> The objective was to evaluate 6- and 12-month (mo) hospitalization rates in RA pts with multiple AI co-morbidities, treated with abatacept, biologic (b) or conventional (c)DMARDs.

**Methods:** Administrative claims data from Optum Clinformatics Data Mart (database A) and QuintilesIMS<sup>TM</sup> PharMetrics Plus (database B) from 2006 to 2015 were used. Inclusion was based on the presence of 2 diagnosis codes for RA plus 1 DMARD prescription, age  $\geq 18$  yrs,  $\geq 1$  of the 5 most prevalent AI conditions: ankylosing spondylitis (AS), Crohn's disease, lupus, psoriasis or ulcerative colitis at or before index,  $\geq 3$  mo baseline (pre-index date) and 3 mo of follow-up (post-index date). Mutually exclusive treatment groups were classified based on the index prescription using hierarchy of abatacept, other bDMARD and cDMARD. Also, an RA group without record of DMARD (NoDMARD) was identified. Date of first DMARD was index date (for NoDMARD, index date was first diagnosis date). Primary outcome was 6- and 12-mo hospitalizations. Treatment groups were compared using descriptive statistics (Wilcoxon rank-sum test for continuous variables or Pearson's chi-square test for categorical variables) and using multivariate Cox regression analyses for hospitalization risk. Covariates included in the multivariate analysis were age, sex, region, past hospitalization, physician office visits during past 3 mo, an indicator variable for 714.0x, medication use (steroids, NSAIDs, salicylates, antidiyslipidemics), the 5 AI and 18 co-morbidity conditions. **Results:** A total of 18,964 and 47,105 RA pts with multiple AI co-morbidities from databases A and B, respectively, were included. The mean (SD) age of study population was 55.4 (15.1) yrs in database A and 50.0 (13.0) in database B. Respectively, 4.4%, 20.7%, 41.6% and 33.3% were prescribed abatacept, bDMARD, cDMARD and NoDMARD in database A; and 3.7%, 25.9%, 40.5% and 29.8% in database B. The most common AI co-morbidities in databases A vs B were AS (29 vs 27%), lupus (32 vs 32%) and psoriasis (32 vs 34%). Abatacept-treated pts had higher past hospitalization rates vs bDMARD and cDMARD groups. 6- and 12-mo pooled adjusted hazard ratios for hospitalization were higher for bDMARDs (and cDMARDs) vs abatacept (Table). Results were consistent in both databases.

**Conclusion:** Among RA pts with multiple AI co-morbidities, adjusted risk of hospitalization in both bDMARD- and cDMARD-treated pts was significantly higher compared with abatacept-treated pts. Though the NoDMARD group had an even higher risk of hospitalization, this should be interpreted with caution as it comprises a heterogeneous pt population

Table. HRs for Hospitalization in RA Patients With Multiple Autoimmune Co-morbidities* by DMARDs		
	HR (95% CI)	p value
<b>6-month hospitalization</b>		
bDMARD (vs abatacept)	1.18 (1.04, 1.35)	0.014
cDMARD (vs abatacept)	1.27 (1.12, 1.44)	<0.001
NoDMARD (vs abatacept)	1.92 (1.69, 2.19)	<0.001
<b>12-month hospitalization</b>		
bDMARD (vs abatacept)	1.16 (1.05, 1.28)	0.005
cDMARD (vs abatacept)	1.19 (1.08, 1.32)	<0.001
NoDMARD (vs abatacept)	1.60 (1.45, 1.76)	<0.001

bDMARD=biologic DMARD; cDMARD=conventional DMARD; HR=hazard ratio

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is evidence linking activation of the innate immune system and insulin resistance. Perturbations in glucose homeostasis upon initiation of tumor-necrosis factor inhibitors (TNFis) and conventional DMARDs have been described in small studies, perhaps due to suppression of inflammation. To evaluate this association, we measured glucose before and after initiation of TNFis and DMARDS in a large registry of patients with rheumatoid arthritis (RA).

**Methods:** Patients enrolled in the Veterans Affairs RA (VARA) registry were retrospectively examined. Subjects were selected who, during study follow-up, initiated treatment with TNFis, prednisone, or DMARDs, and for whom proximate random blood glucose (RBG) or hemoglobin A1C (A1C) values were available. Proximate values were the closest RBG within 2 weeks prior to, and 6 months following, medication initiation. A1C values were the closest A1C within 2 months prior to, and 12 months following, medication initiation. Measurements were compared before and after medication initiations using paired t-tests and multivariate regression, adjusting for demographics and comorbid conditions.

**Results:** 2111 patients contributed at least one proximate measurement surrounding initiation of any agent. Significant decreases in RBG were associated with 653 hydroxychloroquine-initiation events (-3.68mg/dL,  $p=0.04$ ), and increases were noted in RBG surrounding 665 prednisone-initiation events (+5.85mg/dL,  $p<0.01$ ). A significant decrease in A1C was noted surrounding 49 sulfasalazine-initiation events (-0.70%,  $p<0.01$ ). Multivariate regression analyses suggest sulfasalazine and hydroxychloroquine use as predictors of lower post-medication-initiation blood glucose values; congestive heart failure was also a predictor for higher RBG values after all medication-initiation events. We found no association of TNFi initiation with changes in glucose.

**Conclusion:** This study quantifies hyperglycemic effects of prednisone initiation. We also observed hypoglycemic effects of sulfasalazine and hydroxychloroquine initiation. TNFi initiation was not observed to impact measured blood glucose. Further large-scale and prospective investigation of DMARD and TNFi blood glucose effects in other populations is warranted.

## Biosimilar Knowledge Among US Rheumatologists – a Survey

Allan Gibofsky<sup>1,2</sup> and Sam Badawi<sup>3</sup>, <sup>1</sup>Medicine and Public Health, Hospital for Special Surgery, New York, NY, <sup>2</sup>Rheumatology, Weill Cornell Medicine, and Hospital for Special Surgery, New York, NY, <sup>3</sup>Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Four biosimilar tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) inhibitors have been approved by the FDA in the United States as of April 2017. This survey was developed to evaluate US rheumatologists' familiarity with biosimilars, the concept of biosimilarity, and the approval process for biosimilars in the treatment of immune-mediated chronic diseases.

### Methods:

A 20-question survey was administered by WebMD between December 9 and 14, 2016. Physicians (n=958) who were medscape.com members were invited to participate in an online survey via email. Most survey items used a 5-point Likert scale. **Results** were summarized descriptively.

### Results:

Overall, 131 physicians responded, a response rate of 13.67%. Data were collected from 102 participants who were self-identified rheumatologists, practicing in the US for  $\geq 1$  year. All but 1 respondent had prescribed a TNF $\alpha$  monoclonal antibody (mAB) for the treatment of an autoimmune disease. When asked to choose the status of biosimilar development (as of December 2016), the majority (84%) of respondents were aware that an infliximab biosimilar was approved in the US, but only 47% and 34% were aware of the recent approvals of the adalimumab and etanercept biosimilars, respectively. Most physicians were extremely (38%) or moderately (36%) familiar with the FDA's definition of a biosimilar. Most respondents (71%) were aware that an approved biosimilar was not automatically deemed interchangeable by the FDA. When asked to rate their expectations of biosimilar products, 74% indicated that an interchangeable designation was very or moderately important. Regarding other characteristics of the biosimilar compared with the originator, the majority indicated that effectiveness (96%), safety (96%), and durability of response (95%) were very or moderately important. Regarding treatment initiation, 66% of physicians were extremely likely or likely to initiate biosimilar treatment for a biologic treatment-naïve patient with RA if the approval included efficacy and safety studies in the same indication, whereas 5% and 29% were extremely likely or likely, respectively, to initiate biosimilar treatment for a biologic treatment-naïve patient with a different rheumatologic condition than the one on which the approval was based. Approximately 60% of survey respondents were unlikely to switch therapy from an originator to its biosimilar TNF $\alpha$  mAB in patients who were doing well, regardless of whether the patient had the same or a different rheumatologic indication than the one on which the biosimilar approval was based. Also, 21% of respondents were extremely likely or likely to switch to a biosimilar if the patient was failing on the originator.

### Conclusion:

This survey supports a need to further educate US rheumatologists about biosimilars, extrapolation, and interchangeability. Knowledge gaps include a lack of understanding of biosimilarity based on switching, and the availability of currently approved biosimilars.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** AbbVie’s Patient (pt) Support Program (PSP) is offered to pts who are prescribed adalimumab (ADA) for their Rheumatoid arthritis (RA). The purpose of this analysis was to assess the association of Patient Activation Measure (PAM)-13 scores with PSP utilization among pts with moderate to severe RA initiating ADA who had option to enroll in the PSP.

**Methods :** PASSION (NCT01383421) was a 78-week post-marketing observational study of pts with RA receiving ADA in routine clinical care. Pts from the EU, Israel, Mexico, Puerto Rico, and Australia with an insufficient response to  $\geq 1$  disease-modifying antirheumatic drug (DMARD) newly initiating ADA (1 prior biologic DMARD was allowed) were enrolled. Pts were offered a panel of “Core elements” (starter pack, call center/hotline, nursing services, educational material, and injection guide; offered in all participating countries) and “Other elements” (e.g, refill reminders, email communications, newsletters, support groups, home medication delivery, and financial assistance; vary by country) of PSP. Pts were divided in 2 groups based on their participation in the PSP: ever (PSP users) vs never (PSP non-users). The PAM-13 scores were collected at baseline (BL) and at week 78. PAM-13 scores evaluate knowledge, skills, and confidence essential to a pt managing his/her own health. PAM-13 scores were classified a priori into 4 levels (higher level = greater pt involvement in disease management). Multivariate inferential analysis was used to examine the associations between PSP utilization (yes/no) and PAM-13 scores after adjusting for the following BL characteristics: age, gender, race, RA disease duration, prior use of biologic DMARD, BL Health Assessment Questionnaire Disease Index (HAQ-DI), and BL PAM-13 score. The response variable of the model was PAM-13 scores change from BL.

**Results :** PSP users had significantly larger increase in the PAM-13 scores (2.33, 95% CI 0.05 – 4.61,  $P=0.045$ ) compared to the BL than the PSP non-users after adjusting for relevant BL characteristics (**Figure 1A**). Percentage of pts that demonstrated improvement in PAM-13 levels were significantly higher among PSP users vs PSP non-users at week 78 compared to BL (35.7% vs 28.1%,  $P=0.01$ ) (**Figure 1B**). Additionally, lower PAM-13 and HAQ-DI BL scores were statistically significantly associated with increases in the PAM-13 scores at week 78 compared to BL.

**Conclusion :** Among pts with moderate to severe RA that initiated ADA treatment, PSP users reported significantly larger improvement from BL to week 78 in PAM-13 scores compared to the PSP non-users. Greater increase in PAM-13 scores among PSP users (vs. non-users) from baseline to week-78 indicate towards their increased ability in managing their health, gaining confidence and knowledge about their health, and taking action to maintain and improve their health.

**Figure:** Patient Activation Measure (PAM-13) for PSP users and PSP non-users. PAM-13 scores by PSP utilization (A), and Percentage of patients showing improvement in PAM-13 levels from baseline (B).

\* $P=0.045$ , \*\* $P=0.01$ .

## **Influences for Therapeutic Changes in Rheumatoid Arthritis Patients from the Veterans Affairs Rheumatology Arthritis Registry Who Have Moderate to High Disease Activity**

**Brian Sauer**<sup>1</sup>, Jacob R. Stever<sup>1</sup>, Chia-Chen Teng, MS<sup>1</sup>, Neil Accortt<sup>2</sup>, David Collier<sup>2</sup> and Grant Cannon<sup>1</sup>, <sup>1</sup>Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, <sup>2</sup>Amgen Inc., Thousand Oaks, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Current guidelines encourage the measurement of rheumatoid arthritis (RA) disease activity to achieve a low disease state (treat-to-target). Many RA patients with documented moderate to high disease activity, however, remain on their current regimen. This study used clinical and administrative data of US Veterans, identified as having moderate/high disease activity (DAS28 $\geq$ 3.2), to identify patient and treatment characteristics associated with a major change in therapy.

**Methods:** Patients in the Veterans Affairs (VA) RA registry were included if they had: 1) moderate/high disease activity on the index date, 2) 18-months of VA activity prior to the index and 3) two or more prior DAS28 measures during the preceding 18-months ( $\geq$  three months apart). Patients were defined as having a major change in therapy if any of the following occurred within 7 days prior to 30 days after the index date: 1) initiation or escalation of DMARDs, 2) initiation or increase dose of prednisone and/or 3)  $\geq$  2 joint injections. Disease stability was determined during the observation period prior to the index date using an area under the curve calculation and compared to the index DAS28. Patients were categorized as improving (index DAS28 was  $\geq$  0.6 points lower), worsening ( $\geq$  0.6 higher) or stable. Poisson multivariable regression was used to explore how demographic, clinical and treatment patterns influenced the initial finding that stability of disease activity was a strong predictor of a major treatment change.

**Results:** Of the 941 patients who met enrollment criteria only 41% had a major therapeutic change. Major therapeutic changes occurred in 50%, 37% and 30% with worsening, stable and improved DAS28, respectively. In multivariable models, patient demographics and individual components of the DAS28 score were not independently associated with a major therapeutic change. In the full model, the current DAS28, and oral steroids and non-biologic DMARDs in the past year increased the likelihood of a major change. Non-biologic DMARDs in the past 90-days decreased the likelihood of a major change. Table 1 displays the RR with “stable DAS28” as the comparison group after adjustment for demographic, demographic + DAS28 and clinical components and the full model, which added indicators of medication use, surgery, radiographs and comorbidity scores.

**Conclusion:** More than half the patients did not experience a major change in therapy despite moderate/high disease activity even among those patients with worsening disease. In crude analysis, the likelihood that RA patients with moderate/high RA disease received a change in therapy was highly associated with worsening disease activity, but this effect was diminished when accounting for current DAS28, indicators of non-biologic DMARDs and steroid use in the previous year. The decision to modify therapy is complex and we are conducting chart-review to better understand why providers are not modifying therapy.

Table 1. Effect of stability of disease activity on major therapeutic change after adjustment for patient, clinical and treatment variables

Comparisons	Crude Model			Demographic Adjusted			Demographic + DAS and components			Full Model		
	RR	LCI	UCI	RR	LCI	UCI	RR	LCI	UCI	RR	LCI	UCI
Worse vs stable DAS28	1.32	1.07	1.63	1.31	1.06	1.61	1.08	0.8	1.45	1.10	0.82	1.48
Improved vs stable DAS28	0.79	0.55	1.14	0.8	0.55	1.15	0.87	0.56	1.32	0.85	0.55	1.3
Index DAS28*										1.42	1.07	1.89
Oral Steroids										1.42	1.07	1.89
Non-Biologic DMARD year										1.69	1.08	2.63
Non-Biologic DMARD 90-d										0.67	0.49	0.92

\*variables with significant association from the full model are presented – all variables and models will be displayed in the presentation. RR = Risk Ratio, LCI= Lower bound of 95% confidence interval (CI), UCI = Upper bound of the 95% CI

## Perceptions of US Community Rheumatologists on Biosimilars

Janna Radtchenko, Yolaine Smith, Jonathan Kish and Bruce Feinberg, Specialty Solutions, Cardinal Health, Dallas, TX

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biosimilars contain a highly similar version of the active substance of an already approved biologic or “reference product.”<sup>1</sup> Regulatory agencies mandate that safety, efficacy, dosing, route of administration, and immunogenicity are established. The FDA allows extrapolation of safety and efficacy data from one biosimilar indication to another significantly lowering drug development cost. Biosimilars are thereby expected to have a lower price point than their reference product and result in reduced healthcare spending, but that will largely depend on how providers perceive and prescribe them. As of May 2017, four biosimilars have been FDA approved for rheumatologic conditions. We have evaluated the perceptions of U.S. community rheumatologists to identify areas of opportunity to support biosimilar adoption

**Methods:** Using audience response technology, we surveyed 24 community rheumatologists and 20 rheumatology practice managers (PMs) during a live meeting in April 2017. Participating physicians and PMs represented various practice sizes and geographic locations throughout the U.S.

**Results:** Regarding the legal and regulatory aspect of biosimilars and their reference biologics: only 51% of the respondents understood the concept of interchangeability between biosimilars and reference biologic; 76% were unaware of compatibility requirements for reference biologics following a manufacturing change; while only 40% believed biosimilars match the safety and efficacy of their reference biologics. When asked if they or their practice would prescribe a biosimilar approved for anti-rheumatic treatment: 20% would not prescribe at all, only 23% would switch a patient from the reference biologic, and 57% responded that they would prescribe it to patients initiating biologic therapy. The responses to the query, “Which issues are most concerning?” in descending order are: Regulations related to substitutions, understanding when to prescribe a biosimilar versus a reference biologic, and coordinating with pharmacists on substitutions. Information about safety and efficacy, guidelines on when to prescribe a reference biologic versus a biosimilar, and reimbursement information were named as tools for achieving a greater understanding of biosimilars.

**Conclusion:** Significant barriers to biosimilar adoption for rheumatologic conditions exist due to physicians’ perceptions. Education around biosimilar efficacy, safety, appropriate use, and reimbursement may improve perceptions and facilitate usage.

**Disclosure:** J. Radtchenko, None; Y. Smith, None; J. Kish, None; B. Feinberg, None.

## Real-World Utilization of Biosimilars for Management of Rheumatoid Arthritis (RA) in the US

Janna Radtchenko, Yolaine Smith, Jonathan Kish and Bruce Feinberg, Specialty Solutions, Cardinal Health, Dallas, TX

First publication: September 18, 2017

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** A biosimilar product is a biological product highly similar to another FDA-approved biological product, reference product, and has no clinically meaningful differences in safety and effectiveness from the reference product. While four biosimilars have been approved by the FDA in rheumatology in 2016-2017, only one biosimilar infliximab-dyyb (IFX-b) has launched. We have evaluated early uptake of IFX-b in RA following its approval in April 2016 and launch in November 2016.

**Methods:** Symphony Health longitudinal prescription and medical claims data was used to evaluate the uptake of IFX-b relative to its reference product infliximab (IFX) from biosimilar approval through Q1 2017. The database contains claims records for 279 million unique patients representing an estimated 63% of specialty prescriptions, 58% of medical claims, and 25% of hospital claims in the US. Duration of therapy was defined as days from biologic initiation to the last administration. Time to treatment discontinuation (TTD) was defined as months from biologic initiation to switch or last administration + 90 days if no other biologic was administered. Duration of therapy was described with a Kaplan-Meier curves. Patient characteristics were evaluated using frequencies for categorical and mean and standard deviation (SD) for continuous variables.

**Results:** Of the 78,481 patients who initiated a biologic/biosimilar therapy for RA since IFX-b approval, 90 (0.1%) were treated with IFX-b and 5,178 (6.6%) were treated with IFX. The first patient started IFX-b in May 2016 and 78 IFX-b patients (86.7%) started in Q1 2017. Of the patients treated with IFX-b, 66 (73.3%) were female, 58 (64.4%) were 65 or older, 1 patient was commercially insured, the rest were with unknown insurance status, 31 (34.4%) were previously treated with IFX, 56 (62.2%) received IFX-b as their first biologic. Mean (SD) age for IFX-b patients was 65.9 (12.4) compared to 55.0 (16.7) for infliximab patients ( $p < 0.0001$ ). Mean (SD) number of prior biologics was 0.5 (0.8) for IFX-b and 0.5 (0.9) for IFX patients. Median (mean) duration was 1.0 (4.5) days for IFX-b and 60.0 (101.2) for IFX (Log Rank  $P < 0.001$ ) due to late IFX-b adoption.

**Conclusion:** Adoption of IFX-b in the US so far has been low and has not yet significantly impacted the reference biologic. The majority of IFX-b patients received it as first biologic, however a third of them switched from IFX. Duration of therapy on IFX-b is relatively short due to delayed launch. Future monitoring of IFX-b uptake is warranted especially as other approved biosimilars prepare for launch.

Remote Management of Osteoporosis Screening and Treatment in US Veterans using a Bone Health Team: A Cost-effectiveness Analysis

**Background/Purpose:** To evaluate the cost effectiveness of a bone health team (BHT) as a primary prevention service to screen, monitor, and treat Veterans at risk for fragility fractures compared to current clinical practice from the Veteran's Administration (VA) perspective over a life-time.

**Methods:** We conducted this analysis by adapting a previously validated Markov microsimulation model of osteoporosis incidence and outcomes in the VA. The model was used to estimate fracture events, quality-adjusted life years (QALYs), and direct healthcare costs of using a BHT vs current clinical practice. Model inputs were derived from national sources, published literature, and program estimates from the BHT. Uncertainty in model parameters was assessed by conducting one-way and probabilistic sensitivity analyses.

**Results:** In the base-case, the BHT was associated with a substantially higher proportion of patients with underlying osteoporosis or osteopenia diagnosed and treated with bisphosphonates (osteoporosis: 38.0% vs 6.9%, osteopenia: 25.5% vs 0.2%). This resulted in the BHT strategy being associated with a modestly lower fracture rate than current clinical practice. In probabilistic sensitivity analysis, the BHT was the dominant option; however, in all analyses, no meaningful differences were observed in life-time estimated costs, unadjusted survival, and QALYs between the prevention strategies.

**Table 1.** Base-case Results (per patient average)

	Bone Health Team	No Bone Health Team	Difference
Costs (mean)	\$58,250	\$59,617	-\$1,367
Unadjusted life years (mean)	11.937	12.059	-0.122
QALYs (mean)	8.379	8.446	-0.068
ICER			
Costs/life year		\$20,190	
Costs/QALY		\$11,174	
Treated			
Percent with osteoporosis	38.0%	6.9%	31.1%
Percent with osteopenia	25.5%	0.2%	25.3%
# AEs/1000 treatment years	1.92	5.05	-3.122
Years of treatment (mean)	9.93	5.42	4.518
Fracture Incidence (per 1,000 patient years)			
Clinical Vertebral	15.399	16.587	-1.188
Hip	3.797	4.073	-0.276
Subclinical Vertebral	5.062	5.494	-0.432
Wrist	0.808	0.977	-0.169
Death	70.548	70.089	0.459
Other (#/1000 patients)			
Dependence	27.336	27.084	0.252
Nursing home placement	13.907	13.857	0.050

**Conclusion:** A BHT appears to be a potentially cost-effective method for screening and treating US Veterans for osteoporosis compared to no intervention. Quality improvement programs addressing primary prevention of osteoporotic fractures provide a feasible, team-based, approach to this important problem, while unburdening the increasingly limited time and availability of primary care providers.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Previous HA studies have focused on the Medicare population, but less is known of the treatment patterns and cost of HA relative to knee arthroplasty (KA) and other therapies for younger privately insured patients. We evaluated the overall cost of treating knee OA in a large group of Blue Cross/Blue Shield (BCBS) patients, including those from KA and non-arthroplasty therapies, such as HA, corticosteroid injections, and physical therapy. We hypothesized that non-arthroplasty interventions would account for the majority of knee OA costs in the younger patient population.

**Methods:** Knee OA-related claims were identified from Blue Health Intelligence claims data (2011-2015). The dataset contains claims for 140+ million unique BCBS members nationwide in the U.S. Cumulative costs (adjusted to November 2016\$) were evaluated from a payor perspective and grouped into various categories, such as physical therapy, corticosteroid injections, HA, and KA.

**Results:** The overall cost of treating knee OA for 1,567,024 knee OA patients over the five-year period was \$5.7B (average \$3,600/patient). HA accounted for \$196.9M (3.5%) of the overall cost, based on 216,523 HA patients (13.8% of knee OA cohort). KA accounted for \$3.6B (63.5%) of the overall costs, while office visits, arthroscopy, anesthesia for knee surgery, arthrocentesis, knee imaging, and physical therapy accounted for \$229.3M (4.0%), \$141.8M (2.5%), \$140.8M (2.5%), \$124.6M (2.2%), \$115.0M (2.0%), and \$51.9M (0.91%), respectively. 16.5% of the HA patients subsequently underwent knee arthroplasty during the study period, but HA contributed to 2.8% of their overall knee OA treatment costs compared to KA, which contributed 82.9%. For those who received KA, the median costs for the HA cohort were lower at 1 and 2 years compared to the no-HA cohort, but similar at 3 years and marginally higher at 4 years (Table 1). If the 180,862 HA patients who avoided KA during the study period had, instead, undergone arthroplasty, the cost of KA would be estimated to total \$4.8B. Instead, there was a cost savings of \$4.3B (90.1%) by utilizing non-arthroplasty therapies.

**Conclusion:** Non-arthroplasty therapies accounted for about a third of the costs (36.5%) in treating knee OA in our cohort of younger patients. Interventions that were not recommended or determined to have inconclusive evidence by AAOS accounted for 3.5% (HA), 0.12% (corticosteroid), and 0.54% (knee brace) of the overall costs. Although questions have been raised about the effectiveness of HA, the majority of HA patients avoided knee arthroplasty during the study period; they saved an estimated 90.1% by utilizing non-arthroplasty therapies. With the wide spectrum of therapies to treat knee OA, efforts to identify the most appropriate candidates for arthroplasty and non-arthroplasty therapies, such as HA or other non-HA therapies, can help reduce costs to the healthcare system.

Table 1. Knee OA-related costs (median) stratified by HA and knee arthroplasty groups.

	No HA (Without arthroplasty) n=1,247,689	No HA (With arthroplasty) n=102,812	HA (Without arthroplasty) n=180,862	HA (With arthroplasty) n=35,661
1 year	\$173	\$18,832	\$1,197	\$2,429
2 year	\$198	\$24,521	\$1,603	\$20,568
3 year	\$223	\$27,014	\$1,959	\$27,945
4 year	\$260	\$28,066	\$2,364	\$29,793

## SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a morbid, mortal, and costly condition without a cure. Treatments for RA have expanded over the last two decades with the introduction of biologic disease modifying anti-rheumatic drugs (bDMARDs). Biologic DMARDs offer alternatives for patients unresponsive to traditional synthetic DMARDs, but carry an increased financial burden. Detailed understanding of the cost of care for RA patients since the advent of bDMARDs is of importance to policy makers, administrators, and physicians, as the high cost of RA treatments impacts the use of limited medical resources.

**Methods:** We conducted a systematic literature review and meta-analysis to assess direct annual medical cost for RA patients in the US receiving any treatment regimen for RA since the marketing of the first bDMARD in 1999. Studies were identified through a search of Medline using MeSH search terms related to cost of care and RA. Data were extracted independently by two reviewers (AH and DHS). Total direct medical costs as well as RA-specific costs were calculated using random effects meta-analysis. A subgroup analysis addressed costs for RA patients using bDMARDs.

**Results:** We found 541 potentially relevant studies and 11 papers met the selection criteria for meta-analysis. Total direct annual medical costs were estimated at \$12,509 (95% CI \$7,451-21,001) for all RA patients using any treatment regimen (see **Figure 1**) and \$36,053 (95% CI \$32,138-40,445) for bDMARD users (see **Figure 2**). RA-specific annual costs were \$3,723 (95% CI \$2,408-5,762) for all RA patients using any treatment regimen, representing 30% of total costs for all care. RA-specific annual costs were \$20,262 (95% CI \$17,480-23,487) for bDMARD users, representing 56% of total costs for all care.

**Conclusion:** The total and disease-specific direct annual medical cost of patients with RA is substantial. Among bDMARD users, cost of RA care is over half of all direct medical costs. These findings indicate that the burden of RA patients on the US health care system may become outsized compared to the disease's relatively small prevalence as more patients use bDMARDs in the future. While patients that use bDMARD's have increased annual cost over typical RA patients, the increment is below the total cost of bDMARDs themselves. This discrepancy suggests that either the use of bDMARD's is associated with lower total non-drug direct medical costs or that there are crucial underlying demographic differences between bDMARD and traditional DMARD users.

## The Potential Value of a Shared Decision-Making Intervention for Choices Regarding Triple Therapy in Rheumatoid Arthritis

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies have shown that using Triple Therapy (a combination of 3 generic drugs) prior to a biologic, is the most cost-effective strategy for patients with rheumatoid arthritis. While studies also find that many patients would prefer to trial Triple Therapy prior to a biologic, fewer than 5% of patients do so in the US. We determined the potential value of an intervention that promotes informed shared decision-making between patients and clinicians around triple therapy use after failure of methotrexate.

**Methods:** We developed an economic model that compared a strategy where patient preferences for triple therapy use were integrated into treatment decisions, versus usual care. A previous study suggests that 59% of patients would choose triple therapy first if provided the comparative evidence of benefits, potential adverse events and dosing schedule. We assumed a cost of \$50 for a shared decision making intervention such as a patient decision aid. Patient's trialling triple therapy first were assumed to switch to a sequence of biologics upon withdrawal. We extrapolated the influence of the initial treatment decision on subsequent disease progression, resource use such as hospitalizations, quality of life, mortality and Quality Adjusted Life Years (QALYs). Various sensitivity analyses were performed. A scenario that incorporated the value patients assign to the process of shared decision-making was also considered.

**Results:** Incorporating patient preferences into the decision was estimated to reduce average costs for a patient by \$40,000 over a lifetime through delaying the introduction of biologic therapy. Even under the most pessimistic assumptions regarding the potential for earlier biologic use delaying joint erosions, only 0.08 QALYs (28 days of full health) over a lifetime were estimated to be lost. The consequent incremental cost-effectiveness ratio for usual care vs the patient preference strategy is over \$500,000/QALY. Sensitivity analysis supported this finding. Incorporating the process of shared decision-making offsets the negative QALYs, implying the patient preference strategy saves costs and increases QALYs.

**Conclusion:** This study demonstrates that systematically giving patients with rheumatoid arthritis who fail methotrexate an informed choice between triple therapy and a biologic as the initial treatment is cost-saving and can even provide more 'benefits' to the patient. This strategy allows patients who prefer biologic therapy to choose it, but saves costs by delaying the biologic initiation in patients who choose triple therapy first. The results suggest that strategies used elsewhere for increasing shared decision-making such as building infrastructure for implementing patients decision aids, or introducing fee codes for shared decision-making, could be cost-effective and should be explored to promote value based prescribing in rheumatology.

Schadler<sup>1</sup> and Aleksander Lenert<sup>3</sup>, <sup>1</sup>University of Kentucky, Lexington, KY, <sup>2</sup>Rheumatology, University of Kentucky, Lexington, KY, <sup>3</sup>Internal Medicine, Div. of Rheumatology, University of Kentucky, Lexington, KY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treatment with biological DMARDs (bDMARD) and targeted synthetic DMARDs (tsDMARD) has led to improved outcomes for chronic rheumatic diseases. Current treat-to-target (T2T) strategy relies on quick escalation in therapy to achieve disease control. A delay in escalation of therapy may impact clinical outcomes adversely. Insurance prior authorization, required for specialty DMARD approval, represents a significant bottleneck to care. Clinical pharmacists embedded in a collaborative clinical team could optimize rheumatologic care by shortening time to specialty medication authorization. Our aim was to assess the impact of pharmacy support on specialty DMARD approval in an academic rheumatology clinic.

**Methods:** We performed a retrospective review of patient records followed in the Rheumatology Clinics at the University of Kentucky who were prescribed specialty medications for RA, PsA and AS. All patients were diagnosed by clinical rheumatologists and met ACR, CASPAR or ASAS criteria respectively. We included 8 bDMARDs and 2 tsDMARDs currently prescribed. We collected data during two 6 month periods from prescriptions written pre-pharmacy (1/2014-6/2014) and post-pharmacy establishment (1/2016-6/2016). We excluded the transition to pharmacist period of 7/2014-12/2015. Our primary outcome was the time to authorization defined as time (in days) between rheumatologist's prescribing and pharmacist's completion of authorization for a given specialty DMARD. We compared the mean time to authorization pre- and post-pharmacist establishment in the rheumatology clinic. Statistical analysis was performed with IBM SPSS Statistics 23; continuous variables were analyzed utilizing an independent samples t-test and categorical variables with Pearson's chi-square test.

**Results:** We screened 423 specialty prescriptions; 112 were eligible for study inclusion. Thirty-one specialty prescriptions from 28 patients were completed pre-pharmacist (Group 1) and 81 specialty prescriptions from 71 patients were completed post-pharmacist (Group 2) (Table 1). There were no significant differences between the groups in baseline characteristics that were tested including age, gender, diagnosis, and type of insurance. The majority of patients were women with RA; most patients had commercial insurance or Medicaid. The mean time to authorization was significantly shorter post-pharmacist compared to pre-pharmacist routine care (6.43±15.48 vs. 52.03±58.64 days, p=0.002).

**Conclusion:** In a large tertiary academic rheumatology practice, the mean time to authorization of specialty DMARDs was significantly reduced to <7 days with establishment of a clinical pharmacist in a collaborative clinical team, facilitating implementation of T2T strategy.

**Table 1.** Baseline Characteristics and Comparison of Time to Authorization of DMARDs

	Group 1 (Pre) (N = 31)	Group 2 (Post) (N = 81)	P-value

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Background/Purpose:** Adalimumab (ADA) induces and maintains clinical remission in patients with rheumatoid arthritis (RA) and Crohn's disease (CD) but is an expensive drug. Drug-level and antidrug antibody testing has the potential to facilitate personalization of dosing, particularly the use of less frequent dosing of ADA (de-escalation). The cost-effectiveness of drug-level guided dose de-escalation of therapy is unknown.

**Methods:** We evaluated the effectiveness (in quality adjusted life years [QALYs]) and cost-effectiveness of a drug-level guided dose-reduction strategy for ADA compared with standard dosing in patients with CD who are in clinical remission, from a health system perspective using a 4-year horizon. We chose CD rather than RA because drug-level guided dose de-escalation studies have not been conducted in RA. We developed a discrete-time Markov simulation model for the analysis, using inputs from published randomized controlled trials and observational studies. The intervention studied was reduction in frequency of ADA dosing from 40mg every other week (EOW) to 40mg every three weeks (ETW) among patients with sustained clinical remission and therapeutic ADA trough levels. Patients who lost clinical remission would undergo drug-level testing. A switch to an alternate biologic was indicated with positive antidrug antibodies or drug resistance (adequate levels despite active symptoms); otherwise the dose was re-escalated back to 40mg EOW. Standard dosing (control arm) involved continuation of 40mg EOW dosing and switch to an alternate biologic on loss of clinical remission.

**Results:** Among patients with CD in remission on standard dose ADA, reductions in dose yielded similar QALYs but lower costs compared with continuing standard dosing strategy. The difference between the standard and dose-reduction strategies ranged from 0.00 to 0.06 QALYs across the range of probabilities tested (with standard strategy being marginally more effective), but the intervention resulted in cost-savings in every circumstance. In sensitivity analyses, the dose-reduction strategy was the dominant option (less costly and more effective) when  $\geq 87\%$  of patients who were controlled on standard dosing continued to be in remission under the dose-reduction strategy. The findings were most sensitive to the probability of formation of antidrug antibodies after dose reduction and the cost of ADA.

**Conclusion:** Based on lower costs and similar overall efficacy, dose reduction may be a cost-saving alternative among patients with CD who are in sustained remission with therapeutic ADA levels. These findings suggest that further research to explore drug-level guided tapering in RA may also be warranted. Given the small difference we observed in incremental effectiveness, our proposed strategy may prove to be dominating if future studies also demonstrate that reduced dosing improves the safety of ADA.

**Table 1: Cost effectiveness rankings by study horizon**

Horizon	Strategy	Cost	Incremental Cost	Efficacy	Incremental Efficacy	ICER
4 years	Standard dosing arm	97,824	25,657	3.26	0.02	1,365,107
	Intervention arm	72,168		3.24		
3 years	Standard dosing arm	74,841	20,822	2.50	0.01	1,681,483
	Intervention arm	54,019		2.49		
2 years	Standard dosing arm	50,918	15,024	1.70	0.01	2,188,130
	Intervention arm	35,894		1.70		
1 year	Standard dosing arm	25,994	8,075	0.87	0.00	3,128,977
	Intervention arm	17,918		0.87		

ICER: Incremental cost effectiveness ratio. Costs are in USD. Difference in incremental effectiveness between the two arms was reduced to 0.00 using a study horizon of 1 year. Cumulative probability of clinical remission at 4 years was 67% in the dose reduction arm versus 74% in standard dosing arm ( $p=0.2778$ ).

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) need to take lifelong oral or injectable medication to alleviate their symptoms and prevent disease progression. However, some patients may not adhere or poorly adhere to treatment and have poor understanding of biological agents. Poor or no adherence may be attributed to the following factors: complex regimen for medications, such as methotrexate (MTX), difficulty in self-administration of injectables due to hand deformities, and forgetfulness due to dementia. This study aimed at determining the effect of educating visiting pharmacists regarding administration of oral medication and injectables for patients with RA who poorly adhere to treatment regimens.

**Methods:** A prospective analysis was performed by enrolling 21 patients with RA who were treated with different types of medication, including self-injectable biological agents. Two cases were excluded because one had been added on subcutaneous tocilizumab and the other on MTX with increased dosage. The remaining 19 cases did not have any change in their treatment, including dosage or intervals between drug administration, just before and after the pharmacist visit. Baseline characteristics, such as age, Steinblocker Stage and Class, disease duration, use of biological agents, use of MTX and its dosage, use of prednisolone (PSL) and its dosage, presence of dementia, and living or not living alone, were assessed. DAS28-ESR, SDAI and CDAI as markers of RA disease activity were evaluated just before and after the pharmacist visit.

**Results:** Mean  $\pm$  SD were as follows: age (years),  $74.4 \pm 6.1$ ; Stage I, 1; II, 4; III, 6; IV, 8; Class 1, 0; 2, 7; 3, 8; 4, 4; disease duration (months),  $144.2 \pm 114.5$ ; use of biological agents; 36.8%; use of MTX and its dosage (mg/week), 84.2% and  $6.6 \pm 2.7$ ; use of PSL and its dosage (mg/day), 47.4% and  $4.4 \pm 1.2$ ; presence of dementia, 10.5%; living alone, 42.1%. The mean values of DAS28-ESR, SDAI, and CDAI just before and after the pharmacist visit showed improvements; they were  $3.56 \pm 1.46$  and  $3.12 \pm 1.16$  ( $p = 0.084$ ),  $7.99 \pm 6.88$  and  $4.39 \pm 3.47$  ( $p = 0.0176$ ), and  $6.85 \pm 5.74$  and  $3.90 \pm 3.18$  ( $p = 0.0148$ ), respectively. All patients reported satisfaction with the overall effectiveness of the care.

**Conclusion:** Adherence to treatment in patients with RA may decline with increasing age. For such patients, education regarding oral and injectable medication may be useful in controlling RA activity and avoiding any adverse effects due to consumption of wrong medication. This finding is important for better and safer management of patients with RA in the ageing communities in Japan and other developed countries.

## Heart Rate Variability Testing with Autonomic Nervous System Optimization: Could It Change the Course of Spending for Rheumatoid Arthritis Patients in the U.S.? an Exploratory Minimal Model Analysis

**Marita Zimmermann**<sup>1</sup>, Elisabeth Vodicka<sup>2</sup>, Andrew J Holman<sup>3,4,5</sup> and Louis P Garrison<sup>2</sup>, <sup>1</sup>Constants in Global Health, University of Washington, Seattle, WA, <sup>2</sup>Consultants in Global Health, University of Washington, Seattle, WA, <sup>3</sup>Rheumatology, Pacific Rheumatology Associates Inc PS, Seattle, WA, <sup>4</sup>Inmedix, Normandy Park, WA, <sup>5</sup>Pacific Rheumatology Research, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Autonomic nervous system (ANS) testing with heart rate variability (HRV) has been shown to predict 52-week anti-TNF therapeutic outcomes in rheumatoid arthritis (RA).<sup>1</sup> HRV testing could be combined with the three currently available putative ANS biologic

pathways (vagal nerve stimulation,<sup>2</sup> obstructive sleep apnea,<sup>3</sup> and restless leg [RLS] medications<sup>4</sup>) to improve treatment response for RA patients. We explored the potential costs and health outcomes of introducing HRV testing into RA treatment, both without vs. with ANS optimization.

### **Methods:**

A decision tree exploratory economic model compared HRV testing to standard care in moderate-to-severe biologic-eligible patients over a 10-year time horizon. Patients were stratified by HRV test scores into “low probability of response” and “moderate to high probability of response” (parasympathetic HRV  $\leq$  vs.  $>0.12$ ) with positive predictive value (PPV)=33% and negative predictive value (NPV)=100%.<sup>5</sup> We then explored adding ANS optimization (RLS method<sup>4</sup>) based on HRV score, with patients stratified into parasympathetic  $\leq$  vs.  $>0.19$ , PPV=0.63, NPV=0.88.<sup>5</sup> Finally we explored a hypothetical scenario expanding the eligible population to all RA patients using hypothetically analogous ANS-prediction and ANS-enhancement of non-biologic treatment (no study yet done) over a range of potential PPV values (10-25%). We also evaluated model outcomes when biologic utilization was assumed to increase from current 26%<sup>6</sup> of eligible patients to 35-55%. Costs and quality-adjusted life-years (QALYs) per patient and for the US population were estimated. Cost-effectiveness was defined as an incremental cost-effectiveness ratio (ICER) below \$150,000/QALY.

### **Results:**

HRV testing in biologic-eligible patients decreased non-effective biologic use, reducing US costs by \$9.8B over 10 years with QALYs unchanged. When combined with ANS optimization in biologic-eligible patients, HRV testing could increase costs by \$1.5 billion over 10 years and save 102,000 QALYs (ICER \$14,000/QALY). Our hypothetical analysis estimated that, among all RA patients, HRV testing with ANS optimization could save \$15-20 billion and 780,000 QALYs over 10 years, depending on PPV of the HRV test. In this scenario, if biologic use increased from current uptake, costs could increase from \$13 to 98 billion, ICER maintained  $< \$150,000/\text{QALY}$ .

	Standard of Care	Incremental Change with HRV Testing	Standard of Care	Incremental Change with HRV Testing	Standard of Care	Incremental Change with HRV Testing
HRV testing vs. no testing (10 year total)

	QALYs	9,348,102	780,335	9,348,102	852,805	9,348,102
	ICER	--	--	\$23,049/QALY	--	\$62,759/QALY
Total costs	\$207.38 bil	-\$19.98 bil	\$207.38 bil	\$13.30 bil	\$207.38 bil	\$50.29 bil
PPV 25%	Biologics	\$122.27 bil	-\$27.99 bil	\$122.27 bil	\$4.66 bil	\$122.27 bil
	QALYs	9,348,102	946,503	9,348,102	1,015,410	9,348,102
	ICER	--	--	\$13,100/QALY	--	\$46,055/QALY

## Conclusion:

The potential US health economic impact of introducing HRV testing and ANS optimization into RA treatment appears substantial and is possibly cost-effective. Additional rigorous studies are warranted in larger patient samples, particularly investigation into non-biologic therapeutic applications.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The elective nature of knee replacement (KR) creates difficult decisions and the potential for both overuse and underuse. We examined the temporal relationship between needing a KR and actually undergoing one to determine the rates and investigate predictors of overuse and underuse.

**Methods:** We pooled longitudinal data from the Osteoarthritis Initiative (OAI) and the Multicenter Osteoarthritis (MOST) Study to estimate KR overuse and underuse. These cohorts closely followed 8,002 participants with or at risk of knee OA over multiple years and collected demographic, patient-reported, radiographic, and clinical exam information. To determine need for KR, we longitudinally applied the modified and validated Escobar KR appropriateness criteria (AC) to classify participants as either appropriate or inappropriate for KR (Table 1). Examining the temporal relationship between appropriateness status and KR utilization, we classified participants into: 1) appropriate and had KR (appropriate use), 2) appropriate but did not have KR (potential underuse), and 3) inappropriate but had KR (potential overuse). We used multinomial logistic regression to estimate the association between overuse and underuse and age, sex, race, educational status, obesity categories, CESD depression score >16, SF-12 PCS, Charlson comorbidity score, and living alone. We repeated our analyses by dividing potential underusers into those with and without extreme pain (an indicator of necessity and a likely substantial benefit from KR).

Table 1: Elements of the modified Escobar appropriateness criteria for KR\*

Factor	Levels
Age	1-<55 years 2-55-65 years 3->65 years
Knee Stability	1-Preserved mobility and stable joint (<5 degrees flexion contracture and normal or minor medial or lateral gapping in the 20 degrees flexed knee) 2-Limited mobility and/or unstable joint (>=5 degrees flexion contracture and/or moderate or severe medial or lateral gapping in the 20 degrees flexed knee)
Compartments involved	1-Uni-compartmental 2-Bi/ tri-compartmental
Radiographic findings	1-Slight (KL grade <=3) 2-Moderate or severe (KL grade = 4)
Symptomatology	1-Slight (mild overall functional loss and function-related pain [e.g. up to half of WOMAC pain and physical scale items scored from 0 to 11]) 2-Moderate (moderate overall functional loss and function-related pain [e.g. up to half of WOMAC pain and physical scale items scored from 12 to 22]) 3-Intense (intense overall functional loss and function-related pain [e.g. up to half of WOMAC pain and physical scale items scored from 23 to 33]) or 4-Severe (severe overall functional loss and function-related pain [e.g. up to half of WOMAC pain and physical scale items scored from >=34])
*16 combination of factors, depending on levels involved, determined whether person was appropriate or inappropriate for surgery. Example: for a 54-year-old patient with KL=4 and moderate symptoms TKR is inappropriate; however, if the symptoms are intense or severe TKR becomes appropriate	

**Results:** 3,449 of 8,002 participants fell into one of the 3 groups, with 843 (24.4%) classified as appropriate users, 2256 (65.4%) as potential underusers, and 350 (10.1%) as potential overusers. Of potential underusers, 988 (43.8%) were deemed likely to receive substantial benefit. Compared to appropriate use, the odds of underuse were greater in blacks (OR=2.9, 95% CI [2.3, 3.8]). The odds of overuse increased with postgraduate degree, higher SF-12 PCS score, living alone, and decreased with being overweight or obese, having depressive symptoms, and having comorbidities. Distinguishing necessary from not necessary but appropriate in the underuser group increased racial disparities in KR underuse (blacks OR=4.9, 95% CI[3.8, 6.5]), without significantly affecting findings related to the other predictors.

**Conclusion:** We found a substantial proportion of patients either overuse or underuse KR. For the underusers, almost 50% would likely receive substantial benefit if they underwent KR and of these, African Americans are at greatest risk for underuse. Overuse appears to be less of a issue but still occurs approximately 10% of the time. Future work needs to focus on ways of reducing rates of overuse and underuse of KR given the substantial costs and consequences of the procedure.

## Telemedicine for Rheumatoid Arthritis in the Alaska Native Population

**Elizabeth Ferucci**<sup>1</sup>, Tammy Choromanski<sup>1</sup>, Gretchen Day<sup>2</sup> and Sarah Freeman<sup>3</sup>, <sup>1</sup>Division of Community Health Services, Alaska Native Tribal Health Consortium, Anchorage, AK, <sup>2</sup>Clinical and Research Services, Alaska Native Tribal Health Consortium, Anchorage, AK, <sup>3</sup>Alaska Native Tribal Health Consortium, Anchorage, AK

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Access to a rheumatologist and frequent monitoring of disease activity in rheumatoid arthritis (RA) are associated with higher quality of care and improved outcomes. With the current rheumatology workforce shortage in the US and concentration of rheumatologists in urban areas, there is a need for strategies addressing barriers to access. Telemedicine video consultation has been implemented within the Alaska Tribal Health System specialty clinics, including rheumatology. The purpose of this study is to evaluate the impact of telemedicine follow-up for RA on disease activity, quality of care, and access to care and to investigate patient perceptions of telemedicine. This analysis describes the baseline characteristics and perceptions of enrolled study participants.

**Methods:** Study participants with a diagnosis of RA were recruited when seeing a rheumatologist, either in-person or by telemedicine. At the study visit, participants completed the RAPID3 and a telemedicine survey and agreed to medical record review for demographics, disease characteristics, and measures of quality and access to care. Participants also agreed to telephone contact at 6 and 12 months for follow-up surveys and RAPID3. For data analysis, participants are categorized as being in the telemedicine group if they have had at least one telemedicine visit with a rheumatologist and in the in-person group otherwise.

**Results:** To date, 65 participants have enrolled in the study (25 telemedicine and 40 in-person). Age, sex, disease duration, and baseline RAPID3 score were similar across groups. The telemedicine group had a higher mean number of rheumatologist visits in the past year (3.3 vs. 2.3,  $p=0.002$ ). Both groups expressed a preference of seeing a specialist in-person rather than by video and the opinion that it is important for the specialist to physically examine them. However, those seen by telemedicine were more likely to consider telemedicine an acceptable way to receive health services ( $p=0.008$ ) and to have favorable opinions about other aspects of telemedicine, including respect for culture ( $p=0.002$ ), patient involvement in decision-making ( $p<0.001$ ), ability to talk easily and openly to provider ( $p<0.001$ ), and trusting the equipment to work ( $p=0.04$ ). Finally, those seen by telemedicine were more likely to consider the care given in video visits to be as good as in-person visits ( $p<0.001$ ).

### Conclusion:

Telemedicine can improve access to care in patients with RA. Although patients in both groups expressed a preference for in-person visits, those seen by telemedicine were more likely to have favorable opinions of it. Whether telemedicine can improve quality of care and disease activity is not yet known.

## Systematic Review of Modelling Approaches and Quality for the Cost Effectiveness of sequential Targeted Therapy in Patients with Rheumatoid Arthritis That Show an Inadequate Response to at Least One Tumor Necrosis Factor Alpha Inhibitor

Aliza Matusevich<sup>1</sup>, Maria Suarez-Almazor<sup>1</sup>, Scott B. Cantor<sup>2</sup> and **Maria A. Lopez-Olivo<sup>1</sup>**, <sup>1</sup>Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX, <sup>2</sup>Department of Health Services Research, Division of Cancer Prevention and Population Sciences, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose: Results** from cost-effectiveness analysis (CEAs) comparing treatment options for patients with rheumatoid arthritis (RA) who have an inadequate response to an initial tumor necrosis factor inhibitor (TNFi) have been inconclusive. Our objective was to systematically review the modelling approaches and quality of economic evaluations comparing the cost-effectiveness, cost-utility, or cost-minimization of subsequent TNFi (cycling) versus a therapy with a different mode of action (swapping) in order to understand their discrepant results.

**Methods:** We searched seven electronic databases until 2016, sources of gray literature and the references of relevant publications. Two independent reviewers screened retrieved citations, including studies published in English-language and economic evaluations comparing second line biological treatments in RA patients. We excluded reviews, conference abstracts and poster presentations. Data extraction was done by one reviewer and crosschecked by another. Reporting quality was evaluated based on the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) statement. Reported incremental cost-effectiveness ratios (ICERs) were synthesized and adjusted to 2016 US dollars according to rules specified by the Panel on Cost-Effectiveness in Health and Medicine.

**Results:** Of 4,563 citations, ten economic evaluations comprising 21 comparisons and representing six European countries, Canada and the United States were included. Most studies (8 of 10) were funded by the pharmaceutical industry. There were two discrete event simulations, three microsimulations, two Markov cohort models, two decision trees and one single study-based evaluation. The most common time horizons were lifetime (6/10) and one year (2/10). Seven studies were from a payer perspective. The cohorts were predominantly female (78%), on average aged 53.4 years, disease duration of 10.2 years and baseline health assessment questionnaire (HAQ) of 2.3. Adherence to reporting standards was good with seven studies scoring  $\geq 26$  out of 36. The most common failing point was justification of modelling choices. One study did not report any sensitivity analysis, but most performed probabilistic as well as one-way sensitivity analysis. Common influential parameters include rituximab dosing schedule as well as assumptions regarding HAQ progression and conversion to utilities. In the cost-utility analyses, the median ICER was US\$25,617 for the swapping strategy, rituximab dominated in half of the comparisons. Of the CEA comparisons, tofacitinib dominated adalimumab while the ICER for abatacept versus infliximab was \$20,803 and \$27,976 per case of low disease activity and remission respectively. The single cost-minimization study found in favor of rituximab.

**Conclusion:** Despite disparate modelling approaches it appears that swapping to a targeted agents with an alternative mechanism of action is cost-effective at the \$50,000/QALY threshold as ICER's ranged between \$9,323 to 41,467/QALY, dominating in 8 of 20 comparisons.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early diagnosis and treatment of rheumatoid arthritis (RA) is crucial in minimizing disease damage. Step-therapy, a form of prior authorization used by payers to manage costs, determines which medications will be covered and thus affordable. Expansion of the Institute for Healthcare Improvements Triple Aim initiative to the Quadruple Aim initiative added the aim to promote workplace happiness for providers. We examined provider beliefs regarding the role of step-therapy in managing health care costs, quality of care delivered, and on clinical autonomy and job satisfaction in North Carolina. We also evaluated provider awareness and agreement with proposed state policies aimed at streamlining step-therapy exceptions processes.

**Methods:** In this cross-sectional survey study, a web-based questionnaire was emailed on March 7 and March 16, 2017 to all members of the North Carolina Rheumatology Association. We summarized the data through frequency counts to determine knowledge, beliefs and perception of step-therapy, and chi-square tests were used to compare respondent knowledge of state legislation, NC HB 1048, to their beliefs about autonomy and job satisfaction.

**Results:** The survey was sent to 118 providers, and the final analysis included 38 completed surveys (effective response rate of 32.2%). Respondents were more likely to be male (58%), report 20+ years in practice (53%), work in a private practice (87%), and see patients with Medicare (34%) or private insurance (38%). Providers disagreed that step-therapy reduced costs for society overall (52%) or patients (57%). Instead, 82% agreed that step-therapy reduced costs for insurance companies. With respect to quality, 92% of providers believed step-therapy negatively impacted the quality of care provided to patients (50% somewhat reduced quality, 42% greatly reduced quality) and 82% of providers agreed that step-therapy delayed beginning proper treatment (50% agree, 31% strongly agree). Nearly 90% of providers reported step-therapy negatively affects their autonomy and 87% reported step-therapy negatively impacting their job satisfaction. When considering the burden of step-therapy on providers, 79% of providers reported step-therapy as being common when prescribing for RA. Most respondents (76%) were directly involved in processing step-therapy paperwork. In addition, half of respondents reported spending >60 minutes on step-therapy paperwork in an average clinic day. Despite the burden of step-therapy, only 47% of providers were aware of proposed NC state legislation to reduce the burden of step-therapy. Notably nearly all surveyed providers agreed with the exceptions proposed within the state legislation.

**Conclusion:** Providers view step-therapy as a burden without justifiable results for cost and quality. This unjustified burden coupled with provider agreement with state proposed legislation suggests that providers should engage with policy makers to support legislative action on this topic. Additionally, provider groups such as the ACR should create advocacy groups to increase awareness of state and federal legislation.

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Utilization patterns in rheumatoid arthritis (RA) are complex. For targeted interventions, patients with special healthcare needs should be recognized. Our aim was to explore healthcare utilization profiles in RA by cluster analysis.

**Methods:** The RA patients attending Jyväskylä Central Hospital rheumatology unit, Finland, are as of 2007 enrolled prospectively in a structured digital database, from which we identified patients with rheumatology clinic visits in 2012-2014. We combined this clinical data with well-recorded administrative data on fiscal year 2014 on all public healthcare visits, both in primary and specialty care. For each patient, we considered the median of time dependent clinical variables. Clustering variables were disease activity score (DAS28-3), health assessment questionnaire index (HAQ index, 0-3), pain on visual analogue scale (VAS, 0-100) and total annual health services related direct costs (€), excluding out of pocket medication costs. The number of clusters was set based on dendrogram examination. We applied hierarchical clustering with Ward's minimum variance method with Euclidean distance.

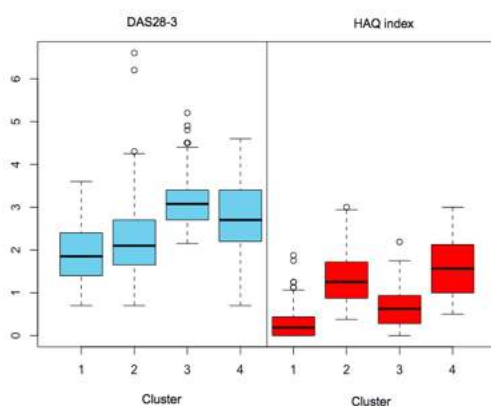

**Results:** Of 844 patients with RA, complete-case analysis (n = 827) derived four clusters. Descriptive statistics are in Table 1 and distributions for DAS28-3 and HAQ index are in Figure 1. Cluster 1 was the largest cluster constituting relatively young patients with low costs, low disease activity, and minimal disability. Cluster 2 was characterized by high pain levels and disability, despite fairly low average DAS28-3. Compared with cluster 2, patients in cluster 3 had high average disease activity and rheumatic disease -related costs, and biologics were more frequently used. Still, they presented with less pain and disability compared with cluster 2. Cluster 4 was small, heterogeneous and characterized by exceptionally high average costs. These patients had costly and severe comorbidities in addition to RA.

**Conclusion:** Over half of patients had low costs and favorable outcome measures, whereas a fifth was characterized by high disease activity and active treatment of RA, yielding higher costs. Pain and disability did not necessarily relate to high rheumatic disease -related costs. In all clusters, over half of costs were attributable to comorbidities.

	Cluster 1	Cluster 2	Cluster 3	Cluster 4
n	467	147	180	33
Age (mean ± SD)	58.2 ± 15.3	66.5 ± 11.8	63.3 ± 13.9	71.1 ± 10.8
Disease duration (median)	11.8 ± 8.5	16.3 ± 12.6	16.0 ± 12.5	18.6 ± 12.9
Pain (mean ± SD)	15.9 ± 12.2	55.2 ± 18.3	37.2 ± 15.8	47.0 ± 20.9
RF+ (%)	65	71	77	90
Ever biologics (%)	23.3	24.5	43.3	45.5
Number of comorbidities	2.1 ± 2.1	3.7 ± 2.1	3.4 ± 2.8	5.7 ± 3.5
Mean total costs/patient (€)	2367	3785	6772	36206
Mean rheumatic disease costs/patient (%*)	1054 (48.5)	1455 (44.8)	3076 (48.5)	4323 (13.0)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Early identification and treatment of inflammatory arthritis (IA) and in particular rheumatoid arthritis (RA) can lead to improved outcomes. However, there are often delays in diagnosis. We hypothesized that evaluation of individuals in a health-fair setting could identify those with previously undiagnosed IA/RA. In addition, because performing physical examinations is difficult to perform on a large scale, we sought to evaluate the diagnostic characteristics of self-reported symptoms and antibody testing to identify IA.

## Methods:

Subjects who self-reported no prior diagnosis of RA were evaluated from 2012 to 2015 at a Colorado based health-fair. Each subject reported presence/absence and location of joint symptoms in the wrists and hands on a cartoon picture of these joints. All subjects additionally underwent ACPA testing (CCP3, Inova) and a joint examination of the wrists and hands (excluding DIPs) by a rheumatologist who recorded presence/absence of IA. The diagnostic accuracy of symptoms and ACPA as single variables or an overall score were evaluated using regression techniques.

## Results:

1703 subjects were evaluated, and 98 (5.8%) were found to have IA (Table 1). Of single joint areas, self-reported symptoms of joint pain, stiffness or swelling in the MCPs had the strongest association with the presence of IA on examination (OR 4.8). CCP3(+) was also significantly associated with IA (OR 3.1) but was present in only 8% of all subjects with IA, and 45 subjects were CCP3(+) without hand/wrist IA. In multivariate analyses, four variables including symptoms in wrists, MCPs, PIPs, and CCP3(+) were significantly associated with IA. When these 4 variables were evaluated as counts, the highest positive predictive value (PPV) for IA was 22% (3 items present), and the highest negative PV was ~98% (0 items present) (Table 2).

## Conclusion:

Health-fair evaluations can be used to identify individuals with IA, some of whom likely have RA due to CCP3(+), and others with potentially other forms of IA. A scoring system using a combination of self-reported joint symptoms and CCP3 testing can be used to identify those with IA in the hands, with varying predictive values depending on the score used. Further evaluations including determining what specific forms of arthritis are identified and cost-effectiveness need to be performed, but overall these findings support a health-fair based approach using questionnaires and ACPA testing as a way to improve identification of IA. Additionally, N=46 CCP3(+) subjects did not have IA, indicating this method could be used to identify individuals at future risk for RA.

**Table 1. Univariate analyses of differences in demographics, CCP positivity and joint symptoms between subjects with/without IA**

	IA	No IA	OR (95% CI)	P-value
N	98	1605		
Mean Age at Visit (Years)	56.43	56.07		0.7835
Percent Female	64.29	69.84	0.51 (0.47, 1.19)	0.2458
N, (%) CCP+	8 (8.16%)	46 (2.90%)	3.08 (1.41, 6.73)	0.003
Self-Reported symptoms of pain, stiffness or swelling on the day of the health-fair evaluation				
Wrist	22.45	10.9	2.37 (1.44, 3.90)	0.0005
MCP	57.14	21.74	4.80 (3.16, 7.28)	<0.0001
PIP	48.98	17.26	4.60 (3.03, 6.98)	<0.0001

**Table 2. Counts of symptoms in wrists, MCPs, PIPs, and CCP3 positivity and diagnostic accuracy for inflammatory arthritis**

Number of Items Positive (joint symptoms in wrists, MCPs, PIPs and positive for CCP3 each get 1 point)	Sensitivity	Specificity	Positive Predictive Value (PPV)	Negative Predictive Value (NPV)
1 or more*	80.61	63.36	11.84	98.17*
2 or more	42.86	86.29	16.03	96.11
3 or more	11.22	97.63	22.45	94.74
All 4 items	2.04	100.00	100.00	94.36

\*Of note, the 1036 subjects who reported no symptoms in their wrists, MCPs and PIPs or had CCP3 positivity, 19 were found to have IA on examination

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

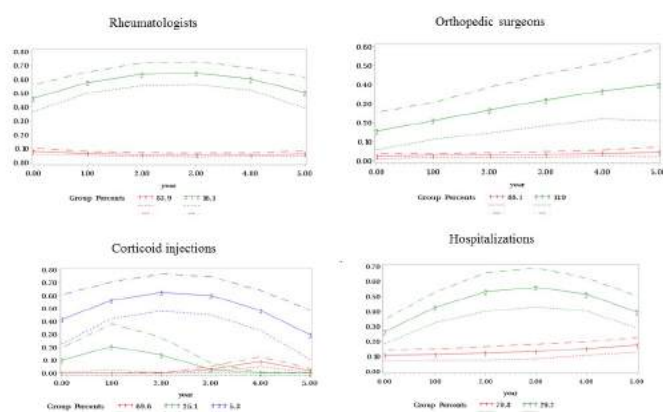

- **Background/Purpose:** in hip and knee OA, one of the leading causes of global disability, recent population-based data of health care practices and utilization are scarce. Describing trajectories of patients' patterns of care and their predictive factors is important to adapt health care practices and guide interventions to optimize patients' use of health care services. The aim of the study was to describe health care utilization trajectories and associated factors of a representative sample of patients with knee or hip symptomatic OA.

- **Methods:** the KHOALA cohort is a French population-based multicenter cohort of 878 patients with symptomatic knee and/or hip OA, aged between 40 and 75 years old recruited between 2007 and 2009. Patients are followed annually by self-report questionnaires. Analyses used the data from the 5 first years of the follow up. We used Latent Class Growth Analyses (LCGA) to define homogeneous

subgroups of trajectories based on the individual health care consumptions over time, and logistic regressions to explain the differences between the identified trajectories with baseline characteristics.

- **Results:** Among the 878 patients, 609 (69%) were women, 222 (25%) have hip OA, 607 (69%) knee OA and 49 (6%) both hip and knee OA. Groll comorbidity index (0-18) was 3.1 (1.6). The most optimal and clinically relevant models retrieved by LCGA were two group models for consultations with the different health care professionals (primary care physician (PCP), rheumatologist, orthopedic surgeon, physiotherapist), hospitalizations, use of assisting devices and acid hyaluronic (AH) injections, and 3 group models for corticoids injections and use of complementary and alternative medicine (CAM). In multivariate analyses, increasing age was independently associated with the trajectory of high number of consultations with PCP and rheumatologist, and with a high use of corticoids injections or complementary medicine. Impaired mental health was associated with the groups of frequent consultations with PCP, rheumatologists and physiotherapists and with corticoid injections. Pain was only associated with increasing number of orthopedic surgeons consultations and high use of assisting devices. Impaired function abilities were only associated with frequent hospitalizations. Comorbidities are associated with PCP consultations and hospitalizations (frequent use).

- **Conclusion:** In multivariate analyses, mental health impairment is the only symptom associated with trajectories of frequent use of medical care while pain is only associated with orthopedic surgeon consultations.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Infliximab (IFX) is more frequently selected than golimumab for intravenous use (GLM-IV) in patients with Rheumatoid Arthritis (RA) but differences in dosing and administration recommendations for these products may have budgetary consequences. This study aimed to determine the budgetary impact of IFX and GLM-IV based upon real-world treatment patterns and commercial reimbursement in a matched sample of RA patients.

**Methods:** Truven Commercial Claims and Encounters and Medicare Supplemental data were used to evaluate maintenance infusion interval, frequency of first or subsequent hour billing code and cost of infusions for adult RA patients starting a new episode of IFX (J1745) or GLM-IV (J1604). Adult patients with  $\geq 12$  months continuous enrollment before and after the 1<sup>st</sup> IFX or GLM-IV claim (index) between 1/1/2014 and 3/31/2016 and no evidence of index medication use 12 months before index were studied. IFX and GLM-IV patients were matched 1:1 on index medication treatment duration, gender, payer type, prior-biologic use and post-index methotrexate (MTX). The payer paid drug plus administration cost was used applied to population treatment patterns. Descriptive statistics summarized key variables (mean, SD, median, n, %). Chi-squared tests determined differences between categorical variables and t-test was used for continuous variables.

**Results:** A total of 1,094 matched patients were identified (n=547 GLM-IV; n=547 IFX). In both groups, median age was 56 years; 82% were female and 38% had no prior biologic use. Mean (SD) follow-up was 609 (161) days (d) for GLM-IV and 613 (163) days for IFX. Mean (SD) duration of GLM-IV use was 396 (240) d and 397 (239) d for IFX. A total of 3,961 GLM-IV infusions and 4,716 IFX infusions were administered. The proportion of maintenance infusions given every 8 wk was 80% for GLM-IV vs 39% for IFX; 6% of GLM-IV vs 53% of IFX infusions occurred more frequently than every 8 wk ( $P<0.0001$ ). Mean drug plus administration cost per infusion was \$5,846.10 (GLM-IV) and \$5,443.66 (IFX). Mean GLM-IV administration cost was \$224.26 with  $<1\%$  of infusions having a second hour billing code vs IFX with mean administration cost of \$360.36 and 96% of IFX infusions requiring a second hour billing code ( $P<0.0001$ ). Based upon the average maintenance infusion interval, GLM-IV patients cost approximately \$10,507 less than IFX patients in the first year and approximately \$6,774 less than IFX patients in subsequent years.

**Conclusion:** From the commercial health plan perspective, annual GLM-IV drug plus administration cost was less than IFX in RA patients due to differences in real-world dosing and administration. These findings have important implications for population health decision makers.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Absent contraindications to conventional DMARD (cDMARD) use, the Veterans Administration (VA) requires a 3-month trial of 2 cDMARDs prior to the use of biologic DMARD (bDMARD), for active rheumatoid arthritis (RA). In this national VA study, we used a time-to-event analysis in cases of newly-identified RA to examine variation between VA Integrated Service Network (VISN) areas in prescriptions following MTX monotherapy.

## Methods:

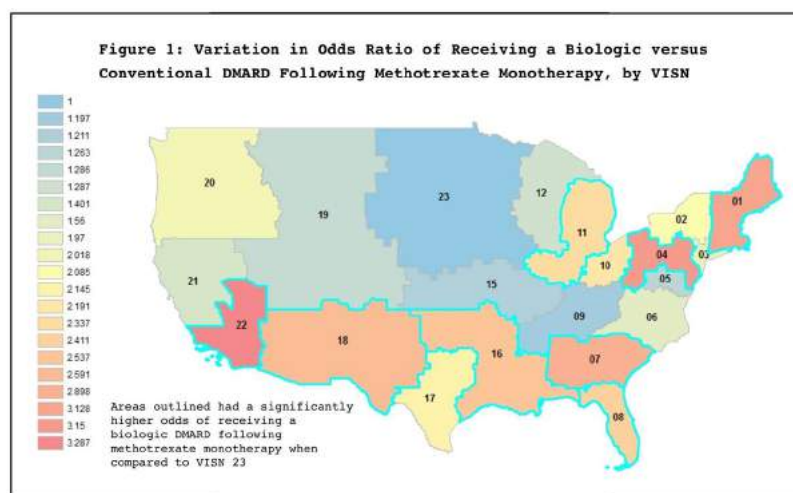

A previously validated, 3-part definition was used to identify patients with RA within the VA Musculoskeletal Disorder (MSD) cohort ( $N > 5$  million, Jan 1, 2000-Dec 31, 2013). The date of the first VA DMARD prescription was used to define both RA diagnosis and RA cohort entry. To limit our analysis to newly-identified RA, we included patients with  $>1$  year in the MSD cohort prior to RA diagnosis. To make our RA cohort as uniform as possible, we included only patients who first received a  $>90$ -day period of VA-prescribed MTX monotherapy. Kaplan Meier survival analysis and bivariate logistic regression were used to assess patient demographic and clinical data. After adjusting for significant predictor variables, we used a multivariate logistic regression to examine initial, non-MTX DMARD prescription by VISN.

## Results:

A total of 4,823 patients (91% male, median age 64yrs, median observation time 3.91 yrs) met our inclusion criteria. All 21 VISN areas were represented (mean number of RA patients per VISN = 230 pts; range 88-488). Overall, 1,911 patients (40%) were prescribed only MTX monotherapy while observed in the RA cohort. Of the remaining patients who did receive a non-MTX DMARD, 748 (15%) went on to receive a bDMARD, whereas 2,164 (45%) received a cDMARD, as their initial, non-MTX DMARD prescription. The median interval between the first MTX prescription and initial, all non-MTX DMARD prescription was 1.13 years (IQR 0.56-2.25); a Kaplan Meier survival analysis did not show a significant difference between bDMARD and cDMARD interval prescription times (Kaplan Meier log rank  $p=0.94$ ). Examining regional variation, 8 VISN areas were at statistically higher odds of receiving an initial bDMARD prescription, when compared to the VISN with lowest percentage bDMARD prescriptions (OR range 1.0-3.29, reference cDMARD prescription in VISN 23, see Figure 1).

## Conclusion:

Following MTX monotherapy for newly-identified RA, we found a 3-fold variation by VISN in the prescription of biologic versus conventional DMARDs (see Figure 1; base 1.0 [VISN 23] in blue, highest 3.29 [VISN 22] in red). Further work is needed to assess the causes of these differences.

## Cost-Effectiveness of Tai Chi Versus Physical Therapy for Knee Osteoarthritis

John B. Wong<sup>1</sup>, Mei Chung<sup>2</sup>, Lori Lyn Price<sup>3</sup> and **Chenchen Wang**<sup>4,5</sup>, <sup>1</sup>Tufts Medical Center, Boston, MA, <sup>2</sup>Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, <sup>3</sup>Biostatistics Research Center, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, <sup>4</sup>Rheumatology, Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA, Boston, MA, <sup>5</sup>Division of Rheumatology, Tufts Medical Center, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Health Services Research Poster II: Osteoarthritis and Rheumatoid Arthritis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A single-blind randomized comparative effectiveness trial showed that Tai Chi yielded beneficial effects similar to those of a standard course of physical therapy in the treatment of knee osteoarthritis, so we aimed to examine the cost-effectiveness of Tai Chi vs. physical therapy for knee osteoarthritis.

**Methods:** Using standard microeconomic methods, we developed a simulation model to estimate healthcare resource utilization (hospitalizations, inpatient, outpatient, testing, medications and nutraceutical use) and cumulative effectiveness outcomes (WOMAC pain, WOMAC function, Global Visual Analog Scale and SF36 pain component score) over 12 weeks, 24 weeks, and a year. Based on available data, we fit longitudinal models for each patient. To account for uncertainty in the results and estimates, we performed Monte Carlo simulations incorporating the uncertainty surrounding all estimates. We estimated physical therapy costs at \$100 per session for 6 weeks twice a week and group Tai Chi classes at \$25 per session at twice a week for 12 weeks and accounted for the adherence observed in the study.

**Results:** In the 1000 simulations for 12, 24 and 52 weeks, Tai Chi was always less expensive than Physical Therapy, with mean (SD) savings of \$289 (47) at 12 weeks, \$648 (60) at 24 weeks and \$1668 (112) after 52 weeks. The analysis was most sensitive to the cost of PT or Tai Chi. At \$25 per session for PT, PT was cost-saving at 12 and 24 weeks but Tai Chi was cost saving at 52 weeks. At \$60 per session for Tai Chi, Physical Therapy was cost-saving at 12 weeks, but Tai Chi became cost-effective at 24 and 52 weeks.

In terms of effectiveness for 100 patients with knee OA, Tai Chi improved WOMAC pain (0-500) by 50,925 points over 12 weeks, 220,159 points over 24 weeks and 368,642 points over 52 weeks. Similarly, Tai Chi improved WOMAC function (0-1700) by 93,339 points over 12 weeks, 279,460 points over 24 weeks and 439,979 points over 52 weeks. Tai Chi improved Global Visual Analog Scale (0-10) by 1899 over 12 weeks, 5770 over 24 weeks and 12,724 over 52 weeks. Lastly, Tai Chi improved SF36 Physical Component Score (0-100) by 13,589 over 12 weeks, 44,197 over 24 weeks and 84,294 over 52 weeks.

**Conclusion:** Our analysis suggests that Tai Chi is cost-saving relative to physical therapy because it on average both reduces costs and improves outcomes. The results are relatively robust (consistent) when varying the cost of physical therapy and Tai Chi until extreme values were considered. The results suggest that reimbursement for Tai Chi as a treatment for knee osteoarthritis should be considered by health payers.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interferon regulatory factor 5 (IRF5) is a key mediator of pathogen-induced immune responses that acts downstream of Toll-like receptors (TLRs), NOD-like receptors (NLRs) and RIG-I-like receptors (RLRs). IRF5 polymorphisms leading to its elevated expression and activation have been detected in patients with autoimmune diseases; yet, the contribution of IRF5 to disease onset and/or severity remains to be fully elucidated. IRF5 typically remains inactive in the cytoplasm of a cell but upon stimulation by external signals, IRF5 undergoes post-translational modification(s), homo-dimerization, and nuclear translocation, where the dimeric protein induces transcription of antiviral and pro-inflammatory genes. Here, we report the evaluation of novel cell-penetrating peptides (CPPs) designed to disrupt IRF5 dimerization which is considered critical for nuclear translocation and function in immune cells.

**Methods:** We designed CPPs targeting IRF5 Helix 2 or Helix 5 regions based on a modelled structure of the IRF5 dimer. CPPs binding to the IRF5 monomer were measured in a time-resolved fluorescence resonance energy transfer (TR-FRET) assay. Potencies of IRF5-CPPs were assessed in an IRF5 dimerization assay using recombinant biotin- and his-tagged IRF5 (222-467, S430D). Cell penetration was first tested in HeLa cells with FITC-conjugated CPPs followed by confocal microscopy. The effects of IRF5-CPPs on nuclear localization and phosphorylation of IRF5 in CD14<sup>+</sup> monocytes, CD123<sup>+</sup>BDCA2<sup>+</sup> plasmacytoid dendritic cells (pDC) and CD19<sup>+</sup> B cells were analyzed on an ImageStream Mark II cytometer following stimulation of peripheral blood mononuclear cells (PBMCs) with CpGA, R848 or SLE serum. Levels of inflammatory cytokines (IL-6, TNF $\alpha$ ), IgG and IFN $\alpha$  in PBMCs were measured by AlphaLISA.

**Results:** Biochemical and imaging analyses showed that IRF5-CPPs are cell permeable, non-cytotoxic at concentrations <50  $\mu$ M, and directly bind to IRF5 ( $K_D$  = 0.5-0.93  $\mu$ M). FRET assays revealed that IRF5-CPPs disrupt IRF5 homo-dimerization ( $IC_{50}$  = 8.5-10.9  $\mu$ M). Stimulation of PBMCs with TLR ligands revealed that IRF5-CPPs blocked pro-inflammatory cytokine production (IL-12, TNF $\alpha$ , and IL-6), IgG production in B cells, and IFN $\alpha$  production in pDCs. Inhibition of cytokine and IgG production from primary immune cells correlated with a significant, concentration-dependent reduction in the nuclear localization of phosphorylated IRF5. Similar findings were made in PBMCs derived from patients with systemic lupus erythematosus (SLE) or lupus nephritis (LN).

**Conclusion:** Rational design of novel cell-penetrating peptide inhibitors that target IRF5 dimerization not only provides new tools for the functional interrogation of IRF5 in healthy and disease-relevant cells, but also facilitates the development of new therapeutics to treat inflammatory and autoimmune disorders such as SLE.

## Cardiac Endothelial Cell Transcriptome Analyses Support a Pathological Role of Metabolic and Inflammasome Genes in Anti-SSA/Ro-Associated Congenital Heart Block

Sara Rasmussen<sup>1</sup>, Robert M. Clancy<sup>2</sup> and Jill P. Buyon<sup>2</sup>, <sup>1</sup>Department of Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY, <sup>2</sup>NYU School of Medicine, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The role of Type I IFN in anti-SSA/Ro-associated Congenital Heart Block (CHB) may include an adverse consequence to the cardiac vasculature. One scenario consistent with injury is that the phenotype of cardiac endothelial cells contributes to Caspase-1/Interleukin-1 converting enzyme (inflammasome) to account for chronic levels of inflammatory cytokines and oxidative stress. This study sought to

test the hypothesis that anti-SSA/Ro-mediated injury to the vasculature occurs via a Type 1 IFN-enriched environment, which acts on the endothelial cells to upregulate the inflammasome along with metabolic changes contributing to damage by decreasing oxygen to the tissue.

#### **Methods:**

Two sources of endothelial cells were studied. In an in vitro approach, cultured HUVECs were evaluated in the presence and absence of supernatants generated from macrophages treated with ssRNA (hY3) since previous studies have identified macrophages as a potential source of IFN in CHB. Both transcriptomic analyses and cellular metabolism as reflected in the extracellular acidification rate (ECAR) and mitochondrial oxygen consumption (OCR) were analyzed using the Seahorse platform. A second in vivo approach used freshly obtained endothelial cells (DAPI negative cells isolated by flow using antibodies to CD31) from a 19 week fetus dying with CHB and an otherwise healthy 22 week heart.

#### **Results:**

For the in vitro experiments, IFIT1 (IFN response gene) was significantly increased by 163-fold in HUVECs incubated with hY3 macrophage supernatants compared to HUVECs treated with macrophage supernatants alone ( $p=0.023$ , qPCR). The inflammasome components NLRP3 and CASP1 were also significantly increased by 2.8 fold and 2.1 fold in HUVECs treated with hY3 macrophage supernatants vs macrophage supernatants alone ( $p=0.025$ ,  $p=0.05$ , respectively). Reflecting oxidant stress, significant increases in ECAR were observed in the HUVECs treated with hY3 macrophage supernatants compared to macrophage supernatants alone ( $15\pm4$  mpH/min vs  $5\pm3$  mpH/min,  $p=0.05$ ,  $N=3$ ). For bioenergetic health index (BHI), a composite of spare capacity, coupling efficiency, Proton leak and non mitochondrial respiration, there was a trend to be lower EC + hY3 macrophage supernatants vs EC + macrophage supernatants ( $2.0$  vs  $3.3$ ,  $p=0.2$ , respectively).

Transcriptomes of the two hearts for each isolated endothelial cell fraction were compared. Based on DAVID annotation, data were organized into clusters of closely related genes. The top GO category was the type I IFN signaling pathway with 5 IFN inducible genes in the top 10. Regarding targeted genes with greater than two-fold upregulation (CHB vs control), there were genes within the inflammasome pathway, including IFN inducible NLRC5, which serves to interact with NLRP3, along with well characterized multiprotein oligomer of the inflammasome such as NLRP3, IRF7, IRF9 & CASP1. Inflammasome precursors including IL18, IL1B, & IL1A were also upregulated.

#### **Conclusion:**

Anti-SSA/Ro-induced cardiac injury may include a previously unappreciated effect on the vasculature mediated by IFN. This vascular effect is reflected in the upregulation of metabolic and inflammasome genes.

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Genetic factors contribute strongly to Rheumatoid arthritis (RA) risk. *Protein tyrosine phosphatase non-receptor 22* [PTPN22] encodes the hematopoietic-specific Lymphoid Phosphatase [“Lyp”]. A *PTPN22* coding variant “LypW” is the most potent non-HLA genetic risk factor for RA. TLR agonists potentially suppress inflammatory arthritis in murine models of RA. Our previous work revealed that Lyp promotes induction of type 1 interferon [IFN1] and IFN1-dependent genes during TLR3 agonist treatment of serum transfer arthritis (STA). RA-associated variant LypW shows loss of function behavior in arthritis suppression. The molecular and cellular mechanism(s) by which Lyp promotes IFN1-dependent inflammatory arthritis amelioration are not known. The goal of this study was to analyze the PTPn22-dependent transcriptome within arthritic synovium of animals receiving TLR agonist treatment.

## Methods:

Wild-type (WT) or Lyp-deficient (Lyp<sup>-/-</sup>) mice (n = 6 per genotype) were injected with K/BxN serum on days 0 and 2. On days 4 and 6, half of the mice were given 150 µg poly I:C [pIC], a TLR 3 agonist and arthritis-suppressing agent, by intraperitoneal injection. 12 hours after the second dose of pIC, mice were sacrificed. Total RNA was extracted from ankle synovial aspirates. RNA-Seq mapping, gene quantification and differential expression were done in Bowtie2, Feature Counts and edgeR.

## Results:

15 genes were differentially-regulated by pIC in Lyp<sup>-/-</sup> arthritic synovium. Among the genes with known immune-modulating function, Signaling lymphocytic activation molecular family member 7 [*Slamf7*] and family member 4 [*Slamf4*] had the highest fold-change differences between genotypes. pIC treatment robustly upregulated expression of *Slamf7* in synovium from arthritic WT mice, but upregulation was markedly attenuated in Lyp<sup>-/-</sup> animals (figure 1). In contrast, *Slamf4* transcripts were reduced after pIC treatment in both genotypes; *Slamf4* suppression was greater in Lyp<sup>-/-</sup> mice. Because SLAM family members are important for innate immunoregulation, we examined TLR-signaled SLAM expression within candidate SLAM-expressing innate immune cells. Preliminary results from studies of TLR3 or TLR4-treated bone marrow-derived macrophages or dendritic cells, or of splenic macrophages after *in vivo* pIC exposure revealed minimal upregulation of *Slamf7*, regardless of Lyp genotype. NK cells from pIC-treated animals showed upregulation of surface SLAMf7, and suppression of SLAMf4, but not in a Lyp-dependent manner.

**Figure 1:** SLAMf7 and SLAMf4 mRNA expression (reads  $\pm$  1 SD) in day 7 synovial fluid in WT and Lyp<sup>-/-</sup> (n = 3 per group) with serum transfer arthritis with or without administration of pIC (days 4 and 6). P values were determined by edgeR and DESeq software using negative binomial distribution to calculate differential gene expression.

## Conclusion:

TLR agonist treatment induced modulation of SLAMf4 and 7 and is differentially regulated by Lyp during serum transfer arthritis. Preliminary studies do not support the hypothesis that Lyp modulates TLR-stimulated SLAM family receptor expression in key inflammation-regulating innate immune cell types, including dendritic cells, macrophages, or NK cells.

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

The innate immune system is important for initiation and development of OA. Increased degradation of the cartilage release fragments into the synovial fluid, which can then bind to innate immune receptors in the synovium. The aim of this study was to investigate the effect of Toll like receptor 2 (TLR2) activation by synthetic agonists and a synthetic aggrecan 32 amino acid fragment (32-mer) on the tissue turnover and IL-6 secretion, in a human synovial membrane explant model.

## **Methods:**

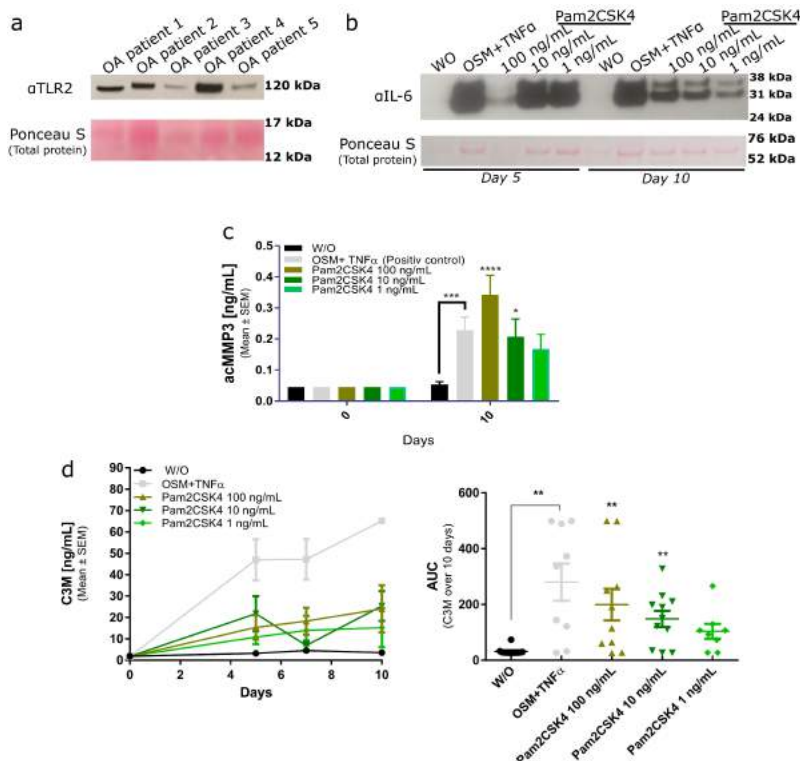

Human synovial membrane biopsies retrieved from OA patients undergoing total knee replacement were lysed and the presence of TLR2 were investigated by western blotting. Human synovial membrane explants (SME) were prepared from the synovial biopsies: Excess fat was removed and the biopsies were cut into explants of 30±5 mg. The SMEs were cultured for 14 days without treatment (WO), OSM [10ng/mL] + TNFα [20ng/mL] (positive control), Pam2CSK4 in three doses (100 ng/mL, 10 ng/mL, or 1 ng/mL), or Pam3CSK4 in three doses (300 ng/mL, 30 ng/mL, or 3 ng/mL). Furthermore, stimulation with a synthetic aggrecan 32-mer (100000 ng/mL, 10000 ng/mL, 1000 ng/mL, 100 ng/mL and 10 ng/mL, respectively) was evaluated. Release of the neo-epitope biomarkers acMMP3 and C3M were measured by ELISA and secretion of IL-6 was evaluated by western blotting at day 5 and 10 in the conditioned media.

## **Results:**

Western blotting confirmed the presence of TLR2 in untreated OA synovial biopsies (Fig. 1a). Activation of the SMEs were assessed by acMMP3, C3M, and IL-6 release. OSM+TNFα significantly increased the release of IL-6 secretion, acMMP3 ( $P<0.05$ ), and C3M ( $P<0.01$ ) (Fig. 1). The TLR2 agonists, Pam2CSK4 and Pam3CSK3, significantly increased the release of acMMP3 at day 10 compared to WO (PAM2CSK4: 100 ng/mL  $P<0.001$ , 10 ng/mL  $P=0.016$ , Pam3CSK4: 30 ng/mL  $P<0.001$ ) (Fig. 1c). The overall C3M release was significantly increased by Pam2CSK compared to WO (100 ng/mL  $P=0.007$  and 10 ng/mL:  $P=0.008$ ) (Fig. 1d). Pam3CSK tended to increase the overall C3M and significantly increased C3M release at day 10 compared to WO (100 ng/mL:  $P=0.035$ , 10 ng/mL:  $P=0.008$ ). The western blotting confirmed increased secretion of IL-6 from SMEs stimulated with Pam2CSK4 (Fig. 1b) and Pam3CSK4 compared to WO. Synthetic aggrecan 32-mer did not show any significant increase of C3M release from the synovium.

## **Conclusion:**

TLR2 is expressed in synovium of OA patients and their activation by synthetic ligands resulted in increased tissue turnover confirmed by release of activated MMP3, acMMP3, and MMP-mediated degradation of type III collagen, C3M. Additionally, activation of TLR2 lead to an increased secretion of the pro-inflammatory cytokine IL-6. A synthetic peptide of the potential biological ligand of TLR2, the aggrecan 32-mer failed to generate a significant C3M response compared to WO. We hypothesize that it may be different with the glycosylated native aggrecan 32-mer.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Tolerogenic dendritic cells (tDCs) are a promising therapeutic tool for specific induction of immunological tolerance. Human tDCs can be generated ex vivo using various compounds. However, the compound(s) most suitable for clinical application remain undefined. For clinical application of tDCs, three functional characteristics are required: 1) CCR7-dependent migration toward secondary lymphoid organs; 2) efficient induction of functional regulatory T cells; and 3) stability upon exposure to proinflammatory stimuli. We found that DCs (PKCI-tDCs) treated with protein kinase C inhibitor (PKCI) had potent tolerogenic properties. Since aberrant activation of T cells, especially CD4<sup>+</sup> T cells, plays an important role in the initiation and/or perpetuation of rheumatoid arthritis (RA) and primary Sjögren's syndrome (pSS), both diseases may be suitable for tolerance-inducing therapy. In this study, we described the characterization of PKCI-tDCs and examined whether PKCI-tDCs could be generated from patients with RA or pSS.

## Methods:

1) Generation of human tDCs: Immature DCs (iDCs) were generated from the monocytes by culturing them in X-VIVO medium with GM-CSF and IL-4 for 5 days. To induce mature DCs (mDCs), iDCs were incubated with a maturation cocktail for a further 48 h. Compound-treated tDCs were generated by culturing iDCs with a maturation cocktail in the presence of each compound for 48 h. 2) Other methods: In vitro T cell proliferation assay; cytokine production; phagocytic ability; induction of regulatory T cells; in vitro T regulatory activity; stability of DCs under proinflammatory stimuli; and chemotaxis assay.

## Results:

PKCI-tDCs had a semi-mature phenotype, showing high production of IL-10, and efficiently induced IL-10-producing T cells and functional Foxp3<sup>+</sup> regulatory T cells, thus eliciting a strong immunosuppressive function. They also showed CCR7 expression and sufficient capacity for migration toward CCR7 ligands. In addition, PKCI-tDCs were highly stable when exposed to inflammatory stimuli. PKCI inhibited NF-κB activation of both the canonical and non-canonical pathways of DC maturation, thus suppressing the expression of costimulatory molecules and IL-12 production. High production of IL-10 in PKCI-tDCs was due to not only an increase of intracellular cAMP, but also a synergistic effect of increased cAMP and NF-κB inhibition. PKCI-treated DCs from the patients with RA or pSS had similar phenotypes and suppressive properties to those from healthy donors.

## Conclusion:

PKCI-tDCs may be useful for tolerance-inducing therapy, since they satisfy the required functional characteristics for clinical-grade tDCs. In addition, PKCI-tDCs were generated from patients with RA or pSS not only before but also after treatment with agents such as methotrexate and prednisolone.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mucosal-associated invariant T (MAIT) cells contribute to protection against certain microorganism infections and play an important role in mucosal immunity. However, the role of MAIT cells remains enigmatic in autoimmune diseases. Here, we examined the level and function of MAIT cells in patients with rheumatic diseases.

**Methods:** Patients with systemic lupus erythematosus (SLE; n = 54), rheumatoid arthritis (RA; n = 66), Behçet's disease (n = 9), ankylosing spondylitis (n = 21), and healthy controls (n = 136) were enrolled in the study. MAIT cell, cytokine and programmed death-1 (PD-1) levels were measured by flow cytometry.

**Results:** Circulating MAIT cell levels were significantly reduced in systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) patients. In particular, this MAIT cell deficiency was more prominent in CD8<sup>+</sup> and double-negative T cell subsets, and significantly correlated with disease activity, such as SLE disease activity index (SLEDAI) and 28-joint disease activity score (DAS28). Interestingly, MAIT cell frequency was significantly correlated with natural killer T (NKT) cell frequency in SLE patients. IFN-γ in MAIT

cells was impaired in SLE patients, which was due to an intrinsic defect in the Ca<sup>2+</sup>/calcineurin/NFAT1 signaling pathway. In SLE patients, MAIT cells were poorly activated by  $\alpha$ -galactosylceramide-stimulated NKT cells, thereby showing the dysfunction between MAIT cells and NKT cells. Notably, an elevated expression of PD-1 in MAIT cells and NKT cells was associated with SLE. In RA patients, MAIT cell levels were significantly higher in synovial fluid than in peripheral blood.

**Conclusion:** Our study primarily demonstrates that MAIT cells are numerically and functionally deficient in SLE. In addition, we report a novel finding that this MAIT cell deficiency is associated with NKT cell deficiency and elevated PD-1 expression. These abnormalities possibly contribute to dysregulated mucosal immunity in SLE.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IgG4-related disease (IgG4-RD) is a disorder characterized by elevated serum IgG4 concentration and infiltration of IgG4-positive plasma cells into affected organs, however, the role of IgG4 in the pathophysiology of IgG4-RD is not sufficiently elucidated. Although animal models are required, mice only have IgG1, 2 and 3 subclasses but no IgG4. Therefore, we invented human IgG4 (hIgG4)-knock-in (KI) mice and evaluated their phenotypes.

**Methods:** The hIgG4 gene is inserted in the cite of mouse IgG1 (mIgG1) gene, which is promoted by Th2 cells associated with the pathophysiology of IgG4-RD. In order to preserve the rearrangement system of VDJ region of IgH gene, constant region of hIgG4 gene was only transfected into ES cells of C57BL/6 mice by gene targeting method. 1) We quantitated levels of mRNA extracted from spleens of homozygous (Homo) and heterozygous (Hetero) IgG4-KI mice by quantitative PCR method. 2) Serum IgG4 levels in Homo, Hetero and wild-type (WT) mice were quantitated by ELISA and turbidimetric immunoassay (TIA) used in daily clinics. 3) To enhance the production of IgG4, we established MRL-lpr/IgG4-KI mice and analyzed them by ELISA and flow cytometry (FCM).

**Results:** 1) Expression of hIgG4 mRNA, mIgG1 mRNA and hIgG4+mIgG1 mRNA were detected in the spleen of Homo, WT and Hetero mice, respectively. 2) hIgG4, mIgG1 and hIgG4+mIgG1 proteins were detected in sera of Homo, WT and Hetero mice, respectively (Fig. 1). Serum hIgG4 level in Homo mice was 7.0 mg/dL by TIA (Table 1). 3) Serum hIgG4 level in MRL-lpr/IgG4-KI Homo mice was increased to 289 mg/dL. We detected the spleen cells that express IgG4 on surface by FCM.

**Conclusion:** The transfected IgG4 gene seemed to work physiologically, as we confirmed secretory IgG4 in blood and membranous IgG4 on spleen cells in the mice. Serum IgG4 level was high in MRL-lpr/IgG4-KI mice. Their histopathology is to be examined.

Table 1. Serum hIgG4 titer by TIA

	B6/WT	B6/IgG4-KI Homo	MRL-lpr	MRL-lpr/IgG4-KI
hIgG4 (mg/dL)	Not detected	7.0	Not detected	289

## Clinical Significance of Anti-Dense Fine Speckled 70 and Dense Fine Speckled Pattern in Diagnosis of Systemic Autoimmune Rheumatic Disease

**You La Jeon**<sup>1</sup>, Ji Yun Ryu<sup>1</sup>, Jiyoung Baek<sup>1</sup>, Woo-In Lee<sup>2</sup>, Myeong Hee Kim<sup>1</sup> and So Young Kang<sup>1</sup>, <sup>1</sup>Department of Laboratory Medicine, School of Medicine, Kyung Hee University and Kyung Hee University Hospital at Gangdong, Seoul, Korea, Republic of (South), <sup>2</sup>School of Medicine, Kyung Hee University and Kyung Hee University Hospital at Gangdong, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The dense fine speckled (DFS) pattern in IIF-ANA on HEp-2 cell is perhaps the most frequently observed pattern in most clinical laboratories. The DFS70 or lens epithelium-derived growth factor p75 (LEDGFp75) is the known corresponding antigen to the DFS pattern. Identification of this antibody can be an evidence to exclude the presence of systemic autoimmune rheumatic diseases (SARD), however this correlation requires more definite clinical correlation. The aim of our study is to confirm the presence of anti-DFS70 in specimens showing DFS pattern by western blot (WB) and enzyme immunoassay (EIA). Also the association between the anti-DFS70 and SARD or certain clinical conditions is discussed.

**Methods:** A total of 227 serum specimens showing DFS (n=180, only DFS (158) and DFS+other (22)) and homogeneous (H) (n=47, only H (33) and H+other (14)) patterns in IIF-ANA screening test were included. All specimens were tested twice by IIF-ANA and the results interpreted by two separate expert specialists of Laboratory Medicine. The cases with discrepant results between the two interpreters were excluded. The results of first and second test results of IIF-ANA were compared. In-house WB was performed using deriving cell lysate from cultured HeLa cells. Detection of anti-DFS70 IgG was done using a commercial EIA kit. The clinical information regarding disease status or the presence of SARD of subjects was obtained from retrospective review of individual medical records.

**Results:** Forty four cases (19.4%) showed discrepant reading in their repeated IIF-ANA test results. The majority of those results included the following: 19 cases (DFS pattern in first test result then interpreted as another in second test result, especially 14 cases as H pattern), 9 cases (from DFS pattern to negative), and 13 cases (changed with only combined pattern). There were also 17 other cases in which the results were complex and indeterminable. Among 155 cases with DFS pattern in the second test results of IIF-ANA, 134 cases (86.5%) were positive by WB and 114 cases (73.5%) positive by EIA. WB had covered all cases in which this autoantibody was detected. The number of cases detected of anti-DFS70 are divided into three groups which are as follows; 114 (73.5%) in WB+/EIA+,

20 in WB+/EIA-, and 21 in WB-/EIA-. There was no case which showed only EIA positivity. More than half of the patients from each group were referred to the department of dermatology, where many were given their diagnoses of androgenic alopecia. SARD patients with DFS pattern were 1 (SLE) in WB+/EIA+, 3 (1 SSc, 2 RA) in WB+/EIA-, and 1 (RA) in WB-/EIA-.

**Conclusion:** The prevalence of SARD (2.2%) was very low in this study of randomly selected 180 DFS and 47 H pattern cases. This result suggests the utility of anti-DFS70 to exclude SARD when detected. DFS pattern can also provide a clue to exclude SARD based on the results that anti-DFS70 was detected in 86.5% of cases with DFS pattern given that IIF-ANA tests were conducted twice and interpreted carefully by two separate specialists. However presence of a confusing pattern or the absence of monospecific anti-DFS70, additional tests are necessary to rule out the diagnosis of SARD.

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Auto-immune diseases are in constant progression in the US. Biologic therapeutics have been used successfully to treat these diseases, but have presented some unique regulatory challenges. Although they can be very efficacious, the response to these therapeutics can initially be quite variable among patients and patients who are initially responsive can develop resistance to them over time. We propose that the gut microbiome could play a role in the initial variability and impact the response to treatments.

**Methods:** Germ Free (GF) mice colonies have been successfully developed in a sterile environment in the CBER/CDER Animal Facility. We used these GF mice to test human monoclonal antibodies and fusion proteins, following a treatment regimen consistent with patient regimens, to evaluate the role of the microbiome when GF mice are compared to conventional mice controls treated in parallel. Our pilot study is analyzed from two different approaches: assessment of taxonomy changes and an immunologic variation in the mouse gut.

**Results:** Our results show a break in the symbiosis of the commensal bacteria communities after TNF antagonist treatment. These mice present a shift in the ratio Firmicutes/Bacteroidetes with a statistically significant increase in this latter family over uncultured bacteria. Differences are reported between males and females and between young (3 month-old) and old (9 month-old) mice. When the mucosal immune system is explored, comparing conventional and GF mice, it appears that the Innate Lymphoid Cells (ILCs) colonizing the lamina propria of the gut have two very different profiles and therefore, are likely to respond differently to cross-talk with commensal bacteria in the gut. A preliminary mechanistic link to the plasticity between ILC1 and LC3 is suggested in older mice.

**Conclusion:** Our results show that the Microbiota indeed plays a regulating role in TNF antagonist treatment, involving a dysbiosis and a regulation through ILCs. This observational study should be followed by *in vivo* functionality studies.

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Sjögren's syndrome (SS) is a chronic inflammatory, autoimmune disorder characterized by diminished lacrimal and salivary gland secretion resulting in keratoconjunctivitis sicca and xerostomia. Autoantibodies, directed against 60 kD Ro protein is found in up to 90% of patients with SS. Free radical mediated oxidative damage has not been well characterized previously in SS. Therefore, we studied oxidative damage (conjugate diene formation) and modification of serum proteins by the lipid peroxidation by-product 4-hydroxy-2-nonenal (HNE) or malondialdehyde (MDA) in SS and age-and sex matched controls.

### Methods:

Sixty nine primary SS subjects, 25 age and sex matched subjects that do not meet criteria (incomplete SS), and 18 normal controls were studied. We studied indices of oxidative damage, namely conjugate diene formation, and HNE or MDA-protein adducts in the sera of SS, incomplete SS and normal controls. Sera from SS subjects or normal controls were coated on ELISA plates as antigen. HNE or MDA adducts in serum proteins was determined with rabbit anti-HNE or anti-MDA antibodies purchased commercially. Sera from SS or normal controls were electrophoresed, transferred to nitrocellulose by electroblotting and subjected to immunoblotting with rabbit anti-HNE antibody. For determination of conjugate diene, 25 µl of SS or incomplete SS sera were extracted with chloroform:methanol (2:1) and the samples were centrifuged. Two ml of the clear supernatant was evaporated to dryness at 45°C and reconstituted in one ml methanol. The spectra ranging from 200 to 360 nm was read using a spectrophotometer.

### Results:

We found significantly increased oxidative damage in the sera of primary SS subjects compared to normal controls by ELISA and immunoblotting. Serum proteins from SS subjects were found to contain HNE adducts. There was significantly more HNE-modified proteins in SS sera (n=10) compared to controls (n=10; age and sex matched) by ELISA ( $0.074 \pm 0.017$  versus  $0.046 \pm 0.007$ ;  $p=0.00015$ ; average OD $\pm$ SD). However, there was no significant difference in MDA-modified proteins between SS and controls by ELISA. When SS sera (n=34) were analyzed by immunoblotting, we found HNE adducts in several serum proteins, and significantly in a 18 kD protein. Control sera did not show significant HNE-modification (n=8). Our preliminary results for conjugate diene formation show that there is no significant difference between conjugate diene levels in the Sjogren's syndrome patients (n=25) and incomplete SS subjects (n=25). We are pursuing HNE-modification in the sera of incomplete SS subjects and also identifying the protein bands in SS subjects with HNE adducts by matrix assisted time of flight mass spectrometry.

### Conclusion:

Significantly elevated HNE- but not MDA-protein adducts occur in the sera of SS subjects compared to normal controls, showing that oxidative damage occurs in SS.

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The antiphospholipid syndrome (APS) is an autoimmune condition characterized by thrombosis, pregnancy complications and the presence of antiphospholipid antibodies. Basophils, which have long been associated with allergy and parasitic infections, are known to be activated and able to enhance the production of autoantibodies in autoimmune diseases, particularly in systemic lupus erythematosus (SLE). Herein we investigated the role of basophils in APS.

### Methods:

Peripheral basophils of patients with primary APS, SLE-associated APS (SLE-APS), and healthy controls (HC) were analyzed using flow cytometry.

**Results:** Forty-three consecutive patients with APS, including 10 patients with SLE-APS, and 20 HC were recruited. None of the patients was treated with corticosteroids or immunosuppressants. Thirty-five (81.4%) patients had lupus anticoagulant, 33 (76.7%) had anti-cardiolipin antibodies, and 24 (55.8%) had anti-β<sub>2</sub> glycoprotein I. Twenty (46.5%) patients had obstetric APS, 20 (46.5%) patients experienced arterial thrombosis and 19 (44.2%) patients experienced venous thrombosis. Six patients (14%) had a catastrophic APS (CAPS). Basophil activation markers revealed a decreased proportion of CD193<sup>+</sup> basophils in patients with APS vs HC (63.0% [27.3 – 85.0] vs 90.4% [74.1 – 97.1]; p < 0.05) and an increased mean fluorescence intensity (MFI) of CD69 within basophils in patients with APS vs HC (839 [436 – 1434] vs 318 [103 – 755]; p < 0.05). Basophils functional markers revealed a decreased proportion of CD62L<sup>+</sup> basophils in APS vs HC (99.0% [95.6 – 100] vs 100% [99.6 – 100]; p < 0.05), and an increased proportion of HLA-DR<sup>+</sup> basophils in APS vs HC (32.3% [16.8 – 77.2] vs 10.0% [3.4 – 21.7]; p < 0.05). There was no difference between patients with APS and patients with SLE-APS, or patients with CAPS. When compared to patients without obstetric APS, patients with obstetric APS (46.5%) had a decreased proportion of CD196<sup>+</sup> basophils (25.5% [11.3 – 32.5] vs 31.9% [25.8 – 66.3]; p < 0.05), an increased proportion of CD63<sup>+</sup> basophils (34.8% [0.25 – 53.3] vs 7.4% [0 – 37.9]; p < 0.05), and an increased proportion of HLA-DR<sup>+</sup> basophils (49.0% [23.4 – 79.6] vs 20.8% [8.7 – 70.8]; p < 0.05). Lastly, the proportion of CD154<sup>+</sup> basophils was higher in patients who experienced miscarriages than those who did not (47.6% [38.2 – 56.1] vs 19.7% [5.1 – 35.8]; p < 0.01) and MFI of basophil CD62L was higher in patients who experienced fetal death in utero than those who did not (11823 [9862 – 15546] vs 7978 [4628 – 10160]; p < 0.05).

### Conclusion:

Main phenotypic characteristics of basophils in APS are an increased expression of CD69 marker, a decreased expression of CD193 marker, and an increased expression of HLA-DR marker suggesting a role for basophils. Patients with obstetric APS differed from other APS patients by a skewed distribution of CD196<sup>+</sup>, CD63<sup>+</sup> and HLA-DR<sup>+</sup> basophils.

## Increased Susceptibility of SLE-Prone Mice to Pulmonary *Haemophilus Influenzae* Infection Was Attributed to Dysfunctions of Innate Immune Responses

**Wenchao Li** and Lingyun Sun, Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Aside from the disease itself, infections represent the major cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients. Although the daily usage of immunosuppressive drugs is considered to be responsible for the increased rates of infection, inherent defects in immune system should not be overlooked.

**Methods:** To better understand the proclivity of SLE patients to suffer infections, we infected lupus-prone mice B6/*lpr* with 1X10<sup>8</sup> CFU of *Haemophilus influenzae* (Hi) intranasally and monitored bacterial clearance, body weight change and lung pathology after infection. Apoptosis of lung cells was analyzed by TUNEL assay. Immune cells recruited by infection were determined by flow cytometry. Cytokines in the bronchoalveolar lavage fluid (BALF) were measured by ELISA.

**Results:** Although both wild-type (WT) and B6/*lpr* mice survived after pulmonary Hi infection, a delay of bacterial clearance and inflammatory resolution was observed in B6/*lpr* mice (Fig1A-C). Besides, tissue damage was more severe in B6/*lpr* mice, as more apoptotic cells appeared in the lung on D2 after infection (Fig1D). When looked at the cytokine production, we found that cells from lupus-prone lungs produced much more proinflammatory cytokines IL-6, IL-17 and chemokines MCP-1 and KC. However, TNF- $\alpha$  is comparable between the two groups (Fig2). NK,  $\gamma\delta$  T and CD4 T cells are very important in control of bacterial infection. Here, we showed that compared with WT controls, in response to infection fewer NK cells were detected in B6/*lpr* lungs. The numbers of  $\gamma\delta$  T and CD4 T cells in the lung were not different, but their ability to secrete IFN- $\gamma$  was significant lower in B6/*lpr* mice (Fig3).

**Conclusion:** The increased susceptibility of SLE-prone mice to pulmonary *Haemophilus influenzae* infection may due to the elevated inflammatory responses and the deficiency of immune cells.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous reports showed that peptidylarginine deiminase (PPAD) from *Porphyromonas gingivalis* (*P.g.*) is not able to citrullinate proteins internally. Mutated PPAD (mPPAD) from *P.g.* involved in periodontal disease (PD) cloned out of *P.g.* strain was characterized and analyzed for its reactivity in sera from patients with systemic autoimmune diseases.

**Methods:** We cloned an enzymatically active recombinant mPPAD from *P.g.* Mutations and citrullination sites were analyzed by DNA sequencing and protein mass spectrometry (MS). Autocitrullination activity, its enzymatic-activity and human autoantigen protein citrullination was investigated by 2D-Elektrophoresis, MS, immunoblot analysis and ELISA. Furthermore we tested anti-mPPAD/cit-mPPAD with human sera (n=123) from early rheumatoid arthritis (RA) before and after onset of RA (n=30), established RA (n=32), systemic lupus erythematosus (n=15), osteoarthritis (n=16) and healthy blood donors (n=30) in ELISA assays. In RA mouse model collagen antibody-induced arthritis (CAIA), mPPAD-containing vesicles from *P.g.* were injected by intraperitoneal injection (IP).

**Results:** Recombinant mPPAD lacks 43 amino acids at the N-terminus and exhibits so far two new amino acid mutations (aminoacid position 73 (F>L) and 447 (E>V). We were able to demonstrate, mPPAD is enzymatically active over a huge pH-range (3-10) and autocitrullinates at amino acid position 63 the arginine to citrulline. Moreover mPPAD citrullinates major autoantigens in RA (Fibrinogen, Vimentin and hnRNP-A2/B1) which are detectable by RA patient sera and specific anti-citrulline monoclonal antibodies. MPPAD citrullinates HeLa-protein extracts and these specific citrullinated proteins are recognized by RA patient sera. Anti-citrullinated mPPAD antibodies were detected in 41% (n=32) of patients with RA but not in SLE (n=15), OA (n=16) and control sera (n=16). In an RA follow-up study (n=30), we detected nearly similar antibody-sensitivities for citrullinated mPPAD before and after onset of RA (13/20%). Only a minority (7%) of RA patients show higher mPPAD antibody levels after RA diagnosis. In the CAIA RA mouse model mPPAD containing *P.g.* vesicles when injected IP showed a TLR2-dependent protective anti-inflammatory effect like *P.g.* LPS and Lipomannan.

**Conclusion:** *P.g.* infection and RA disease diagnosis occurs at different time points and *P.g.* infection induces a TLR2-dependent protective anti-inflammatory effect. We show the first time that mPPAD can citrullinate major human autoantigens internally and their immunologically and diagnostic relevance in RA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary Sjögren's syndrome (pSS) is a complex heterogeneous systemic autoimmune disease. Biomarkers for patient stratification are scarce. Several single nucleotide polymorphisms within type I interferon (IFN) signaling pathways are associated with pSS. To define novel biomarkers for pSS patient stratification, we analyzed the temporal profile of MAPK/ERK and JAK/STAT signalling networks in PBMCs upon stimulation with IFN $\alpha$  by flow cytometry.

**Methods:** PBMCs from pSS patients and healthy matched donors were stimulated for 15, 30, 60, 120, 180, and 240 min with IFN $\alpha$  at 100 ng / ml. Nine different phospho epitopes were measured, STAT4(pY693), ERK1/2(pT202/pY204), NF- $\kappa$ B p65(pS529), STAT1(pS727), STAT1(pY701), p38 MAPK(pT180/pY182), STAT3(pS727), STAT3(pY705) and STAT5(pY694). Cell surface markers were CD3, CD20 and CD56.

**Results:** Cells from pSS patients display significant differences in basal and IFN $\alpha$  induced phosphorylation levels of numerous signaling proteins compared to cells from healthy donors. PCA using IFN $\alpha$  induced phosphorylation levels after 15 minutes showed clustering of pSS patients and pSS patient subgroups. PCA visualization showed a positive shift for pSS samples away from healthy donor samples with positive movement influenced by changes in phosphorylation of STAT1 Y701 in T, NK and B cells in PC1, and PC2 positive movement influenced by STAT1 Y701 in NK and B cells, and negative movement by STAT3 S727 in T cells. Medicated and SSA- patients grouped closer to healthy donors than non-medicated or SSA+ patients.

**Conclusion:** pSS patients show increased responses to IFN $\alpha$  through STAT1. Increased responses to IFN $\alpha$  may in part drive an up-regulation of interferon induced genes.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by immune complex- deposition in the synovium, leading to increased bone destruction. In RA, joint destruction has been associated with high cholesterol levels, largely transported in low density lipoprotein (LDL) particles and enhanced LDL oxidation (oxLDL). Apolipoprotein E (Apo E) is an important regulator of LDL transportation and its absence strongly elevates LDL levels in the serum, which may lead to increased oxLDL levels during inflammation. In this study, we investigated the effects of high LDL levels on bone destruction during antigen-induced arthritis (AIA), which is largely immune complex driven and how increased LDL/oxLDL levels affect osteoclast formation.

**Methods:** AIA was induced by injection of methylated BSA (mBSA) into the right knee joint of Apo E<sup>-/-</sup> and wild type (WT) control mice previously immunized with mBSA and complete Freund's adjuvant (CFA). WT and ApoE<sup>-/-</sup> Hoxb8 myeloid precursor cells were differentiated into osteoclasts using 20 ng/mL RANKL and 30 ng/mL M-CSF, then stimulated for 24h with 10  $\mu$ g/mL LDL/oxLDL. Oil Red O staining was performed to assess lipid uptake by osteoclasts. mRNA levels of NFATc1, DC-STAMP, TRAP, CTR and Cat K were measured by qPCR, whereas TRAP activity in culture supernatants was detected using a spectrophotometric assay. Bone erosion was quantified by histological analysis using an arbitrary scale from 0 to 3 and TRAP<sup>+</sup> cells were determined using immunohistochemistry.

**Results:** Apo E<sup>-/-</sup> mice showed significantly higher LDL serum levels than WT controls. Histology showed that at day 21 after AIA induction, bone destruction was significantly decreased in the Apo E<sup>-/-</sup> mice, as indicated by the reduction of erosion pits (25% reduction from 1.5±0.2 to 1.1 ±0.1). ). In line with that, ApoE<sup>-/-</sup> mice showed a lower number of osteoclasts within the knee joints (36% lower from 20±4 osteoclasts/section in WT mice to 12±5 in ApoE<sup>-/-</sup> mice), as determined by image analysis of TRAP staining. To study the role of ApoE and high LDL levels on osteoclastogenesis in more detail, we differentiated WT and ApoE<sup>-/-</sup> myeloid precursor cells (Hoxb8) into osteoclasts and found similar mRNA levels of osteoclast markers. Whereas the number of osteoclasts was comparable between WT and ApoE<sup>-/-</sup> osteoclasts, we observed significantly decreased mRNA expression of TRAP (2.6 fold decrease) in ApoE<sup>-/-</sup> cells as compared to WT cells. In line with this, TRAP activity was reduced by 49%, suggesting a decreased osteoclast activity in ApoE<sup>-/-</sup> cells. Stimulation of osteoclasts by oxLDL strongly impaired cell fusion keeping them in a mononuclear state. mRNA levels of DC-STAMP were significantly down-regulated in both WT and ApoE<sup>-/-</sup> osteoclasts (1.4 and 2.3 fold decrease, respectively) as well as TRAP activity (49% and 58% reduction in WT and ApoE<sup>-/-</sup> osteoclasts, respectively), indicating a major role of oxLDL in the inhibition of osteoclastogenesis.

**Conclusion:** High LDL/oxLDL levels by apoE deficiency affect bone destruction by reducing the number of osteoclasts within the synovium during AIA probably by interfering osteoclastogenesis.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Behçet disease (BD) is a rare, systemic, inflammatory disorder with multiorgan damage and various clinical manifestations such as oral ulcers, genital ulcers and uveitis. Pathogenesis is still unknown but it is considered a MHC-I-opathy<sup>1</sup>. Despite HLA-B51 and some gene polymorphisms have been associated with BD<sup>2</sup>, the diagnosis is based on clinical parameters and currently laboratory tests are only of a little help in the diagnosis of BD. The aims of this study were: 1) to increase the knowledge about BD pathogenesis; 2) to identify laboratory tests which can support BD diagnosis.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were collected from 40 BD patients (according to 1990 ISGB criteria) and 15 healthy subjects, aged and sex matched, used as controls. The frequency of Natural Killer (NK), Natural Killer T cells (NKT) and T cells expressing the Natural Killer Group 2D activating receptor (NKG2D) was assessed by flow cytometry using anti-CD56, anti-CD3 and anti-NKG2D antibodies. NK, NKT and T cells were defined as CD56<sup>+</sup>CD3<sup>neg</sup>, CD56<sup>+</sup>CD3<sup>+</sup> and CD56<sup>neg</sup>CD3<sup>+</sup> cells respectively. Cytotoxic potential of NK cells was evaluated by flow cytometry as the percentage of cells expressing on their surface the degranulation marker CD107a, after incubation with K562 cells, optimal target for NK cell activation<sup>3</sup>. Statistical analyses were performed by Mann-Whitney and Spearman test. P-values less than 0.05 were considered statistically significant.

**Results:** A significant increase in the percentages of NKG2D<sup>+</sup> lymphocytes in the NK, NKT and T lymphocyte gates was detected in BD patients respect to healthy subjects ( $P < 0.01$ ). ROC curve analysis showed that the evaluation of NKG2D<sup>+</sup> NKT cell percentage better allowed to discriminate between BD patients and healthy subjects ( $AUC = 0.7385$ ;  $P = 0.0071$ ). In particular, a frequency higher than 75% could identify BD patients with a 93.3% specificity and 38.5% sensitivity. After incubation of PBMCs with K562 cells, a significant higher frequency of NK cells expressing CD107a was detected in BD patients respect to healthy subjects (13.4% versus 9.5%,  $P = 0.0124$ ). In BD patients we also observed a correlation between frequencies of NK cells positive for NKG2D and CD107a ( $r = 0.3573$ ;  $P = 0.0255$ ). Instead the median percentages of NKT and T cells expressing CD107a was low: 0.88% and 0.51% and similar between groups.

**Conclusion:** We found that expression of NKG2D by NK, NKT and T lymphocytes might be involved in the pathogenesis of BD in a subset of patients. BD patients were also characterized by a higher cytotoxic potential of NK cells than healthy subjects. We can speculate that NK and NKT cells of BD patients are more prone to respond to stress signals when exposed on target cells leading to cyclic auto-inflammation. Monitoring both the frequencies of NKT cells positive for NKG2D and of NK cells positive for CD107a after activation with K562 cells could help to identify BD patients.

## TGF- $\beta$ 1 Induces AXL in Murine and Human Synovium and Protects Ankle Joints, but Not Knee Joints, during Murine Inflammatory Arthritis

Claire E.J. Waterborg, Mathijs G.A. Broeren, Esmeralda N. Blaney Davidson, Marije I. Koenders, Peter L. van Lent, Peter M. van der Kraan and Fons A.J. van de Loo, Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) manifests in a symmetrical fashion in anatomically distinct synovial joints. The innate immune system, which plays a crucial role in the pathogenesis of RA, is regulated by anti-inflammatory feedback mechanisms such as the tyrosine kinase receptor family TYRO3, AXL and MER. Of importance, AXL is mainly expressed on sentinel cells. We investigated the synovial expression of AXL and its putative anti-inflammatory role in a macrophage-dependent model of arthritis.

**Methods:** Tissue sections of ankle and knee joints of naïve mice were studied for protein expression of AXL. KRN serum transfer arthritis was induced in *Axl*<sup>-/-</sup> and wild-type (WT) mice. Ankle and knee joints were assessed macroscopically and histologically. Naïve WT mice were injected intra-articularly in the knee joint with adenoviruses overexpressing active TGF- $\beta$ 1 or Luciferase. Protein expression of AXL on tissue sections and/or gene expression in synovial biopsies from naïve, arthritic and adenovirus-treated ankle and/or knee joints was examined. Human RA synovium was examined for gene expression. Human monocyte-derived macrophages were treated with recombinant TGF- $\beta$ 1.

**Results:** When examining naïve murine joints, synovial cells of the ankle joints were AXL positive, but knee joints of the same mice were not, indicating a profound difference between these two weight-bearing joints. To examine whether AXL played a protective role during arthritis, we induced arthritis in *Axl*<sup>-/-</sup> and WT mice. The ankle joints of *Axl*<sup>-/-</sup> mice showed an increased macroscopic disease

score during arthritis development ( $p < 0.001$  at day 7). In agreement with this, histology of ankle joints showed significantly increased arthritis pathology in *Axl*<sup>-/-</sup> mice. No effect of *Axl* gene deletion was observed on gonarthritis pathology and the synovial expression of inflammatory genes. To unravel the cause for the noteworthy difference in AXL expression between knee and ankle, we investigated the role of TGF- $\beta$ , a factor known to induce AXL. As hypothesized, *Tgfb1* expression was significantly higher in synovium of ankle compared to synovium of knee joints in naïve mice ( $p < 0.01$ ), which correlated with *Axl* expression (Pearson  $r = 0.8860$ ,  $p = 0.0012$ ). In addition, adenoviral overexpression of *TGFB1* induced AXL expression in synovium of knee joints ( $p < 0.05$ ), a tissue devoid of AXL during homeostasis. The TGF- $\beta$ 1-induced AXL expression appeared to be conserved in humans. We observed a correlation between *TGFB1* and AXL expression in human RA synovium (Pearson  $r = 0.7233$ ,  $p = 0.0035$ ) and TGF- $\beta$ 1 stimulation enhanced the expression of AXL in human macrophages ( $p < 0.01$ ).

**Conclusion:** Our study shows remarkable differences in synovial AXL expression between ankle and knee joints and this is in accordance with the observation that AXL dampens arthritis in ankle but not in knee joints. We provide evidence that these local differences in AXL are due to TGF- $\beta$ 1. It is tempting to speculate that the differences in AXL expression and its innate immune protective effector role could explain the lower arthritis incidence in ankle joints compared to other weight-bearing joints in humans (reviewed in DiStefano and Pinney. Semin Arthro. 2010).

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The pathogenesis of Systemic Lupus Erythematosus (SLE) involves complement activation. It is well established that activation of complement through the classical pathway (CP) and deficiencies of this pathway are associated with SLE. Our knowledge about the Lectin Pathway (LP) of complement activation in relation to SLE is very limited. Since the LP is also activated through pattern recognition of, i.e., intracellular components and apoptotic cells, we hypothesize that this pathway is also activated in SLE and could have similar implications as the CP in the development of SLE.

### Methods:

We examined the 11 known LP proteins in a large well-defined SLE cohort of 372 SLE patients and 170 controls. We estimated LP protein concentrations using in house developed time resolved immuno-fluorometric assays (TRIFMA). We assessed if changes in concentrations were associated with complement activation and disease activity based on C3 measurements. To follow the protein concentrations over time in relation to disease activity, a cohort of 52 SLE patients followed for five years with repeated blood samples were additionally included.

## Results:

Concentrations of the LP proteins were altered in a specific pattern in this cross sectional SLE cohort compared with the controls. The differences in LP proteins observed between patients and controls were associated with complement activation and disease activity based on C3 measurements and SLEDAI. M-ficolin, CL-L1, CL-K1, MASP-3 and MASP-19 showed a significant negative correlation with disease activity. When followed over time the concentrations of several LP proteins correlated with SLEDAI and particularly the serine protease, MASP-2, increased with SLE disease activity.

## Conclusion:

In this large SLE cohort, specific changes in LP proteins were associated with complement activation and disease activity, indicating that the LP is activated in patients with SLE. These novel findings substantiate the involvement of the LP of complement activation in the complex pathogenesis of SLE.

## Initial Combination Therapy Versus Step-up Therapy Is More Effective and Less Costly As a Treat to Target Strategy for RA: A Markov Model Based upon the Dutch Rheumatoid Arthritis Monitoring Registry Cohorts

Celine J. van de Laar<sup>1</sup>, Laura M.M. Steunebrink<sup>2</sup>, Martijn A.H. Oude Voshaar<sup>3</sup> and Harald E. Vonkeman<sup>4</sup>, <sup>1</sup>Transparency in Healthcare B.V., Hengelo, Netherlands, <sup>2</sup>Medisch Spectrum Twente - Arthritis Center Twente, Enschede, Netherlands, <sup>3</sup>University of Twente, Department of Psychology, Health and Technology, Enschede, Netherlands, <sup>4</sup>koningsplein, Medisch Spectrum Twente - Arthritis Center Twente, Enschede, Netherlands

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Adjusting medication of patients with rheumatoid arthritis (RA) until predefined disease activity targets are met, i.e. Treat to Target (T2T), is the currently recommended treatment approach. However, not much is known about long-term cost-effectiveness of different T2T strategies.

We model the 5-years costs and effects of a step-up approach (MTX mono -> MTX + csDMARD combination -> Adalimumab -> second anti-TNF- $\alpha$ ) and an initial combination therapy approach (MTX + csDMARD + prednisone if needed -> MTX + csDMARD high dose -> anti-TNF- $\alpha$ 's) from the healthcare and societal perspectives, by adapting a previously validated Markov model.

## Methods:

We constructed a Markov model in which 3-monthly transitions between DAS28-defined health states of remission ( $\leq 2.6$ ), low ( $2.6 < \text{DAS28} \leq 3.2$ ), moderate ( $3.2 < \text{DAS28} \leq 5.1$ ), and high disease activity ( $\text{DAS28} > 5.1$ ) were simulated. Hypothetical patients proceeded to subsequent treatments in case of non-remission at each (3-month) cycle start. In case of remission for two consecutive cycles medication was tapered, until medication-free remission was achieved. Transition probabilities for individual treatment steps were estimated using data of Dutch Rheumatology Monitoring registry Remission Induction Cohort I (step-up) and II (initial combination). Expected costs, utility, and the ICER after 5 years were compared between the two strategies. To account for parameter uncertainty, probabilistic sensitivity analysis was employed through Beta, Normal, and Dirichlet distributions. All utilities, costs, and transition probabilities were replaced by fitted distributions.

## Results:

Over a 5-year timespan, initial combination therapy was less costly and more effective than step-up therapy. Initial combination therapy accrued €16226.3 and 3.552 QALY vs €20183.3 and 3.517 QALYs for step-up therapy. This resulted in a negative ICER, indicating that initial combination therapy was both less costly and more effective in terms of utility gained. This can be explained by higher ( $\pm 5\%$ ) remission percentages in initial combination strategy at all time points. More patients in remission means less healthcare and productivity loss costs and more accumulated utility. Additionally, higher remission percentages caused less bDMARD use in the initial combination strategy, again lowering overall costs.

## Conclusion:

Initial combination therapy was found to be favourable over step-up therapy in the treatment of Rheumatoid Arthritis, when considering cost-effectiveness. Initial combination therapy resulted in more utility at a lower cost over 5 years.

Figure 1: Cost-effectiveness plane comparing initial combination and step-up therapy

X-axis: incremental effect (Quality-Adjusted Life Years). Y-axis: Incremental cost (€'s). Probabilistic sensitivity analysis shows initial combination strategy is cost-effective.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The purpose of the T2T approach in RA is to achieve remission or LDA according to results from objective activity measurements. This strategy has proven clinical benefits, however objective adherence T2T measurement tools are lacked in daily practice. Objectives: To evaluate the setting, usage of a T2T adherence measure: T2T70 and T2T100, and its association with sustained low disease activity (LDAS) as a measure of outcome.

**Methods:** Prospective study, consecutive patients with RA diagnosis (ACR / EULAR 2010) and follow-up between 1 and 24 months were included. Data from electronic medical record (EHR) were collected. Demographic variables, characteristics of the disease and treatment were recorded. The following T2T characteristics were defined and collected from each patient: number of visits, visits where treatment was adjusted, CDAI measurements, use of ultrasound to measure disease activity and achievement of LDA. Sustained LDA (LDAS) was defined when the patient had 2 or more records of that consecutive state of activity. Measures of adherence to T2T were defined as follows: T2T-70, when therapeutic decisions were accompanied by the measurement of activity by 70% and the interval between visits did not exceed 6 months; And T2T-100, when 100% of the decisions were accompanied with the activity measurement and the interval between each visit did not exceed 6 months. Statistical analysis: a descriptive analysis of the variables was performed and Chi2 test (categorical) and Student or MannWhitney test (continuous) were applied. For multivariate logistic regression analysis we considered as dependent variable LDAS.

**Results:** 96 patients were included, with a mean follow-up of 15 months (DS 7.8), equivalent to 120.6 patients / year. Eighty percent of the patients were women, mean age 53.7 years (SD 13), disease duration 36 months (RIC, 12-52), 64% had early diagnosis, 85% and 75% positive For FR and ACPA, respectively. According to T2T characteristics, 526 visits were recorded, 270 were treatment adjustment and 208 (78%) of them were performed according to the CDAI value. The frequency of LDAS was 20% (IC95: 12-30). The frequency of T2T-70 compliance was 62.5% (IC95: 52-72) and T2T-100 was 42% (IC95: 32-52). Compliance with T2T-70 and T2T-100 presented a statistically significant association to the achievement of LDAS in the uni and multivariate analysis (p: 0.000). Compliance with T2T-70 and T2T-100 was associated with a shorter time course of disease; And T2T-70 also showed association with early diagnosis.

**Conclusion:** T2T-70 and T2T-100 adherence were 62% and 42%, respectively, patients who met these criteria reached more LDAS. The early diagnosis and shorter time to disease evolution at baseline were variables that were associated with more compliance of these tools.

## Electronic Patient Reported Outcomes Increase Pediatric Rheumatology Clinic Operations Efficiency While Increasing Patient and Caregiver Satisfaction

Y. Ingrid Goh<sup>1</sup>, Talia Goldberg<sup>2</sup>, Nicholas Lao<sup>3</sup> and Brian M. Feldman<sup>4</sup>, <sup>1</sup>Child Health Evaluative Sciences, The Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>University of Toronto, Toronto, ON, Canada, <sup>3</sup>University of Western Ontario, London, ON, Canada, <sup>4</sup>Rheumatology, The Hospital for Sick Children, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Electronic Patient Reported Outcomes Increase Pediatric Rheumatology Clinic Operations Efficiency While Increasing Patient and Caregiver Satisfaction

**Background/Purpose:** Patient reported outcomes (PROs) are powerful tools that facilitate communication between patients and their healthcare team. In paper format, PROs may be incomplete, misplaced and incorrectly scored. Electronic version (e-form) of PROs may reduce the occurrence of these issues. As more healthcare institutions move toward electronic medical systems, it is important to assess its impact on healthcare. Not only is the system impact important, it is imperative to assess patients' and caregivers' perspective on these changes. The objectives of this study were to a) determine whether the e-form could improve efficiency; b) assess user satisfaction with the e-form; and c) identify additional improvements to the e-form.

**Methods:** An e-form of the Childhood Health Assessment Questionnaire (CHAQ) and the Quality of My Life (QoML) questionnaire was created in REDCap. Patients/caregivers attending the rheumatology clinic at The Hospital for Sick Children were asked to participate in this quality improvement study by completing both paper and e-form of the PROs (the order of which was determined by a table of random numbers). They were then asked to complete a satisfaction survey which asked them about their experience and for suggestions on how to improve the e-form. Changes in efficiency were compared by noting the time differences between both forms as well as calculating the annual differences in cost. Prior to comparing the times, 2.5 minutes were added to the paper form times to account for scoring and data entry times. Survey results were analysed using descriptive statistics and thematic identification.

**Results:** 197/209 participants completed both forms. The median times to complete the paper forms were longer than completing the e-forms (Table 1). This was more significant when paper forms were completed prior to e-forms.

The Division's costs for photocopying paper forms amounts to ~ \$1000/year, whereas the REDCap database cost ~\$300 to build and does not require any additional maintenance funding. Therefore, an e-form results in significant cost savings.

191/209 participants completed the satisfaction survey. 64% (122/191) respondents indicated that they preferred the e-form over the paper form.

Suggestions for improvements included improving the sliding scale mechanism and increasing the text size.

**Conclusion:** Implementation of an e-form resulted in greater efficiency—it was faster and saved money. Patients also liked it better. The e-form should be modified to reflect participants' suggestions and these modifications should be subsequently assessed.

Table 1. Time to complete paper vs. electronic form

	Randomized to Paper then Electronic Form		Randomized to Electronic then Paper Form	
	New Patient	Follow-Up Patient	New Patient	Follow-up Patient
N	17	86	20	74
Median time to complete paper form (mm:ss)	6:17	3:45	3:58	2:56
Median total time for paper form completion, scoring and data entry (mm:ss)	8:47	6:15	6:28	5:26
Median time to complete electronic form (mm:ss)	3:50	4:10	6:26	4:58
	P=0.0005	P=0.0002	P=0.99	P=0.06

## Improving Patient-Reported Outcomes Collection and Documentation for Patients with Rheumatoid Arthritis at Multilingual, Safety Net Hospital Rheumatology Clinic

Todd Liou<sup>1</sup>, Omotoke Odimeyomi<sup>1</sup>, Laura Trupin<sup>2</sup>, Jinoos Yazdany<sup>2</sup> and Mary Margaretten<sup>3</sup>, <sup>1</sup>University of California San Francisco, San Francisco, CA, <sup>2</sup>Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, <sup>3</sup>Medicine, University of California San Francisco, San Francisco, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Patient-Reported Outcomes Measurement Information System (PROMIS) Physical Function-10a (PF10a) survey is a reliable and valid measure of function in patients with rheumatoid arthritis (RA). National quality measures recommend that

patient-reported outcomes such as PROMIS PF10a be collected regularly in routine care. However, safety net health systems may face barriers in implementing PRO collection, including patients with low health literacy and limited English-language proficiency. Our objective was to increase collection and documentation of the PROMIS PF10a from 0% to 50% for all adult RA patient visits in our diverse, safety net clinic during a 9 month period.

**Methods:** We used the Institute for Healthcare Improvement's Model for Improvement and Plan-Do-Study-Act (PDSA) methodology over 4 cycles. In cycle 1, PF10a surveys were administered to English-speaking patients, after vitals were taken. Staff offered to read the survey to all patients, an approach commonly used to ensure patients with low health literacy feel comfortable participating. Cycle 2 separated the process of collecting PROMIS PF10a scores into two steps: (1) administering the survey throughout clinic workflow rather than only after vitals were taken and (2) uploading the score into the electronic health record (EHR), which were delegated to a high school research volunteer and medical assistants. Cycle 3 created a folder for the volunteer and medical student team to communicate and track weekly progress. In the final PDSA cycle, the forms were administered to Spanish-speaking patients by language concordant staff.

**Results:** Our rheumatology clinic has approximately 96 RA encounters per month and 70% of the patient population speaks languages other than English (the majority speaking Cantonese or Spanish). The quality improvement project began in the fall of 2016 and PROMIS PF10a score collection percentage was 12.5% after the first PDSA cycle. During the second cycle, the proportion of visits with a completed PROMIS PF10a rose to 22.2%. After the 4th PDSA cycle, there was a sustained improvement over 6 months, with 35.5% of RA patient visits having the PROMIS PF10a collected and recorded in the EHR (Figure).

**Conclusion:** Using an interprofessional team approach and the Model for Improvement, we significantly improved collection and documentation of the PROMIS PF10a measure in a multilingual safety net rheumatology clinic. Although we fell short of our goal of 50% of our RA patient visits, we were able to record the PROMIS PF10a measure for 48.6% of the 212 individual patients seen throughout the course of our project. Efforts are ongoing to expand collection to further engage our clinic staff and volunteers to create a sustainable PRO collection workflow.

Figure. PROMIS PF10a Administration RA Quality Improvement Project Run Chart (Nov 2016 - Mar 2017). 1-4 correspond to PDSA cycles. A is when research intern was absent due to a 3-week vacation.

### Responsiveness and Minimally Clinically Important Differences of PROMIS Measures in Rheumatoid Arthritis

**Background/Purpose:** The ability to detect meaningful change in clinical status (responsiveness) is an important aspect of validity. Minimally clinically important difference (MCID) is a patient-centered construct reflecting the smallest difference of value to patients. PROMIS is a generic family of measures developed for use across chronic diseases. We examined the responsiveness and estimated MCIDs of selected PROMIS measures reflecting domains that people with RA have identified.

**Methods:** Data are from the first two visits of an observational trial in Baltimore, MD. Patients completed PROMIS Physical Function (PF), Pain Interference (PI), Participation Ability (PA), and Fatigue computer adapted tests and other patient-reported outcomes (PROs) using a tablet. At the second visit, patients also completed a 5-point item assessing change in RA status from the previous visit (much worse to much better) and the self-reported health rating. Descriptive statistics were calculated, and ANOVA was used to identify significant differences in scores on 9 PROMIS measures.

**Results:** The 196 RA patients who completed outcomes at clinical visits approximately 4 months apart were mostly female (81%), white (82%) with a mean age of 55 (13). All met ACR 1987 or 2010 criteria for RA. One-third reported the same health status at both visits (68 [35%]); 13% were a little better; a similar number were much better; 27% were a little worse, and 7% were much worse. Correlations between PROMIS and other measures assessing similar domains ranged from 0.32 to 0.83. Among patients reporting being “much worse”, PROMIS scores worsened from 1.0 to 8.1 points (mean CDAI change 9.2)(Table). Among patients feeling much better, PROMIS scores improved from 1.6 to 6.9 points (mean CDAI change -6.6). Change in PROMIS scores were largest in relation to changing disease activity for symptoms highly relevant to RA (e.g., PI, fatigue, PF); notably patients with worsening in RA did not report higher anxiety or depression scores.

**Conclusion:** These initial data suggest PROMIS measures are responsive to clinical changes in RA status and contribute to the growing literature supporting the use of PROMIS measures to assess physical, social, emotional and health in people with RA.

Response Outcome	Anchor measure of change at Second Visit				
	Much Better (n=26)	A little better (n=25)	Same (n=68)	A little worse (n=52)	Much worse (n=13)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA) had profound negative effects on their health-related quality of life (HRQoL) that can be assessed using the 36 item Medical Outcome Study Short-Form survey (SF-36). Remission might have a different impact on patient's HRQoL depending on the specific disease diagnosis.

In 2004 and 1999, respectively, recent-onset rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) cohorts were initiated; the 36 item Medical Outcome Study Short-Form survey (SF-36) was incorporated to routine assessments from 2005 onwards in the SLE cohort and the SF-36v2 beginning from enrollment in the RA cohort. **Objectives of the study** were to compare the SF-36v2 scores between patients from both cohorts who achieved sustained remission (SR) and to define the role of disease diagnosis as associated to SF-36v2 normative data.

**Methods:** SLE and RA were diagnosed based on corresponding ACR classification criteria. Routine assessments were performed every 2-6 months and included at least the SLE disease activity index 2000 update (SLEDAI-2K) for SLE patients, and the Disease Activity Score (28 joints) (DAS28) for RA patients.

SR was considered when RA and SLE patients achieved at least 12 months of continuous follow-up with either SLEDAI-2K=0 or DAS28  $\leq 2.4$ , respectively. Up to December 2015, data from 172 RA patients and 211 SLE patients respectively, were reviewed.

SF-36v2 scores were available for the totality of SR assessments. The SF-36v2 licensee performed the re-scoring of the SF-36 that was used in the SLE cohort. In all the cases, Spanish (for México) versions were used and scoring was adjusted by gender and age. Logistic regression models were used to investigate factors associated with normative SF-36v2. Written informed consent was obtained from all patients.

**Results:** A higher proportion of RA patients achieved SR: 106 (58%) RA patients vs. 75 (30.6%) SLE patients,  $p \leq 0.001$ . SR was achieved earlier in patients from the former group: (mean $\pm$ SD) follow-up was 30.8 $\pm$ 23.9 months vs. 59.4 $\pm$ 37.5 months in SLE patients,  $p \leq 0.001$ . The length of time in SR and the number of patients who had a disease flare were similar in both cohorts.

At baseline, RA patients scored significantly lower all the domains of the SF-36v2 and both the mental and physical summary measures, than SLE patients. At SR, RA patients scored better than SLE patients in 6 out of 8 domains of the SF-36v2 and the physical health component summary (Figure).

Age ( $\beta$ : 1.06, 95% CI: 1.02-1.1,  $p=0.03$ ) and SLE diagnosis ( $\beta$ : 9.64, 95% CI: 3.61-25.75,  $p \leq 0.001$ ) were predictors of not achieving normative physical component summary measure.

**Conclusion:** Patient's perspective of (absence of) disease activity represents an important aspect of the assessment of rheumatic diseases. RA patients in SR achieved better quality of life than SLE patients.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** RAPID3 (routine assessment of patient index data) on a multi-dimensional health assessment questionnaire (MDHAQ) distinguishes active from control treatments in RA clinical trials as effectively as disease activity score 28 (DAS28) or clinical disease activity index (CDAI), and is informative to monitor patients with osteoarthritis, spondyloarthropathies, vasculitis, gout, etc. (1). Therefore, many versions of an electronic RAPID3 (eRAPID3) have been developed, although generally mutually incompatible, mimicking electronic medical records (EMRs), and not easily merged into an EMR or into multicenter databases to study patient outcomes (2). More recently, another index of MDHAQ scores, FAST3 (fibromyalgia assessment screening tool3), has been described, which agrees >80% with ACR fibromyalgia (FM) criteria to identify FM (3). Here, we assess eFAST3 and eRAPID3 on an eMDHAQ to recognize possible secondary FM in patients with osteoarthritis (OA) or rheumatoid arthritis (RA).

**Methods:** A patient- and doctor-friendly eMDHAQ meets HIPAA, privacy and security requirements, and is designed to interface with any EMR, using FHIR (Fast Healthcare Interoperability Resources) for integration and interoperability, although requiring collaboration with the EMR vendor, and to be merged easily into common collaborative research databases. eRAPID3 on an eMDHAQ is a 0-30 sum of a 0-10 physical function (FN) scale and two 0-10 visual analog scales (VAS) for pain (PN) and global assessment (PATGL). eFAST3 on eMDHAQ is a 0-3 scale; 1 point is assigned if PN  $\geq 6/10$ , RADA painful joint count  $\geq 16/48$ , and MDHAQ symptom checklist  $\geq 16/60$ ; FAST3  $\geq 2$  is clue to FM (3). eRAPID3 and eFAST3 were compared in 89 osteoarthritis (OA) vs 91 rheumatoid arthritis (RA) patients, using STATA to compute means and cross-tabulations.

**Results:** Mean eRAPID3 scores were 14.9 in OA vs 11.1 in RA patients. eRAPID3 was  $>12$  (high severity) in 59 OA (66%) and 39 RA (43%) patients. eFAST3  $\geq 2$ , suggesting secondary FM, was seen in 21 of the 59 OA patients (24% of all OA patients) and 17 of the 39 RA patients (19% of all RA patients) with RAPID3  $>12$  (Table). No patient with RAPID3  $<12$  had eFAST3  $\geq 2$ , suggesting a good screen for the absence of FM. Most patients with RAPID3  $>12$  also had FAST3  $<2$  (Table), suggesting limited specificity of RAPID3 for FM.

Number of patients with OA or RA according to eRAPID3 vs eFAST3 on eMDHAQ.

(%) are of all OA or RA patients

OA n=89	RAPID3 Remission=0-3	RAPID3 Low severity=3.1-6	RAPID3 Moderate severity=6.1-12	RAPID3 High severity>12	Total
FAST3=0	2 (2%)	6 (7%)	14 (16%)	8 (9%)	30 (34%)
FAST3=1	0	0	8 (9%)	30 (34%)	38 (43%)
FAST3=2	0	0	0	13 (15%)	13 (5%)
FAST3=3	0	0	0	8 (9%)	8 (9%)
Total	2 (2%)	6 (7%)	22 (25%)	59 (66%)	89
RA n= 91	Remission	Low severity	Moderate severity	High severity	Total
FAST3=0	15 (16%)	20 (22%)	11 (12%)	2 (2%)	48 (53%)
FAST3=1	0	0	6 (7%)	20 (22%)	26 (29%)
FAST3=2	0	0	0	10 (11%)	10 (11%)
FAST3=3	0	0	0	7 (8%)	7 (8%)
Total	15 (16%)	20 (22%)	17 (19%)	39 (43%)	91

**Conclusion:** An eMDHAQ offers reports of eRAPID3 and eFAST3 for improved clinical decisions, doctor-patient communication, and documentation. Further development of the eMDHAQ, eRAPID3, and eFAST3, and interface to the EMR, are needed for optimal value. Rheumatologists and organizations are encouraged to implement an electronic MDHAQ, rather than simply an electronic RAPID3.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In 2012, the ACR released guidelines for monitoring and treatment of lupus nephritis (LN), but studies have yet to evaluate adherence to these recommendations. Using measures from the SLE Quality Indicators Project (Yazdany, et al., 2009) and

new measures derived from ACR guidelines, we evaluated quality of care for LN among patients enrolled in the California Lupus Epidemiology Study (CLUES), a multi-ethnic, population-based cohort study.

**Methods:** We reviewed charts of CLUES patients to evaluate performance on quality measures (N=116 of 281 enrolled in the study to date). Patients were followed either in tertiary academic centers or by community rheumatologists in the study catchment area. Seven quality measures were assessed. For those without LN, we evaluated whether recommended screening processes were completed in the year preceding study enrollment (2014-2016) (urinalysis, urine protein: creatinine ratio and serum creatinine checked every 6 months; C3/C4 and anti-dsDNA levels every 6 months; and blood pressure checked every 3 months). For those with prevalent LN, we looked to see if patients had a renal biopsy at the time of diagnosis, received an immunosuppressant within 30 days of LN diagnosis, and were started on an ACEi/ARB and anti-malarial therapy within 1 year. "Pass rates" (% eligible patients receiving recommended care) for these measures were analyzed for the entire group and compared for tertiary vs community treatment settings using chi-squared tests.

**Results:** Among the 116 patients, 55 had a diagnosis of LN. 75 were followed in tertiary care settings and 41 by community rheumatologists. For patients with no history of LN, 40% had recommended screening of urine and renal function every 6 months, and 45% had screening for immunological activity every 6 months (Table). Adherence to blood pressure checks every 3 months was better (74%). For patients with LN, most patients (87%) had renal biopsies for diagnostic confirmation and 82% were started on an immunosuppressant within 1 month of diagnosis. 80% were placed on an anti-malarial and 68% on a renal protective antihypertensive (ACEi or ARB) within 1 year of diagnosis. We found no differences between community and tertiary care settings in measures assessing the diagnosis and treatment of LN. However, performance on measures examining screening of urine, renal function, immunological activity, and BP for patients with no history of LN was lower among community rheumatologists (see Table).

**Conclusion:** We found relatively high performance on quality measures regarding LN diagnosis and treatment, with no differences between community and tertiary care settings. For patients with no history of LN, we found that screening for renal disease was performed less in community settings. Next steps include reviewing additional records from CLUES and validating our chart review procedures across health care settings.

**Table 1: Quality Measure Pass Rates for the Screening and Treatment of Lupus Nephritis**

	With No History of LN (n=61)			
	Q1: UA, Urine Protein:Creatinine ratio, Serum Creatinine q6m	Q2: C3/C4, anti-dsDNA q6m	Q3: Blood pressure check q3m

## Screening and Intervention of Depression in Rheumatoid Arthritis and Systemic Lupus Erythematosus

Rui Zhang<sup>1</sup>, Priya Prakash<sup>2</sup>, Amy Wasserman<sup>3</sup>, Kirk Sperber<sup>4</sup> and Julia Ash<sup>5</sup>, <sup>1</sup>Medicine -Rheumatology, New York Medical College / Westchester Medical Center, Valhalla, NY, <sup>2</sup>Rheumatology, NYMC /WMC, VALHALLA, NY, <sup>3</sup>Medicine - Rheumatology, New York Medical College / Westchester Medical Center, VALHALLA, NY, <sup>4</sup>New York Medical College / Westchester Medical Center, Valhalla, NY, <sup>5</sup>Medicine -Rheumatology, New York Medical College / Westchester Medical Center, Valhalla, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Depression is common and associated with worse outcomes among patients with RA and SLE. Our study assessed depression using Patient Help Questionnaire (PHQ-9) and its correlation with disease activity. We also examined the outcome of intervention on depression score.

**Methods:** This is a single center cross-sectional study of mainly uninsured patients with RA and SLE in Rheumatology clinic. PHQ-9 scores were collected at each clinic visit. Physicians assessed corresponding disease activity using Clinical Disease Activity Index (CDAI) or SLEDAI. Patients with at least moderate depression (PHQ-9  $\geq 10$ ) were offered depression intervention, counseling or medications. PHQ-9 was re-administered after intervention.

**Results:** 45 RA patients with a mean age of 50 years ( $\pm 12$ ) and 16 SLE patients with a mean age of 42 years ( $\pm 11$ ) were screened. In RA group 82% were females with average disease duration of 7 ( $\pm 6$ ) years. In SLE group 94% were females with average disease duration of 8 ( $\pm 7$ ) years. Depression was diagnosed in 51% of RA patients: 29% mild, 13% moderate and 9% moderately severe (Table.1). Severity of depression positively correlated with disease activity in RA patients (Figure. 1, Pearson R=0.636, p <0.001). In contrast, depression was diagnosed in 25% of SLE patients: 12.5% mild and 12.5% moderate and did not correlate with disease activity (Pearson R=0.209). RA patients with moderate/high CDAI had significantly higher PHQ-9 than those with low CDAI (7.7 vs 1.5, p<0.001; 9.6 vs 1.5 p<0.001, t-test). Of 12 patients who met criteria for depression intervention (Table. 2), 33% were treated, 33% are pending treatment and 33% declined. With intervention, 2 patients had improved PHQ-9 scores, 1 patient's score worsened confounded by cancer surgery, and 1 patient had no change in score.

**Conclusion:** Our study shows higher prevalence of depression in RA (51%) and SLE (25%) than in general population (7-12%).<sup>1</sup> Correlation between disease activity and depression score is only found in RA. Depression intervention resulted in PHQ-9 improvement in some patients, supporting the benefit of depression screening and treatment in rheumatology practice.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smoking predicts higher incidence, greater severity, and reduced treatment responses in rheumatoid arthritis, lupus, and spondyloarthritis. However, cessation advice and quit line referral occur in just 10% and 0.6% of rheumatology visits, respectively. Primary care staff protocols improve guideline-based care, and electronic referrals increase use of free, state tobacco quit lines by 13-fold. We sought to examine a similar staff protocol in rheumatology using electronic health record (EHR) tools to connect eligible patients to a free, state quit line.

**Methods:** We conducted a pre- post-analysis of EHR data (2012-16) including our 6-month Quit Connect project. During implementation, cessation experts and project staff provided an hour of Quit Connect protocol training to nurses and medical assistants at three rheumatology clinics. The protocol included EHR prompts to assess smoking status, 30-day readiness to quit or cut back, and willingness to try a quit line. EHR data measured process steps. Referral to the quit line (vs. our published baseline) was the primary outcome. The quit line reported patient outcomes. The IRB exempted this as standard of care with permission to publish.

Logistic regression models examined process measures and referrals pre- and post-protocol. Multivariable process models included age, sex, race, body mass index (BMI), socioeconomic status (SES; defined as ever receiving Medicaid), and comorbidity (Johns Hopkins Adjusted Clinical Groups (ACG) score).

**Results:** For 54,090 rheumatology visits, 4,601 (9%) reported current smoking. 4,078 pre-protocol visits with patients who smoke (2012-15) were compared to 523 visits after protocol implementation (2016). Documenting smoking status remained high (96 v. 97%). 30-day readiness to quit assessment rose from 3% to 80% post-protocol (Table 1, OR 120, 91-159). Among those asked, 29% reported being ready to quit. Of those ready, 76% had a referral to the state tobacco quit line compared to our pre- rate of 0.6% (OR 26, 6-106). When offered, 71% accepted referrals (54% of ready to quit; 13% of smokers).

Patients with higher comorbidity were less often ready to quit (ACG OR 0.6, 0.4-0.9 unadj.); older patients accepted fewer referrals (OR 0.8, 0.7-0.97 unadj. per 10 yrs.). Adjusted models did not change results.

Among 66 referred patients, 11 (17%) accepted counselling, nicotine replacement, and set a quit date, and 5 more reported a quit in process. Overall, 24% of referred patients set a quit date or reported a quit attempt.

**Conclusion:** Our Quit Connect protocol for rheumatology staff increased quit line referrals over 20-fold. When asked, a third of patients were ready to quit and half agreed to referral. Given the importance of cessation to reduce immune and cardiopulmonary disease, future rheumatology studies should investigate cessation protocols to leverage quit lines, which are free in all states.

Table 1. Tobacco cessation care pre- and post-protocol implementation

	Pre n=4,078	Post n=523	Unadj. OR, 95% CI
Ready to quit asked	135 (3%)	421 (80%)	120, 91-159
Patient ready to quit/cut back	59 (44%)	122 (29%)	
Quit line referral offered	[0.6% historic]	93 (76%)	26, 6-106
Quit line referral accepted	NA	66 (71%)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Centers for Disease Control and Prevention director has said “nothing will save more lives” than protocols to control blood pressure (BP). BP is relevant in rheumatology clinics because it is causally linked to cardiovascular disease. Hypertension control is also one of ten RA quality measures endorsed by ACR and Medicare for 2017 quality payment reporting. Yet, minimal evidence exists on how to improve BP control in busy rheumatology clinics. We previously implemented a staff protocol that doubled timely follow-up after high BPs in rheumatology clinics, and now aimed to examine its impact on population BP control.

**Methods:** We assessed population trends in the rate of monthly high BPs (% of all visits) before and after the implementation of a staff BP Connect Health protocol in three rheumatology clinics (10/2012-10/2014 vs. 11/2014-12/2016). During implementation, clinical educators trained nurses and medical assistants in an hour-long session on BP in rheumatic diseases, proper BP measurement, and the BP Connect Health protocol steps. Protocols included EHR prompts to re-measure high BPs, and if confirmed high, offer timely primary care follow-up. Follow-up orders automatically routed to scheduling staff for patients with in-network primary care, and printed on after visit materials for all patients. EHR data reported the monthly percentage of adult rheumatology clinic visits with an initial BP >140/90 mmHg.

We performed time series regression with Newey-West standard errors to examine changes in rates of high BPs in the 24 months before and after protocol implementation.

**Results:** A total of 28,109 pre-protocol rheumatology clinic visits were compared to 28,285 visits after protocol implementation. Monthly rates of high BP, when averaged over the periods before and after implementation, fell from 17% pre- to 8% post-protocol. Time series analysis demonstrated a significant reduction after protocol implementation and continued improvement over time (Figure 1.  $p < 0.003$  &  $p < 0.03$ ). Strengths included 2-year protocol feasibility; limitations include our single center pre-post design.

**Conclusion:** After implementing the rheumatology staff protocol, we observed a 9% reduction in mean rates of high BP across rheumatology clinic populations. Early improvements likely reflected staff BP training, while later improvements may reflect improved follow-up, adherence, and management of BP. Future multi-site studies will test the BP Connect Health protocol in other rheumatology and specialty populations at risk for cardiovascular disease.

## Large Variations in Tuberculosis Testing for New Biologic Users with Rheumatoid Arthritis Among Providers in the RISE Registry

**Gabriela Schmajuk**<sup>1</sup>, Michael Evans<sup>2</sup>, Julia Kay<sup>3</sup> and Jinoos Yazdany<sup>4</sup>, <sup>1</sup>San Francisco VA Medical Center, University of California San Francisco, San Francisco, CA, <sup>2</sup>University of California San Francisco, San Francisco, CA, <sup>3</sup>Medicine/Rheumatology, University of California - San Francisco, San Francisco, CA, <sup>4</sup>Medicine/Rheumatology, University of California San Francisco, San Francisco, CA  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tuberculosis (TB) testing prior to biologic DMARD use helps prevent potentially fatal, medication-related adverse events and is a National Quality Forum-endorsed quality measure. We used data from a national registry to describe practice variations on this measure among US rheumatologists.

**Methods:** The ACR's RISE is a national registry that passively collects electronic health record (EHR) data on all patients seen by participating practices. As of December 2016, RISE was connected to 632 providers representing an estimated 20% of the US clinical rheumatology workforce. We calculated the proportion patients  $\geq 18$  with rheumatoid arthritis who were newly prescribed a biologic DMARD or tofacitinib during 2016 and who had TB testing in the 12 months preceding the biologic prescription, by practice and geographic region. We examined associated EHR data for the type of TB test performed (PPD or quantiferon-based assays). Consistent with other national performance analyses, providers with fewer than 30 qualifying patients in the denominator were excluded. Proportions were compared using chi-square tests.

**Results:** We analyzed data from 18,079 patients across 533 providers and 95 practices. 77% of patients were female, 20% were non-white, and mean age was 58 (SD 13.5). Overall, patient-level performance on the measure was 56%, with a range of 0 to 96% across practices (Figure), and significant variation across regions (Table;  $p < 0.0001$ ). Among the patients in the numerator with a TB test found in the EHR data ( $N=7828$ ), 93% received a Quantiferon test while 7% had a PPD.

**Conclusion:** We found large variations in TB testing prior to new biologic DMARD starts across RISE practices. Given that quantiferon-based assays represented the majority of TB screening tests identified, we suspect that PPD testing remains undercaptured in the EHR. As value-based incentive programs become more widespread, accurate capture of performance on patient safety measures will be increasingly important and may require practices to standardize documentation of important safety processes such as TB testing.

**Disclaimer:** The data presented here was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors and do not necessarily represent the views of the ACR.

Figure. Proportion RA patients who received TB test prior to a new biologic prescription, by provider. Red bars indicate 95% confidence intervals.

Table. Proportion of RA patients who received TB test prior to a new biologic prescription, by region.

Geographic Region (included U.S. States)	N patients	Mean (%)	95% CI (%)
New England (CT, ME, MA, NH, RI, VT)	613	83.7	80.7, 86.7
Mid Atlantic (DE, NJ, NY, PA)	1138	57.1	54.2, 60.1
East North Central (IL, IN, MI, OH, WI)	1900	64.8	62.6, 67.0
West North Central (IA, KS, MN, MO, NE, ND, SD)	2980	30.7	29.0, 32.4
South Atlantic (FL, GA, MD, NC, SC, VA, DC, WV)	5341	61.0	59.6, 62.3
East South Central (AL, KY, MS, TN)	2926	47.6	45.7, 49.4

## A Multidisciplinary Performance Improvement Approach to Achieving Goal Serum Uric Acid Levels in Patients with Gout

**Luke Monteagudo**<sup>1</sup>, Jefferson Roberts<sup>2</sup>, Donna Kido<sup>3</sup>, Collette Chin<sup>3</sup> and Susan Fujii<sup>3</sup>, <sup>1</sup>Internal Medicine, Tripler Army Medical Center, Honolulu, HI, <sup>2</sup>Rheumatology, Tripler Army Medical Center, Honolulu, HI, <sup>3</sup>Pharmacy, Tripler Army Medical Center, Honolulu, HI

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In patients with gout, hyperuricemia leads to inflammation induced by mono-sodium urate crystal deposition. This causes irreversible physical and radiographically evident destruction of the affected joint. Current guidelines recommend a serum uric acid (sUA) level < 6 mg/dL, while data has shown that sUA of < 5 mg/dL has benefit. The aim of this performance improvement project was to assess how to better achieve these goals. We hypothesized that through a multidisciplinary approach, we could more effectively achieve sUA goal levels.

**Methods:** We enrolled patients with a new or chronic diagnosis of gout. We excluded pregnant women and those under the age of 18. Baseline sUA levels were obtained on all patients. If elevated and not already on urate lowering therapy, patients were started on 100mg Allopurinol daily and 0.6mg Colchicine twice daily. A clinical pharmacist followed our algorithm for a step wise increase in therapy intensity every two weeks, with a corresponding sUA level.

**Results:** A total of 40 patients participated. The average starting uric acid level of the experimental group was 8.06 mg/dL. After 12 months, 48% (n=19) of patients reached a level below 6 mg/dL. After an average of 18.5 months of enrollment, 33% of patients (n=13) reached a serum uric acid level below 5 mg/dL and 53% (n=21) reached a serum uric acid level below 6 mg/dL.

**Conclusion:** The aim of our approach to gout treatment is to decrease sUA, gout attacks, and ultimately joint damage. We were able to show that a multidisciplinary approach could improve sUA level compared with primary physicians alone. This effect is due to clinical pharmacists' ability to perform more frequent sUA evaluations and medication changes for patients. Future work will evaluate secondary end points, like the number of acute care visits and gout attacks during the study period. The summation of this data supports the multidisciplinary approach to the treatment of gout.

## **The Utility of Electronic Consultation in the Management of Gout at the Veterans Affairs Medical Center**

**Juliana Chang**<sup>1</sup>, Michelle DiFiore<sup>1</sup> and Maida Wong<sup>2,3</sup>, <sup>1</sup>Internal Medicine, University of California, Irvine, School of Medicine, Orange, CA, <sup>2</sup>Rheumatology, University of California, Irvine, School of Medicine, Orange, CA, <sup>3</sup>Rheumatology, Tibor Rubin VA Medical Center in Long Beach, Long Beach, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is the most common inflammatory arthritis in adults worldwide. It can be managed by primary care physicians (PCPs), but complex cases often require rheumatology input. However, the average wait time for a first rheumatology clinic visit varies from 38 days to 47 weeks. By utilizing electronic consultation (e-consult) which allows two-way communications between referring and rheumatology physicians (pre-consult exchange), rheumatologists can decide whether patients can be managed by addressing the clinical questions electronically, or a face-to-face patient evaluation is necessary. We analyzed the effectiveness of gout management via e-consult compared to PCP and face-to-face rheumatology visits at the VA Medical Center in Long Beach.

**Methods:** A retrospective study of 133 VA gout patients from 2013 to 2014 was constructed and grouped by their management under rheumatology e-consults (n = 33), rheumatology clinic visits (n = 52), or PCP visits (n = 37). Electronic medical records were reviewed for a 24-month period from their initial gout flare or e-consult date. The effectiveness in management was measured by the change in frequency of gout flares and related emergency department (ED) visits, renal function and serum uric acid levels (sUA).

**Results:** Of the 48 gout e-consults, 33 cases were resolved electronically, and 15 were converted to rheumatology clinic visits. The wait time for recommendations from e-consult was 3.7 days. Face-to-face clinic visit took 20.3 days after pre-consult exchange (vs 71.3 days for direct clinic consult). Compared to PCP managed patients, both e-consult and rheumatology clinic patients have more gout attacks and related ED visits at baseline (p = 0.08). They have fewer attacks in the first 12 months of management, with decreased sUA and improved renal function (p = 0.06), (p = 0.1), and are more likely to be treated with allopurinol, colchicine, febuxostat and corticosteroids than with NSAIDs alone (p < 0.05). E-consult management was comparable but second to rheumatology clinical visits (p not significant), but beyond 12 months, disease activity was stable and similar in all groups.

**Conclusion:** More effective gout management can be achieved by referring patients with uncontrolled disease to direct rheumatology visits or e-consults in the first 12 months. Patients can be transitioned to PCP management after 12 months if disease is stable. Overall, e-consult serves as a reasonable alternative in managing gout. Clinical questions can be addressed electronically resulting in a shorter wait time and more efficient referrals to the rheumatology clinic.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** A large proportion of patients with rheumatologic diseases are now being treated with biologic therapies. Estimates of the use of biologics in patients with rheumatoid arthritis (RA), for example, now range from 30-40%. While biologics improve disease outcomes, they also increase the risk of infections, autoimmunity, and possibly malignancy. Screening for these conditions, as well as completion of routine vaccinations, has shown to decrease complication rates. Despite these benefits, compliance with current guideline recommendations tends to be low in practice. Development of The Ottawa Biologic Safety & Screening Tool (OBSST) is a quality initiative at The Ottawa Hospital with the objective to increase compliance with guideline recommendations and ultimately improve patient safety. The Ottawa Hospital is an academic teaching hospital in Ontario, Canada with 1,122 beds, facilitating 1.155 million ambulatory care visits each year. Our rheumatology clinic serves more than 880 patients using biologic therapies.

**Methods:** A chart review of randomly selected patients (n=50) who started a biologic treatment at our centre from 2011 to 2013 revealed baseline rates of compliance with guidelines. American College of Rheumatology and Canadian Rheumatology Association Guidelines for treatment of rheumatoid arthritis were used to determine screening goals (Singh et al, 2012; Bombardier et al, 2011-2012). The OBSST was then developed using a Nominal Group Technique, and implemented by a multidisciplinary team. OBSST is a checklist reviewing 1) patient characteristics which may preclude the use of certain biologics, 2) recommended laboratory and imaging screening, and 3) vaccination counselling. After one year of OBSST use, a chart review of randomly selected patients (n=50) initiating biologic therapy from October 2015 to September 2016 was completed. Descriptive statistics are reported for pre- and post-implementation rates.

**Results:** Following implementation of the OBSST, rates of documented Hepatitis B serology increased significantly from 50% to 94% (25/50 to 47/50 patients, P<0.0001). Hepatitis C serology documentation showed similar rates of improvement, from 46% to 98% (23/50 to 49/50 patients, P<0.0001). Prior to the implementation of OBSST, the rate of documented vaccination counselling was low; 6% of patients (3/50) had documented counselling regarding influenza, herpes zoster, and pneumococcal vaccines. With the OBSST, vaccination counselling increased to 98% (49/50, P<0.0001) for influenza, 96% (48/50, P=0.0003) for herpes zoster, and 94% (47/50, P<0.0001) for pneumococcal vaccines. Screening rates for tuberculosis with a TB skin test and chest X-ray were relatively high at baseline. Rates increased with OBSST but not reach statistical significance.

**Conclusion:** The Ottawa Biologics Safety & Screening Tool, administered by a multidisciplinary team, led to significantly increased rates of recommended screening and vaccine counselling of patients starting biologic therapies. Use of a standardized tool, combined with a team approach, may be beneficial in aligning institutional practices with current guideline recommendations when initiating biologics.

## Effectiveness of the Outreach Model for Rheumatology Specialty Clinics to On-Reserve First Nations in Canada: System-Level and Individual Measures of Performance and Outcomes

Sujay Nagaraj<sup>1</sup>, Claire Barber<sup>2</sup>, Margaret Kargard<sup>3</sup>, Tyler White<sup>3</sup> and Cheryl Barnabe<sup>4</sup>, <sup>1</sup>McCaig Institute for Bone and Joint Health, University of Calgary, Calgary, AB, Canada, <sup>2</sup>Medicine, University of Calgary, Calgary, AB, Canada, <sup>3</sup>Siksika Health Services, Siksika, AB, Canada, <sup>4</sup>Department of Community Health Sciences, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inflammatory arthritis (IA) disproportionately affects Canada's First Nations population. A Model of Care (MoC) consisting of rheumatology specialty services embedded in the primary care context on-reserve was instituted to reduce barriers to care and improve treatment outcomes. This study assessed the system-level performance of the MoC as well as its effectiveness on disease activity measures and patient-reported outcomes over 7 years (2011 - 2017) at one centre.

**Methods:** Patients with incident and prevalent IA were enrolled in a longitudinal cohort. Clinical characteristics, disease activity measures, and treatment recommendations were systematically recorded over follow-up. System-level performance was evaluated according to established measures including: wait times for new referral, proportion of patients seen in yearly follow-up, proportion of patients prescribed DMARD treatment, and time to DMARD initiation. Treatment escalation (new DMARD or biologic prescribed) was characterized in relation to disease activity state at each visit. Mixed-model regression was performed to determine rates of change for disease activity measures over time, with adjustment for baseline demographics and disease activity measures.

**Results:** 59 participants (78% female, mean age 47 (SD 13)) with IA (n=39 RA, n=7 PsA, n=7 SLE and related CTD, n=3 JIA, n=1 SpA, n=2 crystal arthritis; 29 with incident and 30 with prevalent disease, mean 16 (SD 13) years duration) were followed for a mean of 29 (SD 23) months with a mean of 6 (SD 5) visits per participant.

At the system-level, the 50th and 90th percentile wait times were 69 and 695 days, respectively. Only 33% of patients were seen in the benchmark waiting time of 4 weeks but 83% of patients were followed up in each measurement year. Nearly all (96%) of patients received a DMARD in each measurement year and 90% were prescribed a DMARD within 2 weeks of diagnosis.

At the baseline visit, 70% of participants were in DAS28 moderate or high disease activity. Treatment was escalated at 60% of visits where the individual was in moderate or high disease activity. Swollen and tender joint counts significantly improved during follow-up (SJC28 adjusted slope -0.16, 95%CI -0.27 to -0.05, p=0.004; TJC28 adjusted slope -0.16, 95%CI -0.32 to -0.0057, p=0.04). Pain (adjusted slope -0.014, 95%CI -0.70 to -0.04, p=0.62), MD Global (adjusted slope -0.028, 95%CI -0.095 to 0.040, p=0.42), HAQ (adjusted slope 0.0028, 95%CI -0.0088 to 0.014, p=0.64), and DAS28 (adjusted slope -0.038, 95% CI -0.078 to 0.0016, p=0.060) did not significantly improve over time. Patient global continued to increase over time (adjusted slope 0.081, 95%CI 0.025 to 0.137, p=0.005). No significant differences were found in a sensitivity analysis comparing outcomes for incident and prevalent patients.

**Conclusion:** Evaluation of the MoC highlighted areas for further improvement. The program met several system-level performance measure targets however patients still experience long wait times. Despite improvement in swollen and tender joint counts, disease activity measures and patient-reported outcomes did not significantly improve during follow-up. This suggests that there are still gaps in meeting relevant outcomes.

## **A Model for Improved Management of Fragility Fractures: Navigating the Fracture Liaison Service**

**Marcy B. Bolster**<sup>1</sup>, Smriti Cevallos<sup>2</sup>, Lisa Beyer<sup>2</sup>, Henry M. Kronenberg<sup>2</sup> and Ben Leder<sup>2</sup>, <sup>1</sup>Massachusetts General Hospital, Boston, MA, <sup>2</sup>Endocrine, Massachusetts General Hospital, Boston, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fragility fractures are associated with significant morbidity, mortality and healthcare costs, yet most fracture patients are neither evaluated nor treated for their underlying osteoporosis (OP). A Fracture Liaison Service (FLS) can improve OP treatment in patients with fragility fractures, including hip fractures. Our model uses a physician assistant Navigator to coordinate interdisciplinary care and provide a seamless transition between inpatient surgical care and outpatient OP management. The Navigator enhances patient education, facilitates communication amongst all providers, performs diagnostic evaluation as warranted, and initiates OP treatment.

**Methods:** A patient-centered care algorithm (Figure 1) begins in the Emergency Department (ED), continues for inpatient hospital care with Geriatric, FLS and Orthopaedic co-management, and the FLS Navigator then transitions care to the outpatient setting (orthopaedic clinic). Communication between the FLS Navigator and patient's PCP occurs at each step.

**Results:** A comparison of outcomes (Table 1) is made from 1/1/2013-12/31/2013 (Group 1, pre-MGH FLS) to 2/1/2016-1/31/2017 (Group 2, year 1 of MGH FLS). There were 314 hip fragility fractures in Group 1 (66% female, 83% age ≥ 65 years), and 259 fragility fractures in Group 2 (71% female, 91% age ≥ 65 years).

Of 314 Group 1 inpatients treated for a hip fragility fracture, 127 (40%) had a PCP in our health care system. Treatment was prescribed for 7 of 127 (5.5%) patients within 6 months of hip fracture and 11/314 (3.5%) were seen by an OP specialist within 1 year of fracture.

Of 259 Group 2 inpatients, 102 (39%) were seen as an outpatient by the FLS Navigator in the orthopaedic clinic or by a specialist in OP clinic. Of Group 2 patients, 68 (26%) declined a follow up appointment with the FLS Navigator and 32 (12%) did not keep the FLS outpatient appointment. Preliminary data reveal that 62 of 259 (24%) Group 2 patients were receiving OP therapy 6 months post-hospitalization, a greater than 4-fold increase compared to Group 1 (additional data not available for many Group 2 patients due to insufficient time since fracture).

**Conclusion:** The MGH FLS utilizes an innovative model to improve health outcomes, including morbidity, mortality and reduced healthcare costs, in a high risk population. Future goals include increasing the FLS scope to ensure all patients admitted with all fragility fractures are evaluated, improving 6-month treatment rates to >80%, expanding the FLS to fracture patients not requiring inpatient care, and using telemedicine to develop networks with regional hospitals.

Figure 1: FRACTURE LIAISON SERVICE ALGORITHM

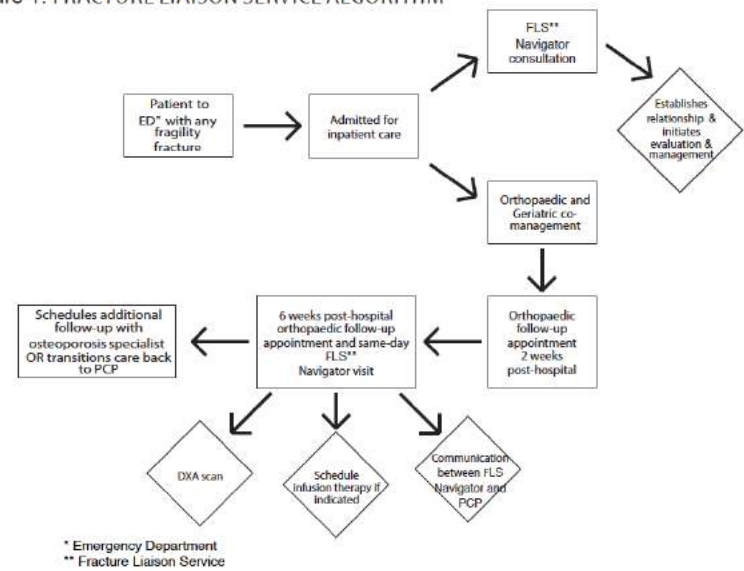

Table 1: MGH Fracture Liaison Service: Before (Group 1, 2013) and After (Group 2, 2016)

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patients with autoimmune conditions are at increased risk for cardiovascular disease (CVD) compared to the general population. It is not routine practice at UT Rheumatology to manage lipids. Since rheumatologists often play the role of PCP for patients with autoimmune diseases, they are at a unique position to modulate the CVD risk. Our aim was to increase the percentage of patients with an annual lipid panel checked to 50% and to prescribe statin therapy for LDL more than or equal to 190 or if the 10-year risk for atherosclerotic cardiovascular disease (ASCVD) is more than or equal to 7.5%.

### Methods:

Patients over 18 years of age with RA, SLE, Psoriatic arthritis, Polymyositis and Dermatomyositis were included in this study. This quality improvement project was undertaken by a single attending provider at a single clinic location. The baseline data from chart

review was collected from July 2016 to August 2016. The post-intervention data was collected in 3 phases between December 2016 and May 2017. For the first phase of intervention a reminder card with a flowchart was attached to the work stations, and ASCVD risk calculator was downloaded to the provider's cell phone. For appropriate patients, lipid profiles were ordered and ASCVD risk calculated. If indicated, atorvastatin was prescribed. During the second intervention phase, in addition to the above the provider reviewed the daily schedule and printed appropriate lab orders for each patient the day prior to the visit.

### Results:

During baseline period, lipid profiles were ordered on 20% of appropriate patients (5/30) with 13% (4/30) on statins. After the first intervention, lipids were checked in 33% (12/36) with 13.8% (5/36) on statins. During the second intervention phase, lipids were checked in 77% (10/13) with 23% (3/13) on statins. During maintenance (about 3 months later), lipids were ordered on 81% (13/16) with 25% (4/16) placed on statins. It was also noted that 5 of the 65 patients in the intervention phases declined having lipid panel measured.

### Conclusion:

The initial intervention did not result in significant improvement. For the second intervention, pre-clinic reviews with labs checks were performed, which increased success. Next steps will involve spread to other rheumatology providers in the clinic and interventions to increase appropriate prescribing of statins based on lipid panel results.

## Clinical Significance of RNP Antibodies in Diagnosis of Systemic Autoimmune Rheumatic Disease When Detected By Multiplex Immunoassay

**Heather Bukiri**<sup>1</sup>, Amish Dave<sup>2</sup>, Erin Bauer<sup>2</sup>, Vivian Stone<sup>2</sup>, Chris Chong<sup>3</sup> and Punam Verma<sup>4</sup>, <sup>1</sup>Graduate Medical Education, Virginia Mason Medical Center, Seattle, WA, <sup>2</sup>Rheumatology, Virginia Mason Medical Center, Seattle, WA, <sup>3</sup>Virginia Mason Medical Center, Seattle, WA, <sup>4</sup>Microbiology/Immunology General Lab, Virginia Mason Medical Center, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

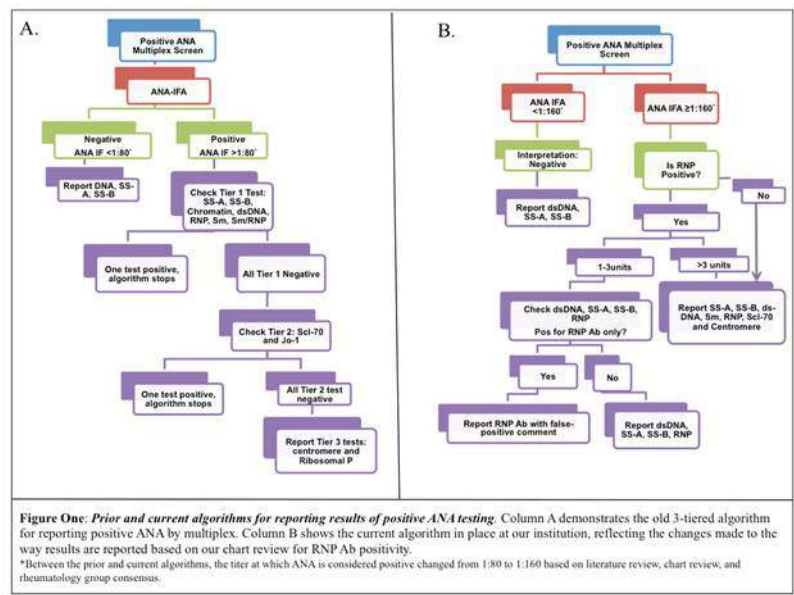

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Background/Purpose:** A large multicenter healthcare system recently adopted multiplex immunoassay as an initial screen for antinuclear antibody (ANA) with confirmatory reflex testing by immunofluorescence antibody assay (IFA). When both are positive, a 3-tiered cascade reporting algorithm is activated (Figure 1A). This ANA testing method led to an increase in rheumatology referrals for RNP antibody (ab) positivity in patients lacking clinical features of systemic autoimmune rheumatic diseases (SARD). We conducted a multiphase quality improvement project to determine the clinical significance of RNP ab positivity.

**Methods:** A retrospective review of all ANA tests completed at our institution was conducted from July to September 2016. Specimens positive in the multiplex assay were further reviewed for both RNP ab and ANA by IFA positivity. A titer of  $\geq 1:160$  was considered positive. Positive RNP ab results ( $> 1$  antibody index (AI)) were characterized as either low (1-3 AI) or high ( $> 3$  AI). Two independent physicians conducted chart review on all RNP results to determine if diagnosis of SARD was made. Methods are summarized in Figure 2.

**Results:** Of 1058 ANA multiplex performed, 183 were positive (17.3%) and 60 were positive for RNP ab. Of the 60 RNP ab positive samples, 28 had negative ANA IFA testing (47%). One-hundred and twenty-three ANAs were positive both multiplex and IFA (11.6%), 32 of which were also RNP ab positive (26.2%). Fifteen out of 32 were positive to only RNP ab, and negative to abs to all other extractable nuclear antigens (ENAs). Thirteen of those 15 patients (87%) had no evidence of SARD. PPV for SARD among RNP ab positive patients, sorted by AI is summarized by Table 1.

**Conclusion:** Within our testing, an isolated positive RNP ab has a poor PPV for SARD and likely represents type I error. When RNP ab is positive with  $\geq 1$  additional ab to ENA, there is a higher probability for SARD. The highest probability for SARD exists when RNP ab is  $> 3$  AI with  $\geq 1$  additional ab to ENA. Healthcare systems should consider a modified algorithm for reporting RNP positivity as either low (1-3 AI) or high ( $> 3$ ) to help clarify the clinical significance of RNP ab positivity with multiplex testing (Figure 1B).

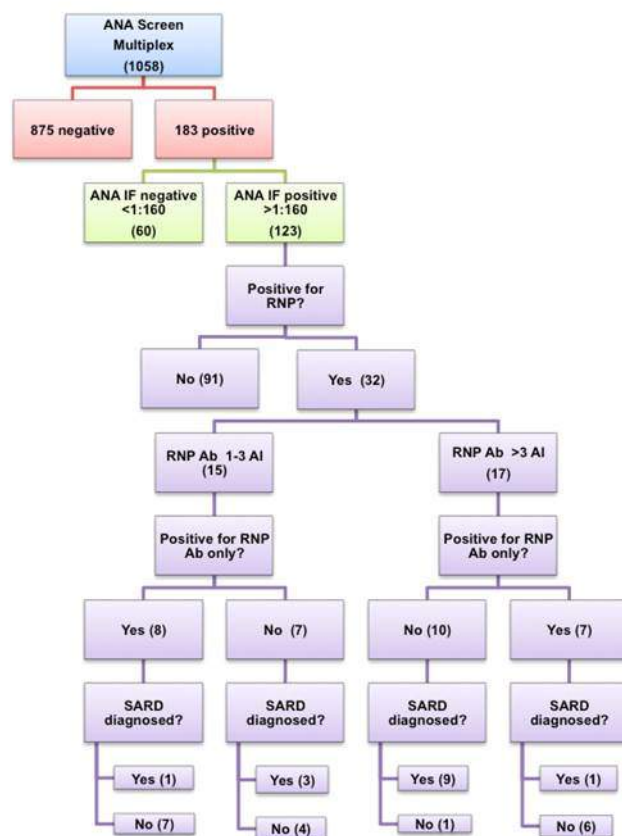

Figure 2. Summary of analysis and chart review of 1058 ANA multiplex screening tests ordered over a three month period in evaluating the significance of RNP Ab positivity.

Table One: Incidence of Systemic Autoimmune Rheumatic Disease\* Between Isolated RNP Ab and Non-Isolated RNP Ab at Varying Titers

	True Positive	False Positive	Total	Positive Predictive Value for SARD
Isolated RNP Ab > 1 AI	2	15	17	11.7%
Isolated RNP Ab 1-3 AI	1	7	8	12.5%
Isolated RNP Ab ≥ 3 AI	1	6	7	14%
RNP Ab 1-3 AI with Ab positivity to additional ENA	3	6	9	42.9%
RNP Ab >3 AI with Ab positivity to additional ENA	9	1	10	90%

# Investigating Opportunities for Cost Conscious Care: A Review of Physician Practice in Ordering Anti-Nuclear Antibody Testing at an Academic Community Hospital

Hrudya Abraham, Jorge Espinal and Sindhu Joseph, Internal Medicine, MacNeal Hospital, Berwyn, IL

First publication: September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

More than 94,000 ANA tests are performed each year resulting in an estimated cost of 2.24 million dollars annually. The American College of Rheumatology Choosing Wisely Campaign emphasizes the appropriate use of autoantibody testing focusing on high value and cost conscious care. Besides rheumatologic diseases, positive ANA results can be seen in several non-rheumatic pathologies and in normal healthy individuals. Improper use of immunologic testing can result in misdiagnosis, patient concerns, inappropriate therapy and wasted health care resources. We sought to review physician practicing habits of utilizing the ANA screen prior to ordering ANA panel, unless otherwise warranted in specific clinical settings.

## Methods:

We conducted a retrospective chart review of patients aged 18 years or older admitted to our teaching hospital from Jan 1<sup>st</sup>, 2012 to December 31<sup>st</sup>, 2014 who had an ANA screen and/or an ANA panel ordered. Fifty percent of these charts were selected using a random number generator and a total of 625 charts were reviewed. Data was collected on the ANA test that was ordered, date of the test performed, result of the tests, history of prior SLE, history of other autoimmune diseases, and prior positive ANA testing.

## Results:

Of the 625 patient charts that were reviewed, five patients (0.8%) had a preexisting diagnosis of SLE and 20 patients (3.2%) had previously been diagnosed with non-SLE autoimmune disorders. 208 (33%) patients had an ANA screen ordered, and 417 (67%) had only an ANA panel. Of those patients who had an ANA screen ordered (208), 73% appropriately had the ANA screen ordered first, and 27% had an ANA screen ordered at the same time or after the ANA panel. In those patients who had an ANA screen ordered, 91% of those screens were negative and 9% were positive. Interestingly, in those patients where only an ANA panel was ordered without any prior ANA screening, only 0.05% (2/417) was actually positive.

## Conclusion:

Sixty six percent (417) of patients had an ANA panel ordered without an ANA screen, of which 99.5% were negative, leading to an estimated excess cost of 342,254 dollars over 3 years in this test alone. Our Electronic Medical Recording system has different ANA testing options which currently includes the option to only order an ANA panel without the ANA screen. An expanded ANA panel without specific clinical suspicion may result in falsely positive results leading to unnecessary workup. Our next step in implementing change is to remove the option of 'ANA panel only' in our Electronic Medical Recording system, and to replace it with 'ANA screen with reflex to ANA pattern, titer and panel' to avoid unnecessary testing.

## Glucose-6-Phosphate Dehydrogenase Testing in a US Veterans Healthcare System: Are We Ordering Unnecessary Tests?

Tracy Driver<sup>1</sup>, Kevin Hsu<sup>2</sup>, Meika A. Fang<sup>3</sup> and Ari Weinreb<sup>3</sup>, <sup>1</sup>Medicine, Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA, <sup>2</sup>Cedars-Sinai Medical Center, Los Angeles, CA, <sup>3</sup>VA Greater Los Angeles Healthcare System, Los Angeles,

**SESSION INFORMATION****Session Date:** Monday, November 6, 2017**Session Title:** Measures and Measurement of Healthcare Quality Poster I**Session Type:** ACR Poster Session B**Session Time:** 9:00AM-11:00AM**Background/Purpose:**

Glucose-6-phosphate dehydrogenase (G6PD) deficiency is an X-linked genetic defect that causes a non-immune hemolytic anemia affecting more than 400 million people worldwide. When initiating medications with oxidant potential such as sulfasalazine (SSZ), patients are frequently tested for G6PD deficiency. The objectives of this study include determining the prevalence of G6PD deficiency among those tested and characterizing G6PD test ordering patterns.

**Methods:**

Retrospective chart review was performed using the electronic medical record at the VA Greater Los Angeles Healthcare System. The database was searched for all patients who had a G6PD test ordered between 2009-2014. Data collected included demographics, reasons G6PD testing was done, number of patients who underwent repeat testing, and the specialty of the provider who ordered the test. Prevalence of G6PD deficiency was determined. Descriptive analysis of categorical variables was done with the Chi-Square test. The odds ratio (OR) with 95% confidence interval (CI) was used to evaluate the association between ethnicity and G6PD deficiency.

**Results:**

G6PD levels were measured in 737 patients. The study population included 661 males (89.7%) and 76 females (10.3%) with a mean age of 56.6 ( $\pm$  SD 14.9). There were 60 (8.1%) patients with G6PD deficiency. The percentage of patients with G6PD deficiency by gender and within each self-reported race/ethnicity was as follows: 8.4% (N=56) males, 5.3% (N=4) females, 18.2% (N=2) American Indian, 17.9% (N=47) African American, 7.7% (N=2) Asian, 2.5% (N=7) Caucasian, 1.1% (N=1) Hispanic, and 100% (N=1) Brazilian. Observed differences in G6PD deficiency prevalence were statistically significant based on gender and self-reported race/ethnicity ( $p < 0.001$  for both). Odds ratios were calculated to evaluate the association between race/ethnicity and G6PD deficiency: African American (OR 7.77, [95% CI 4.12-14.66]), American Indian (OR 2.56, [95% CI 0.54-12.12]), Asian (OR 0.94, [95% CI 0.22-4.07]), Caucasian (OR 0.20, [95% CI 0.09-0.45]), and Hispanic (OR 0.11, [95% CI 0.02-0.82]). Repeated testing was carried out in 105 (14.2%) patients. Reasons for G6PD testing included initiation of SSZ for inflammatory arthritis (52.3%), dapsone for PCP prophylaxis (14.2%), and anemia workup (11.1%). Rheumatology ordered the majority of repeat tests (60.7%) for the following reasons: SSZ (65), hydroxychloroquine initiation (1), anemia workup (4), and dapsone initiation (4).

**Conclusion:**

G6PD deficiency occurred in 8% of our study population, mainly in African Americans, American Indians, and Asians. Rheumatologists ordered most of the tests measuring G6PD levels primarily before considering SSZ therapy and were more likely to order duplicate tests when compared to other specialists. Unnecessary repeat testing is an issue that could be reduced with pop-up computer reminder. This study supports G6PD deficiency testing for high risk populations, including African Americans, American Indians, and Asians, but routine screening of all rheumatology patients for G6PD deficiency when considering SSZ therapy may not be needed.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The widespread usage of biologic disease modifying anti-rheumatic drugs (bDMARDs) in rheumatology has increased the risk of hepatitis B virus (HBV) re-activation. The prevalence of chronic HBV infection was estimated at 3.0% and 3.5%, respectively in two large, cross-sectional studies in rheumatoid arthritis and spondyloarthropathies internationally. HBV reactivation (HBVr) after using immunosuppressive medicines has been observed in 6.8% of fulminant hepatitis cases in Japan. We aimed to quantify the knowledge gap in the practice of rheumatologists with regards to management of HBVr in rheumatologic patients using a Canada-wide survey.

**Methods:** In order to assess the discrepancy in practice with regards to dealing with HBV infection in patients started on biologic and non-biologic DMARDs, we conducted a short pilot survey of 15 rheumatologists and 2 rheumatology fellows at an inter-city rheumatology rounds aimed at assessing any knowledge gap. Subsequently, an expert panel of five hepatologists, two infectious disease specialists and four rheumatologists helped generate a final questionnaire. The final survey included questions regarding chronic hepatitis B monitoring and anti-viral prophylaxis with either biologic or non-biologic DMARDs or corticosteroids. A Canada-wide survey was sent to the Canadian Rheumatology Association (CRA) members. The results were compared to the American Gastroenterology Association (AGA) guidelines.

**Results:** There were 17 respondents to the pilot survey. Of 7 questions in the pilot survey, there were 47% of questions that were either answered incorrectly or marked "I don't know". The final survey was sent to 521 members of CRA. The response rate was 27.25% for a total of 142 responses. Interestingly, 8.8% of the responders thought not to send their HBsAg positive patients to a gastroenterologist, although anti-viral prophylaxis would be indicated and hepatology monitoring. There were 58% of the respondents who would order unnecessary test like anti-HBs for monitoring a patient who is HBsAg positive and is on immunosuppressive medication. Another 43% answered incorrectly to start anti-viral prophylaxis for patients who are HBsAg positive and are on DMARDs.

**Conclusion:** The results of our survey highlight the knowledge gap in monitoring and treating chronic hepatitis B in rheumatology patients. All patients with hepatitis B surface antigen positivity on immunosuppression including prednisone should be referred to gastroenterology. Similarly, patients on high risk medicines with hepatitis B core antibody positivity despite hepatitis surface antibody status should be monitored and started early on anti-viral prophylaxis.

## Communication between Inpatient and Outpatient Specialty Clinicians: Developing a Better Understanding of Patients with Rheumatoid Arthritis Who Are Admitted to the Hospital

Abraham Tacang<sup>1</sup>, Christina Downey<sup>2</sup>, Alfred Denio<sup>1</sup>, Eric Newman<sup>3</sup> and Lisa L. Schroeder<sup>4</sup>, <sup>1</sup>Rheumatology, Geisinger Medical Center, Danville, PA, <sup>2</sup>Geisinger Medical Center, Danville, PA, <sup>3</sup>Department of Rheumatology, Geisinger Medical Center, Danville, PA, <sup>4</sup>Rheumatology, Geisinger Health System, Danville, PA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

## Background/Purpose:

Effective communication is essential in caring for medically complex patients with rheumatoid arthritis (RA). Communication between clinicians becomes even more crucial when a patient gets admitted to the hospital. Our study aims to investigate how often communication gaps occur at our institution, focusing primarily on RA patients, and subsequent consequences.

## Methods:

This is a retrospective cohort study of RA patients admitted to our institution from July 1, 2015 to June 30, 2016. All patients were seen by a rheumatologist at least twice within a 14-month period prior to the admission date. Data gathered include: admission type based on principal diagnosis (infection, cardiac, surgical, other), baseline glucocorticoid and immunosuppressive therapy, rheumatology service notification of a patient's current or upcoming admission and communication mode (inpatient consult, clinic visit, telephone encounter, discharge instructions or summary), flare up and/or glucocorticoid dose increase up to 3 months after discharge, appropriate preoperative C-spine xray, appropriate medication continuation or discontinuation, and appropriate re-initiation of discontinued medications.

## Results:

Two hundred twenty-nine admissions were included. Rheumatology was notified 57.6% of the time across all admission types. Medications (immunosuppressive and/or glucocorticoid) were appropriately held 36.4% of the time. Medications were rightfully continued for 73% of our patient cohort. Nineteen percent of our patients developed a flare within 3 months after discharge. Only 11% of our patients admitted for surgery had a preoperative C-spine xray. Among our surgical patients, 4 developed non-life-threatening infection and 1 patient had wound healing issues within 3 months after surgery.

## Conclusion:

Our retrospective study highlights both gaps in communication between rheumatology and admitting services, and in the care of RA patients admitted to the hospital. To our knowledge, this is the first study to investigate these gaps, and subsequent consequences, among RA patients followed in a large integrated healthcare system. One potential intervention to address the problem in communication is integrating an automated notification system within our electronic record to inform rheumatology clinicians when one of our RA patients is scheduled for an elective surgery, or gets admitted to the hospital. To bridge gaps in patient care, we are exploring ways to increase our rates of appropriate preoperative C-spine xrays, as well as appropriate medication continuation or discontinuation among our RA patients. This will be done through collaboration with our surgeons to establish a standardized evidence-based approach to the perioperative management of patients with RA.

Admission Type (n, %)	Notification Number (n, %)	Primary Notification Method (n, %)	Medication Continued Appropriately				Medication Held Appropriately			Flare within 3 Months After Discharge (n, %)	Preoperative C-spine			Infection Within 3 Months After Surgery			Wound Healing Issue Within 3 Months After Surgery

## Systematic Physician Assessment Beyond Inflammation in Routine Rheumatology Care Using Visual Analog Scale Scores for Inflammation, Damage, and Distress to

# Document Patient Status and Support Clinical Decisions: Analysis of Inter-Rater Reliability

**Shakeel M. Jamal**<sup>1</sup>, Theodore Pincus<sup>2</sup>, Isabel Castrejón<sup>2</sup>, Jacquelin R. Chua<sup>1</sup>, Aman Kugasia<sup>1</sup>, Juan Schmukler<sup>1</sup>, Stacy Weinberg<sup>1</sup> and Joel A. Block<sup>3</sup>, <sup>1</sup>Division of Rheumatology, Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology, Rush University Medical Center, Chicago, IL, <sup>3</sup>Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A physician global estimate of patient status (DOCGL) on a 0-10 visual analog scales (VAS) is as effective as any rheumatoid arthritis (RA) Core Data Set measure to quantify inflammatory activity in patients selected for clinical trials<sup>1</sup>. However, in routine care, DOCGL may be affected by joint damage and/or distress (e.g., fibromyalgia, depression, etc.), in addition to inflammation. Different physicians may consider these findings variably in formulating DOCGL. One approach to document the contribution of inflammation, damage, and distress to DOCGL is for the physician to complete 3 additional 0-10 VAS. We analyze inter-rater reliability between two rheumatologists for DOCGL and 3 VAS subscales for inflammation, damage, and distress.

**TABLE:** Mean and SD for the four physician estimates according to the rheumatologist (rheum) and the fellow, intraclass correlations and levels of concordance and discordance for each estimate. \*p<0.003

VAS (0-10)	Rheum Mean (SD)	Fellow Mean (SD)	Mean Difference	Intraclass Correlation (95% Confidence Interval)	Rheumatologist (Rheum) and Fellows concordance and discordance by 2/10 units, number (%)		
					Rheum> Fellow	Rheum= Fellow	Rheum< Fellow
Overall DOCGL	3.8 (1.9)	3.8 (2.2)	0.01	0.63 (0.46, 0.75)	22 (22%)	<b>73 (68%)</b>	12 (11%)
DOCINF	1.8 (1.5)	1.5 (1.6)	0.25	0.74 (0.62, 0.82)	7 (7%)	<b>91 (85%)</b>	9 (8%)
DOCDAM	2.7 (2.2)	2.7 (2.2)	-0.04	0.80 (0.70, 0.86)	20 (19%)	<b>76 (71%)</b>	11 (10%)
DOCSTR	3.2 (3.0)	2.2 (2.4)*	1.02	0.69 (0.55, 0.79)	11 (10%)	<b>68 (63%)</b>	28 (26%)

**Methods:** At one academic site, 4 VAS for overall DOCGL, and levels of inflammation [or reversible findings] (DOCINF), organ damage [or irreversible findings] (DOCDAM), and distress [or symptoms not explained by inflammation or damage such as fibromyalgia, depression] (DOCSTR), are scored in patients with all rheumatic diagnoses in routine care. At a weekly fellows' clinic, the four 0-10 VAS estimates scores were recorded independently by a senior rheumatologist and a rheumatology fellow at the same visit. The estimates of the 2 observers for each subscale were analyzed for mean levels, differences, intraclass correlation coefficients (ICCs), and possible discordance - defined as a difference of 2 units/10 between the 2 observers.

**Results:** Estimates of 2 rheumatologists were analyzed in 107 patients with different rheumatic diseases. Mean differences ranged from 0.01 for DOCGL to 1.02 for DOCSTR, significant only for DOCSTR (Table). The ICC ranged from 0.63 (DOCGL) to 0.80 (DOCDAM), a range higher than for joint counts<sup>2</sup>. Concordance of estimates (within 2/10 units) ranged from 63% (DOCSTR) to 85% (DOCINF).

**Conclusion:** Good agreement between two observers with different levels of clinical experience was seen for 4 physician 0-10 VAS estimates for overall global assessment, inflammation, damage, and distress. These data extend evidence for the value of physician VAS, as DOCGL distinguishes active from control treatments in rheumatoid arthritis (RA) clinical trials more efficiently than joint counts or laboratory tests<sup>1</sup>. Mean scores for damage and distress were higher than for inflammation, indicating the possible value for doctors, patients, and payers of quantitating damage, in addition to inflammation, to document patient status and support clinical decisions in routine care.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The ACR in 2013 and the Canadian Rheumatology Association (CRA) in 2015 published their respective Choosing Wisely recommendations to promote evidence-based care and reduce medical services that may have questionable value. HLA-B27 testing was #7 in ACR's and #2 in CRA's Choosing Wisely list of recommendations. HLA-B27 testing is not to be ordered unless features suggestive of a SpA are present. We sought to assess adherence to CRA's Choosing Wisely recommendations (presence of 2 or more features or 1 feature with radiographic sacroiliitis) by primary care physicians (PCP) ordering HLA-B27 within a large integrated healthcare system and to identify additional areas for quality improvement.

### **Methods:**

Retrospective analysis of all patients who had HLA-B27 testing at Regions Hospital/Health Partners, a large academic vertically and horizontally integrated healthcare system, from 1/1/2014 - 7/1/2015. Chart review identified features of SpA (defined as inflammatory back pain > 3 months with onset < 45 years old, peripheral synovitis, enthesitis, dactylitis, psoriasis, or uveitis) at the time of HLA-B27 testing. We assessed if any imaging (Xray, CT, or MRI) identifying sacroiliitis +/- 6 months from HLA-B27 order was present, the presence of inflammatory markers (ESR or CRP) +/- 1 month from the HLA-B27 order, and if an eventual diagnosis of SpA was made. Data were analyzed to generate descriptive information regarding frequency, demographics, as well as a cost analysis.

### **Results:**

During the 18 months, a total of 627 tests were ordered; 336 by Rheumatologists, 68 by Ophthalmology, and 223 by PCPs. Age ranged from 1 to 92 years. We focused on PCP ordered HLA-B27 testing habits. Applying Choosing Wisely recommendations, only 31 of 223 tests (13.9%) were ordered correctly; 20 (9%) had two or more features, and 11 (4.9%) had one feature with a positive imaging result. Even if ONE feature alone was allowed to be an indication for testing (as opposed to the CRA recommended TWO), only 38.1% of tests were ordered correctly. In comparison, 80% of tests ordered by rheumatologists had one feature and 35% had at least two. The average cost of HLA-B27 test within our payer system is \$70-100. Thus, a cost savings of \$15,000-20,000 would have occurred if ordered correctly. This does not include secondary costs of referrals to specialists for positive results.

### **Conclusion:**

Improperly ordered HLA-B27 tests occurred nearly 86% of the time from PCPs within our large integrated healthcare system resulting in a cost of \$15,000-20,000. EMR educational implementation plans have been shown to be effective for quality improvement. We are planning on utilizing EMR ordering alerts to aid HLA-B27 ordering that is more consistent with Choosing Wisely recommendations which promote evidence-based care.

**Table 1. Demographics and features in HLA-B27 testing between 1/2014 and 7/2015 in a large integrated healthcare system.**

	N (%), PCP Correctly Ordered	N (%), PCP Incorrectly Ordered	N (% of total)
Male	17 (54.84%)	104 (54.17%)	121 (54.26%)
Female	14 (45.16%)	88 (45.83%)	102 (45.74%)
<= 17 years old	0 (0.00%)	26 (13.54%)	26 (11.66%)
>= 18 years old	31 (100.00%)	166 (86.46%)	197 (88.34%)
<= 45 years old	22 (70.97%)	106 (55.21%)	128 (57.40%)
>45 years old	9 (29.03%)	86 (44.79%)	95 (42.60%)
Inflammatory Back Pain	20 (64.52%)	28 (14.58%)	48 (21.52%)
Peripheral Synovitis	13 (41.94%)	7 (3.65%)	20 (8.97%)
Enthesitis	1 (3.23%)	3 (1.56%)	4 (1.79%)
Dactylitis	5 (16.13%)	0 (0.00%)	5 (2.24%)
Psoriasis	11 (35.48%)	9 (4.69%)	20 (8.97%)
Uveitis	3 (9.68%)	7 (3.65%)	10 (4.48%)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Functional status assessment measures (FSAMs) are important outcomes in rheumatology and used to monitor response to treatment and aid in prediction of rheumatic disease outcomes. We conducted a systematic review of FSAMs used in the evaluation of patients with rheumatoid arthritis (RA). In this first phase of the study, we report on the identification and characteristics of the FSAMs. The ultimate objective is to develop American College of Rheumatology (ACR) recommendations for the use of FSAMs in clinical practice and quality measurement.

**Methods:** A search strategy was developed in consultation with a medical librarian and based on a published strategy for finding studies that evaluate the measurement properties of clinical instruments from the COnsensus-based Standards for the selection of health Measurement Instruments (COSMIN) group. This strategy involves the use of MeSH terms/keywords in three themes: #1 construct search (functional status), #2 population search (rheumatoid arthritis), #3 instrument search (including terms for instruments of interest). MEDLINE, EMBASE, Cochrane Library and CINAHL were searched from inception until March 16<sup>th</sup> 2017. Two reviewers independently considered papers for inclusion with disagreements resolved by consensus. FSAMs were included if the primary objective of the study was to develop, validate or establish the psychometric properties of a patient-reported FSAMs. Performance-based measures (e.g., grip strength, walk tests) and FSAMs addressing function of a single body part/region were excluded. Health related quality of life or health status measures that only in part addressed function were also excluded as they captured different constructs.

**Results:** 11,835 unique citations were found and 649 were selected for full-text review. Twenty-three FSAMs met inclusion criteria including 7 published variations of the Health Assessment Questionnaire (HAQ). Eleven measures were developed in the USA (48%), while the remainder were developed in Europe or with international participation. All of the FSAMs were questionnaires varying in length from 2 to 47 items with the exception of a single visual analogue scale. Eight (35%) FSAMs included questions about the use of assistive devices and one FSAM was specific to valued life activities. Range of scores was also often based on the original HAQ range of 0-3 (52% of measures). Where reported, time to administer scores was universally <10 minutes. Preliminary results indicate that the Patient-Reported Outcomes Measurement Information System (PROMIS) physical function questionnaires were highly robust and were correlated with the HAQ but had fewer ceiling effects, were sensitive to change and had high convergent validity.

**Conclusion:** There are 23 FSAMs for RA in the published literature of varying complexity. Further evaluation of the FSAMs along the 9 domains of COSMIN rating (internal consistency, reliability, measurement error, hypothesis testing, responsiveness and validity (content, structural, criterion and cross-cultural) is presently ongoing and will help determine final ACR recommendations for FSAM use in clinical practice.

### A genome-wide association study of gout in people of European ancestry

**Background/Purpose:** Genome wide association studies (GWAS) have provided considerable insight into the molecular control of urate levels. However, less is known about the progression from asymptomatic hyperuricemia to gout. Our aim was to conduct a GWAS for gout in people of European ancestry using the largest number of cases of gout to date.

**Methods:** This GWAS (7,431 cases and 105,631 controls) was comprised of three data sets: a mixed New Zealand (NZ), Eurogout, and Ardea Biosciences group (3,961 cases; 1,547 controls; genotyped using the Illumina CoreExome v24 array, 547,644 markers), a composite set from the Health Professionals Follow-Up (HPFS) and Nurses' Health Studies (NHS) (1,038 cases; 1,095 controls; genotyped using the Illumina OmniExpress v12 array, 730,525 markers), and UK Biobank (2,432 cases; 102,989 controls; genotyped using an Affymetrix Axiom array, 820,967 markers). The UK Biobank genotypes were imputed to ~73.3M SNPs. Neither the NZ/Eurogout/Ardea nor NHS/HPFS genotype sets were imputed. Markers found within all three data sets (234,062) were identified and associated with gout (adjusted for sex and age), within each data set separately, using PLINK v1.9. An inverse-variance weighted meta-analysis of the results was then performed using the meta v4.4 package within R v3.2.3. The overall genome inflation factor was 0.90.

**Results:** There were nine loci with experiment-wide significance ( $0.05/234,062$ ;  $P < 2 \times 10^{-7}$ ) for association with gout: *ABCG2* (OR=1.77), *SLC2A9* (OR=1.69), *GCKR* (OR=1.24), *MLXIPL* (OR=1.18), *SLC17A1-A4* (OR=1.22), *SLC16A9* (OR=1.18), *SLC22A12* (OR=1.16), *PDZK1* (OR=1.16), *TRIM46* (OR=1.15). All nine of these loci have been previously associated with serum urate levels in genome-wide studies with the urate-increasing alleles also associated with increased risk of gout in this study.

**Conclusion:** Our data emphasize the central importance of genetic involvement in serum urate levels, compared to the genetic involvement in MSU crystal formation, or the innate immune response, in determining gout.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Allopurinol at higher than CrCL based doses remains controversial due to concerns over increased risk of adverse events (AE). A recent 12month randomized controlled trial (RCT) reported that allopurinol above CrCL-based doses is effective and well tolerated. Here, we report the results of the 12month open label extension phase of this RCT. The aims were to determine the long-term safety and efficacy of allopurinol dose escalation to achieve target serum urate (SU) in people with gout.

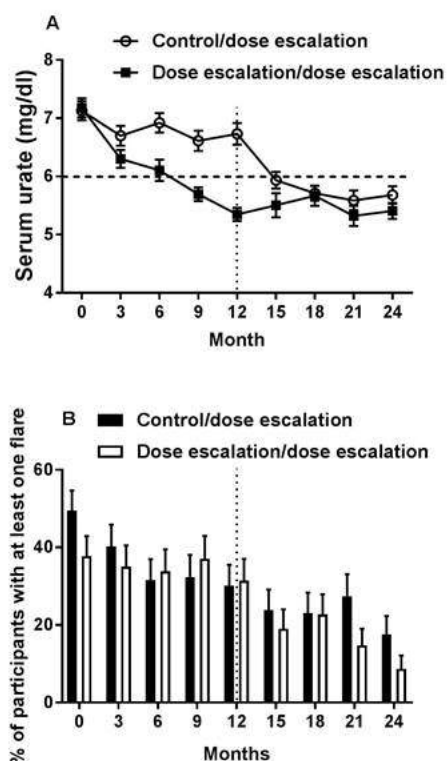

**Methods:** People who completed the first 12months of a randomized, controlled, parallel-group, comparative clinical trial continued into a 12month open label extension study (from Month 12 to 24). Participants randomised to the control group who continued their usual dose of allopurinol for the first 12months began allopurinol dose escalation at month 12 if SU was  $\geq 6\text{mg/dl}$  (control (C)/dose escalation (DE)). Those in the DE arm for the first 12months who had achieved target SU maintained the dose of allopurinol, while those with SU  $\geq 6\text{mg/dl}$  continued dose escalation (DE/DE). Allopurinol was increased monthly until SU was  $< 6\text{mg/dl}$ . The primary endpoints were reduction in SU and AEs at month 24. Secondary endpoints included the proportion of individuals with gout flares.

**Results:** Of the 183 participants who entered the study, 143 (78.1%) completed the month 12 visit and 137 (74.9%) completed month 24. The mean (SE) change in SU from month 12 to month 24 was -1.1 (0.2) mg/dl in the C/DE group and 0.1 (0.2) mg/dl in the DE/DE group ( $p < 0.001$ ) with a mean difference of 1.3mg/dl (95%CI 0.8-1.7),  $p < 0.001$ ). In the C/DE group mean (SE) SU was 7.13 (0.16) mg/dl at baseline and 5.7 (0.2) mg/dl at final visit, and 7.18 (0.2) mg/dl and 5.4 (0.1) mg/dl in the DE/DE group (Fig). SU was  $< 6\text{mg/dl}$

at final visit in 69.1% of the C/DE group and 79.7% in the DE/DE group ( $p=0.16$ ); odds ratio (OR) 1.8 (95%CI 0.8-3.8). There was a significant reduction in the percentage of individuals having a gout flare in the month prior to month 12 and month 24 in both groups ( $p<0.001$ ), but no difference between randomised groups ( $p=0.29$ ). There were similar numbers of AEs and serious AEs between groups. Mild elevations of AST, ALT and ALP were noted while some higher grade abnormalities in GGT were observed.

**Conclusion:** The majority of people with gout can achieve and maintain target SU with dose escalation of allopurinol above CrCL-based doses. Higher doses of allopurinol are well tolerated.

Figure: Mean serum urate (A) and percentage of participants reporting at least one gout flare in the preceding month (B) in control/DE and DE/DE groups. The vertical line represents the start of the open label extension phase of the study.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Allopurinol is the most widely used urate-lowering drug. However, some patients treated with allopurinol do not achieve serum urate (SU) treatment target of  $<6\text{mg/dl}$ , despite daily doses  $>300\text{mg}$ . *ABCG2 rs2231142* has been reported to be associated with poor response to allopurinol, while there are conflicting data on the association between *ABCG2 rs10011796* and allopurinol response. The aim of this study was to replicate the association of *ABCG2 rs2231142* and *rs10011796* with allopurinol response and perform a meta-analysis.

**Methods:** Participants in the Long-term Allopurinol Safety Study Evaluating Outcomes in Gout Patients (LASSO) with available allopurinol dose, plasma allopurinol, oxypurinol, serum urate and genotyping data from a single visit were studied ( $n=395$ ). In patients with evidence of adherence to allopurinol therapy (oxypurinol  $>20\mu\text{mol/l}$ ), good response was defined as serum urate (SU)  $<6\text{mg/dl}$  on allopurinol  $\leq 300\text{mg/d}$  and poor response as  $\text{SU} \geq 6\text{mg/dl}$  despite allopurinol  $>300\text{mg/d}$ . Association of *rs2231142* and *rs10011796* with poor response was tested in logistic regression models that included age, sex, body mass index (BMI), ethnicity and estimated glomerular filtration rate (eGFR). **Results** from the LASSO study and a subset of participants in Genetics of Gout in Aotearoa study on allopurinol with available data as outlined above ( $n=296$ , including 264 from the previously published report) were combined by meta-analysis.

**Results:** 24.3% (96/395) of the LASSO cohort and 13.5% (40/296) of the NZ cohort either did not fit the pre-defined response criteria and/or had plasma oxypurinol suggestive of non-adherence ( $<20\mu\text{mol/l}$ ) and were therefore excluded. 46.5% (139/299) of patients in the LASSO cohort and 50.8% (130/256) of patients in the NZ cohort were defined as poor responders. There was evidence for association of *rs2231142* with allopurinol response ( $\text{OR}=2.35_{\text{A allele}}$ ,  $P=7.3 \times 10^{-4}$ ) but not for *rs10011796* ( $\text{OR}=1.21_{\text{G allele}}$ ,  $P=0.33$ ) in the LASSO cohort using a fully adjusted logistic regression model. Meta-analysis with the Genetics of Gout in Aotearoa study participants provided strong and consistent evidence of an association for *rs2231142* with allopurinol response ( $\text{OR}=2.43$ ,  $P=6.2 \times 10^{-7}$ ), but not for *rs10011796* ( $\text{OR}=1.06$ ,  $P=0.69$ ) (Figure).

**Conclusion:** This study replicates the association of *ABCG2 rs2231142* with poor response to allopurinol. Testing *ABCG2 rs2231142* may assist in prediction of SU response in people treated with allopurinol.

## An Illness By Any Other Name: The Effect of Changing the Disease Label of Gout on the Perceptions of the Illness and Its Management

Keith Petrie<sup>1</sup>, Kate MacKrill<sup>1</sup>, Christina Derksen<sup>2</sup> and Nicola Dalbeth<sup>1</sup>, <sup>1</sup>University of Auckland, Auckland, New Zealand, <sup>2</sup>University of Marburg, Marburg, Germany

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is a chronic disease caused by deposition of monosodium urate crystals. Although diet is a risk factor, many other factors also contribute to development of gout, including age, male sex, kidney disease and genetic variants. Historical and contemporary narratives frequently depict gout as an acute condition caused by dietary overindulgence. These perceptions of illness may have a negative impact on healthcare-seeking and management strategies. The aim of this study was to examine the effect of changing the disease label of gout on the perceptions of the illness and its management.

**Methods:** Supermarket shopper participants were recruited into this study (n=189). Participants were advised that the aim of the study was to examine the perceptions of different types of arthritis. Participants were randomised to read an identical description of an illness labelled as either gout or urate crystal arthritis (UCA), and complete a questionnaire examining their perception of the illness, likely causal factors, and the usefulness of various management strategies. The label urate crystal arthritis was selected to represent the core pathophysiological elements of disease, including urate as the causative biochemical substrate, crystal deposition, and joint inflammation. Differences between the two illness labels were tested using independent sample t-tests.

**Results:** The gout-labelled illness was attributed more to patient behaviour ( $p = 0.030$ ) through poor diet ( $p = 0.013$ ) and overconsumption of alcohol ( $p = 0.039$ ), while the UCA- labelled illness was attributed more to aging ( $p = 0.006$ ). There were no differences in beliefs about other causal factors. The gout-labelled illness was viewed as under more personal control ( $p = 0.001$ ) and as more socially embarrassing ( $p < 0.001$ ), whereas the UCA- labelled illness was viewed as having a more chronic timeline ( $p = 0.044$ ) and as a more serious condition ( $p = 0.037$ ). Changing to a healthier diet was perceived as more helpful for the gout-labelled illness ( $p = 0.014$ ). In contrast, taking long-term medications for the condition was viewed as more helpful for the UCA-labelled illness ( $p = 0.041$ ). There was no significant difference between the illness labels in perceptions that reducing stress, adopting regular exercise, losing weight or using alternative medicine would be helpful for managing the illness ( $p$  for all  $> 0.08$ ).

**Conclusion:** The negative cultural stereotypes surrounding the disease label gout may be a barrier to effective treatment. Changing the name of the illness from gout to a pathophysiological illness label such urate crystal arthritis may have a positive benefits for patient understanding of the condition and the adoption of effective management strategies.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

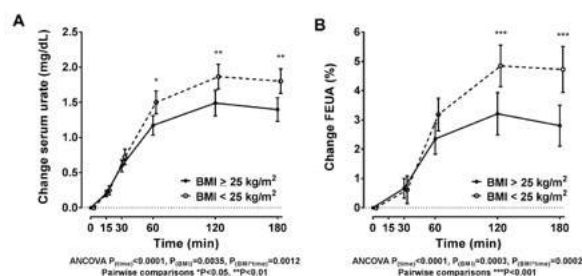

**Background/Purpose:** Increased body mass index (BMI) is an important risk factor for hyperuricemia and gout. It is unknown whether overweight and obesity influences serum urate primarily through increased urate production or reduced renal clearance of uric acid. Inosine is a purine nucleoside that functions as an intermediate in the purine salvage and degradation pathways. Oral administration of inosine allows analysis of the effects of a standardized purine load on both serum urate concentrations and renal uric acid handling. The aim of this study was to determine the influence of body mass index on the response to an inosine load.

**Methods:** Following an overnight fast, 100 healthy participants, recruited by public advertising, attended a study visit. Exclusion criteria included chronic kidney disease stage 3 or worse, gout, diabetes mellitus and diuretic use. Blood and urine samples were obtained for urate and creatinine, prior to and then 15, 30, 60, 120, and 180 minutes after a single oral 1.5g dose of inosine. Clinical features including age, sex, ethnicity and BMI were recorded. Data were analysed according to increased BMI (25kg/m<sup>2</sup> or more) and low/normal BMI (less than 25kg/m<sup>2</sup>). The primary endpoint was change in serum urate and secondary endpoint was change in fractional excretion of uric acid (FEUA). Data were analysed using a mixed models approach to repeated measures.

**Results :** In the entire study population, oral intake of inosine led to large increases in serum urate (mean increase 1.6mg/dL) and FEUA (mean increase 3.7%) over the 180 minute study period (P<0.0001 for both). Although participants in the increased BMI group (n=52) had higher serum urate concentrations at baseline (age, sex, ethnicity-adjusted P=0.002), this group had a smaller increase in serum urate following the inosine load (age, sex, ethnicity-adjusted ANCOVA P=0.0035, Figure 1A). The two BMI groups had a similar FEUA at baseline (age, sex, ethnicity-adjusted P=0.98), but those in the increased BMI group had a smaller increase in FEUA following the inosine load (age, sex, ethnicity-adjusted ANCOVA P=0.0003, Figure 1B).

**Conclusion:** People with increased BMI do not have an exaggerated hyperuricemic response to a standardized purine load. However, those with increased BMI do have reduced renal excretion of uric acid following inosine loading. These data demonstrate impaired renal clearance of uric acid following dietary purine intake in those with overweight and obesity.

**Figure 1.** A Change in serum urate, and B. Change in FEUA following an oral inosine load in different BMI groups. Data are presented as unadjusted mean (95% CI). Age, sex and ethnicity-adjusted ANCOVA P values are shown.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

While gout is the most common form of inflammatory arthritis, there are relatively few studies on the influence of sex with regard to disease presentation and comorbidities as well as flare and hospitalization rates among patients with gouty arthritis. Possible determinants of these outcomes in patients with gouty arthritis based upon sex were evaluated using a population-based cohort.

### Methods:

The individual medical records of all patients with a potential diagnosis of gout in a geographically defined area were retrospectively reviewed using a resource insuring complete capture. All individuals with a possible diagnosis of incident gout in 2009-2010 were identified. Incident cases had to fulfill at least 1 of 3 criteria: the 1977 American College of Rheumatology proposed criteria for gout, the Rome or New York criteria. All identified cases were followed up through their records for 5 years after incident gout attack, death or migration, whichever came first. Clinical characteristics were compared using chi-square and rank sum tests. Person-year methods were used to estimate and compare flare and hospitalization rates over time.

### Results:

A total of 271 patients (196 males; 72%) with incident gout in 2009-2010 were identified. Females had significantly higher mean (SD) age at diagnosis 66.3 (15.7) years compared to males 57.6 (16.9) years ( $p<0.001$ ). Although the mean (SD) body mass index (BMI) for females 32.1 (8.9) did not differ from males 32.0(5.8) ( $p=0.48$ ), more females were morbidly obese ( $BMI \geq 40 \text{ kg/m}^2$ ) than males (25% vs 8%;  $p<0.001$ ). Podagra was less common in females than males (51%vs 62%), but this did not reach statistical significance ( $p=0.10$ ). Females had significantly more chronic kidney disease stage 3/4 (36% vs 20%;  $p=0.006$ ) while hypertension, diabetes and heart disease were non-significantly increased in females compared to males.

During a median of 4.7 years of follow up, 127 males and 31 females experienced at least one gout flare with no significant difference in the number of involved joints. Males reported a total of 323 flares with a rate of 3.97 person-years (py), higher than the 74 flares experienced by females with a rate of 2.28 per 10 py (rate ratio: 1.73; 95% confidence interval [CI]: 1.36-2.25). This difference persisted after adjustment for multiple flares per person (hazard ratio: 1.51; 95% CI: 1.14-2.00).

In the follow up period, 69 male patients and 41 female patients were hospitalized. Males were hospitalized 169 times for a rate of 2.08 per 10 py which is less than the reported 137 hospitalizations for females with a rate of 4.22 per 10 py (rate ratio: 0.49; 95% CI: 0.39 -0.62). However, this difference was no longer significant after accounting for the older age of the females

### Conclusion:

Female patients with gout are older at incidence than males and tend to have more associated common co-morbidities, particularly chronic kidney disease. Podagra is less common in females than males. Female patients tend to have fewer flares as compared to males. Adjusted for age, there was no difference in hospitalization rates between males and females.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate the clinical features and risk of gout recurrence in patients with normouricemia during an acute attack

## Methods:

This study was conducted in patients diagnosed with acute gout attack by the presence of urate crystals. Clinical features of normouricemic and hyperuricemic patients were compared. Multivariate analysis was performed to determine whether normouricemic patients during an acute attack were less likely to have a recurrent gout attack.

**Results:** Among a total of 221 gout patients, 88 (39.8%) had normouricemia during an acute attack. Postsurgical gout (22.7% vs 6.0%,  $P < 0.001$ ), hemodialysis initiation (9.1% vs 2.3%,  $P = 0.029$ ) and inflammatory activity were higher in normouricemic patients than in hyperuricemic patients. The frequency of renal insufficiency was lower in normouricemic patients (25.0% vs 53.4%,  $P < 0.001$ ). However, the recurrence rate of gout attack was not different between the two groups during the follow-up period (24.7% vs 33.0%,  $P = 0.220$ ). In multivariate analysis, female sex, history of urinary stone, presence of tophi, and use of thiazide were associated with risk of recurrent gout attack, but not with serum urate status during an acute attack (HR 1.075, 95% CI 0.972-1.190,  $P = 0.159$ ).

**Conclusion:** Normouricemia during an acute gout attack was more frequently observed in postsurgical episodes, hemodialysis initiation and patients with preserved renal function. The recurrent attack was not associated with serum urate levels during an acute gout attack. Thus, careful follow-up should be considered in gout patients regardless of serum urate levels during an acute attack.

## Protective Effect of Allopurinol Use on Kidney Function Among Patients with Gout and Chronic Kidney Disease

Ana Beatriz Vargas-Santos<sup>1</sup>, Christine Peloquin<sup>2</sup>, Yuqing Zhang<sup>3,4</sup> and Tuhina Neogi<sup>4</sup>, <sup>1</sup>Internal Medicine - Rheumatology, State University of Rio de Janeiro, Rio de Janeiro, Brazil, <sup>2</sup>Clinical Epidemiology Unit, Boston University School of Medicine, Boston, MA, <sup>3</sup>School Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>4</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is increasing evidence that allopurinol may be protective of kidney function among hyperuricemic subjects, though clinicians are often cautious about using allopurinol in renal insufficiency. Further, studies have been conflicting and few have involved patients with gout. We sought to evaluate the relation of allopurinol to kidney function among gout patients with chronic kidney disease (CKD) stage 3-4 at the start of therapy.

**Methods:** We conducted a time-stratified propensity score (PS)-matched cohort study in The Health Improvement Network (THIN), a general practitioner electronic medical records database representative of the UK general population. Our study sample included subjects 18-89 years-old with gout and CKD 3 or 4 who had not previously been on urate-lowering therapy. We used PS matching to minimize the effects of confounding by indication. Specifically, we identified new users of allopurinol among this cohort, and matched them 1:1 with an unexposed subject based on the PS using greedy matching within 1-year cohort accrual blocks. We computed the PS using logistic regression, with incident allopurinol use as the dependent variable and potential confounders that reflect indication for allopurinol use and/or risk of CKD (table) as the independent variables. Subjects were followed from the index date (date of 1<sup>st</sup> allopurinol prescription for the exposed, and randomly assigned date for the unexposed within the 1-year accrual block) until the last glomerular filtration rate (GFR) assessment within 1 year after the index date (before dialysis, kidney transplant, or death if they occurred), or end of study. We analyzed the relation of incident allopurinol use to the changes in GFR using linear regression adjusted for the potential confounders included in the PS model.

**Results:** Of those with a diagnosis of gout and CKD 3-4, we PS-matched 9,830 allopurinol initiators to 9,830 non-users, among whom 41% and 42% were female. Other covariates were also well-balanced, with mean age of 74 years, mean BMI of 30 kg/m<sup>2</sup> and 9% of CKD4 subjects in both groups. Time to post-baseline GFR, and dialysis/transplant were similar in both groups. The mean GFR prior to study entry was 46.8 mL/min among allopurinol initiators and 49.8 mL/min among non-users, while the last GFR within one year was 47.8 and 50.0 mL/min, respectively. Allopurinol initiators had an adjusted mean increase in GFR that was 0.8 mL/min (95% CI 0.6-1.1) greater than that of the non-users (Table).

Table. Mean difference in GFR between allopurinol initiators and non-users with CKD stage 3-4 at baseline.

	Allopurinol initiator (N=9,830)	Non-allopurinol user (N=9,830)
Mean GFR prior to index date (mL/min)	46.82	49.83
Mean GFR within one-year post-index date (mL/min)	47.83	50.01
Mean GFR difference (mL/min)	1.01	0.18
Propensity scores-matched mean difference (95% CI)	0.84 (0.58-1.09)**	
Adjusted* mean difference (95% CI)	0.84 (0.58-1.10)**	

\* Variables included in the propensity score model and included in the adjusted propensity-score model: 1) baseline CKD stage 4; 2) general (age, gender, body mass index); 3) hospitalization; 4) comorbidities (cardiovascular disease/heart failure/hypertension; diabetes mellitus); 5) medication use (diuretics; angiotensin-converting-enzyme inhibitor/non-losartan angiotensin II receptor blockers; losartan; aspirin; colchicine; nonsteroidal anti-inflammatory drugs).

\*\* p-value <0.0001

GFR: glomerular filtration rate; CKD: chronic kidney disease; CI: confidence interval.

**Conclusion:** In this community-based cohort, allopurinol use appeared to confer a renoprotective effect among those with pre-existing CKD 3-4 and gout, suggesting that allopurinol does not contribute to worsening renal function among gout patients with renal insufficiency. Physicians should seek other contributors to renal function decline in patients on allopurinol with concomitant gout and CKD if renal function deteriorates.

## Efficacy of High Dose Versus Moderate Dose Prednisone in the Treatment of Acute Gout

Rochella A. Ostrowski<sup>1</sup>, Elizabeth Araujo<sup>2</sup>, Richard Hariman<sup>3</sup> and Elaine Adams<sup>4</sup>, <sup>1</sup>Division of Rheumatology, Loyola University Medical Center, Maywood, IL, <sup>2</sup>Rheumatology and Immunology, Department of Internal Medicine 3, Universitätsklinikum Erlangen, Erlangen, Germany, Erlangen, Germany, <sup>3</sup>Rheumatology, Medical College of Wisconsin, Milwaukee, WI, <sup>4</sup>Rheumatology, Edward Hines Jr Hospital, Veterans Administration, Hines, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Despite the use of corticosteroids in acute gout, there exist wide variations in treatment doses and duration. No studies have evaluated the ideal dose of steroids for gout flares. However, occurrences of treatment failure and side effects from treatment warrant an evaluation for the lowest effective dosing. The goal of this double blinded prospective pilot study is to compare efficacies of a moderate dose and high dose prednisone course in treating acute gout.

### Methods:

Male subjects age 18 years and older at Edward Hines Jr Hospital VA with acute gout were included. Patients with heart failure exacerbation, uncontrolled diabetes mellitus, infection, pseudogout, or chronic prednisone use were excluded. Subjects were randomized to a high or moderate dose of prednisone (high: 60mg on day 1, decreased by 10mg each day for a 6 day course; moderate: 30mg on day 1, decreased by 5mg each day for 6 days).

The primary endpoint was improvement in pain at 48 hours based on a 200mm visual analog scale. Secondary endpoints included the proportion of patients with resolution of synovitis by Day 7; absence of recurrent flares at 28 days; the proportion of patients who returned to baseline pain by day 7; and the number of days to return to baseline pain levels.

An intention-to-treat approach was used for analysis. Student t-test was used to compare mean values and Fishers exact test was used to compare proportions (STATA 11.1).

### Results:

139 patients were screened, and 33 patients were enrolled between September 2007 and December 2014. All patients enrolled were male, with a mean age of 62.2 ( $\pm$  11.8) and 63.4 ( $\pm$  15.8) years in the moderate and high dose groups respectively. Results are summarized in Table 1. The mean percent improvement in pain severity at 48 hours was higher in the high dose group (51.9 vs 43.7%), though it did not achieve statistical significance. Of 26 patients examined at day 7, a higher proportion of patients in the moderate dose group experienced resolution of synovitis, though this finding did not reach statistical significance (0.75 in moderate group vs 0.36 in high group).

The proportion of patients back at baseline pain on day 7 was significantly higher in the moderate dose group (0.73 vs 0.26,  $p=0.013$ ). The time to return to baseline pain levels was also shorter in the moderate dose group but did not achieve statistical significance.

Response to Steroid Treatment

	Moderate Dose	High Dose	P value
Mean Percent improvement in pain severity at 48 hours (95% CI)	43.7 (28.7, 58.6) n=16	51.9 (32.9, 71.0) n=15	0.4673
Proportion of patients with resolution of synovitis at day 7 (95% CI)	0.75 (0.48, 1.02) n=12	0.36 (0.08, 0.63) n=14	0.062
Proportion of patients without recurrence of flares between days 7 and 28 (95%CI)	0.75 (0.52, 0.98) n=16	0.73 (0.49, 0.97) n=15	0.618
Proportion of patients who achieved baseline status based on pain scale (95%CI)	0.73 (0.49, 0.98) n=15	0.26 (0.02, 0.51) n=15	<b>0.013</b>
Mean days to return to baseline status based on pain scale (95%CI)	5.41 (4.23, 6.59) n=17	6.2 (4.94, 7.46) n=15	0.338
Proportion of patients who resumed functional status of affected joint at 48 hours (95%CI)	0.88 (0.72, 1.05) n=17	0.87 (0.68, 1.05) n=15	0.650

Table 1

### Conclusion:

In this randomized double blinded pilot study, there were no significant differences between the response of acute gout to high dose versus moderate dose prednisone at 48 hours and exam findings on day 7. Furthermore, the proportion of patients who returned to baseline pain levels was lower in the high dose group, contrary to what investigators hypothesized would occur. Despite size limitations of this pilot study, our findings warrant larger trials to establish a standardized, evidence based practice for appropriate dosing of steroids in acute gout.

## Risk of Cardiovascular Events in Older Patients with Gout Initiating Probenecid Versus Allopurinol: A Population-Based Cohort Study

Seoyoung C. Kim<sup>1</sup>, Tuhina Neogi<sup>2</sup>, Eun Ha Kang<sup>3</sup>, Jun Liu<sup>4</sup>, Rishi J. Desai<sup>5</sup>, MaryAnn Zhang<sup>6</sup> and Daniel H. Solomon<sup>7</sup>,

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is associated with an increased risk of cardiovascular (CV) disease including myocardial infarction (MI), stroke and heart failure (HF). Although both probenecid and allopurinol have been available for treatment of gout for many decades, no studies have directly compared CV safety of these drugs. Both drugs lower uric acid through different mechanisms and have other pharmacologic effects possibly tied to CV disease.

**Methods:** To determine comparative CV safety of probenecid versus allopurinol, we conducted a cohort study of gout patients enrolled in Medicare (2008-2013). Gout patients aged  $\geq 65$  years who initiated probenecid or allopurinol were identified with having continuous enrollment in Parts A/B/D for  $\geq 1$  year free of a given drug prior to the 1<sup>st</sup> dispensing date (i.e., index date). Patients with ESRD, dialysis or renal transplant were excluded. The primary outcome was a composite CV endpoint of MI or stroke using a validated claims-based algorithm (PPV $>94\%$ ). Secondary outcomes included MI, stroke, coronary revascularization, and HF. Follow-up time started from the day after the index date to the earliest CV endpoint, drug discontinuation, nursing home admission, death, or end of study period. To control for  $\geq 50$  potential confounders at baseline, probenecid initiators were matched to allopurinol initiators on a propensity score (PS) with a ratio of 1:3. Incidence rates (IR) and hazard ratios (HR) were estimated in the PS-matched cohort. We also conducted subgroup analyses among patients with no known CV disease or chronic kidney disease (CKD) at baseline.

**Results:** We included a total of 9,722 probenecid initiators PS-matched on 29,166 allopurinol initiators with mean ( $\pm$  SD) age of 76 ( $\pm$  7) years and 54% were men. All the baseline covariates were well-balanced between the two PS-matched groups. During the 365-day baseline period prior to the index date, 28% had evidence of CVD, 27% HF, 45% diabetes, and 28% CKD. 71% had any use of colchicine, 48% opioids, and 35% oral steroids at baseline. The IR of MI or stroke per 100 person-years was 2.29 in probenecid and 2.82 in allopurinol initiators with HR of 0.78 (95%CI 0.67-0.90). In the secondary analyses, probenecid was associated with a decreased risk of MI, stroke and HF exacerbation versus allopurinol (see **Table**). Subgroup analyses in probenecid initiators vs. allopurinol showed consistent results with HR of 0.82 (95%CI 0.67-0.99) for the composite CV endpoint of MI or stroke among those without baseline CV disease and HR of 0.84 (95%CI 0.70-1.01) in those without baseline CKD.

**Conclusion:** In this large cohort study of 38,888 elderly gout patients enrolled in Medicare, use of probenecid appears to be associated with a modestly decreased risk of CV events including MI, stroke and HF exacerbation compared to allopurinol. Previous research has found direct positive CV effects of probenecid, suggesting that it should be investigated as a potential CV treatment.

**Table. Risk of cardiovascular events in probenecid initiators versus allopurinol: 1:3 fixed ratio PS-matched**

	Probenecid (n=9,772)				Allopurinol (N=29,166)			
	Event (n)	Person-years	IR * (95% CI)	HR (95% CI)	Event (n)	Person-years	IR * (95% CI)	HR (95% CI)

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The goal of gout treatment is to reduce serum uric acid (sUA) concentrations below the urate solubility limit. Diacerein is known as an oral IL-1 $\beta$  modulator and also discovered to possess uric acid-lowering effects by inhibiting urate transporter 1 (URAT1). This study was a randomized, placebo-controlled multicenter, 16-week Phase 2 study designed to test the urate-lowering effects, safety and tolerability of diacerein controlled release tablets (CR), which is designed for bioavailability and pharmacokinetic improvement, and adverse effect alleviation as compared with the currently available immediate-release oral formulation.

**Methods:** The study comprised 4 periods of 4 weeks each: blinded study medication only, combination with febuxostat 40 mg once daily (QD), study medication plus febuxostat with titration to 80 mg febuxostat QD for those not achieving sUA <6 mg/dL, and finally febuxostat alone. A total of 127 subjects with hyperuricemia and gouty arthritis were randomized to diacerein 100 mg or placebo twice daily (BID). Subjects were Asian, primarily male, mean age 47 years, mean duration of gout 8.7 years, and mean sUA 9.0 mg/dL at baseline.

**Results:** The study was powered to show a difference in proportion of subjects achieving target sUA <6 mg/dL at Week 8 with significance assessed at a 1-sided p-value <0.05. Significantly more diacerein than placebo subjects (64% vs 55%) achieved the endpoint (p = 0.0337). Also, more diacerein subjects achieved sUA <5 mg/dL at Week 8 (39% vs 27%; p=0.0140). The overall flare rate was not different between groups.

There were no serious adverse events in either group; 6% of diacerein subjects withdrew due to an adverse event. The most common adverse events with diacerein were diarrhea (27%) and soft stools (13%).

**Conclusion:** This study showed that treatment with diacerein 100 mg BID increased the odds of achieving the clinical sUA target of <6.0 mg/dL at Week 8, after 4 weeks of treatment with diacerein alone and 4 weeks of diacerein in combination with 40 mg febuxostat QD. Treatment with diacerein was shown to be safe and well tolerated with no new safety trends noted in this study. In combination with a low-dose xanthine oxidase inhibitor, diacerein could be a potential formulation to increase the percentage of gout patients who reach the sUA target without increasing flare rates.

Table 1. Demographic and Baseline Characteristics

Characteristic	Diacerein 100 mg BID (N = 67)	Placebo BID (N = 60)
Age (years) – Mean (SD)	47.2 (11.7)	47.5 (13.1)
Gender – n (%)		
Male	62 (92.5)	59 (98.3)
Female	5 (7.5)	1 (1.7)
Race – n (%)		
Asian	67 (100)	60 (100)
sUA (mg/dL) at baseline – Mean (SD)	9.1 (1.7)	8.9 (1.5)
Weight (kg) – Mean (SD)	76.6 (12.9)	78.1 (15.0)
Gout duration (yr) – Mean (SD)	9.0 (7.8)	8.3 (8.4)
Flares in prior year – Mean (SD)	3.0 (3.8)	2.2 (2.4)
Subjects w/ tophus – n (%)	6 (9.0)	4 (6.7)
Metabolic disease history – n (%)	41 (61.2)	35 (58.3)
SD = standard deviation.		

Table 2. Proportion of Subjects Achieving sUA <6.0 and <5.0 mg/dL at Week 8			
	<b>Diacerein</b> 100 mg BID (N = 67) n/N (%)	Placebo BID (N = 60) n/N (%)	p-value
			1-sided
sUA <6.0	43 / 67 (64.2%)	33 / 60 (55.0%)	0.0337
Odds Ratio (95% CI)	2.1069 (0.9508, 4.6687)		
sUA <5.0	26 / 67 (38.8%)	16 / 60 (26.7%)	0.0139
Odds Ratio (95% CI)	2.5352 (1.0955, 5.8667)		
CI = confidence interval.

## Long-Term Adherence to Urate-Lowering Therapy in Gout: Do Not Blame on the Patients

**Fernando Perez-Ruiz**<sup>1</sup> and Sandra Chinchilla<sup>2</sup>, <sup>1</sup>Rheumatology Division, Hospital Universitario Cruces, Baracaldo, Spain, <sup>2</sup>BioCruces Health Research Institute, Barakaldo, Spain

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** adherence to urate-lowering treatment (ULT) in patients with gout is reported to be lower than 50% in the first year and below 20% at 2-year, and worse than in other chronic conditions such as hypertension, diabetes, or hyperlipidemia. This was to evaluate adherence to ULT both overall and during follow-up, to compare it to the adherence to medications for associated comorbidities, and to explore potential causes for non-adherence to ULT.

**Methods:** transversal study of a nested cohort of patients in a gout-office hospital setting who were scheduled for a follow-up visit during 6 months in 2016. General data of patients, along with variables related to gout and to comorbid conditions are systematically retrieved at first visit; prescribed ULT, doses, adherence, and serum urate levels were obtained during the follow-up visits. Adherence was retrieved as medication possession rate (MPR) according to pharmacy offices from government electronic databases (including >98% of the general population). Also, MPRs of drugs prescribed for hypertension, diabetes (only oral), and hyperlipidemia were obtained; if more than one drug prescribed for any of the previous, the best adherence per comorbidity treatment was entered. Good adherence was considered as MPR>80 per cent of that prescribed, target serum urate (sUA) as <0.36 mmol/L.

Patients are educated at first visit and encouraged to be adherent from baseline through to follow-up visits.

**Results:** adherence data were available from 209 patients who were scheduled for a follow-up visit during the observation period; 14 (6.7%) patients did not attend the visit. This sample was formed by 90% male, only 55% had received ULT previous to first visit, median age was 65 years at follow-up visit, 47% and 44% showed polyarticular and tophaceous disease at baseline, respectively. MPR overall showed a median of 89% (IQR 79-94, N= 209) for ULT (72% showed MPR>80), and 89% (IQR 81-94, N= 119), 88% (IQR 79-94, N= 65), and 82% (IQR 77-93, N= 28) for hypertension, hyperlipidemia, and diabetes respectively (p<0.05 only for diabetes).

Adherence was lower for patients who did not attend the scheduled visit (median MPR 58% vs. 86%, MPR > 80, 21% vs. 75%, p<0.01). Adherence was lower during the first year (80%, N=67) compared to 2-3 year period (86%, N=67) or 4 or over (89%, N=75). MPR>80 were 57%, 76% y 81% for the same periods of follow-up, respectively. Good adherence was associated to a rate of target serum urate of 90%, compared to 72% for patients showing MPR<80.

Male gender and un-attendance to scheduled visit were statistically associated to MPR<80 in multivariate analysis; rate of achieving MPR80 was numerically higher with increasing age and overall comorbidity.

**Conclusion:** adherence to ULT measured as MPRs in a cohort of educated patients is good, sustained during follow-up, and similarly good to that for comorbid conditions (hypertension, hyperlipidemia, and diabetes); therefore, we cannot blame poor adherence on the patients any more. Avoiding absenteeism could be an opportunity for further improvement.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with gout frequently have multiple serious co-morbidities, take concomitant medications, and have complex clinical profiles, making treatment of acute flares in hospital settings difficult. We evaluated the current management of inpatient acute gout in an academic tertiary-care hospital.

**Methods:** Retrospective data review of acute gout flares occurring during hospitalization at the University of Chicago Medical Center in the period 01/01/2013 to 10/01/2015 was undertaken. To be included, a rheumatology consulting service had to have confirmed acute gout (ICD-9 code 274.xx) as a primary or secondary diagnosis. We reviewed demographics, comorbidities, gout flare characteristics, serum uric acid and creatinine levels, and treatment of gout flare. Multivariate logistic regression was performed to determine factors associated with discontinuation or dose reduction of baseline XOI therapy.

**Results:** 112 patients were included in the study. Mean patient age was  $63.8 \pm 13.7$  (SD) years, and 75% were male. Baseline characteristics included a prior history of gout (70%), chronic kidney disease (58%), heart failure (47%), and diabetes mellitus (37%). Active infection (34%) and acute kidney injury (43%) were common preceding the acute gout attack. Mean serum urate levels during flares were  $8.2 \pm 2.7$  (SD) mg/dL, but 29 % of values were  $\leq 6.0$  mg/dL. Treatments for acute attacks included non-steroidal anti-inflammatory drugs (2%), colchicine (18%), intra-articular steroids (49%), and systemic steroids (64%). 79% of systemic steroid administration were administered to patients at high risk for steroid-induced complications, including heart failure, diabetes, active infection, or immediate post-operative status. In patients on baseline XOIs prior to admission, discontinuation or dose reduction occurred in 33% (18/54) of cases. Multivariate logistic regression analysis, when adjusted for age and sex, revealed discontinuation or dose reduction of baseline XOI therapy was more likely in patients with acute kidney injury (OR: 8.34, 95% CI [2.04, 43.22]), but less likely when acute gout was the primary reason for hospitalization (OR: 0.086, 95% CI [0.0038, 0.70]). 23% of patients with a prior history of gout were not on urate lowering therapy despite meeting ARA criteria for acute gout.

**Conclusion:** Acute gout treatment in hospitalized patients is complicated by a high prevalence of comorbidities, multiple concomitant medications, and acute organ dysfunction. Systemic steroids are ordered frequently for hospitalized patients with acute gout that are at risk for steroid-induced complications. Discontinuation or dosage reduction of XOIs during hospitalization commonly occurs during acute kidney injury, but the evidence basis for this remains to be established.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hyperuricemia i.e. increased s-uric acid levels (s-UA), is established risk factor for clinical gout. Studies regarding the absolute and relative effect on population level have suggested a dose-dependent increase in risk of developing gout with increasing serum urate level (1). We aimed to explore the long-term risk of developing gout among asymptomatic adults with different levels of baseline hyperuricemia who participated in Malmö Preventive Project (MPP).

**Methods:** MPP is a screening program for cardiovascular risk factors, alcohol abuse and breast cancer in Malmö, Sweden. Overall, 33,346 individuals (67% male, mean age 45.7 years at inclusion, mean follow up 28.2 years) participated. The study population was screened between 1974 and 1992. A baseline health screening included: *questionnaire* with 260 questions (socioeconomic factors, alcohol consumption, smoking, physical activity, dietary habits, history of gout and other co-morbidities); *physical examination* (length, weight, blood pressure), and *laboratory tests* (s-UA, fasting glucose, s-creatinine). Endpoint was defined as date of first gout diagnosis, death, moving from area or December 31<sup>st</sup> 2014.

In order to identify all gout diagnoses (using ICD-codes) given at visits to physicians within primary care, specialized in-patient and out-patient specialized care, MPP cohort was linked to regional health care register and to national patient register, respectively. Baseline s-UA levels were stratified into 4 categories: normal levels ( $\leq 360 \mu\text{mol/L}$ ); 361-405 (levels under tissue solubility of UA); 406-500 and  $>500$ . The absolute risks for gout by these s-UA strata are presented and Cox regression models are used to determine the relative risks; unadjusted and age-adjusted.

**Results:** Overall, 1279 individuals (3.8%), 1018 men (4.5%) and 261 women (2.4%) of these middle-aged subjects developed gout during the follow up. Of those with s-UA 406-500 and  $>500 \mu\text{mol/L}$  corresponding absolute risks were 14% and 21.7% (men) and 15.6% and 52.9 (women). Compared to subjects with low s-UA levels, subject with different levels of hyperuricemia had an increase HR for being diagnosed with gout, with HRs varying in men between 3 -15 and in women between 6 -106 (Table).

**Conclusion:** The risk for developing gout over 30 years in middle-aged subjects was 3.8% but varied considerably with baseline s-UA levels. Compared to normal S-UA levels, having s-UA $>500 \mu\text{mol/L}$  was associated with 15- and 100-fold increased risk of gout in men and women, respectively. These results indicate the risk for developing gout in hyperuricemic subjects may be higher than previously reported.

## Diabetes and Gout: Real-World Evidence Evaluating Patient Characteristics, Treatment Patterns, and Health Care Utilization

**Douglas C.A. Taylor**<sup>1</sup>, An-Chen Fu<sup>1</sup> and Robert Morlock<sup>2</sup>, <sup>1</sup>Ironwood Pharmaceuticals, Inc., Cambridge, MA, <sup>2</sup>YourCareChoice, Ann Arbor, MI

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout and type 2 diabetes mellitus (T2DM) are common in the United States (US), but little is known about potential associations of T2DM and hyperuricemia/gout with clinical outcomes. This study examined variations in gout severity, management, and health care utilization among gout patients with and without T2DM.

**Methods:** Data were assessed from a survey of US physicians and patient chart audits. Participating physicians managed the care of ≥50 patients with gout annually; chart audits were of their last 5 consecutive adult patients with confirmed gout. Gout severity was measured by physician global assessment, flares, organ/joint damage, and tophi. Treatment characteristics, presence of clinician-confirmed T2DM, and sociodemographics were identified. Descriptive and multivariate (stepwise logistic regression) statistics analyzed the differences among gout patients with and without clinician-confirmed comorbid T2DM, and assessed urate-lowering therapy (ULT) use and gout control.

**Results:** Overall, 1159 charts of patients with gout were abstracted (246 with T2DM, 913 without T2DM; 80.50% male; 71.18% Caucasian); for patients with gout aged ≥61, a significantly higher proportion had T2DM than did not have T2DM (68.71% vs 31.29%,  $P<0.01$ ). Patients with gout and T2DM had longer mean duration of gout (63 vs 41 months), were more likely to have tophi (37% vs 20%), joint damage (24% vs 13%), and clinician-rated severe gout (27% vs 13%) than those without T2DM (all  $P<0.01$ ). Patients with gout and T2DM were also more likely to receive ULT (86% vs 71%;  $P<0.01$ ), and among those receiving ULT, T2DM patients treated with allopurinol received a similar mean daily dose (321 mg vs 298 mg;  $P=0.17$ ). Gout patients with T2DM were more likely to have additional comorbidities (cardiovascular disease, kidney disease, COPD, depression, diabetes, hyperlipidemia, hypertension, obesity, prostate problems [men]) and have chronic pain than those without T2DM (all  $P<0.05$ ). Gout patients with T2DM reported more office visits (4.1 vs 3.5), were more likely to have an emergency department visit (17% vs 9%), and were more likely to be hospitalized (5% vs

2%) (all  $P < 0.01$ ). In both groups, ULT use was associated with better gout control, but the specific factors predictive of ULT use and disease control varied between those with and without T2DM.

**Conclusion:** Gout patients with T2DM were more likely to have a greater impact on health system spending, with additional comorbidities and more severe gout than those without T2DM. These data suggest that patients with gout and T2DM constitute a less healthy group in need of careful monitoring and more aggressive gout management.

## Uncontrolled Gout Patients with Higher Heart Failure Hospitalization Rates in US

Robert Morlock<sup>1</sup>, Pierre Chevalier<sup>2</sup>, An-Chen Fu<sup>3</sup> and Douglas C.A. Taylor<sup>3</sup>, <sup>1</sup>YourCareChoice, Ann Arbor, MI, <sup>2</sup>IMS Health, Zaventem, Belgium, <sup>3</sup>Ironwood Pharmaceuticals, Inc., Cambridge, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is the most common form of inflammatory arthritis and is caused by elevated serum uric acid (sUA). Elevated sUA is associated with worsened outcomes in patients with heart failure, however, little is known about the association between gout and acute heart failure (AHF). The objective of this study was to assess the impact of gout control on the rate of hospitalization for AHF in a prevalent gout population.

**Methods:** A retrospective analysis using the IMS Pharmetrics Plus database from 01/01/2009 to 12/31/2011. Patients were required to have evidence of “prevalent established gout” (ie, treated with urate-lowering therapy [ULT] or eligible for ULT based on American College of Rheumatology [ACR] guidelines) between 01/01/2009 and 12/31/2009, be aged  $\geq 18$  years on index date (01/01/2010), and have  $\geq 1$  sUA measurement reported during the year of evaluation of gout control status. Follow-up extended from 01/01/2010 to 12/31/2011. AHF rate was calculated as percentage of eligible patients having  $\geq 1$  AHF-related hospitalization over the course of calendar year 2011. In a given calendar year, patients were considered to have controlled gout if they had no elevated sUA ( $\geq 6$  mg/dL), no diagnosis of tophus, and no flare documented, while uncontrolled gout was defined as  $\geq 1$  elevated sUA or  $\geq 1$  tophus diagnosis. The odds ratio (OR) of AHF was modeled using multivariable logistic regression adjusting for gout control status (in previous or current year), gender, age, and Charlson Comorbidity index as covariates.

**Results:** A total of 2,556 eligible gout patients with available sUA data in 2011 were identified in the US of which 67% had uncontrolled gout status ( $n=1,720$ ). The unadjusted AHF hospitalization rates were 1.51% (95% confidence interval [CI]: 0.93%-2.09%) in patients with uncontrolled gout in 2011 and 0.72% (95% CI: 0.14%-1.29%) in patients with controlled gout. After adjusting for the covariates, AHF rate was significantly higher in patients whose gout was uncontrolled during the same year (adjusted OR: 2.66 [ $P=0.037$ ]). Among the patients with available sUA data in 2010 ( $n=2,200$ ), there was a trend indicating that patients with uncontrolled gout in 2010 were at higher risk of AHF hospitalization in 2011 (adjusted OR: 2.54 [ $P=0.059$ ]).

**Conclusion:** This study suggests that patients with uncontrolled gout have a higher risk of being hospitalized for AHF. Further studies would be required to validate this finding on larger samples with availability of sUA data.

## Less Than Half of Patients Treated with High-Dose Allopurinol Reach Serum Uric Acid Target

**Robert Morlock**<sup>1</sup>, Douglas C.A. Taylor<sup>2</sup> and Scott Baumgartner<sup>3</sup>, <sup>1</sup>YourCareChoice, Ann Arbor, MI, <sup>2</sup>Ironwood Pharmaceuticals, Inc., Cambridge, MA, <sup>3</sup>drB Consulting, Spokane, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although allopurinol is FDA approved for up to 800 mg per day and EMEA authorized for up to 900 mg per day, most patients receive 300 mg per day or less. The objective of this study was to describe physician, patient, and treatment characteristics in gout patients treated with allopurinol and to assess the proportion of patients reaching serum uric acid (sUA) target by allopurinol dose.

**Methods:** Patient data from a quantitative survey of physicians were utilized and results confirmed through chart review. Initial and current dose of allopurinol, presence of co-morbid conditions, sUA lab results, physician specialty, and patient characteristics were assessed. Data on number of patients achieving target sUA  $\leq 6$  mg/dL were also collected. Descriptive characteristics are presented as proportions or means and standard deviations (SD). Multivariate and descriptive statistics are used to describe patients with sUA  $\leq 6$  mg/dL.

**Results:** 251 rheumatologists and 250 primary care physicians were interviewed. Of 2505 patients with gout, 1437 (57%) were treated with allopurinol. Use of high-dose allopurinol significantly differed by country with less than 6.5% of patients in France, Germany, and Spain given  $>300$  mg, whereas 10.2%, 19.5%, and 33.6% of patients in Italy, the US, and the UK, respectively, received a daily dose  $>300$  mg ( $p<0.01$ ). Over 12 months the percentage of patients achieving sUA  $\leq 6.0$  mg/dL differed across the 6 countries. Overall, across all countries, only 43.8% and 44.7% of patients achieved sUA  $<6.0$  mg/dL with 301-599 mg and  $\geq 600$  mg of allopurinol daily, respectively. A multivariable-adjusted model found patients with tophi (OR 3.42;  $p<0.01$ ), co-existing alcoholism (OR 1.73;  $p<0.05$ ), chronic obstructive pulmonary disease (OR 2.02;  $p<0.05$ ), smoking cessation treatment (3.49;  $p<0.05$ ), and from the UK (OR 3.98;  $p<0.01$ ) were more likely to be using  $>600$  mg of allopurinol. Regardless of allopurinol dose, the co-variables UK vs. other countries (OR 3.51;  $p<0.01$ ), time on therapy  $>24$  months (OR 1.39;  $p<0.01$ ), and chart-documented co-existing hypertension (OR 1.36;  $p<0.05$ ) were predictive of achieving sUA  $<6$  mg/dL, whereas physician sub-specialty [general practitioners vs. rheumatologists (OR 0.56;  $p<0.01$ )], having tophi (OR 0.72;  $p<0.05$ ), and chart-documented co-existing alcoholism (OR 0.67;  $p<0.05$ ), hyperlipidemia (OR 0.74;  $p<0.05$ ), and kidney stones (OR 0.49;  $p<0.05$ ) were found to be associated with not achieving sUA  $<6$  mg/dL. After adjusting for confounding factors, over a 12-month period, there was no difference in achieving sUA  $<6$  mg/dL for those treated with high- vs. low-dose allopurinol.

**Conclusion:** Allopurinol is approved for up to 800 mg in the US and 900 mg in the EU but the majority of patients are treated with  $\leq 300$  mg per day. Less than 50% of patients achieve sUA  $<6$  mg/dL at any dose of allopurinol, and those on a higher dose of allopurinol are not more likely to reach this target. These data suggest a need for consideration of new treatment options on top of allopurinol for uncontrolled gout patients.

## Allopurinol Treatment for Gout: How Long to Reach Serum Urate Goal?

**Jean J. Lim**<sup>1,2</sup>, An-Chen Fu<sup>2</sup>, Jami Giordano<sup>2</sup>, David S. Reasner<sup>2</sup> and Douglas C.A. Taylor<sup>2</sup>, <sup>1</sup>Tufts University School of Medicine, Boston, MA, <sup>2</sup>Ironwood Pharmaceuticals, Inc., Cambridge, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Urate-lowering therapy (ULT) is essential in chronic gout management. For decades, allopurinol has remained the most frequently prescribed ULT. Reaching a goal of serum urate (sUA) level of <6.0 mg/dL has been suggested by gout management guidelines. However, limited studies have reported time duration needed to reach the sUA goal among allopurinol users. The aim of this study was to estimate time for allopurinol-treated gout patients to reach sUA goal.

**Methods:** This retrospective study used the Truven Health MarketScan® Database (Commercial). Study cohort included patients with a gout diagnosis during the study period (2010-2015),  $\geq 1$  allopurinol prescription fill during 2011-2015 (intake period, the earliest allopurinol date as index date),  $\geq 90$  days of allopurinol continuous therapy,  $\geq 2$  sUA results (the first sUA test was within 90 days before and 30 days after the index date; the second sUA test was after first sUA test and index date), aged  $\geq 18$  years on index date. Prevalent allopurinol users (allopurinol prescription fill during 1 year prior to index date) were excluded. Time duration to sUA goal was estimated from index date until reaching sUA goal of <6.0 mg/dL. Patients not reaching sUA goal were followed until end of therapy, health plan disenrollment, or end of 2015, whichever came first (censor date). Patient characteristics included age, gender, provider specialty, and initial dosage (ID) at the index date (used in subgroup analysis). Survival analyses of Kaplan-Meier estimators and unadjusted Cox proportional hazards regression model were conducted.

**Results:** There were 1404 patients included in the study cohort (Table 1) with a median time of 8 months to sUA goal (Figure 1). Stratifying by ID, the proportions of patients reaching sUA goal in 1 and 2 years were 36% and 49% with ID <300 mg versus 65% and 77% for patients with ID  $\geq 300$  mg (Figure 2).

**Conclusion:** Patients with gout who do not reach goal within 1 year using allopurinol, regardless of initial dosage, are unlikely to reach goal in the next year and therefore may benefit from additional treatment.

Table 1. Demographic characteristics and provider types of study patients

	Total	Patients in subgroup analyses, by initial dosage (mg/day)	
		<300 mg/day	$\geq 300$ mg/day
N	1,404	684	447
Age, mean (years)	53	53	53
Gender, %			
Male	81%	81%	84%
Female	19%	19%	16%
Provider type, %			
Rheumatologist	16%	16%	15%
Nephrologist	3%	4%	2%
Primary care provider	68%	66%	70%
Other/Unknown	14%	14%	14%

## Prevalence of Chronic Kidney Disease and Uncontrolled Serum Uric Acid Levels in US Adult Gout Population: Results from the National Health and Nutrition Examination Survey 2007–2012

Jean J. Lim<sup>1,2</sup>, An-Chen Fu<sup>2</sup>, David S. Reasner<sup>2</sup> and Douglas C.A. Taylor<sup>2</sup>, <sup>1</sup>Tufts University School of Medicine, Boston, MA, <sup>2</sup>Ironwood Pharmaceuticals, Inc., Cambridge, MA

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is the most common form of inflammatory arthritis, mainly caused by elevated serum uric acid (sUA) levels. The American College of Rheumatology guidelines recommend lowering sUA levels to <6 mg/dL for all patients with gout. Studies reported that elevated sUA levels are also associated with chronic kidney disease (CKD). It is suggested that urate-lowering therapy, predominantly xanthine oxidase inhibitors (XOIs), can potentially slow progression of renal disease. This study aims to estimate the prevalence of CKD among US adult patients with gout, both controlled (sUA <6 mg/dL) and uncontrolled (sUA ≥6 mg/dL), stratified by XOI treatment status.

**Methods:** The National Health and Nutrition Examination Survey (NHANES) is a large, cross-sectional study conducted by the National Center for Health Statistics using a multistage, complex sampling design. This study utilized NHANES (2007–2012) by combining interviews, physical examinations, and laboratory data. Participants aged ≥20 years with valid gout status, gender, race/ethnicity, and sUA/serum creatinine were included in the study sample. Participants were assumed to have gout if they had ever been told by a doctor or other health professional that they had gout. CKD stages were defined using both estimated glomerular filtration rate (estimated by the Chronic Kidney Disease Epidemiology Collaboration equation) and albumin-creatinine ratio. CKD stages were grouped into “normal to Stage 2 CKD,” “Stage 3a CKD,” and “Stage 3b-5 CKD”. Descriptive analyses were performed accounting for the survey’s complex sampling design to estimate the US population from the study sample.

**Results:** Out of 15,868 participants in NHANES 2007–2012 (representing 206 M US non-institutionalized population, aged 20 years or older), 715 participants had been told by a doctor that they had gout. These participants represented an estimated total of 7.7 M with gout (US prevalence of 3.7%). Among the gout population, 5.7 M (74%) had kidney function of normal to Stage 2 CKD, 1.1 M (15%) had Stage 3a CKD, and 0.8 M (11%) had Stage 3b-5 CKD. Of the gout population, 22% with normal to Stage 2 CKD, 42% with Stage 3a CKD, and 44% with Stage 3b-5 CKD were currently taking an XOI, most of whom were taking allopurinol. The majority of gout patients were uncontrolled regardless of CKD stage (63% of those with normal to Stage 2 CKD, 62% of those with Stage 3a CKD, and 72% of those with Stage 3b-5 CKD). Among those taking an XOI, 34% were uncontrolled and had normal to Stage 3a CKD (Figure 1).

**Conclusion:** The majority of non-institutionalized US adults who self-report that they have been diagnosed with gout have uncontrolled gout regardless of CKD stage. Even among those patients with gout who are taking an XOI, 34% are uncontrolled and have normal to Stage 3a CKD, and therefore, may benefit from alternative treatment options indicated for their CKD stage.

Figure 1. Estimated US prevalence of CKD with uncontrolled and controlled gout by XO1 treatment status

\*Percentages were calculated within the same XO1 treatment status.

## Random Urinary Uric Acid/Creatinine Ratio Is Useful in the Estimation of 24-Hour Urine Uric Acid Excretion in Patients with Gout

Sang Tae Choi<sup>1</sup>, Seong-Jin Moon<sup>2</sup> and Eun-Jin Kang<sup>3</sup>, <sup>1</sup>Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea, Republic of (South), <sup>2</sup>Internal Medicine, Catholic Kwandong University College of Medicine, Incheon, Korea, Republic of (South), <sup>3</sup>Internal Medicine, Busan Medical Center, Busan, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is a chronic inflammatory disease resulted from hyperuricemia. The measurement of 24-hour urinary uric acid excretion is frequently used to evaluate disease status and select drugs that lower uric acid level. However, 24-hour urine collection is cumbersome and inconvenient, and sometimes unreliable because of incomplete sampling. Approximately 1 g of creatinine is excreted into the urine on a daily basis, and the ratio of random urine protein to creatinine is known to be closely related to the amount of 24-hour urine protein excretion. Therefore, in this study, we assessed the utility of the random urinary uric acid/creatinine (UA/Cr) ratio in the estimation of 24-hour urine uric acid excretion in patients with gout.

**Methods:** Eighty-seven patients with gout without any use of uric acid lowering agents were enrolled in this study. The mean age was  $49.8 \pm 16.8$  years old and the male patient was 89.6% (78/87). For the evaluation of uric acid excretion and renal function, patients were collected 24-hour urine. Random urine uric acid and creatinine specimens were gained on the same day of 24-hour urine collection. Chronic kidney disease was defined as a creatinine clearance (CCr) level of less than 60 ml/min/1.73m<sup>2</sup> measured in 24-hour urine collection sample. Excretion of more than 650 mg of uric acid in the 24-hour urine sample was defined as uric acid over-excretion.

**Results:** Mean serum uric acid level was  $7.77 \pm 1.92$  mg/dl, and the mean 24-hour uric acid excretion and mean CCr value were  $669.6 \pm 237.9$  mg and  $109.6 \pm 39.0$  ml/min/1.73m<sup>2</sup>, respectively. Random urinary UA/Cr ratio showed good correlation with the 24-hour urine uric acid excretion in the absolute and log-transformed value ( $\gamma = 0.413, p < 0.001$ ;  $\gamma = 0.585, p < 0.001$ , respectively). Correlation

between these two variables was also found in the patients with chronic kidney disease ( $\gamma = 0.789$ ,  $p = 0.011$ ). In the linear regression analysis, absolute 24-hour urine uric acid excretion was estimated to be  $402 \times (\text{random urinary UA/Cr ratio}) + 218.73$  ( $p < 0.001$ ). The best cut-off value for the random urinary UA/Cr ratio to distinguish between uric acid over-excretion and normal uric acid excretion was 0.533, and its sensitivity and specificity were 35.6% and 97.6%, respectively ( $\text{AUC} = 0.686$ ; 95% CI, 0.576 - 0.796,  $p = 0.003$ ).

**Conclusion:** There was a good correlation between the random urinary UA/Cr ratio and 24-hour urine uric acid excretions. The random urinary UA/Cr ratio would be a useful predictor of 24-hour urine uric acid excretion in patients with gout.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Circulating urate is an important biomarker, not only in the detection and management of gout, but also in assessing the risk of related comorbidity. The impact of biobanking processes and assay type on uric acid (UA) measurement has been the subject of limited study but is important given the role of biorepositories in biomarker assessments. Thus, we analyzed banked samples of citrated pUA (CpUA) and serum UA (sUA) using two separate assays and compared results to heparinized plasma UA (HpUA) from electronic health data.

**Methods:** Two clinical laboratories, one based at an academic medical center (Lab A) and the other at a VA affiliate (Lab B), measured CpUA and sUA using banked samples from 30 rheumatic disease patients. Samples were collected using acid citrate dextrose ACD (plasma) and SST tubes (serum) between 2003 and 2017 and were stored at -70 °C until analysis. Lab A used the Beckman Coulter AU 5800 analyzer while Lab B used the VITROS URIC Slide method for UA measurement. UA measures were compared to lifetime average HpUA as part of routine care and abstracted from electronic health data from 15 of the 30 patients.

**Results:** There was no association of CpUA or sUA with year of sample collection. In contrast, mean ( $\pm$ SD) sUA was higher than CpUA at Lab A ( $5.9 \pm 1.7$  mg/dl vs.  $3.5 \pm 1.5$ ,  $p \leq 0.01$ ) and Lab B ( $6.0 \pm 1.7$  vs.  $3.7 \pm 1.9$ ,  $p \leq 0.01$ ). Serum UA values from Lab A and Lab B were highly correlated ( $r=0.98$ ,  $p < 0.01$ ) with less than 5% variability overall. In contrast, CpUA values from the same samples differed on average by nearly 39% between Lab A and Lab B. Percent differences and correlations for the 4 measures are shown by lab and sample type (Table). Lifetime average HpUA concentrations measured as part of routine care were similar to sUA values obtained from both labs using banked samples, but were on average 50 to 80% higher than CpUA levels measured on banked samples (Table).

**Conclusion:** We observed a nearly 2-fold difference in UA values measured from banked serum compared to banked citrated plasma. Moreover, CpUA values showed greater variability when measured in different laboratories with different assays, variability that did not appear to be related to the time elapsed from sample procurement. Compared to CpUA values, sUA measures were much more strongly associated with HpUA values measured in 'real-time' as part of routine care. Although additional study will be needed to understand the mechanisms driving these observations, these results suggest that UA measurement of banked citrated plasma leads to marked assay variability in addition to falsely low concentrations.

### UA Percent Difference and Correlation

Comparison	Mean Percent Difference	Correlation coefficient (r)
Lab A CpUA vs. Lab A sUA	81.2%	0.83
Lab B CpUA vs. Lab B sUA	105.9%	0.63
Lab A sUA vs. Lab B sUA	4.9%	0.98
Lab A CpUA vs. Lab B CpUA	38.5%	0.73
<i>Ratio of Lifetime Avg. HpUA Abstracted from Medical Record and sUA / CpUA Measured in Lab A and Lab B</i>		
	Mean (SD)	Median (Range)
Lifetime Avg. HpUA / Lab A sUA	0.92 (0.34)	0.92 (0.39, 1.71)
Lifetime Avg. HpUA / Lab B sUA	0.91 (0.27)	0.96 (0.39, 1.36)
Lifetime Avg. HpUA / Lab A CpUA	1.53 (0.55)	1.54 (0.67, 2.50)
Lifetime Avg. HpUA / Lab B CpUA	1.80 (1.04)	1.57 (0.43, 3.90)

## Factors Associated with Acute Gouty Arthritis in Patients Hospitalized with Acute Coronary Syndromes and Congestive Heart Failure

**Gabriela Montes-Rivera**<sup>1</sup>, Carla F Gamarra-Hilburn<sup>2</sup>, Lorena González-Sepúlveda<sup>3</sup> and Luis M. Vilá<sup>4</sup>, <sup>1</sup>Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, PR, <sup>2</sup>Department of Medicine, Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, PR, <sup>3</sup>Puerto Rico Clinical and Translational Research Consortium, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, <sup>4</sup>Department of Medicine, Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hyperuricemia and untreated gout appears to be independent prognostic markers for poor all-cause and coronary heart disease mortality in patients with recent acute myocardial infarction. Moreover, gout attacks among patients with acute myocardial infarction are linked with short-term and long-term adverse non-fatal cardiac events. Similarly, serum uric acid levels correlate with morbidity and mortality of patients with congestive heart failure. However, the factors associated with gouty arthritis in patients presenting with acute cardiovascular events are not well known. Thus, we sought to study the demographic and clinical factors in patients with acute coronary syndromes and congestive heart failure who developed acute gout during hospitalization.

**Methods:** In-patient rheumatology consults of patients admitted to a cardiovascular hospital with either acute coronary syndromes (angina pectoris or myocardial infarction) or congestive heart failure between January 2006 and May 2015 were evaluated. Data on demographic parameters, type of medical insurance, primary diagnosis on admission, comorbidities, and pharmacologic treatment were compared between patients who developed acute gouty arthritis during hospitalization versus those who did not, using Chi-square test, Fisher's Exact test and Student's T test, as appropriate. Shapiro-Wilk test was used to assess normal distribution.

**Results:** A total of 189 patients admitted with acute cardiac events were consulted to the rheumatology service. Of those patients, 83 (43.9%) had acute gouty arthritis during the hospitalization. The mean (SD) age was similar between patients with and without acute gout [57.4 (15.0) vs. 58.7 (15.3) years,  $p=0.561$ ]. Most patients with acute gout were men (92.8% vs. 33.0%,  $p < 0.001$ ). Patients with acute gout were more likely to have chronic kidney disease (30.1% vs. 11.3%,  $p=0.001$ ) and less likely to have systemic lupus erythematosus (0.0% vs. 14.2%,  $p < 0.001$ ), rheumatoid arthritis (0.0% vs. 13.2%,  $p < 0.001$ ), hypothyroidism (4.8% vs. 15.1%,  $p=0.023$ ), and exposure to antiplatelet therapy (8.4% vs. 27.4%,  $p=0.001$ ) than those without acute gout. As expected, patients with acute gout had a previous history of gout (53.0% vs. 5.7%,  $p < 0.001$ ) and were more commonly taking allopurinol (15.7% vs. 3.8%,  $p=0.005$ ) and colchicine (19.3% vs. 1.9%,  $p < 0.001$ ) at the moment of admission than those who did not present acute gout. However, of those with previous history of gout, only 30% were taking allopurinol at the moment of admission. No statistical differences ( $p > 0.05$ ) were found for type of health insurance, arterial hypertension, diabetes mellitus, dyslipidemia, and exposure to diuretics and angiotensin receptor blockers.

**Conclusion:** Male gender, chronic kidney disease, and previous history of gout were associated with acute gout attack in this group of patients admitted with acute coronary syndromes and congestive heart failure. The awareness of these factors may help to recognize and manage patients promptly and prevent further complications in this population.

## High Osteoprotegerin:RANKL Ratios in Synovial Fluid Correlate with the Presence of Calcium Pyrophosphate Crystals

Ian Chang<sup>1</sup>, Daisy Obiora<sup>2</sup>, Ann Rosenthal<sup>3</sup> and Charlene J. Williams<sup>4</sup>, <sup>1</sup>Medicine/Rheumatology, Medical College of Wisconsin, Milwaukee, WI, <sup>2</sup>Urology, Cooper Hospital, Camden, NJ, <sup>3</sup>Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, <sup>4</sup>Department of Biomedical Sciences, Cooper Medical School of Rowan University, Camden, NJ

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Calcium pyrophosphate deposition disease (CPDD) is a common cause of both acute and chronic arthritis in the elderly. It is estimated that twenty percent of patients with knee osteoarthritis (OA) have undiagnosed CPDD based on analysis of synovial fluid performed at the time of joint replacement. Calcium pyrophosphate (CPP) crystals can be difficult to identify in synovial fluid, and no biomarkers for CPPD currently exist.

Familial forms of CPDD have been recognized since the original descriptions of this disease. Associated mutations have been identified at one of two loci. One locus (CCAL2) is comprised of mutations in the ANKH protein, which is an ATP/PPi transporter. The second locus (CCAL2) codes for osteoprotegerin (OPG), a decoy receptor for the RANKL/RANK pathway. Little is known about ANKH and OPG levels in synovial fluids of patients with sporadic CPDD and whether these factors might be biomarkers for CPDD. We set out to measure ANKH, OPG and RANKL levels in synovial fluids from patients with chronic knee effusions with and without CPP crystals.

### Methods:

Knee synovial fluids were obtained for diagnostic or therapeutic purposes at an academic rheumatology practice from patients with OA or chronic CPDD. No patients had clinical signs or symptoms of active inflammatory arthritis at the time of joint aspiration. De-identified synovial fluids were used with permission from the local IRB. All fluids were examined for crystals using compensated polarized light microscopy by an expert observer (AKR). Cell counts were not performed. Any fluids containing monosodium urate crystals were discarded. Fluids were aliquoted and stored at -20° C. Levels of OPG, ANKH, and RANKL were measured by ELISA and compared in groups with and without CPP crystals by a Mann Whitney test.

## Results:

Thirteen synovial fluid samples were analyzed. Seven samples contained CPP crystals and 6 samples did not contain CPP crystals. Levels of ANK, OPG, and RANKL were measurable in all fluids (Table 1). CPDD fluids had statistically higher mean levels of OPG ( $p < 0.026$ ) and similar levels of RANKL compared to OA fluids. Mean ANKH levels were also higher in fluids with CPP crystals compared to OA fluids but this did not reach statistical significance due to the large variability of values. Mean OPG:RANKL ratios were 84.2 in CPDD fluids and 5.0 in OA fluids.

**Table 1.**

	OPG (ng/ug protein)	ANKH (ng/ug protein)	sRANKL (pg/ug protein)
OA	2.6 ± 2.5	8.2 ± 9.4	0.52 ± 0.32
CPDD	42.1 ± 26.1	64.3 ± 87.4	0.50 ± 0.34

## Conclusion:

Synovial fluids from patients with OA or CPDD contain easily measurable quantities of ANKH, OPG, and RANKL. In this small pilot study of well-characterized fluids from patients with and without CPDD, we noted a very high ratio of OPG:RANKL in patients with CPDD. These findings provide additional support for the importance of OPG in CPDD pathogenesis. If validated in a larger study, the OPG:RANKL ratio may be a useful biomarker for CPDD.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout results from formation of monosodium urate (MSU) crystals in the presence of hyperuricemia. Genome wide association studies have provided significant insights into hyperuricemia, however, the genetic basis of the progression from hyperuricemia to gout is still unclear. Previously, Chang et al (*Rheumatology* 2016;56:457-466) reported an association of the

peroxisome proliferator-activated receptor gamma coactivator 1B (PPARGC1B) missense variant *rs45520937* A-allele with gout risk in a Taiwan Han Chinese population (OR= 1.96,  $P_{OR} = 4.0 \times 10^{-10}$ ) [1]. PPARGC1B is a regulator of NOD-like receptor family pyrin domain containing 3 inflammasome (NLRP3)-activated inflammation. Our aim was to replicate the *rs45520937* association in New Zealand (NZ) Polynesian (Māori and Pacific) and European ancestral groups to investigate the association of PPARGC1B variant with gout.

**Methods:** A total of 2645 clinically-ascertained gout cases based on American Rheumatism Association 1977 criteria and 2125 controls were utilized from the NZ population. There were 1143 Māori and Pacific (Polynesian) people with gout and 1241 without gout. The European data set was comprised of people with gout from Germany, The Netherlands and Scotland (n=571), and New Zealand (n=931) and 884 people without gout. Taqman® genotyping of PPARGC1B *rs45520937* was undertaken, followed by multivariate-adjusted association analysis in R 3.2.2 version with gout as the outcome.

**Results:** The A-allele was at a lower prevalence in European controls compared to Polynesian controls (0.055 vs 0.418). The A-allele of *rs45520937* was associated with increased risk of gout in the Polynesian sample set (OR= 1.17 [1.02-1.35],  $P=0.02$ ) but not in the European sample set (OR=0.96 [0.73-1.27],  $P=0.81$ ).

**Conclusion:** We replicated the association between the PPARGC1B risk A-allele of *rs45520937* and gout in the NZ Polynesian group. However this association was not evident in the European group suggesting that this population-specific effect is restricted to the Asia-Pacific region. PPARGC1B is one of several inducible nodes, including PPARG and AMPK-activated protein kinase, in the complex regulatory network for damping NLRP3 inflammasome activation and the inflammatory arthritis phenotype in gout.

## Effect of Urate-Lowering Treatment on the Risk of Urolithiasis in People with Gout

Wen-Ching Lan, Kuang-Hui Yu, Shue-Fen Luo, Chang-Fu Kuo and Tien-Ming Chan, Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Appropriate dose of urate-lowering therapy (ULT) is needed for gout patients to dissolve existing urate crystals to prevent acute gout attacks and reduce the risk of urate nephropathy and urolithiasis. This study aimed to investigate the associations between ULT use in different doses and the risk of urolithiasis in incident gout patients.

### Methods:

We conducted a nested case-control study in a cohort of incident gout using the UK-based Clinical Practice Research Data-link (CPRD). Overall, 63,095 people with incident gout 1990–2010 were identified. Among them incidence cases of urolithiasis were identified and they were 1:4 age-, sex- and diagnosis year-matched to patients without urolithiasis. Conditional logistic regression was used to estimate the association between cumulative defined daily dose (cDDD) and risk of urolithiasis.

### Results:

We identified 700 gout patients with incident urolithiasis occurring after the initial diagnosis of gout aged 20-89 matched to 2,800 controls with incident gout but no urolithiasis. After adjusting for body mass index, smoking, alcohol consumption, pertinent drugs and comorbidities, the odds ratio (OR) of urolithiasis associated with use of ULT among gout patients were 1.41 (95% confidence interval

[CI], 1.09–1.81) for those with 1–180 cDDD, 0.90 (95% CI, 0.59–1.37) for 180–365 cDDD and 1.01 (95% CI, 0.77–1.31) for > 365 cDDD, compared with those never used. The relative risk for urolithiasis was 0.89 (0.52 to 1.50) for current ULT use (within 30 days), 1.64\* (1.12 to 2.41) for recent ULT use (30–180 days) and 1.09 (0.88 to 1.34) for remote ULT use (>180 days) compared with ULT non-users.

### Conclusion:

Short-term and low dose ULT use was associated with an increased risk for urolithiasis while adequate ULT dose results in a neutral effect on urolithiasis risk.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Diuretics have been associated with impaired response to allopurinol and refractoriness in gout, but whether this stills after new urate-lowering treatments (ULT) and treat-to-target strategies is unknown. The aim of this study was to assess the impact of the diuretic therapy on the response to ULT in patients with gout.

**Methods:** Retrospective analysis of an inception cohort of patients with crystal-proven gout (Jan2014-Nov2016). Patients were classified according to the type of ULT received and whether they were on diuretics (loop and/or thiazide) at baseline. The last visit of follow-up was registered. The primary outcome variables were a) reduction of serum uric acid (SUA) levels from baseline; b) achievement of different SUA targets (6, 5, and 4mg/dL); and c) maximum dose of ULT employed. Clinical, laboratory and ULT-related variables were also registered. A comparative analysis was performed according to the use of diuretics, using Student's t and chi-2 tests, stratified by the type of ULT prescribed. Also, to properly determine the influence of diuretics on gout management (maximum dose of ULT used), a multiple linear regression model was built.

**Results:** The inception cohort included 225 patients with an average age of 65 years (SD 14.1), 86.2% of them men, with a median duration of gout at inclusion of 4 years (p25-75 1-10) and tophi in 21.3%. Follow-up data was available from 209 patients (92.9%), with a median 9 months of follow-up (4-14). A total of 98 patients (43.6%) were on diuretics, mainly for hypertension (64.7%), heart failure (9.4%), and renal failure (5.9%). These patients were older ( $p<0.001$ ), had higher rates of females ( $p<0.001$ ), hypertension ( $p<0.001$ ), diabetes ( $p=0.001$ ), and cardiovascular disease ( $p<0.001$ ), and showed higher SUA ( $p=0.003$ ) and lower glomerular filtration rate ( $p<0.001$ ), compared to those not on diuretics. ULT used was allopurinol in 172 patients (82.6%) and febuxostat in 34 (16.5%) – benzbromarone was excluded due to minimal use (two cases). The table shows the outcome comparison according to diuretic treatment, stratified by type of ULT. Except for a lower achievement of SUA<5 in the allopurinol subgroup, no significant differences were found in SUA reduction and targets. Contrary to febuxostat, a trend to lower maximum dose of allopurinol in those on diuretics was noted, also in the bivariate analysis ( $\beta=-37.9$ ,  $p=0.053$ ,  $R^2=0.022$ ); however, this association was lost after multivariate adjustment for baseline characteristics ( $\beta=-18.1$ ,  $p=0.499$ ).

**Conclusion:** Despite its common use, diuretics currently show no significant impact on the achievement of treatment outcomes in patients with gout.

Outcome variable	Diuretic therapy		<i>p</i>
	No	Yes	
<i>Allopurinol</i> (N=158)	N=92 (58.2%)	N=66 (41.8%)	
SUA reduction (mg/dL), mean (SD)	3.1 (1.9)	3.2 (2.0)	0.813
SUA<6 (%)	80.6	74.2	0.337
SUA<5 (%)	60.2	43.9	0.043
SUA<4 (%)	28.0	21.2	0.334
Maximum dose (mg/day), mean (SD)	316.5 (126.9)	278.6 (121.8)	0.053
<i>Febuxostat</i> (N=33)	N=14 (42.4%)	N=19 (57.6%)	
SUA reduction (mg/dL), mean (SD)	3.7 (3.4)	5.6 (3.1)	0.147
SUA<6 (%)	70.0	82.4	0.456
SUA<5 (%)	70.0	76.5	0.711
SUA<4 (%)	60.0	58.8	0.952
Maximum dose (mg/day), mean (SD)	80.0 (16.3)	80.0 (25.3)	0.348

## Can Alcohol Intake in Moderation Lower the Risk of Myocardial Infarction and Mortality Even Among Gout Patients?

Sarah Keller<sup>1</sup>, Sharan K. Rai<sup>2</sup>, Na Lu<sup>1</sup>, April Jorge<sup>3</sup>, Yuqing Zhang<sup>4</sup> and Hyon K. Choi<sup>2</sup>, <sup>1</sup>Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>2</sup>Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>3</sup>Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>4</sup>Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Alcohol is a well-established risk factor for gout. However, more than 60 prospective studies have also shown that moderate alcohol intake is associated with a 25-40% reduced risk of coronary heart disease (CHD) and death. The American Heart Association (AHA) suggests that "if you drink alcohol, do so in moderation." As gout is associated with an increased risk of CHD and premature mortality, the potential benefit of moderate alcohol use may also apply to gout patients. To address this question, we examined the relationship between alcohol intake, the risk of acute myocardial infarction (AMI) and all-cause mortality among gout patients in a general population context.

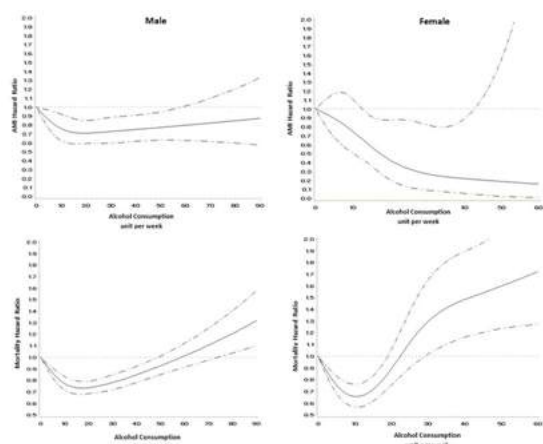

**Methods:** We conducted a cohort study using data from an EMR representative of the UK general population. The study population included individuals aged  $\geq 20$  years who had a diagnosis of gout between 1995 and 2015. The exposure of interest was the first alcohol intake measured after gout diagnosis. Study endpoints were incident cases of AMI and all-cause mortality. We estimated sex-specific hazard ratios (HR) according to alcohol intake category (i.e., 0, 1-9 [light drinking], 10-24 [moderate drinking], 25-42, and  $> 42$  UK

alcohol units/week [1 unit = 8 mg]). In the multivariable-adjusted regression model, we adjusted for age, smoking status, body mass index, duration of gout, presence of tophi, comorbidities, and medication use, including anti-gout medications. We performed a cubic-spline model analysis to depict the dose-response relationship between alcohol intake and all-cause mortality in a continuous manner.

**Results:** Among 55,584 gout patients (78% male, mean age of 63 years), 1,332 developed AMI and 8,362 died. The mean follow-up time was 5.6 years. As shown in the **Figure**, there is an apparent U-shaped relationship between alcohol intake after gout onset and the risk of AMI and all-cause mortality. Men who drank a moderate amount of alcohol had a lower risk of AMI and mortality. The multivariable HRs for developing AMI in men with gout were 1.0, 0.76 (95% CI, 0.63-0.93), 0.68 (0.55-0.83), 0.69 (0.53-0.89), and 0.71 (0.52-0.95) for each increasing alcohol intake category. The corresponding HRs for mortality were 1.0, 0.77 (95% CI 0.71-0.82), 0.71 (0.66-0.77), 0.74 (0.66-0.82), and 0.89 (0.78-1.01). While alcohol use and sample sizes were smaller among women, a similar U-shaped relationship was present. Women who drank > 42 UK units/week had the highest risk of mortality (HR 1.68 95% CI, 1.09-2.61).

**Conclusion:** This general population-based study indicates that moderate alcohol consumption is associated with a lower risk of AMI and all-cause mortality among gout patients, similar to general population studies. This finding suggest that the AHA recommendation regarding moderate alcohol use may apply to gout patients (for their cardiac health and improved survival) provided that their gout is well-controlled.

## The Dietary Approaches to Stop Hypertension (DASH) and Mediterranean Diets and Risk of Gout in Women: 28-Year Follow-up of a Prospective Cohort

Sarah Keller<sup>1</sup>, Sharan K. Rai<sup>2</sup>, Leo Lu<sup>3</sup>, Yuqing Zhang<sup>4</sup> and Hyon K. Choi<sup>2</sup>, <sup>1</sup>Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>2</sup>Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>3</sup>Allergy, Immunology, and Rheumatology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>4</sup>Department of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is increasing recognition of a gout epidemic, exacerbated by an unhealthy diet and a sedentary lifestyle. Indeed, our recent study among men confirmed that the Western dietary pattern was associated with an increased risk of gout (Rai et al. BMJ 2017). In contrast, the Dietary Approaches to Stop Hypertension (DASH) diet was associated with a lower risk of gout (Rai et al. BMJ 2017). The extrapolation of these findings to women should be done with caution given the substantial difference in uric acid metabolism, gout incidence, and role of estrogen on serum uric acid levels. We aimed to examine the DASH, Mediterranean, and Western diets in relation to gout risk among women.

**Methods:** We evaluated the risk of incident gout in ~70,000 women who reported a physician diagnosis of gout from 1984-2012. Using dietary intake information obtained from validated Food Frequency Questionnaires, we used a previously derived DASH diet score, emphasizing fruits, vegetables, nuts and legumes, whole grains, low-fat dairy foods, and reduced intake of saturated and total fat and sugar-sweetened beverages (SSBs). We also used a previously derived Mediterranean diet score, based on high intake of monounsaturated fat, plant proteins, whole grains, and fish, moderate intake of alcohol, and low consumption of red meat, refined grains, and sweets. Finally, we used a previously derived Western diet score, characterized by higher intakes of red and processed meats, SSBs, desserts, French fries, and refined grains. We assigned a diet score for each participant and prospectively examined the association between the diets and incident gout risk, adjusting for age, menopausal status, total energy intake, body mass index, diuretic use, hormone therapy use, hypertension, and alcohol and coffee intakes.

**Results:** During 28 years of follow-up, we documented 3,076 cases of incident gout. The DASH diet score was associated with a lower risk for gout (relative risk [RR] for extreme quintiles, 0.68 [CI, 0.60 to 0.76];  $P < 0.001$  for trend). Similarly, the Mediterranean dietary pattern score was associated with a modestly lower risk for gout (RR for extreme quintiles, 0.86 [CI, 0.77 to 0.96];  $P = 0.05$  for trend). In contrast, the Western diet score was associated with an increased risk for gout (RR, 1.56 [CI, 1.37 to 1.79];  $P < 0.001$ ).

**Conclusion:** The DASH and Mediterranean diets are associated with a lower risk of incident gout in women, although the DASH diet shows an even greater protective benefit; conversely, the Western dietary pattern is associated with an increased risk of gout. These findings confirm the associations observed in the recent study among men and provide the first such prospective evidence among women. The DASH diet appears to offer an attractive dietary approach for gout, as it also reduces blood pressure among patients with hypertension, present in 81% of female gout patients (Zhu et al. Am J Med 2012).

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The gold standard for crystal-related arthritis diagnosis remains synovial fluid analysis by a microscope fitted with compensated polarized filters as it has been shown an immediate, valid, easy to learn, and reliable procedure (for the last, only in two studies not designed for this purpose). The objective was to analyze the agreement between multiple observers in crystal identification using a compensated polarized optic microscope. Finding good reliability results between multiple observers would reinforce the value of the technique.

## Methods:

Cross-sectional, observational study performed at a single center with consecutive synovial fluid sampling. Samples were immediately analyzed when possible or kept refrigerated at 4°C. Five different observers analyzed samples under a compensated polarized optical microscope to detect and identify crystals, independently and blinded to clinical data. All observations were performed at 400x fields. It was recorded the presence and type of crystal (No crystals; monosodium urate -MSU-; and calcium pyrophosphate dihydrate -CPPD-). Inter-rater agreement by Cohen's kappa (k) statistic was measure. Also, sub-analyses were performed on a) time of sample visualization (≤24 hours or >24 hours of sampling) and b) expertise on crystal identification (≤10 years or > 10 years).

## Results:

Synovial fluid samples were obtained mostly from knees (67.3%), ankles (13.2%) and wrist (6.8%) of patients seen at rheumatology clinic or during admissions. Main rheumatic diseases were gout (33.8%), rheumatoid arthritis (18.4%), CPPD related arthritis (15%) and arthritis under study (8.3%). A total of 31 samples were analyzed by all five observers (155 observations). Overall k was 0.76 (CI95% 0.63-0.89) thus indicating good agreement. Agreement for detection was k 0.75 (CI95% 0.61-0.90) and k for MSU was 0.91 (CI95% 0.76-1.05) while for CPPD was 0.66 (CI95% 0.47-0.84). Regarding secondary endpoints, no differences were noted neither between observations made before or after 24 hours (p 0.68 for k comparison), nor in expertise in crystal analysis (p 0.63 for k comparison).

## Conclusion:

Even requiring agreement among multiple observers, compensated polarized microscopy remains consistent in the detection and identification of crystals in synovial fluid, confirming its high utility in clinical practice.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is a rising cause of hospital admissions and emergency consults. It has even replaced rheumatoid arthritis as the principal rheumatological condition causing hospitalizations. Some questions arise in this setting: What are the characteristics of our patients? How have they changed over the past years? Our objective is to analyze possible changes in the clinical profile of gout patients during a period of 25 years.

**Methods:** Data was collected from a prospective cohort of gout patients, from a crystal arthritis clinic in a tertiary hospital (reference population: half a million inhabitants). The period, between 1992 and 2016 ( $n = 1137$ ) was reviewed, with division into five quinquennia (Q). All patients fulfilled ACR/EULAR 2015 gout classification criteria. When entering the cohort, epidemiologic, clinic, laboratory and imaging data are systematically collected. Variables susceptible to change in time were considered: age, gender, gout clinical data, previous admissions due to gout and comorbidities. Complex patients were defined as those who presented at the first visit with polyarticular disease and/or tophi plus chronic kidney disease and/or cardiovascular disease. Quantitative variables were analyzed with ANOVA and Bonferroni correction; qualitative variables with chi-square test. Inclusion of patients to the cohort was approved by the hospital ethics committee. Data from extreme quinquennia are reported (1<sup>st</sup>Q: 1992-1996 / 5<sup>th</sup>Q 2011-2016 or 2<sup>nd</sup>Q: 1997-2001 / 4<sup>th</sup>: 2006-2010). All results are statistically significant unless stated otherwise.

**Results:** Differences were observed regarding age at first visit (1<sup>st</sup>Q:  $54.1 \pm 10.9$  / 5<sup>th</sup>Q:  $64.6 \pm 13.8$  years) and gender (1<sup>st</sup>Q: 2.6% / 5<sup>th</sup>Q: 12.2% of women, respectively).

**Initial comorbidities:** See graph 1.

**Initial clinical characteristics:** See graph 2

The overall prevalence of complex patients was of 67.1%, with increasing incidence through time (1<sup>st</sup>Q: 53.9% / 5<sup>th</sup>Q: 77.1%). Globally, less than half of these patients (39.7%) had received urate lowering treatment prior to their first visit.

**Conclusion:** The profile of gout patients has notably changed in the past 25 years: we have elder, more complex patients, with higher rates of hospital admissions, with severe forms of disease and important comorbidities. Nevertheless, most of these complex patients have not been appropriately started on urate lowering therapy. When considering these results, we believe that a substantial proportion of gout patients will require specialized attention in the coming years.

## A Case Series of Gout and Downs Syndrome – a New Paradigm for Detecting Disease Associations Using Big Data

Ann Igoe<sup>1,2,3</sup>, Bryan A Roller<sup>4,5</sup>, Abbinaya Elangovan<sup>5,6</sup>, Kristin L Kaelber<sup>4,6</sup> and David Kaelber<sup>4,5,6,7</sup>, <sup>1</sup>Internal Medicine & Pediatrics, Metrohealth Medical Center, Cleveland, OH, <sup>2</sup>Rheumatology, Metrohealth Medical Center, Cleveland, OH, <sup>3</sup>Metrohealth Medical Center, Metrohealth Medical Center, Cleveland, OH, <sup>4</sup>School of Medicine, Case Western Reserve, Cleveland, OH, <sup>5</sup>Center for Clinical Informatics Research and Education, Metrohealth Medical Center, Cleveland, OH, <sup>6</sup>Dept of Internal Medicine & Pediatrics, Metrohealth Medical Center, Cleveland, OH, <sup>7</sup>Departments of Information Services, Metrohealth Medical Center, Cleveland, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Down syndrome (Trisomy 21) is known to have higher prevalence of certain conditions including cardiac defects, hypothyroidism, hearing defects and early Alzheimer's disease, but no studies have looked at the association between Downs syndrome and gout.

**Objective:** The aim of this study is to estimate the prevalence of gout among Down syndrome patients compared to non-down syndrome patients.

**Methods:** We reviewed electronic health record (EHR) data over 14 years (1999-2013) from 25,840,730 patients using a third-party cloud-based platform (Explorys, Cleveland OH). 994,793 patients from our institution (The MetroHealth System) were analyzed. International Classification of Disease – 9 (ICD-9) diagnoses codes were used to define Downs syndrome and gout. Prevalence data was

compiled among patient diagnoses of Downs syndrome only, gout only, both Downs Syndrome and gout, and neither Downs Syndrome or gout. The odds ratio of a gout diagnosis in a Downs Syndrome patient relative to a non-Downs syndrome patient was calculated

**Results:** Among the almost 26 million patient cohort, the odds ratio of a gout diagnosis in a patient with Downs syndrome diagnosis compared to a patient without Downs syndrome diagnosis was 3.66 [95% CI 3.32-4.03] and within the MetroHealth system subset, the odds ratio was 4.26 [2.81-6.46].

**Conclusion:** In the setting of a Downs syndrome patient presenting with articular pain, gout should be higher on the differential diagnoses than in non-Downs syndrome patients. This study also illustrates the potential of aggregated EHR data from tens of millions of patients to create a new paradigm for case series and disease association identification.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chondrocalcinosis (CC) results from deposition of calcium pyrophosphate dihydrate (CPPD) in articular cartilage. It is a relatively common radiographic finding of the joints, especially the knee. This study investigated the incidence of knee CC and sought to identify the risk factors for the development of knee CC in the general population.

**Methods:** We used a prospective, ongoing cohort, composed of 5,018 people, which was established in 2001 to investigate the epidemiologic characteristics of major chronic diseases in Korea. The incidence of knee CC was assessed per 1,000 person-years, and the risk factors were explored by Cox proportional hazard regression analyses.

**Results:** A total of 4,319 patients who did not have knee CC at enrollment, year 2001-2002, were evaluated with a mean follow-up duration of 8.4 years (SD, 4.2 years). The crude incidence of knee CC was 3.19 per 1,000 person-years (women, 3.55; men, 2.70), and the whole cumulative incidence of knee CC was 2.7%. Older age ( $\geq 55$  years) and higher HbA1C were associated with increased risk of knee CC.

**Conclusion:** This is the first study to report the incidence of knee CC in the general population. Older age and high HbA1C were independent risk factors for development of knee CC.

## Urate-Lowering Treatment and Risk of Total Joint Replacement in Patients with Incident Gout: A Population-Based Cohort and Nested Case-Control Study

Jung-Sheng Chen, **Chang-Fu Kuo**, Ping-Han Tsai, Shue-Fen Luo and Kuang-Hui Yu, Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

This cohort study aimed to investigate the risk of total joint (hip/knee) replacement (TJR, THR and TKR) among patients with incident gout at initial diagnosis and subsequent periods. Furthermore, we estimate the exposure dose of urate-lowering treatment (ULT) on the TJR risk by using a nested case-control study.

### Methods:

An incident gout cohort during 1995 to 2009 was retrieved from the UK Clinical Practice Research Datalink (CPRD) and were age-, sex and general practice-matched in a 1:4 ratio to controls. Multivariate odds ratios (ORs) for TJR at diagnosis and hazard ratios (HRs) for TJR after diagnosis were estimated adjusting for age, gender, Charlson comorbidity index, BMI level, smoking status, alcohol consumption and comorbidities. Adjusted ORs derived from conditional logistic regression were used to estimate the association between cumulative defined daily dose (cDDD) of urate-lowering treatment and TJR using a nested case-control design.

### Results:

There were 40,160 incident gout patients diagnosed during study period and matched to 160,640 controls. Gout was associated with adjusted ORs (95% CIs) of 1.34 (1.15–1.57) for THR and 1.24 (1.02–1.51) for TKR at diagnosis. The incidence of both were higher in gout patients compared with their corresponding controls (3.72 vs 2.47 cases/1000 person-years for THR and 3.57 vs 2.31 cases/1000 person-years for TKR). Multivariate HRs (95% CIs) were 1.22 (1.10–1.35) for THR, 1.09 (0.99–1.21) for TKR and 1.14 (1.06–1.23) for

TJR. Using a nested case-control study with gout cohort, ORs (95% CI) for TJR was 1.00 (0.83–1.20) for 1–180 cDDD of ULT, 1.03 (0.80–1.33) for 180–364 cDDD and 1.09 (0.94–1.27) for >365 cDDD compared with non-ULT user.

#### Conclusion:

Gout was associated with a higher risk of TJR at diagnosis and the risk continue to rise afterwards. TJR risk was not modified by ULT use after gout diagnosis.

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Gout is frequent and severe in Vietnam, where urate-lowering drugs (ULD) are seldom used and many patients are treated only with traditional herbal medicine. We looked at the effect of a Treat to Target strategy (T2T) using allopurinol on severe Vietnamese gout.

**Methods:** One hundred Vietnamese, ULD- free, crystal-proven gout patients (99 men, 1 woman) with a GFR > 60 ml/min, were prospectively followed during an aimed period of 12 months (M) after allopurinol (ALLO) initiation. The median age of patients was 47 years (y), median disease duration 10 y, median BMI 25 kg/m<sup>2</sup>, 91 patients had multiple palpable tophi, 32 had hypertension, 7 type 2 diabetes, 31 dyslipidemia, 47 coronary heart disease, 16 were on long term steroid. Treatment protocol included full patient information, titration of ALLO up to reaching a predefined SUA target (6 mg/dL in 5 patients and 5 mg/dL in 95), flare prophylaxis by colchicine (0.5 to 1mg/d) during the first months, and traditional herbal medicine. At each visit, gout flares from the last visit were counted using a daily diary, palpable tophus size was assessed using a Vernier caliper, SUA was measured. Ultrasound (US) scan was performed at inclusion and every 3 M and allowed search for double contour (DC) sign at the knees and first MTP joints -which were found in all patients at baseline and classified into 4 classes (thick, medium, thin and none)- and measurement of a hand or foot index tophus. Quality of life (gout impact scale (GIS) and function were recorded at inclusion and after 12 M. The effect of SUA lowering was explored by comparing inclusion and 12-M data, in patients who reached their SUA target and those who did not, using standard statistics.

#### Results:

Eighty four and 68 patients were seen at M6 and M12, respectively. Reasons for loss of follow-up were major improvement (12), alcoholism (2), long distance from the center (8), inter-current disease or personal problem (9), and intolerance to ALLO (4). The mean maximal dose of ALLO was 520 (+165) mg/d and was reached after a median of 2 (+1.3) M. SUA target was obtained in 89 patients. Mean flare rate per M significantly declined from 2.5 on M1 (n=98) to 1.1 at M6 (n=84) (p<0.001), and 0.15 at M12 (n=68) (p<0.001), at a time when all patients were free of prophylactic colchicine, NSAIDs or steroid but remained under herbal treatment, with no significant influence of SUA. GIS significantly similarly strongly improved in all dimensions (p<0.02) except for fear of side effects

( $p=0.13$ ) and did not significantly correlate with SUA target. Function significantly ( $p<0.004$ ) improved, and even more in patients at target ( $p<0.001$ ). Tophi ( $p<0.001$  for both caliper and US measurements) and DC sign ( $p<0.03$  for all locations) significantly decreased between inclusion and M12 and both decreases correlated with achievement of SUA target ( $p=0.004$  for tophi, and  $<0.03$  for DC disappearance).

**Conclusion:** The T2T strategy strikingly improved patients. Tophi and DCs decreased, and function improved in correlation with achievement of SUA target. Flare rate dramatically decreased and GIS strongly improved but these changes did not correlate with SUA, suggesting a lack of statistical power or an anti-inflammatory effect of high dose ALLO and/ or herbal medicine.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Allopurinol, effectively regulates and controls serum uric acid levels but may cause allopurinol-induced life-threatening severe cutaneous adverse reaction (SCAR). Previous studies reported that single nucleotide polymorphisms (SNP) rs3117583 and rs9263726, as well as HLA-B\*5801, were genetic markers for allopurinol-induced SCAR. This study aims to investigate the allele frequency of rs3117583 and rs9263726 in patients with hyperuricemia and/or gout, and the possible effect on predicting allopurinol-induced SCAR.

**Methods:** We enrolled 100 patients with hyperuricemia and/or gout, diagnosed by clinicians at our University in Southern China. Genomic DNA was extracted and the alleles were tested by liquid chip using a Luminex 200 analyzer. Allele frequencies and allele carrying rates were calculated. We investigated the relationship between rs3117583, rs9263726 and HLA-B\*5801. We used Plink software to explore the linkage disequilibrium analysis of rs3117583 and rs9263726.

**Results:** Observed genotype frequencies for rs3117583 (AG&GG) were 22%, while the risk allele G frequency was 11.5%. Similarly, rs9263726(AA&AG) exhibited the same genotype frequencies as rs3117583, and the risk allele frequency was 11.5%. HLA-B\*5801 was observed in 19% of patients. Patients who carried the HLA-B\*5801 allele, tended to carry the risk allele of rs3117583(G), with an odds ratio (OR) of 25.55 (95%CI:7.28-89.64,  $p<0.01$ ), and rs9263726, with an OR of 468.00 (95%CI:45.97-4764.48). Rs3117583 showed a weak linkage disequilibrium with rs9263726 ( $D_i^- = 0.58$ ,  $r^2 = 0.34$ ).

**Conclusion:** The technology of liquid chip can allow rapid and reliable detection of HLA-B\*5801 and SNPs to identify individuals at risk of allopurinol-induced SCAR. Our study suggests that, since there is no strong linkage disequilibrium between rs3117583 and rs9263726, prospective screening combining these two SNPs and HLA-B\*5801 genotyping can improve the predictive value of prescreening for allopurinol-induced SCARs in Southern Chinese patients.

Table 1 genotype of rs3117583, rs9263726 and HLA-B\*5801 in patients with hyperuricemia and/or gout

	Rs3117583			Rs9263726		
	AA	AG	GG	GG	AG	AA
HLA-B*5801 (+)	5	13	1	0	18	1
HLA-B*5801(-)	73	8	0	78	3	0
Total	78	21	1	78	21	1

## Management of Gout – a Survey for Healthcare Providers in South Australia

Nieves Leonardo<sup>1</sup> and Julian McNeil<sup>2</sup>, <sup>1</sup>Rheumatology, The Queen Elizabeth Hospital, Woodville South, Australia, <sup>2</sup>Rheumatology, Northern Adelaide Local Health Network, Modbury, Australia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Gout is a treatable arthritis and while the rate of gout in Australia has been steadily rising, drugs used to treat acute gouty arthritis have a variety of toxicities. A South Australian coroner's case in 2014 drew attention to the fact that there are differences in approach to the treatment of gout that medical professional should be aware of.

We conducted a survey to help understand how South Australian healthcare providers manage Gout.

1. To identify which treatment approaches are favoured for management of acute gouty arthritis
2. To determine whether there are misconceptions in the management of gout according to current recommendations.
3. Whether healthcare providers are familiar with the “treat to target” approach when it comes to management of chronic hyperuricemia.

### Methods:

An anonymous voluntary survey was conducted from 1<sup>st</sup> of May till the 31<sup>st</sup> of July 2015. The targeted population consisted of general practitioners working in the South Australian Health Care System. A random sample size of 326 was determined with 95% confidence level and confidence interval of 5. The population total was based on 2012 figures of practicing general practitioners which is 2138.

The questionnaire was based on published guidelines for management of gout:

- 1) Acute symptomatic management: (NSAIDs, colchicine, and prednisolone)
- 2) Knowledge regarding use of urate lowering therapy
- 3) Familiarity with different published treatment recommendations.

Ethics and site-specific approval was obtained before the start of the survey.

### **Results:**

A total of 146 responses (response rate 48.6%) were received from general practitioners from both rural and metropolitan areas. At least half of whom see more than one patient with gout per week.

Most responders (63%) managed acute gouty arthritis with non-steroidal anti-inflammatory drugs while 24% uses Colchicine. For those who used colchicine, greater than 50% used a greater than 1.5mg per 24-hour dosing, 2.2% prescribed colchicine 500mcg 2-3 hourly until the patient has diarrhea.

Although, 66% commenced allopurinol and up titrate it, only 17% increased the dose more than 300 mg per day if serum urate remains elevated.

Out of the 146 responders only 27 knew of febuxostat as an alternative therapy for allopurinol, while 83% of responders were not aware of the “Treat to Target” approach.

### **Conclusion:**

Gout is primarily managed by GPs in Australia. In recent years there has been a paradigm shift in terms of management. In published guidelines for acute attack of gouty arthritis the recommended options have been oral NSAIDs, systemic corticosteroid or colchicine. However, there remains to be ambiguity in the published dosing guidelines of colchicine.

Our study is the first to examine gout knowledge, belief and treatment approaches in the South Australian Health care system. Despite the recent coroner’s report and updates in the management of gout there continues to be a gap in our responder’s approach to its management.

We identified that suboptimal management of gout is due to poor dosage adjustment of urate lowering therapy to aim for the target urate level and lack of education with alternative to allopurinol as a urate lowering therapy.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is an independent risk factor for any type of cardiovascular disease (CVD). The exact mechanism behind remains to be elucidated, but persistent crystal-related inflammation is presumed as a key factor. The aim of this study was to assess whether gout characteristics that may indicate a more severe disease and higher inflammatory load are associated with the presence of CVD.

**Methods:** Case-control study, performed at baseline of an inception cohort including consecutive crystal-proven gout patients seen at a rheumatology unit. Gout features (time since first attack, number of attacks, number of joints ever affected, pattern of presentation, tophi) were registered after interview and physical exam. Presence and duration of CVD (which included coronary heart disease, heart failure, stroke or peripheral artery disease) was registered after interview and records review. Those patients who have suffered from CVD prior to the onset of gout were excluded. Other cardiovascular risk factors, as well as clinical and laboratory variables, were also registered. Odds ratios with 95% confidence intervals (95%CI) for each gout feature were calculated between patients with and without CVD, using a multiple logistic regression model to adjust for confounders.

**Results:** The inception cohort includes 308 patients; 54 were excluded for this study because gout onset occurred after CVD, so finally 254 cases were analyzed. Mean age was 61.4 years (SD 13.9), being 225 (88.6%) men. Regarding gout, median duration was 5 years (IQR 1-12), median number of reported attacks was 5 (IQR 2-14) that had involved a median of 3 joints (IQR 2-5); presenting attack was monoarticular in 77.4% cases, oligoarticular in 16.7%, and polyarticular in 6%, and 58 patients (22.8%) showed tophi at enrolment. A total of 32 patients (12.6%) had suffered from CVD at enrolment. **Table** shows the results of logistic regression analysis: time since first attack and polyarticular presentation of gout both significantly associated with the presence of CVD, while other variables showed no association. After multivariate analysis, time since first attack persisted associated with CVD, while polyarticular involvement showed a trend towards signification.

**Conclusion:** Time since first attack and likely a polyarticular presentation, two variables that may estimate crystal and inflammatory load in gout patients, are independently associated with the presence of CVD, adding evidence to the role of persistent inflammation on its development.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pegloticase is a pegylated recombinant mammalian uricase approved for treatment of persons with chronic gout refractory to standard urate lowering therapy<sup>1</sup>. Despite initial reduction of serum urate (sUA) to near 0 mg/dL, patients may lose the urate lowering effect of pegloticase owing to the development of anti-drug antibodies (ADA)<sup>2</sup>, and as a result, only 42% of treated subjects had sustained urate lowering in the registration trials<sup>1</sup>. In the absence of stopping rules, infusion reactions (IRs) occurred in 26% of patients in the biweekly dosing regimen compared to 5% of placebo-treated patients. Gout flares occurred in 74% of pegloticase treated subjects in the first 3 months of treatment compared with 51% receiving placebo. Examination of pegloticase pharmacokinetics (PK)<sup>2</sup> indicated that the biweekly regimen may not maintain high levels of drug during the first month of therapy, possibly contributing to the immunogenicity of pegloticase. PK modelling suggested that an additional dose of 8 mg of pegloticase 1 week after the initial dose and 1 week before the subsequent dose might be sufficient to maintain high serum pegloticase levels and contribute to the development of high zone tolerance with decreased ADA. The TRIPLE (Tolerization Reduces Intolerance to Pegloticase and Prolongs the Urate Lowering Effect, NCT02598596) was designed to address this question.

**Methods:** is was a multi-center open label trial enrolling subjects with chronic gout whose sUA was not maintained at 6mg/dL or below. Background urate lowering therapy was discontinued and subjects were treated with 3 weekly doses of 8mg pegloticase followed by biweekly administration of 8 mg of pegloticase for a total of 10 doses over 17 weeks. SUA was measured immediately before each dose. After the first administration, dosing was only permitted if the sUA was 6 mg/dL or less. Standard infusion prophylaxis and gout flare prophylaxis was required. The primary outcome was the maintenance of sUA at 6 mg/dL or less throughout the treatment period.

**Results:** 47 subjects have been enrolled with a mean age of 62.0+/- 15.4 years, and BMI Of 30.0+/-4.5. Subjects have received a total of 282 infusions to date. There has been a total of 2 IRs, both in the same subject (2.1% of subjects with IRs, 0.7% of infusions with IRs). None of these IRs met criteria of anaphylaxis and were thought to be mild/moderate. There have been 5 serious adverse events in 3 subjects, 4 of which were felt to be unrelated to pegloticase and 1 of which was a gout flare. A total of 24 subjects (51.1%) experienced gout flares with each experiencing a mean of 2.2 flares. A total of 5 (10.6%) discontinued treatment before completion of the study. Of the 36 subjects who have completed the treatment regimen, 19 (52.8%) were persistent responders.

**Conclusion:** The tolerization regimen of pegloticase treatment appears to improve outcomes and is well tolerated. Few IRs were noted as administration of pegloticase was avoided in those with a sUA > 6mg/dL . The tolerization regimen may also be associated with a somewhat higher frequency of subjects achieving a persistent urate lowering effect.

## A Case Control Study of Anakinra Use for Acute Gout in a VA Patient Cohort Reveals Association with East Asian Descent, High Urate Burden, and Increased Co-Morbidities and All-Cause Mortality

**Ena Sharma**<sup>1</sup> and Robert Terkeltaub<sup>2</sup>, <sup>1</sup>Rheumatology, University Of California San Diego, San Diego, CA, <sup>2</sup>Rheumatology, VA San Diego Healthcare System, San Diego, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Effectiveness of the IL-1 receptor antagonist anakinra, in resolving flares of acute gout, has been reported in several case series. Here, studying a VA gout cohort with a plurality of minorities, we analyzed patient characteristics in those who needed anakinra prescription to control acute gout flares. In doing so we tested the hypothesis that anakinra was prescribed for gout patients who were sicker (more comorbidities and ultimate mortality), and with higher urate burden (uncontrolled hyperuricemia, palpable tophi). We also analyzed ethnic/racial factors, since in East Asians the ABCG2 variant Q141K is very common (with an allele frequency up to 0.5) in gout. An emerging line of investigation links inflammation with the ABCG2 Q141K variant, and is associated with hyperuricemia and subsequent early onset tophaceous gout. ABCG2 Q141K inhibits autophagy and may increase systemic inflammation.

### Methods:

More than 6000 patients fulfilling 2015 ACR/EULAR criteria for gout were seen at the VA between 01/2003 and 01/2015, with more than 1300 of these evaluated at least once for management by Rheumatology. During this time period, 14 patients (100% male) received anakinra at varying times, for a total of 55 courses. Demographics of the gout cohort were 52% White, 12% Black, 34% East Asian (including ~25% Pacific Islanders), and 2% other. In retrospective case-control analyses, for each patient, 4 age and gender matched controls were chosen. Each patient's first visit with the Rheumatology department was analyzed for factors predictive of the patient eventually requiring anakinra for gout. Demographics, urate burden, baseline co-morbidities, and all-cause mortality were analyzed for anakinra use.

### Results:

Patients who were prescribed or not prescribed anakinra had no significant difference in mean number of comorbidities, (mean of 3.9 in anakinra, 3.1 in controls),  $p = 0.08$ , CI -0.11 to 1.65. Patients receiving anakinra were more likely to have very poorly controlled hyperuricemia and a high body urate burden at baseline (anakinra group 10/14 with tophi vs. controls 17/56 with tophi,  $p = 0.018$ ; anakinra group had mean serum urate of 10.2 mg/dL vs. 7.6 mg/dL in controls,  $p = 0.0002$ ). The anakinra treated group had higher all-cause mortality (7/14 in anakinra group, 9/56 in controls  $p = 0.012$ ) as well as greater predominance of East Asian patients (8/14 in anakinra group vs. 16/56 in control group,  $p = 0.049$ ). In contrast, the distribution of Black patients was not statistically significant between groups ( $p = 0.18$ )

### Conclusion:

Anakinra use for acute gout was associated with patient characteristics including East Asian descent, uncontrolled hyperuricemia and a high body urate burden (reflected by palpable tophi), and significant increases in both the number of co-morbidities and all-cause mortality. The results suggest not only that in gout, patients who are sicker and have less poorly controlled serum urate, more frequently require anakinra to help control acute gout flares. Moreover, the possibility that East Asian patients have a genetic predisposition for more refractory inflammation in gout merits further investigation.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The poor adherence to urate lowering therapy is due to a lack of appropriate information. This study performed to analyze the effect of education for patients with gout.

**Methods:** Patients were enrolled by categorizing in two groups, education and non-education. Face-to-face education was conducted by the specialist nurse, and an information leaflet about lifestyle advice and urate lowering therapy was also given to all participants. Non-education group also received an education on their second visit (after two or three month from first visit). The patient satisfaction were assessed using the visual analogue scale (0 to 100 mm) and patients' satisfaction questionnaire, Questionnaire regarding patient's knowledge about gout. Also, we analyzed the serum uric acid level and drug compliance.

**Results:** A total of 100 patients were randomized to education or non-education group. patients' satisfaction in visual analogue scale was significantly higher in education group (education group:  $87.5 \pm 24.5$  mm, vs. non-education group:  $75.4 \pm 20.3$  mm,  $P=0.008$ ). Also, patients' satisfaction questionnaire was significantly higher in education group (education group:  $4.02 \pm 0.4$ , vs. non-education group:  $3.71 \pm 0.39$ ,  $P<0.001$ ). The level of knowledge about gout was higher in education group (education group:  $7.38 \pm 2.0$ , vs. non-education group:  $6.08 \pm 2.42$ ,  $P=0.004$ ). The serum uric acid level on second visit (after two or three month from first visit) is decreased in education group (baseline:  $5.73 \pm 1.72$  mg/dL, vs. second visit:  $5.09 \pm 1.62$  mg/dL,  $P=0.032$ ). Besides, drug compliance on second visit is improved in education group without statistical significance (baseline:  $88.76 \pm 18.47$  %, vs. second visit:  $92.91 \pm 11.56$  %,  $P>0.05$ ).

**Conclusion:** Nurse-delivered face -to-face education including the nature of gout and its treatment options is improved the patients' satisfaction and their treatment adherence.

## Initiating Colchicine and Urate-Lowering Therapy Reduces Baseline Inflammation, and Improves Vascular Endothelial but Not Smooth Muscle Function in Gout Subjects: Resistance to Endothelial Improvement Among Patients with Cardiovascular Comorbidities

Talia Igel<sup>1,2</sup>, Aaron Garza Romero<sup>2</sup>, Virginia Pike<sup>3</sup>, Yu Guo<sup>4</sup>, Stuart Katz<sup>5</sup>, Binita Shah<sup>5</sup>, Irina Dektiarev<sup>5</sup>, Svetlana Krasnokutsky Samuels<sup>2</sup> and Michael Pillinger<sup>2</sup>, <sup>1</sup>Medicine, Monash University School of Medicine, Melbourne, Australia, <sup>2</sup>Medicine/Rheumatology, New York University School of Medicine, New York, NY, <sup>3</sup>Medicine/Rheumatology, New York University School of Medicine, Division of Rheumatology, New York, NY, <sup>4</sup>Population Health/Statistics, New York University School of Medicine, New York, NY, <sup>5</sup>Medicine/Cardiology, New York University School of Medicine, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have previously reported that patients with gout have impaired vascular endothelial and smooth muscle responsiveness, but whether initiating appropriate gout therapy ameliorates these impairments, or improves baseline inflammatory status, has not been determined.

**Methods:** We performed an observational pilot study to assess whether initiating gout therapy improves vascular function as well as markers of inflammation. Subjects meeting ACR classification and treatment criteria for gout, but not actively receiving gout medications, were enrolled. Baseline demographics were obtained. Subjects were given colchicine daily for 6 weeks, followed by addition of urate-lowering therapy (ULT; allopurinol or febuxostat at the discretion of the treating physician) and titration to a target serum urate (sUA) of <6.0 mg/dL, or <5.0 mg/dL for subjects with tophi. hsCRP was measured pre and post the colchicine-only period, and 4 weeks after achieving target sUA. Endothelial responsiveness was assessed using ultrasound as brachial artery dilation in response to application/release of a blood pressure cuff (flow-mediated dilation, FMD). Vascular smooth muscle function was assessed as brachial artery dilation in response to sublingual nitroglycerine (0.4 mg) administration (nitrate-mediated dilation, NMD).

**Results:** 34 male subjects were enrolled, and 28 completed all study phases. Mean age was 57.9 years, and mean BMI 30.3. Co-morbidities included hypertension (HTN, 71%); hyperlipidemia (HL, 50%); coronary artery disease (CAD, 21%); chronic kidney disease (14.7%) and diabetes (6%). 26% were current smokers. Mean baseline sUA was 9.1 mg/dL, and declined after ULT (p baseline vs post-ULT, <0.001) (Table). Baseline hsCRP was elevated, and FMD and NMD reduced, vs healthy controls. We observed a pattern of improvement in hsCRP and FMD after colchicine treatment, and further improvement after ULT initiation (mostly allopurinol), but no NMD improvement. Whereas subjects without comorbidities (HTN, HL, CAD and/or BMI>30) experienced improvements in both hsCRP and FMD, subjects with individual or multiple CV co-morbidities experienced improvement in hsCRP but not FMD. In contrast, smokers experienced improvement in both inflammatory and endothelial parameters in response to treatment.

**Conclusion:** Initiating colchicine prophylaxis and ULT in gout patients reduces systemic inflammation. Improvement in endothelial function is also observed, but patients with established CV comorbidities may be resistant to endothelial improvement. These data suggest that proper gout treatment may have direct benefit in reducing CV risk. Whether longer term treatment could have additional impact, particularly on patients with established CV comorbidities, remains to be determined.

Table. Responses to colchicine, and to colchicine plus ULT, in gout patients without HTN, HL, CAD or BMI > 30			
	Pre-treatment	On colchicine	On colchicine + ULT
sUA (mg/dL)	9.4	9.4	5.2
hsCRP (mg/L)	4.2	3.8	2.0
FMD (endothelial response)	0.6	1.6	3.39
NMD (smooth muscle response)	22.2	24.2	21.5

## Effectiveness of a Multidisciplinary Gout Clinic on Timely Achievement of Serum Uric Acid Goals

**Kah Mun Cheong**<sup>1</sup>, Archana Vasudevan<sup>2</sup>, Melonie Sriranganathan<sup>2</sup>, Elena Lee<sup>1</sup>, Serene Yeow<sup>1</sup> and Prista Ramskay<sup>1</sup>, <sup>1</sup>Department of Pharmacy, Changi General Hospital, Singapore, Singapore, Singapore, <sup>2</sup>Department of Medicine, Changi General Hospital, Singapore, Singapore, Singapore

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Metabolic and Crystal Arthropathies Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The concept of a multidisciplinary gout clinic is relatively new in Singapore. Changi General Hospital launched **such** a clinic in 2014 to provide treat-to-target management of gout in a shared care model of rheumatologists and pharmacists.

This study aims to demonstrate the effectiveness of a multidisciplinary gout clinic on the optimization of urate lowering agents to achieve target serum uric acid (sUA) levels.

## Methods:

We reviewed case notes and medication records of gout outpatients who were started on either Allopurinol or Febuxostat in the 24 months prior to (pre-group) and 33 months following (post-group) the launch of the multidisciplinary gout clinic. Patients with stage 5 chronic kidney disease or end-stage kidney disease as well as those who defaulted their appointments were excluded.

The primary efficacy end-point was mean time taken to attain goal sUA in patients who achieved target sUA between both pre- and post- groups. Secondary outcomes include percentage of patients who experienced a gout flare at one year of drug initiation, the mean dose of urate lowering therapy required to achieve target sUA levels, the proportion of patients that achieved target sUA of 360µmol/L or less at one year of drug initiation and mean reduction in sUA.

## Results:

In 98 eligible subjects enrolled in our study, 50 patients were managed only by the rheumatologist (pre-group) and 48 patients were seen by both the rheumatologist and pharmacist (post-group). Among patients who have achieved target sUA level, the mean time taken to attain target sUA was shorter in the post-group as compared to the pre-group (147 days vs. 314 days,  $p<0.001$ ). The percentage of patients who experienced a gout flare at one year of drug initiation is lower in those who achieved target sUA levels as compared to those who did not achieve target sUA levels (29.5% vs. 78.4%,  $p<0.001$ ). The mean (standard deviation) daily allopurinol and febuxostat dose to achieve target sUA levels were 276mg (138mg) and 76mg (37mg) respectively. A higher proportion of patients achieved sUA of 360µmol/L or less at one year of drug initiation in the post-group as compared to pre-group (70.8% vs. 22.0%,  $p<0.001$ ). The mean change in sUA among pre-group and post group were 113.02 µmol/L vs. 169.27 µmol/L,  $p=0.049$ , respectively.

## Conclusion:

Our results demonstrate that the implementation of a multidisciplinary gout clinic provides a more timely achievement of target sUA level and the attainment of goal sUA is associated with reduced incidence of gout flares. This suggests that a structured multidisciplinary approach is effective in providing better disease management in gout patients.

## Associations between Gout and Cancer in an Nhanes Cohort

**Patricia Kachur**<sup>1</sup>, Venkatesh Gondhi<sup>2</sup>, Yinjin Wert<sup>3</sup> and Pramila Cheriyan<sup>2</sup>, <sup>1</sup>Internal Medicine, Ocala Regional Medical Center, Ocala, FL, <sup>2</sup>Ocala Regional Medical Center, Ocala, FL, <sup>3</sup>Pinnacle Health System, Harrisburg, PA

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Metabolic and Crystal Arthropathies Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Gout is the most common inflammatory disease in the United States (US), affecting more than 4% of the population. Although uric acid (UA) can function as an antioxidant at low levels, high levels have been postulated to play an important role in the pathogenesis of cancer. Recent evidence has demonstrated that hyperuricemia is associated with excess cancer risk, cancer recurrence, and mortality. However, this may be confounded by common comorbidities such as alcoholism and obesity that likewise increase risk for malignancy. The National Health and Nutrition Examination Survey (NHANES) provides a good basis to study these associations in the general US population.

### **Methods:**

11,262 individual from the general population between 2011-2014 were surveyed through the NHANES project using a combination of questionnaires, physical examinations and laboratory studies. Of all subjects, 403 had a diagnosis of gout and 825 had a diagnosis of cancer. Statistical modeling of disease associations were adjusted for age, gender, college education, and the presence of rheumatoid arthritis, smoking status, alcohol use, and BMI. All analyzes were performed using SAS software version 9.4 (Cary, North Carolina).

### **Results:**

There was a significantly higher proportion of cancer diagnoses in gout patients (21% vs 7%;  $p < 0.001$ ). Adjusted multivariate analysis showed that those with gout were 50% more likely to have a diagnosis of malignancy (Odds ratio [OR] = 1.54; 95%CI, 1.16-2.04,  $p = 0.003$ ). Interestingly, patients with rheumatoid arthritis also had a direct association with a diagnosis of cancer (OR 1.6, 95% CI 1.22-2.00,  $p = 0.001$ ), and this was independent of the association with gout. The most common cancer was prostate cancer (25%), followed by breast, cervix, and colon.

### **Conclusion:**

Our study shows evidence of an independent association between gout and malignancy. Prostate cancer was the most common type of cancer this group. The association between gout and cancer warrants further investigation, as confirming these findings have the potential to modify screening practices in those with gout.

<b>Table 1: Multiple logistic regression model - Demographics and risk factors associated with cancer</b>

# Macrophage Activation Syndrome or Acquired Hemophagocytic Lymphohistiocytosis in Adults: Demographics, Clinical Characteristics, and Survivorship in an American Academic Medical Center

Seema Malkana<sup>1</sup> and Irene Tan<sup>2</sup>, <sup>1</sup>Internal Medicine, Temple University Hospital, Philadelphia, PA, <sup>2</sup>Section of Rheumatology, Temple University Lewis Katz School of Medicine, Philadelphia, PA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Macrophage Activation Syndrome, also known as acquired Hemophagocytic Lymphohistiocytosis in adults, is an immune-mediated systemic inflammatory state. It is associated with multisystem organ failure and high mortality. Diagnostic criteria are extrapolated from children with primary Hemophagocytic Lymphohistiocytosis as there is a paucity of literature on adults. Additionally, most recent evidence is reported from non-U.S. populations. These gaps in the literature may contribute to under-recognition and under-diagnosis of adults in the U.S. Study objectives were to characterize the demographic, clinical, and biopsy features of adult Macrophage Activation Syndrome or acquired Hemophagocytic Lymphohistiocytosis at a single American academic medical center; along with treatments, outcomes, and possible predictive factors in the outcomes.

**Methods:** The study center's Electronic Health Record was queried for adult patients in the inpatient or outpatient setting between 1/1/2010-8/30/2015 with ICD-9 codes for hyperferritinemia, adult-onset Still's disease, Macrophage Activation Syndrome, Hemophagocytic Lymphohistiocytosis, or combinations of these. This produced 42 patients. A chart review was performed to confirm diagnosis and patients with only hyperferritinemia or adult-onset Still's disease were excluded. Patients without primary data or reliable report thereof for the first presentation of the disease were also excluded. A detailed chart review followed.

**Results:** Thirteen patients met criteria during the study period. As compared to the global literature, the majority of patients with Macrophage Activation Syndrome or acquired Hemophagocytic Lymphohistiocytosis were male at our center and more often autoimmune-triggered as opposed to viral infection-associated. Ten patients (77%) had biopsy findings or elevated biomarkers for Macrophage Activation Syndrome or acquired Hemophagocytic Lymphohistiocytosis, though soluble IL-2 receptor and CD25 were more commonly positive than bone marrow aspirate. Although cardiopulmonary compromise requiring ICU-level care was common, normal renal function was often maintained. Combination immunosuppressive therapy with anakinra was the most common treatment. Importantly, ten of the eleven patients (91%) whose index encounter was at the medical center survived to discharge.

**Conclusion:** This study reviewed data for adult patients from an American population that is under-represented in the literature. Patient demographics and key clinical features differ from globally observed trends. This may reflect characteristics innate to the study center or the limitations of using EHR-captured data retrospectively. Molecular and biochemical markers can provide a diagnosis when pathognomonic hemophagocytes are not seen in the bone marrow or lymph organs. Combination immunosuppressive therapy remains important but survivorship is difficult to predict without standardization of treatment regimens.

## Arthritis after Cancer Immunotherapy: Symptom Duration and Treatment Response

Melanie H. Smith<sup>1</sup> and Anne R. Bass<sup>2,3</sup>, <sup>1</sup>Medicine, New York Presbyterian Hospital (Cornell), New York, NY, <sup>2</sup>Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, <sup>3</sup>Rheumatology, Hospital for Special Surgery Weill Cornell Medical College, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Checkpoint inhibitor immunotherapy has fundamentally changed the treatment for an actively expanding list of cancers, however its use is associated with immune related adverse events (irAEs). Rheumatologic manifestations of irAEs remain incompletely characterized and poorly understood. A recently published case series suggested that immunotherapy-induced arthritis is an aggressive process requiring high dose corticosteroids.

**Methods:** This was a retrospective chart review of all patients with musculoskeletal irAEs first seen by one of the authors prior to October 2016. All patients had been treated for a malignancy with immune checkpoint inhibitors targeting PD-1 (nivolumab, pembrolizumab), PD-L1 (durvalumab) and/or CTLA-4 (ipilimumab, tremelimumab) at Memorial Sloan Kettering Cancer Center between 2013 and 2016.

**Results:** We identified 10 patients with a mean ( $\pm$  standard deviation) age 63.2 ( $\pm$  9.7) years (Table 1). Seven patients were treated with a combination of checkpoint inhibitors and three with nivolumab monotherapy. Four patients developed inflammatory polyarthritis, four oligoarthritis and two tenosynovitis. Six were ANA positive and two had anti-CCP antibodies. Mean time from the first dose of immunotherapy until joint involvement was 6.3 ( $\pm$  4.3) months (Table 2). Of the two patients with the shortest interval between immunotherapy and the onset of arthritis, one had had mild polymyalgia rheumatic (PMR)-like symptoms prior to the initiation of immunotherapy, and the other had a sister with rheumatoid arthritis (RA). All 10 patients were treated with systemic corticosteroids, and eight required 20 mg or less per day of prednisone. Five patients received steroid-sparing agents. The mean time until resolution of joint symptoms after the last dose of immunotherapy was 15.2 ( $\pm$  4.1) months.

**Conclusion:** Patients experiencing musculoskeletal irAEs can have a wide variety of manifestations ranging from oligoarthritis and tenosynovitis, to PMR, to a polyarthritis consistent with RA. The onset of arthritis appears to be relatively late compared to other irAEs. Musculoskeletal symptoms can last more than a year after the last dose of immunotherapy, however they can generally be managed with low doses of corticosteroids.

Table 1. Patient Demographics and Arthritis Manifestations

Case	Age	Sex	Malignancy	CTLA4	PD-1	other IT	Poly	Oligo	Tenosyn	Joints	Comments	Other
1	57	M	NSCLC	X	X				X	wrists	De Quervain's, ANA+	hypophysitis, dermatitis

## Clinical Implications of Ultrasonography (US) in Monitoring Disease Activity of Relapsing Polychondritis (RP) and Comparative Investigation By US between Auricle of RP, Repeated Trauma and Healthy Subject

Eri Amano<sup>1</sup>, Yoshinori Taniguchi<sup>2</sup>, Satoshi Inotani<sup>1</sup>, Hirofumi Nishikawa<sup>1</sup>, Tatsuki Matsumoto<sup>3</sup>, Shuichi Nakayama<sup>4</sup> and Yoshio Terada<sup>5</sup>, <sup>1</sup>Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi Medical School, Nankoku, Japan, <sup>2</sup>Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi University, Kochi, Japan, <sup>3</sup>Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi University, Nankoku, Japan, <sup>4</sup>Kochi Medical School, Nankoku, Japan, <sup>5</sup>Kochi University, Nankoku, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Relapsing polychondritis (RP) is a rare systemic inflammatory disorder and might often be refractory. Therefore, the discovery of more convenient imaging modality than contrast-CT, MRI and FDG-PET/CT would be required on diagnosis and treatment. The objective is to assess the clinical implications of ultrasonography (US) in monitoring disease activity and diagnosis of RP.

**Methods:** Firstly, auricular chondritis of patients with RP (n=5) were assessed by US before and after treatments. Second, the relationship between US findings and other serum inflammatory markers were evaluated. Moreover, the comparisons of US findings between the auricle of patients with RP (n=5), repeated trauma (n=5) which is similar to auricle of RP, and healthy subjects (n=5) were also assessed.

**Results:** US of the auricular chondritis before treatment showed low-echoic swollen auricular cartilage with increased power Doppler signals (PDS) in all cases. US findings corresponded to biopsy findings. After treatment with prednisolone (PSL) combined with methotrexate, the swollen ear completely resolved in all cases. Then, US findings also showed dramatic reductions in swollen cartilage with the decrease in PDS. When serum inflammatory markers completely improved, but US finding remained, 1 of 5 cases showed flare due to PSL tapering. On the other hands, US imaging could differentiate between inflammation, vascular lesions, and tumors in the ear pinna. RP could be differentiated from the damage of repeated trauma (i.e. rugby) with producing subperichondrial serous effusion.

**Conclusion:** US imaging of the external ear and auricular cartilage in RP possibly facilitates evaluation of auricular lesions and monitoring of disease activity, especially when we consider the treatment response and the timing of drug tapering.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Behçet's disease (BD) is a chronic inflammatory syndrome with features of multi-organ involvement and presents with mucocutaneous and ocular symptoms. We have previously found that eye involvement was significantly associated with neurologic lesions, while the coexistence with intestinal involvement was uncommon. Moreover, a couple of studies have revealed some phenotypical clustering among the patients with BD. This study aimed to identify the high-risk patients for ocular involvement

**Methods:** The Japanese Ministry of Health, Labour and Welfare provided the dataset of ongoing nationwide BD registration project. We analyzed newly registered patients who fulfilled the International Study Group (ISG) criteria. To have an overview on the associations between manifestations, we made Yule's Q matrix. After this screening process, we estimated how each risk factor associated with ocular lesions using odds ratio (OR). We also conducted a logistic regression analysis, wherein the ocular lesion was a dependent variable.

**Results:** Among 2399 eligible BD patients, 941 (39%) were men and 1458 (61%) were women with a median age of 37 years (interquartile range (IQR) 29-44 years) (Abstract Table 1). The median duration between onset and registration was 0 year (IQR 0-3). Genital ulceration and skin lesions had Yule's Q values of -0.82 and -0.75, respectively. These values indicated that the absence of genital ulceration and skin lesions were risk factor of ocular involvement. Among 1915 patients with genital ulceration, 383 (20%) had ocular lesions, while among 484 patients without genital ulceration, 348 (72%) had ocular lesions (Abstract Table 2). This yielded an OR of 0.10 (95%CI 0.08-0.12,  $P < 0.001$ ). Among 2308 patients with skin lesions, 664 (29%) had ocular lesions, while among 91 patients without skin lesions, 67 (74%) had ocular lesions, yielding an OR of 0.15 (95%CI 0.09-0.23,  $P < 0.001$ ). Subgroup analyses constantly replicated these results (Abstract Table 2). The logistic regression analysis identified skin lesion (OR 0.08, 95%CI 0.05-0.13,  $P < 0.001$ ) and genital ulceration (OR 0.08, 95%CI 0.06-0.10,  $P < 0.001$ ) as protective factors for ocular lesions (Abstract Table 3).

**Conclusion:** The absence of genital ulceration and skin lesions were risk factor of ocular involvement of BD.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Behçet's disease (BD) has a broad spectrum of clinical phenotypes. Sex differences in BD presentation has been one of the major topics of BD epidemiology. The prevalence of BD was found not to be very different between men and women, whereas that of each symptom showed a clear difference between the sexes. However, it is important to consider age factor in discussing sex differences, because the differences are mainly caused by sex hormone environments in the reproductive age besides sex chromosome gene products. In principle, genetic factors contribute to disease phenotype more prominently in young aged onset patients than elderly ones in any diseases. On contrary, elderly individuals are more exposed environmental factors and the effects are accumulated. Unfortunately, age differences in BD was reported in few studies with smaller numbers of cases.

**Methods:** The database of newly registered BD was obtained from the Japanese Ministry of Health, Labour and Welfare. Patients who met International Criteria for Behçet's Disease (ICBD) were selected and analyzed. Prevalence of manifestations was compared after stratifying by sex alone, age alone, and simultaneous sex plus age.

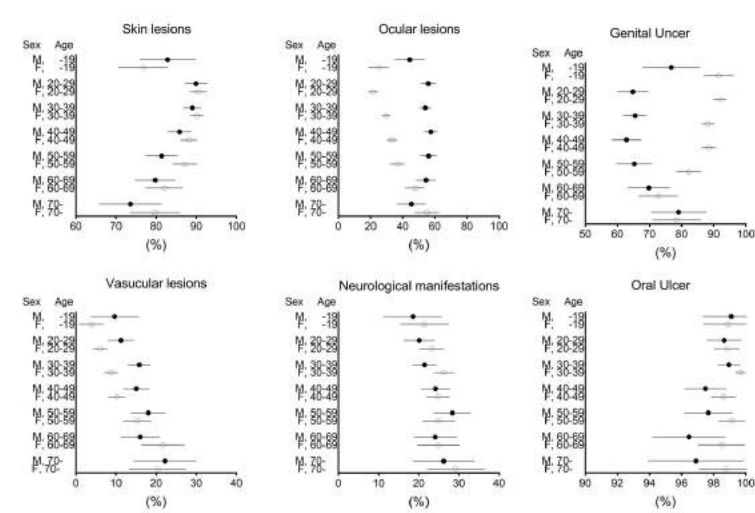

**Results:** Among 6627 ICBD cases, 2651 (40.0%) were men and 3976 (60.0%) were women with a median age of 39 years (IQR 31-50 years) (Abstract Table 1). Ocular lesion was more common in male (odds ratio (male: female) 2.64 (95%CI: 2.35-2.95,  $P < 0.001$ ) and genital ulceration was more common in female (odds ratio 0.29, 95%CI 0.25-0.32,  $P < 0.001$ ). Ocular lesion ( $P < 0.001$ ), arthritis ( $P < 0.001$ ), and vascular lesions ( $P < 0.001$ ) were more frequently observed in elderly-registered patients. Contrarily, genital ulceration ( $P < 0.001$ ), epididymitis of males ( $P = 0.023$ ), and oral ulceration ( $P = 0.003$ ) were more common in younger patients. Simultaneous assessment of sex and age revealed that male predominance of ocular involvement was found in the young adult generation, but not in patients over 70 year of age (Abstract Figure 1). A female predominance of genital ulcer was prominently observed in patients 20-59 year of age; however, the sex difference was not found in patients over 60 years of age. Sensitivity analysis using International Study Group criteria replicated the results.

**Conclusion:** We showed that clinical phenotype in early phase of BD was different depending on onset age and sex.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Diagnosis and accurate measurement of disease activity in adult-onset Still's disease (AOSD) are still challenging due to its heterogeneous clinical manifestations and the lack of serological markers. A few serological markers, such as ferritin, C-reactive protein (CRP), interleukin (IL)-18 have been suggested but their clinical role is limited. IL-37 is a novel anti-inflammatory cytokine belonging to IL-1 cytokine family. However, there has been no study on the role of IL-37 in AOSD patients.

**Objectives:** We aimed to investigate the role of IL-37 as a disease activity marker of patients with AOSD.

**Methods:** A total of 51 patients meeting the Yamaguchi criteria were recruited at a single university hospital. Patients' clinical data and additional laboratory study including serum IL-18 and IL-37 were acquired both at the definite disease flare status (defined as modified Pouchot score 4 or more) and at the definite disease remission status (with modified Pouchot score 2 or less without significant clinical symptoms for more than a month). AOSD disease activity markers were compared between flare and remission status by Wilcoxon signed rank test and their correlation were evaluated by Spearman's correlation test.

**Results:** The mean age of study population was 48.8  $\pm$  2.0. The mean interval between flare and remission was 7.2  $\pm$  0.6 months. There were significantly higher levels of modified Pouchot score, serum ferritin, CRP, IL-18 and IL-37 level in flare status compared to remission ( $p < 0.01$ ) supporting their roles as disease activity markers. IL-37 level positively correlated with other AOSD disease activity markers including modified Pouchot score, CRP, and ferritin at flare status. The sensitivity and specificity of IL-37 for the disease flare status were 80 % and 82 %, respectively, at a cut-off value of 82.1 pg/mL. The AUC for IL-37 was 0.85 (95% confidence interval of 0.78-0.93). IL-18 level showed highest correlation with ferritin level at flare status (Spearman's Rho = 0.632,  $p < 0.01$ ). In contrast, IL-37 level had highest correlation with CRP level at flare status (Spearman's Rho = 0.574,  $p < 0.01$ ). And, there was no significant correlation between IL-18 and IL-37 levels ( $p = 0.13$ ). These differences in the presentation of interactive relationship between cytokines and other disease activity markers suggest the different role of IL-37 from that of IL-18 in activated AOSD status.

**Conclusion:** IL-37 can be used as an efficient disease activity marker in AOSD patients. And, it has a distinctive role as disease activity marker and inflammatory modulator in AOSD patients.

Table 1. Comparison of AOSD disease activity marker levels between flare and remission status (n, 51)

	Flare	Remission	p
Modified Pouchot score	6.0 (4.0, 7.0)	0 (0, 0)	<0.01
Ferritin	3425.0 (538.4, 9733.0)	60.8 (39.5, 108.1)	<0.01
CRP	7.6 (3.2, 12.7)	0.4 (0.15, 0.4)	<0.01
IL-18	91552.2 (49764.2, 141944.5)	1316.9 (637.2, 6069.9)	<0.01
IL-37	231.6 (86.5, 740.1)	28.2 (7.5, 62.6)	<0.01

Data shown are median (Interquartile range). CRP, C-reactive protein; IL, interleukin.

Table 2. Correlation between AOSD disease activity markers in flare and remission status

flare status	modified Pouchot score	CRP	ferritin	IL-18	IL-37
modified Pouchot score	1	0.501**	0.642**	0.417**	0.359**
CRP	0.501**	1	0.439**	0.260	0.574**
ferritin	0.642**	0.439**	1	0.632**	0.335*
IL-18	0.417**	0.260	0.632**	1	0.129
IL-37	0.359**	0.574**	0.335*	0.129	1
remission status	modified Pouchot score	CRP	ferritin	IL-18	IL-37
modified Pouchot score	1	0.398**	0.347*	0.455**	0.237
CRP	0.398**	1	0.440**	0.263	0.106
ferritin	0.347*	0.440**	1	0.179	0.266
IL-18	0.455**	0.263	0.179	1	0.334*
IL-37	0.273	0.106	0.266	0.334*	1

By Spearman's correlation coefficients. \*Correlation is significant at the 0.05 level.

\*\* Correlation is significant at the 0.01 level. CRP, C-reactive protein; IL, interleukin.

## Rheumatic Manifestations of Whim Syndrome

Ananta Subedi<sup>1</sup>, Shubhasree Banerjee<sup>1</sup>, Blas Betancourt<sup>1</sup>, James D. Katz<sup>1</sup>, Peter C. Grayson<sup>1</sup>, Elena Cho<sup>2</sup>, Daniel Velez<sup>2</sup>, Philip M. Murphy<sup>2</sup> and David H. McDermott<sup>2</sup>, <sup>1</sup>National Institute of Arthritis, Musculoskeletal and Skin Disease (NIAMS), Bethesda, MD, <sup>2</sup>National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** WHIMS (Warts, Hypogammaglobulinemia, Infections, and Myelokathexis Syndrome) is a rare autosomal dominant primary immunodeficiency due to gain of function mutations of the CXC chemokine receptor 4 (CXCR4). CXCR4 signaling is crucial in hematopoietic stem cell homeostasis, and plays an important role in innate and adaptive immune responses. The disease often manifests with recurrent bacterial infections and Human Papilloma Virus (HPV)-induced warts of the hand, feet and genitals. The focus of our study is to characterize the rheumatological manifestations in WHIMS patients.

**Methods:** Nine patients out of 36 diagnosed with WHIM syndrome enrolled in a treatment protocol were assessed. These 9 patients were identified owing to rheumatological complaints. Demographics, clinical presentation, laboratory data and imaging studies were tabulated to look for common characteristics and patterns of presentation.

**Results:** The majority of our cohort had onset of rheumatological complaints as children or young adults. Six out of nine were female. The spectrum of initial complaints ranged from arthralgia to overt arthritis. The pattern of joint involvement included asymmetric or symmetric oligo- or polyarthritis involving small and large joints. Three patient exhibited symptoms after a known trigger. In one case, an Oligoarticular small and large joint arthritis postdated a positive urethral chlamydia PCR. Three patients had presentation satisfying a retrospective diagnosis of juvenile idiopathic arthritis. Only one patient had septic arthritis. Another had idiopathic avascular necrosis of the hip in the childhood. We observed that four patients had worsening of joint symptoms temporally related to the treatment of the primary disease. Two patients had tenosynovitis involving the fingers leading to deformity. Auto-antibodies were negative in all eight patients and none were HLA B27 positive. Arthrocentesis data was available in two patients and revealed inflammatory synovial fluid. One of the patients underwent synovial biopsy demonstrating chronic synovitis with T and B lymphocytes. Overall, the response to NSAIDs was variable. Sulfasalazine was used in two of the five patients for purposes of steroid sparing with partial benefit.

**Conclusion:** Rheumatological manifestations have not previously been reported as a major component of the clinical manifestation of WHIM syndrome. We present the first detailed cataloging of such manifestations in a cohort of WHIM patients. Our finding of a high prevalence of joint findings warrants further study. The etiology of arthritis in WHIM syndrome is unknown but could relate to impaired clearance of infectious organisms associated with arthritis or alternatively, an increased risk for autoimmune disease. The rheumatological management of these patients is challenging due to the underlying immunodeficiency.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Yamaguchi's criteria for classification of adult-onset Still's disease (AOSD) has been widely applied in clinic despite it was established decades ago. However, hyperferritinemia, which is a hallmark of AOSD, is not included in the criteria. Moreover, the criteria requires differential diagnosis of malignancy, infection, etc., which has been challenging. Heme oxygenase (HO)-1 is a stress-inducible heme degrading enzyme highly expressed in monocyte/macrophage, serum levels of which has been reported as a promising biomarker for AOSD. We here report data on the use of serum ferritin and HO-1 levels in an attempt to improve the classification of AOSD.

**Methods:** Under the Hypercytokinemia Study Group collaboration, we collected sera from a total of 145 AOSD cases. Three independent experts judged whether the patient is definite AOSD depending on clinical information. These "definite AOSD" patients were further divided into active, remission, and relapse groups, based on their clinical status. Other rheumatic diseases such as ANCA-associated vasculitis, and culture-positive sepsis were included as disease controls. Serum ferritin and HO-1 levels were measured in all of the collected samples by means of ELISA. An association among clinical symptoms, serum ferritin, and HO-1 was explored. Multivariate regression analysis was performed to identify the independent variables associated with definite AOSD diagnosis.

**Results:** Serum ferritin and HO-1 levels were significantly higher in active and relapsed AOSD cases compared to disease controls, and were reduced by the treatment. Although significant correlation between serum ferritin and HO-1 levels were observed, discrepancy was found in some cases such as patients with iron-deficient anemia (**Figure**). ROC analysis identified optimal levels of serum ferritin (> 833 ng/ml; sensitivity 77.5%, specificity 81.1%), and HO-1 (>96.4 ng/ml; sensitivity 92.5%, specificity 81.1%) that differentiate AOSD from disease controls. Multivariate analysis identified typical skin rash, lymphadenopathy/splenomegaly, seronegative, high HO-1 as independent variables associated with AOSD diagnosis.

**Conclusion:** We confirmed that serum ferritin and HO-1 serve as biomarkers for AOSD. Including biomarkers in the Yamaguchi's criteria may reduce heterogeneity of the included patients, although further validation is necessary.

**Figure:** Comparison of serum ferritin and serum HO-1 in AOSD and disease-controls.

Horizontal and vertical dots indicate cut-off values determined from ROC analysis.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The morbidity associated with the use of immunosuppressants is well described in patients (pts) with autoimmune ophthalmic disease and presents a challenge to treating physicians. The purpose of this analysis was to determine the impact of adalimumab (ADA) on immunomodular (IMM) use in pts with active and inactive non-infectious uveitis in the ongoing open label study: VISUAL-III.

**Methods:** Adults who met treatment failure criteria<sup>1,2</sup> in VISUAL-I/VISUAL-II studies (defined as pts with active uveitis) or who successfully completed the parent studies without treatment failure (defined as pts with inactive uveitis) were eligible to enroll in VISUAL-III and received ADA 40-mg every other week for the study duration. Corticosteroids (CS) and/or IMM therapy were permitted as needed. For this analysis, proportion of pts on IMM and percent change in systemic IMM dose were analyzed in pts using medications for immunosuppression. Interim follow-up data from VISUAL-III baseline (week 0) through week-78 are described. In

addition, proportion of pts who achieved a  $\geq 50\%$  reduction in immunosuppression load (CS + IMM) relative to week 8 (for active uveitis) and relative to week 0 (for inactive uveitis) is reported. Data are presented as-observed. Adverse events are reported from first ADA dose up to the data cut-off date of 31-October-2016.

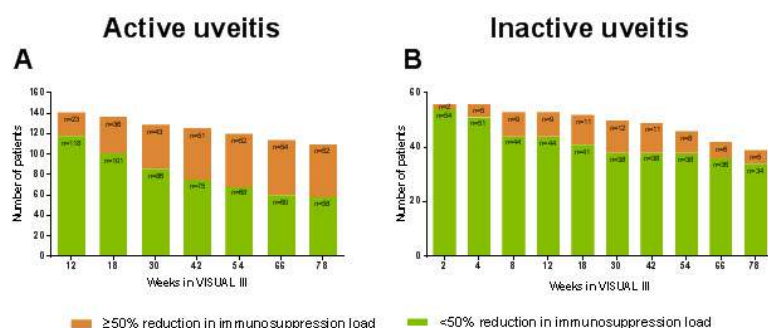

**Results:** Of 424 pts enrolled, 371 (active uveitis; n=242 and inactive uveitis; n=129) were included in the intent-to-treat analysis. Of these 371 pts, 117 (32%) (active uveitis; n=65 (56%) and inactive uveitis; n=52 (44%)) were using IMM at VISUAL-III entry. By week 78, the number of pts using IMM decreased (active uveitis, n=36 and inactive uveitis, n=32). The systemic IMM dose was substantially reduced by week 78 compared to baseline in pts with active and inactive uveitis. In pts with active uveitis using CS + IMM, 47% (52/110) achieved a  $\geq 50\%$  reduction in immunosuppression load relative to week 8, while in pts with inactive uveitis 13% (5/39) achieved a  $\geq 50\%$  reduction in immunosuppression load relative to week 0 (**Figure A-B**). Adverse Event rates were consistent with previous VISUAL trials.

**Conclusion:** Long-term treatment with ADA suggests decreased IMM dependence along with substantial reduction in IMM dose in pts with active and inactive uveitis.

**Figure.** Number of patients that achieved a  $\geq 50\%$  reduction in immunosuppression load relative to week 8 (active uveitis; A) and week 0 (inactive uveitis; B) over time\*.

Data are presented as observed. \*Immunosuppression load was adapted according to Nussenblatt et. al (2005)<sup>3</sup> which provides a combined, single numeric score for the total immunosuppression load per unit body weight per day and includes prednisone and immunomodulators (cyclosporine, azathioprine, mycophenolate, methotrexate, cyclophosphamide and chlorambucil). No patients were administered cyclophosphamide and chlorambucil as these were contraindicated in the VISUAL III trial.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The new and emerging field of immune related adverse events (irAEs) from cancer immunotherapies presents many unanswered questions. The spectrum of irAEs is broad and the underlying pathophysiology, natural history, and relationships among many of these complications is incompletely understood. Most commonly encountered irAEs (skin, gut, liver) tend to be either self-limited or resolve with immunosuppressive therapy. Others, such as some endocrine irAEs, do not resolve and may represent end-organ damage rather than ongoing auto-inflammation. Rheumatic irAEs are among the least understood and their natural history has not been previously described. In our early experience we observed that many rheumatic irAEs are persistent. It is the purpose of this study to report on the expanding clinical spectrum of irAEs observed in our clinic and describe the natural history of rheumatic irAEs.

**Methods:** Beginning in February 2016 an interdisciplinary group was created to manage irAEs. Patients were identified by the treating oncologist and triaged by a designated advanced practitioner with assistance from a registered nurse. Each patient was seen by one of two designated rheumatologists. A detailed review of the EMR was performed including demographics, malignancy details, checkpoint inhibitor (drug(s), date started, date of last dose), pre-existing autoimmune history, nosology of irAE (type, date of onset, diagnostic testing), autoimmune serology. Information was also obtained regarding duration of follow up, status of malignancy, relationship of rheumatic irAEs to other irAEs and to establish chronology and duration of irAEs.

**Results:** irAEs were evaluated in 21 patients including 18 patients without and 3 with pre-existing autoimmune disease. 10 patients received anti-CTLA-4 or anti-PD-1/PD-L1 monotherapy and 11 received them in combination. Of the de novo irAEs, we observed 12 cases of inflammatory arthritis, 4 sicca, 4 PMR-like syndromes and 1 myositis. Immunotherapy was interrupted based on rheumatic irAEs in 12/18 patients and for endocrine irAEs in 3. Median time between first dose and onset of rheumatic irAE was 16 weeks (range 1.7-213). Median time between onset of rheumatic irAE and last follow up was 61 weeks (range 15.1-153). At follow up only 4/18 patients were able to discontinue rheumatic irAE treatment. 7 patients were stable on irAE treatment. 7 were symptomatic despite escalating therapy. During the course of managing irAEs 17/18 patients received glucocorticoids for rheumatic irAE (prednisone 15-60mg), 5/18 (28%) received at least one bDMARD and 2/18 (11%) at least 2 bDMARDs.

**Conclusion:** These data further our understanding of the expanding spectrum of rheumatic irAEs and add new observations on their natural history with particular attention to chronology of onset, duration and relationship to intercurrent irAEs affecting other organ systems. Our data further suggest that rheumatic irAEs are not self-limiting, may require prolonged immunosuppressive therapy, occasionally with biologics, and often may lead to permanent cessation of immunotherapy. This has important ramifications for rheumatologists, who will continue to see an ever-growing number of patients with rheumatic irAEs.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hypocomplementemia frequently occurs in IgG4-related disease (IgG4-RD), especially IgG4-related kidney disease (IgG4-RKD). This study aimed to investigate the clinical features of IgG4-RD patients (pts) with hypocomplementemia using a large-scale cohort of 328 IgG4-RD pts, in order to clarify the clinical significance and mechanisms of hypocomplementemia.

**Methods:** We retrospectively evaluated the clinical features at diagnosis of 328 pts diagnosed with IgG4-RD according to the comprehensive diagnostic criteria or each organ-specific diagnostic criteria; the features we evaluated included age; sex; serum IgG4, IgE, CH50, C3, C4, and CRP levels; gaps between serum IgG and IgG4 levels (IgG-IgG4 levels); the serum IgG4/IgG ratio; and the affected organs. These data were longitudinally analyzed over the clinical course for patients whose data were available. Hypocomplementemia was defined as a decrease below the normal range for the serum CH50, C3, or C4 level. We applied multivariate logistic regression analysis to the variables with  $P < 0.05$  in univariate analysis to search for factors related to hypocomplementemia in the group of all pts, pts with IgG4-RKD, and pts without IgG4-RKD.

**Results:** The pts comprised 201 men and 127 women (average age 63.9 years). At diagnosis, the average serum IgG4 level was 750 mg/dL (range: 18 to 3,510). Hypocomplementemia was observed in 138 pts (42.1%). The salivary glands were involved in 241 pts, lacrimal glands in 188, pancreas in 85, retroperitoneum/arteries in 82, kidneys in 80, and lungs in 76. Compared with pts without hypocomplementemia, pts with it had significantly higher age (65.0 vs. 63.0 years,  $P = 0.044$ ), serum IgG4 (947 vs. 608 mg/dL,  $P < 0.001$ ) and IgG-IgG4 levels (1,976 vs. 1,428 mg/dL,  $P < 0.001$ ), IgG4/IgG ratio (31.0% vs. 27.2%,  $P = 0.028$ ), and number of involved organs (3.5 vs. 3.0 organs,  $P = 0.007$ ). They also had a higher incidence of renal (34.8% vs. 16.8%,  $P < 0.001$ ), pancreatic (34.1% vs. 20.0%,  $P = 0.005$ ), and lung (29.7% vs. 18.4%,  $P = 0.024$ ) involvement. Multivariate logistic regression analysis for all pts indicated that the elevation of IgG-IgG4 levels [per 100 mg/dL, odds ratio (OR) 1.102, 95% confidence interval (CI) 1.036-1.173,  $P = 0.002$ ] and the presence of pancreatic lesions (OR 1.909, 95% CI 1.063-3.428,  $P = 0.031$ ) were independent factors related to hypocomplementemia. Of note, the same analysis in pts with IgG4-RKD showed that only the elevation of IgG-IgG4 levels (per 100 mg/dL, OR 1.227, 95% CI 1.094-1.375,  $P < 0.001$ ) was an independent factor, whereas the presence of pancreatic lesions (OR 1.963, 95% CI 1.048-3.676,  $P = 0.035$ ), but not the elevation of IgG-IgG4 levels (OR 1.046, 95% CI 0.984-1.111,  $P = 0.153$ ), was an independent factor in pts without IgG4-RKD. In IgG4-RKD, both pts with and without hypocomplementemia showed serum IgG4 re-elevation upon relapse of renal lesions. Notably, the pts with hypocomplementemia showed exacerbation of hypocomplementemia and re-elevation of IgG-IgG4 levels, while the pts without it did not.

**Conclusion:** The present study shows that hypocomplementemia is related to the elevation of IgG subclasses other than IgG4 in IgG4-RD, especially IgG4-RKD.

## Treatment of Non-Infectious Uveitis: A Comparative Long-Term Study between Biologic Therapy with Adalimumab and Two Conventional Disease-Modifying Antirheumatic Drugs

Esteban Rubio Romero<sup>1</sup>, Roberto Aguilar Galán<sup>2</sup>, Raúl Menor Almagro<sup>1</sup>, Alejandro Muñoz<sup>1</sup> and Juan Povedano<sup>1</sup>, <sup>1</sup>Rheumatology, Hospital Universitario Virgen del Rocío, Sevilla, Spain, <sup>2</sup>Ophthalmology, Hospital Universitario Virgen del Rocío, Sevilla, Spain

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Uveitis is inflammatory processes of the vascular layer of the eye, the uvea, which is divided into iris (anterior uvea), ciliary body (intermediate) and choroid (posterior uvea). Many of these uveitis will have severe repercussions on the visual function and quality of life of the patients. We propose a clinical trial that allows us to evaluate the presence of differences in disease control (frequency and severity of relapses, and need for addition of another drug over time of the study) between biological therapy with adalimumab (ADA) and conventional disease-modifying antirheumatic drugs.

**Methods:** Prospective interventional study at 2 years of follow-up, type III clinical trial, with a sequential randomization of treatments. A sample size of 92 outpatients from a multidisciplinary autoimmune unit with one rheumatologist and one ophthalmologist, were assigned to ADA, methotrexate (MTX) or cyclosporine (CyA). Inclusion criteria for study selection were: non infectious uveitis, recurrent uveitis ( $\geq 3$  relapses) and 1 episode of previous uveitis with severity criteria. Indicators of inflammation were: decreased visual acuity, tyndall effect, flare, par planitis and cells in vitreous. Severity indicators were: onset of synechiae, band-keratopathy, cataract, cystic macular edema, retinitis, choroiditis and vasculitis. Clinical response was defined as the improvement of one inflammation indicator without worsening of the rest, from 6 months to the end of study. The patients were assessed at 0, 2, 6, 12, 18 and 24 months.

**Results:** A total of 92 patients were reviewed, 57.6% males. The mean age at initiation of the study was  $40.9 \pm 14.9$  years. The most frequent diagnosis was idiopathic uveitis (66.3%), uveitis associated with autoimmune disease (22.8%) (ankylosing spondylitis 5, psoriatic arthritis 4, juvenile idiopathic arthritis 3, inflammatory bowel disease 3) and primary uveitis due to juvenile idiopathic arthritis "like" (7.6%). Granulomatous uveitis were 68 (73.9%) vs non-granulomatous 24 (26.1%).

Data analyzed showed the 3 drugs groups achieved clinical response maintained in 100% of the cases. Outcome measures to evaluate effectiveness as number of recurrence of uveitis showed significant differences ( $\chi^2_{\text{kruskal-wallis}} = 7.146$ ;  $p=0.028$ ), with more patients without relapse in ADA group. There was not significative difference in severity uveitis relapse ( $\chi^2_{\text{k-w}} = 1.408$ ;  $p=0.495$ ) (table 1) or addition of another drug (21 patients,  $\chi^2_{\text{k-w}}=0.651$ ;  $p=0.722$ ).

**Conclusion:** In our study we show such as ADA, MTX and CyA therapy are effective in non-infectious uveitis control in the disease inflammation, severity relapse and need for another drug, without statistical difference between groups. A total of 52 patients had at least one relapse over time the study, with better result in ADA group. This fact is very important due to the relation between number of relapse and the structural damage in uveitis.

Table 1		
UVEITIS RELAPSE		
	Severity relapse	Non-severity relapse
	N (%)	N (%)
ADA	7 (13,4)	5 (9,6)
CyA	10 (19,2)	8 (15,3)
MTX	16 (30,7)	6 (11,5)
	33 (63,4)	19 (36,5)

Spain, León, Spain

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anterior uveitis (AU) is the most common pattern of uveitis, that might lead to important ocular complications including blindness. Immunomodulatory drugs have been used in order to prevent recurrences of uveitis. Nevertheless, it is not clear which drug could be preferred in each patient. The aim of the project was to generate recommendations on the use of immunomodulators in adult patients with non-infectious, non-neoplastic anterior uveitis (AU) based on best evidence and experience

**Methods:** Delphi methodology was followed. A multidisciplinary panel of 5 experts (2 ophthalmologists, one immunologist, one rheumatologist, one internist) was established, who, in the first nominal group meeting, defined the scope, users, and chapters of the document. A systematic literature review was performed to assess the efficacy and safety of immunomodulators in patients with non-infectious, non-neoplastic AU. All of the exposed above was discussed in a second nominal group meeting and 33 recommendations were generated. Recommendations agreement grade was tested also in 25 additional experts. Recommendations were voted from 1 (total disagreement) to 10 (total agreement). We defined agreement if at least 70% voted  $\geq 7$ . The level of evidence and grade or recommendation was assessed using the Oxford Centre for Evidence-based Medicine Levels of Evidence.

**Results:** The 33 recommendations were accepted. They include specific recommendations on patients with non-infectious, non-neoplastic UA, as well as different treatment lines. Methotrexate (MTX) or Sulfasalazine were recommended as a first line drugs in refractory cases to topic treatments in patients with AU and spondyloarthritis, inflammatory bowel disease, psoriasis, idiopathic HLA-B27 positive or negative AU. Etanercept was recommended for patients with TRAPS syndrome, and for those with other autoinflammatory syndromes canakinumab or anakinra. In case of bilateral sarcoidosis, relapsing polychondritis or TINU syndrome, MTX was recommended along with systemic steroids. For patients with a flare of AU and Behçet disease, systemic steroids along with azathioprine or a calcineurin inhibitor were recommended. The indication of an immunomodulatory drug in patients with multiple sclerosis was considered to be decided with a neurologist. For patients refractory to all exposed above and/or intolerant, depending on AU type, a change to another classical immunomodulatory drug or to an anti-TNF was recommended (adalimumab, infliximab, certolizumab or ). Except for patients with TINU, etanercept was not recommended because current evidence does not support the use of it to prevent AU flares

**Conclusion:** In patients with non-infectious, non-neoplastic AU, these recommendations on the use of immunomodulators might be a guide in order to help in the treatment decision making, due to the lack of robust evidence or other globally accepted algorithms

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Increased Incidence of Upper and Lower Gastrointestinal Events in Patients with Sarcoidosis: A Population-Based Cohort Study

**Background/Purpose:** An increased incidence of gastrointestinal (GI) events has been observed in patients with autoimmune diseases such as rheumatoid arthritis. However, there is little information about GI complications among patients with sarcoidosis.

**Methods:** 345 patients (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) with incident sarcoidosis in 1976-2013 in a geographically well-defined population were identified based on comprehensive individual medical record review. Inclusion to this cohort required physician diagnosis supported by histopathology, compatible clinical presentation, and exclusion of other causes of granulomatous inflammation. A total of 345 sex and age-matched comparators (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Medical records of both cases and comparators were individually reviewed for upper and lower GI events. Upper GI events included ulcer, hemorrhage, perforation, obstruction, esophagitis and esophageal varices. Lower GI events included ulcer, hemorrhage, perforation, obstruction, colitis and inflammatory bowel disease. The cumulative incidence of all and individual GI events adjusted for the competing risk of death was estimated. Cox proportional hazards models with adjustment for age, sex, and calendar year were used to compare the rate of development of GI events, individually and in combination, between cases and comparators.

**Results:** A total of 101 patients with sarcoidosis and 63 comparators developed GI events after index date during a median follow-up of 13.6 years among patients with sarcoidosis and 15.9 years among comparators. After adjusting for age, sex and calendar year, the risk of GI events after index date was significantly higher among patients with sarcoidosis with adjusted hazard ratio (HR) of 1.90 (95% confidence interval (CI), 1.38 – 2.61). The risk was increased for both upper GI events (HR 1.90; 95% CI, 1.27 – 2.83) and lower GI events (HR 1.97; 95% CI, 1.27 – 3.05). Analysis by individual GI event revealed a significantly increased risk of upper GI hemorrhage, upper GI ulcer and diverticulitis as shown in table 1.

**Conclusion:** This first ever population-based evaluation of GI events in sarcoidosis revealed that patients with this disease have a significantly increased risk of events affecting the upper and lower GI tracts.

Table 1: Hazard ratio of GI events after index date, comparing patients with sarcoidosis with subjects without sarcoidosis

Subtype of GI event	HR (95% CI) for all events after index date, adjusting for age, sex and calendar year
<b>Upper GI events</b>	
Ulcer	2.56 (1.27 – 5.17)
Hemorrhage	2.36 (1.24 – 4.47)
Perforation	Not available
Obstruction	1.20 (0.43 – 3.32)
Esophagitis	1.58 (0.87 – 2.88)
Esophageal varices	6.51 (0.78 – 54.16)
Any upper GI events	1.90 (1.27 – 2.83)
<b>Lower GI events</b>	
Ulcer	3.51 (0.73 – 16.92)
Hemorrhage	1.32 (0.62 – 2.82)
Perforation	Not available
Obstruction	Not available
Diverticulitis	2.29 (1.03 – 5.10)
Ischemic colitis	2.38 (0.61 – 9.26)
Infectious colitis	1.99 (0.79 – 5.00)
Drug-induced colitis	Not available
Other colitis	Not available
Inflammatory bowel disease	1.87 (0.95 – 3.70)
Any lower GI events	1.97 (1.27 – 3.05)

### Clinical Characteristics of Ocular Sarcoidosis: A Population Based Study 1976-2013

**Background/Purpose:** To characterize the epidemiology and clinical characteristics of ocular involvement in patients with systemic sarcoidosis.

**Methods:** An inception cohort of patients with systemic sarcoidosis in 1976-2013 in a geographically well-defined population was identified based on comprehensive individual medical record review. Inclusion required physician diagnosis of sarcoidosis supported by histopathology of non-necrotizing granulomata, characteristic radiologic features of intrathoracic sarcoidosis and exclusion of other granulomatous diseases. Medical records of those patients were then reviewed for ocular involvement.

**Results:** A total of 345 incident cases of systemic sarcoidosis were identified. Ocular involvement occurred in 23 patients (mean age 51.8 years, 65% female and 78% Caucasian). The most common ocular disease was uveitis (61%) followed by conjunctival nodule (17%). Other types of ocular involvement that were observed in this cohort included episcleritis, anterior scleritis, conjunctivitis, lacrimal gland involvement, eyelid lesion, dry eye disease and optic neuritis. ACE level was elevated in 83% of patients (10 out of 12 tested patients) while hypercalcemia was found in 46% of patients (6 out of 13 tested patients) in whom these tests were obtained. All patients had intrathoracic involvement of sarcoidosis (hilar adenopathy and/or interstitial infiltration).

Among 14 cases with uveitis, 86% were female; 86% were Caucasian, 7% were African-American and 7% were Native-American. Mean age at diagnosis of uveitis was 56.5 years. Anterior uveitis was the most common type of uveitis (71%) followed by intermediate uveitis (21%), posterior uveitis (7%) and panuveitis (7%). Uveitis was the initial presentation prior to the diagnosis of systemic sarcoidosis in 8 (57%) of 14 uveitis cases. Visual acuity (VA) of patients with uveitis was generally good at diagnosis with the majority of eyes having VA of 20/20 to 20/25 in each eye. Visual outcome was also good; only 2 of 24 affected eyes with adequate follow-up lost more than or equal to 3 lines of VA (define as losing more than or equal to 0.3 logMAR) during follow-up due to uveitis, and only 1 eye had VA worse than 20/200 at last visit.

The majority of patients with sarcoid uveitis in this cohort were treated with topical glucocorticoids for the eyes (78%) and/or oral glucocorticoids (64%). Disease modifying anti-rheumatic agents (DMARDs) and biologic agents were infrequently required (only 1 case with methotrexate and 1 case with hydroxychloroquine).

**Conclusion:** Ocular involvement occurred in 7% of sarcoidosis patients in this first ever population-based study of ocular sarcoidosis. Uveitis was the most common type of ocular disease. Visual outcome was generally good.

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Langerhans cell histiocytosis (LCH) is a rare condition, and mostly affects children. Bone is the most commonly involved organ, with bone lesions in 50% of patients. In a recent work, Aricò et al. described that the probability of survival in children suffering from a multisystemic LCH with risk organ involvement was reduced if patients did not have any bony lesion. There is no such study in adult patients in order to know the bone impact on the prognosis.

## **Methods:**

A retrospective monocentric study was performed using data from the patients hospitalized for a LCH at Centre Hospitalier Régional Universitaire de Lille, a university hospital between 2001 and 2015. All patients with LCH and at the age of 18 years or older were included. Patients were excluded if they did not receive any osteoarticular imaging (radiography, bone scan, PET, MRI).

## **Results:**

Our study initially included 70 patients had LCH. After screening 54 patients met the inclusion criteria :31 had bone localization (BLG) and 23 none (NBLG). The two groups showed differences. The lesion leading to the diagnosis was mostly osteoarticular (18 patients) in BLG and pulmonary (18 patients) in NBLG. The BLG presented more multisystemic form than the NBLG (20 vs 2,  $p<0.0001$ ). Treatment was required for 14 patients in BLG and for 2 in NBLG. In BLG, 8 patients were treated medically, mostly by corticosteroid therapy and chemotherapy (7), one patient underwent radiotherapy. 6 patients were treated by surgery. In NBLG, 2 patients were treated by corticosteroid therapy. There was no surgery in NBLG (table 1). 3 patients died in BLG, 2 directly related to LCH and one from postoperative infectious complications. One patient died in NBLG from haematological pathology (chronic myelomonocytic leukaemia). The time between diagnosis and death was one, six and 22 months in BLG, 36 months in NBLG. 7 patients presented relapses in BLG. 5 had been treated by medical treatment, one surgically and one had no previous treatment. The time of relapse was six, 8, 12, 14, 16, 52 and 72 months. 4 presented new bone lesions, 1 pulmonary lesions, 1 dermatological lesions and 1 neurologic lesion (table 1). There was no relapse in NBLG. Unfortunately, there was a lack of statistical power to conclude about the bone impact on the prognosis.

Both groups were equivalent for comorbidities ( $p=0,206$  for cancer and  $p=0,756$  for cardiovascular disease), number of smokers and age at diagnosis ( $36.8\pm 3.0$  years vs  $36.7\pm 3.0$  years,  $p=0.96$  and 25 vs 22,  $p=0.063$ , respectively in the bone location group (BLG) and the no bone location group (NBLG).

## **Conclusion:**

Patients with bone location and those with no bone location are two different phenotypes of adult LCH. Patients with bone location are more prone to have a multisystemic relapsing disease. A multicentric study with a larger number patients is needed to bring more robust data to answer about bone impact on the prognosis of adult LCH.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interleukin-1 (IL-1) is highly active pro-inflammatory cytokine, which is responsible for clinical and laboratory findings in hereditary and acquired auto-inflammatory disorders. Blocking IL-1 activity in these conditions results in a rapid and sustained reduction in inflammatory activity and disease severity. RPH-104, a novel heterodimeric fusion protein containing IL-1R1 and IL-1RAcP linked to immunoglobulin heavy chains, highly selectively binds IL-1 $\beta$ , but can also bind IL-1 $\alpha$  and IL-1Ra with lower affinity. In this First-in-Human study, we aimed to evaluate safety as well as pharmacokinetic (PK) and pharmacodynamic (PD) parameters of RPH-104. **Methods:** A total of 35 healthy volunteers (HV) were enrolled in this randomized, double-blind, placebo-controlled, single-dose study. Five different dosages (4 mg, 20 mg, 40 mg, 80 mg and 160 mg) were tested in cohorts consisted of 7 HV in each. Each HV was hospitalized for 72 hours and followed up to 60 days after subcutaneous (SC) injection of RPH-104. Evaluation of safety data after each subgroup was performed by the Independent Data Monitoring Committee; and the next subgroup could be dosed when the previous dose results did not reveal any risk safety concern. **Results:** Totally 35 HV were dosed, 5 HV were administered RPH104 and 2 HV were administered placebo (saline) in each cohort; All 35 HV were included in the safety analysis but 33 HV were included in PK analysis (2 drop outs). Totally 70 adverse events (AE) were reported, none of them were serious. None of the AE was related to the study drug nor led to subject withdrawal. All AE were of mild intensity. RPH-104 was safe and well tolerated in terms of AE and other clinical and laboratory parameters at all dose levels. PK parameters of RPH-104 are summarized at Table 1 and Figure 1. Mean terminal elimination half-life ( $t_{1/2}$ ) was similar in all cohorts. Initial results suggest linear PK for RPH-104 at all dose levels. PD analysis are ongoing. However, according to the PD analysis of the first 2 cohorts, administration of RPH-104 resulted in a decrease in Serum Amyloid A levels starting from the first hour post-dose in 20 mg cohort, and they remained suppressed throughout the study which may suggest the first biologic activity of RPH-104. **Conclusion:** RPH-104 was administered first time in humans, and it was considered safe and well tolerated following single dose SC administration at different dose levels. A linear PK was observed.

Table 1: Pharmacokinetic (PK) parameters Mean ( $\pm$ SD) of RPH-104 at all dose levels, N=33

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Adult-onset Still disease (AOSD) is a rare systemic inflammatory disorder characterized by spiking fevers, polyarthritis and an evanescent salmon-pink maculopapular eruption. Several cases of atypical persistent skin eruption (APSE) have been reported in AOSD to date. APSE could be associated with AOSD poor prognosis and resistance to treatment. We report the second largest series of AOSD with accurate clinical and histological data.

## Methods:

A multicenter retrospective study was conducted (6 french centers) including all patients with a diagnosis of AOSD (Yamaguchi and/or Fautrel criteria) with skin involvement and a skin biopsy between 2005 and 2017. Clinical, biological and histological data, delay of diagnosis and treatments used were recorded. A review of all APSE cases described in the literature was also performed.

## Results:

Thirty-six patients were included (median age: 46 years-old, female: 69%). Nineteen (53%) presented an APSE (Figure 1). Extracutaneous attempts included: arthralgia/arthritis (94%), lymphadenopathy (36%), hepato/splenomegaly (25%), pericarditis/pleurisy (11%). The following factors seemed to be increased in patients with APSE (n=19) in comparison with patients without APSE (n=17): time to diagnosis (p=0,1), arthritis (p=0.09), liver dysfunction (p=0,08), ferritin level higher than 1,500 ng/mL (p=0.018), number of line of treatments to achieve complete remission (p=0,08). Reactive hemophagocytic syndrome and associated malignancy were similar in both groups. Ninety-four cases of APSE in AOSD were previously reported, characterized by urticarial lesions (with a linear configuration in some cases), pigmented papules or plaques, lichenoid lesions or dermatomyositis-like lesions. Histology of APSE compared with evanescent salmon-pink maculopapular skin eruption displayed increased dermal inflammatory infiltrate and neutrophils, and increased epidermal alterations (dyskeratosis/necrotic keratinocytes, spongiosis).

## Conclusion:

Cutaneous clinical and histological spectrum in AOSD is large and should not delay the diagnosis. These results have to be confirmed by large prospective cohorts.

**Figure 1:** A 58-year-old woman presenting a pruritic APSE (erythematous and pigmented papules and plaques of the cheeks and the leg) (A,B). Skin biopsy of the leg lesion revealed a moderate perivascular and interstitial dermal infiltrate composed of lymphocytes and neutrophils, a dermal oedema and vascular walls infiltrate (C)

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Familial Mediterranean fever (FMF) is an auto-inflammatory disease characterized by recurrent episodes of fever and polyserositis. Most patients have their first febrile attack before the age of 20. Elderly onset (after 40 years) is very rare, but we do encounter these patients sometimes. Therefore, the aim of this study was to evaluate the demographic, clinical, and genetic characteristics of late-onset FMF patients in the Japanese population.

**Methods:** We analyzed clinical features and mutations in the *MEFV* gene of 384 patients, who were referred to our laboratory (Department of Medicine [Neurology and Rheumatology], Shinshu University School of Medicine) between September 2003 and September 2016. All patients were clinically diagnosed with FMF by the Tel-Hashomer criteria. Patients were divided into three groups based on the age of disease onset; group I: 19 years and younger (early-onset group), group II: 20–39 years, group III: 40 years and older (late-onset group). Mutation analysis of the *MEFV* gene was performed by direct sequencing of the product of polymerase chain reaction amplification for hotspot regions (exons 1, 2, 3, 5, and 10). Differences between categorical variables were analyzed using chi-square test with Bonferroni correction. Continuous variables were evaluated with Kruskal-Wallis test and multiple comparison.

**Results:** The study enrolled 63 patients (16.4%) who experienced their first FMF attack when older than 40 years. In this patient group, high fever (90.5%) was the most common clinical finding. In contrast, the percentage of patients with peritonitis (66.2% in group I, 66.8% in group II, 34.9% in group III) and pleuritis (47.0% in group I, 36.5% in group II, 27.0% in group III) was significantly lower in late-onset patients compared with early-onset patients. In the late-onset group, the frequency of patients having a mutation in the *MEFV* gene (57.1%) and a mutation in exon 10 (12.7%), which induces a severe clinical FMF phenotype, was significantly lower than in early-onset patients. The response to colchicine therapy was good (88.6%) and similar in all groups. Family history of FMF was less frequent in the late-onset group.

**Conclusion:** In Japan, there are a number of FMF patients with late-onset. Our observation indicates that they have a milder form of the disease with less frequent peritonitis and pleuritis and a good response to colchicine treatment. However, careful differential diagnosis

may be needed because they have a lower prevalence of the *MEFV* gene mutation, especially in exon 10.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Degos disease (Malignant Atrophic Papulosis) is a thrombotic microvasculopathy of complement activation, endothelial cell injury and progressive microvascular obliteration. Lesions are marked by vascular C5b-9 deposition and a type 1 interferon rich microenvironment. Systemic disease historically results in death within 2-3 years, most commonly from gastrointestinal perforations and the resulting sepsis or stroke. There have been no effective treatment options. Experience with this combination therapy for systemic Degos disease has resulted in prolonged survival for our patients with improved quality of life.

### Methods :

We performed a retrospective analysis of the clinical outcomes of 4 patients with Degos disease treated with treprostinil and eculizumab.

## Results:

Patients 1 and 2 were critically ill in late 2009 with gastrointestinal complications of systemic Degos disease. Patient 1, a 51 year old man was started on eculizumab in October 2009. Patient 2, a 25 year old man was started on eculizumab in December 2009. Both patients experienced immediate, dramatic response. Because of disease progression despite ongoing therapy with eculizumab, Patient 2 began therapy with treprostinil in December 2010 and Patient 1 in March 2014. Despite lasting disease damage, both Patient 1 and 2 have regained good quality of life, are in stable health and are working full time.

Patient 3, is a 45 year old woman with cutaneous Degos lesions who developed sudden monocular vision loss and severe eye pain requiring enucleation. Pathologic findings of microvascular changes were consistent with systemic Degos disease. Exploratory laparoscopy in October 2012 revealed innumerable Degos lesions. Based on the experience of the first 2 patients, and difficulty obtaining eculizumab, patient 3 began treatment with treprostinil. Due to inadequate disease control, eculizumab was added. Other than loss of vision in the affected eye, patient remains stable on dual therapy, working full time.

Patient 4 is a 56 year old woman who was seen with a 4 year history of biopsy confirmed cutaneous Degos disease and persistent and 1 year of intermittent episodes of intensifying abdominal pain, pericarditis and peripheral neuropathy suggestive of systemic progression. Laparoscopy detected intestinal and hepatic lesions consistent with Degos disease. Eculizumab was initiated in October 2015 and treprostinil in May 2016. Since patient 4 began this treatment regimen her abdominal pain has resolved. Her condition has been quiet and stable without major disease complication in two years of treatment. Her quality of life is good and she is working full time.

## Conclusion:

Systemic Degos disease is extremely rare and our cohort is small (n=4), but these cases provide promising results in terms of patient survival and quality of life. Among our 4 patients, two are approaching the 8-year survival mark. Therapy with eculizumab and treprostinil may be an effective treatment for systemic Degos disease, especially if initiated prior to catastrophic sequelae. Heightened awareness, early assessment for systemic involvement, rapid initiation of treatment and vigilant follow-up have been associated with prolonged survival.

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patients with common variable immunodeficiency (CVID) have a higher incidence of rheumatologic disorders. To delineate this clinical association, we investigated the phenotypical features of patients with CVID affected by these conditions.

## Methods:

We conducted a retrospective analysis of 870 pediatric and adult patients with CVID included in the United States Immunodeficiency Network (USIDNET) registry. Outcomes included clinical characteristics (age, gender, ethnicity, rheumatologic diagnosis, comorbidities) and basic immunophenotype (immunoglobulin levels, T- and B- cell counts) in patients with rheumatologic disorders compared with those with non-inflammatory CVID. Demographic and clinical data were compared using chi-square, Fisher's exact or Wilcoxon-Mann-Whitney tests. For immunological variables, Generalized Estimating Equations (GEE) regression models were built to evaluate the relationship between IgA, IgM, CD19+ B-cell counts and CD4/CD8 ratios and CVID-associated rheumatologic disorders.

## Results:

Physician-reported rheumatic diseases were present in 5.9% of patients with CVID (n=51) included in the registry. Although CVID affects both sexes equally, there were more females (3.3:1 female to male ratio) in the rheumatic disease group ( $p<0.05$ ). Specific disorders included: inflammatory arthritis (n=18), Sjogren's syndrome (n=11), SLE (n=8), Raynaud's syndrome (n=8), medium and small vessel vasculitis (n=8), MCTD (n=3), other (n=5). There were no significant differences in the frequency of other CVID complications such as bronchiectasis between the two groups ( $p>0.05$ ). Additionally, no significant differences in immunoglobulin levels (IgA and IgM), CD19+ B-cells counts or CD4/CD8 ratio were detected.

## Conclusion:

These results highlight the coexistence of primary antibody disorders and systemic autoimmune diseases. Importantly, hypergammaglobulinemic, autoantibody-associated disorders such as Sjogren's syndrome and SLE were among the most common, demonstrating that they can occur even in the setting of a primary antibody deficiency. Basic immunophenotypic parameters demonstrated no significant differences, although characteristics such as specific T- and B-cell subpopulations were not evaluated. Finally, the female predominance in the rheumatic disease group, brings into question whether sex-related factors may play a role in the development of certain CVID manifestations. This study has several limitations, namely the retrospective nature of the analysis, variable amounts of missing data and lack of confirmation of rheumatic diagnosis using current classification data. Nonetheless, these findings should raise awareness for primary antibody immunodeficiencies among patients with rheumatic disorders. Delineating the link between systemic autoimmunity and humoral immunodeficiencies can also provide novel insights into the immune abnormalities underlying these related conditions.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Eosinophilic fasciitis (EF) is a rare disease and there have been few published series that include clinical, pathological and serological data. These studies have provided disparate information on clinical course, with high rates of complete resolution and recurrence reported. Furthermore, no clear direction has emerged on the prognostic significance of features initially reported to be characteristic for EF.

**Methods:** We conducted a retrospective review of all EF patients evaluated at our institution from 1/1/1997 to 12/30/2016. Clinical records were reviewed to confirm the diagnosis of EF. Baseline demographic data, clinical, laboratory features at time of diagnosis and information on clinical course were collected. Kaplan-Meier methods were used to determine response and recurrence rates over time.

**Results:** We identified 83 patients with eosinophilic fasciitis seen within the study period. The median age of diagnosis was 53 years and the female to male ratio was 1:1. Majority of patients (90%) were diagnosed with combination of clinical features and biopsy, 6 (7%) were diagnosed based on clinical presentation alone, and 2 were diagnosed by clinical and imaging (MRI) features. Mean time to diagnosis from symptom onset was 7.9 months (range 1 – 45). Twenty-one patients (25%) reported exercise as a possible trigger. Groove sign was noted in only 24 (29%). Active inflammatory arthritis was noted in 9 patients at the time of initial EF evaluation, and only one of these had a known diagnosis of rheumatoid arthritis. Muscle weakness was described in 8 (10%), and EMG was interpreted as indicative of inflammatory myopathy in 6/17 (35%). The median absolute eosinophil count was  $0.4 \times 10^9/\text{ml}$  and peripheral eosinophilia was noted in 37/74 patients (50%). Elevated erythrocyte sedimentation rate was seen in 16/70 (23%) and elevated CRP in 33/56 (59%). CK was elevated in 2/40 (5%), but aldolase was elevated in 9/33 (27%). High titer ( $\geq 1:320$  or  $\geq 3$  units by ELISA) positive ANA was seen in 5/66 (8%). The median follow up was 2.3 years (range 0.2 – 18.5) among 46 patients with at least one follow up visit. Of those, 35 were initially seen within 1 year of diagnosis, and were included in prognosis analysis. By 3 years, 57% (95% confidence interval [CI] 32 -73%) had achieved a complete response with resolution of skin thickening. The rate of recurrence was 47% (95% CI 20 - 65%) at 3 years.

**Conclusion:** In a cohort of patients with EF defined by clinical diagnosis, rates of classic features in addition to, complete response and recurrence rates, are similar to those in previously published reports. To our knowledge, this is the largest retrospective cohort study of patients with EF.

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

In uveitis, remission-inducing therapy with even more vigor than does rheumatology is mandatory. Since the eye is so much less forgiving of chronic inflammation than is the joint, with profound life-altering consequences. Cystoid macular edema (CME) is the leading cause of blindness in uveitis.

Our aim was to evaluate the rapid efficacy of Tocilizumab (TCZ) in refractory CME.

**Methods:** Multicentre study of 25 patients with CME due to non-infectious uveitis who had inadequate response or intolerance to traditional treatment with corticosteroids and at least one conventional immunosuppressive drug including in most cases biological therapy (n=22). CME was defined by (OCT >300 µm).

The outcome variables were the degree of inflammation of the anterior chamber and vitreous, visual acuity, macular thickness. The results are expressed as mean ±SD for normally distributed variables, or as median [interquartile range] when are not. Comparison of continuous variables was performed using the Wilcoxon test.

**Results:** 25 patients (17 women/8 men), mean age, 33.6±18.9 years were studied. The associated diseases were: juvenile idiopathic arthritis (9), Behçet's disease (7), Birdshot retinochoroidopathy (4), idiopathic (4), sarcoidosis (1). The ocular pattern was: panuveitis (9), anterior uveitis (7), posterior uveitis (5) and intermediate uveitis (4). Most patients had bilateral involvement (24). Prior to biological therapies patients received: intraocular corticosteroids (22), iv. methylprednisolone (7), methotrexate (MTX) (19), cyclosporine A (CSA) (17), mycophenolate (4), azathioprine (2), leflunomide (2), cyclophosphamide (1), sulfasalazine (1), acetazolamide (1) and thalidomide (1). The biological used before the administration of TCZ were infliximab (8), adalimumab (19), etanercept (2), golimumab (2), rituximab (2), abatacept (3), anakinra (1) and daclizumab (1).

TCZ administration schedule was 8 mg/kg/4 weeks iv. (n=23), every 2 weeks (n=1) and subcutaneously 162 mg/2 week (n=1). TCZ was used in monotherapy (13) or combined with conventional immunosuppressive (12). Most of intraocular inflammation parameters showed a rapid improvement after TCZ onset (**TABLE**), with corticosteroid-sparing effect (15.9±13.6 to 8.5±5.17 mg; p=0.001). Remission was achieved in 8 patients and improvement in 17. After a month, no minor side effects were observed, so no patient had to stop treatment. No side effects were observed.

**Conclusion:** TCZ seems a rapid effective treatment in refractory uveitic CME.

**TABLE**

	Baseline	1st week	2nd week	1st month

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The information content of multi-parametric flow cytometry-based immune-phenotyping experiments is routinely underexploited given the paucity of adequate tools and strategies for large-scale unbiased data analysis.

**Methods:** We developed and applied a data analysis approach taking into account all mathematically possible combinations of markers in a given flow cytometry panel. We analyzed mined ([dx.doi.org/10.5061/dryad.v6st3](https://dx.doi.org/10.5061/dryad.v6st3)) flow cytometry data generated from peripheral blood samples of healthy humans and subjects with a uniform ocular patho-phenotype (pan-uveitis) caused by 2 different autoimmune diseases: Behcet's disease and sarcoidosis. Flow data were gated in bivariate plots. We employed combinatory mathematics to generate a matrix quantifying the representation of all possible cell populations using given sets of markers within the respective starting populations and coded the algorithm in Java. Computed metadata were tested against primary data sets of manually gated cell populations with known markers and immunological properties. External variables defined by biological characteristics of the subjects, *i.e.*, 'healthy vs diseased' and 'Behcet's uveitis vs Sarcoid uveitis' were used as independent measures of truth for sample classification.

**Results:** Our method increased the retrievable information content from each panel exponentially in relation to the number of markers used instead of linearly as in conventional approaches. Computed cell populations matched those in primary data sets. The method enabled clustering of healthy vs diseased subjects using only 4 common markers (CD3, C8, CD197, and CD45), and of sarcoid vs Behcet's uveitis subjects with minimal error.

**Conclusion:** Our approach demonstrates that multi-dimensional analysis of flow cytometry data allows meaningful screening of biologically relevant markers enabling classification and characterization of states of health and autoimmune disease. The approach is unbiased and has the potential to facilitate the discovery of cell populations with relevance as potential biomarkers or biological research targets.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess the efficacy of mycophenolate mofetil (MMF) in treatment of adult patients with interstitial pneumonia with autoimmune features (IPAF).

**Methods:** A retrospective medical record review was performed using electronic health record searches for interstitial lung diseases and either autoimmune diseases or positive ANA in the years 2000-2013 at an academic center. Records were then manually reviewed to include all adult subjects who met European Respiratory Society/American Thoracic Society classification criteria for IPAF and to exclude those with other specific connective tissue diseases. Sociodemographic, clinical, and pulmonary function data were manually abstracted for patients with and without MMF treatment and followed longitudinally from the date of IPAF diagnosis. In this analysis, we examined diffusing capacity for carbon monoxide (DLCO) and forced vital capacity (FVC) recorded over 4 years (24 months before or after MMF initiation) to compare rates of change between treated and untreated and within treated patients.

**Results:** We identified 52 subjects who met criteria for IPAF, 63% female, ranging from age 31 to 83 years. Of the 52 subjects with IPAF, 28 were treated with MMF and 24 were not treated with MMF. Median time to MMF initiation among those treated was 22 months. Within the MMF group, 11 and 14 subjects had DLCO and FVC measurements, respectively, before and after MMF initiation. Median time to MMF start among those who were treated was 22 months. The average decline in FVC% and DLCO% between the MMF treated and untreated groups was not significantly different (FVC% change  $p=0.08$ ; DLCO% change  $p=0.17$ ); however, there was a trend to more rapid decline of both FVC% and DLCO% in the MMF-treated group.

Among subjects treated with MMF, the rate of decline of DLCO (mL/min/mmHg) significantly improved after therapy with MMF (Figure 1,  $p=0.007$ ). There was not a significant difference in rate of change of FVC (L) before and after MMF treatment ( $p=0.07$ ) although many stabilized (Figure 2).

DLCO (mL/min/mmHg) before and after MMF

Figure 1. Change in DLCO (mL/min/mmHg) before and after MMF therapy in IPAF subjects

FVC (L) Before and after MMF Initiation

Figure 2. Change in FVC (L) before and after MMF therapy in IPAF subjects

**Conclusion:** MMF therapy stabilized the decline of DLCO and was associated with a trend toward stabilization of FVC in treated IPAF patients. These findings suggest that MMF may slow the progression of PFT changes in IPAF. Further studies are needed to confirm these findings.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The term interstitial pneumonia with autoimmune features (IPAF) has recently been proposed to identify those patients with ILD and clinical and/or serological autoimmune manifestations who do not meet diagnostic criteria for a specific CTD (UCTD-ILD). Our aim was to re-classify our patients with ILD and features of CTD according to the 2015 European Respiratory Society/American Thoracic Society research statement proposed criteria for IPAF and examine their applicability in clinical practice. We also evaluate other clinical tools which might improve their specificity.

**Methods:** Retrospective review of medical records of 100 patients with ILD attending the multidisciplinary Pulmonary and Rheumatology clinic at our centre between 2011 and 2016. Fulfilment of the proposed IPAF criteria was assessed in all patients who did not meet current criteria for a definite CTD. Additional autoimmune/inflammatory data not included in the IPAF domains, as well as nailfold capillaroscopy findings (available in 47 patients), were also recorded. Analysis was carried out with non-parametric tests and significance laid at 95%.

**Results:** We identified 62 CTD-ILD, 26 IPAF and 12 non-IPAF patients, with 71% women. Therefore, 68% (26/38) of patients previously regarded as UCTD-ILD were captured by the IPAF criteria. Age at onset was higher in patients from the non-IPAF group ( $p < 0.01$ ). Definite or possible Usual Interstitial Pneumonia (UIP) and Non-Specific Interstitial Pneumonia (NSIP) were found in 41% and 40% of patients, respectively. A non-UIP morphologic pattern predominated in CTD-ILD patients (58%), while NSIP was more frequent than UIP in IPAF (46% versus 27%) and UIP predominated in non-IPAF (67%). Pulmonary hypertension and vasculopathy were associated to UIP ( $p < 0.05$ ). Coexistent hypersensitive pneumonitis was marginally more frequent in IPAF and non-IPAF than in CTD-ILD. There was a 72% of ANA+ and 37% RF+ patients with no differences among groups. In contrast, ACPA and dsDNA were found in 0 but only in 1 non-IPAF case. Interestingly, two patients with antisynthetase antibodies fulfilled both the preliminary criteria for antisynthetase syndrome and for IPAF. As regards items included in the IPAF clinical domain, RP was present in 27% (6/22) of IPAF patients and only in 1 non-IPAF. No differences were found for arthritis or RP between IPAF and non-IPAF. Capillaroscopy changes were found in 67% (8/12) and 50% (6/12) of non-IPAF and IPAF patients, respectively. Haemolytic anemia, high CRP and LDH, hyperferritinemia and hypertriglyceridemia were associated to a fatal outcome ( $p < 0.05$ ), with no differences between groups.

**Conclusion:** We found few phenotype differences between patients re-classified as IPAF and those with non-IPAF according to the new criteria. This indicates that the proposed IPAF criteria might not be able to capture all patients with inflammatory and/or isolated features of CTD. In addition, only some of the proposed items for IPAF were prevalent in patients with UCTD-ILD, being the presence of RP a dominant one. The use of capillaroscopy could therefore help characterize a set of patients with UCTD-ILD. Prospective and larger cohorts are needed to confirm these findings.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Immune checkpoint therapy with programmed cell death protein 1 (PD-1) inhibitors has led to significant survival benefits in the treatment of multiple cancers. This strategy interrupts inhibitory signals within the immune system, but this may additionally cause immune-related adverse events (irAEs) that resemble a spectrum of well-recognised autoimmune conditions. Detailed study of these may also further the understanding of the development of spontaneous autoimmune disease. At present, characterisation of rheumatic irAEs is limited as reports from clinical trials have inadequate detail for this purpose and the current literature largely consists of case series. Few reports describe in detail all rheumatic irAEs in a whole cohort of patients receiving PD-1 inhibitors, which would enable determination of frequency and context to this emerging entity. To the best of our knowledge, we describe the largest such series to date.

**Methods:** A retrospective chart review was performed on all patients dispensed nivolumab or pembrolizumab in 2016 at our center. Patients diagnosed with a non-cutaneous irAE were identified as were patients with undiagnosed symptoms possibly consistent with a rheumatic irAE. Information recorded included details regarding the malignancy and its therapy, the nature of the irAE and its treatment and outcomes.

**Results:** Of the 149 patients, 54 (36.2%) had at least one non-cutaneous irAE. Thyroid irAEs were the most common, occurring in 22 patients (14.8%) followed by rheumatic irAEs, which were diagnosed in 18 patients (12.1%). Of these, 11 were de novo diagnoses and 7 were exacerbations of existing autoimmune disease. A further 4 had symptoms possibly consistent with a rheumatic irAE but without a diagnosis from the treating physician. Inflammatory arthritis was the most common rheumatic irAE, with a diagnosis in 15 patients. The median time to developing a rheumatic irAE was 5 months (range 1-28). Rheumatic irAEs were more common in patients with an oncological response to therapy (RR 10.0,  $p < 0.01$ ) and receiving combination therapy with ipilimumab (RR 3.5,  $p = 0.016$ ). Most patients were treated with corticosteroids and only 4 patients required introduction of DMARDs. Confirmation by a rheumatologist only occurred in 10 patients but supportive findings on imaging were available in 13 patients, including 8 patients not reviewed by a rheumatologist.

**Conclusion:** Rheumatic irAEs are a relatively common consequence of PD-1 inhibitor therapy, and frequently require the use of corticosteroids. They would benefit from systematic investigation to explore, amongst other characteristics, the apparent association with oncological response to therapy. Our findings also suggest that many rheumatic irAEs are not routinely referred to rheumatological services. While imaging may be able to assist with retrospective identification, if insights are to be made regarding the pathogenesis of the spontaneous diseases from irAEs, consistent rheumatological assessment will be required. A reliance on conventional mechanisms may be insufficient for this purpose and electronic biosurveillance may be necessary.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Colchicine is the main therapy for familial Mediterranean fever (FMF); however, around 5-10% of FMF patients are colchicine-resistant. Currently there is no standard and validated definition for colchicine resistance. We aimed to compare the existing definitions for colchicine resistance in both adult and pediatric FMF patients to find out the best definition to determine the colchicine-resistant patients.

**Methods:** 385 FMF patients were evaluated and patients receiving anti-interleukin-1 (IL-1) treatment were included. Nine different definitions (found out after PubMed search for colchicine resistance in FMF) (Table 1) were applied to all patients. **Results** were re-analyzed after excluding the patients with no clinical attacks but had persistently high acute phase reactants (APRs) and/or amyloidosis.

**Results:** Among 385 FMF patients 60 (40 (66.7%) adults, 20 (33.3%) children) were colchicine-resistant. The highest percentage of FMF patients fulfilled the definition 5 (93.3%), while definition 9 had the poorest performance (28%) (Table 2). Significantly higher percentage of adult patients were meeting definitions 4 and 6 than pediatric patients (87.5% vs 50%,  $p=0.002$ ; 75% vs 40%,  $p=0.008$ ; respectively) (Table 2). After excluding patients without clinical attacks, the highest percentage of patients fulfilled definition 2 (94.4%). We combined the attack frequency definition ( $> 1$  typical episode per 3 months) of definition 2 and presence of amyloidosis /APR definition (increase in at least two out of three acute phase reactants (C-Reactive Protein, Erythrocyte sedimentation rate, and serum amyloid A) of definition 5 to create a new definition. The new criteria set were met by 59 (98.3%) colchicine-resistant FMF patients.

**Conclusion:** Definition of colchicine resistance is still controversial. Definitions of colchicine-resistant patients with both clinical and laboratory criteria were met by a higher percentage of patients than without laboratory criteria. However, the proper definitions for the attack-free period and persistence of APRs are still lacking.

**Table 1.** The definitions for colchicine resistance in familial Mediterranean fever (FMF) in the literature

<b>Definition 1</b>	i) Despite taking 2 mg/day of colchicine, at least 1 episode per month
<b>Definition 2</b>	i) Despite taking 2 mg/day colchicine, more than 1 typical episode per 3 months
<b>Definition 3</b>	i) Despite receiving 2 mg/day colchicine, 3 or more attacks have been reported in the last 6 months
<b>Definition 4</b>	i) Despite the fact that adequate doses of colchicine are taken in children and increased doses of 2 mg/day in adults, at least one episode per month during the following 3 months and increased ESR or increased CRP or increased SAA  ii) Presence of amyloidosis  iii) Protracted febrile myalgia that needs steroid treatment  iiii) Presence of persistent arthritis
<b>Definition 5</b>	i) More than 3 episodes in 4-6 months, or more than 6 typical episodes per year, despite adequate doses of colchicine  ii) An increase in at least two out of three acute phase reactants (CRP, ESR, and SAA) between attacks
<b>Definition 6</b>	i) 1 or more episodes per month despite the use of colchicine at the maximum dose of at least 6 months  ii) and/or presence of amyloidosis
<b>Definition 7</b>	i) At least 1 episode per month despite taking 2 mg/day colchicine  ii) Persistently elevated AFR  iii) Organ involvement (especially renal)  iiii) Losing job or not continuing to school
<b>Definition 8</b>	i) Despite taking 2 mg/day of colchicine (or the maximum dose that can be tolerated), at least 1 episode per month  ii) Symptoms continue despite 2 mg/day colchicine intake (or maximum tolerable dose)  iii) SAA, ESR and CRP elevation 1.5 times higher than the normal limit between attacks
<b>Definition 9</b>	i) Despite 2 mg of colchicine, at least 2 episodes per month and elevation of CRP and/or SAA between attacks

*AFR, acute phase reactants; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; FMF, familial Mediterranean fever; SAA, serum amyloid A*

**Table 2.** Number of familial Mediterranean fever (FMF) patients defined as colchicine resistant according to different definitions

Definitions	All patients (n=60)	Adult patients (n=40)	Pediatric patients (n=20)	P value
Definition 1, n (%)	29 (48.3)	21 (52.5)	8 (40)	0.36
Definition 2, n (%)	51 (85)	33 (82.5)	18 (90)	0.44
Definition 3, n (%)	50 (83.3)	32 (80)	18 (90)	0.32

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Rituximab for Idiopathic and IgG4-Related Retroperitoneal Fibrosis

**Background/Purpose:** Untreated retroperitoneal fibrosis (RPF) can lead to chronic back and flank pain and/or renal failure. The mainstay of treatment for non-malignant (IgG4-related disease [RD] or idiopathic) RPF is glucocorticoid (GC) therapy which often has insufficient efficacy or is complicated by toxicity. We performed a retrospective review of patients with RPF treated with rituximab (RTX).

**Methods:** We reviewed the database of the Massachusetts General Hospital's Center for IgG4-RD and identified all patients with RPF treated with RTX who had follow-up (2010-2016). RPF was diagnosed by CT or MRI following commonly accepted radiographic criteria (*Lancet* 2011;378:338). Demographics, date of diagnosis, symptoms, co-morbidities, laboratory values, use of stents or percutaneous nephrostomy (PCN) tubes, biopsy results, and symptomatic response to treatment were collected from the database. A

board-certified radiologist (AS) reviewed baseline and follow-up imaging. Response to treatment was defined as symptom improvement and/or radiographic improvement defined as reduction in lesion size in at least two radiographic planes (*Lancet* 2011;378:338).

**Results:** Twenty-six RPF patients received RTX (**Table 1**). The median age was 55 years (IQR 43, 58) and a majority was male (85%) and former or current smokers (85%). Pathology was available in 20 (77%) patients. In 17/20 (85%) patients, diagnostic features of IgG4-RD were present; in the remaining 3/20 (15%), malignancy and infection were ruled out. Of the six patients not biopsied, 2 (33%) met clinical diagnostic criteria for IgG4-RD and four had typical radiographic idiopathic RPF with no clinical suspicion of infection or malignancy. Ten of 26 (39%) patients had previously failed GC therapy. RTX was used as monotherapy in 20 (77%) patients and in combination with GC in 6 patients (23%); ten (39%) patients required ureteral stents or PCN tubes. Of the 21 patients with baseline symptoms (e.g., pain), all (100%) had improvement. Twenty-two (88%) of the 25 patients with follow-up imaging had radiographic improvement; in the remaining 3 patients, the RPF remained stable. Of the 10 patients with a stent or PCN, 4 (40%) had it successfully removed. Four of the six patients whose stents or PCN were not removed had disease duration for greater than 1 year prior to RTX.

**Conclusion:** In this retrospective study of patients with idiopathic or IgG4-related RPF, peripheral B cell depletion with RTX was highly effective, used as monotherapy in the majority of patients. A striking proportion (85%) of patients were current or former smokers. Future research could explore whether patients with disease for greater than 1 year prior to RTX respond less well.

<b>Table 1: Baseline Demographics and Features with Treatment Response</b>	
Sample Size	26
Age at Diagnosis (Median, IQR)	55 (43, 58)
Male (%)	22 (85%)

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Polymyalgia rheumatica (PMR) is a common condition of unknown etiology with a lifetime risk of 2.43% in women and 1.66% in men.<sup>1</sup> PMR is characterized by pain and stiffness in the neck, shoulders and/or pelvic girdle, and is more severe in the morning with a duration >1 hour in most patients. It is generally agreed that the absence of a prompt response to a moderate glucocorticoid (GC) dose (15 mg prednisone daily) indicates a diagnosis other than PMR.<sup>2</sup> This higher dose of a GC is associated with more adverse drug effects than lower doses.<sup>3</sup> Blood concentrations of interleukin (IL) -6 increase during the night and peak in the early morning hours in parallel with PMR patients' pain and stiffness.<sup>4</sup> A timed (delayed) release prednisone preparation (DR GC) was developed to target treatment to the nighttime increase in IL-6.<sup>5</sup> It has been shown that this formulation provides better control of rheumatoid arthritis symptoms than the same dose of conventional immediate release prednisone (IR GC) taken in the morning and possibly permit a lower initial dose.<sup>6</sup>

**Methods:** In this preliminary 4-week, randomized, controlled, open-label two period trial, conducted in collaboration with OMERACT, patients with PMR responsive to GC received one of 3 nighttime doses of DR GC (4 mg, 7 mg or 10 mg) for 2 weeks followed by treatment with 15 mg IR GC in the morning for 2 weeks. The primary outcome was the change from baseline in the severity of morning stiffness (measured on a 10-point visual analog scale [VAS]) with DR GC vs that with IR GC with each patient as their own control. Pain was also evaluated using a 10-point VAS.

### Results:

A total of 8 patients were enrolled (n=3 for 4 mg DR GC, 1 for 7 mg DR GC, 4 for 10 mg DR GC) and all completed the trial. The mean baseline value for morning stiffness was 5.2, and changes from baseline with 4, 7 and 10 mg DR GC were -4.5, -1.0, and -3.1, respectively. Those for 15 mg IR GC in the patients who received 4, 7, or 10 mg DR GC during the first treatment period were -4.2, -2.5, and -3.9. The mean baseline pain score was 5.2 and the reductions from baseline with 4, 7, and 10 mg DR GC were -4.4, -0.8, and -2.7, respectively. Those for 15 mg IR GC in the patients who received 4, 7, or 10 mg DR GC during the first treatment period were -4.3, -2.0, and -3.6. Two patients treated with 10 mg DR GC experienced mild adverse events (1 mild skin tear and 1 decrease in vitamin D). No adverse events were reported during treatment with 15 mg IR GC.

**Conclusion:** Results of this small-scale study indicated that a low-dose DR GC has effects on PMR-associated pain and stiffness similar to those of 15 mg IR GC. The efficacy of low-dose DR GC may improve the long-term safety of PMR treatment. These data warrant consideration for initiation of a larger study evaluating the efficacy and safety of DR GC in this patient population.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Relapsing polychondritis (RP) is a rare multiorgan disease. Involvement of the upper and lower airways is associated with significant morbidity and mortality. Isolated airway involvement can be seen in patients with RP. The objective of this study is to determine the prevalence of airway inflammation and damage in patients with RP who endorse clinical symptoms suggestive of airway disease.

### **Methods:**

Patients described in this cohort were selected from a prospective natural history protocol. All patients met McAdams or Damiani's diagnosis criteria for relapsing polychondritis. Patients were selected if they reported voice changes, choking sensation, shortness of breath or cough. All patients underwent laryngoscopy and dynamic 4D cine computed tomography (CT) scanning of the trachea and central airway obtained during forced exhalation.

### **Results:**

A total of 31 patients have been evaluated in our prospective cohort, 4 adult patients were excluded because of a different CT scan technique was used, 12 patients were younger than 18 years old and one patient did not meet criteria for RP diagnosis. The 14 remaining patients were included in this report. Patient demographic information includes: average age 46.7 years (SD 7.5), 93% female, 86% white. All the patients reported voice changes, dry cough and shortness of breath, and all but one patient reported choking sensation. On laryngoscopy, 86% of the patients had arytenoid swelling (Image 1), 50% of the patients had nasal ulcers, one patient had septal perforation, and no patient had a saddle nose deformity. On dynamic 4D cine CT scans of the airways, 36% of the patients had tracheomalacia, 14% had tracheal calcifications, 14% of the patients had tracheal wall thickening, 14% had bronchomalacia, 21% had bronchial wall thickening, none of the patients had bronchial calcifications, 21% had alveolar opacities and 28 % had air trapping. The percentage of tracheal collapse (Image 2) ranged from 40-87%.

### **Conclusion:**

Airway symptoms such as voice changes, cough, choking sensation and shortness of breath in patients with relapsing polychondritis should be further investigated with laryngoscopy and dynamic 4D cine CT imaging of the airways to assess for airway inflammation and damage. Arytenoid swelling is a common finding in RP and may be indicative of active disease.

## Sympathetic Joint Effusion in an Urban Hospital

Jessica L. Barlow<sup>1</sup> and Irene J. Tan<sup>2,3</sup>, <sup>1</sup>Internal Medicine, Temple University Hospital, Philadelphia, PA, <sup>2</sup>Temple University Hospital, Philadelphia, PA, <sup>3</sup>Section of Rheumatology, Temple University Lewis Katz School of Medicine, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Sympathetic joint effusion (SJE) or sympathetic synovial effusion (SSE) is a rheumatologic entity that has not been well defined in the medical literature. It is a non-inflammatory synovial fluid collection that is associated with infection or inflammation of an adjacent anatomic structure. The epidemiology and clinical characteristics of SJE/SSE are largely unknown. This knowledge gap has led to a lack of recognition and misdiagnosis by clinicians. Our study aimed to determine incidence, demographic information, and describe the clinical characteristics and potential triggering conditions for this presumptive reactive phenomenon.

### Methods:

We conducted a study of patients >18 years of age hospitalized at Temple University Hospital (TUH) between January 31, 2010 and December 10, 2016 who underwent diagnostic arthrocentesis for painful effusions. Individuals with synovial fluid white blood cell count (WBC) in the normal range of 200 WBC/mm<sup>3</sup> or less were included. Patients with non-inflammatory range synovial fluid of 200-2,000 WBC/mm<sup>3</sup> were excluded to limit confounders. Demographic and clinical data of 72 patients were included for detailed analysis.

## Results:

SJE/SSE was seen in 80/882 hospitalized patients (incidence of 9%). Seventy-two patients fulfilled inclusion criteria for detailed chart review. Demographic information revealed: male 46/72 (64%), female 26/72 (36%), African-American 38/72 (53%), Caucasian 16/72 (22%), Hispanic 10/72 (14%), undefined and other 8/72 (11%). Onset was typically acute, with 45/72 (63%) of patients developing symptoms within six days of arthrocentesis. All patients (100%) with SJE/SSE presented with painful effusion, and a minority had physical findings of warmth 23/72 (32%) or erythema 12/72 (17%). Interestingly, nearly a third of patients 21/72 (29%) were misdiagnosed with crystal or septic arthritis based solely on clinical exam, and empiric treatment was often administered prior to arthrocentesis. The most commonly affected joint was the knee 61/72 (85%), followed by the elbow 5/72 (7%), shoulder 3/72 (4%) and hip 3/72 (4%). Identifiable pathology in the affected limb was found in 29/72 (40%) of patients. Infection was the most common etiology, found in 17/29 (59%) of patients, and included cellulitis, abscess, osteomyelitis, septic bursitis, myositis, and necrotizing fasciitis. The majority of cases of SJE/SSE 23/29 (79%) were associated with concomitant infection, DVT or intramuscular hematoma in the affected limb which required specific therapeutic interventions.

## Conclusion:

Sympathetic joint effusion or sympathetic synovial effusion (SJE/SSE) is relatively common in hospitalized patients. SJE/SSE may be a sentinel sign for a more serious disorder affecting the same limb. Clinicians should maintain a heightened index of suspicion for SJE/SSE. A search for underlying infection, venous thrombosis, and intramuscular hematoma in the affected limb is warranted when encountering acute painful joint effusion with normal range synovial fluid WBC count.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Some of clinical features of the plasma cell type of human herpesvirus-8-negative multicentric Castleman's disease (idiopathic MCD or iMCD) are similar to those of IgG4-related disease (IgG4-RD). These conditions are associated with lymphadenopathy (LAD), a polyclonal hypergammaglobulinemia, as well as constitutional symptoms (e.g., weight loss, fatigue). The histologic features of iMCD LAD overlap with those of IgG4-related LAD. This has led to suspicion that iMCD is either overdiagnosed in some institutions or underdiagnosed in others, or that variation in disease expression across countries may alter clinical disease phenotypes. Levels of acute phase reactants, particularly the C-reactive protein (CRP), have been proposed as useful in discriminating iMCD from IgG4-RD.

**Methods:** American and Japanese clinicians and pathologists exchanged pathology slides of 60 cases (30 cases from the US, 30 from Japan) accompanied by clinical vignettes. Japanese investigators submitted 15 cases in which they suspected a diagnosis of iMCD and 15 cases they felt were typical IgG4-RD. Cases considered iMCD had at least focal extranodal manifestations. US investigators submitted 12 cases considered to represent IgG4-RD with an elevated CRP and 18 IgG4-RD cases with normal CRP. All investigators were blinded to CRP and IL-6 concentrations as well as treatment responses. The US investigators were blinded to the designated diagnoses of the Japanese cases. The diagnosis of iMCD was evaluated based on expert pathology opinion as well as recently published diagnostic criteria (Fajgenbaum, *Blood* 2017).

**Results:** Of the 15 suspected iMCD cases from Japan, 14 had mixed nodal and extranodal manifestations and 1 had pure extranodal abnormalities. All but one had elevated serum IgG4 concentrations. Twelve (80%) had extensive extranodal polyclonal plasma cell infiltrates with increased IgG4-positive plasma cells affecting the kidneys, lungs, and skin that were similar to the lymph node appearance. Nine (60%) fulfilled iMCD diagnostic criteria. When reviewed by expert American pathologists, however, the histopathology of all suspected iMCD cases were considered to be a nonspecific, reactive process characterized by a nonspecific plasmacytic infiltrate without regressed follicles. No association was observed between CRP elevations in the US IgG4-RD cases and whether or not the Japanese investigators considered the case to be IgG4-RD ( $P=0.5$ ). None of the US IgG4-RD cases were considered iMCD by the Japanese investigators.

**Conclusion:** A condition characterized by multifocal LAD with polyclonal IgG4+ plasma cell infiltrates, extranodal lesions of similar histologic appearance, and elevated inflammatory markers mimics IgG4-RD and iMCD but is often not clearly classifiable as either condition even with iMCD diagnostic criteria. Although these and similar cases are commonly reported as iMCD, future studies using alternative but common nosology are critical to better characterize them. Furthermore, the diagnosis of IgG4-RD was agreed on regardless of the CRP concentration, suggesting that CRP can be elevated in otherwise typical IgG4-RD and that CRP is not a useful measure to distinguish iMCD and IgG4-RD.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Only a few reports have focused on the rate of renal function deterioration in IgG4-related tubulointerstitial nephritis (IgG4-TIN). Some cases show acute or progressive chronic renal failure, and others progression of renal failure slowly over one year or more. This study aimed to investigate the rate of renal function deterioration in patients with biopsy proven IgG4-TIN, leading to clarification of the divergence of the deterioration rate of renal function, identifying the factors affecting the deterioration rate, and confirming the influence of the deterioration rate on the final renal function of each case.

**Methods:** We extracted 18 patients with IgG4-TIN between July 2006 and March 2017 in four hospitals. Based on the rate of renal function deterioration using estimated glomerular filtration rate (eGFR) before starting corticosteroid therapy, we divided them into a rapidly deteriorating group (deterioration rate more than or equal to 4 ml/min/1.73m<sup>2</sup>/month) (n=8) and a slowly deteriorating group

(deterioration rate less than 4 ml/min/1.73m<sup>2</sup>/month) (n=10), and retrospectively analyzed various clinical features (age, sex, serum IgG levels, serum IgG4 levels, serum IgE levels, serum complement levels, serum eGFR levels at start of corticosteroid and the last visit, initial dose of prednisolone, multiple organ lesions) during the clinical course in the two groups.

**Results:** The mean age of the 18 patients was 69 years (range: 43 to 81 years). 89% of the patients were male. The average number of affected organs was 4 (range: 1 to 9). All patients had elevated serum IgG4 levels, and average was 977 mg/dL (range: 207 to 2800). In all patients, the diagnosis of IgG4-TIN was made by histopathological confirmation of the kidney biopsy specimen with immunostaining. The mean kidney function decline rate per month before starting corticosteroid therapy was 4.4 ml/min/1.73m<sup>2</sup>/month. In seven cases, the deterioration rate of kidney function was less than 2 ml/min/1.73m<sup>2</sup>/month, while 10 cases had a rapid deterioration rate more than 4 ml/min/1.73m<sup>2</sup>/month. Corticosteroid was effective in all cases, and average recovery of eGFR after corticosteroid therapy was 17.4 ml/min/1.73m<sup>2</sup> (range: -0.4 to 46.5). In group A (a slowly deteriorating group), the recovery of eGFR was less than that in group B (a rapidly deteriorating group) (6.4 ml/min/1.73m<sup>2</sup> vs. 26.3 ml/min/1.73m<sup>2</sup>, P < 0.05). Hypocomplementemia was more frequent in patients in group A than those in group B (P < 0.05). No differences were noted regarding gender, age, eGFR before starting corticosteroid therapy, eGFR at the last visit, the number of affected organs, eosinophil count, serum IgG levels, IgG4, or IgE between the groups.

**Conclusion:** Regarding the deterioration rate of renal function before corticosteroid therapy in patients with IgG4-TIN, there are two groups, i.e. a rapidly deteriorating group and slowly deteriorating group. Hypocomplementemia is associated with the rapid deterioration of renal function, and a slowly deteriorating group shows lower recovery of renal function after the corticosteroid therapy.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Measuring severity of interstitial lung disease (ILD) usually depends on the extent or pattern of imaging findings on computed tomography (CT) and the parameters of pulmonary function test. Krebs von den Lungen 6 (KL-6) is a sialylated glycoprotein mainly expressed on the surface membrane of type II pneumocytes and bronchiolar epithelial cells (1). Serum level of KL-6 had been reported to be associated with presence or outcome of ILD associated with connective tissue diseases (CTD-ILD) (2-4). We aimed to evaluate KL-6 as a potential biomarker reflecting severity of CTD-ILD.

**Methods:** Study population was a retrospective cohort of 464 Korean patients with rheumatoid arthritis (RA), systemic sclerosis (SSc), inflammatory myositis (IM), Sjogren's syndrome (SS), and systemic lupus erythematosus (SLE) who had concurrent ILD or not. Serum concentration of KL-6 (U/mL) was measured by Nanopia KL-6 assay (SEKISUI MEDICAL, Tokyo), using latex enhanced immunoturbidimetric assay method. Temporally nearest CT and PFT results were collected within 2 years from each serum sampling. Semi-quantitative grade of ILD extent (grade 1: 0-25%, grade 2: 26-50%, grade 3: 51-75%, grade 4: 76-100%) was evaluated by CT scan. Student t-test and Pearson's coefficient (PC) were applied to evaluate the correlation of KL-6 level and severity of ILD.

**Results:** The patients with CTD-ILD (n=162) had elevated serum level of KL-6 compared to CTD without ILD (n=302) (mean $\pm$ SEM, 737.9 $\pm$ 457.5 vs 238.2 $\pm$ 10.1 U/mL, p<0.001) (Fig 1). In subgroup analysis, RA (544.6 $\pm$ 100.3 vs 241.7 $\pm$ 19.6, p<0.001), SSc (766.4 $\pm$ 103.7 vs 224.0 $\pm$ 26.3, p=0.002), IM (808.1 $\pm$ 99.8 vs 291.4 $\pm$ 33.1, p<0.001), and SS or SLE (914.1 $\pm$ 227.1 vs 215.0 $\pm$ 10.25, p<0.001) also had significant difference according to the presence of ILD. Semi-quantitative grade of ILD in CT scan was significantly proportional to KL-6 level except for grade 1 and 2 (Fig 2). Percent diffusion capacity for carbon monoxide (DLCO%) and forced vital capacity (FVC%) had negative correlation with KL-6 level (PC=-0.587, p<0.001; PC=-0.399, p<0.001, respectively).

**Conclusion:** Serum levels of KL-6 were increased in CTD-ILD and had good correlation with CT grade, FVC, and DLCO. Higher serum level of KL-6 may reflect severity of CTD-ILD.

**Figure 1.** Comparison of serum levels of KL-6 in different types of connective tissue disease with or without ILD.

**Figure 2.** Association of serum level of KL-6 with semi-quantitative grade of chest CT.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoantibodies (AAB) targeting self-antigens can be found in two clinically and immunologically opposing diseases, autoimmune diseases and cancer. While in autoimmune diseases, the immune system is hyperactivated against self-antigens, many tumors suppress the anti-tumor immune response. The therapeutic cancer vaccines PSA-Tricom (Prostvac) is designed to generate an antigen-specific tumor response in metastatic castration-resistant prostate cancer (mCRPC), which is in phase 3 testing. To further augment the immune response, combination therapies of Prostvac with ipilimumab are currently tested in clinical studies. Ipilimumab is an antibody that blocks the immune checkpoint molecule cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4). However, treatment with ipilimumab is associated with immune-related adverse events (irAEs) (1). Since there are no biomarkers for predicting irAEs, we investigated AAB profiles as biomarkers associated with irAE in mCRPC patients treated with prostvac and ipilimumab combination therapy.

**Methods:** Serum samples from 24 mCRPC patients treated with prostvac and ipilimumab therapy were tested for the presence of serum autoantibodies against 842 preselected antigens. Candidate antigens comprise immune-related and cancer signaling pathway proteins, autoimmune disease antigens, and tumor-associated antigens (TAA). Samples were collected prior to treatment (T0 samples), at 3 and 6 month. IrAEs included rash, elevated aminotransferases, neutropenia, diarrhea, colitis and endocrine irAEs. Overall survival was also captured and correlated with AABs. Autoantibody levels were measured by Luminex FlexMap3D bead based multiplex protein arrays (2) and data were analyzed by significance analysis of microarrays (SAM), Partial least squares regression (PLS) and Pearson's correlation.

**Results:** In total, 87 AABs were found that were significantly different in patients with irAEs and those without irAEs (SAM  $|d| > 2.5$ ; Pearson's correlation  $|r| > 0.35$ ). PLS analysis revealed that AABs associated with irAEs were also associated with overall survival. Gene ontology analysis of pathways, molecular function and cellular localization revealed that AABs predicting irAEs target cancer, cell cycle, cell adhesion and apoptotic pathways. We also found elevated levels of AABs in patients who do not experience irAEs. Interestingly, these 40 AABs target proteins that are involved in inflammatory, adaptive and cellular immune response pathways or are autoimmune disease antigens.

**Conclusion:** AABs that target antigens involved in cancer signaling pathways are associated with irAEs following prostvac plus checkpoint inhibitor combination therapy. In contrast, AABs targeting immune response pathways were found in patients who do not develop irAEs and may counteract the action of inflammatory molecules. Similarly, anti-cytokine AABs have been found in autoimmune diseases, where they appear to counteract the pathological effects of cytokines (3). Further studies in larger sample sets are needed to confirm these findings.

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Studies on bone involvement of sarcoidosis (BS) are scarce. To analyze in depth main features, treatments and follow up of patients presenting a BS.

**Methods:** Among 926 patients with a proved sarcoidosis from four tertiary hospitals in Paris (France) seen between 2000 and 2015, all cases of BS were retrospectively analyzed for demography, clinical features, biological tests and imaging results. Inclusion criteria were a) a bone biopsy with epithelioid granuloma and no casein necrosis, or b) radiological evidence of BS, after exclusion of other diagnoses.

**Results:** 27 out 926 (2.9%) sarcoidosis patients fulfilled inclusion criteria for BS. Most patients were caucasian (56%), M/F sex ratio 1.5, 30% were active smokers, mean age at sarcoidosis diagnosis was 39±12 yrs and at BS diagnosis 43±11 yrs. Extra-osseous involvement of sarcoidosis was found in lymph nodes (93%), lungs (78%), skin (52%), CNS (33%), ENT (33%), and heart (19%). BS was symptomatic in 15/26 (56%) patients i.e. bone pain (15/15), local inflammation (5/15), bone deformation (3/15), arthritis (4/15), and myalgia (5/15). BS was never the revealing symptom of sarcoidosis. BS was more frequently symptomatic when it was a Perthes-Jüngling osteitis and an appendicular skeleton involvement.

On imaging exams, BS lesions were found at the spine skeleton alone (14/27, 52%), appendicular skeleton alone (10/27, 37%) or both (3/27, 11%). BS lesions had an aspect of pseudo-metastasis (59%), micro-cysts (Perthes-Jungling, 37%) or Paget disease (4%). Bone lesion was unique in 22% and 26% of patients had more than 10 lesions. When a bone biopsy was done it always confirmed the diagnosis (n=9) ; in all other cases extra-osseous biopsies confirmed the diagnosis of sarcoidosis.

Nine patients received a treatment for BS, i.e. prednisone (n=8, 0.25-1 mg/kg/day), hydroxychloroquine (n=8), and methotrexate (n=5). Response to treatment was complete (n=3), partial (n=4) or nul (n=2). Of note, 21 out of 27 patients received an immunosuppressant for a severe form of systemic sarcoidosis (n=11) or for a steroid-sparing effect (n=10). A relapse of BS was noted in 13 patients, with a mean number of relapse of 2 (1-24). After a mean follow up of 49 months, BS was in complete remission (8/27, 30%), partial remission (16/27, 59%) or remained active (3/27, 11%).

**Conclusion:** Bone involvement remains a rare manifestation of sarcoidosis. It was symptomatic in 56% of patients, mainly when Perthes-Jüngling osteitis and appendicular skeleton involvement were present. Extra-osseous involvement of sarcoidosis were always present at the time of BS diagnosis. Treatment remains difficult with frequent relapses.

## Response to Methotrexate and Glucocorticoid Injection in New Onset Arthritis after Checkpoint Inhibitor Therapy

Lisa Christ<sup>1</sup>, Jan Leipe<sup>1</sup>, Ilana Goldscheider<sup>2</sup>, Markus Heppt<sup>2</sup>, Carola Berking<sup>2</sup>, Frank Berger<sup>3</sup>, Claudia Dechant<sup>1</sup>, Alla Skapenko<sup>1</sup> and Hendrik Schulze-Koops<sup>1</sup>, <sup>1</sup>Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, University of Munich, Munich, Germany, <sup>2</sup>Department of Dermatology and Allergology, University of Munich, Munich, Germany, <sup>3</sup>Department of Radiology, University of Munich, Munich, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster I

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The recent introduction of biologic agents targeting immunologic checkpoints (immunologic checkpoint inhibitors, ICI) established immunotherapy as a highly effective cancer therapy. ICI that trigger an anti-tumor response by activation of T cells, may also cause immune-related adverse events (irAEs). Characterization of rheumatic adverse events such as arthritis and data on treatment of irAEs are scarce. The aim of this study is to characterize patients with new-onset arthritis under ICI therapy and to assess the efficacy and safety of treatment that aimed to balance anti-tumor and anti-inflammatory therapy.

**Methods:** In this prospective observational study, patients with melanoma or NSCLC receiving ICI therapy who experienced arthralgias were evaluated for the presence of musculoskeletal inflammation. Data on demographics, ICI regime, time of onset and response to therapy of musculoskeletal irAEs, imaging, joint count, CRP/ESR, and immune serology were collected. Further, clinical response to antiinflammatory therapies including NSAR, glucocorticoids (GC) and methotrexate was assessed before and after an antiinflammatory treatment with VAS GH by patients and two expert rheumatologists aware of all clinical data but blinded for treatment, patient identity and study purpose.

**Results:** Of 10 patients with arthralgias after initiation of ICI therapy, arthritis was demonstrated in 9 patients: 4 monoarthritis, 3 oligoarthritis (SpA pattern), 2 polyarthritis (RA pattern). PMR-like disease with typical ultrasound findings was evident in 1 case and in 3 cases concurrent with arthritis. Upon first visit in our clinic, CRP levels were elevated in 7 of the patients (5.5 to 107 mg/l) while immune serology was positive only in two patients.

The mean baseline VAS GH patient was  $7.4 \pm 0.9$  and was significantly reduced after a median of 24 weeks of antiinflammatory treatment to  $2.0 \pm 1.3$ . Initially, all patients were treated with NSAID and/or systemic GC. Six patients received intraarticular GC. Five patients flared on GC treatment upon tapering and were given methotrexate. Remission was achieved in all and prednisolone could be tapered.

Patients were followed for a median of 272 days, and no safety signal with regard to tumor reappearance was detected.

Retrospective analysis of cancer staging imaging studies revealed good sensitivity for PET-CT in the detection of synovitis, as opposed to contrast-enhanced CT.

Interestingly, in one patient low RF and ACPA titers had been detected when she presented with arthralgias without synovitis five years prior. This patient developed highly active RA one day after the first infusion of nivolumab.

**Conclusion:** Inflammatory manifestations were associated with high disease burden and not self-limiting. In monoarthritis, GC joint injection resulted in long-term remission. In oligo- and polyarthritis flares were frequent after tapering and, thus, potential side-effects including attenuation of the antitumor efficacy of ICI are a concern. This is the first report on the efficacy and safety of methotrexate as a GC-sparing agent in ICI-induced arthritis.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Knee osteoarthritis (KOA) is a major public health problem and a leading cause of long-term pain and disability. Few effective medical treatments for the disease currently exist. Acupotomy has been used as a new type of minimally-invasive surgical treatment for KOA pain. It combines techniques from acupuncture and micro-surgery that separates subcutaneous adhesions and muscle knots, resulting in immediate pain relief. A comprehensive literature review is an important step in understanding its benefits and for guiding treatment for KOA pain. We conducted a systematic review and meta-analysis to evaluate the efficacy of acupotomy for joint pain associated with KOA.

**Methods:** We performed a search on Cochrane Library, PubMed, EMBASE, 3 universal Chinese databases (CNKI, Wan Fang and VIP), and reference lists of published articles through June 2017. We include randomized controlled trials using acupotomy therapy for KOA patients who met the ACR diagnostic criteria. The effect of acupotomy on joint pain relief was measured with WOMAC pain subscale, VAS and other pain scores. Study quality was evaluated with Jadad criteria. The differences between treatment groups were reported as mean change (P-value).

**Results:** After screening 721 abstracts, 16 studies met eligibility criteria and were conducted between 2007 and 2015. A total of 1,416 KOA patients (65.2% female, mean age = 59 years, mean symptom duration = 87 months) were included. **Table 1** summarizes the trials evaluating the effect of acupotomy therapy on joint pain relief. The typical treatment was once a week, for 1-5 weeks until pain relief. Additional massage therapy after acupotomy was included in four studies. Nine studies used acupuncture (1 traditional acupuncture and 9 electroacupuncture) as controls and others used therapeutic massage, oral nonsteroidal anti-inflammatory analgesics, or intra-articular hyaluronate injection. The overall quality of trials was modest (mean Jadad score=3). Almost all studies reported an effect of acupotomy on joint pain compared to a variety of controls. **Figure 1** shows a meta-analysis comparing effects of acupotomy therapy with acupuncture controls on pain relief. A meta-analysis comparing acupotomy with other controls is not reported due to variation in outcomes assessed. Adverse events were not reported.

**Conclusion:** Acupotomy treatment may improve joint pain associated with KOA. Further rigorously designed and well-controlled RCTs with long-term follow-up are warranted.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Joint injuries, including sports- or combat-related ligamentous tears and fractures, can lead to post-traumatic osteoarthritis (PTOA), a chronic condition that causes pain, disability and limited quality of life. Current treatment options only provide symptomatic relief without modifying the progressive course of the disease, and are plagued by dose- or duration-limiting toxicity. Pharmacologic inhibition of catabolic factors, including cartilage degrading enzymes, pro-inflammatory cytokines and catabolic cell signaling pathways appears to reduce progressive joint damage in preclinical and clinical studies. However, the clinical translation of such disease modifying osteoarthritis drugs (DMOADs) has been hampered by short half-lives following intra-articular administration. Although platforms have been developed for local delivery of therapeutics, most suffer from major drawbacks, including a lack of control points to tune release kinetics and complex design that limits scalability and adaptability to a wide range of DMOADs. A localized drug delivery depot that provides long-term release of DMOADs in response to OA associated local factors like matrix metalloproteinase-2 (MMP-2) would represent an attractive paradigm shift in OA therapy.

**Methods:** We designed a self-assembled hydrogel depot using small molecules that are Generally Recognized As Safe (GRAS) by the FDA without chemical modifications, and evaluated the hydrogel's ability to encapsulate an MMP-13 inhibitor (Sigma-Aldrich) and a Cathepsin-K inhibitor (TOCRIS Bioscience). Release studies were performed *in vitro* to explore the responsiveness of the system to

MMP-2 and synovial fluid (SF) collected from healthy and arthritic human joints. Hydrogels were evaluated *in vitro* for biocompatibility using chondrocytes and synoviocytes. Therapeutic efficacy of Cathepsin-K inhibitor loaded gels was determined *in vivo* using the medial meniscal tear model of PTOA in Lewis rats.

**Results:** Hydrogels encapsulated both MMP-13 and cathepsin-K inhibitors with high loading efficiencies and showed excellent hydrolytic stability in PBS and synovial fluid from healthy human joints, with cumulative drug release <30% over a 30-day period. The encapsulated DMOADs were released from the hydrogel in response to MMP-2 and synovial fluid collected from arthritic human joints. The release of DMOADs was directly proportional to the dose of enzyme or amount of arthritic synovial fluid added. Drug-loaded gels showed biocompatibility with both chondrocytes and synoviocytes, suggesting their safety for intra-articular administration. In the medial meniscal tear model of PTOA, intra-articular treatment with Cathepsin-K inhibitor-loaded hydrogels resulted in a significant reduction in cartilage damage compared to controls (rats injected with blank hydrogel).

**Conclusion:** Our results suggest that self-assembled hydrogels are a promising strategy for efficient, localized delivery of DMOADs and can offer improved therapeutic benefit in the treatment of PTOA.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inflammation in osteoarthritis (OA) has been characterized by infiltration of immune cells and secretion of cytokines into synovial tissues. Noradrenaline levels, sympathetic nerve fiber distribution and  $\beta$ 2-AR expression in the bone of rats have been associated with subchondral bone loss and increased osteoclast activity. All these data suggest the participation of the adrenergic and immune systems in the development and evolution of OA. However, the relationship among the systemic adrenergic and immune systems activation with OA progression and treatment response is less well known.

**Methods:** Serum samples from patients participants in a 6-month controlled, double blind and randomized clinical trial comparing the efficacy of pharmaceutical grade Chondroitin sulfate/Glucosamine hydrochloride (CS/GH) and Celecoxib (CE) were analyzed to determine cytokines (IL-2, IL-4, IL-6, IL-10, IL-8, IL-1 $\beta$ ) using BD™ Cytometric Bead Array (CBA) immunoassay, catecholamines (noradrenaline, adrenaline and dopamine using ELISA LDN®) and the presence of endotoxin or lipopolysaccharide (LPS; LAL test Lonza®).

**Results:** Samples from 100 knee OA patients (age: 62 $\pm$ 8 yr.; BMI: 31 $\pm$ 6 kg/m<sup>2</sup>; 86 females; VAS: 73 $\pm$ 15; WOMAC: 369 $\pm$ 43) treated with CS/GH (50) or CE (50) were analyzed. There were no baseline differences between treatment groups. After 6 months of treatment, both groups of patients showed a similar reduction in VAS and WOMAC score (Table 1). Serum IL-2, IL-4, IL-6, IL-8, IL-10 and dopamine levels did not change significantly over treatment. Adrenaline levels were significantly reduced by both treatments. Moreover, serum noradrenaline was reduced only in the group treated with CS/GH although the difference was not significant because of the great data variability. LPS levels were doubled in both treatment groups but attained values remained very low and were accompanied by a small and non-significant increase in IL-1  $\beta$  (p=0.07). These effects were similar in patients who attained a clinically meaningful VAS score decrease compared with those who didn't.

**Conclusion:** Six month treatment with CS/GH reduces significantly and in a similar fashion to NSAID CE the pain intensity and systemic adrenergic activation in patients with OA. Reduction in adrenergic activation was independent of pain response. Further studies are needed to ascertain the relationship between systemic adrenergic changes and subchondral bone loss and osteoclast activity.

Table 1.

Variable	Baseline		6-month

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

There is a draught of available effective treatments of knee osteoarthritis (OA) and tests of new therapies are needed. Polyacrylamide hydrogel (PAAG) is a non-toxic, non-degradable synthetic product, used for years in the augmentation of soft tissues. Animal studies have shown that intra-articular (IA) PAAG significantly alleviates lameness and joint effusion over 2 years among horses with OA. Thus, IA injection of PAAG may be a promising treatment for knee OA in humans, albeit with a need for scientific evaluation of efficacy and safety. The present study has been conducted to establish an initial estimate of effectiveness of IA injection of PAAG for the symptomatic treatment of knee OA.

Methods:

Patients with OA of the knee were invited into a prospective open-label cohort study. The patients received IA injection of 3 ml of PAAG (a proprietary 2.5% cross-linked PAAG manufactured by Contura International A/S) twice within 1 month. The WOMAC questionnaire was used to estimate efficacy, and was collected at baseline and after 4, 7 and 13 months. Efficacy was mainly estimated as a change from baseline for the WOMAC pain subscale after 4 months (Normalised to 0-100 points; 100 worst). WOMAC stiffness and WOMAC physical function were measured as secondary estimates of efficacy. The efficacy variables were analyzed using a mixed-effect model repeated measure approach without imputation of missing data. Sensitivity analyses were done using baseline observation carried forward imputation.

Results:

118 patients (62 females) received IA PAAG. Of these there were WOMAC data available from 81 after 4 months, 66 after 7 months, and 47 after 13 months. At baseline the mean WOMAC pain score was 43.7 (SD17.5). There were statistically significant reductions in WOMAC pain after 4 months (mean change -13.3 points [95% CI: -17.3 to -9.3]; P<.0001), which exceeds established minimal clinically important improvements margins of 9 points. Similar results were found in WOMAC stiffness and physical function (figure 1). The improvement was sustained throughout the observation period. In the sensitivity analyses the estimates were generally lower caused by the non-responder imputation approach (table 1).

Conclusion:

These results suggest beneficial effects of IA injection of a 2.5% PAAG on knee OA symptoms, even in the long term (1 year). This is promising but efficacy needs to be confirmed in a randomized study with adequate measures taken to reduce risk of bias.

Figure 1. Changes from baseline in WOMAC. No imputation of missing data.

Table 1. Sensitivity analyses of changes from baseline in WOMAC. Missing data imputed using BOCF technique.

Change from baseline in	4 month (n=118)		7 month (n=118)		13 month (n=118)	
	Mean (95% CI)	P	Mean (95% CI)	P	Mean (95% CI)	P
WOMAC pain	-9.5 (-12.1 to -6.9)	<.0001	-7.6 (-10.2 to -5)	<.0001	-6.1 (-8.7 to -3.4)	<.0001
WOMAC stiffness	-6.6 (-9.7 to -3.5)	<.0001	-6.4 (-9.4 to -3.3)	<.0001	-6.1 (-9.2 to -3.1)	0.0001
WOMAC function	-6.6 (-8.5 to -4.6)	<.0001	-4.5 (-6.4 to -2.5)	<.0001	-3.5 (-5.5 to -1.5)	0.0005

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Increased aggrecanase activity is a well-known trigger factor for osteoarthritis (OA), initiating loss of cartilage aggrecan that precedes more severe cartilage degradation. A disintegrin and metalloproteinase with thrombospondin motifs-5 (ADAMTS-5) is a key aggrecanase in humans and is a relevant target for the development of disease-modifying OA drugs (DMOADs).

GLPG1972 is a potent small molecule inhibitor of ADAMTS-5 displaying high selectivity versus a number of other zinc metalloproteases. The anti-catabolic activity of GLPG1972 was shown in murine and human cartilage explants, and its DMOAD activity was demonstrated in the destabilization of the medial meniscus (DMM) mouse model.

In the current study, the safety, tolerability, pharmacokinetics and pharmacodynamics of GLPG1972 in healthy male subjects were evaluated.

## Methods:

GLPG1972 was administered as single oral doses (60 mg up to 2100 mg) or multiple doses (300 mg/day to 1050 mg/day for 14 days) formulated as a solution. Ascending single doses were evaluated in an alternating fashion between two panels of 8 male healthy subjects and multiple doses were evaluated sequentially in 3 groups of 8 male healthy subjects. In both parts, 6 subjects received GLPG1972 and 2 placebo. Plasma and urine were collected at several time points and intervals for the quantification of GLPG1972 by LC-MS/MS. Pharmacodynamics was assessed by measurement of the aggrecan ARGS neopeptide levels in plasma by an enzyme-linked immunosorbent assay.

## Results:

Administration of single (up to 2100 mg) and multiple (up to 1050 mg q.d.) ascending oral doses of GLPG1972 in healthy subjects was well tolerated, with no clinically relevant effects on ECGs, vital signs or laboratory parameters.

GLPG1972 given as a single oral dose in fasted state was rapidly absorbed with a median  $t_{max}$  range of 1 to 4 h and eliminated with a terminal half-life of approximately 10 h. The rate of absorption decreased with higher doses, whereas the plasma exposure in terms of AUC increased dose-proportionally. After once-daily dosing for 14 days in fed state, GLPG1972 plasma exposure (both  $C_{max}$  and AUC) increased dose-proportionally over the entire dose range. Pharmacokinetic steady state was reached after 2 dosing days, with minimal accumulation. The excretion of unchanged GLPG1972 in urine over a 24 h period was low (<11% of the administered dose).

The aggrecan ARGS neopeptide levels decreased progressively over time during treatment with GLPG1972 but not with placebo. The extent of the pharmacodynamic effect was similar for the 3 tested doses. The maximal reduction in plasma concentrations of aggrecan ARGS neopeptide was about 60% at day 14 versus baseline. No plateau had been attained on day 14, suggesting that it may take longer to obtain the maximum effect.

## Conclusion:

GLPG1972 was shown to be safe and well-tolerated in healthy male subjects with a suitable pharmacokinetic profile and a marked decrease of the aggrecan ARGS neopeptide biomarker, indicating target engagement. These data and the preclinical data package confirm the potential of GLPG1972 to be a potential DMOAD treatment. GLPG1972 will be progressed to a Phase 2 study in osteoarthritis.

### Orosomucoid 2 Serves as Predictor of Therapeutic Response in Osteoarthritis Patients Treated with Chondroitin Sulfate/Glucosamine Hydrochloride

V. Calamia, M. Camacho, I. Rego-Pérez, L. González, P. Fernández-Puente, F. Picchi, M. Herrero, H. Martínez, C. Ruiz-Romero, F. J. Blanco.

#### Background/Purpose:

The present study explored potential protein biomarkers useful to predict the therapeutic response of osteoarthritis (OA) patients treated with pharmaceutical grade Chondroitin sulfate plus glucosamine hydrochloride (CS+GH) or the COX-2 selective nonsteroidal anti-inflammatory drug Celecoxib, in order to optimize therapeutic outcomes in OA.

#### Methods:

A shotgun proteomic analysis was performed on sera from 80 patients enrolled in the Multicentre Osteoarthritis interVENTion trial with Sysadoc (MOVES), employing the iTRAQ labelling technique (Sciex) followed by LC-MALDI-MS/MS analysis. One of the altered proteins was selected to be validated using commercially available ELISA Kit (Uscn Life Science) in the whole MOVES cohort at baseline. Logistic regression models adjusting for the confounder variables of gender, age, BMI, KL grade, VAS score and WOMAC score at baseline, as well as receiver-operating-characteristics (ROC) curves, were used to analyze the accuracy of the measured protein as predictive biomarker for OA treatment.

#### Results:

We employed a quantitative proteomic approach to identify differentially expressed proteins between OA responders and non-responders before starting the pharmacological treatment (Chondroitin sulfate/glucosamine hydrochloride or Celecoxib). Serum levels of orosomucoid 2 (ORM2) were measured by ELISA assays in 451 OA patients (n=229 for CS+GH group and n=222 for Celecoxib group). As shown in figure 1A, baseline ORM2 levels were significantly higher in patients who obtained unfavorable outcome (reduction in WOMAC score <20%) after 6 month of treatment with CS+GH (252,2 vs 195,4 ug/mL; n=51 vs 178;  $p=0,003$ ), while no statistically significant differences were found in the Celecoxib group (data not shown). Both WOMAC and VAS scores at baseline significantly influence patients' response regardless of treatment ( $p=0,001$  and  $p<0,001$  respectively). Notably, if we include baseline ORM2 as covariate, we found a specific interaction between response to CS+GH and baseline ORM2 levels ( $p=0,012$ ) thus increasing the predictive power of our study (Figure 1B).

#### Conclusion:

Our results show that ORM2 levels significantly correlate with patients' response to pharmaceutical grade Chondroitin Sulfate/Glucosamine Hydrochloride suggesting the possibility of its use in predictive assays in order to optimize therapeutic outcomes in OA.

Figure 1: A) Levels of ORM2 in sera from responders and non-responders to CS+GH. B) ROC curves were created using values predicted by logistic regression with markers considered as predicted variables with and without ORM2 as covariate.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CNTX-4975, a highly purified, synthetic *trans*-capsaicin, targets transient receptor potential vanilloid 1, producing analgesia via reversible desensitization of end terminals of primary afferent pain fibers within the joint. This phase 2 dose-ranging study evaluated CNTX-4975 in subjects with osteoarthritis (OA) knee pain.

**Methods:** Subjects aged 45–80 years with chronic knee OA and stable moderate to severe knee pain who failed previous oral/intra-articular (IA) analgesics were randomized 2:1:2 to a single IA injection of placebo, CNTX-4975 0.5 mg, or CNTX-4975 1.0 mg. Randomization was stratified by Kellgren-Lawrence (K-L) grade (2–3 vs 4) and body mass index (<30 vs ≥30 kg/m<sup>2</sup>). The primary efficacy endpoint was area under the curve (AUC) for change from baseline in daily Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) A1 score (pain with walking) through week 12 (analysis of covariance). Additional efficacy endpoints included mean change from baseline in weekly WOMAC A1 score, WOMAC B stiffness subscale, and WOMAC C physical function subscale through week 24 (mixed model for repeated measures). Symptomatic improvements were assessed with modified Outcome Measures in Rheumatology Clinical Trials–Osteoarthritis Research Society International (OMERACT-OARSI) criteria (Table 1). Statistical tests were 2-sided (alpha, 0.10). Safety assessments included treatment-emergent adverse events (TEAEs).

**Results:** Efficacy was evaluated in 172 subjects (placebo, n=69; CNTX-4975 0.5 mg, n=33; CNTX-4975 1.0 mg, n=70), most with K-L grade 2–3 (placebo, n=62; CNTX-4975 0.5 mg, n=30; CNTX-4975 1.0 mg, n=65). Mean baseline WOMAC A1 pain score was 7.3 (Numeric Pain Rating Scale, 0–10). WOMAC A1 scores (AUC analysis) were significantly improved vs placebo at week 12 with CNTX-4975 0.5 mg (least squares mean difference [LSMD]: –0.8; *P*=0.07) and 1.0 mg (LSMD: –1.6; *P*<0.0001) and at week 24 with CNTX-4975 1.0 mg (LSMD: –1.4; *P*=0.0002). Additional efficacy analyses are reported in Table 2. At week 12, more subjects treated with CNTX-4975 0.5 mg and 1.0 mg met modified criteria for OMERACT-OARSI response (76% [*P*=0.11] and 86% [*P*=0.0005], respectively) vs placebo (59%). The incidence of TEAEs was 30% for placebo or CNTX-4975 1.0 mg and 47% for CNTX-4975 0.5 mg at week 24. Most TEAEs were considered unrelated to study treatment. Arthralgia was the most common TEAE with placebo and CNTX-4975 1.0 mg.

**Conclusion:** A single IA injection of CNTX-4975 1.0 mg improved pain with walking, knee stiffness, and physical function and was well tolerated in subjects with moderate to severe OA knee pain.

## Patient Characteristics That Predict the Effect of Laparoscopic Adjustable Gastric Band Weight Loss Surgery on Knee Osteoarthritis Pain

Shannon Chen<sup>1</sup>, Fernando Bomfim<sup>2</sup>, Heekoung Youn<sup>3</sup>, Christine Ren-Fielding<sup>4</sup> and Jonathan Samuels<sup>5</sup>, <sup>1</sup>Medicine, NYU Langone Medical Center, New York, NY, <sup>2</sup>NYU Langone Medical Center, New York, NY, <sup>3</sup>Surgery, NYU Langone Medical Center, New York,

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Obesity is a modifiable risk factor for knee osteoarthritis (OA), yet diet and exercise often fail to achieve sustained weight loss or knee improvement. Recent studies suggest that bariatric weight loss surgery has a significant impact on both obesity and knee pain in this population. We aimed to quantify knee pain improvement in obese patients opting for the laparoscopic adjustable gastric band (LAGB), and further support its use in refractory knee OA.

**Methods:** We identified bariatric surgery patients from the New York University Langone Weight Management Program Research Registry (2002-2015) who were <sup>3</sup>18 years old at the time of surgery, reported knee pain pre-operatively, and had no previous history of rheumatoid arthritis, psoriatic arthritis, or lupus. Participants rated their knee pain on a scale from 0 (best) to 10 (worst) at three time points: (1) before bariatric surgery, (2) one year after surgery, and (3) at the time of survey administration. They reported any family history of OA, knee injury or surgery before onset of knee pain, and presence of OA in other joints. We obtained patient height and weight from their charts at the first two time points, and used self-reported weight for the third time point. ANOVA was used to analyze the relationship between change in knee pain rating and various perioperative and postoperative patient characteristics, including baseline age and body mass index (BMI).

**Results:** Of the 617 bariatric patients eligible for the study, 120 LAGB patients were included. By one year post-LAGB, the BMI decreased by a mean of 11.2 kg/m<sup>2</sup>, and knee pain decreased from 6.88 to 3.34. We found a significant difference in knee pain improvement by age group at one year post-LAGB (p=0.009). Those who had a knee injury prior to onset of knee pain showed less improvement at one year post-LAGB than did those who were injury-free (p=0.04), though a history of knee surgery was not similarly significant. Patients with OA in other joints had less improvement by a margin of 2.75 vs 4.22 (p=0.001). There was no significant relationship between baseline BMI and knee pain improvement at one year post-LAGB, but the subgroup with the highest BMI improvement had the most knee improvement (p=0.043). Though knee pain improvement trended with decreased BMI at one year post-LAGB, the difference between BMI groups was no longer significant at the time of survey administration (mean 9.14 years, median 10 years).

**Conclusion:** LAGB weight loss surgery results in a significant reduction of knee OA pain, especially in younger patients and those without prior knee injury or other involved joints. This further supports LAGB as a viable treatment option in the algorithm for refractory knee OA pain in obese patients, irrespective of a patient's degree of obesity.

**Table 1.** Various perioperative and postoperative factors affecting knee OA pain rating improvement in a cohort of 120 laparoscopic gastric banding patients (2002-2015)

Covariate	Mean Knee Pain Improvement $\pm$ SD (1 year post-surgery)	P-value

## A Randomized, Placebo-Controlled, Double-Blind, Phase II Clinical Trial of the First-in-Class Imidazoline-2 Receptor Ligand CR4056 in Pain from Knee Osteoarthritis and Disease Phenotypes

Lucio C. Rovati<sup>1</sup>, Nadia Brambilla<sup>1</sup>, Tomasz Blicharski<sup>2</sup>, Nicholas J Probert<sup>3</sup>, Cristina Vitalini<sup>1</sup>, Giampaolo Giacobelli<sup>1</sup>, Federica Girolami<sup>1</sup> and Massimo D'Amato<sup>1</sup>, <sup>1</sup>Clinical Research Department, Rottapharm Biotech, Monza, Italy, <sup>2</sup>Lubelskie Centrum Diagnostyczne, Świdnik, Poland, <sup>3</sup>MAC Clinical Research, Manchester, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Background/Purpose:** CR4056 is a novel imidazoline-2 receptor ( $I_2R$ ) ligand endowed with potent analgesic activities in several and diverse animal models of nociceptive and neuropathic pain, by innovative modulation of the monoaminergic descending inhibitory pathway (Li JX, Pharmacol Ther 2017). The present proof-of-concept study was undertaken to investigate the efficacy and safety of CR4056 in patients with knee osteoarthritis (OA) pain.

**Methods:** This was a multicenter, prospective, randomized, placebo-controlled, double-blind, parallel group design trial (EudraCT n. 2015-001136-37). Patients with knee OA (ACR clinical and radiological criteria, Kellgren & Lawrence grade 2/3) and moderate to severe pain (score  $\geq 50$  on the 0-100 normalized WOMAC pain subscale) were randomized in a 2:1 ratio to a pharmacologically effective dose of oral CR4056 (100 mg b.i.d. in women and 200 mg b.i.d. in men, to assure similar exposure due to slight gender differences in pharmacokinetics) or matching placebo for 14 days. Intention-to-treat (ITT: Worst-Case approach for non-completers) changes in WOMAC pain (primary endpoint) were analysed by the Wilcoxon test in the overall study population and in different OA phenotypes, including patients with a neuropathic pain component (as per the painDETECT questionnaire), or obesity ( $BMI \geq 27.5$  kg/m<sup>2</sup>, i.e. the WHO threshold for pre-obesity).

**Results:** A total of 213 patients were blindly randomized at 20 sites in Poland and UK: 92 women to CR4056 100 mg b.i.d., 52 men to 200 mg b.i.d. and 69 overall to placebo, with median (range) WOMAC pain baseline scores of 61 (50;90), 58 (50;90) and 58 (50;84), respectively, that were similar across groups and OA phenotypes. Three patients withdrew with CR4056 100 mg b.i.d., 5 with 200 mg b.i.d. and 6 with placebo. There were no serious adverse events and treatments were equally well tolerated. CR4056 decreased WOMAC pain vs. placebo after only 14 days and with a similar pattern in the overall population and the selected OA phenotypes. While only 21/213 (9.9%) patients had a neuropathic pain component, 73.2% (156 out of 213) had  $BMI \geq 27.5$  (mean 33.4). In these patients, CR4056 significantly decreased WOMAC pain (Figure) in a clinically relevant fashion: pooled CR4056 ITT median (range) change was -14 (-80;22) vs. 0 (-56;8) with placebo ( $P=0.011$ ;  $n=105$  and 51, respectively). Secondary pain and function outcomes followed a pattern consistent with the primary endpoint.

**Conclusion:** CR4056 is the first  $I_2R$  ligand to show analgesic activity in humans. The compound was safe and effective in reducing knee OA pain in this very short phase II trial, especially in overweight and obese patients. This observation prompts longer-term trials and the exploration of possible links between the  $I_2$  pathway and the overweight or metabolic OA phenotype altered pain perception. Conversely, a neuropathic pain component had low prevalence in unselected knee OA patients in this study.

Figure. ITT WOMAC pain change from baseline after 14 days (box-plot of median score and interquartile range with max/min values), in  $BMI \geq 27.5$  patients. P values vs. placebo (Wilcoxon test)

## **Are Bisphosphonates Efficacious in Knee Osteoarthritis? A Meta-Analysis of Randomized Controlled Trials**

Mikala C. Osani<sup>1</sup>, Elizaveta Vaysbrot<sup>1</sup>, **Raveendhara R. Bannuru**<sup>2</sup>, Mia-Cara Musetti<sup>1</sup> and Timothy E. McAlindon<sup>1</sup>, <sup>1</sup>Division of Rheumatology, Tufts Medical Center, Boston, MA, <sup>2</sup>Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA, Boston, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

One of the key aspects of osteoarthritis (OA) pathogenesis is subchondral bone remodeling. Bisphosphonates have been touted as disease-modifying agents for OA due to their ability to limit excessive bone remodeling and block osteoclast-mediated pain pathways. Prior meta-analyses on the topic suggested efficacy of bisphosphonates in OA but had major methodological flaws in data extraction and analyses, resulting in misleading conclusions. The latest review combined observational studies with randomized controlled trials (RCTs) in the same analysis, blended various OA sites, and mixed active with placebo comparators; this produced high heterogeneity ( $I^2$  up to 99%). We aimed to elucidate the true effects of bisphosphonates using rigorously implemented meta-analysis of RCTs. We chose to isolate our analysis to knee OA patients, because this population is more homogenous and has been widely studied.

### **Methods:**

We searched Medline, EMBASE, Google Scholar, Web of Science, and Cochrane Database from inception until April 2017 and hand-searched reference lists. We included only RCTs in knee OA patients that compared any bisphosphonates vs. placebo and reported validated pain and function scales, radiographic progression, and adverse events outcomes. Studies using active comparators or concomitant medications besides NSAIDs and acetaminophen were excluded. We calculated standardized mean differences to account for variation in outcome scales. Random effects meta-analyses were performed.

### **Results:**

We included seven RCTs (3,013 patients, 69% female) (Table 1). Most patients ( $N=2,767$ ) received oral risedronate, and a majority were taking concomitant NSAIDs. No pain or function outcomes, regardless of dose, route, time point or measuring instrument, revealed statistically significant results (Table 2). Similarly, we found no statistically significant effect on radiographic progression. One small RCT in patients with bone marrow lesions (BML) suggested a reduction in BML size at 6 months. Bisphosphonates displayed good tolerability, with no statistically significant differences in adverse event outcomes vs. placebo.

### **Conclusion:**

Contrary to prior reviews, our analysis showed that bisphosphonates neither provide symptomatic relief nor defer radiographic progression in knee OA. However, these agents may still be beneficial in certain subsets of patients who display high rates of subchondral bone turnover. Future studies should be directed at defining such OA subsets and investigating the effects of bisphosphonates in those patients.

Table 1: Characteristics of included studies

Author, year; Study name	N of patients	Age, mean (years)	% female	Intervention vs. comparator	NSAID use, %	Study duration	Overall risk of bias*
Spector, 2005; BRISK study	284	63.3	60%	Risedronate 5 or 15 mg/day vs. oral placebo	Rescue analgesia with paracetamol and diclofenac (% unknown)	12 months	Unclear
Bingham, 2006; KOSTAR efficacy data; E.U. trial	1,251	63.6	79%	Risedronate 5 or 15 mg/day or 35 mg/week vs. oral placebo	57%	24 months	Unclear

## Efficacy and Safety of Subcutaneous Tanezumab in Patients with Knee or Hip Osteoarthritis (NCT01089725)

Charles A. Birbara<sup>1</sup>, Eugene J. Dabiezies<sup>2</sup>, Aimee M. Burr<sup>3</sup>, Robert J. Fountaine<sup>4</sup>, Michael D. Smith<sup>3</sup>, Mark T. Brown<sup>3</sup>, **Christine R. West<sup>3</sup>**, Rosalinda H. Arends<sup>3</sup> and Kenneth M. Verburg<sup>3</sup>, <sup>1</sup>University of Massachusetts Medical School, Worcester, MA, <sup>2</sup>Pensacola Research Consultants, Pensacola, FL, <sup>3</sup>Pfizer, Inc., Groton, CT, <sup>4</sup>Pfizer, Inc., Groton, CT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Tanezumab (TNZ) is a monoclonal antibody that inhibits nerve growth factor and reduces hip or knee osteoarthritis (OA) pain. A placebo-controlled phase 3 study (NCT01089725), evaluated efficacy of subcutaneous (SC) TNZ (2.5, 5, and 10 mg) and compared therapeutic equivalence of TNZ 10 mg SC to TNZ 10 mg intravenous (IV) every 8 weeks in the treatment of

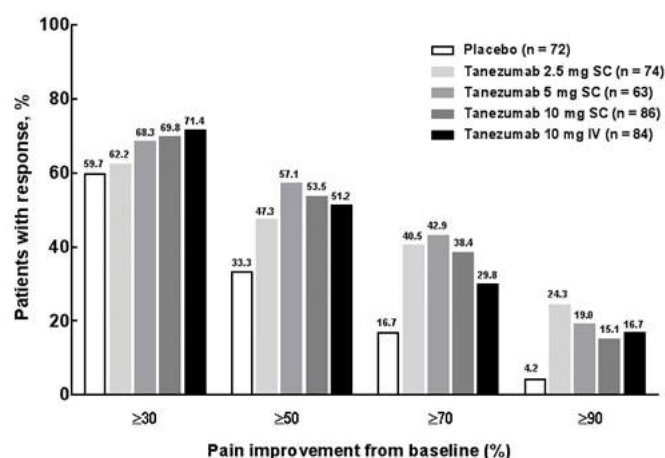

symptomatic OA. Co-primary endpoints were Western Ontario and McMaster Universities (WOMAC) OA Pain and Physical Function Indices and Patient's Global Assessment of OA (PGA OA) at Week 8.

**Methods:** Patients (N=379) with knee or hip OA were randomized and treated with placebo (n=72), TNZ 2.5 mg SC (n=74), 5 mg SC (n=63), 10 mg SC (n=86) or 10 mg IV (n=84) every 8 weeks. Efficacy analyses included change from baseline in WOMAC Pain and Physical Function subscales, PGA OA, and percentage of patients with  $\geq 30\%$ ,  $\geq 50\%$ ,  $\geq 70\%$ , and  $\geq 90\%$  improvement in WOMAC Pain. Safety assessments included adverse event (AE) reporting, physical and neurological examinations, and laboratory tests.

**Results:** The study discontinued prematurely due to a FDA partial clinical hold on TNZ non-cancer pain studies; thus no statistical testing was conducted. Since  $<10\%$  of patients received a second dose at Week 8, efficacy results are described for change from baseline to Week 8 only. Mean (standard error [SE]) change from baseline to Week 8 in WOMAC Pain in TNZ groups ranged from  $-3.59$  (0.26) to  $-3.89$  (0.32); versus  $-2.74$  (0.25) with placebo. Percentage of patients with  $\geq 30\%$ ,  $\geq 50\%$ ,  $\geq 70\%$ , and  $\geq 90\%$  reductions in WOMAC Pain score at Week 8 was greater in all TNZ groups versus placebo (**Figure**). Mean (SE) change from baseline to Week 8 in WOMAC Physical Function ranged from  $-3.13$  (0.25) to  $-3.51$  (0.28) with TNZ and  $-2.26$  (0.24) with placebo. For PGA OA, mean (SE) change from baseline to Week 8 was  $-0.90$  (0.11) to  $-1.08$  (0.12) with TNZ and  $-0.78$  (0.10) with placebo. Inspection of the efficacy-time curves indicated that onset and duration of analgesia with all SC doses were similar to the 10-mg IV dose over the 8-week dosing interval. Overall incidence of all-causality AEs was highest with TNZ 10-mg IV (52.4%) and placebo (51.4%). No AEs of osteonecrosis were reported by investigators. Two placebo-treated patients and 3 TNZ 2.5-mg SC patients underwent total joint replacements. AEs in  $\geq 5\%$  of patients in any treatment group included arthralgia, paresthesia, hypoesthesia, worsening OA, headache, and joint swelling; paresthesia and hypoesthesia occurred only in patients receiving TNZ. Injection site reactions were reported by 4.7%, 3.6%, 2.8%, 2.7% and 0% of those treated with TNZ 10 mg SC, TNZ 10 mg IV, placebo, TNZ 2.5 mg SC and TNZ 5 mg SC, respectively and the majority were mild (none were severe).

**Conclusion:** SC TNZ provided improvements in Pain, Physical Function, and PGA OA at all doses. Efficacy and safety of SC TNZ were generally similar to IV in patients with OA pain.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Animal studies suggested that inhibiting IL-1 $\alpha/\beta$  with ABT-981 may reduce pain and slow structural progression in OA. This study (NCT02087904; ILLUSTRATE-K) assessed the safety and efficacy of ABT-981 in subjects with knee OA.

**Methods:** Subjects (N=350; 347 analyzed) with Kellgren-Lawrence (KL) grade 2–3 knee OA, synovitis on MRI or US, and visual analog scale knee pain score 4–8 (range, 0–10) were randomized to placebo (PBO) or ABT-981 25, 100, or 200 mg subcutaneously (sc) every 2 wk (E2W) for 50 wk. The primary endpoints were change from baseline (BL) in WOMAC pain at wk 16 and change from BL in MRI synovitis at wk 26. Other endpoints included WOMAC function and OMERACT/OARSI response (wk 16, 26, and 52) MRI cartilage volume (wk 26 and 52), and x-ray joint space narrowing (JSN) (wk 52). Continuous efficacy assessments used ANCOVA (main factors: treatment, age group, KL grade; covariates: BL values).

**Results:** BL demographics and disease characteristics were balanced (KL grade 3, 36.0%–38.8%; mean WOMAC pain (scale 0–50), 26.2–28.4). The primary endpoint of WOMAC pain at wk 16 improved significantly, compared with PBO, with ABT-981 100 mg ( $P=0.050$ ; **Figure 1**), but not 25 mg ( $P=0.834$ ) or 200 mg ( $P=0.415$ ). WOMAC pain reduction in all ABT-981 groups was sustained from wk 16 to 52, but differences between ABT-981 and PBO for WOMAC pain and other key signs and symptoms were not significant (**Table 1**). Synovitis-related imaging, cartilage volume endpoints, and JSN were similar between ABT-981 and PBO groups at wk 26 and 52. ABT-981 was well tolerated; serious adverse events (SAEs), treatment-related SAEs, and infections and serious infections were similar with ABT-981 vs PBO (**Table 2**). Injection site reactions, grade 2/3 neutropenia, and discontinuations due to neutropenia were more frequent with ABT-981 vs PBO. ABT-981 exposures reached steady state after wk 6 and were stable through wk 52. Pharmacodynamic responses (neutrophil and high-sensitivity CRP levels) plateaued at the 100 mg dose and data were similar at 200 mg. The low immunogenicity to ABT-981 did not meaningfully affect outcomes.

**Conclusion:** ABT-981 was generally well tolerated and met the primary endpoint of reduction in WOMAC pain at wk 16 compared with placebo at a dose of 100 mg, but not at 25 mg or 200 mg; cartilage thickness, synovitis, and other structural endpoints were similar between ABT-981 and PBO.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A major challenge regarding intraarticular hyaluronic acid (IAHA) treatment in knee osteoarthritis (OA) is identifying patients who will benefit most. This study aimed to identify determinants associated with response level to IAHA treatment for symptomatic knee OA.

**Methods:** Data were from the Osteoarthritis Initiative (OAI) database. Subjects were selected based on the following question: “During the past 6 months, have you had an injection of HA in one or both knees for treatment of arthritis?” Included were subjects with radiographic OA who received a single treatment in one or both knees, and with data on demographics and WOMAC scores at visits before (T0) and after (T1; within 6 months) treatment. Data from the WOMAC pain scores were analyzed for demographic, clinical, and imaging (X-ray; Kellgren-Lawrence [KL] and joint space width [JSW], and MRI; cartilage volume [CV], bone marrow lesions [BML], and synovial fluid effusion size) at T0 and change (T1-T0) over time. Subjects with WOMAC >0 at T0 were included and subdivided based on WOMAC pain score tertile (first=lower pain). Analyses were also done on “responders” (improvement in pain score ≥20%) and “non-responders” (unchanged or worsening of pain score).

**Results:** Participants (n=310) received a total of 404 treatments (one/knee). WOMAC pain scores at T0 showed in the first and second vs. the third tertile, lower WOMAC score, BMI and KL grade, and greater JSW ( $p \leq 0.010$ ), and in the first vs. the third tertile, significantly greater CV and effusion size ( $p \leq 0.033$ ). Participants with decrease in pain score ≥20% were greater in the third tertile ( $p < 0.001$ ). Other WOMAC scores (function, stiffness, total) yielded similar results. These indicate a more severe disease in the third tertile. Analyses on participants in the third tertile, pain score ≥8 (greatest probability of improvement in pain with IAHA treatment), showed that responders vs. non-responders were usually younger ( $p = 0.014$ ), with greater medial compartment CV ( $p = 0.046$ ) and a trend

toward lower BML score and greater JSW. In this group, differences between responders and non-responders in all WOMAC score changes were significant ( $p < 0.001$ ). The majority of responders had a reduction in WOMAC scores (except stiffness) of about 40%, while non-responders showed worsening of symptoms. The use of concomitant arthritis medication was similar in both groups.

**Conclusion:** This study has successfully allowed the identification of new reliable predictive factors that can identify patients who could best benefit from IAHA treatment. Patients with moderate to severe symptoms, younger, and with greater medial compartment CV are the most likely to respond to treatment with the greatest level of improvement. These predictive factors can potentially be implemented in daily clinical practice and will be a useful guide for physicians.

## Intra-Articular Hyaluronic Acid Delay to Total Knee Arthroplasty By Number of Injection Courses Received: Analysis of an Administrative Database

Andrew Concoff<sup>1</sup>, Faizan Niazi<sup>2</sup>, Peter Shaw<sup>2</sup> and Jeffrey Rosen<sup>3</sup>, <sup>1</sup>Rheumatology, St. Jude Medical Center, Fullerton, CA, <sup>2</sup>Ferring Pharmaceuticals Inc., Parsippany, NJ, <sup>3</sup>Department of Orthopaedics & Rehabilitation, New York Presbyterian Queens; Department of Clinical Orthopaedic Surgery, Weill Medical College of Cornell University, New York, NY, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Total knee arthroplasty (TKA) is the standard surgical treatment for patients with osteoarthritis (OA) that no longer experience symptom relief from conservative or pharmacologic treatments. Intra-articular hyaluronic acid (IA-HA) is a common treatment option for mild to moderate knee OA that provides relief for patients who do not respond to conservative treatment and are not ready for TKA. The primary objective of this study is to determine if there is a correlation between receiving IA-HA injections and a delay to TKA in patients with knee OA compared to patients not receiving IA-HA, and if more courses of IA-HA injections relates to a longer delay to TKA.

**Methods:** This was a retrospective analysis of the Blue Cross/ Blue Shield (BCBS) claims database from October 1st, 2010 through September 30th, 2015. The primary outcome was time to TKA, which was defined as the time from treatment to the time TKA. Kaplan-Meier survival analysis was conducted to determine the TKA-free survival of patients who received IA-HA injections stratified by the number of injection courses received versus those who did not receive any IA-HA injections. A Cox proportional hazards regression analysis was also conducted to compare hazards ratios between the non IA-HA treated group and the IA-HA injection subgroups.

**Results:** A total of 744,734 patients were included in the analysis. Of these, 181,631 received at least one IA-HA injection, while 563,103 did not receive an IA-HA injection. A delay to TKA compared to the non IA-HA treated group was generally observed within the first year after IA-HA treatment for patients treated with 1 injection course, while patients treated with multiple courses demonstrated an incremental increase in delay to TKA with more injections (**Figure 1**). The model demonstrated a gradual decrease in hazard ratio (HR) with each subsequent course of IA-HA injection in comparison to the no IA-HA injection group, suggesting that the risk of TKA is reduced with subsequent IA-HA courses. The hazard ratio for a single course of injections was 0.85 (95% CI 0.84 - 0.86). The HR for TKA was smallest in the 5 or more injection courses group (HR 0.27, 95% CI 0.25 to 0.28).

**Conclusion:** These results demonstrate that within a large cohort of knee OA patients, individuals who received multiple courses of HA injections had a progressively greater delay to TKA compared to patients who did not receive HA treatment. The results demonstrated that with a greater number of injection courses received over time, there may be a relationship to a longer delay in TKA. Based on these results, multiple, repeat courses of IA-HA injection may be beneficial in substantially delaying TKA in knee OA patients.

## Costs Associated with Osteoarthritis Care Using Intra-Articular Hyaluronic Acid: Analysis of an Administrative Database

Andrew Concoff<sup>1</sup>, Faizan Niazi<sup>2</sup>, Peter Shaw<sup>2</sup> and Jeffrey Rosen<sup>3</sup>, <sup>1</sup>Rheumatology, St. Jude Medical Center, Fullerton, CA, <sup>2</sup>Ferring Pharmaceuticals Inc., Parsippany, NJ, <sup>3</sup>Department of Orthopaedics & Rehabilitation, New York Presbyterian Queens; Department of Clinical Orthopaedic Surgery, Weill Medical College of Cornell University, New York, NY, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many treatment options are available for the management of knee osteoarthritis (OA). The need for non-operative management is motivated by the large costs associated with the total knee arthroplasty (TKA) procedure. Intra-articular hyaluronic acid (IA-HA) is a non-operative treatment for knee OA that provides significant pain relief for patients with mild to moderate knee OA. The purpose of this study is to assess the annual insurance claim costs of patients who have undergone IA-HA treatment for knee OA versus those who did not, to determine if IA-HA ultimately results in a lower total annual cost of healthcare for knee OA patients.

**Methods:** This was a retrospective analysis of the Blue Cross/ Blue Shield (BCBS) claims database from October 1st, 2010 through September 30th, 2015. The primary outcome was the median annual OA related cost of healthcare for patients who received IA-HA vs those who did not for treatment of their knee OA. Additionally, annual costs for patients who have progressed to TKA will be compared between people who have received IA-HA and those who did not receive IA-HA prior to their TKA. Annual cost data specific to professional and facility claims between the two groups are also summarized. Due to the large sample size, comparisons between

healthcare costs were conducted using Mann-Whitney U test. The large sample size has eliminated the need to report p-values, as interpretability is minimal.

**Results:** A total of 744,734 patients were included in the analysis. Of these, 181,631 received IA-HA injections, while 563,103 did not receive an IA-HA injection. In all patients who received TKA, annual costs separated by professional and facility claims are included within Table 1. The analysis demonstrated that the annualized median healthcare costs of patients treated with IA-HA who progressed to TKA was \$871.31 (IQR \$3.82), while the annualized median healthcare costs of patients who did not receive IA-HA was \$2697.28 (IQR \$8.25). In all patients, the annualized costs over the course of the study timeframe was \$22.20 (IQR \$0- \$71.52) for patients who received HA, and \$21.12 (IQR \$0 - \$225.88) for patients who did not receive HA.

**Conclusion:** This database analysis concludes that from the initiation of treatment for knee OA until TKA, patients who receive IA-HA have a lower median annual healthcare cost than knee OA patients who do not receive IA-HA. In particular, for individuals who eventually progressed to TKA, receiving IA-HA prior to their TKA resulted in significantly lower annual healthcare costs than those who did not receive IA-HA as a treatment.

**Table 1: Total Annual Costs for Included TKA Patients**

	IA-HA Group	Non IA-HA Group
Annual Professional Costs (Median, IQR)	\$15.03 (2.64)	\$32.14 (6.30)
Annual Facility Costs (Median, IQR)	\$862.64 (3.82)	\$2724.39 (8.17)

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A recent meta-analysis concluded that intra-articular corticosteroids (IACS) for knee osteoarthritis (OA) may be associated with moderate improvement in pain compared with control treatment.<sup>1,2</sup> Notably, evidence quality was graded “low” due in part to inclusion of many small trials and trial heterogeneity.<sup>1,2</sup> Only 3 trials were moderate to large in size (≥50 patients/arm), with a variety of control treatments and pain endpoints. Across those 3 trials, at 1–2 weeks, 4–6 weeks, and 3 months post-treatment, standardized mean difference (SMD) corresponded to numbers needed to treat (NNT) of 8, 15, and infinity (indicating that the benefit of treatment cannot be determined; **Figure**).<sup>2</sup> FX006 is an extended-release formulation of triamcinolone acetonide for IA injection. We updated the meta-analysis by including data from two large, randomized, placebo-controlled trials of FX006 in patients with knee OA and heuristically compared the analysis of FX006 to the moderate to large trials to help assess the clinical relevance of FX006.

**Methods:** In studies FX006-2014-006 (NCT02116972) and FX006-2014-008 (NCT02357459), knee OA patients (Kellgren-Lawrence Grade 2 or 3; Average Daily Pain (ADP)-intensity  $\geq 5$ – $\leq 9$ ) received a single IA injection of FX006 40 mg (N=104 and N=161, respectively) or saline-placebo (N=104 and N=163, respectively). ADP was collected for 24 weeks post-injection. SMD (95% CI) was computed for ADP-intensity at 2 weeks, 6 weeks, and 3 months post-treatment using least-squares mean (LSM) difference for FX006 from saline-placebo derived from each trial. Weighted-average SMD (95% CI) for FX006 and corresponding NNT for FX006 vs saline-placebo were determined and compared to NNTs reported for IACS.<sup>1,2</sup>

**Results:** FX006 yielded a weighted average SMD (95% CI) of  $-0.51$  ( $-0.72$ ,  $-0.31$ ),  $-0.56$  ( $-0.74$ ,  $-0.36$ ), and  $-0.34$  ( $-0.52$ ,  $-0.14$ ) at 2 weeks, 6 weeks, and 3 months post-treatment, respectively, corresponding to a NNT (95% CI) of 4 (1 to 7), 4 (1 to 6), and 10 (7 to 13) at the corresponding time points (**Figure**). The magnitude of the FX006 effect is favorable compared with that determined for IACS, with a lower NNT (pooled estimate): 4 vs 8 (1–2 weeks), 4 vs 15 (4–6 weeks), and 10 vs infinity (3 months).

**Conclusion:** The two large FX006 studies in the expanded analysis demonstrated effective analgesia through 3 months with reduced NNT compared with traditional IACS. Limitations of the heuristic comparison include small sample sizes, trial heterogeneity, non-placebo controls, and other factors among the comparator trials.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Kellgren-Lawrence [KL] radiographic grading is used to classify knee osteoarthritis (OA), but may not accurately reflect disease progression. Classifying subjects by baseline medial joint space width (mJSW) may be a more specific measure. This hypothesis was assessed in a post-hoc analysis of data from a phase 2, multicenter, 52-week, randomized controlled trial of SM04690, a small molecule Wnt pathway inhibitor in development as a potential disease modifying drug in knee OA.

**Methods:** In the trial, subjects with KL grade 2-3 knee OA were randomized to a single, 2 mL, intra-articular injection of 0.03 mg, 0.07 mg, 0.23 mg SM04690 or placebo (PBO) into their target (most painful) knee at Day 0. WOMAC Pain and Function were assessed at 0, 4, 13, 26, 39 and 52 weeks, with fixed location radiographic assessment of mJSW at Weeks 0, 26 and 52. Exploratory analysis of clinical outcomes in the intention to treat (ITT) population was conducted by analysis of covariance adjusted for baseline mJSW with multiple imputation. This post-hoc analysis examined a group with baseline mJSW of 2-4 mm in comparison to the full ITT population.

**Results:** 455 subjects (mean age 60.3 [ $\pm$ 8.7] years, BMI 29.9 [ $\pm$ 4.6] kg/m<sup>2</sup>, 268 [58.9%] female, 293 [64.4%] KL Grade 3) were enrolled. Contralateral knee KL grade was equal or worse than target knee in 91% of ITT population. 258 subjects had baseline mJSWs of 2-4 mm. At week 52, in the placebo group, imputed mean mJSW change from baseline was -0.14 [SE 0.06] mm. In the ITT population, compared to placebo, imputed mean mJSW changes from baseline were positive for 0.03 mg and 0.07 mg SM04690 doses (**Table, figure**). In the post-hoc analysis of the smaller 2-4mm mJSW subgroup, heterogeneity was similar to ITT for all doses compared to PBO and for the 0.03 mg and 0.07 mg doses changes beyond measurement error ( $>0.13$  mm)<sup>1</sup> were observed. In addition, improvement in WOMAC Function compared to placebo was seen in the 0.07 mg SM04690 group at Week 52 within the mJSW subgroup (change compared to placebo -13.6, 95% CI (-25.5, -1.7), P=0.025).

**Conclusion:** Stricter inclusion criteria for mJSW provided a less heterogenous baseline group, reducing sample size by 42% without increasing standard error. When applied to this dataset, meaningful radiographic changes were demonstrated with 0.03 mg and 0.07 mg SM04690 groups compared to placebo. Future trials of structure modification in knee OA should consider specific mJSW inclusion criteria.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Background/Purpose:** No approved OA therapies reduce pain and slow joint damage. Mouse data suggested that inhibiting IL-1 $\alpha$  and -1 $\beta$  with ABT-981 would reduce pain and slow structural progression in EHOA. This study tested the efficacy and safety of ABT-981 in EHOA.

**Methods:** Subjects with HOA per ACR criteria,  $\geq 3$  inflamed IP joints (tender, swollen, or both), hand pain  $\geq 6$  (scale 0–10), and  $\geq 1$  erosive IP joint on X-ray (Verbruggen-Veys) were randomized to placebo (PBO) or ABT-981 200 mg SC every 2 wk for 26 wk. The primary outcome was AUSCAN hand pain at 16 wk. Subjects had radiographs of both hands and MRI of the index hand at baseline and 26 wk. Both radiographs (Verbruggen-Veys, GUST<sup>TM</sup>, OARSI, Kellgren-Lawrence [KL]) and MRIs (HOAMRIS) were read by 2 independent central readers. A modified intent-to-treat population (ie, randomized and treated) was analyzed. Continuous efficacy endpoints were assessed using ANCOVA models with treatment and country as main factors and baseline measurements as covariates with LOCF imputation for the primary endpoint.

**Results:** Of 131 treated subjects (85% women; mean age 66 y), 61/67 randomized to PBO and 49/64 to ABT-981 completed the study; subject characteristics were well matched. AUSCAN pain was not significantly different vs PBO at wk 16 ( $P=.39$ ; **Table 1, Figure**); X-ray data and other endpoints also were not statistically different vs PBO (**Table 1**). ABT-981 significantly decreased hsCRP, neutrophils, IL-1 $\alpha$ , and IL-1 $\beta$ . Immunogenicity had no impact on ABT-981 pharmacokinetics. Besides injection site reactions and neutropenia, ABT-981 was well tolerated and safety was similar vs PBO, with no serious infections (**Table 2**).

**Conclusion:** Despite adequate pharmacodynamics results, targeting IL-1 may be ineffective in EHOA, as ABT-981 did not improve outcomes.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Background/Purpose:** Non-steroidal anti-inflammatory drugs, e.g., celecoxib, are commonly used for inflammatory conditions, including osteoarthritis (OA), but are associated with adverse effects. Combined glucosamine hydrochloride plus chondroitin sulfate (GH+CS) is commonly used for joint pain and has no known adverse side effects. Evidence from *in vitro*, animal and human studies suggests that GH and CS have anti-inflammatory activity, among other mechanisms of action.

**Methods:** In this study, we evaluated a panel of 20 serum proteins involved in inflammation and other metabolic signaling pathways after treatment with pharmaceutical grade 1500 mg GH + 1200 mg CS daily (n=96) versus 200 mg celecoxib once a day (n=93) in a 6-month randomized, parallel, double-blind trial of knee OA patients. All patients had Kellgren and Lawrence grades 2-3 knee OA and moderate-to-severe pain as defined by Western Ontario and McMaster osteoarthritis index (WOMAC) score  $\geq 301$ ; on a 0-500 scale. We used linear mixed models adjusted for age, sex, body mass index, baseline serum protein values, and rescue medicine use to assess the intervention effects of each treatment arm separately and between treatments. Benjamini-Hochberg FDR ( $q < 0.05$ ) was used to control for multiple testing.

**Results:** When evaluating treatments separately, all serum proteins except WNT16 were lower after treatment with GH+CS, while about half of the proteins increased after celecoxib. IL-6 was statistically significantly reduced (by 9%,  $P=0.001$ ) after GH+CS, and satisfied the FDR threshold of  $q < 0.05$ . There were statistically significant increases for CCL20, CSF3, and WNT16 after celecoxib (by 7%, 9% and 9%, respectively,  $P < 0.05$ ), but these proteins were no longer statistically significant after controlling for multiple testing. There were no statistically significant differences in any proteins when comparing serum protein concentrations at end of treatment between GH+CS and celecoxib.

**Conclusion:** The results of this study demonstrate that GH+CS reduces IL-6, an inflammatory cytokine, but is otherwise comparable to celecoxib with regard to effects on other protein biomarkers.

**Trial registration number:** NCT01425853.

**Table 1.** Protein biomarker effect sizes after 6 month treatment with combined glucosamine and chondroitin (GH+CS) and celecoxib

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Knee osteoarthritis (OA) is characterized by pain, disability and joint deformity due to articular cartilage degradation and bone remodeling. Wnt signaling is involved in these processes. SM04690, a potential disease modifying knee OA drug (DMOAD) is a small molecule, intra-articular Wnt pathway inhibitor. A phase 2, multicenter, 52-week, single-dose, randomized, placebo-controlled (PBO) trial was conducted, and a post-hoc analysis evaluated associations of radiographic changes with changes in pain and function.

**Methods:** Subjects were randomized to receive a 2 mL injection of 0.03 mg, 0.07 mg, 0.23 mg SM04690 or PBO in target (most painful) knees at Week 0. Western Ontario and McMaster Universities Arthritis Index (WOMAC) Pain [0-50] and Function [0-170] were assessed at Weeks 0, 4, 13, 26, 39 and 52 and target knee radiographs taken at Weeks 0, 26 and 52. Joint space narrowing was assessed by analysis of covariance adjusted for baseline medial joint space width (mJSW) with multiple imputation. A unilateral symptomatic knee subgroup was pre-specified and investigator defined by patient history and examination. Logistic regression analysis estimated associations between mJSW changes and pain and function changes for subjects who achieved combined WOMAC Pain and Function improvement of >50% and >20 [scaled to 100] points.

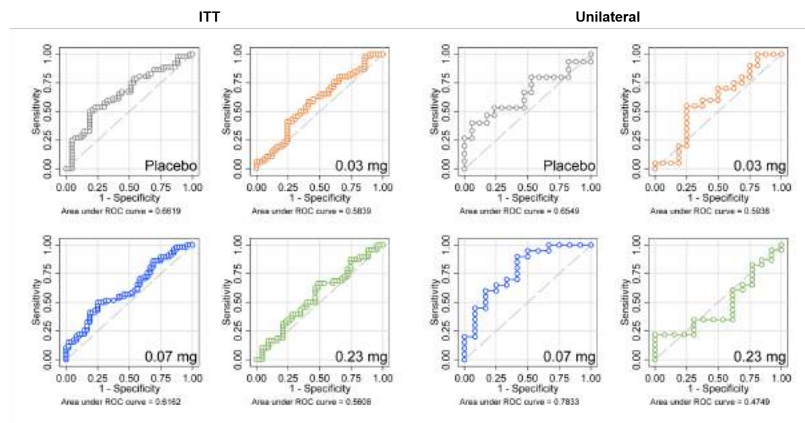

**Results:** 455 subjects were enrolled (mean age 60.3 [±8.7] years, BMI 29.9 [±4.6] kg/m<sup>2</sup>, 268 [58.9%] female, 293 [64.4%] Kellgren-Lawrence (KL) Grade 3, 164 [36.0%] unilateral symptomatic knee OA). Contralateral knee KL grade was equal / worse in 91% of intention to treat (ITT) population. Subjects who achieved a combined WOMAC Pain and Function improvement as defined above were: a) in ITT: 46 (48%) in 0.03 mg, 58 (55%) in 0.07 mg, 48 (53%) in 0.23 mg and 52 (55%) in PBO; and b) in unilateral symptomatic: 20 (56%) in 0.03 mg, 20 (63%) in 0.07 mg, 23 (64%) in 0.23 mg and 15 (47%) in PBO.

At Week 52, in ITT, PBO mean mJSW change was -0.14 [SE 0.06] mm. Mean mJSW changes in dose groups were 0.10 [SE 0.09] mm (0.03 mg), 0.06 [SE 0.09] mm (0.07 mg), and -0.02 [SE 0.09] mm (0.23 mg). In the unilateral symptomatic group, PBO mJSW change was -0.26 [SE 0.11] mm. Mean mJSW changes in dose groups were 0.24 [SE 0.16] mm (0.03 mg), 0.39 [SE 0.17] mm (0.07 mg,  $p=0.02$ ), and -0.04 [SE 0.16] mm (0.23 mg) (**Figure 1**). Logistic regression for ITT showed area under the curve (AUC) > 0.7 was not achieved by any SM04690 dose. In the unilateral symptomatic group, 0.07 mg AUC = 0.78, indicating baseline-adjusted increase in mJSW was concordant with improvement in pain and function (**Figure 2**).

**Conclusion:** Radiographic outcomes from this study demonstrated treatment with SM04690 potentially maintained or increased mJSW compared to PBO. In unilateral symptomatic knee OA 0.07 mg subjects, changes in mJSW were predictive of WOMAC pain and function improvement. These data support potential of SM04690 as a DMOAD for treatment of knee OA.

**Figure 1.** Ladder plots depicting change from baseline in medial joint space width between treatment groups to placebo adjusting for baseline. The x-axis represents change in mJSW of treatment vs. placebo; the long dashed line represents no difference between treatment and placebo, while a minimal clinical important difference is represented by the short dash line. Error bars represent 95% confidence interval.

**Figure 2.** Receiver-Operator Characteristic (ROC) curves depicting prediction of WOMAC Pain and Function response by baseline-adjusted mJSW change.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Previous research in animal osteoarthritis (OA) has shown that low-dose radiation therapy (LD-RT) exerts anti-inflammatory effects, but a systematic review concluded that the evidence for its effectiveness in clinical practice is insufficient. Therefore, we wanted primarily to evaluate the effectiveness of LD-RT on symptoms in knee OA patients. In addition, the effects of LD-RT on inflammatory aspects were examined.

### **Methods:**

Knee OA patients, aged  $\geq 50$  years, fulfilling clinical ACR criteria, with a pain score  $\geq 5$  on a numeric rating scale (0-10), not responding to analgesics and exercise therapy, were included in this triple blinded, sham controlled, randomized clinical trial (RCT). The local Medical Research Ethics Committee, approved the study design (study number 2014-275). Patients were randomly allocated 1:1 to the experimental (6x 1Gy LD-RT in two weeks) or sham (6x 0 Gy in two weeks) intervention.

The primary outcome was the proportion of responders according to the OMERACT-OARSI responder criteria, 3 months post-intervention. Secondary outcomes were changes in inflammatory aspects assessed by both ultrasound (mean synovial effusion and synovial thickness measured at suprapatellar and both medial and lateral parapatellar recesses) and serum inflammatory markers (erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)). Chi squared tests or t-tests were used to compare differences in proportions and differences in changes to continuous variables, respectively.

### **Results:**

Preliminary results enclose the evaluation of 53 patients out of 55 participating patients; 51% was female, mean age 65 years (SD 9) and median body mass index 27 (IQR 24-31) kg/m<sup>2</sup>. A total of 21 out of 53 patients (39.6%) met the OMERACT-OARSI responder criteria at 3 months post-intervention; of whom 10/25 (40%) were assigned to the intervention group and 11/28 (39%) to the sham group. A greater increase in mean synovial thickness in the intervention group than in the sham group was observed (difference intervention minus sham group: 0.07 mm, 95% CI -0.00-0.14). No differences between the two groups in any of the other secondary measures were observed.

### **Conclusion:**

Our preliminary results suggest that LD-RT is not effective in reducing symptoms in knee OA patients and has no impact on inflammatory aspects on the short-term. We therefore suggest not using LD-RT for symptom relief in knee OA.

## Chondroitin Sulfate Reduces Pain and Improves Function in Knee Osteoarthritis Significantly Better Than Placebo, Independently of the Definition of Responders

J-Y Reginster, Bone Cartilage Unit, University of Liege, Liege, Belgium

First publication: September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In addition to the assessment of the two co-primary endpoints – pain and function – regulatory agencies recommend the use of responder rates in percentages as complementary endpoints in order to demonstrate the robustness of the results and their clinical relevance at the level of the individual. Several clinically meaningful responder definitions were in fact proposed by the OMERACT initiative and the OARSI.

**Methods:** The proportion of responders was calculated among the subjects participating in the CONCEPT study, a double-blind, double-dummy Phase III clinical trial in which they received pharmaceutical grade Chondroitin Sulfate (CS) (800 mg/day, during 6 months) or placebo (PL). The following responder definitions were used: pain reduction of 30% vs baseline (moderate pain relief), pain reduction of 40% vs baseline (moderate-to-substantial pain relief), pain reduction of 50% vs baseline (substantial pain relief). Corresponding responder rates were calculated for the decrease in Lequesne index (LI). Moreover, the rates according to the OMERACT-OARSI responder criteria (scenario F) were calculated.

**Results:** 404 of the 604 patients recruited in 5 European countries for the CONCEPT study, suffering from knee osteoarthritis (OA) corresponding to the ACR criteria and belonging to the intention to treat population of the study, were included in the analyses. Of these, 199 were treated with CS and 205 with PL. The remaining 200 patients in the control group with active treatment (celecoxib 200 mg/day) were not considered. The responder rates for pain reduction were consistently higher for the CS group than for the PL group. They were 69% and 61% in the CS and the PL group, respectively, for a pain reduction of 30% vs baseline ( $p=0.098$  between groups, chi-square test), 64% and 52% for a pain reduction of 40% vs baseline ( $p=0.014$ ), and 58% and 40% for a pain reduction of 50 % vs baseline ( $p<0.001$ ). Comparable results were found for the LI. According to the OMERACT-OARSI criteria (scenario F), 66% and 55% of the patients in the CS and the PL group, respectively, were found to be responders after the 6-months of treatment ( $p=0.021$  between groups, chi-square test).

**Conclusion:** Higher percentages of patients with knee osteoarthritis treated continuously for 6 months with 800 mg/day of pharmaceutical grade Chondroitin Sulfate achieved pre-defined levels of pain relief and/or functional improvement as compared to those receiving placebo. The differences in responder rates were both, statistically significant and clinically relevant.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Structural measures of knee OA (KOA) progression include assessment of radiographic joint space width (JSW) and quantitative MRI (qMRI) measurement of cartilage thickness, both of which are endpoints in clinical trials of Disease-modifying Osteoarthritis Drugs (DMOADs). Objectives were 1) to determine if baseline value and 2 year change of medial JSW, and medial and total femorotibial compartment cartilage thickness (MFTC, FTC), are discriminative of the risk of knee replacement (KR); and 2) to evaluate whether these associations differ by sex or Kellgren-Lawrence grade (KLG).

**Methods:** Osteoarthritis Initiative (OAI) knees were selected based on eligibility criteria typical of a DMOAD trials for KOA: KLG of 2 or 3; medial minimum JSW (minJSW)  $\geq 2.5$  mm; knee pain at worst in the past 30 days from 4 to 9 on a 10-point scale, or 0 to 3 if pain medication was taken for joint pain; and availability of structural measures over two years. T-tests were used to look for differences in these measures by KR. Area under the receiver operating characteristic curve (AUC) was estimated for each measure using baseline and 2-year change values, in all patients as well as in male/female and in KLG=2/KLG=3 subgroups, to assess the ability of these measures to discriminate knees that went to future KR.

**Results:** The sample included 627 participants, of which 107 underwent KR, with a median of 6.7 years of follow-up. The 2-year reductions from baseline in all imaging measures were significantly greater in participants who later underwent KR compared with those who did not [Table 1]. Among all participants, the ability of JSW and cartilage thickness to discriminate knees that had future KR was modest (max AUC=0.62); the best discrimination using baseline or 2 year change values was achieved with FTC. Among subgroups, AUCs for 2 year change tended to be numerically higher for males and KLG=2, and pronounced more for fJSW and FTC [Table 2].

**Conclusion:** 2-year changes in all image measures were important in discriminating knees that will undergo KR. Sex and KLG should be considered as factors in discrimination ability.

Table 1. Baseline and 2 Year Change in Imaging Measures

Imaging Measure	Mean (standard deviation)		Mean Difference (95% confidence interval)

## Levels of Serum Biomarkers from a Two-Year Multicentre Trial Are Associated with Treatment Response on Knee Osteoarthritis Cartilage Loss As Assessed By MRI: An Exploratory Study

Johanne Martel-Pelletier<sup>1</sup>, Jean-Pierre Raynauld<sup>1</sup>, François Mineau<sup>1</sup>, François Abram<sup>2</sup>, Patrice Paiement<sup>3</sup>, Philippe Delorme<sup>3</sup> and Jean-Pierre Pelletier<sup>1</sup>, <sup>1</sup>Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, Canada, <sup>2</sup>Medical Imaging Research & Development, ArthroLab Inc., Montreal, QC, Canada, <sup>3</sup>ArthroLab Inc., Montreal, QC, Canada  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is an obvious need to identify biomarkers that could predict patient response to an osteoarthritis (OA) treatment. This post hoc study explored in a 2-year randomized controlled trial in knee OA patients, the likelihood of some serum biomarkers to be associated with a better response to chondroitin sulfate at reducing cartilage volume loss.

**Methods:** Eight biomarkers were studied: hyaluronic acid (HA), C reactive protein (CRP), adiponin, leptin, N-terminal propeptide of collagen IIα (PIIANP), C-terminal crosslinked telopeptide of type I collagen (CTX-1), matrix metalloproteinase-1 (MMP-1), and MMP-3. Patients were treated with chondroitin sulfate (1200 mg/day; n=57) or celecoxib (200 mg/day; n=62). Serum biomarkers were measured at baseline. The cartilage volume at baseline and its loss at 2 years was assessed by quantitative magnetic resonance imaging (MRI). Statistical analysis included ANCOVA.

**Results:** As data from the original MOSAIC trial showed no differences in the lateral compartment between the two treatment groups in cartilage volume and loss in any comparison, only the medial compartment and its subregions were studied. Stratification according to the median biomarker levels was used to discriminate treatment effect. In patients with levels of biomarkers of inflammation (HA, leptin and adiponin) lower than the median, those treated with chondroitin sulfate demonstrated less cartilage volume loss in the medial compartment, condyle and plateau ( $p \leq 0.047$ ). In contrast, chondroitin sulfate treated patients with higher levels of MMP-1 and MMP-3, biomarkers of cartilage catabolism, had less cartilage volume loss in the medial compartment, condyle and plateau ( $p \leq 0.050$ ). Patients with higher levels of PIIANP and CTX-1, biomarkers related to collagen anabolism and bone catabolism, respectively, had reduced cartilage volume loss in the medial condyle ( $p \leq 0.026$ ) in the chondroitin sulfate group.

**Conclusion:** This study provides important and novel information about the association of some serum biomarker levels with cartilage degradation, which could help to identify patients who are most likely to be responsive to a treatment. Moreover, data are suggestive of a potentially greater response to chondroitin sulfate treatment on cartilage volume loss in knee OA patients with low level of inflammation and/or greater level of cartilage catabolism.
