**Methods:** RA patients (ACR 2010 criteria), 18 years old or older, that had a DAS28 ESR > 5.1 in two different occasions separated by at least one month despite the use of at least 3 DMARDs, including methotrexate or leflunomide, for at least 6 months, were included. Patients with any contraindication to use Abatacept were excluded. Information about work status, gender, age, years since diagnosis, comorbidities, and medications used was collected. The patients were followed for 6 months and the DAS28 ESR was measured at baseline and end of follow-up, and the EULAR response criteria was calculated. Changes from baseline to end of follow-up were analyzed using T-test for paired variables or Wilcoxon signed-rank sum test, and associations between variables were assessed using T-test, Mann-Whitney U test and Chi-Squared test or Fisher's exact test, as appropriate

**Results:** 44 patients were included. Baseline characteristics are described in table 1. Of note, 37.2% had a disability pension and the median years with disease were 13 (IQR 7-17). The improvement of DAS28 ESR and its variables was statistically significant (table 2). According to the EULAR response criteria 22.7% of the patients achieved a good response, 52.3% achieved a moderate response and 25% had no response to treatment with Abatacept. 4 of the 10 patients with good response achieved remission (DAS28 ESR <2.6). Gender, age, years since diagnosis, use of Methotrexate or other DMARDs, prednisone or NSAIDs use, comorbidities, tobacco use and basal DAS28 ESR did not influence the response to treatment. No adverse events were reported.

**Conclusion:** In our group of patients, with prolonged disease refractory to treatment with at least 3 DMARDs, 75% achieved at least a moderate response according to the EULAR response criteria without adverse events, but less than one quarter achieved a good response. This probably reflects that in these patients the window of opportunity to initiate a suitable treatment to achieve remission was lost. We believe that it is necessary to allow the inclusion of patients with lower DAS28 among the possible beneficiaries of biological therapy in the public health system of our country.

Table 1. Disease characteristics	
Number of patients	44
Age (mean, SD)	53.9 (10.29)
Female (%)	88.6%
Years since diagnosis (median, IQR)	13 (7-17)
Metothrexate use (%)	77.3%
Sulfasalazine use (%)	52.3%
Hidroxicloroquine use (%)	65.9%
Leflunomide use (%)	50%
Prednisone use (%)	95.5%
NSAIDs use (%)	86.4%
Tramadol use (%)	50%
Work:	
With contract (%)	14%
Independent (%)	7%
Home activities (%)	30.2%
Retirement (%)	11.6%
Disability pension (%)	37.2%
Comorbidities:	
Diabetes (%)	29.5%
Hypertension (%)	58.1%
Dislipidemia (%)	15.9%
Smokers (%)	16.7%
Latent tuberculosis (%)	11.4%
HIV, Hepatitis C or B (%)	0%
Interstitial lung disease (%)	6,8%
Months of follow-up (mean, SD)	6.4 (2.6)

Table 2. Comparison from baseline to end of follow-up			
Characteristics	Basal (44 patients)	Follow-up (44 patients)	P
Tender joints (median, IQR)	12 (10-17)	5 (3-10)	<0.001
Swollen joints (median, IQR)	8 (5-9.5)	2.5 (1-4)	<0.001
VAS for pain (median, IQR)	80 (70-80)	40 (20-60)	<0.001
ESR (median, IQR)	28 (18-40)	19.5 (13.5-28.5)	0.007
DAS28 ESR (mean, SD)	6.11 (0.66)	4.37 (1.25)	<0.001

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is associated with increased mortality. Traditional survival techniques used to identify mortality risk factors, such as the Cox proportional hazards model (CPH), have several limitations, such as reliance on restrictive assumptions. To overcome these limitations, machine learning methods have been developed. Random survival forest (RSF), a non-parametric ensemble tree method, was proposed as an alternative approach to CPH. Our aim is to develop and validate (internally and externally) a predictive model for RA mortality using RSF.

**Methods:** Retrospective longitudinal study involving 2 independent RA cohorts from Madrid (Spain): the Hospital Clínico San Carlos RA Cohort (HCSC-RAC: 1,461 patients diagnosed between 2001 and 2011, followed-up until death or September 2013; used for model development), and the Hospital Universitario de La Princesa Early Arthritis Register Longitudinal study (PEARL: 280 patients diagnosed between 2001 and 2014, followed-up until death or January 2017; used for external validation). Demographic and clinical-related variables collected during the first two years after disease diagnosis were used. RSF models were developed with the *randomForestSRC* R package, based on 1,000 trees. 100 iterations of each model were performed to measure the mean and standard deviation of the prediction error. Based on the predicted mortality estimated by the RSF model, mortality risk groups were established through a survival tree created with the R package *rpart*.

**Results:** 148 and 21 patients from the HCSC-RAC and the PEARL died during a median follow-up time of 4.3 and 5.0 years, respectively. Age at diagnosis, median erythrocyte sedimentation rate, and number of hospital admissions in the first 2 years after RA diagnosis showed the higher predictive capacity. The prediction errors of our model in the training and in the validation cohorts were 0.187, and 0.233, respectively. The survival tree analysis identified 5 risk groups. After combining those three with intermediate risk, we observed that the intermediate and the high risk groups were significantly associated with higher mortality risk compared with the low risk, both in the HCSC-RAC and PEARL cohorts (**Figures 1 and 2**).

**Conclusion:** We developed and externally validated a clinical prediction model for RA mortality using RSF.

**Figure 1:** Kaplan Meier curves for the observed mortality of patients from the HCSC-RAC, grouped in mortality risk categories

**Figure 2:** Kaplan Meier curves for the observed mortality of patients from the PEARL, grouped in mortality risk categories

## Serum Calprotectin Is Not Predictive for Successful Dose Reduction or Discontinuation of TNF Inhibitors in RA Patients with Low Disease Activity

Nathan den Broeder<sup>1</sup>, Lieke Tweehuysen<sup>1</sup>, Noortje van Herwaarden<sup>1</sup>, Thomas Vogl<sup>2</sup>, F.H.J. van den Hoogen<sup>1</sup>, Rogier Thurlings<sup>3</sup> and Alfons A Den Broeder<sup>1</sup>, <sup>1</sup>Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, <sup>2</sup>University of Muenster, Muenster, Germany, <sup>3</sup>Rheumatology, Radboudumc, Nijmegen, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Dose reduction and discontinuation of TNF inhibitors (TNFi) have been shown feasible in a large proportion of RA patients with low disease activity.<sup>1</sup> To date, no predictors for successful dose reduction or discontinuation have been identified.<sup>2</sup> Calprotectin (a heterodimer of S100A8/S100A9) might be a promising biomarker in this context.<sup>3,4</sup>

**Objectives:** To investigate the predictive value of baseline serum calprotectin for successful TNFi dose reduction or discontinuation in RA patients with low disease activity.

**Methods:** Data was derived from the intervention arm of the DRESS (Dose REduction Strategies of Subcutaneous TNFi) study, which showed non-inferiority of a dose reduction strategy of adalimumab or etanercept compared to usual care.<sup>1</sup> TNFi dose interval was reduced stepwise every 3 months until flare (DAS28-CRP increase >1.2 or >0.6 if current DAS28-CRP  $\geq$  3.2) or discontinuation. Patients were classified at 18 months as being successfully dose reduced, discontinued or not able to reduce the TNFi dose. At baseline, quantification of calprotectin was carried out on serum samples using ELISA. Calprotectin levels were compared between each group and receiver-operator-characteristic (ROC) curves were created. In addition, calprotectin was correlated cross-sectionally with several clinical markers for disease activity.

**Results:** Calprotectin levels were available from 102 of 121 patients randomised to the intervention group; 61% were women, 63% received etanercept and 37% received adalimumab. Overall, 46% of patients successfully reduced the TNFi dose, 19% of patients successfully discontinued TNFi and 35% of patients could not reduce the TNFi dose. In these groups, median calprotectin levels were 599 ng/ml (p25-p75: 473-965), 629 ng/mL (p25-p75: 453-896) and 624 ng/mL (p25-p75: 514-931) ( $p=0.801$ ) (Figure 1). The area under the ROC-curve was 0.52 (95% CI: 0.40-0.63) for predicting successful TNFi dose reduction, 0.53 (95% CI: 0.38-0.67) for successful TNFi discontinuation and 0.54 (95% CI: 0.42-0.66) for no dose reduction possible. Calprotectin levels were weakly correlated with C-reactive protein (CRP) levels with a Spearman  $\rho$  of 0.21 ( $p=0.03$ ). No significant correlation was found between calprotectin and age, gender, DAS28-CRP, rheumatoid factor or ACPA positivity.

**Conclusion:** Serum calprotectin is not predictive for successful TNFi dose reduction or discontinuation in RA patients with low disease activity, and calprotectin was only weakly correlated to CRP levels. These results might be caused by the lack of variability in calprotectin levels at baseline as all patients were in low disease activity state.

**Figure 1** Calprotectin levels per outcome

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To date, no clinically useful baseline biomarkers have been found to predict response to TNF inhibitor (TNFi) treatment .<sup>1</sup> Calprotectin was shown to be predictive for treatment response to adalimumab (ADA) while no difference in calprotectin

levels was found between responders and non-responders in RA patients treated with etanercept (ETN) and methotrexate.<sup>2,3</sup>

**Objectives:** To assess the added predictive value of serum calprotectin for clinical response after 6 months treatment with ADA or ETN in RA patients.

**Methods:** RA patients starting treatment with ADA or ETN in the BIO-TOP study (a prospective cohort study) were included. Patients who discontinued TNFi treatment within 2 months were excluded from analysis. Serum calprotectin was measured at baseline using ELISA. EULAR response was measured at 6 months (good versus moderate/no response). Discontinuation of TNFi before 6 months was regarded as non-response (in case of lack of effect) and clinical response at 3 months was carried forward (when stopped for other reasons). First calprotectin levels were correlated cross-sectionally with several clinical baseline markers. Thereafter, receiver-operator-characteristic (ROC) curves were created for ADA and ETN separately. Finally logistic prediction models were created using backward selection, including baseline characteristics and calprotectin levels to examine the added predictive value of calprotectin.

**Results:** Calprotectin levels and EULAR response were available for 125 patients (ADA (n=50), ETN (n=75)), with 40% of patients achieving EULAR good response. Responders showed significantly higher baseline calprotectin levels: 985 ng/mL (p25-p75: 558-1417) versus 645 ng/mL (p25-p75: 415-973) ( $p=0.04$ ). Calprotectin levels were significantly correlated to DAS28-CRP (Spearman  $\rho=0.32$ ,  $p<0.01$ ) and C-reactive protein (CRP) levels (Spearman  $\rho=0.57$ ,  $p<0.01$ ) and significantly higher in rheumatoid factor positive patients ( $p=0.03$ ). No significant correlation was found between calprotectin and age, gender or ACPA positivity. The area under the curve (AUC) for calprotectin in the ADA and ETN group were 0.68 (95% CI: 0.49-0.88) and 0.49 (95% CI: 0.35-0.63), respectively. The basic model (selected variables: baseline DAS28-CRP and medication used (ADA vs ETN)) showed an AUC of 0.73 (95% CI: 0.64-0.82). The calprotectin added model performed similarly with an AUC of 0.76 (95% CI: 0.67-0.84) ( $p=0.27$ ).

**Conclusion:** Serum calprotectin is modestly predictive for EULAR good response to ADA but not ETN treatment after 6 months in RA patients. However, calprotectin does not provide additional predictive value over a basic clinical prediction model.

## Refractory Pain in Spite of Inflammation Control after Start of Anti-TNF Therapy in RA: Observational Data from Southern Sweden

Tor Olofsson<sup>1</sup>, Johan K Wallman<sup>2</sup>, Maria EC Schelin<sup>3</sup>, Anna Jöud<sup>4</sup> and Jon Lampa<sup>5</sup>, <sup>1</sup>Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden, Lund, Sweden, <sup>2</sup>Department of Clinical Sciences Lund, Rheumatology, Lund University, Lund, Sweden, <sup>3</sup>Lund University, Department of Clinical Sciences Lund, Oncology, Lund, Sweden, Lund, Sweden, <sup>4</sup>Lund University, Department of Laboratory Medicine Lund, Division of Occupational and Environmental Medicine, Lund, Sweden, Lund, Sweden, <sup>5</sup>Karolinska Institute, Department of Medicine, Rheumatology Unit, Stockholm, Sweden, Stockholm, Sweden

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pain is a dominant and debilitating feature of RA, but while a lot of focus has been put on the occurrence and management of inflammatory pain, less is reported on pain despite low inflammation. The aim of this study was therefore to investigate the prevalence of refractory pain in spite of inflammation control after start of a first anti-TNF therapy in RA patients and its relation to EULAR treatment response.

**Methods:** RA patients starting a first anti-TNF therapy 2004-2010 were identified in the prospective, observational South Swedish Arthritis Group register (n=1166; 76% women; >95% fulfillment of 1987 ACR criteria) with mean age 56 years and mean disease duration 10 years. Unacceptable pain (>40 mm on a Visual Analogue Scale, VAS; scale 0-100 mm)<sup>1</sup> and unacceptable pain in spite of inflammation control (VAS pain>40 mm combined with CRP<10 mg/L,<sup>2</sup> and ≤1 swollen joint) were assessed 1.5, 3, 6, and 12 months after treatment start. Furthermore, analyses were performed in relation to EULAR treatment response after 3 months (good response, moderate, no). Differences in pain measures between treatment response groups were estimated by logistic regression.

**Results:** At start of first anti-TNF therapy, 79.6% of the RA patients had unacceptable pain (VAS pain>40) which declined to 39.8% after 3 months, and then remained stable during the first treatment year, whereas the frequency of patients with unacceptable pain in spite of inflammation control increased from 4.0% at treatment start to 12.3% after 3 months, and then stabilized (Figure 1). Unacceptable pain at 3 months was strongly related to EULAR response (14.1% of good responders vs. 70.5% of non-responders; p<0.001). In contrast, the frequency of unacceptable pain in spite of inflammation control was largely similar in patients with good response and those with no response (10.9% vs. 14.4%; p=0.23). Among EULAR good responders, unacceptable pain despite inflammation control constituted 78% of all unacceptable pain at 3 months (Figure 2).

**Conclusion:** A substantial proportion of RA patients starting anti-TNF therapy have refractory, unacceptable pain in spite of good inflammation control during the first treatment year. In the present study, this pain status was as common in EULAR good responders as in non-responders. These data are in line with insufficient effects of biologics on a subgroup of patients with inflammation-independent pain, and strongly warrants alternative treatment strategies in these patients.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). We assessed tofacitinib efficacy and safety after temporary discontinuation and reinitiation of therapy in patients (pts) with RA.

**Methods:** Data were from a randomized, parallel-group (grp), controlled, open-label vaccine sub-study in pts with RA participating in a long-term extension study (NCT00413699). Pts were aged  $\geq 18$  years with active RA and had received tofacitinib 10 mg twice daily (BID) for  $\geq 3$  months. The sub-study included 2 treatment (tx) grps: ‘continuous tx’ (tofacitinib 10 mg BID  $\pm$  methotrexate [MTX]) and ‘interrupted tx’ (tofacitinib withdrawn for 2 weeks post-randomization [Day 1–15; Visits 1–3], then tofacitinib 10 mg BID reinitiated  $\pm$  MTX at Visit 3); randomization was stratified by MTX use. All pts received pneumococcal and influenza vaccines on Day 8 (Visit 2; vaccine titers reported previously<sup>1</sup>). Blood samples were taken on Days 8, 15 (Visit 3), and 43 (Visit 4). Efficacy endpoints included change from baseline (CFB) in CRP, HAQ-DI, and DAS28-4(ESR) at each visit. A mixed-effects model with repeated measures was used to evaluate treatment effect at each visit. Efficacy analyses were exploratory, with no multiplicity adjustments.  $P < 0.05$  was considered as statistically significant.

**Results:** Of the 199 pts in this analysis (continuous,  $n=100$ ; interrupted,  $n=99$ ), 117 received concomitant MTX. At study baseline (BL) in the continuous and interrupted grps, respectively: 81.8/83.8% of total pts were white, 84.8/86.9% were female, and mean age was 55.0/53.9 years. CRP, HAQ-DI, and DAS28-4(ESR) BL values were generally similar between groups. At Day 8, mean CRP and DAS28-4(ESR) significantly increased from BL for pts receiving interrupted vs continuous tx; HAQ-DI values were similar between grps (Figure). At Day 15, mean CRP, HAQ-DI, and DAS28-4(ESR) significantly increased from BL for pts receiving interrupted vs continuous tx. After tofacitinib reinitiation for 28 days (Day 43), CFB in CRP, HAQ-DI, and DAS28-4(ESR) were similar between grps and approached BL levels. Adverse events (AEs) were experienced by 35.4% and 49.5% of pts receiving interrupted and continuous tx, respectively. The most frequent treatment-emergent AEs were bronchitis and upper respiratory tract infection (each AE: 6 pts) and vaccination-related immunisation reaction, myalgia, and rash (each AE: 5 pts). Serious AEs occurred in 3 pts (3%) in each grp. In total, 1 pt (1%) in the interrupted grp discontinued due to study drug-related AEs; no pts discontinued due to disease flare.

**Conclusion:** Efficacy of tofacitinib 10 mg BID can be re-established following a temporary (2 weeks) tx discontinuation in pts with RA. Pts receiving continuous tx maintained efficacy throughout the study. Further investigations are required.

## **Efficacy of Monotherapy of the Biologic Dmards in Patients with Rheumatoid Arthritis: Real Life Data from the Hong Kong Biologics Registry**

**Chi Chiu Mok**, Ting Hung Wan and Lai Shan Fong, Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

To report the prevalence and efficacy of biologic DMARD (bDMARD) monotherapy in real life treatment of rheumatoid arthritis (RA).

### **Methods:**

RA patients registered in the Hong Kong Biologics Registry who were receiving bDMARD monotherapy (without concomitant conventional synthetic DMARDs [csDMARDs] except low dose prednisolone) were identified. The efficacy (clinical response and drug retention rate) of bDMARD monotherapy was compared with bDMARD combination therapy (with csDMARDs) using statistical tests.

### **Results:**

From December 2007 to April 2017, 2123 courses of bDMARDs/tsDMARDs were used in 1250 RA patients (83% women, mean age at therapy 53.8±12.7 years). Among 1881 courses of therapies with complete data, 164 (8.7%) was monotherapy at baseline. Low dose prednisolone (<10mg/day) was used in 56% of these courses. In the combination group, the commonest csDMARDs used in combination with bDMARDs were methotrexate (79%), sulphasalazine (27%), hydroxychloroquine (25%) and leflunomide (21%). The bDMARDs/tsDMARDs most frequently used as monotherapy were tofacitinib (14.3%), tocilizumab (11.6%) and abatacept (11.2%). Overall, the non-TNF was more commonly used as monotherapy (11.2%) than the anti-TNF bDMARDs (7.4%). At 6 months of bDMARD/tsDMARD therapy, the DAS remission rate was non-significantly higher in the combination than monotherapy group (11% vs 5%; p=0.42). The change in DAS28 score was also non-significantly greater in the combination group (-1.95±1.26 vs -1.68±1.56; p=0.30). The difference in 6-month efficacy between the combination and monotherapy groups was greater in anti-TNF users. The overall cumulative withdrawal rate of the bDMARDs/tsDMARDs due to either inefficacy or serious adverse events (SAEs) was 0.55 at 3 years and 0.47 at 5 years. The anti-TNF biologics had a significantly higher withdrawal rate than the non-TNF biologics (hazard ratio [HR] 1.83[1.56-3.14]; p<0.001). In Cox regression models, monotherapy of the bDMARDs was not significantly associated with drug withdrawal due to inefficacy (HR 0.95 [0.53-1.71]; p=0.87) or SAEs (HR 1.27 [0.51-3.19]; p=0.61) after adjustment for age, sex, anti-TNF (vs non-TNF) biologic use, previous use of bDMARDs (vs first time use) and DAS28 at baseline. Separate analyses of the anti-TNF and non-TNF biologics again did not reveal a significant relationship between monotherapy of the biologics with the drug withdrawal due to inefficacy or SAEs after adjustment for age, sex, previous use of bDMARDs and disease activity at baseline (HR 1.002 [0.56-1.80]; p=0.99 for anti-TNF and HR 1.20 [0.47-3.08]; p=0.70 for non-TNF biologics, respectively).

### **Conclusion:**

Monotherapy of bDMARD/tsDMARD was used in 8.7% of our RA patients in real life practice, probably due to intolerance, inefficacy or non-compliance to the csDMARDs. Short-term efficacy tended to be better with bDMARDs/csDMARDs combination, especially in the anti-TNF biologics, but the long-term drug retention rate was similar between bDMARD monotherapy and combination therapy with the csDMARDs.

## Serum Levels of the Anti-TNF Biologics Correlate with Clinical Efficacy in Patients with Inflammatory Arthritis

Chi Chiu Mok<sup>1</sup>, Lai Shan Fong<sup>1</sup>, Ling Yin Ho<sup>2</sup> and Chi Hung To<sup>3</sup>, <sup>1</sup>Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, <sup>2</sup>Dept of Medicine, Tuen Mun Hospital, Hong Kong SAR, Hong Kong, <sup>3</sup>Medicine, Pok Oi Hospital, Hong Kong, Hong Kong

First publication: September 18, 2017

### SESSION INFORMATION

Session Date: Sunday, November 5, 2017

Session Title: Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

### Background/Purpose:

To study the correlation between levels of the anti-TNF biologics and clinical efficacy in patients with inflammatory arthritis

### Methods:

Adult patients who fulfilled the criteria for rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PSA) and were commenced on standard dosing regimens of the anti-TNF biologics were recruited. Stored serum samples at baseline, month 6 and 12 were assayed for the trough levels of the biologics ( $\pm$  anti-drug antibodies) retrospectively. Patients were followed longitudinally and efficacy analyses were conducted at 3-month intervals without the knowledge of the drug levels. Biologics would be discontinued from 6 months onwards according to protocol-based improvement criteria for each disease. Clinical efficacy of the anti-TNF biologics was compared among patients with different levels of the drug by statistical analyses.

### Results:

112 patients were studied (58 RA, age  $51.2 \pm 10.9$  years, disease duration  $72.9 \pm 67$  months; 41 SpA, age  $39.1 \pm 9.9$  years, disease duration  $74.3 \pm 81.6$  months; 13 PSA, age  $53.5 \pm 10.7$  years, disease duration  $44.3 \pm 35.4$  years). The number of patients treated with infliximab (IFX), adalimumab (ADM), golimumab (GLM) and etanercept was 3, 31, 36 and 42, respectively. At month 12, neutralizing antibodies against IFX, ADM and GLM were present in 2 (67%), 14 (45%) and 1 (3%) of the patients, respectively. In ADM users, the drug level was significantly lower in those with antibodies than those without ( $1.81 \pm 2.63$  vs  $8.02 \pm 4.14$  ug/ml;  $p < 0.001$ ). Antibody titer against ADM correlated negatively with the levels of ADM (Rho -0.72;  $p < 0.001$ ). Patients were stratified into 3 tertiles for each biologic according to the trough levels of the drugs. Low drug concentrations were defined as levels  $\leq 1.30$  ug/ml, 0.05 ug/ml and 0.60 ug/ml in ADM, ETN and GLM users, respectively. In patients with RA/PSA (N=71), patients with the lowest anti-TNF drug level group (N=30) had a trend of less improvement in DAS28, CDAI scores at month 12 when compared to others (N=41). However, significantly more patients withdrew treatment due to inefficacy at month 12 in this group compared to others (67% vs 7.3%,  $p < 0.001$ ). In patients with SpA (N=41), patients with lowest anti-TNF drug levels stratum (N=9) had significantly less improvement in ASDAS compared with others at month 12 (N=32) ( $-0.57 \pm 0.63$  vs  $-1.93 \pm 1.28$ ;  $p = 0.003$ ). The proportion of patients who achieved an ASAS20 response was also significantly lower in this group of patients (33% vs 75%;  $p = 0.04$ ). In all the 112 patients studied, the cumulative withdrawal rate of the anti-TNF biologics at month 12 (by Kaplan-Meier's analysis) was significantly higher in those with low drug levels when compared to others with higher drug levels (26.1% vs 54.6%;  $p < 0.001$  log rank test).

### Conclusion:

The presence of neutralizing antibodies to the anti-TNF monoclonals is associated with lower trough levels of the drugs. Trough level of the anti-TNF biologics is useful for optimizing the clinical efficacy of the drugs in patients with inflammatory arthritis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Men seem to respond better to antirheumatic treatment than women with RA. In daily practice, expectations towards responsiveness may influence rheumatologists when making treatment choices. We investigated whether male and female RA patients are treated differently and whether they respond differently to treatment in daily clinical practice.

**Methods:** DMARD naive RA patients with symptom duration  $\leq 5$  years,  $\geq 3$  months follow-up, available data regarding medication use and baseline DAS $\geq 1.6$  were selected from the international observational METEOR database. Patients starting biologic DMARD treatment were excluded due to low numbers. Follow-up visits were selected until the first medication switch or the end of follow-up. Missing data were imputed using multiple imputation. Linear mixed model (LMM) analyses were performed to assess whether differences in treatment between men and women lead to differences in DAS or HAQ over time within each treatment group. If an added interaction between gender and treatment was statistically significant ( $p < 0.05$ ), models were stratified for treatment. Analyses were adjusted for potential confounders.

**Results:** Women (n 4393) more often started treatment with HCQ (HCQ monotherapy, MTX + HCQ and HCQ + glucocorticoid, but not more often with MTX + SSZ + HCQ), whereas men (n 1142) more often started treatment with SSZ and/or MTX (SSZ monotherapy, MTX + SSZ and MTX + glucocorticoid, table 1).

Mean (SD) baseline DAS and HAQ for women and men were DAS 3.7 (1.0) vs 3.5 (1.1) and HAQ 1.1 (0.7) vs 1.0 (0.7). LMM analyses showed that in general women improved less on initial treatment over time than men: DAS [ $\beta$  (95% CI) 0.16 (0.12; 0.20)] and HAQ [ $\beta$  (95% CI) 0.13 (0.10; 0.16)]. A statistically significant interaction was only found between female gender and initial HCQ [DAS  $\beta$  (95% CI) -0.17 (-0.33; -0.0045) and HAQ -0.12 (-0.23; -0.0047)] and between female gender and initial MTX + HCQ + SSZ for the outcome HAQ [ $\beta$  (95% CI) -0.19 (-0.38; -0.0048)]. Results were therefore stratified for individual DMARDs and for combination therapy with csDMARDs (table 2). It was found that women had a worse response than men to MTX monotherapy, MTX + HCQ and SSZ + HCQ (for DAS and HAQ) and for SSZ monotherapy and MTX + SSZ (for DAS). For patients using HCQ monotherapy or MTX + HCQ + SSZ there were no gender differences over time.

**Conclusion:** Women more often started treatment with HCQ, as monotherapy or in combination with MTX or a glucocorticoid, whereas men more often started treatment with MTX and/or SSZ. In general women had worse response to treatment than men, but we found no gender differences in response to HCQ monotherapy or to combination of MTX + HCQ + SSZ.

Table 1. Initial treatment of men and women.

	Men (n=1142) N (%)	Women (n=4383) N (%)
csDMARD mono	421 (36.9%)	1804 (41.2%)

MTX + SSZ + GC	26 (22.8%)	111 (24.6%)
MTX + SSZ + HCQ + GC	20 (17.5%)	74 (16.4%)
HCQ + SSZ + GC	13 (11.4%)	32 (7.1%)
MTX + LEF + GC	4 (3.5%)	9 (2.0%)
Other	3 (2.6%)	21 (4.6%)

Table 2. Linear Mixed Model analyses to assess the effect of gender on DAS and HAQ, stratified for baseline csDMARDs in patients starting monotherapy, separate models.

	DAS β (95% CI)	HAQ β (95% CI)
<b>Methotrexate (n patients = 1231, n visits = 5246)</b>		
Female gender (vs male)	0.17 (0.084; 0.26)	0.14 (0.079; 0.20)
<b>Sulfasalazine (n patients = 264, n visits = 924)</b>		
Female gender (vs male)	0.25 (0.10; 0.39)	0.094 (-0.019; 0.21)
<b>Hydroxychloroquine (n patients = 677, n visits = 2050)</b>		
Female gender (vs male)	-0.012 (-0.14; 0.12)	0.015 (-0.078; 0.11)
<b>Methotrexate + Hydroxychloroquine (n patients = 649, n visits = 1983)</b>		
Female gender (vs male)	0.15 (0.0042; 0.29)	0.15 (0.047; 0.24)
<b>Methotrexate + Hydroxychloroquine + Sulfasalazine (n patients = 162, n visits = 385)</b>		
Female gender (vs male)	-0.022 (-0.25; 0.20)	-0.034 (-0.22; 0.16)
<b>Methotrexate + Sulfasalazine (n patients = 262, n visits = 800)</b>		
Female gender (vs male)	0.21 (0.032; 0.38)	0.099 (-0.011; 0.21)
<b>Sulfasalazine + Hydroxychloroquine (n patients = 67, n visits = 190)</b>		
Female gender (vs male)	0.050 (-0.30; 0.40)	0.022 (-0.20; 0.25)

Adjusted for baseline DAS/DAS28/HAQ, symptom duration, first visit year, country and time in follow-up. The interactions between gender and time were non-significant ( $p > 0.05$ ) and were thus removed from the models.

## Impact of Smoking Cessation Advice in Patients with Rheumatoid Arthritis to Help Quit Smoking

Shama Khan<sup>1</sup>, Ahmad Butt<sup>1</sup>, Emmett Brennan<sup>2</sup>, Ausaf Mohammad<sup>1</sup> and Killian O'Rourke<sup>3</sup>, <sup>1</sup>Rheumatology, Midlands Regional Hospital, Tullamore, Ireland, <sup>2</sup>Tullamore, Midlands Regional Hospital, Tullamore, Ireland, <sup>3</sup>Rheumatology, Midlands Regional Hospital, Tullamore, Co Offaly, Ireland

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Smoking is associated with an increased risk of comorbidities in rheumatoid arthritis (RA) and may reduce the efficacy of anti-rheumatic therapies. Smoking cessation is therefore critically important in RA management and may lead to a reduced comorbid burden (1,2). The aim of this pilot study was to investigate whether smoking cessation rates are increased following a smoking cessation advice for people with RA.

### Methods:

We conducted a prospective study of one hundred and eighty RA patients fulfilling the 1987 American College of Rheumatology classification criteria, from October 2016 to March 2017, attending our rheumatology services. Ethics approval was obtained. Information on demographics and cigarette smoking status was collected through patients' interviews and medical notes review. Current smokers were given advice on quitting smoking through face-to-face advice, handout, and nicotine replacement. Subjects were re-interviewed at 6-months to ascertain smoking status. The primary outcome was smoking cessation at 6 months.

### Results:

180 current smokers with RA were included: mean age  $56 \pm 11.9$  years and 76% were females. Overall, 64% of subjects stopped smoking at 6 months, and remainder RA smokers were thinking about quitting. More female subjects quit smoking as compared to males (74% vs. 26%). Those who quit smoking were younger (49 years vs. 57 years), had higher BMI ( $28.7 \pm 3.6$  vs.  $26.7 \pm 3.6$ ), and had aggressive disease, DAS28-CRP ( $4.9 \pm 0.9$  vs.  $2.9 \pm 0.9$ ) ( $P < .05$ ). Subjects who stopped smoking stated “healthy life style” as motivation to quit.

#### Conclusion:

In our study significant proportion of RA patients stopped smoking when given advice on quitting. Smoking cessation advice was very beneficial in motivating them to quit smoking. There should be a structured plan in place to educate RA patients on smoking cessation, both in verbal and written form.

## Repair of Joint Damage Is Rare in Newly Diagnosed Rheumatoid Arthritis Patients and Appears Not to Relate to Previous Suppression of Inflammation

Joy A. van der Pol<sup>1</sup>, Gulsah Akdemir<sup>1</sup>, Marianne van den Broek<sup>1</sup>, Linda Dirven<sup>1</sup>, Pit J.S.M. Kerstens<sup>2</sup>, Willem F. Lems<sup>3</sup>, Iris M. Markusse<sup>1</sup>, Cornelia F Allaart<sup>1</sup> and Tom W.J. Huizinga<sup>1</sup>, <sup>1</sup>Department of Rheumatology, LUMC, Leiden, Netherlands, Leiden, Netherlands, <sup>2</sup>Department of Rheumatology, Reade, Amsterdam, Netherlands, <sup>3</sup>Department of Rheumatology, VU Medical Center, Amsterdam, Netherlands, Amsterdam, Netherlands

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Joint damage in RA is thought to be irreparable. We hypothesized that in patients in whom inflammation is persistently well suppressed, repair may be possible.

**Objectives:** To investigate whether reversal of erosions and joint space narrowing (JSN) in RA occurs and whether clinical variables predict repair.

**Methods:** In the BeSt study, patients with active early RA were randomized to 4 treatment strategies, each with the aim to induce and maintain suppression of disease activity by adjusting medication based on three-monthly calculations of the 44-joint Disease Activity Score (DAS), target  $\leq 2.4$ . Radiographic joint damage was assessed yearly, using the Sharp/van der Heijde score (SHS). In this analysis, 8-years data of the study were used. Repair of erosions or JSN was defined at the individual joint level as a reduction of  $\geq 1$  SHS point compared to the previous available X-ray, present in  $\geq 2$  consecutive visits and with  $\geq 3$  out of 4 independent scorers agreeing. Radiographs were scored in random order per patient, blind for patient identity and treatment arm. Multiple logistic regressions were applied at the patient level for associations between achieving repair and maximum duration of previous remission, mean DAS until repair, previous prednisone use, previous infliximab use, ACPA, gender, age and randomization arm. All models were adjusted for mean joint damage over time in the group with repair. In the group without repair, the models were corrected for mean damage over time until mean time point of repair in the group with repair.

**Results:** Seven out of 508 patients did not have any X-ray images taken in the study. Of the remaining 501 patients, 320 had damage in at least 1 joint and thus could potentially show repair. In total, 2395 X-rays were available, on average 7.5 per patient (range 2-9). Median SHS after 8 years in these patients was 13 (IQR 4-21, range 0.67-255), and mean (SD) DAS from month 3 was 2.00 (0.67). Repair was seen in 17 out of 320 patients, 5.3%; 10 had reduction of JSN, 7 of erosions. In 14 patients repair was seen in 1 joint, in 3 patients repair was seen in 2 joints (same time point). Mean (SD) time to repair was 44.1 (20.1) months. Ten of 17 patients (59%) had previously achieved DAS-remission, compared to 100% of the patients who at a matching time point showed no repair. Adjusted for mean SHS until repair, we found a trend for less repair with longer baseline symptom duration and for less repair in the arm with initial

infliximab. There were no associations with repair for duration of remission, mean DAS until repair, gender, age, presence of ACPA, or previous exposure to prednisone or infliximab (table 1).

**Conclusion:** In this early RA cohort, during 8 years treated to target DAS  $\leq 2.4$ , repair of JSN and erosions was seen in 17 patients (5.3%). Repair does not seem to relate to previous inflammation or other predictors in this cohort.

Table 1. Multiple univariate logistic regression models to investigate associations with repair (n=17)

	OR	95% CI	P
Duration of previous remission*	-	-	-
Symptom duration at baseline (weeks)	0.972	0.95 - 1.00	0.051
Mean DAS from month 3 to time of repair	1.39	0.77 - 2.51	0.270
Previous prednisone	1.09	0.385 - 3.09	0.871
Previous infliximab	0.599	0.206 - 1.74	0.347
ACPA	1.51	0.413 - 5.53	0.533
Gender	1.13	0.401 - 3.16	0.822
Baseline age	1.01	0.975 - 1.05	0.548
Randomization arm			
Sequential monotherapy	ref	-	-
Step-up combination therapy	0.797	0.231 - 2.75	0.721
Initial combination with prednisone	0.597	0.158 - 2.26	0.448
Initial combination with infliximab	0.147	0.0173 - 1.25	0.080

All models were adjusted for mean Sharp/van der Heijde score until repair

DAS: disease activity score, ACPA: anti-citrullinated peptide antibody

\*No results due to 100% remission in non-repair comparator group

## Implementation of a Treat-to-Target Remission Strategy for Rheumatoid Arthritis in Australian Public and Private Rheumatology Clinics – Identification of Clinician and Patient Barriers

**Helen Benham**<sup>1</sup>, Hedva Chiu<sup>2</sup>, Joanne Tesiram<sup>3</sup>, Peter Landsberg<sup>4</sup>, Andrew A. Harrison<sup>5</sup>, Peter Nash<sup>6</sup>, Ranjeny Thomas<sup>7</sup> and Mieke van Driel<sup>8</sup>, <sup>1</sup>The University of Queensland Faculty of Medicine, Brisbane, Australia, <sup>2</sup>The University of Queensland Faculty of Medicine, Woolloongabba, Australia, <sup>3</sup>Rheumatology, Princess Alexandra Hospital, Woolloongabba, Australia, <sup>4</sup>Princess Alexandra Hospital, Woolloongabba, Australia, <sup>5</sup>Department of Medicine, University of Otago Wellington, Wellington, New Zealand, <sup>6</sup>University of Queensland, Brisbane, Australia, <sup>7</sup>Diamantina Institute, Diamantina Institute University of Queensland, Brisbane, Australia, <sup>8</sup>Primary Care Clinical Unit, The University of Queensland Faculty of Medicine, Herston, Australia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treat-to-target in rheumatoid arthritis (RA-T2T) improves outcomes for people living with RA. Implementing T2T in routine clinical practice however presents many challenges and an evidence practice gap has emerged.

**Methods:** Cross-sectional surveys were undertaken in parallel: A survey of RA patients and Australian rheumatologists. Agreement was measured using a 10-point Likert scale for RA-T2T recommendations and 5-point for use in daily practice. Questions related to

willingness to alter practice, education and patient perceptions were included with free-text comments and thematic analysis undertaken.

**Results:** 85 rheumatologists and 107 patients responded. Surveys show the majority of patients have no knowledge of RA-T2T (91%) but report high levels of agreement with the recommendations (8.61 to 9.51). Patients are willing to try a T2T approach (88%) and would be specifically willing to increase blood tests (96%), have joint counts performed (87%) and use a patient-reported-outcome tool (83%). They are less willing to have more frequent appointments (66%) and to spend additional time discussing RA-T2T (69%). 48% of patients feel their RA treatment could be improved and 28% would like to be more involved in treatment decision making. For rheumatologists the mean level of agreement scores ranged from 7.32 to 9.33. Lowest level of agreement was with the recommendation that a disease activity score is required to guide care in routine practice (7.32). 50% of rheumatologists reported they very often/often use a score in daily practice. 44% do not think RA-T2T is necessary for every RA patient. Rheumatologists are willing to schedule more visits (88%), perform joint counts (84%), use a PRO for shared decision-making (76%) and spend time discussing RA-T2T (85%). They are less willing to calculate a disease activity score (64%). Free text identified four thematic barriers to implementation of RA-T2T identified by rheumatologists: time, patient acceptance and adherence to medication change, lack of appointment availability and the lack of a rheumatology nurse in the clinic.

**Conclusion:** RA-T2T is an evidence-based intervention and is recommended for the management of RA. Agreement with some aspects of RA-T2T and uptake in routine clinical practice by Australian rheumatologists is low and the majority of patients are unaware of RA-T2T. Significant clinician and patient barriers exist and an implementation strategy utilizing an electronic and patient-driven knowledge-translation tool, for use at the point of care, is being created and tested for usability in Australian rheumatology clinics.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy and safety of tofacitinib have been shown in patients (pts) with RA in global Phase (P) 2, P3 (one of which included Japanese pts) and a long-term extension (LTE) study and in two P2 and one LTE study in Japanese pts. We evaluated safety of tofacitinib following drug approval in Japanese pts with RA using all-case post-marketing surveillance (PMS) data.

**Methods:** PMS is a regulatory requirement in Japan; an interim analysis of safety data from an ongoing 3-year PMS study was conducted (4 Mar 2017 data-cut). All Japanese pts with RA receiving tofacitinib were consecutively and prospectively registered in the PMS study and were monitored. Follow-up surveillance after discontinuation of tofacitinib was implemented for 3 years for all adverse events (AEs) from the date of treatment initiation with tofacitinib. A 6-month interim analysis of all AEs and serious AEs (SAEs) was conducted. For AEs of special interest, all-period data was used to calculate cumulative incidence rates (IRs) over time (IRs: pts with

events /100 pt-years [pt-yrs]) for herpes zoster (HZ) and serious infection events (SIEs) during treatment +28 days, and for malignancies during the observational period.

**Results:** Overall, 2882 tofacitinib-treated pts were enrolled and included in the 6-month interim safety analysis: 79.9% were female, mean age 62.6 yrs, with 32.0% pts  $\geq 70$  yrs and 1241.4 pt-yrs of exposure. Of these, 686 pts (23.8%) discontinued treatment, mainly due to AEs (276 pts; 9.6%) or lack of effectiveness (260 pts; 9.0%; multiple reasons allowed). At least one AE was observed in 965 pts (33.5%); infections were observed in 367 pts (12.7%); the most frequent AEs were HZ (98 pts; 3.4%) and hepatic function abnormal (48 pts; 1.7%). SAEs occurred in 221 pts (7.7%); the most frequent SAEs were pneumonia (20 pts; 0.7%), HZ (16 pts; 0.6%), interstitial lung disease (14 pts; 0.5%) and condition aggravated (12 pts; 0.4%); serious infections occurred in 101 pts (3.5%). Malignancy (all causality) was reported in 21 pts (0.7%); ovarian cancer, pancreatic carcinoma, lung neoplasm, colon cancer, breast cancer, diffuse large B-cell lymphoma and lymphoproliferative disorder all occurred in 2 pts (0.07%) each. There were 16 deaths (0.6%) during the 6-month observed period; the most common causes of death (including pts with multiple causes listed) were infection (5 cases, all respiratory infections), malignancy (4 cases) and interstitial lung disease (3 cases). For AEs of special interest from all-period data during treatment +28 days, the IR of HZ (serious and non-serious) was 6.43/100 pt-yrs (160 pts; 2489.5 pt-yrs) and SIEs 5.96/100 pt-yrs (150 pts; 2517.0 pt-yrs), and during the observational period IR malignancy was 1.39/100 pt-yrs (42 pts; 3014.1 pt-yrs).

**Conclusion:** For this interim analysis, AEs during the initial 6-month treatment period from PMS reports of tofacitinib in Japanese pts did not reveal any new or unexpected safety signals vs the tofacitinib RA clinical program. Final results from this PMS study are awaited in order to make definitive conclusions on the safety profile of tofacitinib in these pts.

## ACPA and RF as Predictors of Sustained Clinical Remission in Rheumatoid Arthritis Patients: Data From a Rheumatoid Arthritis Cohort

**Background/Purpose:** Positive serology for anti-citrullinated protein antibody (ACPA) and rheumatoid factor (RF) are included among the criteria for definitive RA diagnosis as per the 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA). Previous studies have shown that autoantibodies are positive predictors of response in rheumatoid arthritis (RA) patients treated with some biologics. The purpose of this study was to evaluate the interaction of RF and ACPA in predicting sustained clinical response in a large observational cohort of RA patients followed in routine clinical care. **Methods:** RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) registry, with active disease ( $\geq 1$  swollen joint), available autoantibody information, and at least 1 follow-up assessment were included in the analysis. Sustained clinical remission was defined as CDAI  $\leq 2.8$  in at least 2 sequential visits separated by at least 3 and maximum of 12 months. Time to sustained remission was assessed with Kaplan-Meier survival analysis and multivariate cox regression. **Results:** A total of 970 patients were included in the analysis, of whom 262 (27%) were anti-CCP<sup>neg</sup>/RF<sup>neg</sup>, 60 (6.2%) anti-CCP<sup>pos</sup>/RF<sup>neg</sup>, 117 (12.1%) anti-CCP<sup>neg</sup>/RF<sup>pos</sup>, and 531 (54.7%) anti-CCP<sup>pos</sup>/RF<sup>pos</sup>. At baseline, significant differences were observed between groups in age ( $p=0.02$ ), CDAI ( $p=0.03$ ), tender joint count ( $p=0.02$ ), and HAQ ( $p=0.002$ ), with anti-CCP<sup>pos</sup>/RF<sup>pos</sup> and anti-CCP<sup>pos</sup>/RF<sup>neg</sup> patients being youngest and having the lowest disease activity and disability. No differences were observed in terms of biologic use which occurred in 15.9% of patients. Sustained remission was achieved by 43.5% of anti-CCP<sup>pos</sup>/RF<sup>pos</sup> patients, 43.3% of anti-CCP<sup>pos</sup>/RF<sup>neg</sup> patients, 31.6% of anti-CCP<sup>neg</sup>/RF<sup>pos</sup> patients and 32.4% of anti-CCP<sup>neg</sup>/RF<sup>neg</sup> patients ( $p=0.01$ ). Significant (for RF, borderline non-significant) differences were observed in the time to achieving sustained clinical response based on anti-CCP status ( $p<0.001$ ), RF status ( $p=0.06$ ), and both ( $p=0.004$ ) (Figure 1). Multivariate cox regression adjusting for baseline CDAI score, age and sex also showed differences between groups which reached statistical significance in anti-CCP<sup>pos</sup>/RF<sup>pos</sup> vs. anti-CCP<sup>neg</sup>/RF<sup>neg</sup> patients (HR [95%CI]: 1.30 [1.01-1.67];  $p=0.03$ ). **Conclusion:** These results suggest that anti-CCP but not RF positivity may be associated with improved response to anti-rheumatic medications in RA patients.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biologic therapy for the treatment of RA has increased dramatically and has substantially increased costs of care. This study aimed to identify factors associated with initiation of biologic use, including previous methotrexate (MTX) adherence and dose.

**Methods:** We used U.S. Veteran's Affairs administrative databases to identify RA patients receiving a first-ever prescription of MTX between 2005 and 2014 with at least 6 months of prior baseline data. Patients with prior biologic therapy use or those initiating biologic therapy within 30 days of starting MTX were excluded. Multivariable Cox analysis assessed factors associated with biologic therapy initiation within 2 years of MTX start, censoring at death. To assess impact of MTX adherence and dose on biologic use, we examined a subset of patients who received MTX continuously for at least 6 months with no biologic initiation during this time. In this population we evaluated associations between PDC (proportion of days covered) in the first 6 months and MTX dose at 6 months with subsequent biologic initiation.

**Results:** 17,634 patients met inclusion criteria contributing 29,350 person years of follow-up. 3,263 initiated biologic therapy within 2 years (incidence 11.1%/year). CCP positivity, later calendar year, and concurrent use of glucocorticoids, leflunomide, or sulfasalazine were associated with a greater likelihood of biologic initiation (Table 1). Factors associated with a lower rate of biologic initiation included advancing age, non-white race, greater comorbidity (Charlson score), congestive heart failure, and malignancy (Table 1, Figure 1). Among the smaller cohort of 9,851 patients remaining on methotrexate continuously for 6 months, methotrexate adherence (PDC  $\geq 0.8$ ) was not associated with likelihood of subsequent biologic initiation [aHR 1.00 (0.89-1.13),  $p = 0.94$ ]. Higher methotrexate dose was associated with greater likelihood of initiating biologic therapy (Table 2).

**Conclusion:** Biologic therapy is initiated less frequently in elderly patients and those with comorbidities, possibly reflecting safety concerns. Future studies should evaluate whether these concerns lead to under-treatment of these populations. Surprisingly, low methotrexate adherence and dose were not associated with increased biologic use; the impact of reduced methotrexate effectiveness could be masked by differences in disease severity, follow-up, or medication preferences in these patients.

**Table 1:** Multivariable model evaluating factors associated with subsequent use of biologic therapy in patients starting methotrexate

## Factors Associated with Treatment Adherence in Rheumatoid Arthritis: A Systematic Literature Review

Ee Teng Goh<sup>1</sup>, Alvin Jian Xiong Soo<sup>1</sup>, James Galloway<sup>2</sup>, Sam Norton<sup>3</sup> and Elena Nikiphorou<sup>4</sup>, <sup>1</sup>UCL Medical School, University College London, London, United Kingdom, <sup>2</sup>King's College, and King's College Hospital, London, United Kingdom, <sup>3</sup>Academic Rheumatology, King's College London, London, United Kingdom, <sup>4</sup>Academic Rheumatology Department, King's College London, London, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nonadherence to treatment in rheumatoid arthritis (RA) has been shown to negatively impact on treat to target goals and disease outcomes. Identifying and targeting potential factors influencing nonadherence is therefore crucial in optimising patient management. This review aims to determine factors associated with nonadherence in patients with RA.

**Methods:** An electronic search was performed by two independent reviewers using MEDLINE and focusing on articles published from inception to January 2017. The search strategy combined the thesaurus (MeSH) and expanded keyword searches of two concepts: RA and treatment adherence. Inclusion criteria included observational studies and clinical trials examining potential factors associated with nonadherence. Exclusion criteria included articles not in English or without online access and those with a focus on forms of therapy other than medication. Agreement between raters at the screening stage was high (94.6%, kappa=.88).

**Results:** The primary search yielded 1411 papers, from which 70 were eventually identified as suitable for full review (Figure). Of the 70 papers, 62 were based on observational studies and eight on clinical trials. Factors associated with nonadherence were broadly categorized into patient-related factors (demographics, socioeconomic factors, patient perceptions[beliefs/knowledge/attitudes]), disease-related factors (disease duration, disease activity, comorbidities, functional disability) and treatment-related factors (drug type, method of administration, concurrent treatment, side effects, cost). Many studies (74.3%) looking at beliefs, attitudes and patient knowledge reported significant associations between these factors and nonadherence. Adherence was found to be positively associated with stronger beliefs in the necessity of treatment, positive outlooks on disease control and medication, greater knowledge as well as greater self-efficacy. Studies reported greater comorbidities (n=8) including poorer mental health (n=5) to be implicated in nonadherence. Disease duration was largely non-significant in treatment adherence, although a few studies reported a negative correlation (n=3). The use of biologics was significantly associated with greater adherence. One study identified polypharmacy to be negatively associated with adherence. Drug side effects were associated with nonadherence (n=3).

**Conclusion:** Patient-related factors including personal perceptions were among key contributors to nonadherence to medication in RA patients. This highlights the need for addressing patient-driven perceptions, along with disease and treatment related factors as part of individualised patient care, to minimise the risk of nonadherence.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

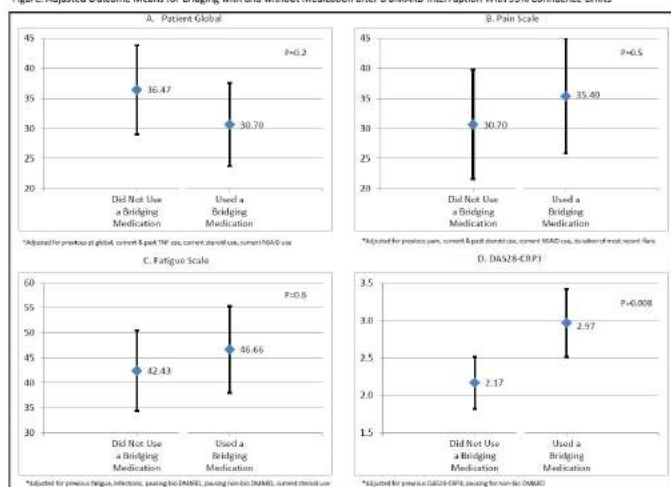

**Background/Purpose:** It is common for RA patients to interrupt their DMARD use due to events like infection, surgery, or pregnancy. Many RA patients may need to manage their symptoms during these times. Little is known about the characteristics of patients who have a break in their DMARD regimen and whether the use of a bridging medication produces better clinical and patient reported outcomes.

**Methods:** Clinical and patient reported data were collected from a prospective RA cohort. Data included whether patients reported DMARD interruption for any duration of time in the past 6 months and if they used a bridging medication (corticosteroid and/or NSAID) during the DMARD break. All data were collected at the time of survey. The outcomes (VAS Pain, fatigue, and patient global) were also collected at a study visit approximately 6 months prior and DAS28-CRP3 collected approximately 1 year prior. In univariate analyses, clinical and demographic characteristics of patients who had a DMARD interruption and used of a bridging medication were compared to patients who did not use of a bridging medication. The outcomes were evaluated in stepwise multiple linear regression models, adjusting for potential covariates of univariate significance ( $p < 0.15$ ) to assess the impact of a bridging medication (Figure).

**Results:** The study surveyed 503 RA patients, of which 112 (22%) reported a DMARD interruption in the last 6 months. Patients who reported a DMARD interruption had a median age of 59 (IQR 49.5, 68), were 85% female, and had median disease duration of 15 years (IQR 9, 25). Patients who used a bridging medication during a DMARD interruption ( $n=39$ ) had higher disease activity ( $p=0.0002$ ), fatigue ( $p=0.03$ ), and pain ( $p<0.001$ ) at the time of the survey compared to patients who did not use a bridging medication. In the final stepwise regression models evaluating the outcomes, comparing patients who did versus did not use a bridging medication, pain, fatigue, and patient global were no better with a bridging medication even after adjustment for baseline outcome severity (Figure). Use of a bridging medication was associated with a worse DAS28-CRP3 ( $p=0.008$ ) after adjusting for covariates and baseline DAS28-CRP3 level (Figure).

**Conclusion:** In this study, nearly one quarter of RA patients reported an interruption of their DMARD regimen in the past 6 months and one third used an NSAID and/or corticosteroid to manage their symptoms during the break. Use of a bridging medication was not associated with better patient reported outcomes and patients had worse disease activity after the break. Better treatments for patients who need to manage symptoms during a DMARD interruption may be warranted.

Figure: Adjusted Outcome Means for Bridging with and without Medication after a DMARD Interruption With 95% Confidence Limits

## Baseline Anemia As a Predictor of Radiographic Progression in Tofacitinib-Treated Rheumatoid Arthritis Patients: Post Hoc Analyses from Two Phase 3 Trials

Burkhard Moeller<sup>1</sup>, Axel Finckh<sup>2</sup>, Godehard Scholz<sup>1</sup>, Harry Shi<sup>3</sup>, Carol A Connell<sup>4</sup> and Sander Strengtholt<sup>5</sup>, <sup>1</sup>Department for Rheumatology, Immunology and Allergology, University Hospital of Bern, Bern, Switzerland, <sup>2</sup>University Hospital of Geneva, Geneva, Switzerland, <sup>3</sup>Pfizer Inc, Collegeville, PA, <sup>4</sup>Pfizer Inc, Groton, CT, <sup>5</sup>Pfizer Inc, Capelle aan den IJssel, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anemia in patients with rheumatoid arthritis (RA) can help to identify those with more rapid erosive disease.<sup>1,2</sup> Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. In this post hoc analysis, we explored whether anemia was a predictor of radiographic progression in patients with RA who were treated with tofacitinib.

**Methods:** Data were from two 24-month, Phase 3 randomized controlled trials in methotrexate (MTX)-naïve (ORAL Start [NCT01039688]) or MTX-inadequate responder (IR) patients (ORAL Scan [NCT00847613]). Patients received either tofacitinib 5 or 10 mg twice daily (as monotherapy or with background MTX), placebo or MTX. Radiographic progression was evaluated by modified Total Sharp Score (mTSS) at baseline (BL), Month (M)6, M12, and M24. Anemia was defined as lower normal hemoglobin limits of 12 g/dL for women or 13 g/dL for men. We used a linear mixed model with repeated measure analysis to analyze the impact of BL anemia on change in radiographic joint damage ( $\Delta$ mTSS), adjusting for treatment, age, gender, disease duration, and BL mTSS, autoantibody status, DAS28, corticosteroid, and non-steroidal anti-inflammatory drug (NSAID) use. Analyses were performed on observed data without linear extrapolation on missing data.

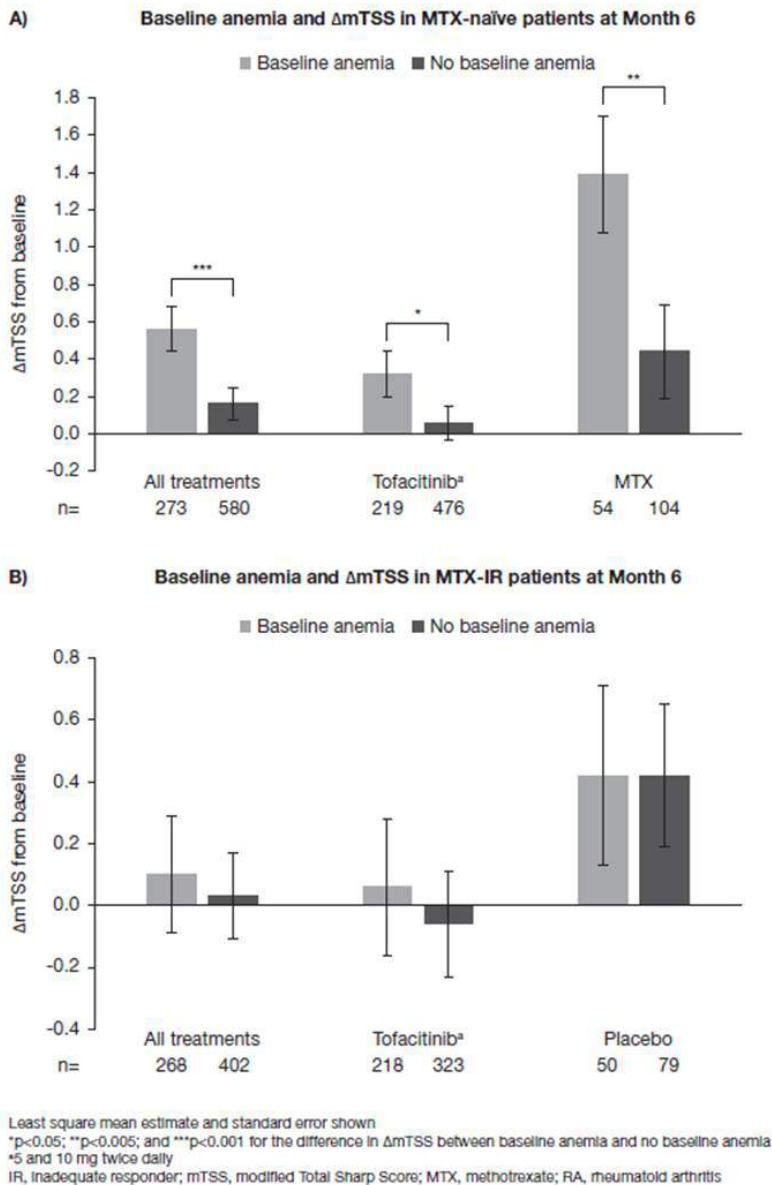

**Results:** Anemia was present at BL in 312/956 MTX-naïve patients (32.6%), RA duration ranged from 2.7–3.4 (mean) and from 0.7–0.8 (median) years, and in 321/797 MTX-IR patients (40.3%), RA duration ranged from 8.9–9.2 (mean) and from 6.0–7.7 (median) years. In MTX-naïve patients, anemia at BL was significantly associated with additional  $\Delta$ mTSS from BL to M6 only (difference in  $\Delta$ mTSS with and without BL anemia = 0.40;  $p<0.001$ ) and increased  $\Delta$ mTSS was also observed at M6 for patients receiving tofacitinib (0.25;  $p<0.05$ ) or MTX monotherapy (0.95;  $p<0.005$ ) (Figure 1A). There were no differences in  $\Delta$ mTSS observed at M12 or M24 for either treatment group according to anemia status (data not shown). No associations between BL anemia and  $\Delta$ mTSS were observed for MTX-IR patients overall or in either treatment group at M6 (Figure 1B), M12, or M24.

**Conclusion:** BL anemia was associated with radiographic progression at M6 in MTX-naïve patients, regardless of treatment received (tofacitinib or MTX monotherapy) but not at later time points (M12/M24). These data support the evidence that anemia at BL is a predictive parameter for joint damage progression in MTX-naïve patients, at least up to M6.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Timely recruitment of patients into interventional trials is necessary for their successful completion. The aim of this study was to evaluate recruitment rates of interventional trials in RA with clinical centers in the United States (US).

**Methods:** We searched the ClinicalTrials.gov registry in May 2017 to identify trials in RA. Inclusion criteria were: phase 3 trials, starting enrollment in 2005 to 2016, adult RA patients, at least one center in the US, an intervention to modify RA activity, and a clinical evaluation (DAS28, ACR20, or other) as the primary endpoint. Exclusion factors were: if patients with other diseases were included, trials carried out only in specific RA subgroups, trials terminated early, trials which had not completed enrollment, and trials with insufficient data to calculate the recruitment rate. The recruitment rate was defined as the average number of patients enrolled per center per month during the recruitment period, with the recruitment period defined as the time between enrollment start date and date of enrollment of the last patient. As the registry only provides the “Primary Completion Date”, this was used as the proxy for date of enrollment of the last patient. Recruitment rate and other trial characteristics were compared in two calendar year periods (2005-2010 and 2011-2016) using the Wilcoxon rank sum test and chi-square test. Negative binomial regression was used to evaluate the relationship between the percent of US centers and recruitment rate.

**Results:** 179 trials were identified using our search strategy. 111 trials were excluded: 35 included other diseases, 24 did not complete recruitment (6 were terminated because low enrollment or sponsor decision), 40 did not use a clinical evaluation primary endpoint, and 12 started enrollment before 2005 or after 2016. Besides, 1 trial was excluded due to inconsistency on reported data. The ACR20 criteria was the most widely used outcome measure (70%). Most trials evaluated efficacy of biological therapies (97%), and only 2 evaluated efficacy of non-biological drugs. 8 trials (12%) assessed the efficacy of biosimilars. All trials but one were industry sponsored. Number of recruitment centers increased more than 25% in the second period (117 [77–154] vs 148 [111–186];  $P = 0.058$ ). Conversely, percent of US centers slightly decreased in the same period (35% vs 31%;  $P = 0.492$ ). The recruitment rate per center per month was lower in the most recent time period (0.11 [0.08–0.16] vs 0.08 [0.05–0.11];  $P = 0.02$ ). Percentage of US centers was not related to recruitment rate ( $P = 0.295$ ) in regression analysis.

**Conclusion:** The recruitment rate per center has decreased in recent years, accompanied by a non-significant rise in the number of centers per trial. While US-based trials remain feasible, understanding the reasons for declining enrollment trends is needed to improve the efficiency and performance of RA trials.

*Table 1. Main characteristics of all 67 studies and by calendar year periods (2005-2010 and 2011-2016)*

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The multi-biomarker disease activity (MBDA) test uses a validated algorithm with 12 serum protein biomarkers to assess disease activity in patients with RA. The MBDA score has previously been found to be a predictor of risk for radiographic progression (RP). We evaluated data from 6 cohorts and performed a meta-analysis to collectively establish the relationship between the MBDA score and risk for RP.

**Methods:** Clinical, MBDA score and radiographic data were analyzed for 6 cohorts with N>100: Leiden, SWEFOT Year 1, SWEFOT Year 2, OPERA Year 1, and AMPLE Year 1 (abatacept and adalimumab arms). Analyses used data on file when published data were not available (ie, for Leiden and for OPERA CRP analyses). Frequency of RP over 1 year was determined by category of MBDA score (low, moderate, high on a scale of 1–100) at the start of the year, as reported for 4 cohorts and at the end of the year as reported for the 2 AMPLE cohorts. RP was defined using the threshold for change in modified total Sharp score ( $\Delta$ mTSS) specific to each study (2 to >5 TSS units). Positive and negative predictive values (PPV and NPV) were determined for each study by comparing patients with high MBDA score (>44), DAS28-(ESR/CRP) (>5.1 or >4.09) or CRP (>3 mg/dL) vs those in a low/moderate category. Relative risk (RR)

for RP was determined for each study. RR values were integrated in a meta-analysis that included only the 3 non-overlapping cohorts that had reported radiographic analyses using MBDA scores at the start of the year. **Results** of published multivariate analyses and analyses that combined MBDA score with other risk factors for RP were summarized.

**Results:** The 6 study cohorts included patients receiving csDMARDs alone or with a biologic. Overall rates of RP were 10–26%. In each study, RP was most frequent among patients with a high vs low/medium MBDA score (>44 vs ≤44). For high MBDA scores, NPVs were 93–97% and PPVs were 18–32%, with RR values of 3.6–9.5 (P=0.002 to <0.0001) (Figure). In a meta-analysis of the Leiden, SWEFOT Year 1 and OPERA Year 1 cohorts, RR was 5.1 (P<0.0001) for MBDA categories, and 1.4 (P=0.23) and 1.6 (P=0.01) for categories of DAS28-CRP or CRP, respectively. Published multivariate analyses in the Leiden and SWEFOT Year 1 cohorts showed MBDA score was an independent predictor of RP after accounting for the effect of other predictors. In the Leiden cohort, MBDA score was the strongest predictor and high MBDA score discriminated between high and low risk for RP among patients with high SJC (>5) or high DAS28-CRP, with PPV as high as 57%.

**Conclusion:** High MBDA scores were associated with increased risk for RP in 6 study cohorts, including patients treated with csDMARDs, TNFi and abatacept. Based on high NPVs (≥93%), the MBDA score used alone had clinical value for identifying patients with little or no risk of RP. Combining the MBDA score with clinical measures yielded PPVs approaching 60%, suggesting that biomarkers can help stratify patients by their risk for RP.

Association between radiographic progression (RP) and high MBDA score (>44) in 6 cohorts and a meta-analysis							
Cohort	N	RP cutoff	Overall % RP	PPV for MBDA >44	NPV for MBDA >44	Relative Risk <sup>a</sup> (95% CI)	P-value <sup>b</sup>
Leiden	163	>5.0	17%	31%	93%	4.3 (1.9, 9.5)	<0.0001
OPERA (Year 1)	164	≥2.0	26%	31%	97%	9.5 (1.4, 66.3)	0.0009

## Analysis of Rheumatoid Arthritis Patients That Did Not Achieve the Treatment Goal By the Treat-to-Target Strategy in Daily Practice

**Hideshi Yamazaki** and Tetsuo Takanashi, Center for Rheumatic Disease, Marunouchi Hospital, Matsumoto, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although the goal of rheumatoid arthritis (RA) treatment is to achieve remission or low disease activity with the treat-to-target (T2T) strategy, some patients do not achieve the goal in daily clinical practice. This study was performed to determine the reasons why these patients do not achieve the treatment goal.

**Methods:** A total of 504 patients with RA that were treated with the T2T strategy using electronic medical record system in 2014 – 2015 were investigated retrospectively. The patients had an average age of 63.7 years, and average disease duration of 15.9 years. A total of 144 patients were evaluated with moderate or high disease activity according to the simple disease activity index (SDAI) in 2014. After 1 year, 84 patients achieved the treatment goal, i.e., remission or low disease activity, while 60 patients still showed more than moderate disease activity and did not achieve the goal. In these patients, each item of SDAI, patient background, and treatment content were investigated.

**Results:**

In 2014, the patients that did not achieve the treatment goal in 2015 had significantly higher age, disease activity, tender joint count, patient global assessment, and HAQ-DI than the patients that did achieve the goal. In the patients that achieved the goal, all items of SDAI were significantly improved. In the patients that did not achieve the goal, swollen joint count and physician global assessment were significantly improved. As disease activity did not decrease, 21 patients were considered to have been treated insufficiently with the T2T strategy. Twenty-one patients had joint pain without arthritis. Eighteen patients were not treated sufficiently for complications, including six elderly patients, respiratory complications in eight patients, and others.

**Conclusion:**

Although the treatment goal of the T2T strategy in RA is remission or low disease activity, this goal is often not achieved in daily clinical practice. The patients that do not achieve the goal have higher disease activity or are not treated sufficiently with complications. It may be possible for these patients to achieve the goal by refining the treatment strategy or providing palliative treatment for pain. Additional T2T is necessary.

## **Rheumatoid Arthritis Patient's Journey: Delay in Diagnosis and Treatment**

Aurelia Luissi<sup>1</sup>, Florencia Pierini<sup>1</sup>, Maria Victoria Garcia<sup>1</sup>, Mirtha Sabelli<sup>1</sup>, Marina Scolnik<sup>1</sup>, Santiago Ruta<sup>1</sup>, Javier Rosa<sup>1</sup> and Enrique R Soriano<sup>2</sup>, <sup>1</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina, <sup>2</sup>Argentina, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** there is a wide variation in the time elapsed between first symptoms and diagnosis of RA, ranging from 1 month to 10 years in different studies; data from Latin America populations are scarce.

**Objective:** to establish the lag times between articular symptoms onset and first rheumatologist consultation, Rheumatoid Arthritis (RA) diagnosis and treatment with disease-modifying antirheumatic drugs (DMARDs), and to assess the impact of delay on radiologic structural damage.

**Methods:** electronic Medical Records of a cohort of RA adult patients, attending a Private Health Care System (PHCS) between 01/01/1996 and 31/12/2016, were retrospectively reviewed. Clinical and demographic data, and dates of first disease symptoms, diagnosis of RA and starting treatment with DMARDs were obtained. Physical function was assessed by Health Assessment

Questionnaire (HAQ). Radiologic structural damage was assessed by Sharp score modified by van der Heijde (SvdH score). For the logistic multivariable analysis, radiologic structural damage was defined as the presence of any value greater than 0 on SvdH score.

**Results:** 246 patients (81% female), with a mean age of 67.25 (SD:14.53) years, were included. Rheumatoid factor was positive in 82.5% and anti-citrullinated peptide antibodies in 91% of patients.

At the end of follow-up (mean: 7 years, SD: 3.8), median HAQ and SvdH were 0.125 (IQR: 0-0.87) and 15 (IQR: 6-33), respectively. Mean lag time between first disease symptom and rheumatologist consultation was 9.2 months [(SD:20) (median: 3 months)], mean lag time to RA diagnosis was 14.2 months [(SD: 24) (median: 4.8 months)] and was 16.9 months [(SD: 25.4) (median: 7 months)] for starting treatment with DMARDs (Table).

**Table.** Delay times in consultations, diagnosis and treatment with DMARDs in RA patients.

	Mean	Median
	(SD)	(IQR)
Time elapsed from the beginning of symptoms to first health professional consultation (months)	8.5 (21.6)	1.8 (0.6-5.1)
Time elapsed from the beginning of symptoms to first rheumatologist consultation (months)	9.2 (20.5)	3 (1.2-7.1)
Time elapsed from the beginning of symptoms to RA diagnosis (months)	14.2 (24)	4.8 (2.4-13)
Time elapsed from the beginning of symptoms to starting DMARDs therapy (months).	16.9 (25.4)	7 (3-17)

More radiologic structural damage was observed in patients with more than 12 months delayed diagnosis of RA (mean SvdH score: 30.9 vs. 21.3,  $p = 0.0325$ ). The presence of radiologic structural damage was associated with more than 12 months delayed diagnosis in logistic multivariable analysis (OR: 1.7 CI 95% 1.3-4.9,  $p=0.04$ ).

**Conclusion:** in this cohort of RA patients from a PHCS there was a significant delay to achieve RA diagnosis and starting DMARDs therapy. A delay greater than 12 months was associated with radiologic structural damage during the follow-up period.

## Social Media Based, Direct-to-Patient Study Designed for Development of “from Home” Testing for Rheumatoid Arthritis Patients Is Feasible and Engaged Individuals with Distinct Clinical Characteristics

Kristen Warren<sup>1</sup>, Olga Derbeneva<sup>1</sup>, Francisco Flores<sup>1</sup>, Michelle Frits<sup>2</sup>, James Healy<sup>1</sup>, Christine Iannaccone<sup>3</sup>, Omar Khalid<sup>1</sup>, Krishna Morampudi<sup>1</sup>, Nancy Shadick<sup>4</sup>, Michael Weinblatt<sup>4</sup>, Hemani Wijesuriya<sup>1</sup> and **Robert Terbrueggen**<sup>1</sup>, <sup>1</sup>DxTerity, Rancho Dominguez, CA, <sup>2</sup>Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>3</sup>Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, <sup>4</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Physicians equipped with low cost, patient-administered, “from home” genomic tests for monitoring disease activity and therapy response could revolutionize treatment for rheumatoid arthritis (RA) by enabling treat-to-target strategies, minimizing the use of ineffective therapies, and detecting changes in disease activity before a flare occurs. However, development of a “from home” strategy for patient care requires rigorous testing in the intended use cohort. In addition, the costs associated with recruiting and analyzing a patient cohort of sufficient size are formidable and further compounded by the possible confounding effects of concomitant RA therapies. Here, we investigated the feasibility of recruiting a patient cohort entirely through social media at minimal cost and cohort metrics were compared with clinical data of patients enrolled in a traditional, clinically managed study.

**Methods:** A cohort of self-reported RA participants were recruited under an IRB-approved, HIPAA compliant, Direct-to-Patient observational study entitled Baseline Rheumatoid Arthritis Verification and Outcomes (BRAVO; [www.bravostudy.com](http://www.bravostudy.com)). Participants were asked to complete 3 rounds of disease monitoring over a one month period, which included a short disease history questionnaire with RAPID3 ePRO and a self-collected 100 µL fingerstick blood sample returned through the US mail. Total RNA (50 ng) was isolated from the self-collected blood samples and sequenced using a custom 1200-gene pan-immunity Ampliseq panel on the Ion S5. Patient cohort metrics were compared with clinical data from the multi-center, longitudinal observational, 14-year, 1,400+ patient Brigham Women’s Rheumatoid Arthritis Sequential Study (BRASS; [www.brassstudy.org](http://www.brassstudy.org)).

**Results:** BRAVO participants ( $n = 109$ ) were recruited over a 12-week period through social media platforms. Most participants (80%) enrolled and completed the questionnaires using a mobile device, and 84% of patient samples yield at least 100ng of isolated RNA with an average RIN of 7.1. Comparison of cohort attributes at baseline between BRAVO and BRASS individuals (Table) exhibited significant similarities between mean age, disease duration, and range of medications. However, the BRAVO cohort tended to have higher disease activity, lower use of biologic and non-biologic DMARDS, higher use of narcotic/opioid pain meds and increased ethnicity.

	BRAVO (109)	BRASS (1402)		Current Medication	Bravo (109)	BRASS (1402)
Age (years)	55.3 ± 11.8	56.3 ± 11.3		Glucocorticoids	30 (27%)	379 (27.0%)
Age Range	28 – 79	24 – 76		DMARDs	24 (22.0%)	283 (20.2%)
Female	95%	92%		Biologics	10 (9.2%)	107 (7.6%)
Ethnicity	84%	92%		NSAIDs	27 (24.8%)	273 (19.5%)
Disease Duration	13.4 ± 10.56	12.7 ± 10.05		Anti-DMARDs	77 (70.6%)	870 (61.9%)
Early RA (<3 yrd)	26.6%	14.8%		Biologics/DMARDs	26 (23.8%)	337 (24.0%)
Disease Activity	RAPI3 (3)	DAI30 (3)		Non-Biologic DMARDs	52 (46.8%)	670 (47.7%)
Low	36.7% (40)	41.0% (29.2%)		DMARDs	22 (20.2%)	267 (19.0%)
Moderate	57.8% (62)	55.9% (39.5%)		NSAIDs	27 (24.8%)	337 (24.0%)
High	5.5% (6)	3.0% (2.1%)		Other Pain Med (non-narcotic)	10 (9.2%)	120 (8.6%)

**Conclusion:** Social media and molecular analysis of patient-collected fingerstick samples are viable and cost-effective methods to examine efficacy of direct-to-patient testing for RA affected individuals. Cohorts however differed significantly on the basis of critical clinical parameters indicating that a direct-to-patient approach has the power to add depth to the complex RA patient population that can be effectively monitored.

# Early Treatment with Hydroxychloroquine Is Associated with Better Long-Term Outcomes in a Group of Hispanic Patients with Rheumatoid Arthritis

Franchesca Cruz-Pérez<sup>1</sup>, Mariangeli Arroyo-Ávila<sup>1</sup>, Ruth Fred-Jiménez<sup>2</sup>, Naydi Pérez-Ríos<sup>3</sup>, Noelia Rodríguez-Pérez<sup>1</sup>, Grissel Ríos<sup>4</sup> and Luis M. ## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hydroxychloroquine (HCQ) has a disease-modifying effect in rheumatoid arthritis (RA) patients but also it is associated with improved lipid profile, and decreased risk for diabetes and cardiovascular events. However, the impact of early HCQ treatment in the long-term outcomes of RA is not well established. Therefore, we sought to determine the clinical manifestations, incident comorbidities, and functional status in a group of Hispanic patients with RA who received early therapy with HCQ.

**Methods:** A cross-sectional study was performed in a cohort of RA patients (per American College of Rheumatology classification criteria). Demographic features, health-related behaviors, cumulative RA manifestations, disease activity (per Disease Activity Score 28 [DAS-28]), functional status (per Health Assessment Questionnaire), incident comorbidities, and pharmacologic treatment were determined. Patients who received early treatment (within the first year from the onset RA symptoms), late treatment (>1 year from the onset of RA symptoms) or no treatment with HCQ were compared. All patients who were treated with HCQ received at least one year of therapy. Data were examined using bivariate and multivariate (logistic regression) analyses.

**Results:** A total of 419 patients were studied. The mean (SD) age of the study population was 56.0 (13.8) years and 87.3% were woman. The mean (SD) disease duration was 14.7 (9.1) years. Seventy-four (17.7%) patients received early treatment with HCQ, 131 (31.3%) late treatment with HCQ, and 214 (51.0%) patients did not receive therapy with HCQ. In the multivariate analysis adjusted for age and disease duration, those who received early treatment had lower HAQ scores (OR 0.59, 95% CI 0.41 – 0.85) and were less likely to have joint replacement surgeries (OR 0.15, 95% CI 0.03 – 0.67) than those who were not exposed to HCQ. These differences were not observed between patients who had late treatment and those who did not received HCQ treatment. No significant differences were observed between the three groups in terms of sex, lifestyle behaviors, joint deformities/contractures, extra-articular manifestations, current disease activity, incident comorbidities (arterial hypertension, diabetes mellitus, dyslipidemia, and cardiovascular events), and exposure to corticosteroids or other disease-modifying anti-rheumatic drugs (synthetic or biological).

**Conclusion:** In this group of Hispanic RA patients, those receiving early treatment with HCQ had better long-term outcomes, having less functional impairment and joint replacement surgeries than those who received late or no HCQ therapy. This study highlights the importance of early treatment with HCQ to prevent disease damage in RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is recommended as part of initial therapy in early RA, but practices range widely. The objective of this analysis was to describe MTX treatment in an early RA cohort, beginning with initial therapy and assessing time to treatment failure across various treatment strategies.

**Methods:** We studied adult patients from a prospective multicenter early arthritis cohort (enrolled 2007-2017 within one year of symptom onset) who fulfilled ACR/EULAR RA criteria. RA patients were eligible for our analyses if they initiated MTX (+/-other DMARDs) within 90 days of cohort entry. The first analyses determined time until 'failure' of that initial MTX-based therapy, from the time of first initiation, left-censored at cohort entry. Treatment failure definition included: change of route for MTX monotherapy, adding or stopping a DMARD/biologic, and changing dose/frequency of a DMARD or biologic, due to inefficacy or a serious adverse event.

**Results:** We studied 1,484 early RA patients, the majority initiating either MTX monotherapy (oral or subcutaneous) or MTX plus a second agent (Table 1). At the time of entry into the early arthritis cohort, their mean (standard deviation, SD) age was 54 (15) years, their mean symptom duration was 5.6 months (2.8), their mean DAS28 scores were 5.3 (1.4), and one third (38%) were on oral steroids. Overall, 911/1464 (61%) had a treatment failure, primarily due to inefficacy (Table 1).

**Table 1: Distribution of initial treatment and reasons for treatment failure**

Treatment	Frequency	%	Length of time remaining on initial treatment (months)*		Any Failure	Drug stopped due to inefficacy	Serious adverse effect	Any side effect <sup>§</sup>
			Median	Range				
Oral MTX monotherapy	398	26.8	6.0	0.3 to 95.9	313 (79%)	13 (3.3%)	0 (0%)	70 (17.6%)
Subcutaneous MTX monotherapy	328	22.1	13.1	0.4 to 106.1	146 (45%)	1 (0.3%)	0 (0%)	61 (18.6%)
MTX plus a second DMARD	642	43.3	9.3	0.3 to 107.8	375 (58%)	23 (3.6%)	0 (0%)	168 (26.2%)
MTX-HQN-SSZ	116	7.8	9.8	0.3 to 96.8	77 (66%)	7 (6.0%)	1 (0.9%)	58 (50.0%)
<b>Total</b>	<b>1484</b>	<b>100.0</b>	<b>9.0</b>	<b>0.3 to 107.8</b>	<b>911 (61%)</b>	<b>44 (3.0%)</b>	<b>1 (0.1%)</b>	<b>357 (24.1%)</b>

<sup>§</sup> The variable reason to stop, serious adverse events and any side effects are MD recorded.

The multivariate cox regression (Table 2) for the first analyses showed that, compared to oral MTX monotherapy, all MTX strategies had longer time to failure.

**Table 2: Adjusted hazard ratios (HR) for drug changes after time zero\* compared to oral MTX monotherapy (the reference)**

Treatment at time zero	Adjusted HR	95% CI
MTX subcutaneous monotherapy	0.91	0.61, 1.35
MTX + another DMARD	0.87	0.62 1.22
MTX+SSZ+HCQ	0.64	0.44, 0.94
Biologics+/- DMARDs including MTX	0.31	0.20, 0.49
Non MTX DMARDs only	1.26	0.89, 1.77

\*Adjusting for baseline characteristics: age, sex, co-morbidities, symptom duration, race, education, smoking, erosions, DAS-28, disease activity, corticosteroids, NSAIDs, and COXIBs.

**Conclusion:** Our data in early RA patients initially exposed to MTX suggest that compared to oral MTX, all other MTX strategies had longer time to failure. These data do not confirm clear differences in outcomes with respect to methotrexate DMARD combinations, as the width of confidence intervals precludes definitive conclusions in this regard.

Variables	Concordant decisions (71%, n=22)	Discordant decisions (29%, n=9)	PtGA >50% of CDAI calculation (68%, n=21)
Age (mean, years)	49	51	48
Sex (% females)	77	77	86
Ethnicity (% Caucasians)	86	89	86
> College education (%)	63 (n=19)	50 (n=6)	66
>1 MSK co-morbidity (%)	32	67	43
Duration of RA (median, years)	6.7	9.8	3
RF and/or CCP positive (%)	95	87.5	94
DMARD treatment (%)	100	100	100
Glucocorticoid $\geq$ 5mg daily (%)	22.7	22.2	18
CDAI score (median)	8.5	7	7
PtGA score (median)	5	4	4
PtGA score $\geq$ 50% of CDAI calculation (%)	68	67	29% discordant decisions
T2T target remission (%)	86	100	90

**Table 1 : Comparison between the concordant and discordant treatment decision groups. 3<sup>rd</sup> column shows details of 21 patients in whom PtGA > 50% of CDAI calculation. MSK = musculoskeletal co-morbidities, PtGA = Patient Global Assessment of Disease Activity, CDAI = Center For Disease Activity Index, T2T = Treat to Target, RF = Rheumatoid Factor, CCP = Cyclic Citrullinated Peptide, DMARD = Disease Modifying Anti Rheumatic Drugs.**

**Background/Purpose:** The American College of Rheumatology strongly recommends using a treat-to-target (T2T) strategy because it has demonstrated improved outcomes compared to a non-targeted approach in RA. The crux of a T2T based strategy is accurate disease activity measurement using a composite disease activity tool like Clinical Disease Activity Index (CDAI) and then adapt therapy as necessary until the clinical target is met. The aim of our study is to measure concordance between usual care-treatment decisions and CDAI-based T2T treatment decisions and to identify reasons for discordance, if any. This is a crucial step in our internal validation of CDAI and development of a T2T-based treatment pathway.

**Methods:** Adult RA patients in our tertiary care rheumatology clinic during the period of 5/20/16 to 5/20/17 were prospectively identified. First, as part of the usual care treatment approach currently used at our clinic, a shared treatment decision was made after consideration of all patient, disease, and treatment related factors. Then a T2T based mutual disease target was established with the patient and a CDAI was scored to determine if the patient has met target or not. The ideal T2T strategy based treatment decision was recorded for study purposes to compare with the usual care decision. We measured concordance between the T2T and usual care treatment decisions, compared characteristics of concordant and discordant groups, and of those where the Patient Global Assessment of Disease Activity (PtGA) contributed to  $\geq$  50% of the total CDAI score. We recorded patient, disease and treatment related data at each visit.

**Results:** Patient demographic, RA disease and treatment related data can be found in Table 1. Of the total 40 patients, 9 patients were in remission and were excluded from the analysis as there was low likelihood of discordance. Of the remaining 31 patients, there were 9 instances (29%) of discordance between T2T and usual care treatment decisions. There were higher number of patients with  $\geq$  1 musculoskeletal comorbidity (osteoarthritis, bursitis, etc) -67% in the discordant group vs 32% in concordant group. There were slightly higher numbers of patients with  $\geq$  college education in the concordant group (63%) than in the discordant group (50%). PtGA contributed to  $\geq$  50% of total CDAI score in 21 patients of the cohort (68%), and of these 43% had  $\geq$  1 musculoskeletal comorbidity.

**Conclusion:** In our small group of 40 RA patients, we found 29% discordance between the T2T and usual care treatment decisions, and the PtGA contributed to  $\geq$  50% of the total CDAI score in 68% patients. As accurate disease activity measurement is central in any T2T

strategy, we believe that this deeper understanding of variation in CDAI, PtGA scores and T2T decisions is very useful. We have accordingly started using PtGA as a patient education opportunity and plan to repeat this study with a new amended CDAI questionnaire.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Clinicians often associate the occurrence of a recent rheumatoid arthritis (RA) flare with an increase in overall disease activity. However, previous studies have shown that patients with RA in low disease states still report flares. The goal of this study is to examine if having a recent flare is independent from disease activity overall, using the FLARE-RA instrument.

**Methods:** Data were collected from a prospective RA registry including patient reported and clinical outcomes, such as flare frequency and the FLARE-RA instrument. FLARE-RA asks patients to rate 11 statements about their disease on a 0-10 scale (not true to absolutely true). The statements are about patient and physician identified flare features covering the following: morning stiffness, joint pain, joint swelling, sleep disturbance, pain killer or NSAID use, fatigue, decrease in physical activity, irritability, depression, withdrawal, and increased need for help. The score is the mean of all 11 items, where a higher score suggests a recent flare. Disease Activity Score 28 joint with CRP (DAS) was dichotomized into low/remission and moderate/high disease. Flare recency (presence of a flare in the past 6 months) was coded into 3 categories; no flare, at least 1 flare, and currently flaring. Nonparametric tests were performed to examine possible covariates in relation to the FLARE-RA score. A multiple regression model with FLARE-RA score as the outcome included covariates that had a  $p < 0.15$  in the univariate analyses.

**Results:** 503 participants were surveyed; 85% were female with a mean (SD) age of 61 (13), 75% had a college degree or higher, and the median disease duration was 16 (IQR 9, 26) years. The median DAS28-CRP3 was 2.1 (1.6, 2.8) and the median FLARE-RA score was 2 (0.5, 4.4). In univariate analyses, a linear trend between DAS category, flare recency, and FLARE-RA was seen (Figure). The regression model found that having a recent flare is associated with a higher FLARE-RA score independent of DAS category, while adjusting for gender, education, and disease duration. Additionally, flare recency had a higher effect size than DAS on total FLARE-RA score.

**Conclusion:** Having a current or recent flare drives the FLARE-RA score more than a patient's current disease activity suggesting that this instrument is able to detect patients' self report of flare. This instrument may be useful in detecting flares even in patients with low disease activity which could provide an additional rationale for treatment change.

**Figure: FLARE-RA Score by DAS Category and Flare Recency**

**Table: Multiple Regression Model: Association between FLARE-RA, DAS, and Flare Recency**

Variable	Parameter Estimate	Standard Error	p-value	Effect Size (Partial Eta-squared)
DAS category (mod/high vs. low/remission)	1.50	0.27	<.0001	0.07
Current flare	3.02	0.28	<.0001	0.21
At least 1 flare in past 6 months	1.82	0.21	<.0001	0.15

\* Adjusted for gender, education, and disease duration.

\*\* Effect size measures the magnitude of effect the variable has on the outcome. The Partial Eta-squared measures the proportion of the variation in FLARE-RA scores (with the variation explained by the other variables removed from the denominator in order to make the effect size comparable across models) attributed to that variable. The parameter estimate is the average difference in FLARE-RA score (1-10) between the individual variables' presence vs. absence.

## Methotrexate Use and Fatigue in Rheumatoid Arthritis Patients: Results from a National Patient Registry

Huifeng Yun<sup>1</sup>, Shuo Yang<sup>2</sup>, W. Benjamin Nowell<sup>3</sup>, Cooper Filby<sup>1</sup>, Lang Chen<sup>1</sup> and Jeffrey R. Curtis<sup>4</sup>, <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Global Healthy Living Foundation, Upper Nyack, NY, <sup>4</sup>Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX), a synthetic disease-modifying antirheumatic drug (DMARD), is the most commonly used medication for rheumatoid arthritis (RA). Considerable variations between patients taking MTX exist due to its potential adverse effects and tolerability issues. Although patient reported outcomes have been used for evaluating effectiveness of RA treatments in clinical trials, much less is understood from real-world settings. This study evaluated the association between MTX use and fatigue in the PCORI-funded Patient Powered Research Network for adult rheumatologic conditions, ArthritisPower.

**Methods:** Patients in the ArthritisPower registry were invited to provide medication information and PROs including the RAPID3 and 4 PROMIS instruments (pain interference, physical function, fatigue, and sleep disturbance) plus disease-specific information via a mobile application (App) on their smartphone or computer. Patients who used selected RA medications of interest (glucocorticoids, non-biologic DMARDs, biologics) and answered  $\geq 1$  instrument were eligible this study. We calculated the mean and standard deviation (SD) of RAPID3 and the 4 PROs across different RA treatments cross-sectionally. Multivariable regression analysis with repeated measures was used to evaluate the association between MTX use and fatigue.

**Results:** As of June 2017, ArthritisPower had recruited 5,830 patients; approximately 57% had RA. A total of 469 participants had RA medication use and answered relevant PROMIS instruments, with mean (SD) age of 48.3 (11.5) years; 32.0% used glucocorticoids, 83.2% used non biologic DMARDs, and 62.5% used biologics. The mean score for pain interference was 62.7 (SD: 7.3), physical function 38.0 (6.9), sleep disturbance 56.9 (8.4), fatigue 62.3 (8.5), and RAPID3 14.7 (5.7). Among different RA treatments, patients on biologic monotherapy had the highest scores for pain interference, sleep disturbance, fatigue, and RAPID3, whereas MTX monotherapy had the lowest. In contrast, MTX monotherapy had the highest physical function score whereas biologic monotherapy had the lowest (Table). Using fatigue as an example, MTX use is associated with 2.29 (95% confidence interval: -3.2, -1.4) units of lower fatigue score after adjusting for age, gender, race, insurance, employment and concurrent RA medications and medical conditions.

**Conclusion:** PROMIS measures are feasible to capture from patients with Smartphone and Web Apps. Despite potential concerns related to fatigue associated with use of MTX, these results suggest that on average, MTX is associated with lower fatigue scores. RA patients on MTX might be associated with better PROs, especially when it was combined with biologics use. More longitudinal data analyses are needed to better understand the relationship.

**Table: Mean of PROMIS instruments on different RA medications**

	N	Pain interference	Physical function	Sleep disturbance	Fatigue	RAPID3
Treatments	Observations (patients)	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)
Methotrexate monotherapy	196 (60)	59.3 (9.1)	41.3 (7.1)	54.9 (8.5)	59.3 (8.3)	11.7 (6.9)

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In general, retention rate in biological DMARDs represent both efficacy and safety. Tocilizumab (TOC) is a humanized monoclonal antibody that binds to the interleukin-6 receptor. So far, TOC was used in randomized controlled trials (RCTs) and longitudinal observational studies (LOSs), as well. The aim of this study was to assess the retention rate of TOC for the treatment of RA patients in RCTs and LOS.

**Methods:** In January 2017, a systematic Review (SR) was performed in PUBMED MEDLINE. Publications were identified using the MeSH terms: (“rheumatoid arthritis and Tocilizumab”) with a limitation to “humans”, “all adults: 19+ years”, “English” and “clinical trials”. All available studies describing the retention rate of TOC were recruited to SR. Retention rate of TOC were calculated according to route (SC or IV), dosage (4 mg/kg vs 8 mg/kg), monotherapy or combination with methotrexate. Of the 662 publications identified by the literature search, 42 were recruited in the analysis. Retention rates of TOC at 12-16 weeks, 24-32 weeks, 48-52 weeks, 2. Years, 3. Years and 5. years were analyzed. Open label extension period of RCTs included to LOS. The causes of withdrawals of TOC were recorded as inefficacy, adverse event, and others.

**Results:** Of the 42 studies, 11 (26.2%) were RCTs and 31 (73.8%) were LOSs. Totally 20590 patients (15574 (75.6%) female) were pooled to analysis that 4817 patients (23.4%) were from RCTs. The mean age was 56.2 years and mean disease duration was 10.1 years. Seropositivity was 75.0% for rheumatoid factor and 76.5% for ACPA. Overall, 8934 (44.4%) of patients were biologic-naïve. TOC was used as monotherapy (5111/16323, 31.3%), or concomitant with methotrexate (11976/19522, 61.4%). Available baseline DAS-28 score, CDAI, SDAI, and HAQ-DI score were 5.8, 30.4, 32.5, and 1.46 respectively. Retention rates of TOC intravenous 8 mg/kg at 48-52 weeks, 2. year, 3. year and 5. year were 75.5 - 85.2%, 48.4 - 76.1%, 69.9%, 66.2%, respectively. Retention rate and causes of withdrawal of TOC according to study type were shown in Table 1.

**Conclusion:** Both RCTs and LOSs, withdrawal of TOC was particularly well known in 24-32. weeks. TOC intravenous 8 mg/kg also had satisfactory retention rate in 48-52 weeks, 2. year, 3. year and 5. year. Moreover, retention rate of TOC in LOSs was comparable with other biologic DMARDs, as well.

**Table 1: Retention Rate of Tocilizumab in Randomized Controlled Trials and Observational Studies**

Durations (weeks)	Study Type	Patients number	Route and dosage	Continue of TOC (%)	Causes of Withdrawals (%)		
					Inefficacy	Adverse event	Others
12-16 w	RCTs	102	iv, 8 mg/kg	85.3	20.0	53.3	26.7
		103	iv, 4 mg/kg	82.5	33.3	50.0	16.7
	LOS	551	iv, 8 mg/kg	88.0	27.5	31.4	41.2
24-32 w	RCTs	3198	iv, 8 mg/kg	92.7	13.8	67.7	25.2
		377	iv, 4 mg/kg	85.9	NA	NA	NA
		1242	sc, 162 mg	92.2	19.7	46.5	33.8
	LOS	12488	iv, 8 mg/kg	83.3	29.0	44.1	27.0
48-52 w	RCTs	209	iv, 8 mg/kg	85.2	25.8	38.7	35.5
	LOS	3761	iv, 8 mg/kg	74.5	34.4	31.5	34.1
2. years	RCTs	209	iv, 8 mg/kg	76.1	26.0	38.0	38.0
	LOS	649	iv, 8 mg/kg	48.4	-	-	-
3. years	LOS	114	iv, 8 mg/kg	69.9	20.0	10.0	40.0
5. years	LOS	240	iv, 8 mg/kg	66.2	7.4	61.7	30.9

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Initial treatment of RA with triple csDMARD therapy can achieve remission in a proportion of patients. Others respond poorly yet must wait at least 6 months to access publically funded bDMARDs in Australia, although they may benefit from earlier introduction of bDMARDs. The purpose of this study was to identify disease activity thresholds after 3 months of csDMARDs that were associated with ACR/EULAR remission after 6 months of therapy.

**Methods:** Consecutive patients >18 years with treatment-naïve RA (1987 ACR or 2010 ACR/EULAR criteria) and ≥ 6 months of follow up were included. Unless contraindicated, participants received triple DMARD therapy of methotrexate, sulfasalazine and hydroxychloroquine according to a treat-to-target approach, and if these failed, leflunomide was added. At baseline, 3 and 6-months, DAS28, SDAI and CDAI were determined. Remission after 6 months was defined by ACR/EULAR 2011 definition of SDAI ≤ 3.3 without initiation of leflunomide. The sensitivity and specificity of disease activity measures at 3 months to predict the 6 month remission rate were determined by a Receiver Operated Characteristics Curve, and the magnitude of association between the optimal

point on the curve and remission rate was determined. Both percentage and absolute reductions in disease activity scores were examined.

**Results:** Median baseline DAS28, CDAI and SDAI were 5.4, 27.7 and 30.0 respectively and 89% were initiated on triple DMARD therapy. Absolute rather than relative changes in disease activity metrics after 3 months of DMARDs were more strongly associated with RA remission after 6 months of treatment. Optimal SDAI and CDAI scores at 3 months had a stronger association with 6 month remission compared to DAS28 (Table).

Association between Optimal Cut-Off Points and Remission Rate after 6 Months of DMARDs				
Disease Activity Cut-Off Point after 3-Months	n	Proportion Reaching cut-point	Remission Rate	Odds Ratio (95% CI)
45% Reduction in DAS28 from Baseline	259	0.24	0.19	8.8 (4.4-17.5)
65% Reduction in CDAI from Baseline	258	0.28	0.18	12.3 (5.9-25.6)
65% Reduction in SDAI from Baseline	250	0.26	0.18	8.5 (4.2-17.3)
DAS28 <3.4	261	0.39	0.19	10.8 (4.9-23.5)
CDAI <8.0	265	0.28	0.18	16.7 (7.8-35.7)
SDAI <8.6	259	0.27	0.19	18.1 (8.4-39.1)

**Conclusion:** CDAI or SDAI scores at 3 months of csDMARD treatment in early RA are highly predictive of remission after 6 months and could be useful in predicting those who may ascertain long-term remission with conventional agents, and equally in identifying those who may benefit from early bDMARD initiation. In practical terms, CDAI has the advantage of providing an immediate score compared with SDAI where the results of CRP levels are required.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Medical bugs, a term used to describe insects and arthropods for medical treatment, have been widely used in the past centuries for pain relief. The treatment is believed to include biologically active substances that induce anti-inflammatory effects. Previous trials have shown that medical bugs may reduce the need for analgesic intake of people with rheumatoid arthritis (RA). However, few studies have been conducted to evaluate the effect of medical bugs on musculoskeletal disease. The aim of this systematic review was to evaluate the pain relief of commonly used medical bugs in RA patients to better understand its benefits and inform clinical practice.

**Methods:** A comprehensive search on PubMed and Chinese databases (CNKI, Wan Fang and VIP) and the Cochrane Library was conducted through May 1, 2017. Only randomized controlled trials (RCTs) using medical bug (including ant, centipedes, scorpions and others) therapy for adult RA patients who met diagnostic by the 1995 ACR criteria or 2002 Traditional Chinese Medicine criteria were included. The effects of medical bugs were evaluated with a tender joint count and pain score of joints. The differences between treatment groups were reported as mean difference (P-value) across the studies. The methodologic quality of the studies was assessed with the Jadad instrument. The heterogeneity of the studies, including varying comparison methods, and methodologic limitations, precluded a formal meta-analysis.

**Results:** Ten RCTs with a total of 1,176 RA patients (age range = 38-62 years, 59% female, disease duration range = 1 month-30 years) met the eligibility criteria. Studies were conducted between 2002 and 2015 in China. Outcomes included the Chinese pain score and Visual Analogue Scale (VAS). Medical bugs were either used singly or in combination with other Chinese herbs. The overall quality of trials was modest (mean Jadad score = 2). **Table 1** summarizes the information from the included studies. All 10 studies utilizing medical bugs either alone or in combination with other Chinese herbs showed efficacy in pain relief for RA. No adverse events were reported in either treatment or control groups.

**Conclusion:** Medical bug therapy appears to relieve pain in patients with RA. These studies did not evaluate disease modifying effects, and the use of combination treatments makes it difficult to ascertain which ingredient may induce the effect. Still, the potential of medical bug treatment and its non-pharmacologic properties may have value and deserve further study. Rigorously designed and well-controlled multicenter RCTs of biological active compounds of medical bugs for RA symptom relief need to be conducted in future studies.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Optimal management of Rheumatoid Arthritis (RA) based in identification of patients with risk factors for Joint Damage (JD) progression, is a main strategy, but there is scarce evidence regarding this aspect in Latin-America (LA). Objective: To determine factors associated with JD and predictors of radiographic progression (RP) in a RA cohort

**Methods:** Prospective analysis of Hospital Almenara RA cohort (Lima-Perú). JD and RP were determined with Sharp-VDH score. A single reader evaluated all X-ray films. Age, gender, ethnicity, socioeconomic level (Graffar), education, age at diagnosis, disease duration, diagnosis delay, tobacco, comorbidities (Charlson), current/past DMARDs, biologic and corticosteroids, biologic withdrawal, DAS28, EULAR-remission, AntiCCP, JD (Sharp-VDH score) and disability (MHAQ) at baseline were analyzed as RP predictors. We applied a multivariate linear regression elimination model ( $p < 0.05$ ) and SPSS-21.0. **Results:** 313 patients from the 432 subjects of the hospital Almenara RA cohort were included, 91.4% women, 98.4% Mestizos, disease duration was 14.94 (12.79) and diagnosis delay 1.71 (2.59) years. Baseline Sharp-VDH was 94.53 (95.81). Most patients were using DMARDs (92%), but only 11.5% biologics. Current (B=42.86, CI: 6.49-79.24,  $p=0.021$ ) or past (B=45.76, CI: 6.42-85.09,  $p=0.023$ ) corticosteroids, current biologic (B=28.63, CI: 4.86-52.40,  $p=0.018$ ) and longer disease duration (B=3.62, CI: 3.02-4.22,  $p<0.01$ ) were associated with baseline JD. One hundred and eighty-four patients were prospectively followed, in this group the rate of RP total/erosion was 4.41(9.24) and 2.17(5.74)/year respectively, there was a DMARDs prescription delay of 6.56(8.02) years and 176 (95.7%) subjects without remission-EULAR criteria. Predictors of RP (erosions) were a longer disease duration (B=0.14, CI 0.01-0.27,  $p=0.04$ ) and withdrawal of biologic (B=8.63 CI 2.28-14.98  $p=0.008$ )

**Conclusion:** This cohort had a high disease duration and delay of DMARD introduction. Disease duration and biologic withdrawal predicted RP. Carefully biologic withdrawal in these patients could be a good strategy to prevent adverse results in our population

# A Matrix Risk Model for Prediction of Radiographic Progression in Early Rheumatoid Arthritis Based on Treatment Response at 3 Months

Pooneh S. Akhavan<sup>1</sup>, Daming Li<sup>1</sup>, Sahar Tabatabvakili<sup>1</sup> and Edward C. Keystone<sup>2</sup>, <sup>1</sup>Mount Sinai Hospital, Toronto, ON, Canada, <sup>2</sup>University of Toronto, Toronto, ON, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The present study aimed to develop a matrix to predict risk of radiographic progression in patients with early rheumatoid arthritis. The focus of this analysis was to identify a threshold for routine disease activity measures at 3 months i.e. response to initial treatment that is associated with the lower risk of future joint damage.

**Methods:** Using data from the PREMIER study, radiographic progression (RP) was defined as a change in modified Sharp/van der Heijde score (SHS) of  $\geq 3.5$  U/year. Patients enrolled into the control arm of the study who received methotrexate only were analyzed. Baseline characteristics and disease activity measures at 3 months were used to predict the risk of RP at 12 months. Logistic regression was used to identify the predictors and to calculate the probability of RP. Significant predictors were categorized in order to make the models more practical to use in daily practice. The results were combined into a matrix model including significant predictors of RP.

## Results:

A total of 205 patients were included in this analysis with a mean (sd) baseline age 52.0 (13.1) years, disease duration 0.8 (0.8) year, 28 swollen joint count 14.7 (5.7), 28 tender joint count 17.1 (6.4), mean sharp score (MTSS) 21.4 (21.2) and CRP 4.0 (4.1). Logistic regression models identified month 3 SJC and CRP as significant predictors of radiographic damage progression at 1 year. These variables were categorized into three groups based on the variable distribution and clinical relevance. The matrix model showed that the SJC < 5 at 3 months was associated with a significantly lower damage progression rate at any given CRP category (Table-1).

		CRP at 3 months		
SJC at 3 months		<1	1 - 2	>2
	< 5	0.15 (0.08, 0.27)	0.36 (0.20, 0.57)	0.50 (0.29, 0.70)
	5 - 10	0.30 (0.18, 0.46)	0.58 (0.35, 0.77)	0.70 (0.49, 0.85)
	> 10	0.35 (0.22, 0.52)	0.63 (0.42, 0.81)	0.75 (0.57, 0.87)

**Conclusion:** The disease activity state at 3 months has a significant impact on future radiographic damage. Patients with less than 5 swollen joints at this time point have lower risk of radiographic damage at 1 year. Further testing in other populations and with different therapies is needed to obtain a definitive risk model that will guide rheumatologists in making treatment decisions for early RA patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

It is an ongoing matter of research, whether the course of rheumatoid arthritis (RA) can be altered by an early intervention, a concept historically referred to as the window of opportunity. So far, only short-term disease outcomes have been investigated, which are, however, inherently affected by the unknown rate of underlying rate of self-limiting disease. It is unclear, whether the disease course is really affected by the timing of initial treatment.

### Methods:

Patients were identified from a clinical database at the Medical University of Vienna. We used stringent criteria to define refractory RA (reRA):  $\geq 3$  treatment courses ( $\geq 1$  biological) over  $\geq 18$  months since diagnosis without reaching low disease activity (LDA) or remission (REM) defined by a Clinical Disease Activity Index (CDAI,  $\geq 10$ ). In contrast, we defined treatment amenable RA (taRA) as patients reaching LDA, or REM within the first 2 treatment courses.

We first matched patients with reRA and taRA 1:1 for time of inception in our database to avoid bias by secular trends in management over time. Using the reRA or taRA status as the dependent variable, we performed logistic regression analysis. Furthermore, we performed the same analyses in an unselected group of all-comers at baseline regarding their probability of developing reRA.

### Results:

We identified 412 patients who had their last clinic visit at or after July 1st, 2016: 70 reRA and 102 taRA patients were identified; 240 patients fulfilled neither definition. In the reRA group, female gender was more frequent, age of disease onset lower, and CDAI higher at first presentation. Remarkably, the time to first DMARD treatment was significantly delayed between reRA and taRA (table 1).

In the matched multivariate model, treatment delay ( $p=0.047$ ), female gender ( $p=0.038$ ) and higher disease activity ( $p<0.001$ ) were significant. In the logistic regression analysis of the 412 patients treatment delay was significant univariately ( $p<0.001$ ) and after adjustment for other significant predictors ( $p=0.007$ ; table 2). We then conducted a matrix model based on this analysis with predicted probabilities of developing reRA (figure).

### Conclusion:

Our data suggest that delay to initial treatment affects the long-term course of RA. Earlier treatment initiation thus may change the severity of RA.

## The Therapy with Tocilizumab Is Not Associated with Periarticular Demineralisation and Finger Joint Space Narrowing in Rheumatoid Arthritis

Alexander Pfeil<sup>1</sup>, Ottar Gadeholt<sup>2</sup>, Joachim Böttcher<sup>3</sup>, Diane Renz<sup>4</sup>, Peter Oelzner<sup>1</sup> and Gunter Wolf<sup>1</sup>, <sup>1</sup>Department of Internal Medicine III, Jena University Hospital, Jena, Germany, <sup>2</sup>Rheumatology/Immunology, Medical Clinic II, University Clinic Wuerzburg, Wuerzburg, Germany, <sup>3</sup>Institut of Interventional and Diagnostic Radiology, SRH Waldklinikum Gera, Gera, Germany, <sup>4</sup>Institute of Diagnostic and Interventional Radiology, Jena University Hospital, Jena, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Digital X-ray Radiogrammetry (DXR) and Computer-Aided Joint Space Analysis (CAJSA) are established computer based techniques for the quantification of metacarpal bone mineral density and finger joint space width. Tocilizumab as humanized anti-interleukin-6 receptor antibody is a successful therapy strategy in rheumatoid arthritis (RA). The aim of this study was the evaluation metacarpal bone mineral density finger joint space width in RA-patients treated with tocilizumab or methotrexate.

### Methods:

The multi-center study includes a retrospective analysis of 44 patients with RA in two matched groups which were treated with methotrexate or tocilizumab. All patients consist of radiographs at baseline and after 2.4 years in the follow-up. DXR was measured to quantify cortical thickness (CT), metacarpal index (MCI) and bone mineral density (BMD) of the metacarpal bones. The CAJSA-technique quantified joint space distance of the metacarpophalangeal joints (JSD-MCP) and proximal interphalangeal joints (JSD-PIP).

### Results:

For the methotrexate group a significant change of BMD (-6.16%,  $p<0.05$ ), CT (-7.05%,  $p<0.05$ ), MCI (-4.74%,  $p<0.5$ ), JSD-MCP (-4.51%,  $p<0.05$ ) and JSD-PIP (-12.29%,  $p<0.05$ ) was observed between baseline and follow-up. The tocilizumab group no significant difference was detected for BMD (-0.20%,  $p=n.s.$ ), CT (-0.70%,  $p=n.s.$ ), MCI (-2.05%,  $p=n.s.$ ), JSD-MCP (-0.76%,  $p=n.s.$ ) and JSD-PIP (0%,  $p=n.s.$ ).

### Conclusion:

The study presented an absence of periarticular demineralisation and finger joint space narrowing in the treatment with tocilizumab, which highlights the effective treatment strategy of a biologic target in RA as well as the detailed computer based analysis of periarticular minerlisation and finger joint space width by DXR and CAJSA.

# Soluble Urokinase Plasminogen Activator Receptor (suPAR) Correlates with Disease Activity in Early Rheumatoid Arthritis and Reflects Joint Damage over Time

**Helena Enocsson**<sup>1</sup>, Alf Kastbom<sup>1</sup>, Tanja Lukic<sup>1</sup>, Christopher Sjöwall<sup>2</sup>, Thomas Skogh<sup>1</sup> and Jonas Wetterö<sup>1</sup>,

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The urokinase plasminogen activator receptor (uPAR) is expressed on various cell types and plays important roles in proteolysis, migration and adhesion. Receptor shedding yields a soluble form (suPAR) that has been intensively studied as a potential biomarker in several inflammatory diseases and malignancies. The previous few studies on suPAR in rheumatoid arthritis (RA) have shown an association with inflammation and swollen joints, but data on changes in suPAR levels in relation to early disease course are lacking. This study investigates whether suPAR levels predict or reflect disease activity and/or joint damage in early RA.

## Methods:

Serum suPAR was measured by ELISA at disease onset (0 months), after 3 months and after 36 months in 252 RA patients from the Swedish early RA cohort TIRA-2. suPAR levels were compared with disease activity (defined by DAS28) and joint damage (Larsen score) at baseline and up to 36 months after disease onset. Healthy individuals (n=100) served as controls.

## Results:

Circulating levels of suPAR were higher in RA patients at all three time points compared to healthy controls (mean suPAR = 3.62 ng/mL;  $p < 0.001$ ). The highest suPAR among patients was found at 3 months (mean = 8.47 ng/mL) and the lowest at 36 months (mean = 7.14 ng/mL). suPAR at inclusion correlated with baseline DAS28 ( $p < 0.001$ ,  $\rho = 0.25$ ) whereas suPAR levels at 36 months correlated with Larsen score at 36 months ( $p = 0.001$ ,  $\rho = 0.24$ ), and 24 months ( $p = 0.002$ ,  $\rho = 0.25$ ), but not with DAS28 at any time point. No correlation was found between baseline suPAR and joint damage at any time point. Categorization of baseline DAS28 revealed higher baseline suPAR at high DAS28 (Fig. 1) whereas Larsen score at 36 month revealed higher suPAR (measured at 36 months) among patients with a high score ( $> 5$ ) compared to those with a low score ( $< 2$ ) (Fig. 2).

## Conclusion:

suPAR levels associate with disease activity in early untreated RA, but at later stages rather reflect joint damage. Since suPAR levels seem to increase at or after damage accrual, we speculate that suPAR reflects active inflammation and ongoing processes in the joint, rather than being a causative agent.

Figure 1. Serum levels of suPAR and in different categories of disease activity (DAS28) at study inclusion. P-values are from One-way ANOVA with Tukey's post hoc test. Error bars indicate 95% confidence interval.

Figure 2. Serum levels of suPAR and the degree of joint damage (Larsen score) 36 months after study inclusion. P-values are from One-way ANOVA with Tukey's post hoc test. Error bars indicate 95% confidence interval.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biosimilar infliximab (CT-P13) was first approved in Europe in 2013. This study compared treatment (tx) patterns of Turkish pts with a diagnosis of rheumatoid arthritis (RA) who initiated originator IFX (IFX) & either continued IFX or switched to CT-P13.

**Methods:** Adult pts with  $\geq 1$  RA diagnosis code & IFX claim were identified in a national Turkish healthcare database. Eligible pts initiated & continued IFX (Continuer cohort; CC) or initiated IFX & switched to CT-P13 (Switch cohort; SC) during the study period (01DEC2010-01JUN2016). The index date was defined as CT-P13 switch date for SC or a random IFX date during period of CT-P13 availability for CC. Cohorts were matched on age, sex, & number of IFX prescriptions during baseline (BL). Discontinuation (d/c) was defined as a switch to another biologic or no index biologic for  $\geq 120$  days without censoring. Pt demographics, d/c & switching were summarized with descriptive statistics.

**Results:** A total of 697 pts initiating IFX were studied; 87% (N=605) continued IFX throughout the study period; 13% (N=92) switched to CT-P13. BL & clinical characteristics are shown in Table. Mean duration of IFX therapy during BL period was 422 days (CC) & 438 days (SC). Average duration of post-index follow-up was 16 months (CC) & 15 months (SC). During the combined BL & post-index periods, median time on any IFX therapy was 1080 days (CC) & 540 days (SC) (Figure). D/c post-index occurred in 19% (CC) & 87% (SC); mean time from index to IFX d/c /censoring was 276 days (CC) while mean time from index to CT-P13 d/c /censoring was 132 days. While switching from IFX to CT-P13 occurred in 13% all IFX initiators on the index date; an additional 10% of the CC switched to a non-IFX anti-TNF post-index. The majority of SC (82%) switched again post-index (off CT-P13) & 88% of those re-initiated IFX. Regional variation in switching was noted. Switching from IFX to CT-P13 occurred most frequently in Central Anatolia (26% of 154 IFX initiators). Switching from CT-P13 occurred in  $>75\%$  of SC pts in all regions except for Aegean (44% switched from CT-P13 to another biologic, predominantly IFX).

**Conclusion:** In Turkey, RA pts maintained on IFX had greater tx persistence than those who initiated IFX & switched to CT-P13. CT-P13 d/c resulted in IFX re-initiation in the majority of pts. Reasons for d/c are unknown, however regional differences in practice patterns were observed.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To understand the RA patient pathway in Latin America from first symptom onset; including time to diagnosis and to first advanced treatment.

**Methods:** Data from the 2015 RA Disease Specific Programme (DSP), a cross-sectional, multi-national survey of patients and rheumatologists conducted in Brazil, Argentina, Mexico, Colombia, Venezuela were analyzed against 2014 DSP data from the US and 5EU. Rheumatologists (n=188 Latin America, n=113 US, n=340 EU) completed forms containing patient demographics, age at first RA symptoms, age at RA diagnosis, age at csDMARD initiation and age at bDMARD initiation. Continuous data were tested using t tests.

**Results:** A total of 801 Latin America, 843 US and 2536 EU RA patients were included in this analysis. Current mean age across Latin America was 51.9 years and 82.8% female. Mean age of patients at RA symptom onset was 40.6 years, with age at diagnosis 42.6 years; resulting in a 2.2 year (3.9 SD) wait from first experiencing symptoms to receiving a confirmed diagnosis. Patients in Latin America waited 2.6 years (5.7 SD) from the point of RA diagnosis to initiation of first csDMARD vs. 1.0 years US (3.2 SD) and 1.1 years EU (3.0 SD) (both  $p < 0.001$ ), and 6.4 years (7.4 SD) from RA diagnosis to initiation of first bDMARD therapy vs. 3.9 years US (5.6 SD) and 5.2 years EU (5.7 SD) (both  $p < 0.001$ ).

**Conclusion:** RA patients in Latin America wait over 2 years from symptom onset to diagnosis and significantly longer than their US and EU counterparts to receive csDMARD and Biologic therapy. This highlights a clear need to shorten RA diagnosis times and time to treatment initiation.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess levels of rheumatologist and patient satisfaction with RA treatment across Latin America and any disconnects that may exist between the two in real world clinical practice.

**Methods:** Data from the 2015 RA Disease Specific Programme (DSP), a cross-sectional, multi-national survey of patients and rheumatologists conducted in Argentina, Mexico, Colombia and Venezuela were analyzed. Rheumatologists (n=141) completed forms containing patient demographics, patient disease severity and treatment satisfaction. Patients self-reported their level of treatment satisfaction and disease severity.

**Results:** A total of 555 RA patients from across Latin America were included in this analysis. Current mean age across Latin America was 51.9 years and 82.3% female. Proportions of rheumatologists and patients reporting satisfaction with treatment were statistically highly similar (79% and 83% respectively), however current disease severity reporting differed between rheumatologists and patients (mild 70% / moderate-severe 30% rheumatologists vs. 51% mild / 49% moderate-severe patients;  $p<0.001$ ). When assessed for alignment, 21% of rheumatologists and patients disagreed on the level of satisfaction, driven mainly by rheumatologists over-stating dissatisfaction (13%) vs. their patient (8%) ( $p=0.031$ ). For current disease severity, 36% of rheumatologists and patients disagreed, driven mainly by patients (28%) over-stating their severity vs. their rheumatologist (8%) ( $p<0.001$ ). Of those patients for whom their rheumatologist was satisfied with treatment, 20% were classified as having moderate to severe RA by that same physician.

**Conclusion:** Despite many rheumatologists and their patients in Latin America reporting high levels of satisfaction with treatment, patients frequently remain moderate to severe and disconnected from their physician. There is a need to improve physician / patient engagement as a means to improving clinical control.

## Improving Knowledge of Rheumatoid Arthritis Clinical Trial Results Among Rheumatologists: Effect of an Online Educational Intervention

Edward Jackson and Piyali Chatterjee-Shin, Medscape Education, LLC, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While major medical conferences provide the most up-to-date evidence regarding diseases and treatments, time demands and financial constraints are often cited as reasons for non-participation. A study was conducted to determine whether an online educational activity could effectively address a knowledge gap in awareness of emerging trial results as presented at a major rheumatology conference in the field of rheumatoid arthritis (RA).

**Methods:** An online educational intervention focusing on key abstracts in RA presented at the American College of Rheumatology Annual Meeting 2016 was developed and made available online. The education consisted of 3 video-based expert discussions covering both trial outcomes and associated clinical implications, for the intended audience of practicing rheumatologists. The educational impact was assessed by comparing participants' responses to 3 identical paired pre- and post-assessment questions. Pairing of responses allows each learner to act as his/her own control. Data representing a statistical sampling of the overall learner population were collected from December 22, 2016 through January 31, 2017. Statistical analysis comprised a paired 2-tailed t-test comparing mean pre-assessment and post-assessment scores, McNemar's  $\chi^2$  statistic for measuring changes in responses to individual questions, and probability values (*P* values) for both t-test and  $\chi^2$  statistics. This analysis considers *P* < .05 as meeting statistical significance. Cramer's V was used to calculate the overall effect size of the intervention.

**Results:** For the rheumatologists who participated in the online activity, comparison of pre- and post-assessment responses demonstrated statistically significant improvements (*n* = 59; *P* < .05) in knowledge and a robust overall effect (*V* = 0.307). As a result of participating in this educational program, significant absolute percentage increases in correct responses were observed (all *P* < .05):

- 25% increase (44% vs 69%) in those who identified the trial design of an open-label extension of the MOBILITY trial regarding the 3-year efficacy of a specific IL-6 inhibitor
- 36% increase (10% vs 46%) in those who recognized the association between different types of disease flare and progression of joint damage as reported in a post hoc analysis of the PRESERVE trial
- 31% increase (44% vs 75%) in those who identified that tumor necrosis factor alpha therapy allowed patients to reduce or discontinue methotrexate or corticosteroid therapy as reported in a 10-year open-label extension of the PREMIER and DE019 trials

**Conclusion:** Participation in video-based expert discussions of clinical trial data from current and emerging agents resulted in significant improvement in knowledge of rheumatologists. A need for further education was also identified regarding the most up-to-date clinical information regarding management of RA as presented at major medical conferences.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

The development of the 2010 classification criteria for rheumatoid arthritis (RA) has led to a redefinition of the patient population, including classification of seropositive versus seronegative patients (1). In our recently published study of early RA patients fulfilling the 2010 ACR/EULAR criteria, we found seronegative patients to have markedly higher disease activity at time of diagnosis, compared to seropositive patients (2). There is very limited information about the disease course of seronegative patients classified according to the new criteria. Our aim was to examine the disease course of seronegative RA patients fulfilling the 2010 ACR/EULAR criteria.

**Methods:**

In the treat-to-target ARCTIC trial, DMARD-naïve RA patients classified according to the 2010 EULAR/ACR criteria were randomised 1:1 to follow-up with or without ultrasound. Patients in both arms were treated according to the same DMARD escalation strategy. Patients were assessed at 13 visits during two years of follow-up (3).

We stratified the patients as seropositive (rheumatoid factor (RF)+, anti-citrullinated peptide antibody (ACPA)+, or both) or seronegative (RF- and ACPA-). At baseline and 24-month follow-up, disease activity measures were compared across groups using independent t-test or Mann-Whitney U test as appropriate. We also compared the change in disease activity measures from 0-24 months across groups.

**Results:**

A total of 230 patients were included. Mean (SD) age was 51.4 (13.7) years and 61.3 % were female; 34 patients (14.8%) were seronegative. Mean age (SD) was 55.4 (2.7)/ 50.8 (0.9) years ( $p=0.07$ ), mean (SD) disease duration was 7.7 (6.8)/7.0 (5.1) months ( $p=0.46$ ), and 56/62 % were females ( $p=0.48$ ) in the seronegative/seropositive groups.

At baseline disease activity measures and radiographic joint space narrowing were higher in seronegative compared to seropositive patients. At 24-month follow-up, measures of disease activity were similar between groups (table). There was a tendency towards more radiographic damage in terms of joint space narrowing in the seronegative patients.

Seronegative patients had a greater reduction (0-24 months) in disease activity measures in terms of DAS, swollen joints, physician global and ultrasound scores (table).

**Table: Measures of disease activity compared across serology status at 0 and 24 months**

Measure	Baseline			State at 24 months			p

PROMIS Physical	39.2 [30-46]	39.3 [33-44]	0.86	51 [44-63]	50 [43-63]	0.50	0.47
ACR/EULAR remission n [%]	-	-	-	53%	48%	0.59	-

Values are median [25-75 percentiles] if not otherwise indicated. \*Mean (SD). †In seronegative versus seropositive patients.

## Conclusion:

In this study of early RA patients, seronegative patients had more inflammatory activity at baseline and a tendency to more radiographic damage, but disease activity after two years of treat-to-target therapy was similar to the seropositive patients. Our findings suggest that seronegative patients classified according to the new criteria respond to modern treatment strategies, with similar rates of patients reaching remission compared to seropositive patients.

Barcelona. Spain, Barcelona, Spain, <sup>5</sup>Arthritis Unit, Rheumatology Dpt,

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

The primary aim of this study was to analyse serum levels differences of angiogenic and inflammatory biomarkers between SDAI, CDAI, ACR, DAS28 and sonographic remission in patients with RA. As secondary objective, we tried to find clinical, serological or ultrasound biomarkers of radiographic progression and clinical flares in RA patients in clinical remission.

## **Methods:**

We selected patients with RA in clinical remission (defined as DAS28-ESR < 2.6 for > 6 months) tested by two independent rheumatologists. Clinical, epidemiological, demographic and serological data were analyzed. PDUS of knees and hands was performed by a sonographer with an ultrasound scanner with a linear probe of 8-12 MHz. Serum levels of biomarkers of inflammation/angiogenesis were determined by Quantibody® Human Array. Patients were classified according to 6 sets of remission criteria: SDAI (<3.3), CDAI (<2.8), ACR/EULAR, DAS28-ESR (<2.6), Doppler (score Doppler=0) and UdAS (ultrasound defined active synovitis: no joints with SH>2+PD). A clinical and radiographic follow-up of the patients was done along 5 years. Clinical flare was defined as the loss of remission (DAS28-ESR > 2.6) and change on the baseline treatment for RA. Radiographic progression was defined as the new appearance of erosions in hands or feet.

## **Results:**

60 patients with RA were collected. 76% female, aged (mean) 53 years; disease duration 110 months. Sixteen (26%) patients were taking oral prednisone (<5 mg/day), 47 (76%) conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), and 27 (45%) biological therapies. At baseline, 67% of patients had PD signal and 48% fulfilled criteria for previously defined UdAS. Although patients in sonographic remission (both Doppler and UdAS) had lower levels of inflammatory biomarkers such as IL-6, IL-17 or IL-23, no significant differences were found between the 6 sets of remission criteria. Angiogenic biomarkers such as CXCL6 (0.039), ENA78 (0.007), SDF1 (0.047) and VEGF-R1 (0.025) were significantly lower in patients fulfilling CDAI remission. Patients with no PD signal (0.009) and no UdAS (0.006) had significantly lower levels of bFGF. After 5 years of follow-up, 12 patients (20%) flared and 14 (23.3%) had radiographic progression. No significant differences were found in flares or X-ray progression between the 6 sets of remission criteria.

Patients fulfilling UdAS but not those with only PD, had more radiographic progression (p=0.014). Patients on biological therapy had less clinical flares along the 5 years of follow-up (p=0.049). Finally, patients with more CD20+ cells infiltrates in synovial membrane had also more radiographic progression (p=0.033).

## **Conclusion:**

RA patients in CDAI remission had significantly-lower levels of angiogenic cytokines. Remission according to DAS28-ESR did not show worse clinical or radiographic progression after 5 years of follow-up. Noteworthy, UdAS and CD20+ cells infiltrates were both significant factors of radiographic progression.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Our objective was to compare RA treatment strategies with conventional and biologic DMARDs after an initial MTX strategy was ineffective or associated with a severe adverse event.

**Methods:** We studied adults from a multicenter early arthritis cohort (enrolled from 2007- 2017 within one year of symptom onset). RA patients were eligible for our analyses if they initiated MTX (+/-other DMARDs) within 90 days of cohort entry and subsequently changed therapy (changed MTX route, lowered or stopped MTX or other DMARD, or added another DMARD or biologic). For this analyses, the time of medication change formed the time zero for a survival analyses of the second treatment approach. Patients were followed from time zero to assess discontinuations of, or additions to, their therapy. Multivariable survival models were used to compare outcomes. We generated hazard ratios (HRs) and 95% confidence intervals (CI), comparing each of the treatment groups to oral methotrexate monotherapy.

**Results:** We included 911 RA patients initially exposed to MTX who had a first treatment failure. At time zero (time of initial failure), the most common second treatment strategies were MTX+ another DMARD (32.9%) and non MTX DMARDs (26.1%) (Table 1).

**Table 1 Distribution of treatment approaches after a first MTX failure**

Treatment	Frequency		Time to discontinuation (in months) <sup>1</sup>		Frequency of any failure*	Loss of efficacy <sup>2</sup>	Serious adverse effect <sup>2</sup>	Any side effect <sup>2</sup>
	N	%	Median	Range	N (%)	N (%)	N (%)	N (%)
MTX oral	58	6.4	7.8	0.3 to 69.5	39 (67%)	6 (10.3%)	0 (0%)	11 (19.0%)
MTX subcutaneous	89	9.8	9.1	0.3 to 89.8	58 (65%)	4 (4.5%)	0 (0%)	17 (19.1%)
MTX + another DMARD	300	32.9	6.8	0.3 to 83.9	196 (65%)	23 (7.7%)	1 (0.3%)	100 (33.3%)
MTX+SSZ+HCQ	126	13.8	12.0	0.3 to 83.0	82 (65%)	7 (5.6%)	0 (0%)	48 (38.1%)
Biologics+/- DMARDs including MTX	100	11.0	12.9	0.4 to 95.7	37 (37%)	11 (11.0%)	0 (0%)	22 (22.0%)
Non MTX DMARDs only	238	26.1	4.5	0.3 to 73.9	182 (76%)	6 (2.5%)	0 (0%)	45 (18.9%)
Total	911	100.0	6.9	0.3 to 95.7	594 (65%)	57 (6.3%)	1 (0.1%)	243 (26.7%)

<sup>1</sup> Estimated by Kaplan-Meier curves

<sup>2</sup>As reported by the treating MD

The multivariable Cox regression analysis for the 911 RA patients suggested that those on biologics and those on triple therapy had a longer time to failure, compared to the group taking MTX oral monotherapy. (Table 2)

**Table 2 Adjusted hazard ratios (HR) for drug changes after time zero\***

Treatment at time zero	HR	95% CI
MTX subcutaneous monotherapy	0.91	0.61, 1.35
MTX + another DMARD	0.87	0.62 1.22
MTX+SSZ+HCQ	0.64	0.44, 0.94
Biologics+/- DMARDs including MTX	0.31	0.20, 0.49
Non MTX DMARDs only	1.26	0.89, 1.77

\*Adjusting for baseline characteristics: age, sex, co-morbidities, symptom duration, race, education, smoking, erosions, DAS-28, disease activity, corticosteroids, NSAIDs, and COXIBs

**Conclusion:** Our data suggest that, in those who fail initial MTX, RA patients given biologics or triple therapy remain on that treatment longer without further changes, versus those taking augmented MTX oral monotherapy. These data do not confirm clear differences in outcomes with respect to MTX(dual or triple) combinations, but width of confidence intervals precludes definitive conclusions in this regard.

## ABP 710: Matching Critical Biological Functions with Infliximab

**Robert Sandrock**<sup>1</sup>, Palanisamy Kanakaraj<sup>2</sup> and Scott Kuhns<sup>1</sup>, <sup>1</sup>Amgen, Inc., Thousand Oaks, CA, <sup>2</sup>Amgen, Inc., Cambridge, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

ABP 710 is being developed as a biosimilar to infliximab, a recombinant chimeric monoclonal antibody that binds tumor necrosis factor alpha (TNFα) and inhibits the TNF receptor-mediated downstream pro-inflammatory signaling cascade. Although ABP 710 and infliximab reference product have the same primary amino acid sequence differences in production cell line and the manufacturing process can impact product quality attributes that may be critical for in vivo efficacy, pharmacokinetics and immunogenicity. To demonstrate that ABP 710 is similar to the reference product, we performed a comprehensive comparative biological characterization of ABP 710 with infliximab reference product.

### Methods:

The functional similarity assessment of ABP 710 and infliximab reference product included: 1) binding to soluble (s) TNFα by ELISA, 2) binding to membrane-bound (mb) TNFα by a competitive imaging cytometry-based assay, 3) inhibition of sTNFα-induced apoptosis in the U937 cell line, and 4) reverse signaling via induction of apoptosis in mbTNFα-expressing Jurkat cells. To confirm similarity of Fc-mediated functions, antibody-dependent cell-mediated cytotoxicity (ADCC) was assessed using cells expressing mbTNFα as target cells and NK92-M1 cells expressing FcγRIIIa (158V) as effector cells. In addition, complement-dependent cytotoxicity (CDC) was assessed using rabbit complement and cells expressing mbTNFα. Data from at least three lots of ABP 710 and infliximab reference product sourced from the US (IFX-US) and infliximab reference product sourced from the EU (IFX-EU) were assessed as described.

### Results:

Relative binding of ABP 710 to sTNFα (ABP 710 =93-105%; IFX-US =88-101%; IFX-EU =93-104%) and mbTNFα (ABP 710 =101-109%; IFX-US =99-106%; IFX-EU =105-113%) were similar between ABP 710 and infliximab reference product. Relative inhibition of apoptosis in U937 cells (ABP 710 =87-112%; IFX-US =78-115%; IFX-EU =89-114%), and to induce apoptosis in Jurkat cells expressing mbTNFα (ABP 710 =99-105%; IFX-US =90-114%; IFX-EU =96-107%) were also similar between ABP 710 and infliximab reference product. Fc-mediated functions, ADCC (ABP 710=102-133%; IFX-US =91-169%; IFX-EU =100-166%) and CDC (ABP 710 =96-110%; IFX-US =93-136%; IFX-EU =98-135%) were similar as well between ABP 710 and infliximab reference product.

### Conclusion:

As one aspect of the “totality of evidence” approach to support similarity, results from this assessment demonstrate that ABP 710 is functionally similar to infliximab reference product in multiple sensitive biological characterization assays.

# Certolizumab Pegol for Fatigue in Chronic Inflammatory Rheumatic Diseases: A Meta-Analysis

**Yesim Ozguler**<sup>1</sup>, Sinem Nihal Esatoglu<sup>1</sup>, Guzin Karatemiz<sup>1</sup>, Ali Ugur Unal<sup>2</sup>, Gul Guzelant<sup>1</sup>, Elif Dincses<sup>3</sup>, Mustafa Erdogan<sup>1</sup>, Sema Kaymaz Tahra<sup>2</sup> and Gulen Hatemi<sup>1</sup>, <sup>1</sup>Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, <sup>2</sup>Departement of Internal Medicine, Division of Rheumatology, Marmara University, Istanbul, Turkey, <sup>3</sup>Istanbul University, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fatigue is an important problem that impairs life quality in patients with rheumatic diseases. Although fatigue is often associated with disease activity, only a modest effect of anti-TNFs on fatigue was observed in patients with RA (1). We aimed to determine the efficacy of different doses of certolizumab pegol (CZP) in chronic inflammatory rheumatic diseases by a meta-analysis of randomized controlled trials.

**Methods:** A systematic literature search including patients with rheumatic diseases who received CZP was performed. We searched PubMed for all randomized controlled trials with CZP up to May 2017 without any restrictions. Studies that assessed fatigue in any rheumatic disease using the fatigue assessment scale (FAS) and reported the FAS score and/or the proportion of patients who met the minimum clinically important difference (MCID) for FAS score were included. The MCID for FAS is 1 over a scale of 0 to 10 where higher scores show increased severity of fatigue. The CZP 200 mg and CZP 400 mg arms of trials were pooled for comparison with the placebo arms.

**Results:** The literature search yielded 68 articles. 55 articles were excluded after evaluating the title and abstract, 5 were excluded after reading the full-text. Among the 8 RCTs that were selected-, the study population was RA in 6 RCTs, and psoriatic arthritis and axial spondyloarthritis in 1 RCT each. Overall, there were 2964 patients treated with CZP and 1056 with placebo. Table summarizes the included studies.

An improvement in the FAS score and an increase in the proportion of patients who met the MCID for FAS were observed in all the included trials regardless of the underlying disease (Figure-1, 2). The pooled results showed that CZP significantly improved fatigue compared to placebo (FAS: MD = -1.50, 95% CI:-1.71- -1.29, p <0.0001, MCID: RR=2.53, 95% CI: 1.74-3.68).

**Conclusion:** This meta-analysis showed that CZP may be an effective treatment modality for fatigue in rheumatic diseases.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Serum level of MMP-3 rises by synovial inflammation in patients with rheumatoid arthritis (RA). It destroys articular cartilage such as proteoglycans so that it has been used as a clinical biomarker of joint destruction. Also it has been reported as a predictor for radiographic progression. The purposes of this study are to confirm a relation between baseline MMP-3 and radiographic progression at 1 year and to examine the association of the MMP-3 level with ultrasonography (US) findings.

**Methods:** A total of 259 (213 women) consecutive patients with RA were enrolled in this study. Their baseline data including age, sex, disease duration, use of glucocorticoid (GC) or DMARDs, disease activity (DAS28), laboratory data (MMP-3, CRP, RF and ACPA), radiographic assessment (modified total Sharp score; mTSS) and the power doppler score (PD) in US assessment at digits and wrists were collected. Baseline MMP-3 level was analyzed in association with the baseline PD value and changes in mTSS ( $f\Delta$ mTSS), erosion score ( $f\Delta$ ERN), joint space narrowing ( $f\Delta$ JSN) at 1 year from baseline using Pearson's correlation method. Correlations between  $f\Delta$ MMP-3 and  $f\Delta$ mTSS, or  $f\Delta$ PD were also analyzed. Multiple regression analysis was performed with  $f\Delta$ mTSS as the outcome for baseline variables. Statistical analysis was performed separately by sex because the upper normal limits of MMP-3 is different between male and female.

**Results:** There was no correlation between baseline MMP-3 and disease duration, GC use, DAS28, RF, CRP and mTSS. There was moderate correlations between baseline MMP-3,  $f\Delta$ MMP-3,  $f\Delta$ mTSS and  $f\Delta$ JSN at 1 year only in men. There was also a weak correlation between the baseline MMP-3 and baseline PD score only in men. However, MMP-3 could not predict joint destruction at 1 year in women. Multiple regression analysis revealed that the baseline MMP-3 level correlated independently with the  $f\Delta$ mTSS only in men ( $p=0.0031$ ), whereas the baseline PD score was correlated independently with the  $f\Delta$ mTSS in women ( $p=0.0003$ ).

**Conclusion:** The baseline MMP-3 level was a good predictor for deterioration of the mTSS at 1 year in male patients with RA, but not in female patients. On the other hand, the baseline PD score was a useful predictor of joint destruction in female patients with RA.

	variables	correlation coefficient	confidence interval	p
Male patients				
Baseline MMP-3	$f\Delta$ mTSS	0.501 <sup>a</sup>	[0.246, 0.691]	<0.001
	$f\Delta$ ERN	0.336 <sup>b</sup>	[0.051, 0.571]	0.022
	$f\Delta$ JSN	0.542 <sup>a</sup>	[0.299, 0.719]	<0.0001
	baseline-PD	0.228 <sup>b</sup>	[-0.074, 0.492]	0.136
$f\Delta$ MMP-3	$f\Delta$ mTSS	-0.435 <sup>a</sup>	[-0.644, -0.165]	0.003
	$f\Delta$ ERN	-0.325 <sup>b</sup>	[-0.562, -0.038]	0.028
	$f\Delta$ JSN	-0.436 <sup>a</sup>	[-0.645, -0.167]	0.002
	$f\Delta$ PD	0.134	[-0.170, 0.414]	0.387
Female patients				
Baseline MMP-3	$f\Delta$ mTSS	0.0011	[-0.130, 0.132]	0.987
	$f\Delta$ ERN	0.0188	[-0.113, 0.150]	0.780
	$f\Delta$ JSN	-0.0148	[-0.146, 0.117]	0.826
	baseline-PD	0.0985	[-0.040, 0.233]	0.163

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis (RA) is associated with neovascularization of the synovial membrane and increased risk of cardiovascular co-morbidity. The extra cellular matrix below the endothelial cells is referred to as the basement membrane, embedding and protecting the cells. Altered remodeling of basement membrane proteins, including type IV collagen is a core characteristic in persistent chronic inflammation. We aimed to investigate the association of type IV collagen turnover with RA disease activity, response to IL-6 inhibition and radiographic progression.

### **Methods:**

The study was based on patients participating in LITHE (NCT00106522, n=687) and RADIATE (NCT00106535, n=217), phase III, double blinded, placebo controlled studies testing 4 and 8 mg/kg tocilizumab (TCZ) on top of methotrexate.

Basement membrane turnover was assessed at baseline and subsequently for up to 52 weeks using ELISA for quantification of circulating C4M, an MMP generated collagen IV fragment in serum. We calculated correlations between C4M and disease activity measures, treatment response and imaging findings.

### **Results:**

Baseline C4M was significantly correlated with clinical disease parameters in both study populations, including DAS28, HAQ score and VASpain (all  $p < 0.00001$ ). TCZ lowered C4M by 11%-40% in a dose dependent manner and the likelihood of achieving an ACR20 response by week 16 was associated with C4M suppression exceeding the median decrease at week 4 ( $p < 0.0001$ ). C4M at baseline correlated significantly with change in JSN ( $p = 0.001$ ) and Sharp score ( $p = 0.00002$ ) at 52 weeks.

### **Conclusion:**

Basement membrane remodeling as assessed by C4M was associated with disease activity and radiographic progression in RA. This remodeling was persistently suppressed by TCZ in a dose dependent manner. These findings probably reflect that RA synovitis suppression and slowing of erosive progression are at least in part attributable to angiostatic effects by tocilizumab

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is the first line treatment for patients with rheumatoid arthritis (RA). For over 30% of patients, MTX fails to diminish DAS28 score in a timely and satisfactory manner. The challenge is to find a way to identify these non-responders at the time of diagnosis. The aims of this study were to determine whether plasma cytokines could be used as biomarkers of early RA and of therapeutic response to MTX.

**Methods:** Thirty RA patients receiving MTX (mean age  $58 \pm 12$  y.o. with symptom duration of  $6 \pm 3$  mo.) from the Group for Early Arthritis Research (GEAR) / CHU de Québec SARD Biobank Data Repository (SBDR). Patients were evaluated clinically at baseline and 6 mo., and classified as responders to MTX or non-responders according to the DAS28CRP EULAR Classification (good response vs moderate/none). Plasma cytokines were measured at baseline by multiplex assay or ELISA and compared to age- and sex-matched healthy controls. Patients were Bivariate logistic regression was used to identify RA patients and non-responders based on cytokine concentration or detection, with Firth bias correction when needed. Optimal cut points were found using distance criteria and their predictive performance was assessed.

**Results:** Plasma concentrations of IL-1RA, CCL11/Eotaxin, CXCL10/IP-10, CCL2/MCP-1, CCL4/MIP-1 $\beta$ , CCL5/RANTES, CXCL12a/SDF-1 $\alpha$  and calprotectin were significantly different in RA patients compared to controls. IL-21, IL-22, IL-1 $\alpha$ , CXCL1/GRO $\alpha$  were detected differently in RA plasma (Table 1). IL-1RA and CCL4/MIP-1 $\beta$  were good predictors of RA with sensitivity and specificity of approximately 95% when dichotomized with cut points of 280 and 124, respectively. Thirty-five percent of patients were non-responders to MTX. IL-1 $\alpha$ , IL-18, IL-17A and IL-27 were less frequently detected in non-responders (Table 2).

**Conclusion:** Several cytokines differentially expressed in plasma are associated with early RA. Absence of detection of IL-1 $\alpha$ , IL-17A and IL-27 and low concentration of IL-18 was associated with non-response to MTX. We propose that these cytokines could be used as predictors of MTX response in RA.

**Acknowledgements:** This work was partly funded by CIHR. We thank Pfizer, Amgen, BMS, Abbvie, Roche, Sanofi-Genzyme and Merck & Co. for unrestricted financial contribution to the SBDR.

**Table 1: Plasma cytokine concentrations significantly different between RA patients and healthy controls at baseline.**

Cytokine	Controls (n=30)	RA (n=30)	Odds Ratios (95% CI)	Pvalue (Wald)
IL-1RA	92 (56-174)	1561 (1175-2607)	1.01(1.00-1.01)	0.0065

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Smoking and Opioid Use Is Associated with Symptom Severity in Rheumatoid Arthritis

**Background/Purpose:** Cigarette smoking, both current and past, is a risk for incident rheumatoid arthritis (RA), even for those with low exposure rates of 1-10 pack years. As smoking is associated with opioid use in patients with chronic pain, the aim of the current analysis was to examine disease status for RA patients and the relationship between current cigarette smoking and opioid use.

**Methods:** As part of a study to evaluate cigarette and marijuana smoking in rheumatic disease patients, 1000 consecutively attending rheumatology patients completed an anonymous self-administered questionnaire including: pain severity on visual analog scale (VAS), patient global assessment (PtGA) and cigarette or marijuana smoking status. Concomitant physician recorded information included: diagnosis, sociodemographics, co-morbidities, treatments for RA and physician global assessment (PGA). Patients were categorized according to current smoking status and opioid use. Patient characteristics were compared between groups with one-way ANOVA.

**Results:** 248 patients were diagnosed with RA [mean (SD) age = 62.4 (14.3) years and 77.4% female] stratified by smoking status and opioid use: 9 patients were current smokers and opioid users, 186 patients non-smokers and non-opioid users, and 53 patients current smokers or opioid users (Table 1). Unemployment/ disability was statistically different between groups (current smokers & opioid users vs. non-smokers & non-opioid users vs. current smokers or opioid users: 11.1% vs. 3.3% vs. 13.5%;  $p = 0.015$ ). Current smokers and opioid users reported significantly worse disease, including higher PGA ( $p < 0.001$ ), PtGA ( $p = 0.021$ ) and pain VAS ( $p = 0.001$ ), followed by current smokers or opioid users. In regard to medication use, current smokers and opioid users took significantly more medications for disease management ( $p < 0.001$ ), specifically NSAIDs ( $p = 0.019$ ) and anti-epileptics ( $p = 0.020$ ) with a trend towards more antidepressant use ( $p = 0.088$ ).

**Conclusion:** Current smoking and opioid use is significantly associated with increased disease severity and other medication use, indicating that RA patients who smoke experience greater symptom severity and may use chemical coping methods to alleviate symptoms.

Table 1. Patient Profile by Smoking Status and Opioid Use

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

While many clinical trials provide direct comparisons between biologic disease modifying antirheumatic drugs (bDMARD) and nonbiologic DMARD (nDMARD), there is a need for additional evidence on the effectiveness of these therapies in routine clinical practice. We evaluated changes in disease activity measures associated with bDMARD therapy, in a large cohort of patients with RA, under conditions of routine clinical practice.

### Methods:

The OM1 platform collects, links, and leverages, structured and unstructured data from electronic medical records (EMR) and other sources in an ongoing and continuously updating manner. The OM1 RA Cohort includes data on >75,000 patients treated by rheumatologists. This analysis included patients who were treated with nDMARD between January 2013 and April 2017, had not received prior treatment with bDMARD, and either added or switched to another nDMARD or initiated bDMARD during the observation period (date of change in therapy is the index date). Established American College of Rheumatology cutpoints for standard disease activity measures (RAPID-3, CDAI, DAS28) were used to define remission. Advanced natural language processing was used to impute missing disease activity categories. Drug eras were defined using Observational Medical Outcomes Partnership (OMOP) definitions. Survival analyses were conducted to evaluate time to initial remission and confirmed remission defined as 2 consecutive scores denoting remission. To reduce the impact of subsequent treatment changes, data were censored at 12 months. Patients who switched or added nDMARD but subsequently initiated bDMARDs within 6 months after the index date were excluded in sensitivity analyses. To reduce the bias that more frequent disease activity measures may be associated with shorter time to remission, we matched the two groups on average number of disease activity measures per patient.

**Results:** The analysis cohort included 4,957 patients who met study inclusion criteria, none of whom were in remission at index date; 1,334 added or switched to another nDMARD and 3,623 added or switched to a bDMARD. There were an average of 4.2 disease activity measures per patient and a total of 20,605 disease activity measures during the 12 month study period. A larger proportion of patients in the bDMARD group achieved initial remission (18% versus 16%,  $p<0.05$ ) and confirmed remission (13% versus 11%,  $p<0.05$ ) compared to the nDMARD group. Time to remission was significantly shorter in the bDMARD group (mean $\pm$ SD=5.2 $\pm$ 3.4 months) compared to the nDMARD group (5.7 $\pm$ 3.2 months,  $p<0.05$ ). These results were unchanged in the sensitivity analysis.

**Conclusion:** Disease activity improved with changes in DMARD therapy; however, the addition of bDMARDs were associated with significantly shorter time to remission. This study uses novel data collection techniques to replicate

findings from prior observational studies in a much larger and contemporaneous cohort of patients under conditions of routine clinical practice.

## Effect of Patient Involvement in Treatment Decision Making on Disease Outcomes in Rheumatoid Arthritis in the USA

Richard Hutchings<sup>1</sup>, Shailja Panchal<sup>2</sup> and Elizabeth Baynton<sup>1</sup>, <sup>1</sup>Ipsos Healthcare, London, United Kingdom, <sup>2</sup>Ipsos Healthcare, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ACR guidelines for treating Rheumatoid Arthritis (2015) suggest that treatment decisions should be made by physicians and patients through a shared decision-making process taking into account patients' values, preferences, and comorbidities. Identifying the impact of patient involvement on disease outcomes in biologic patients would provide further evidence which could support ACR guideline recommendations and be used to inform optimal disease management.

**Methods:** A multi-center medical chart review study of patients with RA was conducted in Q4 2016 among physicians in hospitals and private practices to collect de-identified data on patients who were recently treated with a biologic as part of usual care in the USA. Physicians were screened for duration of practice (3-30yrs) and patient volume ( $\geq 2$  RA biologic patients/week) and recruited from a large access panel to be geographically representative of the country. Eligible patient charts ( $\geq 5$ ) were randomly selected from among the patients visiting each center/practice during the screening period. Physicians abstracted date of diagnosis, treatment patterns/dynamics, and symptomatology/disease status. Physicians identified the level of patient involvement in treatment decision making using a 7 point scale, and patient records were segmented into low-medium involvement (1-4/7) and high involvement (5-7/7). Sites waived local ethics review owing to collection of retrospective de-identified data. High involvement versus low involvement patients were compared using descriptive statistics.

**Results:** 517 biologic RA patients were assessed; overall, Highly involved: 409 (79%), Low-mid involved: 108 (21%). Patient characteristics (Highly involved/Low-mid involved) included: age (in years) 50/54; full time employment status 57%/42%; co-existing conditions: obesity (14%/28%), dyslipidemia (19%/33%), depression (19%/28%), none (45%/24%). Time since diagnosis (in months): 52.2/48.3. Among patients with available data, current lab measures included: ESR(mm/h) 20.3/24.0; CRP(mg/l) 2.8/3.8; rheumatoid factor(positive) 89%/84%; anti-CCP(positive) 80%/72%; measures of disease severity included: disease severity per physician judgment: mild (72%/53%), moderate (25%/40%), severe (3%/7%); disease under control 80%/69%; remission 63%/52%; mean DAS 28 2.7/3.2; mean tender joint count 3.4/3.6; mean swollen joint count 2.3/2.4.

**Conclusion:** In this cohort of RA patients in the USA, majority of patients with high involvement were seen to be younger, healthier patients who were full time employees. These patients were significantly more likely to be considered as mild disease severity (physician judgement) with a higher proportion in remission. Lab measures indicated lower disease burden

with low hematology scores for highly involved patients. Further investigation of the influence of socioeconomic status, insurance type, and other demographics on patient involvement in treatment may warrant further research.

## **Clinical Response to the First Biologic in Rheumatoid Arthritis Patients with Moderate Disease in a Real World Clinical Cohort**

Xiuying Li, Angela Cesta, Mohammad Movahedi and **Claire Bombardier**, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

While most randomized trials assess the effectiveness of biologic DMARDs (bDMARDs) in rheumatoid arthritis (RA) patients with high disease activity, in the real world or routine care, patients with moderate disease activity are often treated with bDMARDs as well. This study aims to evaluate the effectiveness of the first biologic with or without conventional synthetic DMARD (csDMARDs) in patients with moderate disease activity.

### **Methods:**

Biologic naïve patients enrolled in the Ontario Best Practices Initiative (OBRI), with moderate disease activity score (DAS28: >3.2-5.1), or high disease activity score (DAS28: >5.1) were included. Patients were also required to remain on the biologic for 6 months and to have complete follow up data during this time period. Clinical response to their first biologic was measured by the change in DAS28 and by the proportion of patients who reached low disease activity (LDA) during the first 6 months of treatment. The change in DAS28 was assessed using linear regression modelling, adjusted for potential confounders (age, gender, disease duration, and physician global assessment). Multivariate logistic regression was used to compare the proportion of patients who reached LDA in each group at 6 months, adjusting for the same potential confounders.

### **Results:**

The analysis included 443 patients. At initiation of their first biologic, 238 patients had a moderate DAS28 and 205 had a high DAS28. Patient demographics for the two groups are shown in Table 1. At initiation of their first bDMARD, the two groups were similar with respect to age, gender, and disease duration. All of the DAS28 components, as well as the physician global were significantly different between the two groups. A significant change in DAS28 was found in both the moderate disease group [-0.89 (95% CI -1.12, -0.66)] and the high disease group [-1.86 (95% CI -2.10, -1.62)], with greater improvement seen in the high disease activity group. A comparison of the change in DAS28 between the two groups was also significant ( $0.97 \pm 0.16$ ,  $p < 0.0001$ ). After 6 months of biologic treatment, a higher proportion of patients in the moderate DAS28 group reached LDA, when compared to the high DAS28 group (OR: 1.65; 95%CI: 1.03-2.65,  $p = 0.04$ ).

**Table 1.** Patient Characteristics at initiation of first bDMARD, by DAS28 group

<b>DAS28 group at bDMARDs start</b>	<b>Moderate DAS28 3.2-5.1</b>	<b>High DAS28 &gt;5.1</b>	<b>P - value</b>
N	238	205	
Age, years	55.3 (13.2)	57.1 (12.9)	0.14
Female n(%)	192 (80.7%)	169 (82.4%)	0.63
Disease duration, years	7.4 (8.8)	6.7 (7.6)	0.36
DAS28	4.18 (0.54)	5.98 (0.63)	<0.0001
28 swollen joint count	5.4 (3.7)	9.1 (4.7)	<0.0001
28 tender joint count	4.5 (3.5)	12.4 (5.8)	<0.0001
ESR, mm/h	19.1 (16.5)	34.3 (22.7)	<0.0001
CRP, mg/L	8.7 (15.4)	17.7 (24.6)	<0.0001
Patient global assessment (0-10)	5.0 (2.5)	6.7 (2.2)	<0.0001
Physician global assessment (0-10)	4.6 (2.0)	6.3 (1.8)	<0.0001
Rheumatoid factor positive n (%)	160 (72.7%)	143 (75.7%)	0.50
Previous CsDMARDs use $\geq 2$ n(%)	213 (90%)	182 (89%)	0.81
Receiving oral steroid, n (%)	50 (21.0%)	37 (18.1%)	0.43

Values are given as mean (standard deviation) unless otherwise specified.

## Conclusion:

**Conclusions:** Treatment with bDMARDs is effective in patients with moderate disease activity. While patients with high disease activity showed greater improvement after 6 months of biologic treatment, patients with moderate disease activity at initiation of a bDMARD were more likely to reach a LDA state.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) may fail to respond to biologic therapy. We study patients who are resistant to different classes of biologic agents and compare their clinical and serological features to patients who are biologic respondents.

**Methods:** Patient from The Kuwait Registry for Rheumatic Diseases (KRRD) who satisfied the ACR classification criteria for RA from four major hospitals were studied from February 2013 through May 2017. Patients were divided into two main groups, biologic therapy resistant defined as patients previously switched from a biologic agent or who are currently not responding to biologic therapy (DAS28 > 3.2). The second group are patients who are biologic therapy respondents defined as patients who have been in remission or in low disease activity (DAS28 < 3.2) on biologics for at least three months with no previous history of any biologic resistance.

Biologic agents were then divided into anti-TNF and non-anti-TNF agents.

In addition, patients who were resistant to >3 biologics were further studied.

**Results:** Among 1,280 patients with RA, 318(24%) have been prescribed at least one anti-TNF agent sometime during their disease course. Among them, 194(61%) were resistant to one anti-TNF or more. 554(43%) were prescribed at least one non-anti-TNF. Among them, 313(56%) were resistant to one non-anti-TNF or more. Of the total resistant patient, 29/507(5.7%) have failed 3 or more biologics.

Comparing the anti-TNF resistant group with the anti-TNF respondents, there was a tendency toward a thyroid disease (15.5% vs 8.1%,  $p=0.051$ ) and a lower serum uric acid (means=263 vs 283  $\mu\text{mol/L}$ ,  $p=0.06$ ). Patients who were resistant to non-anti-TNFs had more females than patients who responded to non-anti-TNFs (78% vs 68.5%,  $p=0.012$ ) and a lower uric acid (means=249 vs 267  $\mu\text{mol/L}$ ,  $p=0.012$ ). Comparing patients who were resistant to > 3 biologics with patients who are biologic respondents, resistant patients had more females (93.1% vs 69.4%,  $p=0.007$ ), more hyperlipidemia (24.1% vs 9.5%,  $p=0.014$ ), more hypertension (41.4% vs 21.4%,  $p=0.014$ ) and more osteoporosis (24.1 vs 10.4%,  $p=0.026$ ).

Other factors such as age, age at RA diagnosis, body mass index, rheumatoid factor, anti-cyclic citrullinated peptide antibodies, ANA, extra-articular features, family history of a rheumatic disease and other co-morbidities including cardiovascular diseases were comparable between the groups.

**Conclusion:** RA patients resistant to biologic therapy have some features that are different from patients who are respondents. Further study of those patients may allow an early recognition aiming at a better planning of treatment and improving their outcome.

Mikuls<sup>5</sup> and Kaleb Michaud<sup>2</sup>, <sup>1</sup>Division of Rheumatology & Immunology, Department of Internal Medicine, University of Nebraska Medical Center, Omaha, NE, <sup>2</sup>University of Nebraska Medical Center, Omaha, NE, <sup>3</sup>Division of Rheumatology & Immunology, Department of Internal Medicine, Nebraska-Western IA VA Health Care System & University of Nebraska Medical Center, Omaha, NE, <sup>4</sup>Department of Internal Medicine, University of Nebraska Medical Center, Omaha, NE, <sup>5</sup>Internal Medicine, Division of Rheumatology, University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Viral hepatitis may complicate the treatment of RA since select DMARD have the potential to cause hepatotoxicity or reactivation of latent viral infections. Whether treatment patterns and RA outcomes are impacted by this comorbid condition is not well studied. Similarly, little is known about RA factors and the risk the developing of hepatitis. Thus, we assessed the associations of viral hepatitis with RA disease outcomes and DMARD use and determined the RA factors predictive of incident hepatitis.

**Methods:** We studied participants with RA within the National Data Bank for Rheumatic Diseases (NDB) from 2004 to 2017. Sociodemographic, health behaviors, comorbidities, RA measures, and medications were collected every 6 months via self-report. Additionally, participants were assessed for current or prior history of viral hepatitis. We used multivariable linear and logistic regression models to assess associations of prior viral hepatitis with RA outcome measures and treatments. We also assessed the associations of RA measures and DMARD with incident viral hepatitis using multivariable Cox proportional hazard regression models.

**Results:** Among 22,942 participants with RA, current or prior hepatitis was self-reported present in 207 (Hepatitis A), 165 (Hepatitis B), and 317 (Hepatitis C). Adjusting for age, sex, employment, education level, comorbidity index, smoking, alcohol and drug use, patients with prior hepatitis B and C had higher pain scores while patients with hepatitis C had higher patient activity scale (PAS) scores. Hepatitis C was also marginally associated with higher patient global assessment scores. MTX use was less frequent in those with hepatitis B and C while the use of NSAIDs and biologics did not differ between groups (Table 1). Over 90,952 patient-years of follow-up, 132 patients developed incident viral hepatitis. After multivariable adjustment, higher pain and PAS scores were independently associated with an increased risk of viral hepatitis (Table 2). Biologics were not associated with incident viral hepatitis while MTX was associated with a lower risk of incident hepatitis. To assess whether misclassification of prevalent hepatitis as incident hepatitis was occurring, we used a 6-month lag for viral hepatitis diagnosis, finding similar results.

**Conclusion:** History of viral hepatitis infection is associated with worse RA patient reported outcomes measures and lower use of MTX. Clinicians should be aware of the potential for viral hepatitis to influence patient reported outcomes measures in RA. Reassuringly, biologic DMARD do not appear to increase the risk of incident viral hepatitis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is an ongoing Phase 4 comparator study designed to provide a real-world assessment of intravenous golimumab (GLM) and infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA). Although the primary objective of AWARE is to compare the proportion of GLM and IFX pts with an infusion reaction, RA medication utilization patterns and biologic infusion times are collected for purposes of conducting dosing and cost analyses. Although cost and managed care coverage are frequently cited by practicing rheumatologists as variables involved in therapeutic choices, data is lacking in the published literature. Here we report on GLM and IFX drug utilization patterns from an interim analysis (IA) of the ongoing AWARE study.

**Methods:** AWARE is a prospective, noninterventional, observational, multicenter 3-year study conducted at 100 sites in the US. RA pts (1,200 adults) will be enrolled at the time of initiating treatment with either GLM or IFX. All treatment decisions including prescribed dose, administered drug amount and dosing interval are made at the discretion of the treating rheumatologist. Infusion duration was reported by the site. Data shown are mean  $\pm$  standard deviation.

**Results:** 421 GLM pts and 326 IFX pts were included in the IA. GLM pts were  $61.0 \pm 12.97$  years and IFX pts were  $57.2 \pm 13.02$  years. Body weight of GLM pts was  $85.3 \pm 24.6$  kg and body weight of IFX pts was  $85.5 \pm 23.3$  kg. BMI of GLM pts was  $32.2 \pm 13.4$  kg/m<sup>2</sup> and BMI of IFX pts was  $31.7 \pm 9.5$  kg/m<sup>2</sup>. Of GLM pts, 34.7% were bionäive and 49.7% of IFX pts were bionäive. The % of GLM and IFX pts with prior exposure to 1 or 2 biologics was similar (data not shown), however exposure to  $\geq 3$  biologics was 19.2% of GLM pts compared to 9.8% of IFX pts. GLM and IFX were infused at a rheumatologist practice (95.0% and 96.3%, respectively). GLM pts received 1434 infusions at  $2.00 \pm 0.08$  mg/kg, and IFX pts received 1328 infusions at  $3.71 \pm 1.21$  mg/kg. The duration of GLM infusions was  $0.65 \pm 0.23$  hours and IFX infusions was  $2.0 \pm 0.46$  hours. There was a significant ( $p < 0.0001$ ) difference in the % of pts with a reported dose increase from baseline between GLM and IFX (2.6% vs 32.2%, respectively).

Inf #*	Prescribed Dose: mg/kg (n)		Dose Range: mg/kg		Administered Dose (mg) (n)	
	GLM	IFX	GLM	IFX	GLM	IFX
1	$2.0 \pm 0.08$ (417)	$3.36 \pm 0.74$ (323)	1.0 – 3.0	2.0 – 7.0	$172.1 \pm 50.3$ (421)	$298.5 \pm 96.7$ (326)
2	$2.0 \pm 0.07$ (364)	$3.38 \pm 0.73$ (304)	1.0 – 2.5	2.0 – 7.0	$173.0 \pm 51.5$ (366)	$303.0 \pm 99.9$ (307)
3	$2.0 \pm 0.08$ (280)	$3.53 \pm 0.92$ (265)	1.0 – 2.7	3.0 – 8.0	$174.3 \pm 53.9$ (282)	$319.3 \pm 117.5$ (267)
4	$2.0 \pm 0.01$ (187)	$3.99 \pm 1.32$ (188)	2.0 – 2.1	3.0 – 10.0	$182.2 \pm 75.4$ (187)	$359.5 \pm 158.3$ (189)
5	$2.0 \pm 0.00$ (117)	$4.38 \pm 1.57$ (129)	2.0 – 2.0	3.0 – 10.0	$173.3 \pm 48.3$ (117)	$393.3 \pm 171.0$ (130)
6	$2.0 \pm 0.00$ (47)	$4.65 \pm 1.86$ (65)	2.0 – 2.0	2.0 – 10.0	$170.7 \pm 46.3$ (47)	$421.2 \pm 202.7$ (65)
7	$2.0 \pm 0.00$ (12)	$5.06 \pm 2.13$ (29)	2.0 – 2.0	3.0 – 10.0	$157.3 \pm 46.0$ (12)	$445.6 \pm 245.5$ (29)

\* Inf # = Infusion number

**Conclusion:** This IA of the AWARE study, reported on drug and administration utilization characteristics of GLM and IFX. While the dose of GLM was not reported to change over the course of the first 7 infusions, among pts with 7 infusions the mean dose of IFX increased by approximately 152% between the first and seventh dose. IFX dose escalation was evident at the third dose. These data provide evidence that in a real-world rheumatology practice setting, the dose of GLM remains

constant, whereas the dose of IFX is more variable and the mean infusion time of GLM was consistently shorter compared to IFX. The AWARE study will utilize these data to assess the relative cost effectiveness of GLM relative to IFX.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). We evaluated tofacitinib 5 and 10 mg twice daily (BID) efficacy in patients (pts) with moderate vs severe RA.

**Methods:** Tofacitinib 5 and 10 mg BID efficacy data were from 6 randomized, double-blind Phase 3 studies of 6–24 months' (Mos) duration. Pts received tofacitinib as monotherapy (NCT00814307 ORAL Solo; NCT01039688 ORAL Start) or with csDMARDs, mainly MTX (NCT00960440 ORAL Step; NCT00847613 ORAL Scan; NCT00856544 ORAL Sync; NCT00853385 ORAL Standard). Pts receiving MTX monotherapy (ORAL Start) or placebo (PBO) ( $\pm$ csDMARDs) were combined as a single PBO group. Baseline (BL) disease severity was classified as moderate or severe using Disease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28: moderate 3.2– $\leq$ 5.1; severe  $>$ 5.1) and Clinical Disease Activity Index (CDAI; moderate 10– $\leq$ 22; severe  $>$ 22). Mo 3 efficacy outcomes included: pts (%) achieving low disease activity (LDA; DAS28 $\leq$ 3.2, CDAI $\leq$ 10), remission (REM; DAS28 $<$ 2.6, CDAI $\leq$ 2.8), HAQ-DI  $<$ 0.5 (normal physical functioning), HAQ-DI improvement  $>$ 0.22, and mean change from BL ( $\Delta$ ) in DAS28, CDAI, and HAQ-DI. This post-hoc analysis had no multiplicity adjustments.

**Results:** More pts had severe disease at BL by DAS28 (91.8%) and CDAI (90.7%). Mo 3 efficacy outcomes for pts were classified by BL DAS28 disease severity (Table). BL characteristics were balanced between treatment groups in each disease severity category (Table). In general, Mo 3 efficacy was significantly greater for tofacitinib 5 and 10 mg BID vs PBO, regardless of BL disease severity. Larger proportions of tofacitinib-treated pts with moderate vs severe BL RA achieved LDA by either DAS28 (32.3–36.7% vs 13.8–19.1%) or CDAI (49.2–55.0% vs 26.0–31.7%). A higher proportion of pts achieved REM in the moderate vs severe BL groups by DAS28 (20.0–22.8% vs 6.2–9.0%) or CDAI (11.5–12.1% vs 5.1–6.7%). A greater proportion of pts achieved HAQ-DI  $<$ 0.5 with moderate vs severe RA classified by BL DAS28 (45.0–

60.6% vs 24.5–30.0%) or BL CDAI (40.8–52.4% vs 24.7–30.4%). Pts with severe vs moderate RA had greater improvements from BL in disease activity and HAQ-DI when classified by BL DAS28 (Table), and by BL CDAI (tofacitinib 5/10 mg BID  $\Delta$ CDAI: -21.1/-23.0 vs -8.1/-9.4;  $\Delta$ HAQ-DI: -0.5/-0.6 vs -0.3/-0.4).

**Conclusion:** Tofacitinib 5 and 10 mg BID demonstrated efficacy in treating pts with moderate and severe RA with >7 years' mean disease duration. By Mo 3, pts with severe vs moderate BL disease activity had greater improvements in disease activity and physical functioning; higher proportions of pts with moderate vs severe BL disease activity achieved REM, LDA, or normal physical functioning. This post-hoc analysis may be limited by the smaller sample size of the moderate disease group and the combining of mono- and combination-therapy results.

**Table. Baseline Disease Characteristics (A) and Month 3 Efficacy Outcomes (B) by Baseline Disease Severity Assessment using DAS28**

A) Mean (SD) baseline demographics and characteristics

Saunders<sup>1</sup>, Sabrina Rebello<sup>1</sup> and Joel Kremer<sup>4</sup>, <sup>1</sup>Corrona, LLC, Southborough, MA, <sup>2</sup>Eli Lilly and Company, Indianapolis, IN, <sup>3</sup>University of Massachusetts Medical School, Worcester, MA, <sup>4</sup>Albany Medical College and The Center for Rheumatology, Albany, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Response to biologic agents approved for RA may be associated with patient reported factors that are not related to disease and usually not included in studies attempting to predict response to therapy. The objective was to evaluate whether such factors can influence the probability of response to biologic agents and persistency of therapy.

**Methods:** Patients with RA initiating a biologic agent while in moderate or high disease activity (based on CDAI levels) were eligible for participation in the Corrona-CERTAIN comparative effectiveness study and were included in the analysis. ENSEMBLE Minimum Data Set (MDS), which is comprised of 10 patient (pt) reported scales not specific to RA, (such as income levels, depression, perceived stress and depression, social support, education) was used to evaluate prediction of response to biologic agents in combination with factors collected in the Corrona registry (“traditional factors”). ENSEMBLE components were measured at time of initiation of biologic. Response to biologic therapy was evaluated at 6 months as achievement of low disease activity (LDA). Persistency was estimated using the Kaplan-Meier method. Associations of response to therapy and persistency with baseline values of ENSEMBLE components were assessed based on logistic and Cox regression, respectively. To determine whether ENSEMBLE components added value to “traditional” disease related factors in predicting response, Akaike information criterion (AIC) and Bayesian information criterion (BIC) were evaluated for the three models: mix of “traditional” and ENSEMBLE variables; traditional variables only; and emphasis of ENSEMBLE over traditional variables. The resulting response and persistency models with lowest AIC and BIC were identified and further evaluated for discriminatory power.

**Results:** Analysis included 2152 biologic initiations in moderate or high disease activity. At 6 months, 682 patients had achieved LDA (responders) and 1470 had not (non-responders). Of the responders, 58% were treated with a TNF inhibitor and 37% were biologic naïve prior to enrollment in CERTAIN, vs 49% and 30% of non-responders respectively. Of the three response models, the best AIC and BIC values corresponded to the logistic model that emphasized ENSEMBLE over traditional variables and the discriminatory power for this model was comparable (72.6%) to the other two models (72% and 72.5%).%) in predicting response to therapy. For time to discontinuation of biologic, the emphasized ENSEMBLE model was again the best in terms of lowest AIC and BIC and discriminatory power (C-statistic) was comparable (60.8% to 59.7% and 61.7%).

**Conclusion:** The generic, non-disease specific set of scales of ENSEMBLE added value to models predicting response to therapy of RA with biologic agents. Such factors may allow a refined assessment of patient heterogeneity beyond traditionally used disease specific measures and have a similar performance in predicting therapy response and persistency with traditional factors.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Anti-citrullinated protein antibodies (ACPA) display broad cross-reactivities and target proteins including α-enolase, filaggrin, vimentin, fibrinogen, and histones. However, every monoclonal ACPA has a distinct recognition pattern. Citrullination occurs during physiological processes such as NETosis and apoptosis, yet the interaction of ACPA with nuclear antigens in apoptotic cells has not been previously investigated. Apoptotic cells, and especially defects in clearance of apoptotic and dead cells resulting in increased exposure to nuclear antigens, have been postulated to play a pivotal role in the pathogenesis of autoimmune disease.

### **Methods:**

We screened a total of 12 recombinant monoclonal human ACPA-IgG, derived from synovial plasma cells or circulating memory B cells, and two control mAb for binding to full-length citrullinated histones by ELISA. Apoptotic cell binding was determined by flow cytometry and Western blotting, followed by mass spectrometry to identify key antigen targets. Fluorescent microscopy was performed to screen ACPA staining in anti-nuclear antibody (ANA)-Hep-2 tests and for binding to human thymus tissue. A total of 210 seropositive and 50 seronegative RA patients and 157 population controls from the EIRA case-control cohort, were screened for IgG reactivity against full-length native and citrullinated histone 2B (Cit-H2B) by ELISA. Reactivity to citrullinated peptides was determined by antigen microarray multiplex assay.

### **Results:**

A distinct subset of ACPA bound apoptotic cells of human and murine origin. We could also observe nuclear staining for these ACPA in human thymus tissue, and ANA positivity with a nuclear dense fine speckled staining pattern. Mass spectrometry revealed that H2B was the pre-dominant target within apoptotic cells. The ANA-positive ACPA had strong recognition of citrullinated histones (H2B, H4). Among CCP2-positive RA patients, 26% were positive for elevated anti-cit-H2B normalized for reactivity to native H2B, and the titer correlated the strongest with binding to citrullinated filaggrin

and fibrinogen peptides ( $R=0.4$ ,  $p<0.0001$ ). We also observed a weak correlation with disease activity in seropositive RA ( $R=0.20$ ,  $p=0.02$ ). Interestingly, 32% seronegative RA patients had autoreactivity to native H2B compared to 4.5% ( $p<0.0001$ ) among controls, while there was no elevation in reactivity to cit-H2B normalized for native H2B (4% compared to 4.5% in controls).

## Conclusion:

Interactions between ACPA and citrullinated histones facilitate apoptotic cell binding. We hypothesize that this may be a key functional feature in RA pathogenesis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Fab-glycosylation is found in ~15-25% serum IgG and while its exact consequence remains unknown, it may alter IgG functionality. Recent data revealed elevated Fab-glycosylation in polyclonal anti-citrullinated protein autoantibodies (ACPA) from rheumatoid arthritis (RA) patients. Herein, we characterize the Fab-glycan profile of monoclonal ACPA.

## Methods:

A total of 14 recombinant human ACPA, derived from RA synovial plasma cells or circulating memory, were evaluated for predicted N-linked glycosylation sites using the NetNGlyc server. Fab-glycosylation was verified with enzymatic digestion, Western blot, lectin-ELISA, and mass spectrometry. Antigen binding was investigated by CCP3 ELISA. VH-VL structure models were generated using the PIGS tool and the GlyProt server. The frequency of predicted VH-VL sites was compared to single-cell paired heavy and light chains from extensively mutated mAbs (>15 mutation in VH or VL): 51 expressed non-ACPA synovial B cells from seropos. RA, and 27 from seroneg. RA, and 198 bone marrow (BM) plasma cells, and 27 clones from healthy control circulating memory. These were compared to 19 highly-mutated broadly-neutralizing (bn) HIV

mAbs and 103 plasmodium faciparium (PF) specific mAbs from the literature. Fisher's exact test or Kruskal-Wallis test was used in statistical analysis.

## Results:

The majority of ACPA exhibited variable region N-linked motifs (85.7%), compared to 18.5% in control ( $p<0.0001$ ), 21.2% in RA BM plasma cells ( $p<0.0001$ ), 31.4% non-ACPA synovial RA mAbs ( $p=0.0005$ ), 7.4% of clones from seroneg. RA ( $p<0.0001$ ), 25.2% in PF mAbs ( $p<0.0001$ ), and 63.2% of HIV bnAbs ( $p=0.24$ ), featured in both framework and CDRs generated by somatic hypermutation (SHM). Indeed, ACPA displayed high level of SHM (average 30 VL and 52 VH), yet when adjusted for SHM, N-linked motifs were significantly elevated in ACPA compared to all groups including bnAbs. IgG mAb characterization revealed that N-linked motifs were indeed glycosylated, although preliminary data suggested that glycans had no striking effect on antigen-binding. Homology-based structures predicted glycans to be primarily positioned outside of the potential antigen-binding site. Lectin analysis and mass spectrometry suggested that ACPA mAb Fab-glycan composition was distinctly different from Fc-glycans, and could have high sialic acid content.

## Conclusion:

The results support that Fab glycosylation is a key feature of ACPA. Significant increases in N-linked motifs in ACPA compared to other highly-mutated antibodies signifies that this is not solely associated to mutation frequency. Future studies are merited to further investigate the selection mechanisms and functional role of Fab-glycosylated autoantibodies

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Antibodies to citrullinated protein antigens (ACPA) precede the development of rheumatoid arthritis (RA) and may be generated in the lung of established and preclinical RA patients. An association has been demonstrated between serum ACPA and ectopic lymphoid tissue (ELT) in the lung of RA and non-RA patients with lung disease, suggesting that ELT may be a mechanism for ACPA generation in the lung (Rangel-Moreno 2016, Brown ACR 2015, Abstract #963). To further explore the mucosal basis of ACPA, we examined ACPA isotypes and lung histopathology in patients with and without RA.

### Methods:

Using materials from the NIH's Lung Tissue Resource Consortium (LTRC) we evaluated lung biopsies and serum samples from 10 RA patients with interstitial lung disease (RA-ILD), 30 non-RA patients with ILD (Non-RA ILD) and 35 non-RA

patients with emphysema or airway disease (Non-ILD). Serum was tested for IgA and IgG ACPA isotypes using the CCP3 antigen plate (Inova, research only). Lung tissue was evaluated by a pathologist blinded to patients' clinical status to determine the presence of ELT defined as germinal centers (GCs) or lymphoid aggregates. Logistic regression was used to determine associations of isotype levels with ELT.

## Results:

Patients' characteristics are presented in the Table. There were significantly higher mean IgG ACPA levels in RA cases compared to non-RA patients (Figure). Mean IgA ACPA levels were higher compared to IgG in non-RA ILD (83.2 vs. 26.6) and non-ILD patients (40.3 vs. 5.3), although in RA patients, there was no significant difference in isotype levels (Figure). There was an association between serum IgA ACPA levels and ELT in all subjects ( $p=0.01$ ), but not IgG. Smoking, age, and gender were not significantly associated with ELT; however, RA was significantly associated with ELT ( $p=0.03$ ). To evaluate the relationship between serum ACPA isotypes and ELT in absence of RA, an analysis of only non-RA subjects showed that IgA ACPA levels remained significantly associated with ELT (OR 1.14 for every 10-unit increase in IgA; 95% CI 1.01-1.28;  $p=0.02$ ).

## Conclusion:

Our findings support a link between serum ACPA and lung ELT. Given the strongest association was seen between ELT and IgA ACPA for non-RA subjects, it may be that IgA ACPA are related to ELT even in absence of articular disease. The strong association of IgG ACPA with RA may indicate that this isotype is a marker for RA-specific articular processes. Future studies should assess the mechanisms underlying these findings, and how differentiating IgA and IgG ACPA may help in the management of RA and non-RA patients with lung disease.

	RA-ILD n=10	Non-RA ILD n=30	Non-ILD n=35	p-value
Age, mean (SD)	55 (10.1)	61 (10.8)	61 (9.9)	0.24
Female, N (%)	8 (80%)	16 (53%)	19 (54%)	0.34

### Protein carbamylation is induced by activated neutrophil: ex vivo analysis

#### Background/Purpose:

Anti-carbamylated protein (anti-CarP) antibodies were reported to be detected in 45% of rheumatoid arthritis (RA) patients [1]. We previously reported that carbamylated albumin (CarALB) was one of the target antigens of anti-CarP antibodies, and serum myeloperoxidase (MPO) level was elevated in rheumatoid arthritis patients with anti-CarALB antibody [2]. Protein carbamylation occurs by cyanate which MPO produces from thiocyanate ( $\text{SCN}^-$ ) and hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), and MPO abundantly exists in neutrophil. Therefore, neutrophil is a strong candidate for the production of carbamylated antigen. The purpose of this study is to demonstrate that activated neutrophil induces protein carbamylation.

#### Methods:

Human neutrophils were isolated from whole blood by ficoll-dextran methods. They were pre-treated for 30 min at 37°C in RPMI medium with or without 10  $\mu\text{M}$  diphenyleneiodonium (DPI), which inhibits NADPH-dependent reactive oxygen species (ROS) production. Subsequently, they were incubated overnight at 37 °C in RPMI medium containing 0.01mg/mL ALB with or without 10  $\mu\text{M}$  DPI, 20nM phorbol 12-myristate 13-acetate (PMA) and 100  $\mu\text{M}$  potassium thiocyanate (KSCN). Then proteins in the medium were collected by trichloroacetic acid/acetone precipitation. The carbamylation of ALB was confirmed by Western blotting using anti-carbamyl-lysine (CBL) polyclonal antibody. MPO in the medium was detected by Western blotting using anti-MPO polyclonal antibody.

#### Results:

ALB was carbamylated only when both neutrophil and KSCN were present (Figure 1, lanes 4 and 5). Although the carbamylation occurred in the medium both with and without PMA, the level of the carbamylation was much higher in the medium with PMA (lane 5) than without PMA (lane 4). Carbamylation was inhibited by the presence of DPI, which diminishes ROS (lanes 7 and 8). MPO was released into the culture supernatant from the neutrophils (Figure 2, lane 2), and its release was accelerated by PMA (lanes 3 and 5), but attenuated by DPI (lanes 7 and 8).

#### Conclusion:

ALB in the culture medium was carbamylated by neutrophil. Given that PMA induces ROS production of neutrophil, and this reaction subsequently increases the MPO release, our data suggest that carbamylation is dependent on ROS and MPO from neutrophil. Addition of KSCN was necessary. This is the first report that showed direct relationship between neutrophil and protein carbamylation.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoantibodies (RF or ACPA) are found in sera from patients with palindromic rheumatism (PR) but there are no studies analyzing the presence of Anti-carbamylated proteins antibodies (Anti-CarP) in patients with PR. The aim of this study was to analyse the prevalence of Anti-CarP in patients with PR and to evaluate their clinical significance and association with autoantibody status (RF and ACPA).

**Methods:** Patients with pure PR (not associated with any rheumatic disease at the time of serum measurement) with sera collected between June 2012 and June 2013 were included (*Cabrera-Villalba S et al J Rheumatol 2014;41:1650-5*). Anti-CarP were determined by a home-made ELISA test using a synthetic chimeric fibrin/filaggrin homocitrullinated peptide (CFFHP) as antigen. IgG, IgA and IgM isotype were measured using the corresponding secondary antibodies. Cut-off values were determined using ROC curves, with a specificity of 98% compared with a healthy population. ACPA, RF, progression toward persistent arthritis fulfilling ACR/EULAR RA criteria, and remission (no joint attacks in the last 6 months) was analyzed during the follow-up (until May 2017). Patients were treated according to physician criteria. A control group of established RA patients was also included.

**Results:** Anti-CarP antibodies were analyzed in 54 patients with pure PR and 53 patients with established RA controlled by age, gender and disease evolution. ACPA (CCP2) was positive in 64.8% of PR and 66.0% of RA patients. Anti-CarP were found in 9 out of 54 (16.7%) of PR patients. Patients with PR and Anti-CarP (+) were all ACPA positive and presented higher ACPA titers than Anti-CarP (-) patients (Table 1). In PR patients, IgG was the predominant isotype (100%) and only one patient presented IgA (11.1%) and none IgM. In the RA control group, the prevalence of Anti-CarP was 39.6% and the percentages of IgG, IgA and IgM were 57.1%, 47.6% and 38.1% of Anti-CarP (+) patients respectively. DMARDs were administered in 64.8% of patients (in all Anti-CarP (+) patients) at the last assessment, mainly antimalarials and methotrexate. More Anti-CarP (+) patients developed RA (33.3% vs. 16.3%) during follow up although the difference was not significant. Remission was more frequent in Anti-CarP negative patients (Table 1).

## Conclusion:

**Table 1. Clinical and serological characteristics of PR patients according to Anti-CarP status**

	RP with Anti-CarP (+) n: 9	RP with Anti-CarP (-) n: 45	p value
<b>Female</b>	5 (55.6%)	29 (64.4%)	NS

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Human monoclonal ACPA (Human-ACPA) is reported to strongly bind to synovium in RA patients [1]. The aims of our study were 1) To investigate whether Human-ACPA, which was generated from peripheral blood B cells from an RA patient by us, binds to synovium from OA and RA, and 2) To identify cell-type expressing citrullinated proteins in synovium from OA and RA patients.

**Methods:** Human-ACPA was produced by a method published earlier [2, 3]. Joint synovium from OA or RA patients (10 OA, 10 RA) were immunohistochemically stained with Human-ACPA. Double-label immunofluorescence staining with Human-ACPA/CD3, Human-ACPA/CD20 or Human-ACPA/CD68 (3 OA, 3 RA), and confocal laser scanning microscope (3 RA) were performed in the synovia for the images.

**Results:** Human-ACPA bound to all layers in synovium from RA patients. Human-ACPA positive cells were limited in the surface layer in 7 of 10 OA patients, while no Human-ACPA positive cells were found in the remaining 3 OA synovia.

Human-ACPA positive cells in synovium of OA were not double-stained with CD3, CD20 or CD68 monoclonal antibody. On the other hand, there were Human-ACPA/CD3, Human-ACPA/CD20 or Human-ACPA/CD68 double positive cells in synovium of RA patients.

Most of the ACPA positive cells were stained with CD68. Human-ACPA/CD3 and Human-ACPA/CD20 double positive cells also existed in deeper layers of synovium in RA patients.

**Conclusion:** All layers of synovium in RA patients were studded with cells which contained citrullinated proteins. Cells positive for citrullinated protein in RA were mainly macrophage-lineage (CD68<sup>+</sup>). Citrullinated protein was also expressed in T cells (CD3<sup>+</sup>) and B cells (CD20<sup>+</sup>) in RA. Citrullinated protein existed in the strip-shaped form only in the surface layer of OA synovia and may have been induced by mechanical stresses. No macrophages, T cells or B cells were positive for citrullinated protein in OA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### *Background/Purpose:*

Anti-citrullinated protein antibodies (ACPA) associate with more severe joint erosions in rheumatoid arthritis (RA), but the underlying mechanism is unclear. Recent in vitro and murine studies indicate that ACPAs can directly activate osteoclasts leading to bone erosion and pain. This study sought evidence for this hypothesis on the human level and evaluated in arthralgia patients at risk for RA whether ACPA associated with erosions (detected by MRI) independent of inflammation, and also independent of the presence of other autoantibodies (Rheumatoid Factor, RF).

### *Methods:*

225 patients with Clinically Suspect Arthralgia underwent ACPA- and RF-determination and 1.5T contrast-enhanced MRI of metacarpophalangeal, wrist and metatarsophalangeal joints at baseline. MRIs were scored for presence of local inflammation and erosions.

### *Results:*

ACPA-positive patients had higher erosion-scores than ACPA-negative patients ( $p=0.02$ ; Figure Panel A). ACPA-positive patients without subclinical inflammation did not have higher erosion-scores than ACPA-negative patients ( $p=0.45$ ), in contrast to ACPA-positive patients with local inflammation ( $p=0.001$ , Figure Panel B). Mediation analyses suggested that local inflammation is in the causal path of ACPA leading to higher erosion-scores. Compared to autoantibody-negative patients, ACPA-positive/RF-negative patients did not differ ( $p=0.41$ ), but ACPA-positive/RF-positive patients had higher erosion-scores ( $p=0.001$  Figure Panel C).

### *Conclusion:*

The effect of ACPA on erosions is mediated by inflammation and is not independent of RF.

**Figure.** Histograms showing median erosion-scores of patients with Clinically Suspect Arthralgia comparing ACPA-positive and ACPA-negative patients (A), ACPA-positivity and -negativity in relation to the concomitant presence of MRI-detected subclinical inflammation (B) or rheumatoid factor (C).

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-peptidylarginine deiminase (PAD)-4 antibodies (Abs) are present in a portion of RA patients and associate with more severe joint disease, suggesting that they play a role in pathogenesis. A subset of anti-PAD4 Abs cross-react with PAD3, and these Abs are found to enhance PAD4 enzyme activity at physiologic calcium concentrations which can lead to increased citrullination. Anti-PAD3/4 cross-reactive Abs have also been associated with more severe lung disease in RA, suggesting they may have a direct effect in the lung. Because sputum anti-CCP Abs have been identified in RA, we sought to explore the presence and activity of anti-PAD4 Abs in the sputum of RA patients.

**Methods:** We studied 48 serum anti-CCP+ RA patients and 24 healthy controls. Induced sputum was tested for CCP using commercial ELISAs. Serum and sputum were tested for anti-PAD4 Abs using an established immunoprecipitation method. All anti-PAD4+ samples underwent testing for the presence of PAD3 cross-reactivity. To determine the effect of anti-PAD Abs on PAD4 enzymatic activity, Igs were purified from each anti-PAD+ sample and their effect on citrullination of the histone H3 substrate by PAD4 at increasing calcium concentrations (i.e. 0.2 and 2 mM) was measured by an anti-citrullinated histone H3 immunoblot.

**Results:** Serum anti-PAD4 Abs were detected in 6/48 (13%) of RA patients and 0/24 (0%) controls. Of the positive patients, 2/6 (33%) were also serum anti-PAD3+. Sputum anti-PAD4 Abs were detected in 3/48 (6%) of RA patients, and of those positive, 1/3 (33%) was also sputum anti-PAD3+. Serum anti-PAD4 Abs were more prevalent in RA patients with sputum anti-CCP Abs, with all anti-PAD4+ RA patients demonstrating sputum anti-CCP positivity (Table). In serum, anti-PAD4 Abs were predominately IgG, whereas in sputum, anti-PAD4 Abs were predominately IgA (Figure). Interestingly, all three samples (serum and sputum) with measurable anti-PAD3/4 Abs were able to increase PAD4 activity at 0.2 mM calcium (i.e. physiologic levels).

**Conclusion:** We identified serum anti-PAD4 Abs in a portion of RA patients, of which a subset was also anti-PAD3+. We demonstrate for the first time that anti-PAD4 Abs are also present in the sputum in a portion of RA patients, and

predominately IgA. Importantly, we found that anti-PAD3/4 IgA present in the sputum was able to lower the calcium threshold required for PAD4 enzymatic activity. These findings suggest that anti-PAD4 Abs may have pathogenic activity directly in the lung, although larger studies are needed to understand the relationship between anti-PAD3/4 and underlying lung disease.

Table. Characteristics associated with serum anti-PAD4 antibodies			
	Serum anti-PAD4(+)	Serum anti-PAD4(-)	
	(N=6)	(N=42)	p-value*
Age, median (IQR)	51 (29-64)	58 (45-62)	0.49
% Female	83	79	0.24
% Ever smoker	17	55	0.19
% Current smoker	17	19	1.0
% Shared epitope positive	80	66	1.0
% RA disease duration >1 year	33	62	0.22
% Any self-reported lung disease	33	38	1.0
% Sputum anti-CCP positivity**	100	50	<b>0.03</b>
*P-value compares median levels (Mann-Whitney U) or prevalence of positivity (Chi-Square/Fishers) between groups as appropriate.			
**Includes positivity for commercial assays CCP3 (IgG, Inova) and/or anti-CCP3.1(IgG/IgA, Inova). The cut-off level used to determine sputum anti-CCP positivity was established in a separate healthy control group.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

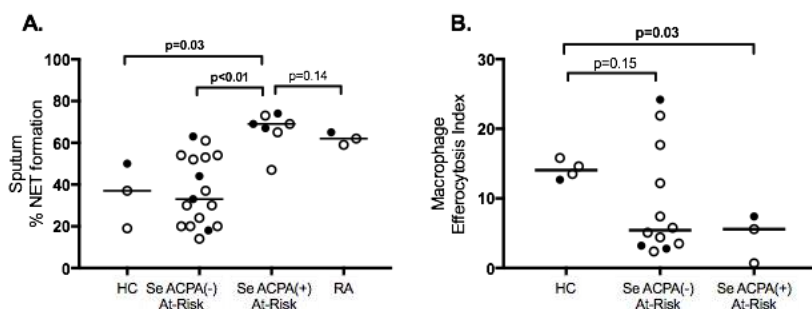

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Data support that ACPAs are generated in the lung in RA-free subjects At-Risk of future RA. Our group previously demonstrated a significant positive correlation between sputum ACPA levels and remnants of neutrophil extracellular traps (NETs) in At-Risk subjects (*Demoruelle 2017*). However, it is unknown if increased sputum NET levels in these subjects is due to aberrant neutrophil function or ineffective macrophage function (e.g. decreased macrophage efferocytosis that is a mechanism of apoptotic cell clearance). Herein, we sought to quantify ex vivo NET formation and macrophage efferocytosis in association with ACPA in the sputum of At-Risk subjects.

**Methods:** We collected serum and induced sputum from 24 subjects At-Risk for RA based on familial RA or serum ACPA positivity identified through community screenings [17 were serum ACPA- and 7 serum ACPA+ based on commercial CCP3.1 (IgG/IgA, Inova)], 3 healthy Controls and 3 serum ACPA+ classified RA patients. Sputum was tested for ACPA using CCP3.1 ELISA and the cut-off for positivity was determined in a separate healthy control group (N=70). Sputum plugs were processed and incubated for 1 hour without stimulation for NET measurements and a subset (N=15) were also incubated with apoptotic Jurkat cells for efferocytosis assays. The formation of NETs was assessed by fluorescence microscopy with staining for Hoechst 33342, neutrophil elastase and citrullinated histone-H3. Microscopy-based methods were used to quantify the percent of neutrophils demonstrating NET formation and the efferocytosis index for macrophages ingesting apoptotic Jurkats.

**Results:** NET formation in sputum neutrophils was significantly higher in serum ACPA+ At-Risk subjects compared to Controls ( $p=0.03$ ) and serum ACPA- At-Risk subjects ( $p<0.01$ ) (Figure Panel A), although a portion of serum ACPA- At-Risk subjects had elevated rates of sputum NET formation. There was a trend toward a higher prevalence of sputum ACPA positivity in At-Risk subjects with  $>60\%$  NETosis [4/8 (50%) vs. 3/15 (20%),  $p=0.18$ ]. There was no difference in NETosis based on smoking history. The efferocytosis index was lower in serum ACPA+ At-Risk subjects compared to Controls ( $p=0.03$ , Figure Panel B).

**Conclusion:** We found that sputum neutrophils in At-Risk subjects exhibit increased NET formation in serologically ACPA+ At-Risk individuals. Furthermore, in these subjects, sputum macrophages exhibited decreased efferocytosis. These findings suggest that enhanced neutrophil NET formation and ineffective macrophage efferocytosis in the lung may both play a role in the development of systemic and potentially local mucosal ACPA generation in subjects At-Risk for RA. Additional studies are needed to determine whether sputum NETs in At-Risk subjects contain unique citrullinated protein cargo as well as whether these processes are aberrant at other mucosal sites.

**Figure. Rates of Ex Vivo Neutrophil Extracellular Trap (NET) Formation and Macrophage Efferocytosis in Sputum.** The figure depicts the rates of NET formation in sputum neutrophils (Panel A) and the macrophage efferocytosis index (Panel B) in each group. The % NET formation is calculated by dividing the number of NETs formed by the total number of neutrophils in each subject. The efferocytosis index is calculated by multiplying the % of macrophages that phagocytosed an apoptotic Jurkat cell by the average number of apoptotic cells engulfed per macrophage. Open circle=sputum ACPA negative, close circle=sputum ACPA positive. Abbreviations: HC=Healthy controls, Se=Serum, ACPA=anti-citrullinated protein/peptide antibody, RA=Rheumatoid arthritis

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Protein citrullination, the post-translational conversion of arginine to citrulline, mediated by peptidylarginine deiminase (PAD) enzymes, is considered a likely mechanism for the stimulation of anti-citrullinated protein antibodies (ACPA) in patients with rheumatoid arthritis (RA). Hypercitrullination, the citrullination of multiple intracellular proteins, is seen in synovial fluid (SF) cells from RA patients. This unique form of citrullination is proposed to occur via immune-mediated, pore-forming membranolytic pathways such as perforin-granzyme activation. Indeed, perforin and granzyme-producing CD8<sup>+</sup> T effector cells are found in the synovium of pre-clinical RA patients as well as in the peripheral blood (PB) and SF of active RA patients, persisting into disease remission.

Insight into the existence of potential cytotoxic mechanisms occurring in RA comes from the co-occurrence of RA in up to 36% of cases of T-cell Large Granular Lymphocyte (T-LGL) Leukemia, a clonal condition characterized by neutropenia attributed to the killing of neutrophils or their precursors by cytotoxic CD8<sup>+</sup> T cells. We thus queried LGL leukemia as a model for neutrophil (PMN)-directed cytotoxicity contributing to hypercitrullination and disease propagation in inflamed joints of ACPA<sup>+</sup> RA patients.

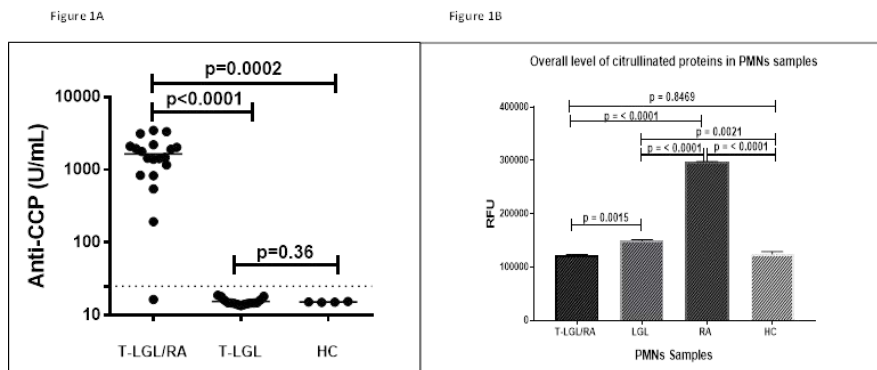

### **Methods:**

The sera of 15 T-LGL leukemia patients (T-LGL), 19 T-LGL leukemia patients with co-existing RA (T-LGL/RA), and 4 healthy controls (HC) were analyzed for ACPA positivity by ELISA. ACPA titers of each group of patients were compared using unpaired two-tailed T tests. Neutrophils (PMN) from each of these groups were isolated from blood cells by density gradient centrifugation. Hypercitrullination of these cells (n=4/patient group) was compared with that of seropositive RA patients by proteomic analysis using Rhodamine-PG labeling, protein precipitation followed by Streptavidin enrichment, and sequent digestion. The resulting products were analyzed using LC-MS/MS on an LTQ-Orbitrap mass spectrometer. The

tandem MS data were searched using SEQUEST algorithm using a concatenated target/decoy variant of the human and mouse International Protein Index database.

## Results:

T-LGL/RA patients had significantly higher serum ACPA positivity than T-LGL patients or HC (Fig. 1A). Surprisingly, however, the overall level of citrullinated proteins in PMN (Fig.1B) was not increased in T-LGL/RA compared to T-LGL patients, and was highest in PMN obtained from RA patients (Fig. 1B).

## Conclusion:

These results reveal an interesting dichotomy between RA that occurs spontaneously versus that occurring in patients with LGL leukemia. Whereas both spontaneous and LGL-associated RA develop high titer ACPA, only RA patients show a high degree of citrullination of neutrophil proteins. Whether this suggests a different source of immunogenic proteins or relates to other biologic processes, remains to be determined.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-citrullinated protein antibody (ACPA) reactivities can precede RA onset, and may be involved in the pathogenesis of the disease. We wanted to assess the prevalence of baseline ACPA reactivities in an inception cohort of early RA patients, including subgroups based on anti-CCP/RF status, and to compare the findings to healthy controls.

**Methods:** 217 DMARD-naïve early RA patients from the ARCTIC trial (1) were analyzed. Radiographs were scored according to van der Heijde Sharp (vdHS) score. Anti-CCP status was analyzed by FEIA (positive if  $\geq 10$  IU/mL) and RF by ELISA (positive if  $\geq 25$  IU/mL). ACPA titres (AU/ml) were considered positive if above the 98-percentile of values in 619 non-RA subjects. Analysis of 13 ACPA reactivities targeting citrullinated peptides from fibrinogen, alpha-1 enolase, vimentin, fillagrin and histone was performed at baseline in patients and 94 controls (blood donors matched for age/gender/smoking), using a multiplex chip-based assay (2). Positivity and median number of ACPA reactivities in the subgroups were compared using Chi-square test and Mann-Whitney U-test, respectively.

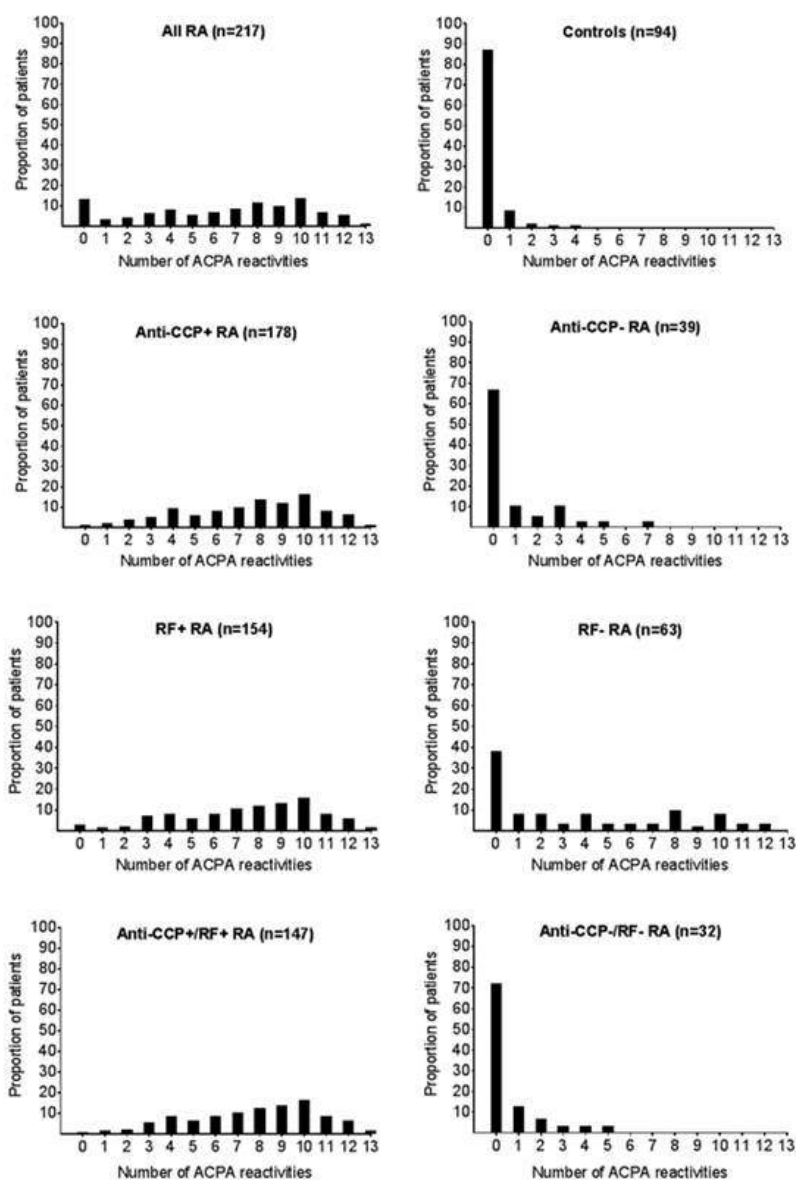

**Results:** Baseline characteristics are presented in the table. The median [IQR] number of antibody reactivities in all patients was 7[3,10], compared to 0[0,0] in controls ( $p < 0.001$ , figure). The corresponding numbers were 8[5,10] and 0[0,1] for the anti-CCP+ vs. anti-CCP- patients ( $p < 0.0001$ ), 8[5,10] and 2[0,8] for the RF+ vs. RF- patients ( $p < 0.001$ ), and 8[6,10] and 0[0,1] for the anti-CCP+/RF+ vs. the anti-CCP-/RF- ( $p < 0.001$ ) (table, figure). Positivity for ACPA reactivities was seen mainly in the anti-CCP+, RF+ and anti-CCP+/RF+ patients, but also occurred more frequently in the anti-CCP-, RF- and anti-CCP-/RF- patients than in controls (anti-CCP- vs controls  $p = 0.002$ , RF- vs controls  $p < 0.001$ , and anti-CCP-/RF- vs. controls  $p = 0.035$ ) (table).

**Table:** Baseline characteristics

**Figure:** Number of ACPA reactivities per patient

**Conclusion:** Prevalence of ACPA reactivities differed in subgroups of DMARD-naïve early RA patients according to anti-CCP and RF status. In general, higher numbers of ACPA reactivities were seen in anti-CCP+ patients, but all RA subgroups, including anti-CCP-, RF- and anti-CCP-/RF- patients, had higher prevalence of ACPA reactivities compared to healthy controls.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Positivity of anti-citrullinated peptides antibodies (ACPA) indicates severity in Rheumatoid Arthritis (RA). There is evidence for chronic periodontitis (PD) in RA autoimmune response by periodontopathogenic bacteria, through protein citrullination. Thus, our objectives were: 1.To determine whether there is an association between PD and its severity with ACPA(+).2.To assess relationship between PD and ACPA titres.3.To identify association between certain periodontal parameters and ACPA titres and their possible cut-off points.

**Methods:** Cross-sectional study RA patients  $\geq 18$  yo with  $\geq 4$  teeth, no tooth cleaning, antibiotic intake 6 months before. Comorbidities, demographics, DAS-28(ESR), DAS-28(CRP) and SDAI were taken. Serum ACPA detection: Ab IgG against CCP2 (ELISA) Immunoscan CCPlus® test kit Euro Diagnostica: positive  $\geq 25$  U/mL; ACPA titres stratification: Low (25–75), moderate (76–300) and high ( $>300$ ). Periodontal parameters: plaque index (PI), bleeding on probing (BoP), probing pocket depth, clinical attachment level (CAL). CAL loss was categorized according to European Workshop 2005 (Tonetti): T level 0 (absence), TL1 (mild), TL2 (severe). Statistical analysis: t-student, Kruskal Wallis, Chi-squared tests.

## Results:

187 RA patients included (table 1), ACPA determined in 168 patients: 67.86% (+) with similar titres distribution: low 18%, moderate 26%, high 23%. PD: 182 patients (97.3%): TL1 52.4%, TL2 44.9%. Although prevalence of severe PD/ACPA(+) was higher compared to PD/ACPA(-) (69.2% vs 30.7%), there was no association between PD and ACPA positivity/titres. Regarding the association with periodontal parameters, there was tendency of association between ACPA(+) and number of periodontal pockets  $\geq 5$ mm, adjusted OR 1.02 (95% CI 0.9–1.04). However, there was a gradient effect, where number of pockets  $\geq 5$ mm increased as ACPA titres increased, which was significant for high ACPA titres ( $p \leq 0.05$ , OR 1.03 95% CI 1.0–1.05). Moreover, RA patients who have 15 pockets  $\geq 5$ mm showed 1.789-fold risk of having high ACPA titres (95% CI 0.928–3.448,  $p$  0.082). In the lineal regression analysis, a statistically significant increase of 6.946 U/mL (95% CI 2.271–11.621) was found for each pocket  $\geq 5$ mm in RA patients with moderate-high disease activity ( $p$  0.004, adjusted by age, gender and smoking). When ACPA(+) was related to %PI and BoP, a strong association was observed for PI, OR 10.32 ( $p < 0.026$ ), and only a tendency for BoP ( $p < 0.062$ ). A risk for ACPA(+) was detected with cut-off points of 8% (OR 2.19) PI and 65% BoP (OR 2.45).

**Conclusion:** 1. Despite higher prevalence of severe PD in ACPA(+) patients, we found no association between the presence of PD and ACPA positivity nor with serum titres. 2. On analysis of ACPA titres in relation to the severity of the periodontal parameters, there was a “gradient” risk, where number of pockets  $\geq 5$ mm increased as ACPA titres increased, which was significant for high ACPA titres. 3. There was a lineal correlation between ACPA titres and number of pockets  $\geq 5$ mm.

## Increased Expression of TNF- $\alpha$ and PAD-2 in Human Monocytes Following Treatment with Protein Modified with Malondialdehyde-Acetaldehyde (MAA) and Citrulline

Logan M. Duryee<sup>1</sup>, Michael J. Duryee<sup>2</sup>, Dahn L. Clemens<sup>1</sup>, Evan M. Ryan<sup>1</sup>, Carlos D. Hunter<sup>2</sup>, Lynell W. Klassen<sup>3</sup>, James R. ### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have previously shown that malondialdehyde-acetaldehyde (MAA) and citrullinated proteins are present together in the synovial tissues of rheumatoid arthritis (RA) patients. Macrophage are a major source of not only TNF- $\alpha$ , but also PAD enzymes and are both involved in the progression of RA. MAA adducts and citrullinated proteins alone have the ability to increase TNF- $\alpha$  release in many different cell types. Therefore, the objective of this study was to determine if proteins modified with both MAA and citrulline increase the expression and secretion of both PAD and TNF- $\alpha$  in a human monocytic cell line.

**Methods:** THP-1 cells were grown and activated with PMA. Following serum starvation the cells were incubated with either 50  $\mu$ g/ml of human albumin (ALB), ALB-MAA, ALB-Citrulline (CIT) and ALB-MAA-CIT for 4 hours. Supernatants were collected and assayed for TNF- $\alpha$  protein by a commercial ELISA kit. RNA was extracted from the cells and subjected to RT-PCR for expression of PAD-2, PAD-4, and TNF- $\alpha$ .

**Results:** Human monocytic cells exposed to ALB-MAA significantly increased levels of TNF- $\alpha$  protein from  $35.5 \pm 0.75$  pg/ml to  $146.8 \pm 33.55$  pg/ml compared to ALB alone ( $P < 0.01$ ) (A). The addition of ALB-MAA-CIT significantly increased the secretion  $435.5 \pm 17.88$  pg/ml ( $P < 0.001$ ) when compared to ALB-MAA (A). Cells incubated with ALB-MAA-CIT showed and increased expression of TNF- $\alpha$  mRNA by 6 fold ( $698.6 \pm 96.62$  RQ) compared to MAA-ALB ( $20.09 \pm 6.48$  RQ) ( $P < 0.001$ ) (B). PAD-2 mRNA was increased following exposure to both ALB-MAA ( $1.79 \pm 0.96$  RQ) and ALB-MAA-CIT ( $4.87 \pm 1.71$  RQ) (compared to each other ( $P < 0.05$ ), although only the latter achieved statistical significance compared to ALB alone ( $P < 0.02$ ) (C). No increase in PAD-4 mRNA was detected in any of the groups. Additionally, results from the stimulation by ALB-CIT were not different that ALB alone.

**Conclusion:** We and others have shown that MAA-modified proteins and citrullinated proteins alone can activate macrophages to release TNF- $\alpha$ . Until now, no studies have reported on the effects of these modified protein moieties commonly found in RA. The significantly increased expression of TNF- $\alpha$  and PAD-2 mRNA in human macrophages following exposure to ALB-MAA-CIT, supported by the clinical observation that these protein(s) are found together in synovial tissues strongly suggests a role in the pathogenesis of RA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Treatment of RA patients is guided by measures of disease activity such as DAS28, best practice recommendation, and less often by a treat-to-target approach. This is due to a lack of diagnostic tools that can make an objective endotypic profile of the patient allowing for better targeted treatment. Another challenge is that traditionally used biomarkers reflect the level of systemic inflammation (e.g. cytokines) rather than the affected tissue. The aims were to test a novel combination of blood-based biomarkers reflecting tissue turnover and inflammation to identify patients with different forms of RA. In addition, we investigated whether such endotypes are associated with clinical disease activity and structural progression.

### Methods:

Post-hoc analysis was conducted on a cohort of patients with active and moderate-severe RA from a biomarker sub-study of LITHE, a phase III clinical trial (N=741). Only patients from the placebo arm were considered, who had serological biomarkers measured at both baseline (BL) and week 4, as well as bone erosion (ERN) measured at BL and week 52 (n=69). Progression was defined as a positive absolute change in ERN from BL to week 52. The following biomarkers reflecting tissue metabolite were measured in BL samples: PIINP and C2M (cartilage formation/degradation); CTX-I, OC PINP and ICTP (bone resorption and formation); C1M and C3M (interstitial matrix degradation); C4M and C6M (basement membrane degradation; and CRPM and VICM (inflammation).

All serum measurements were log transformed and normalized to have values between zero and one. Unsupervised hierarchical clustering was then performed using serological biomarkers taken at BL and week 4. The significance of change in ERN of each group was tested using a Mann-Whitney U test.

**Results:**

Hierarchical clustering revealed two main clusters. Cluster A (see figure) is defined by low levels of collagen biomarkers and varying levels of other biomarkers. Cluster B displays high level of bone, connective tissue and basement membrane markers, and low levels of the cartilage markers. Ten of the 12 biomarkers were significantly lower in cluster A than in cluster B ( $p < 0.5$ ). Cluster A can be divided into several subgroups characterised by high bone biomarkers and low bone biomarkers respectively. Due to the small population size in this study, the significance of these clusters was not investigated.

There is a trend showing that patients in cluster B have a higher DAS28 score at BL ( $p = 0.08$ ). The change in ERN was significantly different between the clusters ( $p = 0.04$ ) indicating group B (55% progressors) progresses faster than group A (29%).

**Conclusion:**

Using hierarchical clustering we were able to identify different endotypes of structural progression, including faster progressors in most need of treatment. Other likely endotypes were also identified, which shall be investigated further.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Antibodies to citrullinated protein antigens (ACPA) can identify individuals who may develop future inflammatory arthritis (IA) and classifiable rheumatoid arthritis (RA). Indeed, there are clinical trials underway where ACPA(+) individuals are treated to determine how IA/RA can be prevented or delayed. However, not all ACPA(+) subjects progress to IA/RA within the 2-3 years that is often duration for a clinical prevention trial. As such, identifying ways to predict which ACPA(+) subjects will most likely progress to IA/RA within defined time periods could improve selection of individuals for RA prevention trials as well as help to improve understanding of the biology of IA/RA development.

### **Methods:**

21 ACPA(+) (CCP3, Inova) individuals without historical or current IA were identified at a Colorado-based health-fair. These individuals were followed prospectively for up to 24 months for incident IA/RA. Clinical and examination factors, and biomarkers including the shared epitope, CCP3, RF-IgM (Inova), and high sensitivity C-reactive protein (hsCRP), were evaluated to determine which factors predicted incident IA/RA. Specifically, optimal levels for association with IA/RA of autoantibodies and hsCRP were determined with machine learning techniques, and these optimal levels were then evaluated with other factors to identify the overall best models for discrimination of the development of IA/RA.

### **Results:**

9 of 21 subjects (43%) developed IA/RA after a median of 11 months (Table 1). In univariate analyses of baseline factors, only self-reported joint stiffness was significantly associated with the development of IA/RA. Results from AUC analyses incorporating various variables are presented in Table 2. Overall, models using a combination of demographic and clinic factors, and optimized biomarker levels, had the highest discrimination (AUC 1.0) for the development of future IA/RA.

## **Conclusion:**

Individuals at high risk for progression to IA/RA can be identified through health-fair evaluations for ACPA. Furthermore, clinically-obtainable factors including biomarkers that are optimized using machine learning techniques can be used to determine with high discrimination which serum ACPA(+) individuals will develop IA/RA within 24 months. Caveats include that this is a small sample set with potential overfitting of the models in regard to the optimized levels of biomarkers; therefore, these findings need additional validation. Nevertheless, this approach appears useful to better identify candidates for IA/RA preventive interventions.

<b>Table 1. Descriptions and univariate analyses of baseline variables of subjects identified with anti-CCP3 positivity in absence of IA</b>			
	<b>Incident IA/RA  N=9</b>	<b>No IA/RA  N=12</b>	<b>P- value</b>

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

In Rheumatoid Arthritis (RA), genetic predisposition and environmental risk factors promote dysbiosis of oral and fecal microbiota. We hypothesized that specific microbial taxa (operational taxonomic units, OTUs) from the oral microbiota differentiate between RA and HC and that bacteria enriched in RA subjects directly promote inflammatory arthritis.

### **Methods:**

We characterized a prospective cohort of RA probands, FDR and HC. Probands met ACR 2010 criteria and/or had a confirmed RA diagnosis. FDRs included parents, full siblings or offspring of an RA proband; HC were drawn from the community. From all individuals, we obtained demographics, medical history, epidemiological questionnaires and tissue collections. After DNA extraction from tongue swabs, we undertook targeted 16S rRNA gene sequencing of all samples and next-generation sequencing of 18 samples. Statistical analysis used the mixOmics R package. Axenic *Streptococcus* isolates (n=3 per group, 16 isolates) were produced.

### **Results:**

116 RA patients, 63 FDR and 43 HC matched for age and gender were recruited. 56% of RA, 4% of FDR and 0% of HCs were ACPA+. Oral microbiota were altered in RA relative to HC. The oral OTU profile of some FDRs segregated with the RA patients and some segregated with HC. The oral community profile in RA was enriched in *Streptococcus*, *Rothia*, *Bifidobacteria*, *Actinomyces* and *Prevotella* spp. Axenic *Streptococcus* isolates grown from oral swabs from 16 individuals were characterised as *Streptococcus Salivarius*, *Streptococcus Parasanguinis* or *Streptococcus Infantis* using 16S rRNA sequencing. The abundance of Streptococcal spp. was strongly associated with smoking history. Streptococcal cell walls (SCW) were generated from reference *Streptococcus pyogenes* and each of the oral isolates. After one i.p. injection of purified peptidoglycan-polysaccharide polymers (PG-PS 10S) from *Streptococcus pyogenes* to ZAP-70<sup>W163C</sup>-mutant BALB/c (SKG) mice, significant acute and chronic swelling occurred in wrist and ankle joints.

### **Conclusion:**

We demonstrate distinct oral community profiles in RA patients and FDR relative to HC, which are influenced by smoking. Thus, compound genetic and environmental risks may create niches for opportunistic pathogens, such as *Streptococcus*, before and after the development of RA. The chronicity of SCW-induced arthritis in SKG mice suggests inability of a genetically predisposed host to effectively clear PG-PS 10S, which is resistant to degradation *in vivo*. Dissemination of persistently activated macrophages loaded with inflammatory bacterial remnants from the oral mucosa to lymphoid organs and peripheral joints may propagate the presentation of bacterial antigens and macrophage-driven inflammation in RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In a recent publication in Science Translational Medicine, Konig et al. (2016) describe a potential explanation for the link between periodontal infection and RA. They identify a specific periodontitis-associated bacterium: *Aggregatibacter actinomycetemcomitans* (Aa), which via its pore-forming toxin (leukotoxin A: LtxA) can dysregulate the activity of citrullinating enzymes in neutrophils. Furthermore, the authors report that the risk conferred by the most important genetic risk factor for RA: the HLA-DRB1 shared epitope (HLA SE) alleles, was limited to RA patients who had been exposed to Aa as determined by seropositivity to LtxA. Aiming to replicate their findings, we focused on two main questions: 1) is the increased exposure to Aa as measured by the presence of anti-LtxA-antibodies specific for RA, or also present in other forms of inflammatory arthritis? 2) can we replicate the finding that the association between HLA SE alleles and ACPA-positive RA is limited to the anti-LtxA-positive subset?

**Methods:** We established an ELISA against purified LtxA (acquired from the same source as in the original article) and tested sera from 594 patients from the Leiden Early Arthritis Clinic with various diagnoses, including RA, OA, SpA, PsA, sarcoidosis, and gout. Serial dilutions of a mix of 3 strongly positive RA patients were used as a standard, and the lowest point of the linear part of the standard curve (2000 AU/ml) was defined as the cut-off.

**Results:** As shown in Figure 1, anti-LtxA antibodies could be found in a substantial proportion of RA patients, but also in patients with other forms of arthritis. Within RA patients, there was no association with the presence of HLA SE alleles and/or ACPA, in contrast to the previous findings.

**Conclusion:** Although microbial influences may well be important in the development of RA, our results do not support a key role of exposure to LtxA originating from the periodontal pathogen Aa in linking the effect of the HLA SE alleles and periodontal disease to anti-citrullinated protein autoimmunity in RA.

## Figure 1.

Distribution of anti-LtxA antibodies in sera of 594 patients suffering from early arthritis. Levels of anti-LtxA antibodies in the serum of each individual are shown.

LtxA Leukotoxin A, RA Rheumatoid arthritis, Aa *Aggregatibacter actinomycetemcomitans*, OA Inflammatory osteoarthritis, SpA Spondylarthritis with peripheral arthritis, PsA Psoriatic arthritis, Sarc Sarcoidosis, ACPA anti-citrullinated protein antibodies, SE shared epitope. Red lines indicate the median level per group. The dashed line indicates the cut-off. The number of patients per group and percentage of patients positive according to the cut-off are shown underneath.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Rheumatoid arthritis (RA) is an autoimmune disease of unknown etiology causing inflammation and irreversible damage in joints and other organs. Methotrexate (MTX) is first-line therapy used in the treatment of RA. However, not all patients respond to MTX -- about 50-60% of patients require additional therapy. Because MTX is a folic acid analogue that may

affect evolutionarily conserved pathways found in bacteria, we hypothesized that the gut microbiome is altered by MTX and that gut bacteria metabolize the drug. Since gut bacteria have been shown previously to metabolize many pharmacologic drugs, we also sought to investigate the impact of the microbiome on inter-individual variations in MTX response. Here, we focus on the response of bacteria to MTX and ask whether bacteria can metabolize MTX.

## Methods:

We tested the *in vitro* growth of 40 gut bacterial isolates in response to MTX. The minimal inhibitory concentration (MIC), or the concentration of MTX required to suppress bacterial growth > 90%, was identified for each isolate. We asked if these *in vitro* findings were recapitulated *in vivo* by colonizing germ-free mice with human gut bacteria and treating with daily oral MTX at high (50 mg/kg) and low (1 mg/kg) doses. Next, we asked if bacteria metabolized MTX by examining either pure bacterial cultures *in vitro* or human stool sample *ex vivo*. Samples were incubated with MTX and metabolism was measured using HPLC. In select cases, we also used UPLC-MS-MS to learn the identity of MTX metabolites.

## Results:

MTX inhibited the growth of 33 of the 40 isolates examined. MICs ranged from 2 ug/ml to >900 ug/ml *in vitro*. At the Phylum level, Bacteroidetes tended to be sensitive and Firmicutes tended to be resistant to the antimicrobial effects of MTX (Wilcoxon rank sum,  $p=0.005$ ). *In vivo* studies showed that high-dose MTX altered the humanized gut microbiome of mice compared to those that were saline-treated (ANOSIM,  $p=0.001$ ). The relative abundance of Bacteroidetes decreased while Firmicutes increased, recapitulating what was seen *in vitro*. Low-dose MTX also produced changes to the microbiome, but this effect was subtler. We next asked whether gut bacteria metabolize MTX, and found that 8 possessed this ability *in vitro*. At least two species metabolized MTX into polyglutamated MTX, which is a novel finding that has not been described previously in the literature. In *ex vivo* studies, human fecal slurries incubated with MTX produced known as well as novel MTX metabolites.

## Conclusion:

We conclude that MTX is an antibacterial drug. Furthermore, we find that gut bacteria metabolize MTX. One metabolite found in our study was polyglutamated MTX, which prior studies have shown to be associated with patient response. Our ongoing and future studies will examine the *in vivo* implications of these findings in mice and examine whether bacterial metabolism of MTX is associated with clinical response in patients. Our findings support the hypothesis that a patient's response to MTX may be influenced by their gut microbiome. Thus, the microbiome may be an important factor in predicting patient response to MTX and perhaps other rheumatologic medications as well.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The mouth is the second most abundantly colonized mucosal surface in the human body. Periodontitis, a polymicrobial infectious and inflammatory disease of tooth-supporting structures, is associated with rheumatoid arthritis (RA) and may be caused by oral microbial dysbiosis, with shift toward pathogenic commensal species. Particular pathogens such as *Porphyromonas gingivalis* (*Pg*), and *Aggregatibacter actinomycetemcomitans* (*Aa*) have been implicated, but few studies have analyzed oral microbiota composition in RA patients.

**Methods:** 73 subjects, 33 RA patients, the majority with new-onset RA, all meeting 2010 ACR/EULAR criteria, 20 age- and gender-matched healthy subjects (HS) without periodontitis or RA, and 20 patients with chronic periodontitis who lacked RA (non-RA CP) completed standardized periodontal examination. Subgingival plaque samples (2 per subject) were evaluated for the presence of 40 bacterial taxa associated with periodontitis biofilms by checkerboard DNA-DNA hybridization.

**Results:** Typical of RA cohorts, the 33 patients were mainly female (85%) with median age of 51; 23 had DMARD-naïve early disease, 58% had rheumatoid factor (RF) or anti-citrullinated protein antibody (ACPA). Only one currently smoked. The majority (91%) received regular dental care with cleanings every 6 months.

Of the RA patients, 10 (30%) had periodontal health, 13 (39%) had gingivitis, and 10 (30%) had periodontitis. Pocket depth, clinical attachment loss, and bleeding on probing were all increased in the 33 patients compared with HS ( $P < 0.002$ ).

The RA patients had a significantly higher total bacterial load in dental plaque ( $111.8 \times 10^5$ ) compared with HS ( $58.9 \times 10^5$ ,  $P = 0.01$ ) and non-RA CP ( $70.5 \times 10^5$ ,  $P = 0.03$ ). RA patients with periodontal health had lower bacterial burden than those with gingivitis and periodontitis ( $P = 0.03$ ). Seropositive RA patients also tended to have a higher oral bacterial load than seronegative patients. By phylum, RA patients had particularly higher levels of *Actinobacteria*, *Proteobacteria*, and *Firmicutes* compared to both HS and non-RA CP ( $P \leq 0.03$ ), whereas *Fusobacteria*, *Spirochaetes*, and *Bacteroidetes* were elevated compared to HS ( $P \leq 0.03$ ) but similar to non-RA CP.

Accounting for multiple comparisons, 21 of 40 individual microbes had higher DNA probe counts (levels) in RA patients versus HS ( $P \leq 0.01$ ), this included only 1 red-complex classic pathogen, *Tannerella forsythia*. Notably, levels of *Pg*, detected in 5 RA patients, were not significantly different from HS. *Aa* was detected in only one RA patient who also had periodontitis.

While none of the 40 organisms correlated directly with ACPA, 4 correlated with RF levels, particularly *Eubacterium saburreum* ( $R = 0.549$ ,  $P \leq 0.001$ ), and 9 organisms correlated with swollen joint counts, 6 of which were *Actinobacteria* species.

**Conclusion:** Despite routine dental care and lack of smoking, new-onset RA patients had an abundance of oral bacteria, with expansion of pathogenic species seen in non-RA CP. Thus dysbiosis is a feature of the oral, as well as gut microbiome, in RA. Besides pathogens such as *Pg* and *Aa*, other oral microbes here were associated with RA autoantibodies and will require further study.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This post-hoc analysis investigated the impact of inflammation severity at baseline (BL) – measured by BL CRP levels and ESR – on efficacy and safety of tofacitinib.

**Methods:** Data were analyzed from studies of tofacitinib in RA patients (pts) with prior inadequate response (IR) to conventional synthetic (cs) or biologic (b) DMARDs, who initiated tofacitinib 5 mg or 10 mg BID as monotherapy or in combination with csDMARDs, mainly methotrexate. Data were pooled from 4 Phase 2 trials (NCT00413660; NCT00550446; NCT00603512; NCT00687193) and 5 Phase 3 randomized, double-blind, placebo-controlled trials (ORAL Scan [NCT00847613]; ORAL Solo [NCT00814307]; ORAL Sync [NCT00856544]; ORAL Standard [NCT00853385]; ORAL Step [NCT00960440]). Analyses were stratified by tertiles, by BL CRP and BL ESR levels, separately. Efficacy variables analyzed at Month (M) 6 included ACR20/50/70 response rates, and changes from BL to M6 in Clinical Disease Activity Index (CDAI), DAS28-4 (ESR), and Simple Disease Activity Index (SDAI). Summary/descriptive statistics were provided. Adverse events (AEs) to M6 were summarized. The results were not adjusted for multiplicity.

**Results:** The pooled population included 2,161 pts in the csDMARD-IR group and 512 pts in the bDMARD-IR group. Pt characteristics at BL (Table) were generally similar between groups and across CRP and ESR tertiles, except for RA duration. In both dose groups, ACR20/50/70 response rates at M6 were generally numerically higher with higher BL CRP for both csDMARD-IR and bDMARD-IR pts (Figure). Generally, a trend for greater improvement from BL in disease activity at M6 was observed with higher BL CRP but not with higher BL ESR. Proportion of pts with AEs, serious AEs, serious infections, and discontinuations due to AEs to M6 were generally similar regardless of BL CRP or ESR.

**Conclusion:** While efficacy outcomes in csDMARD-IR and bDMARD-IR RA pts were improved after 6 months' administration of tofacitinib 5 and 10 mg BID across BL CRP/ESR tertiles, this post-hoc analysis suggests that ACR response rates and disease activity improvements may be numerically greater with higher BL CRP, especially in bDMARD-IR RA pts. Of interest, this was not noted with higher BL ESR. This disproportionate potential predictive value needs further investigation. Analyses investigating the impact of inflammation severity at BL on tofacitinib efficacy in pts with RA are warranted and will include data based on both CRP/ESR tertiles as well as Tender Joint Count (TJC) and Swollen Joint Count (SJC) tertiles.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Extended observations in clinical trials have not demonstrated an increased risk of serious infection events (SIE) in patients with rheumatoid arthritis (RA) treated with rituximab.<sup>1</sup> However, continuous surveillance using large-scale observational data is of importance. Therefore, the objective of this study was to evaluate the rate of SIEs among patients with RA who received only an initial rituximab infusion vs those retreated with  $\geq 1$  rituximab infusion during the first year of therapy, and also to describe characteristics of rituximab-treated patients who experienced an SIE vs those who did not.

**Methods:** Patients with RA enrolled in the Corrona registry (NCT01402661) and treated with rituximab were followed until their most recent Corrona registry visit, first SIE, switch to another biologic or targeted synthetic disease-modifying antirheumatic drug, or 12 months after the most recent infusion with no further retreatment – whichever occurred first. The rate of SIEs was estimated in the overall population as well as in patients retreated with  $\geq 1$  infusion every 12 months after rituximab initiation and in those who did not receive a repeat infusion in the first 12 months. Patient characteristics were compared between those who experienced an SIE and those who did not.

**Results:** A total of 1361 patients with 1821 patient-years (PY) of follow-up were included; there were 59 SIEs for a rate of 3.24 SIE/100 PYs. 637 patients (46.8%) received  $\geq 1$  rituximab retreatment during the first 12 months and 724 (53.2%) received only the initial infusion. In the retreatment population there were 40 SIEs per 1312.8 PY for a rate (95% CI) of 3.05/100 PY (2.18-4.15), and in the no retreatment population there were 19 SIEs per 508.71 PY for a rate (95% CI) of 3.73/100 PY (2.25-5.83). The Kaplan-Meier curve depicting the occurrence of SIEs in the 2 cohorts during the first year of follow-up is shown (**Figure**). In the 59 patients (4.3%) who experienced an SIE, the mean (SD) number of rituximab infusions was 1.88 (1.18), compared with 2.07 (1.70) in the 1302 patients (95.7%) who did not experience an SIE. Patients who experienced an SIE vs those who did not were older (mean age [SD]: 62.9 [9.9] vs 58.1 [12.55] years), had longer disease duration (19.1 [13.1] vs 13.6 [10.4] years), were more frequently diabetic (16.9% vs 8.3%) and more frequently had cardiovascular disease (25.4% vs 12.8%), prior history of SIEs (18.6% vs 5.8%) and pulmonary disease (10.2% vs 4.8%). There were no differences in other clinical, demographic and medication history characteristics; steroid therapy was similar between the groups.

**Conclusion:** Retreatment with rituximab infusions did not result in a higher rate of SIEs in this study. Patients who experienced an SIE had a higher prevalence of risk factors for infections.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Because of their pleiotropic role in cytokine signaling, Janus Kinases (JAKs) are key players in inflammatory diseases. Among the 4 members of the JAK family (JAK1, JAK2, JAK3, TYK2), JAK1 has been demonstrated as a validated target in inflammatory diseases with filgotinib (GLPG0634, GS-6034) displaying efficacy and safety in several phase 2 studies in rheumatoid arthritis (RA) patients. Psoriatic arthritis (PsA) is a heterogeneous chronic inflammatory disease characterized by the association of skeletal involvement and extra-skeletal symptoms such as psoriasis and Inflammatory Bowel Disease (IBD) with common findings including enthesitis and dactylitis. Current treatments include anti-TNF $\alpha$ , anti-IL-17 and anti-IL-12/IL-23 antibodies with varying success rates. The involvement of several pro-inflammatory cytokines suggests that therapies targeting JAKs may be effective. To gain insight in the potential of a JAK1-selective inhibitor in PsA, we evaluated filgotinib efficacy in a mouse model of PsA induced by the overexpression of IL-23.

## **Methods:**

Overexpression of IL-23 was induced by hydrodynamic delivery of mIL23 enhanced Episomal Expression Vector (SBI) to male B10.RIII mice<sup>1</sup>. Evolution of paw and finger inflammation was assessed by clinical scoring as well as by *in vivo* molecular imaging (Bruker In-Vivo Xtreme imaging system). Enthesis, colon and fingers were collected for transcriptomic analysis. Using immunohistochemistry, infiltration of immune inflammatory cells and pSTAT3 positive cells, were analyzed in Achilles' enthesitis, subcutaneous area and skin. Colon was also collected for histology and gene expression analysis.

## **Results:**

High levels of IL-23 were maintained during the time-course of the study and were correlated with severity of finger and paw swelling and associated with inflammation of enthesitis and finger as observed in PsA patients. Only moderate inflammation of the colon was observed. Filgotinib significantly improved clinical scoring and tended to prevent neutrophil/granulocyte infiltration in paw (notably at earlier time points) while strongly decreasing immune cell infiltration in the skin. Transcriptomic analysis of enthesitis, fingers and colon showed that filgotinib reversed the effect of IL-23 for a consistent number of genes. Notably, expression of some upregulated inflammatory genes in enthesitis and/or fingers (CCL20, CXCL1, IL-22, MMP9 and TNF $\alpha$ ) as well as the target-related gene Mx2 were reduced. Filgotinib also significantly counteracted pSTAT3 induction in the subcutaneous area and in the epidermis (mainly concentrated in proliferating keratinocytes) further demonstrating target engagement in the diseased tissue.

## **Conclusion:**

In a mouse model of PsA, filgotinib improved global clinical score and decreased signs of inflammation in hindlimbs. Target engagement both in hindlimbs and colon was also demonstrated. These data support the evaluation of filgotinib in patients with PsA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disease modifying antirheumatic drugs (DMARD) such as methotrexate (MTX), ) or antiTNF $\alpha$  have been implicated in exacerbation of Interstitial lung disease (ILD) of rheumatoid arthritis (RA). Several radiological patterns of ILD have been described: i) usual interstitial pneumonia (UIP), ii) nonspecific interstitial pneumonia (NSIP), iii) obliterating bronchitis (OB), and iv) Organized pneumonia (OP)

Our aim was to assess the response to Abatacept (ABA) in these patterns of ILD

**Methods:** Retrospective multicenter study of RA-ILD treated with ABA. ILD was diagnosed by high-resolution CT scan (HRCT) and classified in radiological patterns (Travis et al). We consider 3 subgroups: a) UIP, b) NSIP and c) "other" (OB, OP or mixed). ABA was used at standard dose. We assessed: a) Dyspnea (Medical Research Council-modified scale; significant variations  $\geq 1$ ); B) Respiratory function tests; significant changes  $\geq 10\%$  in forced vital capacity (FVC) and  $\text{DLCO} \leq 10\%$ , c) HRCT, d) DAS28. A comparative study was performed for the qualitative variables (Fisher test) between the baseline and 3, 6 and 12 months

**Results:** We included 63 patients 29 UIP 17 NSIP 17 Others (27 women/36 men), mean age;  $63.1 \pm 9.6$  years. Patients with RA was seropositive in 85.7%. The ILD was related to DMARDs: MTX (4), etanercept (3), adalimumab (3), certolizumab (2), Infliximab (1). ABA was used in monotherapy (26) or combined with other DMARDs (37); LFN (15), Cyclosporin (1), sulfasalazine (4), MTX (6), hydroxychloroquine (10), azathioprine (4), chloroquine (1). Figure shows the evolution in the available cases. A significant improvement in dyspnea and HRCT. DLCO remained stable in most patients regardless of the radiological pattern. The activity of RA (DAS28) also improved.

a)

b)

c)

Figure a), b) c): Evolution of different ILD patterns.

**Conclusion:** ABA appears to be effective in ILD associated-RA, including the pattern of poor prognosis (UIP).

## Assessment of Early Improvement in Pain and Other ACR Components As Predictors for Achieving Low Disease Activity or Remission in Three Phase 3 Trials of RA Patients Treated with Baricitinib

Michael Weinblatt<sup>1</sup>, Mark C. Genovese<sup>2</sup>, Joel Kremer<sup>3</sup>, Luna Sun<sup>4</sup>, Himanshu Patel<sup>4</sup>, Alisa Koch<sup>4</sup>, David Muram<sup>4</sup>, Jeffrey R. Curtis<sup>5</sup>, Cynthia J. First publication: September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The purpose of this analysis was to assess whether early improvement in ACR components could act as predictors of low disease activity (LDA) or remission (REM) at Week 12 in Phase 3 trials of baricitinib (BARI). The patient's assessment of pain, a patient-reported outcome measured by a 0-100 mm visual analog scale (VAS), was a focus for this analysis.

### Methods:

In RA-BEAM<sup>1</sup>, 487 patients with inadequate response (IR) to methotrexate (MTX) were randomized to BARI 4 mg once daily. In RA-BEACON<sup>2</sup>, a trial of bDMARD-IR patients, 174 patients were randomized to BARI 2 mg and 177 to BARI 4 mg once daily. In RA-BUILD<sup>3</sup>, a trial with csDMARDs-IR patients, 229 patients were randomized to BARI 2 mg and 227 to BARI 4 mg once daily. LDA was defined as CDAI  $\leq 10$  or DAS28-ESR  $\leq 3.2$  and REM as CDAI  $\leq 2.8$  or DAS28-ESR  $< 2.6$  at Week 12. Early improvement, changes from baseline to Week 4, for each of the ACR components (pain VAS, patient global assessment of disease activity [PtGA], physician global assessment of disease activity [PGA], swollen joint count, tender joint count [TJC], HAQ-DI, hsCRP, and ESR) was evaluated on their respective predictability for LDA or REM at Week 12 using area under the curve (AUC) of receiver operating characteristic (ROC) curves. The optimum cutoff point in percent improvement at Week 4 was evaluated based the Youden index and the negative predictive value (NPV).

### Results:

Early improvement in pain VAS, TJC, PtGA, and PGA had among the highest predictability, whereas hsCRP and ESR had among the lowest, as measured by AUC of ROC (Figs. 1 and 2 for RA-BEAM data), for achieving both LDA and REM at Week 12. A threshold of 30-50% improvement in pain from baseline to Week 4 had the optimum range for predicting LDA

and REM at Week 12 (Table). Consistent results were observed for csDMARD-IR and bDMARD-IR patients, and these results were similar for both BARI 2 mg and BARI 4 mg doses.

### **Conclusion:**

In these trials, patients with a lack of early response to BARI, as assessed by improvement in pain VAS at Week 4, tended to be less likely to achieve LDA or REM at Week 12 vs. patients with an early response. A minimum of 30% improvement in pain resulted in optimum NPV in this analysis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). We examined associations of pain and physical function with Patient Global Assessment of disease activity (PtGA) in patients (pts) receiving tofacitinib 5 mg twice daily (BID) or placebo (PBO) with background conventional synthetic disease-modifying antirheumatic drugs (csDMARDs).

**Methods:** This was a post-hoc analysis of pooled data from three Phase 3 randomized controlled trials (ORAL Sync [NCT00856544]; ORAL Standard [NCT00853385]; ORAL Scan [NCT00847613]) in pts with inadequate responses to biologic or csDMARDs (ORAL Sync) or methotrexate (MTX) (ORAL Standard/Scan). Patient Assessment of Arthritis Pain (Pain; visual analog scale [VAS] 0–100 mm), Health Assessment Questionnaire-Disability Index (HAQ-DI), and PtGA (VAS 0–100 mm) scores were recorded at baseline (BL) and Month (M) 3. Associations between ‘low global assessment of disease’ (PtGA  $\leq 20$ ) and mild Pain (VAS score  $\leq 30$ ) or HAQ-DI response (score  $\leq 0.5$  or change from baseline  $\geq 0.22$ ) were independently evaluated. Relationships between PtGA and Pain or HAQ-DI were assessed using Spearman rank correlation coefficients at BL and M3 without adjustments for multiplicity.

**Results:** At M3 216/695 (31.1%) pts receiving tofacitinib 5 mg BID and 62/366 (16.9%) pts receiving PBO reported PtGA  $\leq 20$ ; 346/695 (49.8%) and 109/366 (29.8%) had Pain scores  $\leq 30$ ; 514/694 (74.1%) and 197/365 (54.0%) were HAQ-DI responders. Across treatment groups, of pts reporting PtGA  $\leq 20$  at M3, a larger proportion also reported Pain  $\leq 30$  vs Pain  $> 30$  (Table 1); of pts with PtGA  $> 20$ , a high proportion had Pain scores  $> 30$ . Of pts reporting PtGA  $\leq 20$  at M3, a larger proportion were HAQ-DI responders than HAQ-DI non-responders. Similar associations were noted between PtGA  $\leq 20$  and moderate or substantial improvements in Pain (data not shown). The proportions of pts reporting PtGA  $\leq 20$  and Pain  $\leq 30$  were numerically higher than those with PtGA  $\leq 20$  and HAQ-DI responses. Pain and HAQ-DI were significantly correlated with PtGA at BL and M3 ( $p < 0.0001$ ); correlation coefficients appeared numerically higher between PtGA and Pain than HAQ-DI (Table 2).

**Conclusion:** In this post-hoc analysis, reports of low PtGA scores were associated with low pain levels and improved physical function across treatment groups. Attainment of low PtGA levels appears more associated with improvements in pain than HAQ-DI responses.

**Table 1.** Summary of patients reporting low global assessment of disease (PtGA  $\leq 20$ ) according to Pain  $\leq 30$  and HAQ-DI response at Month 3

		PtGA

## **Patient-Reported Outcomes of Long-Term Upadacitinib Use in Patients with Rheumatoid Arthritis: Interim Analysis Results of a Phase 2, Open-Label Extension Study**

**Vibeke Strand**<sup>1</sup>, Namita Tundia<sup>2</sup> and Alan Friedman<sup>2</sup>, <sup>1</sup>Stanford University, Palo Alto, CA, <sup>2</sup>AbbVie Inc., North Chicago, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Janus kinase (JAK) inhibitors are being evaluated for treatment of active rheumatoid arthritis (RA). The efficacy of upadacitinib (UPA), a selective JAK inhibitor, in improving patient-reported outcomes (PROs) has been demonstrated.<sup>1</sup> These analyses evaluated the long-term benefits of UPA on PROs in patients with active RA.

**Methods:** M13-538 (NCT02049138) is an ongoing, Phase 2 open-label extension study designed to assess long-term efficacy and safety of UPA in RA patients who completed BALANCE I and BALANCE II randomized controlled trials (RCTs) where doses of 3, 6, 12 and 18 mg BID were evaluated. All eligible patients received UPA 6 mg bid within 30 days of completing either RCT. At weeks 6 and 12, patients with <20% improvement from baseline in tender (TJC) and swollen joint counts (SJC) received a dose increase to 12 mg bid UPA. After 6 weeks on 12 mg bid, patients failing to achieve ≥20% improvement in TJC and SJC discontinued treatment. After week 6, at the discretion of the investigator, the dose could be titrated to 12 mg bid for patients who did not meet low disease activity as defined by the Clinical Disease Activity Index. Continuing patients were divided into 3 cohorts: those who remained on 6 mg bid (never titrated); who increased to and remained on 12 mg bid (titrated up); and who increased to 12 mg bid and subsequently reduced to 6 mg bid only for a safety concern or intolerability (titrated up and down). PROs included: Patient's Global Assessment of Disease Activity (PtGA), Pain by Visual Analog Scale (Pain VAS), Health Assessment Questionnaire – Disability Index (HAQ-DI), FACIT – Fatigue Scale (FACIT-F), Work Instability Score for Rheumatoid Arthritis (RA-WIS), and EuroQoL-5D (EQ-5D). For this interim analysis, data collected on or before January 13, 2017 were analyzed. Mean changes from baseline and 95% confidence intervals (CI) were calculated for each PRO at week 48.

**Results:** 493 patients received UPA. Across cohorts, mean age was 53–56 years, 78%–87% were female, and mean duration of RA 8.6–9.5 years. The total patient population exposure to UPA was 725.1 patient-years; with 78% of patients having exposure of ≥12 months and 72% having exposure of ≥18 months. At week 48, patients within all cohorts reported improvements across all PROs (**Table**). The majority of patients who never titrated dose reported the largest improvements from baseline across PROs at week 48, followed by those who titrated up or up and down.

**Conclusion:** Patients treated with UPA maintained clinically meaningful improvements in disease activity, pain, physical functioning, fatigue, work functioning, and overall health status till week 48.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Baricitinib (BARI), is an oral Janus kinase (JAK)1/JAK2 selective inhibitor for treatment of patients with moderately to severely active RA. RA-BEAM was a phase 3 study in patients with RA and an inadequate response to MTX (MTX-IR) in which BARI demonstrated significant improvements in ACR20 response rates and DAS28-CRP compared to placebo (PBO) and adalimumab (ADA). This abstract examines the effects of baricitinib on disease activity scores and the improvement of disease activity compared to PBO and ADA utilizing CDAI, which does not include acute phase reactants and only uses clinical measures (adding physician and patient global assessments, to tender and swollen joint counts).

**Methods:** In RA-BEAM, 1305 patients were treated with PBO (N=488), ADA (N=330) or BARI 4 mg (N=487) and continued to receive background MTX. CDAI for the three treatment groups was determined at baseline (mean [SD] of 37.6 [12.8], 38.1 [12.0], 37.9 [13.0] for PBO, BARI and ADA, respectively) and at each visit post baseline for up to 24 weeks, and for the BARI and ADA groups for up to 52 weeks. In this analysis, CDAI and the improvement from baseline to Weeks 12 and 24 were compared between treatment groups using analysis of covariance (ANCOVA). The proportions of patients reaching a disease activity threshold and improvement threshold at Weeks 12 and 24 were compared between treatment groups using logistic models. Analyses were not adjusted for multiplicity. Missing values were imputed using modified last observation carried forward.

**Results:** At baseline, across all treatment arms, 91% of patients had high disease activity and 9% had moderate disease activity. Treatment with BARI resulted in significantly lower mean disease activity at Weeks 12 and 24 than PBO ( $p<0.001$  at both Weeks 12 and 24) and ADA ( $p=0.008$ , Week 12;  $p=0.035$ , Week 24). Fewer patients treated with BARI (16.4%) remained in high disease activity at Week 24 compared to PBO (47.6%,  $p<0.001$ ) and ADA (22.9%,  $p=0.017$ ). Patients treated with BARI had significantly greater improvement in the mean disease activity compared to PBO ( $p<0.001$ ) and ADA ( $p=0.023$ ) at 24 weeks. A larger proportion of patients receiving BARI (86.2%) were able to achieve at least a 12-point reduction in CDAI, the minimal clinically important difference in disease activity improvement, by Week 24 compared to patients receiving PBO (52.4%,  $p<0.001$ ) or ADA (77.5%,  $p=0.001$ ) (Table and graphs).

**Conclusion:** In MTX-IR RA patients with moderate to severe disease activity, BARI significantly reduced the overall disease activity compared to PBO and ADA.

# BMS-986195 Is a Highly Selective and Rapidly Acting Covalent Inhibitor of Bruton's Tyrosine Kinase with Robust Efficacy at Low Doses in Preclinical Models of RA and Lupus Nephritis

JR Burke, KM Gillooly, MA Pattoli, L Cheng, S Skala, EM Heimrich, TL Taylor, C Pulicicchio, DW Kukral, T Petrone, IM Catlett, N Zheng, W Li, SH Watterson and JA Tino, Bristol-Myers Squibb, Princeton, NJ

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** BMS-986195 is a potent, covalent, irreversible inhibitor of Bruton's tyrosine kinase (BTK), a member of the Tec family of non-receptor tyrosine kinases essential in antigen-dependent B-cell signaling and function. BTK also plays a critical signaling role downstream of low-affinity activating Fcγ receptors (FcγR) in monocytic cells, high-affinity immunoglobulin E receptors (FcεRI) in granulocytes, and the RANK receptor on osteoclasts. Pharmacologic inhibition of BTK, therefore, represents an intriguing approach for the treatment of autoimmune disorders such as RA and lupus. The present report details the cellular and *in vivo* pharmacology of BMS-986195.

**Methods:** The potency and selectivity of BMS-986195 were evaluated against a panel of 245 kinases. Cellular assays included antigen-dependent responses in B cells and immune complex-stimulated cytokine production in human peripheral blood mononuclear cells. BTK inactivation was determined using active-site probe-based measures of unmodified active sites, and these assays were used to determine the *in vitro* rate of inactivation in human whole blood, as well as the kinetics and dose relationships of *in vivo* inactivation of BTK in mice and cynomolgus monkeys after oral administration. The efficacy of BMS-986195 was evaluated in collagen-induced arthritis (CIA) and collagen antibody-induced arthritis (CAIA) models in mice, as well as against nephritis in NZB/W lupus-prone mice.

**Results:** BMS-986195 is a potent and highly selective inhibitor of BTK, which acts by covalently modifying an active-site cysteine residue. The compound is more than 5000-fold selective for BTK over all kinases outside of the Tec family, and selectivity ranges from 9- to 1010-fold within the Tec family. BMS-986195 inactivated BTK in human whole blood with a rapid rate of inactivation ( $3.5 \times 10^{-4} \text{ nM}^{-1} \cdot \text{min}^{-1}$ ) and potently inhibited antigen-dependent interleukin-6 production, CD86 expression and proliferation in B cells ( $\text{IC}_{50} < 1 \text{ nM}$ ) without effect on antigen-independent measures in the same cells. A similar potency was measured against FcγR-dependent TNF-α production in human cells. In mice, a dose as low as 0.5 mg/kg, taken orally (PO) daily (QD), resulted in peak BTK inactivation of 98% after only the second dose. BTK was inactivated to similar levels in whole blood, lymph nodes and spleen in a dose-dependent manner. BMS-986195 demonstrated robust efficacy in murine models of RA including CIA and CAIA, protecting against clinically evident disease, histologic joint damage and bone mineral density loss. In both models, maximal efficacy was observed at doses  $\leq 0.5 \text{ mg/kg PO QD}$ , which achieved  $\geq 95\%$  inactivation of BTK *in vivo*. At similar doses, the compound was also highly protective against nephritis in the NZB/W mouse model of lupus. To investigate the dynamics of BTK inactivation and resynthesis of BTK, cynomolgus monkeys were given single or multiple doses of BMS-986195. 100% peak inactivation of BTK was obtained with a single administration of BMS-986195 at 0.5 mg/kg PO.

**Conclusion:** The high selectivity, rapid rate of BTK inactivation and robust efficacy at low doses in preclinical models of RA and lupus support investigation of BMS-986195 in human autoimmune disorders.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The JAK1 selective inhibitor filgotinib (GLPG0634, GS-6034) has been evaluated in a 24-week phase 2B study (DARWIN 2) as monotherapy in active rheumatoid arthritis (RA) patients who were methotrexate inadequate responders and has shown a good safety and efficacy profile<sup>1</sup>. A broad range of serum biomarkers were measured to characterize the mode of action of filgotinib.

**Methods:** Serum samples from RA patients who received either placebo (PBO), or filgotinib monotherapy at 100mg or 200mg once daily (QD) were collected at baseline, weeks 4 and 12 and analyzed for 35 biomarkers by validated single- or multi-plex immunoassays. Median % changes from baseline for biomarkers are reported. Wilcoxon rank-sum test assessed the significance of the difference between filgotinib treated groups and PBO.

**Results:** Filgotinib monotherapy was associated with significant reductions in a broad panel of immune- and tissue-related biomarkers relevant to RA, compared to placebo (27/35 markers). The largest reductions were in the pro-inflammatory markers IL-6, SAA, and CRP (58-68% median reduction from baseline to week 12,  $p < 0.01$ ). Other top-ranked biomarkers by effect size were related to joint degradation (MMP1, 3, YKL-40), immune cell recruitment (CXCL10, CXCL13), and T<sub>H</sub>17/reg cells (IL-23 and IL-10) (reductions of 28-31%,  $p < 0.05$  for all). These effects were present from week 4 and were maintained at week 12. Other biomarker changes also support down-modulation of T<sub>H</sub>1 (IL-2, IFN- $\gamma$ , IL-12), T<sub>H</sub>2 (IL-4, IL-5, IL-13), B cell (CXCL13, IL-7, IL-21), and myeloid cells (GM-CSF, MIP-1 $\alpha$ ). Filgotinib monotherapy did not increase leptin above PBO-levels.

p-values comparing % changes between filgotinib and PBO groups: NS, p>0.05; \*p<0.05; \*\*p<0.01; \*\*\*p<0.001

**Conclusion:** Filgotinib reduces the systemic levels of pro-inflammatory and RA-associated tissue-derived biomarkers. These effects on biomarkers in multiple disease processes and immune cell subsets provide insight into the efficacy shown by filgotinib evaluated as monotherapy in the Phase 2B study<sup>1</sup>.

## Exposure-Response Analyses of the Effect of Upadacitinib on ACR Responses in the Phase 2b Rheumatoid Arthritis Trials in Patients with Inadequate Response to Methotrexate or to Anti-Tumor Necrosis Factor Therapy

Ben Klünder<sup>1</sup>, Mohamed-Eslam F. Mohamed<sup>2</sup>, Heidi S. Camp<sup>2</sup> and **Ahmed A. Othman**<sup>2</sup>, <sup>1</sup>AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, <sup>2</sup>AbbVie, North Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Upadacitinib, a selective JAK1 inhibitor, demonstrated favorable efficacy in two Phase 2 studies in subjects with moderate to severe rheumatoid arthritis (RA) who had inadequate response to prior treatment with anti-tumor necrosis factor (anti-TNF) therapy in BALANCE I or with methotrexate in BALANCE II. This work was done to characterize upadacitinib exposure-response relationships for effects on ACR responses in RA patients which supported dose selection for the ongoing Phase 3 RA trials.

**Methods:**

The Analyses included data from 276 and 298 subjects in BALANCE I and BALANCE II, respectively. Subjects were randomized to receive 3, 6, 12, or 18 mg twice daily (BID) or matching placebo in BALANCE I and 3, 6, 12, 18 mg BID or 24 mg once daily or matching placebo in BALANCE II. Upadacitinib was administered in both studies as immediate-release formulation. Efficacy assessments and sparse blood samples for pharmacokinetic analyses were collected from over a 12-week period. ACR20, ACR50, and ACR70 responses as well as dropouts were collectively analyzed using a continuous-time Markov model, where upadacitinib enhanced transition of the status of patients to higher levels of response (e.g. no response to ACR20, ACR20 to ACR50, ACR50 to ACR70). The final model was used to predict the efficacy of different upadacitinib doses in both patient populations assuming 300 subjects for each dose. A separate model was utilized for simulation of placebo response in the anti-TNF inadequate responders population to better capture the lower placebo response in that population.

**Results:**

In the Markov analysis, point estimate for upadacitinib plasma concentrations associated with 50% of maximal effect on the transition rates to higher ACR responses was higher for anti-TNF inadequate responders compared with the methotrexate inadequate responders, however with overlapping confidence intervals between the populations. The predicted median (90% Prediction interval) ACR responses are shown in Table 1 compared to the observed ACR responses from BALANCE I and BALANCE II based on non-responder imputation.

**Table 1.** Predicted median (90% Prediction interval) ACR responses compared to the observed ACR responses based on non-responder imputation.

		Methotrexate Inadequate Responders			Anti-TNF Inadequate Responders		
Dose Group		ACR20	ACR50	ACR70	ACR20	ACR50	ACR70
Placebo	Model-Predicted	47 (38-57)	18 (13-27)	8 (4-13)	34 (26-43)	12 (5-20)	3 (1-7)
	Observed	46	18	6	34	16	4
3 mg BID	Model-Predicted	67 (60-72)	40 (33-47)	22 (17-28)	53 (45-62)	30 (23-37)	16 (10-21)
	Observed	62	38	22	53	24	13
6 mg BID	Model-Predicted	69 (63-74)	44 (36-51)	25 (19-31)	58 (51-67)	35 (28-43)	20 (13-27)
	Observed	68	46	28	58	36	26
12 mg BID	Model-Predicted	71 (65-76)	46 (38-54)	28 (21-33)	62 (56-71)	40 (32-49)	24 (17-32)
	Observed	80	50	16	71	42	22
18 mg BID	Model-Predicted	72 (65-78)	47 (39-55)	29 (22-35)	63 (56-73)	41 (35-53)	25 (18-35)
	Observed	64	40	26	67	38	22
24 mg QD	Model-Predicted	69 (63-75)	44 (37-52)	26 (20-32)	-	-	-
	Observed	76	39	22	-	-	-

Simulated dropouts are imputed with non-response.

## Conclusion:

The exposure-response models adequately described upadacitinib exposure-response relationships for ACR20, ACR50, and ACR70 in the BLANACE I and II studies. Using the immediate-release formulation, upadacitinib exposures associated with 6 mg BID dose are predicted to achieve near maximal efficacy in methotrexate inadequate-responders, while exposures associated with 12 mg BID dose may provide additional efficacy benefit in anti-TNF inadequate responders.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Upadacitinib is a selective JAK1 inhibitor being developed for the treatment of several inflammatory diseases, including rheumatoid arthritis (RA). Upadacitinib showed favorable efficacy and acceptable safety profiles in two Phase 2 studies in subjects with RA. Currently, doses of 15 mg and 30 mg once daily (QD) are being evaluated in ongoing Phase 3 studies in RA. Oral contraceptives are expected to be commonly used with upadacitinib in patients with inflammatory diseases. This study evaluated the effect of multiple doses of upadacitinib on pharmacokinetics of ethinylestradiol and levonorgestrel.

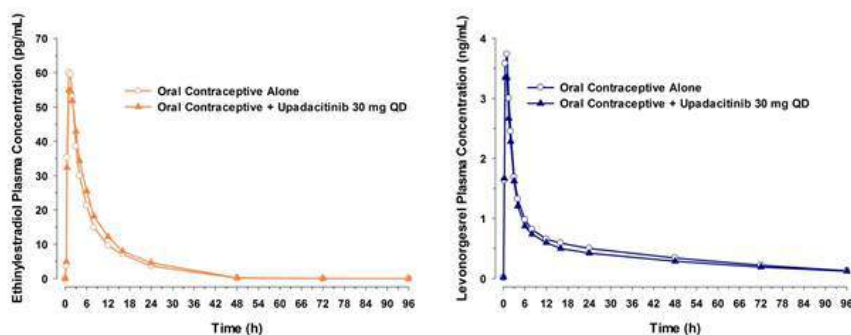

### Methods:

Healthy female subjects (N = 20) received single doses of a combined oral contraceptive tablet containing 30 µg ethinylestradiol and 150 µg levonorgestrel alone (Study Period 1) and on Day 12 of a 14-day regimen of upadacitinib 30 mg QD (Study Period 2). Upadacitinib was administered in the study using the extended-release tablet formulation being utilized in Phase 3 studies in RA. Blood samples for ethinylestradiol and levonorgestrel assays were collected by venipuncture prior to and for 96 hours after the oral contraceptive administration in each Study Period. Pharmacokinetic parameters for ethinylestradiol and levonorgestrel were calculated using non-compartmental analyses.

### Results:

The ratios (90% confidence intervals) for C<sub>max</sub> and AUC<sub>inf</sub> following administration of the oral contraceptive with upadacitinib compared with administration of the oral contraceptive alone were 0.96 (0.89 to 1.02) and 1.11 (1.03 to 1.19), respectively, for ethinylestradiol and 0.96 (0.87 to 1.06) and 0.95 (0.85 to 1.07), respectively, for levonorgestrel.

**Figure 1. Plasma Concentration versus Time Profiles for Ethinylestradiol and Levonorgestrel Following Administration of the Combined Oral Contraceptive Alone and with Upadacitinib 30 mg QD**

## Conclusion:

Upadacitinib has no effect on pharmacokinetics of ethinylestradiol and levonorgestrel; the 90% confidence intervals for the ratios of ethinylestradiol and levonorgestrel AUC and  $C_{max}$  when administered with upadacitinib relative to when administered alone were within the bioequivalence boundaries of 0.8 to 1.25. Therefore, oral contraceptives containing ethinylestradiol or levonorgestrel can be concomitantly administered with upadacitinib.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatologists need to develop primary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tofacitinib (Tofa) plus methotrexate improved left ventricular mass index (LVMI) in patients with rheumatoid arthritis. How about tofacitinib monotherapy? To study the effect of Tofa monotherapy (MTX) on LV morphology and function in conventional DMARDs resistant active RA patients, in a cohort study design.

**Methods:** RA patients were eligible if they had active disease despite treatment with conventional DMARDs. Consecutive 21 patients with moderate to severe active RA patients (DAS28>3.2) despite conventional DMARDs were received Tofa monotherapy. LV morphology and function was assessed with cardio-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

**Results:** 19 patients completed 24 weeks. Left ventricular mass index (LVMI) was attenuated significantly by Tofa (week 0-week24,  $-10.02 \pm 4.8$  g/m<sup>2</sup>;  $p=0.02$ ). Cardiac output (CO) was attenuated significantly by Tofa (week 0-week24,  $-0.65 \pm 0.9$  l/min). DAS28 and CRP improved significantly by Tofa (week 0-week24; DAS28:  $-2.16 \pm 0.95$ ; CRP:  $15.1 \pm 5.7$  mg/l) ( $p<0.05$ ). Surprisingly, the change of disease activity (DAS 28 and CRP) is no correlation with the change of LVMI or CO in this study. Observationally, 2 cases significantly improved right ventricular mass as well as left ventricular mass (20 % improved right ventricular mass index from baseline).

**Conclusion:** Tofa monotherapy improved LVMI and CO in active RA despite MTX. Tofa monotherapy improves LVMI and CO independently of its effects on disease activity. Tofa might be improved right ventricular mass. JAK-STAT pathway might be an important role of LV hypertrophy. Tofa, JAK-STAT pathway blocking, may prevent cardiovascular morbidity and mortality in RA.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

In the Phase 3 RA-BEAM study, baricitinib (BARI) 4 mg once daily showed significant clinical improvements compared with placebo (PBO) and adalimumab (ADA).<sup>1</sup> Switching from ADA to BARI, prompted by rescue or study design, without an ADA washout was associated with improved disease control during the initial 12 weeks after the switch.<sup>2</sup> The objective of this analysis was to evaluate changes in patient-reported outcomes (PROs) from before and after rescue with BARI.

### **Methods:**

1305 patients were randomized 3:3:2 to and treated with PBO for 24 weeks, BARI 4 mg once daily for 52 weeks, or ADA 40 mg every 2 weeks for 52 weeks. All patients received background methotrexate (MTX). Patients whose tender and swollen joint counts were reduced <20% from baseline at Week 16 were rescued to open-label BARI 4 mg once daily; after Week 16, rescue was at physician discretion. In this post hoc analysis, patients who were rescued between Weeks 16 and 24 were followed for 12 weeks after rescue. The pain visual analog scale (VAS, 0-100 mm), Health Assessment Questionnaire-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), SF-36 physical and mental component scores (PCS and MCS), and duration of morning joint stiffness (MJS) were assessed for patients rescued to BARI. Within group changes before and after rescue were assessed with sign tests for each of the evaluated PROs. The percentage of patients who met or exceeded clinically relevant thresholds at Week 12 after rescue, relative to the point of rescue, was also assessed. These analyses were not adjusted for multiplicity.

### **Results:**

More patients randomized to PBO (26%, N=128) were rescued, than ADA (12%, N=40) or BARI (7%, N=35). Of the 203 patients rescued, 102 patients were rescued per protocol (Week 16) and 101 were rescued at the physician's discretion. Patients who failed PBO or ADA and rescued to BARI showed significantly greater improvements in pain, HAQ-DI, FACIT-F, SF-36 PCS, and duration of MJS at 4 weeks after rescue which were sustained through 12 weeks (Table). A greater percentage of patients rescued from PBO to BARI, followed by ADA to BARI patients, tended to show clinically relevant improvements in pain, HAQ-DI, FACIT-F, and PCS compared to patients rescued from BARI to BARI (Figure).

## Conclusion:

Upon treatment failure with either PBO or ADA, rescue with BARI 4 mg resulted in early, sustained, and clinically relevant improvements in PROs representing measures of quality of life and symptoms that are important to patients.

## Long-Term Safety and Efficacy of Upadacitinib (ABT-494), an Oral JAK-1 Inhibitor in Patients with Rheumatoid Arthritis in an Open Label Extension Study

Mark C. Genovese<sup>1</sup>, Joel Kremer<sup>2</sup>, Sheng Zhong<sup>3</sup> and Alan Friedman<sup>3</sup>, <sup>1</sup>Stanford University Medical Center, Palo Alto, CA, <sup>2</sup>Albany Medical College, Albany, NY, <sup>3</sup>AbbVie Inc., North Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Upadacitinib (UPA, ABT-494) is a selective, oral JAK-1 inhibitor studied in two phase 2 randomized controlled trials (RCTs) in patients (pts) with rheumatoid arthritis (RA). We assessed UPA safety and efficacy in BALANCE-EXTEND, an ongoing, combined open-label extension (OLE) of the phase 2 RCTs.

**Methods:** Pts completing the two 12-week RCTs (in TNF-IR and MTX-IR pts)<sup>1,2</sup> could enter the OLE. Pts switched to 6 mg UPA from their RCT dose of UPA 3, 6, 12, 18 mg twice daily (BID), 24 mg once daily (QD) or Placebo. A dose increase to 12 mg BID was required for pts with <20% improvement in both SJC and TJC on 6 mg BID (at wk 6 or 12), and permitted for pts not meeting CDAI LDA. Pts without 20% improvement in SJC and TJC 6 wks after escalation, or at any 2 consecutive visits, were discontinued. The dose was decreased to 6 mg BID only in pts with a safety concern or intolerability. Pts are grouped as: Never-titrated (on 6 mg BID throughout); Titrated-up (from 6 to 12 mg BID); Titrated-up and back down (to 6 mg BID). After Jan 2017, the 6 and 12 mg BID doses were replaced by 15 and 30 mg QD extended-release equivalents currently being studied in phase 3. Data up to Jan 13 2017 are reported. Adverse events (AE) per 100 yrs of pt exposure (PY) are summarized starting from day 1 of OLE. Efficacy is assessed by ACR20/50/70 and LDA (by DAS28-CRP and CDAI), and observed data are presented upto Wk 72 of OLE due to sample size consideration.

**Results:** Out of 516 pts who completed the 2 RCTs, 494 entered the OLE, 493 were dosed, 328 (66.5 %) were never-titrated, 150 (30.4%) were titrated-up, and 15 (3%) were titrated-up and back down; 150 pts (30.4%) were discontinued [42 (8.5%) withdrew consent, 37 (7.5%) due to AE and 24 (4.9%) due to lack of efficacy]. Mean exposure to UPA was 525.4 ± 221.4 days (range 1-961 days), and cumulative exposure was 725.1 PY (**Table 1**). The E/100PY for any AE in the OLE (170.5) was lower than for the RCTs in TNF-IR (697.9, 48 PY) and MTX-IR (408.4, 54.6 PY). The E/100PY was 2.3 for serious infection, 3.7 for herpes zoster, 0.8 for malignancies excluding non-melanoma skin cancer, and 1.0 for adjudicated cardiovascular events. There were 2 deaths. Changes from baseline in laboratory parameters were consistent with observations from phase 2 RCTs. For those pts completing Wk 72, efficacy was maintained in pts on 6 mg BID UPA from day 1 of OLE (never-titrated); 55% pts met ACR70 and 83% were in LDA by DAS28-CRP and CDAI based on as observed data (**Table 2**).

**Conclusion:** No unexpected safety signals were observed during this OLE. Efficacy responses were maintained upto 72 wks in pts on 6 mg BID UPA in the OLE.

**Table 1. Summary of Adverse Events in Patients who Entered the OLE**

	As of Jan 13 2017 N=493, PYs=725.1 Events (E/100PY)

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Filgotinib (GLPG0634, GS-6034) is an oral, selective JAK1 inhibitor that has demonstrated safety and efficacy data in two 24-week placebo-controlled phase 2B studies as add-on to methotrexate and as monotherapy in active rheumatoid arthritis (RA) patients with inadequate response to MTX (MTX-IR)<sup>1,2</sup>.

The objective is to evaluate the association between normalization of patient-reported outcome measures (PRO) and clinical response (ACR20) in MTX-IR RA patients treated with either filgotinib or placebo, as add-on to methotrexate (DARWIN 1), or as monotherapy (DARWIN 2).

## Methods:

Patients with active RA were randomized in a double-blind manner to placebo (PBO) or one of 3 daily doses of filgotinib (FIL, 50mg, 100mg or 200mg) as once daily (DARWIN 1 and DARWIN 2) or twice daily regimen (DARWIN 1) for 24 weeks. This post-hoc analysis at week 12 (W12) included patients treated FIL 100mg and 200mg QD (selected Phase 3 doses), and PBO. PRO included SF-36 (mental and physical components: MCS and PCS respectively; cut-off 50), FACIT-F (cut-off 40), and HAQ-DI (cut-off 0.5).

## Results:

594 and 283 patients with active RA were randomized in DARWIN 1 and 2 respectively. In DARWIN 1, 44%, 64%, and 69% of patients on PBO, FIL 100mg QD and FIL 200mg QD respectively achieved ACR20 response at W12; in DARWIN 2 the respective response was 29%, 66%, and 72%. For all PRO parameters (SF-36 MCS, SF-36 PCS, FACIT-F and HAQ-DI) and in both studies, a higher proportion of patients with normalized scores was achieved in ACR20 responders compared to non-responders at W12 across treatment groups (Table 1).

## Conclusion:

This post-hoc analysis of two phase 2B studies in MTX-IR RA patients after 12 weeks of treatment suggests that normalization of PRO is associated with the ACR20 response, regardless of treatment with filgotinib and background MTX.

Table 1. Percentage of patients reaching normalized values for PRO at Week 12, by ACR20 response status.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Baricitinib (bari), an oral, selective inhibitor of Janus kinase (JAK) 1 and JAK 2, is approved in the EU for the treatment of moderately to severely active RA in adults. We further describe the drug's safety profile with updated data from an on-going long-term extension (LTE) study.

**Methods:** Long-term safety of once-daily bari was evaluated in the “all-bari-RA” dataset, which includes all patients (pts) with active RA exposed to any bari dose from 8 randomized trials (4 Ph3, 3 Ph2, 1 Ph1b) and 1 LTE study (data up to 01-Sept-2016). Previous all-bari-RA analyses<sup>1</sup> are provided for comparison (data up to 10-Aug-2015). Placebo (PBO) comparisons were evaluated for up to Wk 24 in the “PBO-4mg” dataset from the 6 Ph2/3 trials in which pts were randomized to bari 4mg, with censoring at rescue or treatment switch. Dose responses were evaluated based on the 4 Ph2/3 trials in which pts were randomized to 2 or 4mg and includes data from the LTE (the “2mg-4mg-extended” dataset). Data were censored at rescue or dose change (as-treated analysis). Because of the latent period for malignancy, 2mg-4mg-extended was also analyzed without censoring for rescue or dose change (as-randomized analysis). Incidence rates (IR) per 100 patient-years (PY) were calculated.

**Results:** In the current analysis, 3492 pts received bari for 6637 total PY of exposure (an increase of over 2400 PY from previous analysis); maximum exposure was 5.5 yrs (Table 1). No differences were seen for bari 4mg vs PBO in adverse

events (AEs) leading to permanent study drug discontinuation, death, malignancy, serious infection, or major adverse cardiovascular event (MACE) (Table 1). Herpes zoster IR was significantly higher for bari 4mg vs PBO (IR 1.0 vs 4.3; PBO, 4mg, respectively). In 2mg-4mg-extended, no significant differences were observed comparing bari 2mg vs 4mg for the above mentioned events. Malignancy (excluding non-melanoma skin cancer (NMSC)) IR were 0.5 and 1.3 for 2mg and 4mg, respectively, with as-treated analysis and 0.7 and 0.9 with as-randomized analysis. For the above events, the current IRs in all-bari-RA are similar to those previously reported (Table 1). The following IRs were observed in the current all-bari-RA: lymphoma (0.09), gastrointestinal (GI) perforation (0.05), and tuberculosis (TB) (0.15, all in endemic areas). The IRs for these events are also similar to those previously reported (Table 1). Fewer than 1% of pts discontinued due to abnormal lab results.

**Conclusion:** In this updated integrated analysis of patients with moderately to severely active RA, including patients exposed for up to 5.5 years, baricitinib maintained a safety profile that was similar to that previously reported<sup>1</sup> and acceptable in the context of demonstrated efficacy.<sup>2,3</sup>

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a chronic disease and some patients (pts) have an inadequate response (IR) to conventional DMARDs (csDMARDs). Baricitinib is an oral, selective inhibitor of Janus kinase (JAK) 1 and JAK 2<sup>1</sup> approved in the EU for the treatment of moderately to severely active RA in adults. We evaluated the effects of baseline characteristics, including prior csDMARD use, on the efficacy of bari in csDMARD-IR pts.

**Methods:** Eligible pts had active RA, were csDMARD-IR and biologic DMARD (bDMARD)-naïve, and were randomized to bari 4 mg or placebo in 5 global, randomized trials (2 Phase 3, 3 Phase 2). This analysis pooled data to evaluate efficacy outcomes (ACR50, DAS28-CRP  $\leq 3.2$ , change from baseline in HAQ-DI) at Week (Wk) 12 in bari 4 mg vs placebo for potential subgroup interactions based on a variety of baseline characteristics including age, gender, weight, disease duration, etc. A logistic regression model was used to detect significant interactions; p-value  $\leq 0.1$  was considered significant, with significance in  $>1$  measure given more weight.

**Results:** Overall samples were N=881 (4 mg) and N=803 (placebo). Pts were aged ~52 years, ~80% were female, and 44-49% had a history of 1 prior csDMARD (Table 1). In the overall pooled population at Wk 12, responses for ACR50, DAS28-CRP  $\leq 3.2$ , and HAQ-DI change from baseline were significantly improved for bari 4 mg vs placebo (Tables 2, 3).

Across subgroups, odds ratios and least squares mean difference (LSMDs) predominately favored bari 4 mg over placebo at Wk 12 (Tables 2, 3) and were generally similar to the overall pooled population. Significant quantitative interactions were observed for bari 4 mg vs placebo for BMI in ACR50 and DAS28-CRP  $\leq 3.2$  (Table 2) and for race in ACR50 and DAS28-CRP  $\leq 3.2$ . No significant interactions were observed for the number of prior cDMARDs. No qualitative interactions were observed.

**Conclusion:** Consistent with results in the overall pooled population of csDMARD-IR and bDMARD-naïve pts, at Wk 12 the point estimate for each endpoint favored baricitinib 4 mg vs placebo across subgroups. Thus, baricitinib demonstrated a consistent, beneficial treatment effect in subgroups, irrespective of baseline characteristics.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Baricitinib (BARI), an oral, selective Janus kinase (JAK)1/2 inhibitor<sup>1</sup>, has shown efficacy in DMARD naïve RA patients (pts)<sup>2</sup> and in pts with inadequate response to methotrexate (MTX-IR).<sup>3</sup> In the EU, BARI is approved for treating moderate to severe active RA in adults. The objective of this analysis is to evaluate the time to achieve moderate disease activity (MDA), low disease activity (LDA), and remission in pts treated with BARI 4-mg compared to placebo (PBO) or active comparators, MTX and adalimumab (ADA) from the RA-BEGIN<sup>2</sup> and RA-BEAM<sup>3</sup> trials.

**Methods:** In RA-BEGIN, DMARD naïve pts were randomized to BARI 4-mg once daily (QD), MTX or BARI 4-mg+MTX for 52 weeks (wks). In RA-BEAM, MTX-IR pts were randomized to PBO, BARI 4-mg QD or ADA 40-mg biweekly for 52 wks (PBO switched to BARI 4-mg at 24 wks). This post hoc analysis estimated the time to achieve MDA (Clinical Disease Activity Index, CDAI ≤22), LDA (CDAI ≤10), and remission (CDAI ≤2.8) in modified intent-to-treat (mITT) pts and in the subset of pts with high baseline disease activity (HDA) defined as CDAI >22 from the two trials. Cumulative incidence of MDA, LDA, and remission over 52 wks for RA-BEGIN and 24 wks for RA-BEAM were estimated.<sup>4</sup> Hazard ratios between treatments were obtained using Cox proportional hazards regression adjusting for region and baseline joint erosions (1-2 or ≥3 erosions) without control for multiple comparisons.

**Results:** In DMARD naïve population, BARI 4-mg monotherapy pts were 1.6 times more likely to achieve MDA and LDA and twice more likely to achieve remission compared to MTX (p<0.001) (Table). Median time to MDA and LDA with BARI 4-mg treatment (2 and 12 wks, respectively) was 2 and 8 wks shorter than with MTX (4 and 20 wks, respectively) (Figure). Bari 4-mg+MTX performed similar to BARI 4-mg monotherapy.

In MTX-IR population, BARI 4-mg treated pts were 1.7, 2.3, and 3.5 times more likely to achieve MDA, LDA, and remission than PBO (p<0.001) and 1.0, 1.1, 1.4 times more likely to achieve MDA (p=0.557), LDA (p=0.295), and remission (p=0.030) than ADA (Table). Median time to MDA was 5 wks shorter with BARI 4-mg treatment (2 wks) than PBO (7 wks) but similar to ADA (2 wks). Median time to LDA with BARI 4-mg (12 wks) was 2 wks shorter than ADA (14 wks) while PBO pts never reached the median time to LDA during the 24 wk study (Figure). Consistent results were obtained in pts with HDA.

**Conclusion:** DMARD naïve and MTX-IR pts were more likely to achieve LDA and remission, and at a faster pace, with BARI 4-mg than the comparator treatment groups.

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bruton's tyrosine kinase (BTK) is an attractive, novel therapeutic target for autoimmune disease, as it is required for signal transduction and activation via B-cell receptor, Fc receptor and RANKL pathways.<sup>1</sup> Due to the relatively slow turnover of BTK, a covalently bound inhibitor with a short pharmacokinetic (PK) half-life can lead to prolonged pharmacodynamic (PD) effects. BMS-986195 is being developed for the treatment of autoimmune diseases. This study assessed the safety, tolerability, PK and PD of BMS-986195 following oral administration in healthy participants.

**Methods:** Healthy participants (18–50 years) were randomized in a 3:1 ratio to receive a single dose (0.3–30 mg BMS-986195 or placebo; n=30) or multiple doses (0.3–10 mg BMS-986195 or placebo once daily for 14 days; n=24). Safety and tolerability were assessed by physical examinations, vital sign measurements, 12-lead electrocardiograms and clinical laboratory evaluations. Plasma concentrations of BMS-986195 were measured using a validated liquid chromatography–tandem mass spectrometry (LC-MS/MS) assay at various time points. BTK occupancy by BMS-986195 was measured using a novel LC-MS assay, as a PD and target engagement marker. **Results:** BMS-986195 was well tolerated in the single- and multiple ascending dose study. No drug-related serious adverse events were observed. BMS-986195 was rapidly absorbed with peak concentrations occurring in <1 hour and eliminated with a half-life of <2 hours across all dose levels tested.

Increases in the PK exposure (area under the curve and maximum serum concentration) were dose proportional. No time-dependent changes in PK were observed following the multiple-dose administration of BMS-986195. BTK occupancy increased in a dose-dependent manner following single-dose administration of BMS-986195. The mean (SD) peak BTK occupancy following a single dose was 19% (3%) at 0.3 mg, and 100% (0%) at ≥10 mg. 100% BTK occupancy was sustained for up to 24 hours. BTK occupancy returned towards baseline over the following 6 days (Figure). Total BTK levels did not vary over time or by dose group. With multiple-dose administration, 100% BTK occupancy was reached at ≥3 mg once daily, and drug-occupied BTK exhibited similar kinetics to that observed following a single-dose

administration. Additional PD and safety results from the multiple ascending dose study will be presented. **Conclusion:** BMS-986195 was well tolerated at the doses tested in healthy participants. It showed a favorable PK/PD profile with a rapid elimination of the compound and sustained PD activity, due to the relatively slow turnover of BTK and covalent binding of BMS-986195. 100% BTK occupancy over the entire daily dosing interval was observed. Overall results suggest that BMS-986195 is an attractive candidate for further clinical development. 1. Whang JA, et al. *Drug Discov Today* 2014;19:1200–4.

## Leukopenia and Tumor Necrosis Factor Alpha Inhibitor Therapy

Wenlu Xiong<sup>1</sup>, Rochella A. Ostrowski<sup>2</sup>, William Adams<sup>3</sup> and Rodney Tehrani<sup>4</sup>, <sup>1</sup>Rheumatology, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Rheumatology, Loyola University Medical Center, Maywood, IL, <sup>3</sup>Clinical Research Office, Loyola University Medical Center, Maywood, IL, <sup>4</sup>Rheumatology & Immunology, Loyola University Medical Center, Maywood, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

- **Background/Purpose:** Tumor necrosis factor (TNF) alpha, a key proinflammatory cytokine in rheumatoid arthritis (RA) and inflammatory bowel disease (IBD), has been a major target in the treatment of these conditions. Although the immunosuppressant side effects are well-known, recent studies suggest that TNF alpha inhibition is directly linked to the development of leukopenia and that serial complete blood cell (CBC) counts should be monitored. However, most studies investigating hematologic side effects of anti-TNF alpha therapy have been case studies. This study was designed to

identify the frequency of leukopenia in patients on anti-TNF alpha therapy at a tertiary care institution and whether certain demographics, baseline white blood cell (WBC) counts, or other factors correlate with the development of leukopenia.

- **Methods:** The chart review was performed for adult patients who received anti-TNF alpha therapy (adalimumab, etanercept, certolizumab, golimumab, or infliximab) at Loyola University Medical Center between 2007 and 2016 and who had a baseline WBC count in the year prior to therapy. Subjects with baseline leukopenia (WBC <4 K/uL) were excluded. Data analysis was performed using the chi-square test, analysis of variance, Student t-test, and a multivariable general linear model.

- **Results:** Of 89 patients who met the study criteria, 17 patients (19%) developed leukopenia during anti-TNF alpha therapy. Patients in the study were treated for RA, IBD, psoriasis, psoriatic arthritis, IBD with associated arthritis, inflammatory arthritis not otherwise specified, or other diagnoses. Patients who developed leukopenia had significantly lower mean WBC counts compared to those who did not develop leukopenia ( $p = 0.01$ ) while all other factors including sex, race, age, type of TNF inhibitor, diagnosis, duration of therapy, and concomitant methotrexate use were comparable between the two groups (Table 1). After controlling for these variables, baseline WBC count was the only significant predictor of lowest WBC count. For every one unit (K/uL) decrease in baseline WBC, the lowest WBC on therapy decreased by 0.35 K/uL ( $p < 0.001$ ).

- **Conclusion:** In summary, leukopenia developed in a considerable proportion of patients on anti-TNF alpha therapy. This observation was not associated with several variables studied, including type of TNF inhibitor used, diagnosis, duration of therapy, and concomitant use of methotrexate. A lower baseline WBC count was the only significant predictor for both the development of leukopenia and of the greatest degree of leukopenia. These findings suggest that leukopenia should be screened periodically for all patients on TNF alpha inhibitor therapy regardless of baseline demographics and that those who have lower baseline WBC counts may warrant closer monitoring.

# Efficacy of Adding Iguratimod Therapy in Rheumatoid Arthritis Patients Who Had Inadequate Response to Biologic DMARDs

**Toshiaki Miyamoto**, Rheumatology, SEIREI HAMAMATSU GENERAL HOSPITAL, Hamamatsu, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Iguratimod (IGU) was approved in June 2012 and recommended by JCR guideline 2014 in the treatment of rheumatoid arthritis (RA). Although there have been efficacy of monotherapy and concomitant MTX in clinical trials, however, there have been no reports of concomitant biologic DMARDs (Bio). Therefore, we investigated efficacy of concomitant IGU therapy in RA patients who had inadequate response to Bio at the author's institution.

**Methods:** IGU were prescribed to 62 RA patients from August 2012 to June 2016, subjects were 57 patients adding IGU who had inadequate response to Bio. Previous treatment Bio was ADA. And concomitant MTX (mean 12 mg/week) of 54 patients (94%). Baseline characteristics were Mean age 53 years, mean duration of illness 5.5 years, corticosteroid use 14% (mean 2.9mg/day). The course of DAS28, SDAI, CDAI and remission rates were analyzed.

**Results:** Mean DAS28-ESR, DAS28-CRP, SDAI, CDAI were significantly decreased from the initiation of IGU treatment at 24 weeks (3.07→2.27, 2.55→1.63, 6.94→2.21, 6.23→1.95). Remission rates of DAS28-ESR, DAS28-CRP, SDAI, CDAI were 67%, 82%, 72%, 74% at 24 weeks. There were almost no side-effect after adding IGU.

**Conclusion:** IGU might be a new RA treatment option for aiming remission in patients who had inadequate response to Bio.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

Background/Purpose:

Systemic methotrexate (MTX) is the first-line disease-modifying antirheumatic drug (DMARD) for treating early and established rheumatoid arthritis (RA). When compared to oral MTX, subcutaneous MTX enhances tolerability with a significant reduction in gastrointestinal side effects. Subcutaneous MTX has further demonstrated better clinical efficacy than oral MTX in patients who were both oral MTX-experienced and MTX-naïve. This study aimed to better quantify the role of subcutaneous MTX in delaying initiation of biologic DMARD (bioDMARD).

Methods:

In this retrospective cohort analysis, new users of oral MTX were identified between January 1, 2008 and December 31, 2014 (N=42,413). Patients aged 18 years or older with continuous health plan membership, drug benefit, and RA diagnosis (n=7,968) were included in this analysis. Patients who had at least one  $\geq 2.5$  mg increase in the weekly oral MTX dose (n=3,970) were compared to those who switched from oral MTX to subcutaneous MTX (n=421). The primary outcome was the likelihood of initiating a bioDMARD, which was analyzed using Cox proportional hazard model. Other outcomes measured were the timing of changes in treatment, and doses of oral or subcutaneous MTX at the time of switches or at the end of follow-up.

Results:

Comparing the two treatment strategies, the unadjusted and adjusted Cox regression analyses showed no significant difference in the likelihood of initiating bioDMARD. Factors associated with a reduced likelihood of initiation of bioDMARD included older age, African American, and the initiation of azathioprine. In contrast, the use of systemic prednisone at baseline and higher erythrocyte sedimentation rate (ESR) during follow-up were associated with an increased likelihood of initiation of bioDMARD. Among the patients who started bioDMARD, more than two-third of the patients never received MTX at doses  $>20$  mg/week prior to initiating bioDMARD. Compared to patients who had a dose increase in oral MTX, patients who switched to subcutaneous MTX significantly delayed the use of bioDMARDs by 9 months ( $p<0.001$ ).

Conclusion:

There is no significant difference in the likelihood of initiating bioDMARD between the two treatment strategies. Compared to oral MTX group, switching to subcutaneous MTX delayed the use of bioDMARD by 9 months. Given that bioDMARDs are costly and require injections, switching from oral MTX to subcutaneous MTX before using bioDMARD may be a reasonable alternative for patients who fail oral MTX.

Figure 1: Likelihood of BioDMARD Initiation

Treatment Strategies	Unadjusted HR (95% CI, p-value) n = 4,391	Adjusted HR* (95% CI, p-value) n = 2,182
Increased PO MTX Dose	1.00 (reference)	1.00 (reference)
Switched to SC MTX	1.10 (0.93-1.31, 0.280)	1.06 (0.82-1.38, 0.635)

95% CI = 95% confidence interval; PO = oral; HR = hazard ratio; SC = subcutaneous

\*Adjusted for the following covariates:  
Baseline covariates: Age, sex, region, race, time since RA diagnosis, prednisone use, diabetes, Charlson's comorbidity index, rheumatology visits, MTX dose, anti-citrullinated protein antibodies, rheumatoid factor  
Follow-up covariates: Initiation of azathioprine, hydroxychloroquine, leflunomide, sulfasalazine, tofacitinib, gold, cyclosporine, mycophenolate mofetil, cyclophosphamide, minocycline, penicillamine, erythrocyte sedimentation rate, C-reactive protein

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

To investigate the efficacy and safety of zoster vaccines administered in rheumatoid arthritis(RA) patients taking methotrexate(MTX).

## Methods:

By reviewing data through the Kaiser Permanente electronic medical record (EMR) retrospectively, we identified 893 adult RA patients who received zoster vaccination between January 1, 2007 and December 31, 2012 and had at least 2 RA diagnoses documented within one year prior to the vaccination date. Patients treated with any biologic DMARDs within 6 months prior to the index dates were excluded. The cohort was followed until the occurrence of zoster infection, disenrollment, death or the end of study, whichever came first. The primary outcome, vaccination safety, was measured by time to occurrence of zoster infections within 42 days after zoster vaccines administered. The secondary outcome, vaccine efficacy, measured by time to occurrence of zoster infections (after day 42) until the end of follow-up period, was studied among those who maintain the treatment during follow-up period (n=762). Dosage effect was also analyzed among those taking MTX (n=342) by comparing patients taking  $\geq 25$ mg/week and those taking 22.5mg/week or less. Cox proportional model was used to analyze hazard ratios between groups.

## Results:

Among 893 RA patients who were given zoster vaccines, 366 patients were taking MTX within 6 months prior to the zoster vaccination and 527 patients were not taking MTX. At baseline, 707(79%) patients were female with a mean age of 70.1 (SD: .5) and disease duration of 6.6 (3.9) years. The analysis showed that the rate of zoster infection was 0.13 per 1000-person day in the MTX group and the rate was 0.23 per 1000-person day in the non-MTX group. We found no significant statistical difference in the rate of zoster infections within the first 42 days of vaccination with adjusted hazard ratio of .50(95% CI 0.09-2.69, p-value=0.42). During the subsequent follow-up period, 742 patients continued their baseline treatment. The rate of zoster infection was 15.9 per 1000-person year in the MTX group and the rate was 18.6 per 1000-person year in the non-MTX group with the adjusted hazard ratio 0.79(95% CI 0.47-1.33, p-value=0.37). Among the 334 patients taking MTX, 292 patients were taking a dose of 22.5 mg or under while 42 were taking the dose of 25mg or more. The final analysis from the model showed no significant difference in dosage effect, the adjusted hazard ratio was 0.34(95% CI 0.04-2.54, p-value=0.29).

## Conclusion:

Zoster vaccination is safe to be given to RA patients taking MTX regardless of the dosage. The vaccination is equally effective in RA patients taking MTX and not taking MTX.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Filgotinib is a potent and selective Janus kinase 1 (JAK1) inhibitor being developed to treat inflammatory diseases. Safety pharmacology studies and Phase 1 studies indicate that there is a low risk of QT prolongation by filgotinib treatment. This dedicated Phase 1 study was conducted to evaluate the potential effect of filgotinib on the QT interval prolongation in healthy subjects per the International Conference on Harmonization (ICH) E14 guidance.

## Methods:

52 healthy adults were randomized to receive a single dose of moxifloxacin 400 mg (positive control) or once daily doses of filgotinib 200 mg (top therapeutic dose), filgotinib 450 mg (supratherapeutic dose), or placebo for 7 days. There was a washout period of 9 days between each dosing period. Digital ECGs were collected in triplicates within 5 minutes at matched time points on the 1st day (predose) and 7th day (postdose) with 24 hours measurements for each treatment on the 7th day. QTc (QTcF and QTcI) were derived and average of triplicates provided time-matched QTc. Subjects with large QTc or QTc change from baseline were summarized. Changes from baseline in time-matched QTc were fit to a mixed effect model, and difference of QTc change between filgotinib treatments or moxifloxacin vs placebo were quantified. PK of filgotinib was evaluated, and safety was monitored throughout study. The 90% confidence intervals (CIs) were constructed for the ratios of geometric least squares means of filgotinib PK parameters ( $AUC_{\tau}$ ,  $C_{\max}$ , and  $C_{\tau}$ ) for 450 mg vs. 200 mg daily dose. The association between QTc and plasma concentrations of filgotinib was explored.

## Results:

46 (88.5%) subjects completed study drug treatments. The mean (range) age of subjects was 38 (20-55) years, 39 (75%) subjects were female, 28 (53.8%) were white and 15 (28.8%) were hispanic or latino.

Lack of QTcF prolongation has been demonstrated at both doses of filgotinib. The upper limits of the 2-sided 90% CI for mean difference in QTcF between 200 mg or 450 mg vs placebo were less than 10 msec ( $\leq 8.35$  msec) at all time points. Similar results were observed with QTcI. Assay sensitivity was demonstrated using moxifloxacin at 400 mg, with the lower 96.7% CI for mean difference in QTcF above 5 msec ( $\geq 8.32$  msec) at 2, 3, and 4 hours post dose. Filgotinib 450 mg provided 2.1-fold higher  $C_{\max}$  than 200 mg. There were no clinically relevant relationships between change from baseline (placebo-corrected) in QTcF/QTcI and plasma concentrations of filgotinib.

Overall, 8 (15.7%), 15 (30.0%), 0 (0.0%), and 5 (10.0%) subjects experienced treatment-related AEs during filgotinib 200 mg, filgotinib 450 mg, placebo, and moxifloxacin treatment periods, respectively. No serious or severe ( $\geq$  Grade 3) AEs occurred, and the majority of the AEs reported were Grade 1 (mild) in severity. No Grade 4 laboratory abnormalities occurred. There were no clinically significant trends in vital signs, or safety ECG recordings.

## Conclusion:

Filgotinib does not affect QTc interval by definition of a negative thorough QT study per ICH E14 guidance at 200 mg (top therapeutic dose) and 450 mg (supratherapeutic dose; 2.1-fold higher  $C_{\max}$  than 200 mg).

## **Clinical and Structural Responses of Patients with Active Rheumatoid Arthritis (RA) Using Step-up Dosing of Tofacitinib in a Treat to Target Approach**

**Norman Gaylis**<sup>1</sup>, Joanne Sagliani<sup>1</sup> and Steven Needell<sup>2</sup>, <sup>1</sup>Arthritis & Rheumatic Disease Specialties, Aventura, FL, <sup>2</sup>Boca Radiology, Boca Raton, FL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib has been shown to reduce the clinical signs and symptoms of some RA patients at an approved dose of 5 mg bid. Studies report that 10 mg bid is an effective dose. This is the first community practice trial to measure the clinical and structural benefits of stepping up the initial dose of 5 mg bid in non-responders to 10 mg bid in order to achieve a clinical response using a treat to target approach.

**Objective:** This study evaluates the optimal dose of tofacitinib (5 mg bid VS 10 mg bid) needed to reach treatment target in a cohort of patients with active RA while comparing the corresponding structural findings measured by low field MRI

**Methods:** 20 RA patients who were unresponsive to either methotrexate (10-25 mg weekly) or MTX plus up to 2 prior biologics with synovitis, osteitis or erosions on Baseline MRI (Esaote 0.3T) were treated with 5 mg bid tofacitinib with a treat to target goal of LDA or remission depending on the Clinical Activity Index (CAI) score at Baseline. If the target was not met and sustained for 3 months, the dose of tofacitinib was increased to 10 mg bid in an attempt to reach target. MRIs of the hand/wrist were blindly read by a musculoskeletal radiologist using a RAMRIS score. A CAI score of >10 was needed at study entry.

**Results:** Of the 20 enrolled patients, 6 remained at 5 mg bid and 14 were dose escalated to 10 mg bid most at the 12 week period. Of the 5 mg bid group, 3 completed the trial at target and 3 early termed (ET) for lack of efficacy, relocation and AE. Structurally, there was no change in erosions in all 3 patients; 2 showed regression of synovitis and 1 showed no change; 2 showed regression in osteitis and 1 no change. Of the 14 patients escalated to 10 mg bid, 11 completed the trial with 7 remissions, 2 at LDA, and 1 at MDA. 3 patients ET due to lack of efficacy. In the 10 mg bid group, 9 patients showed no change in erosions, 1 regression and 1 progression. 5 patients showed no change in synovitis and 6 showed regression, and 7 showed no change in osteitis, 3 showed regression and 1 showed progression. The CRP values correlated with the improvement of the clinical and structural results, in particular, the levels improved after the dose was increased to 10 mg bid.

**Conclusion:** Our results suggest that a significant number of patients treated with the standard dose of 5 mg bid may potentially have improved outcomes including LDA or remission when treated at a higher dose (10 mg bid). This is evidenced by the results of 11 of the 14 patients having significant improved response most after 3 months of treatment with 10 mg bid. Furthermore, the structural findings correlate in large part to the clinical findings showing stabilization or improvement in most patients. An extension trial is currently ongoing to determine if the positive outcome of LDA or remission at the higher dose (10 mg bid) can be sustained if the dose is reduced back down to 5 mg bid.

Patient	CDAI BSL	CDAI 3 Mnth All taking 5 mg bid	CDAI 12 Mnth Remain on	CDAI 12 Mnth Dose Increased

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The antibody-based targeted pharmacodelivery of cytokines by means of immunocytokines has the potential to enhance therapeutic activity at the site of disease while sparing healthy tissues. Dekavil (F8IL10) is a fully human immunocytokine consisting of the targeting antibody F8 (specific to EDA) fused to the anti-inflammatory payload interleukin-10. Dekavil is currently in phase 2 clinical development for the treatment of rheumatoid arthritis (RA).

### **Methods:**

Patients diagnosed with RA according to ACR/EULAR classification criteria, who have active disease despite MTX therapy and who failed anti-TNF treatment are the target population.

In a recently completed phase 1b dose escalation study with the aim to explore safety, tolerability and the maximum tolerated dose (MTD), cohorts of 3-6 patients were treated with escalating doses of Dekavil (6-600 µg/kg + MTX). Patients received 4 weekly *s.c.* injections of Dekavil in combination with a fixed dose of MTX (10-15 mg). Patients willing to continue the treatment had the opportunity to receive 4 additional weekly injections of Dekavil.

The ongoing multicenter, double-blind, placebo-controlled phase 2 trial assesses therapeutic activity by measuring the mean change from baseline of DAS28-CRP. Patients are randomized into two treatment groups (Dekavil 30 or 160 µg/kg plus MTX) and one placebo group (placebo plus MTX). Study participants receive 8 weekly *s.c.* injections of Dekavil in combination with a fixed dose of MTX (10-15 mg).

Both studies further investigate the possible formation of anti-fusion protein antibodies as well as F8IL10 signature.

### **Results:**

In the phase 1 study, Dekavil was shown to be well tolerated up to the highest investigated dose (600 µg/kg) and an MTD was not reached. In 34 out of 35 patients treated in the phase 1 study, no DLTs, no SAEs and no SUSARs have been reported. One study subject in cohort 9 (450 µg/kg) experienced a DLT (G2 purpura), which was accompanied by a SAE (G2 dyspnea, not drug related). The patient fully recovered within one week after having received corticosteroid treatment. The most frequently observed adverse event was mild injection site reaction and occurred in 60% of the patients. Furthermore, two cases of drug related anemia (G3 and G2; 160 µg/kg and 450 µg/kg, respectively) were reported in this study. All adverse reactions resolved completely. At the first efficacy assessment after 4 cycles of treatment, 36.4% of patients (12/33) revealed ACR responses. The fraction of responding patients increased to 45.8% (11/24) after 8 cycles of treatment. Two patients benefited from a long lasting ACR70 responses for more than 12 months after the last drug administration.

As of May 2017, 23 out of 87 patients have been enrolled in the phase 2 clinical study. Neither SAE nor SUSARs nor treatment-related deaths were recorded so far. An interim analysis performed after 45 patients will allow for a more thorough understanding of the product.

### **Conclusion:**

The currently available data suggest that the biologic agent Dekavil is a safe and well tolerated novel therapeutic approach for the treatment of RA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Here, we report tofacitinib safety and tolerability up to 114 months (Mos) and clinical efficacy up to 96 Mos in long-term extension (LTE) studies.

**Methods:** Data were pooled from 2 open-label studies (NCT00413699 [ongoing; database not locked at March 2017 data cut]; and NCT00661661) of patients (pts) with RA who had participated in Phase 1/2/3 studies of tofacitinib. Pts received tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background DMARDs. As pts in the LTE studies were allowed to switch doses, they were assigned to the 5 mg BID group if the total daily dose was <15 mg/day, and to the 10 mg BID group if it was ≥15 mg/day. Primary endpoints were adverse events (AEs) and confirmed laboratory safety data. Secondary endpoints included clinical efficacy measures (ACR20/50/70 response rates, DAS28-4[ESR], HAQ-DI, and Clinical Disease Activity Index). Safety data were included up to Mo 114 and completer-analyzed efficacy data up to Mo 96 (n≤100 post-Mo 96).

**Results:** 4967 pts were treated (mean [max] duration: 3.5 [9.4] years). Total tofacitinib exposure was 17,738.5 pt-years (py); 76.4% of pts maintained their initial dose. In total, 2518 pts (50.7%) discontinued (AEs: 1189 [23.9%]; insufficient clinical response: 179 [3.6%]). Most common AE classes with highest AEs: infections and infestations (69.6%; exposure adjusted event rate [EAER; events per 100 py], 19.71) and musculoskeletal/connective tissue disorders (40.3%; EAER, 11.40). Most common AEs: nasopharyngitis (19.1%; EAER, 5.41), upper respiratory tract infection (17.9%; EAER, 5.07), bronchitis (12.6%; EAER, 3.58), and urinary tract infection (12.5%; EAER, 3.55). Serious AEs occurred in 29.4% of pts, and serious infections (SIEs) in 8.9% of pts. Malignancies, excluding non-melanoma skin cancer, were reported in 3.0% of pts. Incidence rates (IR; pts with events per 100 py) for AEs of interest, with 95% confidence intervals (CIs), are provided in Table 1. IRs for SAEs, SIEs and malignancies through Mo 114 did not increase vs reported data through Mo 105.<sup>1</sup> Confirmed laboratory data are provided in Table 1. No new safety risks were identified. Clinical responses were sustained from Mo 1 to Mo 96 (Table 2).

**Conclusion:** In patients with RA who remained in the LTE studies, tofacitinib (5 or 10 mg BID), with or without background DMARDs, was associated with consistent safety through Mo 114 and sustained clinical efficacy through Mo 96.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

To study the prevalence of occult hepatitis B carrier status and its associated factors in patients with rheumatic diseases undergoing biological therapies

### **Methods:**

Consecutive adult patients with various rheumatic diseases who were currently receiving biological therapies between November 2016 and April 2017 were recruited in this cross-sectional study. Blood was taken for evidence of hepatitis B infection (HBsAg, anti-HBs, anti-HBc-IgG). For patients tested positive for HBsAg or anti-HBc-IgG, assay of serum HBV-DNA level was also performed. Occult hepatitis B carrier was defined as patients who were HBsAg negative but anti-HBc-IgG positive. Logistic regression was performed to study factors independently associated with occult hepatitis B carrier status in these patients.

### **Results:**

310 Chinese patients were studied (60% women, age at biological therapy  $44.0 \pm 13.0$  years). The underlying rheumatic diseases requiring biological therapies were rheumatoid arthritis (46%), spondyloarthritis (31%), psoriatic arthritis (12%) and systemic lupus erythematosus (8.1%). The biologics being used were the TNF inhibitors (66%), tocilizumab (16%), abatacept (2.9%), rituximab (7.7%), belimumab (5.8%) and tofacitinib (1.3%). Hepatitis B carrier (HBsAg+) status was detected in 11 (3.5%) patients and they were all put on preemptive anti-viral therapy (entecavir). A total of 105 patients (34%) were occult hepatitis B carriers (HBsAg- but anti-HBc-IgG+). Anti-HBs was present in 83/105 (79%) of these patients. Occult hepatitis B carriers were significantly older than the non-carriers ( $49.9 \pm 11.1$  vs  $40.9 \pm 13.3$  years;  $p < 0.001$ ), and were more frequently identified in rheumatoid arthritis than other rheumatic diseases (45% vs 25%;  $p < 0.001$ ). However, there was no gender difference in the prevalence of the occult hepatitis B carrier status (37% in women vs 28% in men;  $p = 0.10$ ). Logistic regression revealed that older age (RR 1.05[1.03-1.08] per year;  $p < 0.001$ ) was the only independent factor significantly associated with occult hepatitis B infection. Rheumatoid arthritis was not significantly associated with occult hepatitis B carrier status after adjustment for age and sex. Of the occult hepatitis B carriers, 9 (8.6%) had detectable HBV-DNA levels but all were very low titers ( $< 100\text{IU/ml}$ ). Five (56%) patients with detectable HBV-DNA levels received entecavir treatment during biological therapies, while 19 (20%) patients without detectable HBV-DNA were put on preemptive entecavir treatment (including all patients who were receiving rituximab). None of the overt (HBsAg+) or occult hepatitis B (HBsAg- anti-HBc-IgG+) carrier patients developed clinical reactivation of hepatitis B during a mean of  $5.0 \pm 3.7$  years of biological therapies.

### **Conclusion:**

Occult hepatitis B carrier status was present in one-third of Hong Kong Chinese patients with various rheumatic diseases undergoing biological therapies. Older age was the only independent factor associated with occult hepatitis B infection. Despite the relatively low rate of preemptive anti-viral treatment in these patients, clinical reactivation of hepatitis B was not reported over 5 years of biological therapies.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several studies have evaluated mortality risk factors in rheumatoid arthritis (RA) but that are no data regarding baseline predictors of mortality in patients under biologic therapy. In fact, definition of these predictors is difficult due to many confounding variables such as age, gender, biologic drug itself and its duration. Therefore, the aim of this study was to identify clinical and laboratory baseline predictors of death in RA patients matched for all these parameters under biologic treatment.

**Methods:** This was a retrospective observational study that included all deceased RA patients (ACR classification criteria) regularly followed in the biologic therapy center of Rheumatology Division of a tertiary university hospital. All relevant parameters were evaluated using an electronic chart database established from 2007 to 2016. All biologic drugs, including subcutaneous and intravenous agents, are regularly administered in-hospital. A control group of RA patients under biologic treatment matched for gender, age, biologic drug and its duration was included. Demographic data, comorbidities, clinical and laboratorial findings and concomitant treatment were assessed at the baseline of last biologic drug and at the last visit before death.

**Results:** During the study, 22/436 (5%) RA patients died after biologic therapy start. Causes of death included infections in 18 (82%), complications of pulmonary fibrosis in 2 (9%), subarachnoid hemorrhage in 1 (4.5%) and hemorrhagic stroke in 1 (4.5%). Deceased and survivors patients were comparable with regard to current age (57 vs. 57 years,  $p=0.34$ ), male gender (27% vs. 27%,  $p=1.0$ ) and last biologic duration (12 vs. 10 months,  $p=0.51$ ). Analysis of baseline therapeutic parameters of the last biologic drug in the deceased group compared to survival groups revealed similar median number of biologic agents ( $p=0.94$ ), need of at least one switching to another biologic agent (68% vs. 63,  $P=0.79$ ) and frequencies of other drugs [prednisone ( $p=0.25$ ), methotrexate ( $p=0.8$ ), leflunomide ( $p=0.79$ ) or sulfasalazine ( $p=0.11$ )]. Likewise, clinical and laboratorial characteristics were alike in both groups [Disease Activity Score in 28 joints (DAS28) (4.75 vs 4.96,  $p=0.75$ ), HAQ (1.75 vs. 1.185,  $p=0.37$ ), RF (68% vs. 84%,  $p=0.2$ ) and anti-CCP (18% vs. 21%,  $p=1.0$ )]. Concerning associated comorbidities, deceased patients had a significantly higher frequency of chronic renal failure (18% vs. 2%,  $p=0.041$ ) and a trend for a higher frequency of osteoporosis (59% vs. 33%,  $p=0.062$ ) compared to the control group. Further analysis of all parameters at last visit before death demonstrated that deceased group had a higher DAS28 (3.84 vs. 3.06,  $p=0.05$ ) and Health Assessment Questionnaire (HAQ) (1.563 vs. 1.0,  $p=0.0054$ ).

**Conclusion:** The present study design with rigorous control for confounding factors identified solely chronic renal failure and possibly osteoporosis (in non elderly population) as the most important baseline predictors of mortality in RA patients starting biologic therapy in a real life setting. High RA activity and severity at the last visit before death are short-term predictors of death in patients already under biologic therapy.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The goal of therapy of rheumatoid arthritis (RA) is to achieve a state of low disease activity (LDA) or remission and reduce joint damage and disability. When treatment with one agent is unsuccessful, an alternative DMARD, biologic or small molecule drug will be prescribed. This retrospective study reports the frequency and reasons for drug changes in RA patients in a tertiary US academic practice.

**Methods:** Records of 1300 RA patients were reviewed by 3 rheumatologists to select patients who received at least one biologic (b) DAMRD, had no other rheumatic disease, no interstitial lung disease or chronic infections, and were followed for at least one year to be included in this report. The study cohort consists of 198 patients who fulfilled the inclusion criteria. Patient demographics, drugs used, duration of use, and reasons for change of therapy were recorded.

**Results:** Of the 198 patients, 75% were females, average age was 51, 65% were ACPA positive, and 31% of patients had erosions at first visit. Patient demographics are summarized in Table 1. These patients received an average of 2.5 drugs before their first visit. They changed to a new drug an average of 2.4 times during their average follow up visits of 6.2 years. The longest average duration of continuous use for any of the DMARDs was 6-24 months (Table 2). The main reasons for discontinuation of these medications were lack of efficacy and the occurrence of adverse events (AEs). The rate of AEs among patients receiving bDMARDs was similar to that in patients receiving conventional DMARDs. The reasons for discontinuation of specific medications are summarized in Table 3.

**Conclusion:** This retrospective review suggests that most patients with RA will require a change of therapy every 2-3 years, primarily due to perceived lack of efficacy or the occurrence of AEs. The frequent change of therapy in patients with chronic disease like RA suggests that patients will use many different drugs in the course of their illness. In the absence of an effective biomarker that predicts response to a specific medication, therapeutic agents selected may not be efficacious and require early recognition of lack of efficacy and subsequent change of therapy.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) can have various pulmonary comorbidities including asthma, chronic obstructive pulmonary disease (COPD) and interstitial lung disease (ILD). Biologics can pose a potential risk for acute exacerbations (AE) of these pulmonary comorbidities by immunosuppression, drug-induced lung injury, or other mechanisms. We therefore compared the risk of pulmonary AE among RA patients initiating abatacept vs. TNF inhibitors (TNFi) with chronic pulmonary comorbidities at baseline.

**Methods:** We conducted a cohort study using claims data from Medicare (2008-2013) or a commercial health plan (MarketScan 2006-6/2015) in the US. Adults with RA and chronic pulmonary condition (i.e., asthma, COPD, or ILD) who initiated abatacept or TNFi were identified based on a combination of diagnosis codes and use of disease-specific medications. The cohort entry date was the 1<sup>st</sup> use of abatacept or TNFi after ≥12 month continuous enrollment. The primary outcome was a composite endpoint defined as any of: 1) inpatient stays or 2) ED visits for asthma, COPD, or ILD, or 3) outpatient visits for asthma, COPD or ILD plus dispensing of oral corticosteroids or antibiotics, or for respiratory complications such as pneumonitis and bronchitis. Secondary outcomes were individual components of the primary composite endpoint. Follow-up time started from the day after cohort entry to the earliest event of outcome occurrence, drug discontinuation, nursing home admission, disenrollment, end of study period, or death. To control for >50 potential confounders at baseline, abatacept initiators were matched to TNFi initiators on a propensity score (PS) with a 1:2 ratio in each of the three pulmonary condition subgroups. We estimated incidence rates (IR) and hazard ratios (HR) of the outcomes among abatacept initiators versus TNFi in the main cohort and the subgroups. PS-matched HRs from the two databases were then pooled using inverse variance-weighted fixed-effect method.

**Results:** After PS matching, we included 1,517 abatacept and 3,034 TNFi initiators with RA and chronic pulmonary condition from both databases. Mean (SD) age was 73.0 (6.1) years in Medicare and 61.2 (12.1) years in MarketScan. At baseline, 44% in MarketScan and 57% in Medicare used methotrexate. IR of the composite outcome per 100 person-years ranged from 47.6-49.6 in the abatacept group and from 51.8-53.5 in the TNFi group. For the primary composite outcome, the HR comparing abatacept to TNFi was 1.00 (95%CI 0.92-1.09) in Medicare and 1.00 (95%CI 0.89-1.12) in MarketScan with a pooled HR of 1.00 (95%CI 0.93-1.07). Secondary and subgroup analyses showed similar results (**Figure**).

**Conclusion:** Among patients with RA and chronic pulmonary condition, acute exacerbations of underlying asthma, COPD or ILD occurred frequently but we found no difference in the exacerbation risk between abatacept and TNFi initiators.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While tocilizumab (TCZ) may increase serum lipid levels, recent studies do not suggest an increased cardiovascular (CV) risk associated with TCZ use compared to TNF inhibitors in patients with RA. The current study examined comparative CV safety of TCZ versus abatacept in RA patients.

**Methods:** We conducted a cohort study using data from 3 U.S. healthcare claims databases – Medicare Parts A/B/D (2010-13), ‘IMS’ PharMetrics Plus (2011-2014) or Truven ‘MarketScan’ (2011-6/2015). Adults aged ≥18 years with RA who newly started TCZ or abatacept entered the cohort on the day of their first use of TCZ or abatacept. All patients had ≥12 month continuous enrollment free of TCZ and abatacept use before cohort entry. The primary outcome was a composite CV endpoint of hospitalization of any length for myocardial infarction (MI) and stroke based on claims-based algorithms (PPV>94%). Secondary outcomes were hospitalization for MI, stroke, coronary revascularization, heart failure and all-cause mortality. For the primary as-treated analysis, follow-up time started the day after cohort entry and ended on treatment discontinuation, outcome occurrence, disenrollment, death, or the end of study period. We estimated a propensity score (PS) to control for >60 potential confounders including demographics, prior DMARD use, comorbidities, medications, and healthcare utilization. TCZ starters were PS-matched to abatacept starters with a variable ratio of 1:3 within each database. We estimated incidence rates (IR) of composite CV events in the TCZ group compared to the abatacept group separately in each database. Hazard ratios (HR) from the 3 PS-matched cohorts were combined by an inverse variance-weighted, fixed-effects model.

**Results:** We included a total of 6,237 TCZ starters PS-matched to 14,685 abatacept starters in all three databases. Mean age (in years) was 72 in Medicare, 51 in IMS and 53 in MarketScan. At baseline, 73% (Medicare), 70% (IMS) and 62% (MarketScan) of TCZ or abatacept patients used methotrexate. In the as-treated analysis, the median follow-up time varied between 175 days (MarketScan) to 183 days (IMS) in the TCZ group and 193 days (MarketScan) to 209 days (Medicare) in the abatacept group. A total of 32 CV events occurred in TCZ starters and 112 events in abatacept starters across the three databases. The IR of the primary composite CV events per 100 person-years ranged from 0.37 (IMS) to 1.64 (Medicare) in the TCZ group and from 0.59 (IMS) to 1.69 (Medicare) in the abatacept group. The risk of the primary composite CV events was similar between the two groups across all three databases (**Table**), with a combined HR of 0.82 (95%CI 0.55-1.22) in TCZ initiators versus abatacept initiators. Analyses on secondary outcomes showed similar results.

**Conclusion:** This large multi-database cohort study found no increase in the risk of CV events in patients with RA who newly start TCZ versus abatacept.

**Table.** Hazard ratios (95% confidence interval) for primary and secondary cardiovascular outcomes in tocilizumab starters versus abatacept: a 1:3 variable ratio propensity score- matched as-treated analysis

Database:	Medicare	IMS	MarketScan	Combined *
<b>Primary:</b>				
Composite cardiovascular endpoint	0.96 (0.56-1.63)	0.67 (0.25-1.84)	0.68 (0.32-1.42)	0.82 (0.55-1.22)
<b>Secondary:</b>				
Hospitalization for MI	1.38 (0.65-2.94)	1.05 (0.27-4.15)	0.83 (0.33-2.05)	1.11 (0.65-1.89)
Hospitalization for stroke	1.03 (0.44-2.42)	0.44 (0.10-2.01)	0.49 (0.14-1.74)	0.73 (0.39-1.39)
Coronary revascularization	0.63 (0.26-1.51)	1.43 (0.41-5.01)	1.22 (0.53-2.83)	0.97 (0.56-1.68)
Hospitalization for HF	0.86 (0.40-1.83)	1.80 (0.71-4.59)	1.28 (0.46-3.55)	1.18 (0.71-1.97)
All-cause mortality	1.01 (0.60-1.70)	N/A	0.91 (0.28-3.01)	0.99 (0.62-1.60)

The abatacept group was the reference group. No death occurred in the IMS-TCZ group.  
Propensity score models included over 60 covariates including demographics, prior DMARD use, cardiovascular comorbidities, medications, and health care utilization.  
N/A listed because one group has no event.  
\* Hazard ratios were combined by an inverse variance-weighted, fixed-effects model.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** to investigate the potential relationship between the number of comorbidities at initiation of biotherapy and the occurrence of a severe infection or recurrent infections under biologic agent in rheumatoid arthritis (RA).

**Methods:** This was a monocentric and retrospective study conducted from 2001 to 2011. Population characteristics, number and nature of comorbidities and treatments were collected at baseline. The occurrence of severe infections leading to hospitalization or life threatening, as well as that of recurrent infections (> 4 per year) was collected during a 2 years-follow-up period after the introduction of an anti-TNF biologic agent or a non anti-TNF biotherapy in RA.

**Results:** 554 RA (70% women) were assessed during this 2 years follow up period. Mean age and RA duration were respectively at 64.1 (+/-13.8) years and at 15.2 (+/-10.4) years. 78% of patients were a rheumatoid factor or anti-CCP positive. The mean Disease Activity Score of C-Reactive protein (DAS 28 CRP) was 4.1. X-rays showed structural damage in 65.5% of cases. The mean dose of prednisone was 6.66 mg/l. 75.4% of patients received methorexate (mean dose: 10.5mg/week). Biological agents were prescribed as follows: abatacept (3.8%), adalimumab (20.6%), anakinra (7.8%), certolizumab (0.36%), etanercept (37.5%), infliximab (25.3%), rituximab (3.2%) and tocilizumab (1.6%). At 1 year, the therapeutic maintenance was 91.3%. In this population, 31.5% had no comorbidity, 27.4% had 1 comorbidity, 19.35% had 2 comorbidities and 21.7% had more than 2 comorbidities. The occurrence of recurrent infections during the 24<sup>th</sup> months was 5.6% whereas the occurrence of a severe infection was 3.8%. After adjustment (age, corticosteroid and DAS 28 CRP), there was a significant correlation between the number of comorbidities (more than 2 comorbidities) and the occurrence of severe infections. The number of comorbidities was not correlated with the occurrence of repeated infections. The Rabbit score predicted the risk of developing a severe infection of the order of 3.5%. Certain types of comorbidities were linked to the occurrence of severe or recurrent infections.

**Conclusion:** The presence of more than 2 comorbidities is significantly related to the occurrence of a severe infection during the 24 months following the initiation of a biological agent.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Use of biological therapy (BT) has dramatically improved Rheumatoid Arthritis (RA) management and outcomes for the last decade. Classic extraarticular manifestations are now uncommon, excepting for pulmonary involvement, which may be due to different factors and may itself affect also treatment election and patient prognosis. The aim of this study is to evaluate the presence of pulmonary complications in RA patients under BT in our hospital, assess its severity and related changes in treatment.

**Methods:** Review of clinical records of 208 RA patients receiving BT in the last 5 years (January 2012 to December 2016). 23 cases of preexisting lung disease for other causes (asthma, smoking) have been excluded. We collected demographic data, characteristics of RA, types of pulmonary involvement, followup and changes in treatment of 26 patients finally included. Statistical analysis were performed using SPSS v22.

## Results:

73.1% were women, mean aged 59 years (31-80); 53.8% were never smokers. They suffered from longstanding RA yet (median 176.92 months, SD 199.34); only 2 patients were early arthritis (RA diagnose during the previous year). 85% were RF positive with positive CCP antibodies in 69.2%, and structural damage with erosions was present in 70%. Other extraarticular manifestations (3 patients with rheumatoid nodules, 4 with cardiac involvement) were present in 25% .

At the time of lung disease diagnosis, 1/2 patients were in remission or low activity (DAS 28), with a median CRP 0.52 mg/dL (SD 1.72). 90% had received methotrexate and almost half of them leflunomide; 30% had been previously treated with BT (50% TNF alpha inhibitors). Interstitial lung disease (ILD) was the most frequent pulmonary involvement (57.7%) and non-specific interstitial pneumonia (NSIP) the most prevalent pattern (> 60%). We also found obstructive pulmonary disease (11.5%) and vascular involvement (7.7%). Gold standard image diagnostic technique was high resolution CT (40% presented a normal X-ray)

Treatment was modified in 53.8% of the cases (synthetic DMARD was kept in 68% and BT in 64%).

The average followup of pulmonary involvement was 37.85 months (1-156). 80% of the patients kept stable or improved from their arthritis and also from respiratory disease. Only one patient received a lung trasplant and another one died.

We haven't found association between different types of pulmonary involvement and the different variables analyzed in the study. We did't show significant differences in prognosis related to pulmonary disease distinct patterns; up to 80% of patients with ILD stabilize or improve

**Conclusion:** Prevalence of pulmonary disease in our experience in RA patients under BT is similar to prevalence in other observational studies (10-20%), diagnosis here was made for a casual detection in a routine chest X-ray or for clinical

suspicion for respiratory symptoms (cough, dyspnea...). Pulmonary involvement evolution here has been good perhaps for the high prevalence of NSIP, which is also thought to require less therapeutic intervention. Protocols for search and management of lung disease in RA patients are an unmet need in clinical practice, and its pathogenesis and treatment are important fields for translational and clinical research.

## **Efficacy and Safety of Baricitinib in Patients with Rheumatoid Arthritis: A Meta-Analysis of Randomized Controlled Trials**

**Sumit Kunwar**<sup>1</sup>, Christopher E. Collins<sup>2</sup> and Florina Constantinescu<sup>2</sup>, <sup>1</sup>Rheumatology, MedStar Washington Hospital Center, Washington, DC, <sup>2</sup>Rheumatology, MedStar Washington Hospital Center, Washington, DC

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Janus kinases (JAKs) play an important role in intracellular signaling for multiple cytokines in the pathogenesis of RA. Baricitinib is an oral, selective JAK 1 and 2 inhibitor which has been shown to be effective in the treatment of RA in several clinical trials. This meta-analysis aims to aggregate currently available data to assess the overall efficacy and safety of baricitinib in RA.

### **Methods:**

We searched PubMed, EMBASE and Cochrane CENTRAL from inception through 05/25/17 without language restriction. Our eligibility criteria included human placebo-controlled RCTs in adults ( $\geq 18$  years of age) that evaluated efficacy and safety outcomes of baricitinib in RA patients. We excluded meeting abstracts without full text publication. We used RevMan 5.3 to perform meta-analysis between groups on baricitinib 4mg per day and placebo using random effect model calculating odds ratio (OR) as well as 95% confidence interval (CI).  $I^2$  statistic was used to identify heterogeneity between studies, and values of more than 50 was used to indicate significant heterogeneity. We measured efficacy using ACR20/50/70 and DAS28-CRP response criteria and safety with adverse events.

### **Results:**

Five studies with a total of 2006 patients (967 on baricitinib and 1039 on placebo) were included for meta-analysis. The maximum study duration was 24 weeks. Baricitinib demonstrated greater efficacy in achieving ACR20/50/70 responses compared to placebo (66.7 vs 36.6%, OR 3.33, 95% CI 2.18-5.07,  $I^2$  75%,  $P < 0.00001$ ; 44.1 vs 17.8%, OR 3.56, 95% CI 2.77-4.58,  $I^2$  20%,  $P < 0.00001$  and 24.4 vs 6.5%, OR 4.62, 95% CI 2.96-7.19,  $I^2$  40%,  $P < 0.00001$  respectively). There was a small increase in any adverse events in the baricitinib group (70.4 vs 61.5%, OR 1.35, 95% CI 1-1.81,  $I^2$  47%,  $P = 0.05$ ), however, no increase in serious adverse events (5.5 vs 4.8%, OR 1.12, 95% CI 0.75-1.67,  $I^2$  0%,  $P = 0.58$ ) or serious infections (1.5 vs 1.5%, OR 0.94, 95% CI 0.46-1.92,  $I^2$  0%,  $P = 0.86$ ) when compared to placebo.

## Conclusion:

Baricitinib is effective in treatment of RA, and did not appear to have significant safety concerns during the first six months of treatment. However, the long term safety profile of this drug should be evaluated by future clinical trials.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To explore the comparative effectiveness of tofacitinib or baricitinib in patients with rheumatoid arthritis (RA) following a systematic review of randomized trials, by performing a network meta-analysis inferring from both direct and indirect evidence.

**Methods:** We used the data of the Cochrane systematic reviews on tofacitinib and baricitinib for treating rheumatoid arthritis. For both reviews, the searches were performed in seven electronic databases and two trial registries. Retrieved records were screened independently by 2 investigators to include controlled trials comparing tofacitinib or baricitinib alone or in combination with methotrexate versus placebo, methotrexate or other traditional or biologic DMARDs. Published and unpublished trials were considered. Quality appraisal and data extraction from the included studies was done independently by 2 investigators. For the network meta-analysis the primary outcome was American College of Rheumatology (ACR) 50% improvement criteria (ACR50) and secondary outcomes included remission according to the Disease Activity Score (DAS28), functional ability measured by the Health Assessment Questionnaire (HAQ), and serious adverse events as defined by the individual trials.

**Results:** Out of 2,673 unique citations, 21 trials met the inclusion criteria (9,839 patients). Most patients were female (74 to 96%) with a mean age and disease duration ranging from 48-56 years and 2.7-13 years, respectively. For the tofacitinib trials, 2 out 14 trials were at high risk of reporting bias. For the baricitinib trials, selection bias could not be evaluated in 6 out 7 trials and for selection and performance bias in 7 out of 7. The network plot for the ACR50 included 12 nodes (i.e., daily doses: tofacitinib monotherapy 5 and 10 mgs, combined with methotrexate 5 and 10 mg, baricitinib monotherapy 4 mg, baricitinib combined with methotrexate 2, 4, and 8 mgs, adalimumab monotherapy, adalimumab combined with methotrexate, methotrexate and placebo). The relative effect achieving an ACR 50 at 12 weeks against placebo in descending order were: Bari8+MTX (13.5; 5.8-31.3), Tofa10+MTX (11.3; 5.9- 21.4), Tofa5+MTX (10.5; 5.4-20.2), Bari2+MTX (9.6; 4.5-19.4), Bari4+MTX (9.5; 5.0-17.9), Bari4 (6.79; 3.2-14.3), ADA+MTX (6.8; 3.5-13.3), Tofa10 (6.2; 3.8-9.9), Tofa5 (5.1; 3.3-8.1), MTX (2.4; 1.4-4.4), and ADA (1.9; 0.8-4.7). When comparing indirectly, the only differences were observed in favor of baricitinib+MTX compared with tofacitinib alone. For DAS 28 there were 11 nodes and the order was (from most to least effective): Tofa10+MTX, ADA+MTX, Bari8+MTX, Bari4+MTX, Tofa5+MTX, Bari2+MTX, Tofa10, Bari4, Tofa5, and MTX. Serious adverse events were less likely to occur in the PBO, ADA, Tofa5+MTX, Tofa10+MTX, MTX, Bari8+MTX, Tofa10, Tofa5, Bari4+MTX, Bari4, and Ada+MTX.

**Conclusion:** All drug combinations were effective compared with placebo in reducing at least 50% of symptoms or achieving remission at 12 weeks. Tofacitinib 10 mg and baricitinib 8 mg combined with methotrexate were among the most efficacious options. Serious adverse events were less likely with the tofacitinib groups, although the within-class differences were small and may not be clinically meaningful.

## **Genetic Predictors of Iguratimod Clinical Response and Toxicity in Patients with Rheumatoid Arthritis**

**Wenjing Xiao**, Department of Rheumatology and Immunology, People's Hospital, , Peking University, Beijing, Beijing, China

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Iguratimod (IGU) is a novel DMARD in rheumatoid arthritis (RA). The purpose of this study was to identify genetic predictors of response and adverse drug events (AEs) to IGU therapy in patients with RA.

**Methods:** Seven single nucleotide polymorphisms (SNPs) of enzyme and transporter proteins related to IGU, CYP1A2\*1F(rs762551), CYP2C19\*2 (rs4244285), NAT2(rs1495741), ABCB1(rs1045642, rs2032582C), ABCG2(rs2231142) and SLCO1B1 (rs4149036), were determined by a genotyping approach in 272 IGU treated RA patients. SNPs were evaluated using real-time polymerase chain reaction. The efficacy of the IGU therapy was estimated using EULAR good response criteria based on the DAS-28. All AEs were recorded.

**Results:** 21.69% patients (59/272) were good responders and 36.40% patients (99/272) had AEs. Univariate analyses and multivariate analyses demonstrated that the ABCG2 *A* allele was associated with good response to IGU (OR=2.084, 95%CI 1.147-3.786,  $P=0.015$ ; OR=1.944, 95%CI 1.038-3.641,  $P=0.038$ ). NAT2 G carrier was significantly associated with less favorable response to IGU (OR=0.476, 95%CI 0.256-0.884,  $P=0.017$ ; OR=0.498, 95% CI 0.256-0.967,  $P=0.029$ ). CYP2C19\*2 A carriers had higher risk for IGU-induced toxicity than did the GG genotyping (OR=2.122, 95%CI 1.273-3.537,  $P=0.004$ ; OR=2.368, 95%CI 1.395-4.019,  $P=0.001$ ). No significant association was found between the genotypes of CYP1A2\*1F, ABCB1 and SLCO1B1 SNP and the IGU response or AEs.

**Conclusion:** Our study suggests that ABCG2 (rs2231142), NAT2 (rs1495741) and CYP2C19\*2 (rs4244285) genotyping may help to identify patients who will benefit from IGU treatment.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The long-term safety and clinical efficacy of tofacitinib 5 and 10 mg twice daily (BID) has been reported in patients (pts) with active RA up to 105 months.<sup>1-3</sup> We evaluated the long-term effects of tofacitinib on progression of radiographic structural damage in pts with RA from a long-term extension (LTE) study.

**Methods:** Data were analyzed from an open-label LTE (NCT00413699 [ongoing; database not locked at Mar 2017 data-cut]) of pts with RA who participated in Phase 2 (NCT01164579, methotrexate [MTX] naïve, early RA) or Phase 3 (NCT00847613, MTX-IR; NCT01039688, MTX naïve) tofacitinib index studies. Baseline (BL) was defined as last visit in the index study prior to LTE entry. In the index studies pts received tofacitinib 5 or 10 mg BID as monotherapy (mono) or with conventional synthetic DMARDs (csDMARDs); at the physicians' discretion pts could switch tofacitinib dose in the LTE, and were assigned to 5 mg BID if average total daily dose was <15 mg/day or to 10 mg BID if ≥15 mg/day. Outcomes to evaluate structural damage from BL to Month (M)36 included: mean and mean change ( $\Delta$ ) from BL in van der Heijde modified Total Sharp Score (mTSS), Erosion Score (ES), and Joint Space Narrowing Score (JSN); % of pts with no radiographic progression ( $\Delta$ mTSS ≤0.5); and % of pts with no new erosions ( $\Delta$ ES ≤0.5). Observed data were analyzed descriptively.

**Results:** A total of 1156 pts from the index studies were pooled in the LTE radiographic analysis; x-rays available in 88% (n=1019) of pts at M6; 497 pts received tofacitinib mono (5 mg BID, n=42; 10 mg BID, n=455) and 659 pts received tofacitinib with csDMARDs (5 mg BID, n=53; 10 mg BID, n=606). N at M12 was 86.8%, at M24 76.0%, and at M36 35.8% of the BL value. From LTE entry, mean duration of tofacitinib treatment in the total population was 1113 days (range 21–2396), and mean mTSS, ES, and JSN only slightly increased from BL to M36 (Figure). Mean (standard error [SE])  $\Delta$ mTSS was 0.25 (0.05) at M12 and 1.17 (0.28) at M36. Mean (SE)  $\Delta$ ES and  $\Delta$ JSN were 0.21 (0.03) and 0.24 (0.02) at M12 and 0.68 (0.17) and 0.78 (0.13) at M36. The % (SE) of all tofacitinib-treated pts with radiographic non-progression decreased from 91.2% (0.9) at M6 to 84.5% (1.1) at M12 and 72.2% (2.2) at M36, and the % of pts with no new erosions decreased from 96.0% (0.6) at M6 to 92.3% (0.8) at M12 and 85.3% (1.7) at M36. Similar trends were observed for all endpoints from BL to M36 in the tofacitinib mono and csDMARD groups (Figure); change from BL in mTSS, ES, and JSN score was similar at most time points in the csDMARD and mono populations (data not shown).

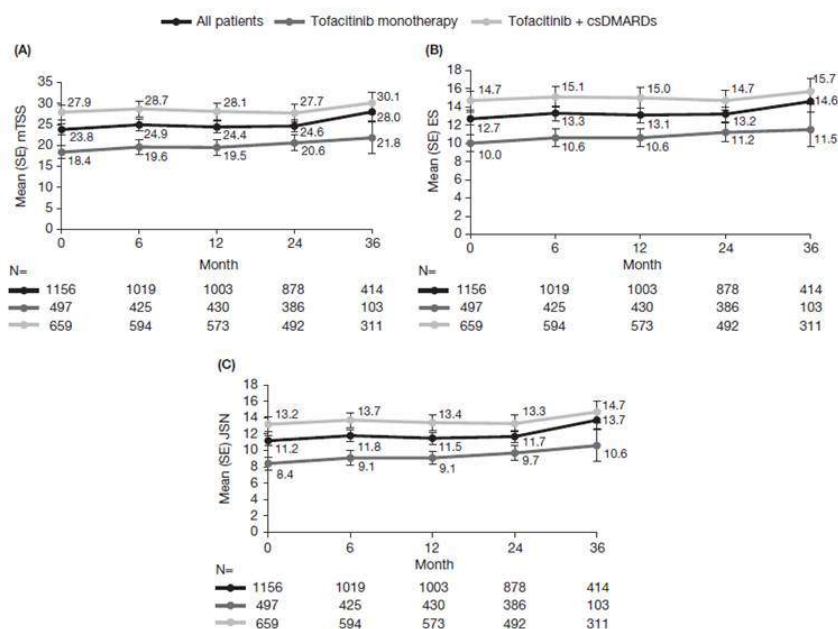

**Conclusion:** Structural damage progression was limited during treatment with tofacitinib alone or with csDMARDs for up to 3 years in pts with RA.

## Effect of Baseline MTX Dose on Clinical Efficacy and Safety in Rheumatoid Arthritis Patients Treated with Filgotinib: Post-Hoc Analysis from a Phase 2B Study

René Westhovens<sup>1</sup>, Annegret Van der Aa<sup>2</sup>, Corinne Jamoul<sup>2</sup>, Chantal Tasset<sup>2</sup> and Pille Harrison<sup>2</sup>, <sup>1</sup>KU Leuven Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium, <sup>2</sup>Galapagos NV, Mechelen, Belgium

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Filgotinib (GLPG0634, GS-6034) is an oral, selective JAK1 inhibitor that has demonstrated safety and efficacy data in two 24-week placebo-controlled phase 2B studies as add-on to methotrexate and as monotherapy in active rheumatoid arthritis (RA) patients with inadequate response to MTX (MTX-IR)<sup>1,2</sup>. The objective was to assess the effect of MTX dose on clinical efficacy and safety in MTX-IR RA patients treated with filgotinib as add-on to background MTX for 24 weeks.

### Methods:

Patients with active RA on stable dose of MTX were randomized in a double-blinded manner to receive either placebo (PBO) or one of 3 daily doses of filgotinib (50mg, 100mg or 200mg) as once or twice daily regimen for 24 weeks<sup>1</sup>. This post-hoc analysis includes patients treated with the selected Phase 3 filgotinib doses, 100mg and 200mg QD, and PBO for the efficacy parameters, and all dose groups for the safety analysis. MTX dose was categorized as low ( $\leq 12.5$  mg/wk), medium ( $>12.5$  to  $<17.5$  mg/wk) or high ( $\geq 17.5$  mg/wk).

### Results:

Baseline disease activity was high and similar across the three MTX subgroups, with an overall mean DAS28(CRP) score of 6.10, mean HAQ-DI of 1.73, mean CDAI score of 42.10 and mean SDAI score of 44.57. Across all MTX subgroups, patients on filgotinib 100mg or 200mg QD for 24 weeks showed efficacy over PBO, as measured by change from baseline in DAS28(CRP), CDAI, SDAI, HAQ-DI, and ACR20 response. No pattern was observed to suggest that the baseline MTX dose had any effect on filgotinib efficacy. The incidences of TEAE and serious TEAE were comparable regardless of the MTX dose (Table 2).

### Conclusion:

Post-hoc analysis of a phase 2B study in MTX-IR RA patients suggests that filgotinib treatment at 100mg and 200mg QD on the background of MTX is consistently associated with improved clinical outcomes compared to placebo, across all key efficacy parameters, irrespective of MTX dose. The safety profile was overall favorable and consistent with previous studies in RA with filgotinib, regardless of MTX dose.

Table 1. Mean (SE) change from baseline in key efficacy parameters at Week 24 by MTX subgroup.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

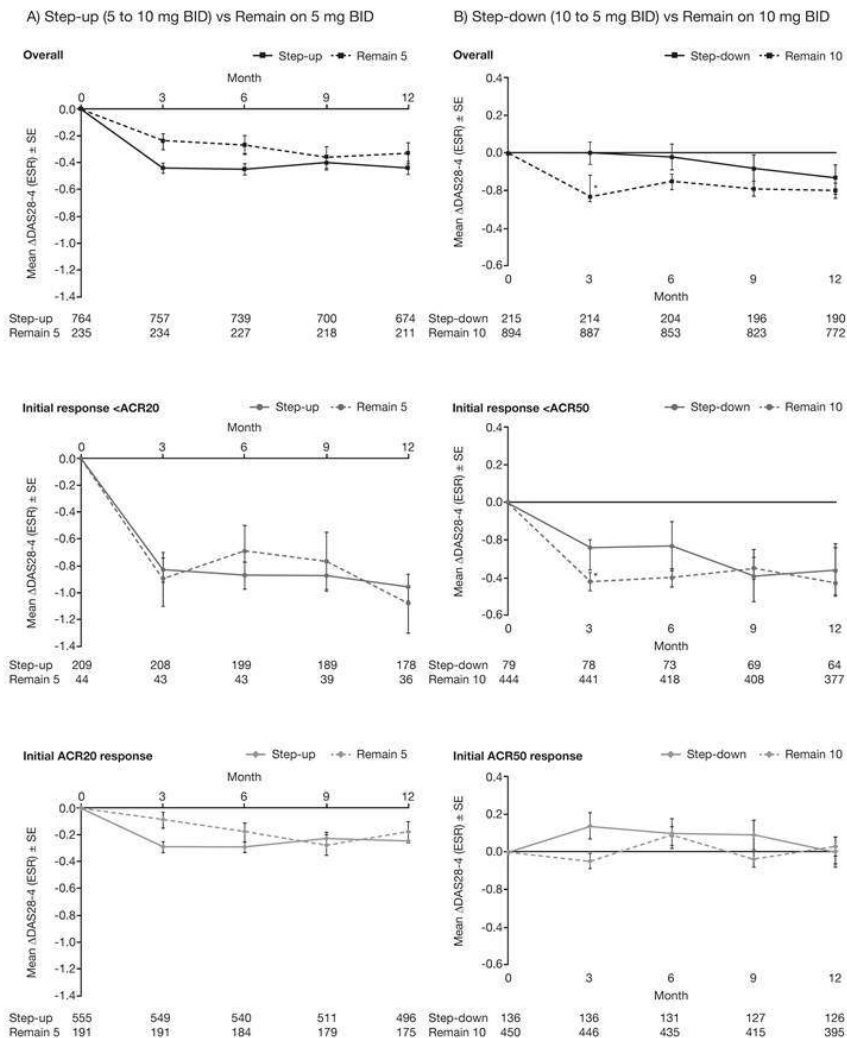

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Efficacy and safety of tofacitinib 5 and 10 mg BID have been shown in long-term extension (LTE) studies up to 105 months. We assessed the impact of tofacitinib dose changes on efficacy and safety in patients (pts) who increased dose (step-up), and pts who decreased dose (step-down), vs pts who remained on the same dose when entering LTE studies.

**Methods:** In this exploratory, post-hoc analysis, data were pooled from 2 open-label LTE studies (NCT00413699 [ongoing; database not locked at January 2016 data-cut]; NCT00661661) of RA pts who had participated in Phase (P) 1/2/3 tofacitinib index studies and had  $\geq 81$  days of tofacitinib exposure (to allow  $\geq 2$  assessments) in each period (P1/2/3 index, LTE). Dose changes from index study dose were either mandated by protocol (upon LTE entry) or at the investigator's discretion (during LTE). This analysis only included pts who remained on their initial/changed dose once in the LTE. Pts were analyzed in 4 groups: 5 mg BID [index]  $\rightarrow$  10 mg BID [LTE] (Step-up; N=833); 5 mg BID [index]  $\rightarrow$  5 mg BID [LTE] (Remain 5; N=248); 10 mg BID [index]  $\rightarrow$  10 mg BID [LTE] (Remain 10; N=951); 10 mg BID [index]  $\rightarrow$  5 mg BID [LTE] (Step-down; N=234). To determine whether initial efficacy (last index study assessment) may affect response following dose change on LTE entry, sub-groups for the Step-up and Remain 5 groups were defined based on initial ACR20 response, and sub-groups for the Step-down and Remain 10 groups were defined based on initial ACR50 response. Efficacy was assessed up to Month 12 in the LTE based on  $\Delta$ DAS28-4(ESR). Exposure-adjusted event rates (pts with event/100 pt-yrs) are presented for the most common AEs for the entire LTE study exposure.

**Results:** No statistically significant differences in  $\Delta$ DAS28-4(ESR) were observed between the Step-up and Remain 5 groups (Figure), whether or not they had an initial ACR20 response. In general, no significant differences in  $\Delta$ DAS28-4(ESR) were observed between the Step-down and Remain 10 groups (Figure), whether or not they had an initial ACR50 response. The rates and types of adverse events (AEs) were similar across all groups (Table).

**Conclusion:** In RA pts, the safety profile was similar regardless of dose change. Step-up from tofacitinib 5 to 10 mg BID, or step-down from 10 to 5 mg BID did not affect efficacy over 12 months vs remaining on the same dose, and was not influenced by initial response. Conclusions are limited by small pt numbers in some groups, the open-label design, and inclusion of pts in the LTE who show tolerability for tofacitinib and drug retention.

**Figure.** Mean  $\Delta$ DAS28-4(ESR) over time for A) Step-up pts and those who remained on tofacitinib 5 mg BID, stratified by ACR20 response in index studies, and B) Step down pts and those who remained on tofacitinib 10 mg BID, stratified by ACR50 response in index studies

\* $p < 0.05$  for statistical comparison between groups using mixed-effect repeated measure models; no significant differences were observed between any Step-up vs Remain 5 groups, or between any Step-down (initial response <ACR50) vs Remain 10 (initial response <ACR50) groups.  
Data presented as observed.  
Baseline values for this analysis were those of the LTE baseline visit, if available, otherwise those of the last index study visit were used.  
Initial response was defined based on ACR response at the last index study visit or at the baseline LTE visit, if available.  
 $\Delta$ , change from baseline; ACR20/50,  $\geq 20/50\%$  improvement in American College of Rheumatology criteria; BID, twice daily; DAS28-4(ESR), Disease Activity Score in 28 joints with erythrocyte sedimentation rate; LTE, long-term extension; pts, patients; SE, standard error.

**Table. Summary of AEs in the LTE study**

	Step-up: 5 to 10 mg BID N=833	Remain on 5 mg BID N=248	Step-down: 10 to 5 mg BID N=234	Remain on 10 mg BID N=951
Total years of exposure	2,729	907	822	3,030
Discontinued due to AEs, n	207	53	48	221
Most common AE system organ classes, n (EAER): EAER >10.00 in any group

## Effectiveness, Tolerability, and Safety of Tofacitinib in Rheumatoid Arthritis: A Retrospective Analysis of Real-World Data from the St. Gallen Cohort

Ruediger Mueller<sup>1</sup>, Frederik Mattow<sup>2</sup>, Florian Popp<sup>3</sup> and Johannes von Kempis<sup>4</sup>, <sup>1</sup>Division of Rheumatology, Cantonal Hospital, St. Gallen, Switzerland, <sup>2</sup>Kantonsspital St. Gallen, St. Gallen, Switzerland, <sup>3</sup>Rorschacherstrasse 95, Kantonsspital St. Gallen, St. Gallen, Switzerland, <sup>4</sup>Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Tofacitinib is an oral JAK inhibitor for the treatment of RA. Efficacy and safety of tofacitinib have been shown in several clinical studies. The study presented here aimed to assess the clinical effectiveness and tolerability of tofacitinib among patients with RA in real life.

### Methods:

Consecutive patients between June 2013 and April 2017 with RA who fulfilled the American College of Rheumatology/EULAR 2010 criteria were analyzed in a prospectively designed analysis of retrospective data. Patients were initiated on tofacitinib 5mg bid. The primary objective was to analyze safety of tofacitinib in a real life cohort. Safety was assessed by the reasons to stop tofacitinib during follow up and changes of liver enzymes, hemoglobin, and creatinine. The secondary outcome was to analyze the frequency and time to achieve low disease activity (LDA) and remission as defined by DAS28.

### Results:

Overall, 58 patients were treated with tofacitinib. 86% of the patients were pre-exposed to at least one biological agent. The average DAS 28 at initiation of tofacitinib was 4.5. 65% were rheumatoid factor and 52% ACPA positive. The mean follow up was 1.74 years after initiation of tofacitinib treatment. 32 (57%) patients remained on tofacitinib during follow up. The average time to stop tofacitinib was 112 days. Reasons to stop tofacitinib were: gastrointestinal (n=12), insufficient response (n=5), flare (n=3), pneumonia (n=2), blue toe syndrome (n=1), thoracic pain (n=1), and myalgia (n=1).

Increased of ALAT and ASAT were detected in 4 and 8 patients (>2x ULN: n=1 and n=2). These elevated transaminase levels were transient in 2 and 5 patients, respectively. The average hemoglobin level decreased by 2.6%. A decrease of more than 10% of the hemoglobin level was found in 7 patients during follow up. The average lymphocyte count increased by 6.6%. A decrease below 1000 Lymphocytes/mcl was detected in four patients. Three of them were transient. The mean creatinine level increased by 3.4%. An increase of more than 10% was detected in seven patients (n=1 with pathological creatinine level).

37 (63.8%) and 31(53.4%) of the patients achieved LDA or remission after 62.0 and 65.3 days respectively.

### **Conclusion:**

Tofacitinib is a safe and effective treatment option for patients with RA. Tofacitinib may induce high rates of LDA and remission in patients with active disease, even after use of one or more biologics, over prolonged periods of time. Tofacitinib may be a valuable option in a treat to target approach because the time to determine its efficacy or adverse reaction leading to discontinuation is short, based on the data of our cohort

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Filgotinib (GLPG0634, GS-6034) is an oral, selective JAK1 inhibitor that has demonstrated safety and efficacy data in two 24-week placebo-controlled phase 2B studies as add-on to methotrexate and as monotherapy in active rheumatoid arthritis (RA) patients with inadequate response to MTX (MTX-IR)<sup>1,2</sup>.

The objective was to evaluate the effect of baseline serum CRP levels on clinical efficacy after 12 weeks of treatment, as assessed by the ACR and DAS28(CRP) subcomponents in MTX-IR RA patients treated with filgotinib.

**Methods:**

Patients were randomized in a double-blind manner to placebo (PBO) or one of 3 daily doses of filgotinib (50mg, 100mg or 200mg) for 24 weeks. In the DARWIN 1 study, filgotinib on MTX background was evaluated as once (QD) or twice daily treatment. In the DARWIN 2 study once-daily filgotinib was assessed as monotherapy. The inclusion criterion for CRP was amended during the studies and was decreased from 13.5 mg/L to 6.3 mg/L. This post-hoc analysis included patients treated with the selected Phase 3 filgotinib doses, 100mg and 200mg QD, and PBO. Efficacy outcomes were analyzed by baseline CRP level (low:  $\leq 9$  mg/L and high:  $>9$  mg/L, with 9mg/L as ULN).

**Results:**

Baseline disease activity was high and balanced across the different treatment groups. Comparable baseline values were shown between both CRP subgroups, except for the mean CRP levels (Table 1).

In both low and high CRP subgroups, patients on filgotinib at 100mg or 200mg QD for 12 weeks showed efficacy over PBO, as measured by change from baseline in different subcomponents of the ACR/DAS28(CRP) composite score (TJC68, SJC66, Pt pain, Pt GDA, Inv GDA, HAQ-DI and CRP) (Table 1). In both studies, there was no clear pattern suggesting that baseline CRP level had a consistent effect on filgotinib efficacy.

**Conclusion:**

This post-hoc analysis of two Phase 2B studies in MTX-IR RA patients suggests that filgotinib treatment once daily at 100mg and 200mg both on the background of MTX and as monotherapy was consistently associated with improved clinical outcomes compared to placebo at Week 12, regardless of baseline CRP levels, as measured by ACR and DAS28(CRP) subcomponents.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is a well-known risk of developing adverse drug reactions (ADR) in rheumatology due, mainly, to the Disease Modifying Drugs (DMARD) used. It is mandatory to increase our knowledge of ADR; especially those that put the patient live at risk. The purpose of our study was to describe the incidence and characteristics of severe ADR to DMARD in patients with incident RA as well as the factors associated to their development.

**Methods:** An observational longitudinal study was conducted. Patients: all recent onset RA patients diagnosed between April 15<sup>th</sup> 2007 and 31<sup>st</sup> June 2011 followed in outpatient clinic at Hospital Clinico San Carlos until December 31<sup>st</sup> 2016, which used any DMARD treatment (synthetic and biologic). Primary outcome: development of a severe ADR (discontinuation and hospitalization or death as a result of the ADR) due to DMARD treatment. Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence

interval [CI]. Comparisons between associated factors were run by Cox bivariate and multivariate regression models.

**Results** were expressed by hazard ratio (HR) and [CI].

**Results:** We included 1054 courses of DMARD treatment in 405 patients (2277.9 patient-years). Of these, 78.27% were women with a mean age at diagnosis of  $57 \pm 15$  years. The median time to the start of the first DMARD was  $0.3 [\pm 0.6]$  days and the median value of ESR at diagnose was  $40 [\pm 27]$  mm/h. 16.3% of patients were taking biological DMARD, 73.3% were using monotherapy and 89% were taking corticoids. There were 369 ADRs in 212 patients, 41 of them (11.1%) severe (IR: 1.8 [1.3-2.4]). Infection was the most frequent cause of severe ADR (n=26, 63.4%), followed by cancer (n=3, 7.3%); 6 patients died during follow up. Incidence rates are shown in table 1. In the multivariate analysis after adjusting by age: female sex (HR: 2.7 [1.2-5.9]), the use of biological DMARD compared to synthetic DMARD (HR: 3.6 [1.03-12.6]), higher ERS at the beginning of the DMARD (HR: 1.01 [1-1.02]) and the presence at baseline of congestive heart failure (HR: 4.3 [2-9.2]), periphery arteriopathy (HR: 3.1 [1.02-9.2]) and cancer (HR: 3.2 [1.6-6.5]) achieved statistically significant association with the development of a severe ADR. Whereas number of concomitant DMARD dropped from the model (HR: 1.23 [0.5-2.6]).

**Conclusion:** This study describes the incidence of severe ADR occurred in RA patients taking DMARD in real life conditions. The IR of severe ADR in our cohort was 1.8% patient-years, increasing to 3.6% in the population over 70 years old. Infection was the main cause of severe ADR followed by cancer. Caution might be taken regarding severe ADR in patients of female sex, those using biological DMARD, with higher ERS at the beginning of treatment or with certain comorbidities.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is the mainstay first-line therapy for rheumatoid arthritis (RA), and it can be given orally or parenterally. Bioavailability of oral MTX may decrease at high doses, and parenteral administration could bypass this limitation. Practice guidelines recommend changing to biologics if response to MTX is suboptimal but these guidelines are based on studies comparing biologics to oral MTX. There is some evidence that parenteral MTX may be more efficacious than the oral form at equivalent doses. Also, studies suggest that the side effect profile of parenteral MTX may be better than oral MTX. We carried out a meta-analysis to compare the efficacy of oral versus parenteral MTX in RA.

### Methods:

PubMed, Web of Science and Embase were systematically searched from inception to June 8<sup>th</sup> 2017 and reviewed following PRISMA 2009 guidelines. We also examined bibliographies of reviews and other articles. To be included, trials had to study adults with RA randomized to the same dose of either oral or parenteral MTX. Studies were selected and data extracted by two independent reviewers and at each stage the reviewers met to adjudicate discrepancies. The primary endpoint was ACR20 at 6 months. Other endpoints included ACR50, ACR70, SDAI, and DAS28 remission. One large trial allowed switching for poor response at 16 weeks and included only 24 week data, and trial authors reanalyzed data at 16 weeks. For another trial, data were reanalyzed to provide ACR20/50/70 rates. Intention-to-treat analyses were used when possible. Data from direct comparisons between oral and parenteral methotrexate were pooled and quantitatively analyzed using maximum likelihood random effects meta-analysis. Relative treatment effects were generated as odds ratio [OR] (OR>1 indicated a benefit for parenteral therapy). We also examined the mean difference in ACR20 rates between parenteral and oral MTX.

### Results:

The search yielded 357 papers or abstracts. After review of titles or abstracts, we excluded 314. We then examined 43 full-text papers or abstracts and found 4 that met inclusion criteria with 703 patients randomized. Dose of MTX started at 15mg/week and increased to as high as 22.5mg/week. In each trial, ACR20 rates were higher for those randomized to parenteral than to oral MTX. The summary OR for achieving ACR20 using parenteral vs. oral MTX was 2.84 (95% CI 1.35, 5.98) (see figure). Those on parenteral had an 18.5% (95% CI 3.3%, 33.6%) greater absolute risk of attaining ACR20 than those on oral MTX. Similar results were seen for ACR50 and 70 and for SDAI and DAS.

### Conclusion:

In this meta-analysis, parenteral MTX therapy had a significantly higher odds than oral MTX of achieving reduction in disease activity. We propose that parenteral MTX is more effective than oral MTX with a better safety profile; its widespread use may lead to better control of disease and a decrease in demand for biologic agents.

## Being Elderly Is Not a Predictive Factor of Discontinuation of Abatacept Due to Adverse Events in Rheumatoid Arthritis Patients with Concomitant Methotrexate: A Retrospective Observational Study Based on Data from a Japanese Multicenter Registry Study

**Nobunori Takahashi**, Toshihisa Kojima, Shuji Asai, Tatsuo Watanabe, Takuya Matsumoto, Nobuyuki Asai, Yasumori Sobue and Naoki Ishiguro, Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Abatacept is a new class of biologic agent for the treatment of rheumatoid arthritis (RA) that inhibits T cell activation by binding to CD80/86. Some evidences demonstrating that the abatacept may offer advantage on safety over the TNF inhibitors have been accumulated. Therefore, we sometimes tend to use abatacept in the elderly patients easily. We studied the clinical response and safety profile of abatacept in the real-world patients using the Japanese multicenter registry data.

**Methods:**

Participants were the consecutive 508 RA patients treated with abatacept who were registered in the Tsurumi Biologics Communication Registry (TBCR). We divided the patients into three groups according to the tertile value of age. As the efficacy endpoints, we compared mean and categorical distribution of DAS28-CRP score and EULAR response rate between the young (<62 years), middle (62-72 years), and elderly (>72 years) group at baseline, 4, 12, 24, and 52 weeks. As the safety endpoints, we studied the incidence rate (Kaplan-Meier method) and the predictive factors (multivariate Cox regression analysis) of the discontinuation of abatacept due to adverse events for up to 4 years. We studied the safety endpoints separately in the patients with and without concomitant methotrexate (MTX) treatment, since the MTX usually affects the safety profile.

**Results:**

There was significant difference between the young, middle, and elderly groups in age (52.7, 67.7, and 78.1 years;  $p<0.001$ ), eGFR value (108.5, 91.1, and 79.6 ml/min/1.73m<sup>2</sup>;  $p<0.001$ ), and MTX usage rate (57.7, 44.9, and 32.2 %;  $p<0.001$ ). There was no significant difference between three groups in all of the clinical efficacy endpoints (data not shown). For the safety analysis, we divided the patients into two groups according to the cut-off value (69.5 years) from the ROC curve for age in the MTX (-) patients (Fig. A). The elderly group (>69.5 years) demonstrated higher incidence rate of discontinuation due to adverse events (1.0 vs 4.9% at 24 weeks,  $p=0.005$ ) in the MTX (-) patients (Fig. B). The age of >69.5 years was identified as an independent predictor of incidence of discontinuation due to adverse events in the MTX (-) patients (Fig. C). However, there was no such difference in the incidence rate (Fig. B) and the being elderly (>69.5 years) was not a predictor in the MTX (+) patients (Fig. C).

**Conclusion:**

It was remarkable that abatacept therapy demonstrated the comparative efficacy in the elderly patients. Similar to a case of other biologics, we should pay attention to the incidence of severe adverse events in the elderly patients without concomitant MTX. However, especially in the patients being treated with MTX concomitantly, abatacept would be a good treatment option in the elderly from the view point of both efficacy and safety.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Infections are the most frequent and concerning serious adverse events related to rheumatoid arthritis (RA) treatment with biologic drugs (bDMARDs). Their safety profile might have substantial regional differences. Since January 2009, BiobadaAmerica, a common platform registry project open to all Latin America countries, was started with the goal of focusing on safety monitoring of bDMARDs. This study aims to present data on the serious infections (SI) incidence rate trend along years in patients with RA exposed to bDMARDs in two no- compulsory Latin America registries.

**Methods:** Data from Brazil (BiobadaBrasil) and Argentina ( BiobadaSar) registries were downloaded on December 31, 2016 and merged. The same constant monitoring process granted data quality. Patients with rheumatic diseases were included prospectively when started on the first bDMARD. Time of exposure was set from starting of treatment to the date of last administration or censorship. SI incidence rate was calculated per 1000 patient/years with 95%CI

**Results:** Data from 2591 RA patients on bDMARDs were analyzed, for a total of 9300 p/y. There were 3784 treatment courses, 64% with aTNF (Adalimumab, Certolizumab, Etanercept, Golimumab, Infliximab), 36% non-aTNF (Abatacept, Rituximab, Tocilizumab) including Tofacitinib. Females 85%, mean age at baseline 53 yrs (SD 12.8) , mean disease duration 10 yrs (8.5), mean follow-up 2.7 yrs (2). The overall incidence rate of SI (2010 – 2016) was 30.54 (CI 27.18-34.30), The trend along the years is reported in the following table.

2010	2011	2012	2013	2014	2015	2016
26.57	26.03	36.59	35.85	18.3	16.18	7.27
(14.71-47.98)	18.09-36.46	28.41-47.12	28.55-45.03	13.62-24.59	12.04-21.75	4.79-11.05

Remarkable, the trend was the same in both registries when data were analyzed separately and reflected the general tendency seen for all serious side effects.

**Conclusion:** A decreasing trend of serious infections incidence rate has been observed along the years in patients with RA exposed to bDMARDs, in accordance with published data from other registries

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** TURKBIO registry is the Turkish version of Danish DANBIO rheumatologic database which has been established in 2011. Demographic and clinical data including age, sex, disease type, disease duration, and previous or current treatment with conventional (csDMARD) and targeted synthetic (tsDMARD), and biological DMARDs (bDMARDs) were collected. In this study, we aimed to investigate the efficacy and safety status of methotrexate (MTX) vs. leflunomide (LEF) use as a concomitant treatment with bDMARDs and tsDMARD in this registry.

**Methods:** Frequencies of achievement of remission or remission+low disease activity (LDA) at the 6<sup>th</sup> month of bDMARD or tsDMARD treatment were compared between patients who were on these medications with MTX vs. LEF as a concomitant treatment. Similarly, patients who were on TNF inhibitors (TNFi), abatacept (ABA), rituximab (RTX), tocilizumab (TCZ), and tofacitinib (TOFA) with MTX vs. LEF were also assessed separately for the achievement of remission and remission+LDA. Drug survival and switch rates of bDMARDs and tsDMARD treatments either with MTX or LEF were compared. The adverse effects with MTX and LEF concomitant use were evaluated as well.

## Results:

The study included 725 bDMARD or tsDMARD receiving RA patients from 8 participating centers of the TURKBIO registry. Of these patients, 462 (63.7%) were receiving concomitant MTX and 263 (36.3%) LEF. Demographic findings are given in the *Table*. Achievement of remission and remission+LDA at the 6<sup>th</sup> month of bDMARD or tsDMARD initiation was similar in concomitant MTX vs LEF groups (51.4% vs. 53%,  $P=0.683$ ). When each bDMARD and tsDMARD was evaluated separately, achievement of remission were again similar in MTX and LEF concomitant users (TNFi: 53% vs. 54%; ABA: 50% vs. 59%; RTX: 53% vs. 61%; TCZ: 42% vs. 35%;  $P>0.05$  for all). For TOFA, although remission+LDA rate was numerically higher in MTX concomitant group than LEF group (42% vs. 21%), the difference was not statistically significant due to the smaller sample size of TOFA ( $N=33$ ). The results were similar for all DMARD groups when remission was evaluated alone. Drug survival ( $17\pm12$  vs.  $16\pm11$  months,  $p>0.05$ ) and drug discontinuation (42,2 vs 38,

p>0.05 ) rates of bDMARDs or tsDMARD were also not different in MTX vs. LEF concomitant users. Adverse effects rate (19.5% vs 20.5%, p>0.05) were similar between MTX vs. LEF concomitant users as well.

**Conclusion:** Achievement of remission or remission+LDA was not different with the concomitant use of MTX vs. LEF with any bDMARD or tsDMARD treatment in RA patients with a similar safety profile. LEF might be an alternative as a concomitant DMARD in MTX-intolerant RA patients initiating bDMARDs or tsDMARD.

Table. Demographic findings of patients.

Sex, n (%)	Female	596 (82,2)
	Male	129 (17,8)

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune chronic disease with disability and deforms joints. After the introduction of biological therapies the prognosis of patients has improved. Approximately one-third of patients do not respond to treatment with conventional disease modifying drugs (sDMARDs). There are registers about adverse events (AE) of biological drugs disease modifying (bDMARDs), BIOBADASAR registry in Argentina with a frequency of adverse events with the use of biologicals of 26%, with respiratory tract infections being the most frequent. According to the BIOBADASER record loss of efficacy is the most frequent cause with more than 42% of cases, infections 21%. Since we do not have reports of this type, our objective is to describe the AE in patients with RA treated with bDMARDs anti TNF and non anti TNF. The bDMARDs used were adalimumab (ADA), golimumab (GLM), Etanercept (ETN) as anti TNF, anti IL6 Tocilizumab (TCZ) and anti CD20 Rituximab (RTX).

**Methods:** A descriptive, ambispective cross-sectional study. Data were collected from the rheumatology service of Hospital Docente Padre Billini, which is a national reference hospital. Statistical analyses were performed using SPSS (V.23). We included all patients diagnosed with RA according to 2010 ACR/EULAR classification criteria treated with bDMARDs during the period January 2013 - April 2017. Patients who did not have continuous follow-up by rheumatology of at least 3 consecutive consultations in one year were excluded.

**Results:** We have 863 patients diagnosed with RA, 398 patients treated with bDMARDs, 220 patients met inclusion criteria. 93% were women, mean age 57.2 years old, time of disease 9.9 years. The bDMARDs distributions was 51.4% TCZ, 19.9% ADA, 12.3% ETN, 9.1% GLM, 7.7% RTX. 46.8% had AE: 37.2% treated with ADA, 48.1% ETN, 30% GLM, 23.5% RTX, 56.6% TCZ. In the follow-up we found a 5% therapeutic failure of which 45.5% were by ADA, 18.2% ETN, 18.2 TCZ%, 9.1% RTX, 9.1% GLM. 14.1% presented infections of which 16% were serious. 0.9% adverse event were due to pulmonary tuberculosis (TB). 8.6% dyslipidemia of these 73.7% were TCZ, 6.4% hypertransaminemia of these 71.4% TCZ. 6.4% (13) neutropenia. 1.4% was diagnosed with neoplasm.

**Conclusion:** We found 46.8% of AE of these only 4.8 were serious unlike other records that report a 13.1%. Patients had a good therapeutic response, in spite of the economic limitations of the population and the shortage of drugs occasionally. The majority of patients used in our cohort TCZ. Even though a tropical country with high TB prevalence of we only found two patients.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IRAK-4 is a key node in innate immune signaling and is activated by the interleukin (IL)-1 family receptors (IL-1R, IL-18R, and IL-33R), in addition to the Toll-like receptors (TLRs). Inhibition of IRAK-4 blocks the production of inflammatory cytokines such as type I interferons, IL-6, tumor necrosis factor (TNF), IL-1, and IL-12 that are key drivers of autoimmune and inflammatory diseases. Therefore, IRAK-4, would be an attractive therapeutic target for autoimmune diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). PF-06650833 is a recently described, small molecule, reversible, highly potent and specific inhibitor of IRAK-4. Nonclinical studies of PF-06650833 have been conducted in rats and dogs that support studies up to 3 months in duration. The current abstract describes the results from the single and multiple ascending dose (SAD, MAD) studies of PF-06650833 in healthy subjects.

**Methods:** The SAD and MAD studies of PF-06650833 were conducted in male and female (of nonchildbearing potential) healthy subjects. The first-in-human study was a 5-way crossover SAD study that explored extemporaneously (extemp) prepared immediate (IR)- and modified release (MR) formulations of PF-06650833 from 1 – 6000 mg. The MAD study was a 14 day sequential ascending dose study of extemp IR and MR tablet formulations administered after a standard meal. Doses from 25 mg BID to 1000 mg QID of the IR formulation and 300 mg MR tablets were explored. Standard clinical, ECG, and laboratory safety monitoring were performed as well as exploratory biomarkers.

**Results:** PF-06650833 was generally safe and well tolerated after both SD and MD up to the maximal planned doses, with dose limiting toxicity. Safety profile in both the SAD and MAD studies were similar, with the most common adverse events (AEs) being headache, and gastrointestinal symptoms (mainly nausea and abdominal pain). There were no clinically significant changes in vital signs, ECGs, or any laboratory parameter (including LFTs). PK analyses showed a moderate absorption rate with median  $T_{max}$  from ~2 h for IR doses and ~4 h for MR tablets after a standard meal at steady state. Exposures increased proportionally up to about 100 mg and somewhat less than proportionally > 100 mg. In the MAD study,  $T_{1/2}$  ranged from ~25 – ~31 h across the top IR and MR doses after a standard meal.

**Conclusion:** PF-06650833, a highly selective and potent inhibitor of IRAK-4, is shown to be generally safe and well tolerated up to 6000 mg SD and 1000 mg QID in healthy subjects, with an MR PK profile sufficient to support QD dosing in patient populations. To the authors' knowledge, PF-06650833 is the first IRAK-4 inhibitor to advance to Phase 2 clinical studies.

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Golimumab (GLM) is a monoclonal antibody targeting TNF-alpha, indicated for the treatment of adults with rheumatoid arthritis in combination with methotrexate (MTX). GLM-IV is recommended to be administered at a dose of 2 mg/kg given as a 30-minute intravenous (IV) infusion at weeks 0, 4 and every 8 weeks thereafter. In two separate trials, GO-LIVE and GO-FURTHER, infusion reactions (IRs) were observed in a relatively small group of GLM-treated patients with 2.2% and 3.3% of patients having documented IRs, respectively. The GO-IV registry was initiated to evaluate the incidence and management of IRs with GLM-IV in a real-world Canadian practice setting.

**Methods:** GO-IV was a prospective, observational, non-interventional, multicenter study conducted at 11 Canadian sites from 2014-2016. GLM infusions were followed to document IRs and their management, pre-medication uses and adverse events (AE). An IR was defined as any AE occurring during the infusion or within 1 hour post-infusion. Patients had to be at least 18 years of age or older, a confirmed diagnosis of rheumatoid arthritis, provide written consent for data collection, be naïve to GLM (both subcutaneous and intravenous formulations) and be seen by a Canadian rheumatologist.

**Results:** The study was terminated early due to lack of public listing for the drug. At that time, a total of 79 patients were enrolled and 62 of them were still ongoing. Reasons for premature discontinuation included AEs (7), lack of response (4), geographic issues (3), mis-diagnosis, switch to subcutaneous GLM or withdrawal of consent (one each). A total of 77 patients were included in the primary analysis and 78 in the safety analysis. Only 4 patients (5.1%) documented an IR over 483 infusion visits (0.8%), none of which classified as serious or leading to discontinuation. Three of those IRs occurred at the first infusion and on at infusion number three. Infusion-related AEs included palpitations, nausea, fatigue, infusion site pain, dizziness and headache (one each). The impact of pre-medication could not be established since only four infusions were pre-medicated with diphenhydramine and one with steroids.

A total of 164 AEs were reported in 45 patients (57.7%); 2 patients (2.6%) reported a serious adverse event (acute myocardial infarction; multiple fractures, pneumothorax, concussion, traumatic haematoma and pneumothorax resulting from a fall). There was one incidence of a lipoma and no death. There were 30 infectious AEs reported in 24 patients.

**Conclusion:** The GO-IV registry shows that, in community-based infusion clinics, IRs to GLM are uncommon and predominantly mild in nature.

## Concomitant Hydroxychloroquine Impact on Anti-TNF Persistence in Patients with Rheumatoid Arthritis

**Ming Zhao**<sup>1</sup>, Harlan Sayles<sup>2</sup>, James R. O'Dell<sup>1</sup> and Kaleb Michaud<sup>2,3</sup>, <sup>1</sup>Rheumatology, University of Nebraska Medical Center, Omaha, NE, <sup>2</sup>University of Nebraska Medical Center, Omaha, NE, <sup>3</sup>National Data Bank for Rheumatic Diseases, Wichita, KS

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tumor necrosis factor- $\alpha$  inhibitors (TNFi) have been widely used in patients who failed conventional DMARDs in the treatment of rheumatoid arthritis (RA). While most patients respond well to TNFi, some patients experience loss of efficacy over time possibly due to forming TNFi antibodies. Studies have shown that concomitant use of methotrexate (MTX) with TNFi is associated with increased drug survival compared with TNFi monotherapy. However, whether hydroxychloroquine (HCQ) may also prolong TNFi persistence is unknown and was the purpose of this study.

**Methods:** We analyzed patients with RA and  $\geq 1$  year participation in the National Data Bank for Rheumatic Diseases (NDB), an ongoing US-wide longitudinal observational study with biannual questionnaires since 1998. Patients initiating 3 TNFi's, infliximab, adalimumab, or etanercept, were categorized according to concomitant DMARD use: none (monotherapy), HCQ +/- other DMARDs but no MTX, MTX +/- other DMARDs but no HCQ, and HCQ and MTX +/- other DMARDs. Patients who have previously taken other biologics were also enrolled into our study. Patients were considered as continuing the TNFi if it was on hold for less than 12 months due to infection or surgery and the same TNFi was resumed after that. Baseline characteristics (including all prior therapies) were collected via self-report at enrollment while therapy continuation was collected on each follow-up questionnaire. We followed patients until TNFi discontinuation, censoring, or death. We compared the discontinuation rate and mean drug survival time between subgroups using Pearson chi-square tests and Kruskal-Wallis tests with Dunn's tests.

**Results:** A total of 8611 patients were included with mean (SD) age of 59 (13) years, 81% female and RA duration 14 (11) years. Patients who received concomitant HCQ with TNFi initiation had similar therapy discontinuation rates compared to TNFi monotherapy. Concomitant HCQ use was associated with a longer drug survival compared to etanercept ( $p=0.007$ ) or infliximab ( $p<0.001$ ) monotherapy. Concomitant MTX use has the largest impact in infliximab comparing to monotherapy, associated with both lower discontinuation rate ( $p<0.001$ ) and longer drug survival time ( $p<0.001$ ). Concomitant MTX use is also associated with longer drug survival in adalimumab ( $p<0.001$ ), while such association was not found with concomitant HCQ use ( $p=0.183$ ). Otherwise, concomitant HCQ use has similar effect in prolonging TNFi survival comparing to concomitant MTX use.

Table 1. Discontinuation and mean drug survival of TNFi by concomitant HCQ and MTX use (+) and nonuse (–)

	A Monotherapy	B +HCQ – MTX	C +MTX – HCQ	D +HCQ +MTX	P values $\leq 0.05$
Etanercept	N=815	N=251	N=1251	N=344	
Discontinued, %	53.7	58.6	53.2	59.3	C vs. D
Drug survival, months (SD)	32 (37)	41 (45)	36 (41)	39 (44)	A vs. B, C, & D
Infliximab	N=1864	N=145	N=1487	N=303	
Discontinued, %	61.2	56.6	52.0	55.8	A vs. C
Drug survival, months (SD)	17 (21)	32 (38)	41 (42)	38 (42)	A vs. B, C, & D  B vs. C & D
Adalimumab	N=640	N=184	N=1106	N=221	
Discontinued, %	58.1	62.0	56.5	56.6	None
Drug survival, months (SD)	25 (29)	28 (33)	30 (32)	30 (31)	A vs. C & D

**Conclusion:** Concomitant use of HCQ with TNFi's is associated with increased TNFi persistence. Our initial findings show promise for increased TNFi effectiveness with either HCQ or MTX, and followup studies examining TNFi-antibody levels may help explain this association.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the United Kingdom (UK), rituximab (RTX) or a second tumour necrosis factor inhibitor (TNFi) are both permitted treatment options for patients with rheumatoid arthritis (RA) who have failed a first TNFi. The risk of serious infection (SI) is similar between these 2 treatments during the first year. However, long-term data on risk of SI for RTX are scarce but required, in light of reports of reduction in IgG following repeated dosing. We compared the risk of SI over 5 years of treatment in patients with RA who had failed a first TNFi and then received either RTX or TNFi.

**Methods:** This study used patients with RA registered with the British Society for Rheumatology Biologics Register (BSRBR-RA) a large national prospective study established primarily to assess the long-term safety of exposure to biologic therapies in patients with RA. This analysis included patients treated with either a second TNFi or RTX after failing a first TNFi. Patients were followed until first SI, 90 days (TNFi) or 9 months (RTX) following last dose when treatment was discontinued, last recorded follow-up or the end of the 5th year after the switch, whichever came first. SI was defined as infection requiring intravenous antibiotics, hospitalisation or resulting in death. The risk of first SI was compared between TNFi and RTX using (i) unadjusted, (ii) adjusted for sex and age, and (iii) propensity score adjusted Cox proportional hazard models. A Nelson-Aalen (NA) plot was constructed to show the cumulative incidence of SI over 5 years.

**Results:** This analysis included 3419 TNFi-treated patients contributing 9527 person-years (pyrs), median (IQR) exposure time per person 2.0 (0.8-3.3) years; and 1396 RTX patients contributing 3570 pyrs, median (IQR) exposure time 2.9 (1.7-3.9) years. A total of 362 and 135 first SI were reported in TNFi and RTX patients respectively, giving a crude incidence rate (95% CI) of 38 (34-42) SI/1000 pyrs (TNFi) and 38 (32-45) SI/1000 pyrs (RTX). The unadjusted, adjusted for sex and age, and propensity score adjusted hazard ratios (95%CI) for SI were 0.9 (0.8-1.1), 0.9 (0.7-1.0) and 0.9 (0.7-1.1) respectively. The NA plot showed a similar cumulative incidence risk of SI between the two groups over 5 years of treatment (figure).

**Conclusion:** The risk of serious infections was comparable over 5 years of treatment between TNFi and RTX treatment in patients who had failed a single prior TNFi.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, has demonstrated efficacy in RA in the phase 3 SIRROUND studies. Lipid elevations have been observed with SIR, consistent with IL-6 pathway inhibition (Lancet 2017. 389:1206). A post hoc analysis evaluated the impact of SIR treatment on plasma lipids and lipid particle subtypes.

**Methods:** Lipids were analyzed in plasma samples obtained from RA patients in SIRROUND-H (active comparator monotherapy study; n=160, 159, and 162 for adalimumab (ADA) 40mg q2w, SIR 50mg q4w, and SIR 100mg q2w treatment groups) and SIRROUND-D (placebo(PBO)-controlled DMARD-inadequate responder (IR) study; n=293, 470, and 437 patients for PBO (excluding early escape patients), SIR 50mg q4w, and SIR 100mg q2w treatment groups). Plasma fasting levels of HDL, LDL, IDL, VLDL and their respective particle subtypes (LipoProfile® test), triglycerides, Apolipoproteins (Apo) A1 and B, and total cholesterol were measured centrally. LDL-receptor (LDL-R) levels on blood leukocytes were measured by flow cytometry in 15 (ADA 40mg q2w), 23 (SIR 50mg q4w), and 20 (SIR 100mg q2w) patients in SIRROUND-H. Significance of differences between baseline and week (Wk)24 sample data was tested using Wilcoxon signed-rank and Mann-Whitney tests (p<0.05 considered significant).

**Results:** Elevations in total cholesterol, LDL, HDL, IDL, VLDL and triglycerides from baseline to Wk24 were observed with SIR compared to PBO or ADA (p<0.05; Table 1 for the SIRROUND-H study). However, atherogenic indices increased slightly (total cholesterol:HDL) or remained unchanged (ApoB/ApoA1) with SIR. Increases in LDL levels with SIR were mainly due to increases in anti-atherogenic large particles, with decreases in smaller pro-atherogenic particle sizes. Increases in HDL were mainly due to increases in small anti-atherogenic particles, with decreases in medium particles. Increases in VLDL with SIR were associated with increases in all particle sizes. Results were similar for both SIR doses and both studies, with similar changes observed by Wk4 (SIRROUND-H). ADA was associated with smaller but significant decreases in very small, small, and medium LDL particles (Table 1). LDL-R levels were decreased (p=0.044) only in the SIR 100mg q2w group, but changes in LDL-R levels did not correlate to changes in lipids or lipid particles (p>0.05).

**Conclusion:** SIR treatment was associated with increased plasma lipid levels compared to placebo and ADA. However, atherogenic indices, which are considered more reliable lipid markers in RA (Mediators Inflamm 2012. 2012: 785946), remained unchanged or changed minimally with SIR. Changes in LDL and HDL levels with SIR were mainly due to a shift towards a more anti-atherogenic lipid profile. Despite the small sample size, modulation of LDL-R levels did not appear to be involved in the observed lipid changes.

Table 1. Week 24 changes from baseline in lipids, lipid particles, and LDL-Receptor in SIRROUND-H study.

Plasma lipid biomarker	week 24 change from baseline <sup>a</sup>		
	ADA 40 q2w	SIR 50 q4w	SIR 100 q2w

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Understanding interactions of inflammatory cytokines and lipid metabolism in RA is of considerable interest. Blocking IL-6 receptor elevates lipid levels in RA while lowering inflammatory disease activity<sup>1</sup>. Sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, demonstrated efficacy in RA in the phase 3 SIRROUND studies. This study evaluated the relationships between lipid levels and the suppression of inflammation and disease activity by SIR compared to adalimumab (ADA) in patients with moderate to severe RA.

**Methods:** Plasma from the SIRROUND-H (monotherapy) study was evaluated: 99 patients in SIR 50mg q4w group, 95 patients in SIR 100mg q2w group, and 140 patients in ADA 40mg q2w group (subcutaneous). Fasting HDL, LDL, IDL, VLDL levels and concentrations of specific particles (large, medium, small, and, for LDL, very small) plus triglycerides were measured using NMR. Apolipoproteins (Apo) A1 and B, total cholesterol, and cholesterol/HDL ratio were measured at Covance, LLC. CRP and SAA were measured using ELISA. Disease activity was measured using CDAI and DAS(CRP). Analyses were performed at baseline (BL), Wk 4, Wk 8 and Wk 24 timepoints. We compared changes from BL using non-parametric Wilcoxon signed-rank and Mann-Whitney tests (comparisons between treatment groups).

**Results:** SIR treatment significantly increased cholesterol, triglycerides, ApoA1, ApoB, HDL, IDL, LDL, and VLDL levels ( $p < 0.0001$  both SIR groups Wk 24 vs BL) while minimal changes were observed with ADA treatment. Increases in lipid biomarkers by SIR were observed by Wk 4 and sustained through Wk 24. Total cholesterol, LDL and large LDL particles were inversely correlated with CRP, and large and medium HDL and medium and small VLDL particles were inversely correlated with both CRP and SAA levels at BL ( $p < 0.0001$ ,  $-0.42 < r < -0.30$ ). Post-treatment increases in lipids were associated with reduced inflammation with SIR treatment: increases in HDL correlated with decreased SAA while increased ApoA1, cholesterol, LDL, and large LDL particles correlated with strong suppression of CRP and SAA at Wk 4 ( $p < 0.0001$  and  $-0.43 < r < -0.31$ ). In contrast, these trends were not observed with ADA as lipid levels post treatment remained similar to BL. BL values and changes from BL in lipid parameters did not correlate with disease activity. Results were similar for both doses of SIR. These results were confirmed in the placebo-controlled SIRROUND-D study.

**Conclusion:** Patients with higher BL inflammation have lower starting lipid levels. IL-6 inhibition by SIR results in significant increases in lipid levels that correlate to suppression of acute phase reactants. These findings were not observed with ADA where lipid levels were generally unchanged. The results suggest that the increase in lipid levels with SIR may be at least in part associated with improvement of underlying inflammation in RA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tocilizumab (TCZ) is a recombinant humanized monoclonal antibody targeted against the interleukin-6 receptor that was approved to treat rheumatoid arthritis (RA) in the EU in 2009 and in the US in 2010, and has now completed long-term extension (LTE) follow-ups in a number of intravenous and subcutaneous RA trials. The objective of this study was to provide an updated report on the incidence of safety events during TCZ treatment in patients with RA using data from multiple completed clinical trials and their LTEs, as well as an update from the global TCZ postmarketing safety database.

**Methods:** To provide an updated report on the incidence of safety events during TCZ treatment in patients with RA using data from multiple completed clinical trials and their LTEs, as well as an update from the global TCZ postmarketing safety database.

**Results:** The clinical trial all-exposure population consisted of 7647 TCZ-treated patients with RA (81.6% female; mean [SD] age, 52 [12.6] years), constituting 22,394 PY (mean follow-up: 2.93 years) of exposure. The overall rate (95% CI) of serious adverse events (SAE) in the clinical trial population was 14.16 (13.67-14.66) per 100 PY. Overall incidence rates for individual events for the clinical trial population are reported in the Table and were consistent in each 6-month period over the 5-year duration. The global postmarketing population included 606,937 patients. The overall spontaneous reporting rate (range) of adverse events of special interest in the postmarketing population was 9.37 (7.35-10.56) cases per 100 patients. Reporting rates of individual safety events of interest in the global postmarketing population are shown in the Table and were consistent in each 6-month period over the 7-year duration.

**Conclusion:** The safety profile of TCZ in the current analysis, which includes information about safety events from 12 clinical trials and their LTEs and across 7 years of real-world postmarketing reports encompassing ~ 600,000 patients, was consistent with previous safety reports. These findings are consistent with the previously reported profile of TCZ and indicate that there is no evidence of increased safety risk with increasing exposure to TCZ.

<b>Table. Adverse Events Across 12 RA Clinical Trials and the Global Postmarketing Safety Database in Patients Who Received TCZ</b>				
	<b>RA Clinical Trial All-Exposure Population</b> <b>(N = 7,647; 22,394 PY)</b>		<b>Global Postmarketing Safety Database Population*</b> <b>(N = 606,937 Pts)</b>	
Adverse event of special interest	Patients With ≥ 1 AE (%)	Incidence Rate (95% CI), Events/100 PY	No. of Cases	Reporting Rate (Range), Cases/100 Pts
Serious infections	730 (9.5)	4.29 (4.02-4.57)	17,350	2.86 (2.11-3.62)

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster I: Comorbidities and Adverse Events; Efficacy and Safety of Small Molecules

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** More than 4 years have passed since 7 biologics became available for patients with rheumatoid arthritis (RA) in Japan, still lack reliable evidence in their differences of tolerability and discontinuation reasons.

**Methods:** A total of 1,037 biologics treatment courses of RA from 2009 to 2016 [female 81.8%, baseline age 59.6 y, disease duration 7.8y, bio continued duration 17.1 months, RF positivity 81.5%, ACPA positivity 86.7%, DAS28-ESR 4.4, CDAI 16.8, HAQ 1.1, Bio naïve 57.1% and switched 42.9%, methotrexate (MTX) 5.9 mg/week (limited to 16mg/week in Japan) (68.6%), prednisolone (PSL) 2.5 mg/day (43.5%), abatacept (ABT) 21.3%, tocilizumab (TCZ) 20.7%, golimumab

(GLM) 16.9%, etanercept (ETN) 13.6%, adalimumab (ADA) 11.1%, infliximab (IFX) 8.5%, certolizumab pegol (CZP) 7.9%] were included in this 7-center, retrospective study. The drug tolerability and discontinuation reasons at 36 months were estimated using Kaplan-Meier method, and adjusted by potent confounders [Sex / Age / Bio started date / Disease duration / ACPA positivity / RF positivity / bio naive or switched / combined csDMARDs (MTX, tacrolimus, bucillamine, salazosulfapyridine, iguratimod) and PSL / baseline DAS28-ESR / HAQ] which may affect biologics retention rates using a Cox proportional hazards model.

**Results:** There were no significant differences in the baseline disease activity (DAS28-ESR and CDAI). The major causes of 7 biologics treatment discontinuation were as follows. Drug inefficacy (47.7%), other nontoxic reasons (12.3%), remission (8.6%), infection (7.5%), patients' preference (7.5%), other adverse events such as malignant, cardiovascular, pulmonary, renal, hematologic complications (6.2%), skin or systemic reaction (5.3%), and changing hospital (5.1%). Adjusted discontinuation reasons and ratio at 36 months in each drug were as follows. Drug inefficacy (TCZ 16.1%, ABT 23.7%, ETN 28.4%, CZP 32.9%, IFX 33.3%, ADA 42.3%, and GLM 46.1%;  $P=0.14$ ), remission (IFX 11.4%, ADA 2.6%, ETN 1.4%, ABT 0.5%, TCZ 0.5%, GLM 0.0%, and CZP 0.0%;  $P<0.001$ ), infection (ABT 1.4%, TCZ 1.5%, GLM 2.0%, ETN 2.3%, ADA 2.5%, IFX 4.0%, and CZP 5.5%;  $P=0.77$ ), other adverse events (ABT 1.2%, ETN 2.0%, CZP 4.9%, GLM 5.6%, ADA 7.2%, TCZ 8.5%, and IFX 11.7%;  $P=0.03$ ), and skin or systemic reaction (ABT 0.0%, TCZ 0.5%, GLM 1.1%, ADA 1.7%, ETN 2.1%, CZP 3.7%, and IFX 4.5%;  $P=0.02$ ), respectively. Adjusted total retention rates at 36 months were as follows. TCZ 58.9%, ABT 55.1%, CZP 51.4%, ETN 50.2%, GLM 37.6%, ADA 32.7%, and IFX 21.7% ( $P=0.006$ ).

**Conclusion:** When adjusted by potent confounders, TCZ showed lowest inefficacy and highest retention rate, ABT showed lowest infection, skin or systemic reaction, or other toxic adverse events rate, and IFX showed highest remission discontinuation rate at 36 months compared to other biologics in RA.

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Mast cells have been implicated in many immune-inflammatory disorders. They mediate a variety of inflammatory and fibrotic conditions, but their role in sialadenitis and interstitial lung disease in patients with primary Sjögren syndrome is unclear. We examined whether mast cells play a critical role in the pathogenesis of Sjögren syndrome.

## Methods:

Labial salivary glands and lung tissue were examined using histological and immunohistochemistry methods. Labial salivary gland samples were collected from 15 individuals with primary Sjögren syndrome and 7 with sicca syndrome (controls). Saliva production was evaluated by Saxon test.

Affected lung tissue from four patients with Sjögren syndrome-associated interstitial lung disease was obtained via biopsy. As control samples, we used 10 noncancerous lung sections from patients who had undergone surgery for lung cancer. We used immunohistochemistry to identify and quantify tryptase-positive mast cells and vimentin-positive fibroblasts. Fibrous tissue was identified by using EVG stain. Human mast cell line 1 (HMC-1) cells were co-cultured with pulmonary fibroblasts for 7 days using a transwell system, and IL-6, TGF- $\beta$ , and VEGF expression in these cells was evaluated by RT-qPCR.

## Results:

We found that the number of mast cells in labial salivary glands and lung tissues of patients with Sjögren syndrome was significantly increased compared to that in control subjects ( $p < 0.001$  and  $p < 0.01$ , respectively). There was a significant negative correlation between the Saxon test results and the number of mast cells ( $r = 0.81$ ,  $P < 0.01$ ), suggesting the involvement of mast cells in decreased salivary secretion. The mast cells were usually present in close proximity to EVG-stained fibrous tissue in the labial salivary glands and lung tissues. Immunohistochemical analysis revealed that the mast cells were proximal to vimentin-positive fibroblasts. We hypothesized that mast cells were involved in the development of tissue fibrosis via modulation of fibroblast immune function, and conducted in vitro co-culture of HMC-1 cells and pulmonary fibroblasts. In these co-cultures, IL-6, TGF- $\beta$ , and VEGF expression was significantly increased compared to in mast cell or fibroblast monoculture. These observations suggest that an amplification loop is generated between mast cells and fibroblasts, enhancing production of IL-6, TGF- $\beta$  and VEGF.

## Conclusion:

These results suggest a novel role for mast cells in the development of sialadenitis and interstitial lung disease in patients with Sjögren syndrome via induction of tissue fibrosis. An amplification loop between mast cells and fibroblasts enhances production of the pro-fibrotic factor, TGF- $\beta$ , and angiogenic factor, VEGF, which may contribute to tissue fibrosis in sialadenitis and interstitial lung disease.

## Decreased Circulating CXCR3+CCR9+ Th Cells Coincides with Elevated Levels of Their Ligands CXCL10 and CCL25 in the Salivary Gland of Sjögren's Syndrome Patients Which Synergistically Facilitate Th Cell Migration

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Primary Sjögren's syndrome (pSS) is characterized by dryness and lymphocytic infiltration in the salivary glands. CXCR3+ T cells and ligands CXCL9/10/11 are known to be abundantly present in the salivary glands of pSS patients. In addition, both CXCR5+ T follicular helper (Tfh) cells and CCR9+ Tfh-like cells and their specific chemotactic ligands CXCL13 and CCL25 are present at increased levels in the salivary glands of pSS patients. Recently, we and others found that CCR9+ Th cells are elevated in pSS peripheral blood and co-express CXCR3 and other chemokine receptors, known to be differentially expressed by Th cell subsets. CCR9+ Th cells play an important role in mucosal immunity and have been shown to produce high levels of IFN- $\gamma$ , like CXCR3+ Th1 cells. Since CXCL9/10/11 and CXCR3 are abundantly expressed in the salivary glands of pSS and CCR9+ Th cells have Th1 characteristics, the potential role in lymphocytic infiltration of the combination of the CXCL10-CXCR3 and CCL25-CCR9 interactions was studied in comparison with other chemokine receptors.

## **Methods:**

CXCL10, CCL25, CXCL13, CCL17 and CCL20 mRNA and protein expression in the salivary gland of pSS and non-Sjögren's sicca (nSS) patients was assessed (mRNA: n=9 vs n=9 and protein: n=24 vs n=33, respectively). Frequencies of CXCR3, CCR9, CXCR5, CCR4 and CCR6 expressing Th cells in blood of pSS patients and healthy controls were assessed by flow cytometry (n=11 vs n=11). Chemotaxis assays (n=6 HC, n=10 pSS) were performed to study migration induced by CXCL10 and CCL25.

## **Results:**

CCL25, CXCL10 and CXCL13 expression were increased in pSS compared to nSS patients, both at mRNA and protein level in salivary gland supernatants (all  $p < 0.05$ ). CCL17 and CCL20 expression were low and detectable in only few patients. Protein levels of CXCL10 and CXCL13 correlated with lymphocytic focus scores and all 3 chemokines correlated with serum IgG levels in pSS (all  $p < 0.05$ ). CCL25 protein levels correlated with CXCL10 ( $p = 0.01$ ) but not with CXCL13. A relative decrease of CXCR3+ cells was found in the CCR9+ Th subset in the peripheral blood of pSS patients ( $p = 0.04$ ), which was most pronounced in the effector and effector memory subsets (64% vs 26%,  $p = 0.03$  and 51% vs 27%  $p = 0.01$ , respectively). CCR4 or CCR6-expressing CCR9+ Th cells and CXCR3 or CCR6-expressing CXCR5+ Th cells were not decreased. To test the hypothesis that CXCR3 ligands and CCL25 facilitate migration, co-migration of lymphocytes in response to CXCL10 and CCL25 was studied. CXCL10 and CCL25 induced synergistic Th cell chemotaxis in vitro (both  $p < 0.01$  as compared to CCL25 or CXCL10 only).

## **Conclusion:**

The decreased frequency of CXCR3+CCR9+ Th cells in blood of pSS patients may be facilitated by a concerted action of overexpressed ligands at the site of inflammation. Elevated expression of ligands CXCL10 and CCL25 in the salivary gland and the synergistic effect on chemotaxis in vitro indicate a potential role for these chemokines in formation of lymphocytic infiltrates in exocrine glands of pSS patients.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The aim of the study was to assess the diagnostic value of salivary gland ultrasonography (SGUS) as a single test for the detection of primary sjogren's syndrome (pSS) and to examine the prognostic factors for severe structural changes of major salivary glands based on SGUS scoring system.

**Methods:** Patients with pSS (n = 80) and idiopathic sicca syndrome (n = 42) were evaluated using a SGUS scoring system (0-48 scale) consisted of five SGUS parameters: parenchymal echogenicity, parenchymal homogeneity, number of hypoechoic areas, hyperechogenic reflections, and clearness of salivary gland posterior borders of both parotid and submandibular glands. The volumes and parenchymal power Doppler signal were also assessed. A multivariate regression was performed to determine factors associated with higher SCUS score.

**Results:** Patients with pSS revealed a significant higher SGUS score in comparison with controls (median (IQR): 25.0 (13.75) vs 6.5 (3.5),  $P < 0.001$ ). The SGUS cut-off  $\geq 12$  showed a sensitivity of 82.5%, a specificity of 92.9%, a positive predictive value of 95.7%, and a negative predictive value of 73.6% for pSS diagnosis. There was no significant difference in the volumes between pSS and controls. Double positivity of anti Ro/SS-A and La/SS-B was independently associated with higher SGUS score ( $\beta = 5.45$ ,  $p = 0.009$ ). The SGUS score was also associated with unstimulated salivary flow test (USFR), rheumatoid factor, and IgG.

**Conclusion:** A new imaging modality, SGUS could be used as a highly specific diagnostic tool in pSS. Our study demonstrates double positivity of anti Ro/SS-A and La/SS-B could independently predict the severe structural damage of major salivary glands in pSS.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Congenital heart block in the fetus and neonate, which can cause acquired QT prolongation, may be associated with maternal anti-SS-A/anti-SS-B autoantibodies. However, there are increasing reports that primary Sjögren syndrome (pSS) is associated with an increased risk of cardiovascular disease and that disease-related clinical and immunological markers may promote cardiovascular disease. We hypothesized that myocardial abnormalities were associated with the corrected QT (QTc) interval in pSS. We used cardiac magnetic resonance imaging (CMR) to assess cardiac involvement and determine its association with the QTc interval in pSS patients without cardiac symptoms.

## Methods:

Consecutive pSS patients, classified according to the 2012 ACR criteria with no history or clinical findings of hypertension, cardiovascular disease, diabetes, or dyslipidemia underwent contrast-enhanced CMR. Late gadolinium enhancement (LGE) was used to assess myocardial fibrosis. Myocardial inflammation was assessed using a black-blood T2-weighted image (T2-WI). The Sjögren syndrome disease activity index (ESSDAI) was determined. Eighty-six percent patients had documentation of a minor salivary gland biopsy. Salivary gland biopsy data were classified by focus score (FS). A QTc interval of 440 ms was considered as prolonged.

## Results:

Fifty-five pSS patients were enrolled (mean age: 53.2±9.6 years). The mean ESSDAI was 2.5±2.7. Myocardial edema was seen in 3 patients (5%) on T2-WI. LGE was found in 9 (16%), 2 of whom demonstrated edema on T2-WI. Raynaud's phenomenon was significantly associated with LGE-positive patients (p=0.0064). The greatest relative difference between LGE-positive and -negative patients was observed in FS ≥4, with an adjusted odds ratio of 4.0, although the FS was not associated with the QTc interval.

PSS patients had a longer mean QTc interval than did controls (432.5±24.9 vs. 420.5±14.4; p=0.003). Furthermore, there was significant difference in the QTc interval between the LGE-positive and LGE-negative group (447.7±15.7 vs 429.5±25.4; p=0.012). Other pSS characteristics, such as disease duration, anti-SS-A/anti-SS-B autoantibodies, ESSDAI, and cardiovascular risk factors, were not significantly associated with myocardial abnormalities and QTc interval.

A receiver operating characteristic analysis showed that the QTc interval reliably detected myocardial abnormalities (area under the curve, 0.77).

## Conclusion:

Subclinical myocardial involvement, as detected by CMR, was frequent in pSS patients without cardiac symptoms. Abnormal CMR findings were associated with a QTc interval. To our knowledge, this was the first study to show that

myocardial abnormalities in pSS were associated with the QTc interval.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** S100 A proteins are multifunctional proteins expressed predominantly by myeloid cells, with a regulatory role in a variety of cellular processes including inflammation. Recently, serum and salivary S100A proteins have been described as increased in patients with primary Sjögren's syndrome (pSS) with respect to healthy volunteers. In this study, we aimed at investigating whether salivary expression of S100 proteins may reflect different pSS disease phenotypes stratified on the basis of the complexity of minor salivary gland biopsies (MSGb) and on the impairment of unstimulated salivary flow rate (USFR).

**Methods:** Patients with pSS (AECG 2002) were included in this study at the diagnosis of the disease. Demographic and clinical data were collected prospectively as well as their USFR and MSGb. A focus score (FS)  $\geq 3$  was considered as high and an USFR  $< 2.5$  ml/15' was considered as low. Saliva samples were collected on ice, centrifuged and stored at  $-80^{\circ}\text{C}$ . After removal of Albumin and IgG, a nano-HPLC system coupled with a Triple TOFTM 5600 mass spectrometer was used for the analysis of saliva proteomes of pSS patients. For the validation phase of the study, S100A7/psoriasin levels were determined by CircuLex S100A7/psoriasin ELISA kit (MBL International Corporation), according to manufacturer's instructions.

**Results:** Fifteen pSS women were enrolled for the proteomic analysis: 5 with high FS and normal USFR, 5 with high FS and reduced USFR and 5 with low FS and reduced USFR. Among differentially expressed proteins, we found that S100 A2, 7, 8, 9, 11 and 12 were significantly over-expressed in pSS with respect to controls. In details, S100 A7 levels were significantly increased in patients with higher FS and lower USFR with respect to the other two groups of patients; S100 A8 and A9 were increased in patients with higher FS and lower USFR only with respect to patients with high FS and normal USFR and S100 A 12 in patients with low FS and reduced USFR with respect to patients with high FS and normal USFR. We validated salivary expression of S100 A7 in 19 additional pSS patients and 8 controls confirming that S100A7 expression was significantly higher in patients with high FS and reduced USFR ( $305.6 \pm 174$  ng/ml vs  $11 \pm 14$  ng/ml vs  $75.7 \pm 21.6$  ng/ml,  $p=0.000$ ).

**Conclusion:** Salivary S100 A proteins appeared as interesting novel potential biomarkers for the non-invasive stratification of homogenous subgroups of patients with pSS. ELISA results excellently mirrored proteomics and open the possibility to be clinically translated into routine diagnostic.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sjögren's syndrome is a systemic autoimmune disease characterized by lymphocyte infiltration and subsequent dysfunction of exocrine glands, finally leading to dryness in the exocrine glands and dysfunction in the affected organs and tissues. The precise mechanism of Sjögren's syndrome remains unclear. Recently, novel insight into the NACHT, LRR and PYD domains-containing protein 3 (NLRP3) inflammasome that is responsible for innate immunity, has implicated it as a crucial regulator that plays a role in the pathogenesis of Sjögren's syndrome. The aim of this study was to identify the association of NLRP3 inflammasome-induced inflammation with disease activity and damage in Sjögren's syndrome.

**Methods:** A total of 33 female patients with Sjögren's syndrome and 34 sex- and age-matched, healthy controls were consecutively enrolled. The mRNA expression levels of NLRP3, ASC, caspase-1, interleukin-1b (IL-1b), and IL-18 in peripheral blood mononuclear cells (PBMCs) were measured, as well as serum IL-1b and IL-18 protein expression levels. The EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and Sjögren's Syndrome Disease Damage Index (SSDDI) were also evaluated.

**Results:** Patients with Sjögren's syndrome group showed higher expression of mRNA IL-1b and IL-1b at the protein level than controls ( $p < 0.001$  of both). The mRNA levels of caspase-1 and ASC were significantly increased in patients with Sjögren's syndrome compared to controls ( $p = 0.001$  and  $p = 0.002$ , respectively). Based on the SSDDI scores, patients with damage ( $SSDDI \geq 1$ ) had higher IL-1b mRNA expression compared to patients without damage ( $SSDDI = 0$ ) ( $p = 0.034$ ). SSDDI scores were closely related with IL-18 protein levels ( $r = 0.357$ ,  $p = 0.041$ ). The levels of IL-1b mRNA and IL-1b protein were correlated with the mRNA level of NLRP3 ( $r = 0.597$ ,  $p < 0.001$  and  $r = 0.502$ ,  $p = 0.003$ , respectively). IL-1b mRNA expression was responsible for the presence of damage for Sjögren's syndrome ( $p = 0.034$ ).

**Conclusion:** This study confirmed that NLRP3 inflammasome-mediated inflammation might be implicated in the pathogenesis of Sjögren's syndrome.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sjögren's syndrome (SJS) is a chronic autoimmune disorder with lymphocytic infiltration of exocrine and non-exocrine epithelia, in which epithelial cells play a critical role in the initiation and amplification of inflammatory processes. Syndecan-1 (sdc-1), a transmembrane heparan sulfate proteoglycan, is predominantly expressed on epithelial cells and functions primarily as coreceptors through the binding of heparan sulfate chain to a wide range of ligands, such as extracellular matrix components, cytokines, and chemokines. Although ectodomain of sdc-1 is constitutively shed, ectodomain shedding is accelerated in response to diverse pathophysiological conditions and may be related with pathogenesis of SJS. In this study, we investigated the association of sdc-1 levels in plasma and saliva with functional parameters of salivary glands in SJS patients.

**Methods:** Unstimulated and stimulated salivary flow rates and sdc-1 levels of saliva and plasma were measured in 37 SJS patients and 34 normal controls (NC). We assessed the disease activity indexes, including ESSDAI and ESSPRI, and performed salivary gland scan and serologic markers in SJS patients.

**Results:** ESSDAI and ESSPRI scores of SJS patients were  $3.78 \pm 3.33$  and  $3.95 \pm 1.50$ , respectively. Salivary flow rates in SJS patients and NC were  $0.02 \pm 0.04$  and  $0.31 \pm 0.20$ , respectively ( $p < 0.001$ ). While unstimulated salivary flow rates were correlated with ejection fraction (EF) of submandibular glands ( $r = 0.423$ ,  $p = 0.025$ ) in salivary gland scan, stimulated salivary flow rates were associated with EF of parotid glands ( $r = 0.531$ ,  $p = 0.04$ ). Salivary flow rates were inversely associated with ESSPRI scores ( $r = -0.390$ ,  $p = 0.036$ ) and dryness domain of ESSPRI ( $r = -0.622$ ,  $p < 0.001$ ) in SJS patients. Plasma and salivary sdc-1 levels were significantly higher in SJS patients than NC (both  $p < 0.001$ ), and inversely correlated with salivary flow rate (plasma,  $r = -0.515$ ,  $p < 0.001$ ; saliva,  $r = -0.472$ ,  $p = 0.003$ ). Plasma sdc-1 levels were positively correlated with salivary sdc-1 levels in SJS patients ( $r = 0.632$ ,  $p < 0.001$ ) but not in NC ( $r = 0.217$ ,  $p = \text{NS}$ ). Plasma and salivary sdc-1 levels were related with submandibular gland dysfunction in salivary gland scan. While plasma sdc-1 levels showed an inverse correlation with EF ( $r = -0.426$ ,  $p = 0.038$ ), salivary sdc-1 levels were inversely correlated with both uptake ratio at 20 minutes ( $r = -0.526$ ,  $p = 0.017$ ) and EF ( $r = -0.446$ ,  $p = 0.019$ ). Furthermore, salivary sdc-1 levels were correlated with serum levels of anti-Ro ( $r = 0.397$ ,  $p = 0.030$ ) and -La antibodies ( $r = 0.441$ ,  $p = 0.015$ ) and IgG, although serum level of IgG showed a marginal statistical significance ( $r = 0.331$ ,  $p = 0.074$ ).

**Conclusion:** Plasma and salivary sdc-1 levels are increased in SJS patients, which is associated with salivary gland dysfunction. In addition, salivary sdc-1 levels may be related with immune dysregulation in pathogenesis of SJS.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The research classification and clinical diagnosis of Sjögren's syndrome (SS) relies heavily on the detection of autoantibodies against Ro/SSA and La/SSB, particularly in the absence of salivary gland biopsy or when the histopathology of the minor salivary gland is normal. However, there is little consensus on the method or combination of methods that yield the best balance of sensitivity and specificity for SS.

**Methods:** We analyzed the results of multiple serology assessment platforms in 1530 subjects with SS or non-SS sicca evaluated at the OMRF Sjögren's Research clinic. Our standard tests include ANA by indirect immunofluorescence on HEp-2 cells, *Chrothidia luciliae* for dsDNA, and double immunodiffusion (DID) for ENA. Anti-Ro/SSA and anti-La/SSB were determined by DID, a line assay (InnoLia ANA Update) and a bead-based assay (Bio-Rad BioPlex 2200) for anti-Ro52, Ro60 and La; and ELISA (Immunovision) for anti-Ro60. A subset of cases were also evaluated for anti-Ro52/TRIM21 by immunoprecipitation with human antigen and anti-La(+)/Ro(-) cases were confirmed by DID on HEp-2000 cells and RT-PCR.

**Results:** We observed significant differences in the performance of the tests in the same individuals. The concordance rate (kappa statistic) is detailed in Fig. 1. The most significant discrepancies were between DID and Bioplex and InnoLia; in almost all discordant cases, DID results were negative while they were positive for at least one of the other tests (anti-Ro 353/1318, 26.8%; anti-La 145/1253, 11.5%). InnoLia and Bioplex were highly concordant for Ro52 and are likely interchangeable; anti-Ro60 also showed high concordance across the three platforms tested but the minor discrepancies would result in the loss of 1.1% of positive subjects. Another clinically relevant finding was that in 1% of Ro52(+)/Ro60(+) cases total anti-Ro was negative, an artifact that has previously been reported. All tests and analytes showed excellent specificity for classification as primary SS, albeit at the expense of low sensitivity (Table 1).

**Conclusion:** The very low sensitivity of anti-Ro and anti-La DID in SS patients may result in misclassification of up to 25% of cases. Algorithms for a tiered approach for additional testing are necessary in the clinical setting to optimize diagnosis at a reasonable cost. For research, in particular clinical trials that require high specificity, all the tested platforms perform very well.

Kroese<sup>1</sup>, <sup>1</sup>Rheumatology and Clinical Immunology, University of Groningen, University

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

During immunoglobulin synthesis in B-cells, kappa and lambda light chains are produced in excess compared to heavy chains, and the surplus of light chains are secreted into serum as free light chains (FLC). Compared to healthy individuals, elevated serum levels of polyclonal FLCs are seen in autoimmune diseases associated with increased B-cell activation, including primary Sjögren's syndrome (pSS). In pSS, serum FLC levels correlate with IgG, rheumatoid factor and systemic disease activity.<sup>1</sup> However, the clinical relevance of serum FLC levels as biomarker in pSS remains unclear. The objective of this study is to assess if I) FLCs are already elevated at the time of diagnosis, II) FLC levels can discriminate non-SS sicca from pSS patients, and III) FLCs can be used to monitor treatment response.

### Methods:

Serum samples of 102 consecutive patients referred to our expertise center for suspicion of pSS were included. Patients were classified by a panel of 3 clinical experts as non-SS sicca, incomplete pSS or pSS and fulfillment of ACR-EULAR criteria for pSS was assessed. Longitudinal serum samples of pSS patients treated with rituximab (n=20) or abatacept (n=15) were also included. Kappa ( $\kappa$ ) and lambda ( $\lambda$ ) FLCs were measured in serum by the Freelite assay (Binding Site, UK). Area under the ROC curve (AUC) was used to assess the ability of serum FLC levels to predict a pSS diagnosis. Generalized estimating equations were used to measure changes during treatment.

### Results:

At the time of diagnosis, FLC $\kappa$  and FLC $\lambda$  serum levels were significantly higher in pSS patients compared to non-SS sicca patients (FLC $\kappa$ : median (IQR)=29 (17-39) vs. 15 (11-17) mg/L,  $p<0.001$ ; FLC $\lambda$ : 27 (18-34) vs. 15 (13-18) mg/L,  $p<0.001$ ). The  $\kappa/\lambda$  ratio was slightly increased in pSS compared to non-SS sicca patients ( $p=0.045$ ). FLC $\kappa$  and FLC $\lambda$  both showed good accuracy to discriminate pSS from non-SS (FLC $\kappa$ : AUC=0.806, 95% CI=0.708-0.904; FLC $\lambda$ : AUC=0.802, 95% CI=0.705-0.899). However, the accuracy of serum IgG was higher (AUC=0.885, 95% CI=0.811-0.959). Interestingly, FLC $\kappa$  was also elevated ( $>20$  mg/L) in 4/9 incomplete pSS patients. In two of them, also FLC $\lambda$  was elevated ( $>32$  mg/L). In patients fulfilling ACR-EULAR criteria, FLC $\kappa$  and FLC $\lambda$  levels correlated with systemic disease activity, assessed by EULAR Sjögren's syndrome disease activity index (FLC $\kappa$ : Spearman's  $\rho=0.282$ ,  $p=0.004$ ; FLC $\lambda$ :  $\rho=0.321$ ,  $p=0.001$ ). Treatment with rituximab significantly lowered FLC $\kappa$  and FLC $\lambda$  levels ( $p<0.001$  for both). Treatment with abatacept also reduced FLC $\kappa$  and FLC $\lambda$  levels, although to a smaller extent ( $p=0.006$  and  $p=0.087$ , respectively).

### Conclusion:

Serum FLCs are elevated in pSS patients at the time of diagnosis and can discriminate non-SS sicca from pSS. FLC $\kappa$  is already elevated in a large part of the incomplete SS patients and may serve as an early diagnostic biomarker. Furthermore, serum FLC levels can be used to monitor the effect of treatment on B-cell activity and may be more sensitive to change than serum IgG, because of a shorter half-life.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by immune cell infiltration in the salivary glands resulting in ocular and oral dryness. Abnormalities in B cell activation and skewing of T cell polarization toward Th2 and T follicular helper (TFH) associated with ectopic germinal center formation in the salivary gland are observed in pSS. However, the interplay between B and T cell subsets, and other immune abnormalities, as well as relationship to disease status, has yet to be fully elucidated. In this study, we evaluated changes in peripheral blood B and T cell populations in pSS compared to SLE and RA diseases and healthy controls.

**Methods:** Two cohorts of patients with pSS according to European-American Consensus and ACR criteria and age-matched healthy controls (HC) were recruited (Rochester, USA and Strasbourg, France) and disease activity assessed by ESSDAI and ESSPRI. The Rochester cohort also included RA (n=20) and SLE (n=15) classified based on ACR criteria. PBMCs were isolated by Ficoll-Hypaque and the frequencies of B and T subpopulations measured by multi-parameter flow cytometry. Data are reported as median [25<sup>th</sup>-75<sup>th</sup> quartile]. Correlation analysis was done by Pearson method,  $p < 0.05$  was considered significant.

**Results:** We examined the expression of ICOS and PD-1, two important co-regulatory molecules of the B7-family, on memory T cells (CD4+CD45RA-) in pSS compare to HC, SLE and RA. pSS and SLE had higher frequency of memory T cells expressing both ICOS and PD-1 than HC while RA had higher frequency of PD-1<sup>+/hi</sup> T cells. Accordingly, T follicular helper cells (TFH: CXCR5<sup>+</sup>ICOS<sup>+</sup>PD-1<sup>+</sup>) were found at higher frequency in pSS and SLE compared to HC (pSS (n=40): 5.96 [3.75-8.71]%; HC (n=58): 4.18 [2.51-4.91]%,  $p=0.0005$ ; SLE (n=15): 4.61 [3.51-9.84]%,  $p=0.002$ ). Further evaluation of TFH subsets (based on CXCR3 and CCR6), revealed higher frequency of TFH1 and lower TFH17 subset in pSS compare to HC and RA, also confirmed in the Strasbourg cohort. Characterization of B cells in pSS patients from Rochester cohort revealed significant contractions of switched memory (SM) and un-switched memory (USM) B cell compared to HC (pSS SM (n=39): 3.52 [1.65-7.28]%; HC SM (n=38): 7.57 [5.49-10.86]%,  $p=0.005$ ; pSS USM (n=39): 10.07 [5.47-15.62]%; HC USM (n=38): 21.44 [15.16-31.27]%,  $p<0.0001$ ). Furthermore, frequencies of ICOSL expressing SM and USM were lower in pSS than HC. There was a significant inverse correlation between ICOSL+ USM B cells and TFH1 in pSS patients ( $\rho = -0.55$ ,  $p=0.0255$ ). There were two distinct clusters of pSS based on T and B cell subsets, with one group distinct from HC and associated with higher disease activity and autoantibodies. In a subset of pSS (n=10), T and B cell frequencies were evaluated longitudinally at 6 months. Significant changes in frequency of ICOSL+ B cells were observed and negatively correlated with changes in CXCR5+ICOS+ T cells ( $\rho = -0.634$ ,  $p=0.049$ ).

**Conclusion:** Our data highlight the significant abnormalities in the peripheral TFH and B cell compartment in pSS and further suggest the critical role of TFH- B cell interactions. The decrease in ICOSL+ memory B cells suggests interaction with ICOS+ T cells in germinal center-like structures in salivary glands.

## **Anti-Muscarinic Receptor 3 Antibodies – a Cross Reactive Result of Ro60 Immunization**

Syed M.S. Quadri<sup>1</sup>, Bijl T Kurien<sup>2</sup>, Kristi A. Koelsch<sup>3</sup> and R. Hal Scofield<sup>4</sup>, <sup>1</sup>Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK, <sup>2</sup>Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>3</sup>Arthritis and Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>4</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sjogren's syndrome (SS) is a chronic autoimmune inflammatory disease characterized by impaired function of salivary and lacrimal glands leading to dry mouth and dry eyes. The hallmark of SS is the presence of autoantibodies against Ro and La antigens. High titers of anti-Ro60 autoantibodies have shown to correlate with severity of the disease. It is yet unclear how these antiRo60 antibodies correlate with severity. Autoantibodies against M3R are also prevalent in SS. Muscarinic receptor 3 abbr. as M3R is an end organ parasympathetic GPCR mainly present in lacrimal and salivary glands. The stimulation of M3R is well studied and is known to induce secretion in lacrimal and salivary glands and so an effect to M3R could possibly lead to a reduction in secretion. We immunized rabbits with Ro60 and found that immunization not only resulted in the formation of antibodies against Ro60 but also to 2<sup>nd</sup> and 3<sup>rd</sup> extracellular domains of the M3 receptor. The reactivity to Ro60 and M3R 2<sup>nd</sup> and 3<sup>rd</sup> extracellular domains has also shown a high correlation.

### **Methods:**

**Immunization of rabbits:** NZW rabbits were immunized with 500µg of either unmodified Ro60, Smith or RNP antigen) emulsified in 0.5 ml of complete Freund's adjuvant given I/P with subsequent boosters at days 26, 53 and 99 with a final I/V boost on day 152. The sera were collected weekly in pre and post-immunized rabbits. **Ro60 and M3R experiments:** Reactivity of sera towards Ro60, MAPS of M3R 2<sup>nd</sup> or 3<sup>rd</sup> extracellular domains were tested using ELISA. Seral dilution ELISA was done using dilution 1:100 to 1: 100,000 and competition ELISA by preincubating sera with either Ro60 and MAPS of 2<sup>nd</sup> ECL was done to see the specificity of antibody binding.

**Results:** Rabbits immunized with Ro60 developed antibodies against Ro60, M3R 2<sup>nd</sup> and 3<sup>rd</sup> ECLs in a progressive way. A positive correlation was found between both Ro60 and M3R 2<sup>nd</sup> ECL ( $R^2 = 0.66$ ,  $p = <0.0001$ ) and between Ro60 and M3R 3<sup>rd</sup> ECL ( $R^2 = 0.789$ ,  $p = <0.0001$ ). A positive correlation was also found between M3R 2<sup>nd</sup> and 3<sup>rd</sup> ECL ELISA ( $R^2 = 0.56$ ,  $p = 0.0001$ ). Rabbits immunized with Smith and RNP antigen did not develop antibodies to any of the extracellular

domains of M3R to significant levels. Serial dilution ELISA showed a sequential decline in reactivity for both the 2nd and the 3rd ECL of M3R. Competition ELISA for 2nd ECL of M3R using sera preincubated with M3R 2<sup>nd</sup> ECL showed an inhibition of 48.2% to 58.99%, sera preincubated with Ro60 showed an inhibition of 54.5 to 89.03% verifying the specific binding.

**Conclusion:** Previously our studies found high reactivity for M3R and Ro60 antigen in fully human recombinant monoclonal antibodies produced from plasmablasts isolated from salivary glands of SS patients and was found to be inhibitory. The subsequent step, immunization of rabbits with Ro60 also supported the same hypothesis. The rabbits immunized with Ro60 developed antibodies to M3R extracellular domains supporting the concept of cross-reactivity. Our next step is to see whether the immunization of rabbits with M3R develops anti-Ro60 antibodies. Our future studies are also aimed at passive transfer of IgGs (from Ro60 immunized rabbit sera as well as human recombinant IgGs positive for M3R and Ro) to mice to see the *in vivo* functional consequences of this cross-reactivity.

## The Effect of Non-Invasive Vagus Nerve Stimulation on Fatigue and Immune Responses in Patients with Primary Sjögren's Syndrome

Jessica Tarn<sup>1</sup>, Sarah Legg<sup>2</sup>, Sheryl Mitchell<sup>2</sup>, Bruce Simon<sup>3</sup> and Wan-Fai Ng<sup>4</sup>, <sup>1</sup>Institute of Cellular Medicine, Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle University, Newcastle-Upon-Tyne, UK, Newcastle-Upon-Tyne, United Kingdom, <sup>2</sup>Freeman Hospital, Newcastle upon Tyne, United Kingdom, <sup>3</sup>electroCore Medical LLC, Basking Ridge, NJ, <sup>4</sup>Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary Sjögren's syndrome (pSS) sufferers have rated chronic fatigue as the most important symptom needing improvement and the main contributing factor to the loss of work productivity. Emerging data suggest cross-talk exists between the autonomic nervous system and the immune system via the vagus nerve in particular. The gammaCore device (electroCore), was developed to deliver stimulation of the cervical vagus nerve non-invasively, and has been CE marked for the treatment of epilepsy and migraine and has recently been FDA approved for the acute treatment of episodic cluster headache. In this study, we use the gammaCore device to dissect the relationship between the vagus nerve, fatigue and immune responses in pSS.

**Methods:** Fifteen female pSS subjects fulfilling the American European Consensus Group Classification criteria (2002) were included. At baseline, blood was drawn before and after non-invasive vagus nerve stimulation (nVNS). The subjects were then instructed to use the gammaCore device twice daily (2 min. over each carotid artery). The participants were followed up at day 7 and Day 28. At each visit, blood was drawn and patient reported outcome measures (PROMs) were collected including EULAR Sjögren's syndrome Patient Reported Index (ESSPRI), Profile of fatigue (PRO-F), visual analogue scale (0-100 cm) of abnormal fatigue and Epworth Sleepiness Scale (daytime sleepiness). Whole blood samples were stimulated with 2ng/mL Lipopolysaccharides (LPS) or RPMI-1640 as control. After 24 hours, the levels of IFN $\gamma$ , IL12-p70, TNF $\alpha$ , MIP1a, IFN $\alpha$ , IL-10, IL-1 $\beta$ , IL-6 and IP10 were measured in the supernatants by cytometric bead array (BD). In addition, whole blood cell subset proportions were profiled using flow cytometry.

**Results:** PRO-F, and Daytime sleepiness were significantly reduced across three visits. Trends of improvement were also observed in Abnormal fatigue VAS, ESSPRI-Dryness and ESSPRI-Physical fatigue subscales. Participants who appeared to have a sustained reduction in fatigue related PROMs over the study period concurrently had a significantly higher proportion of T-cells at most time points. Cytokine production, particularly TNF $\alpha$  by whole blood cells upon LPS stimulation was reduced over the period of device use. Additionally, TNF $\alpha$  and IL-1 $\beta$  levels were significantly reduced after the first device use compared with pre-VNS.

**Conclusion:** To our knowledge this is the first study into the effects of nVNS in pSS. These preliminary observations suggest that in some individuals, nVNS may reduce clinical symptoms of fatigue, which could be underpinned by biological changes detectable in the whole blood.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoantibodies against 60-kD Ro (Ro60)/SSA have been detected in the saliva and serum of patients with primary Sjögren's syndrome (SS) by routine methods that are unable to resolve molecular characteristics of interacting antibodies. Accordingly, it is unknown whether the parallel glandular and systemic anti-Ro60 responses derive from related or independent antibody repertoires. In the present study, we have identified a Ro60-specific salivary IgA repertoire by analysing immunoglobulin variable region (IGV) subfamily composition and mutational profiles of matched salivary and serum proteomes.

**Methods:** Anti-Ro60 autoantibodies were purified and sequenced from Ro-specific precipitins prepared by electrophoresing native Ro60 protein against whole saliva or serum collected from 9 patients with seropositive primary SS. Microgram amounts of precipitating anti-Ro60 Igs were separated by SDS-PAGE, and in-gel chymotrypsin digests performed on heavy (H) and light (L) chain bands. VH/VL and constant-region peptides were subjected to nano-high performance liquid chromatography-mass spectrometry (nHPLC-MS/MS) followed by combined *de novo* amino acid sequencing and database matching using Peaks 8.0 software utilising ImMunoGeneTics (IMGT) and Uniprot databases.

**Results:** High-resolution MS sequencing of purified salivary anti-Ro60 H- and L-chains revealed a common (9/9 patients) oligoclonal IgA Ro60 repertoire dominated by IGHV3-23 and IGKV3-20 subfamily expression. Paired serum anti-Ro60 proteomes expressed a more diversified IgG1 repertoire with expression of additional IGHV1 and IGHV3 families in the systemic compartment. IGHV3-23-encoded H-chains were present in matched saliva and serum samples but were distinct in terms of their patterns of somatic mutations, suggesting independent pathways of affinity maturation. Three of 9 patients showed a less abundant IgG1 salivary anti-Ro60 proteome that was similar to the paired serum proteome.

**Conclusion:** Proteomic profiling of salivary and serum anti-Ro60 autoantibodies in primary SS reveals a unique salivary IgA repertoire with specific V-region peptide profiles, consistent with a parallel yet distinct salivary gland pathway of somatically selected anti-Ro60 autoantibodies. The novel proteomic workflow reported herein will allow analysis of clonal turnover of mucosal and systemic autoantibody repertoires in early versus established disease and provide molecular biomarkers to assess responses to therapy in the glandular and peripheral compartments.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary Sjögren's syndrome (pSS) is a chronic autoimmune rheumatic disease causing various symptoms including dryness, fatigue and pain. Previous work by our group has suggested that certain pro-inflammatory cytokines are inversely related to patient-reported levels of fatigue. This model in that study using pro-inflammatory cytokine levels, disease-specific and clinical parameters was able to predict fatigue with 67% accuracy. To date, these findings have not been validated. This study aims to validate this observation.

**Methods:** Blood levels of seven cytokines were measured in 120 patients with pSS from the United Kingdom Primary Sjögren's Syndrome Registry and 30 age-matched healthy non-fatigued controls. Patient-reported scores for fatigue were classified according to severity and compared to cytokine levels using analysis of variance. The differences between cytokines in cases and controls were evaluated using Wilcoxon test. A logistic regression model was used to determine the most important predictors of fatigue.

**Results:** Three cytokines, interferon- $\gamma$ -induced protein-10 (IP-10), tumour necrosis factor- $\alpha$  (TNF $\alpha$ ) and interferon- $\alpha$  (IFN $\alpha$ ) were significantly higher in patients with pSS (n=120) compared to non-fatigued controls (n=30). Levels of two pro-inflammatory cytokines, TNF- $\alpha$  (p=0.021) and lymphotoxin- $\alpha$  (p=0.043), were inversely related to patient-reported levels of fatigue. Based on the model previous used a regression model was created to predict fatigue in pSS. Cytokine levels, disease-specific and clinical parameters as well as pain, anxiety and depression were used as predictors in this validation model. The model correctly predicts fatigue levels with 85% accuracy.

**Conclusion:** Depression, pain and proinflammatory cytokines appear to be the most powerful predictors of fatigue in pSS, which is consistent with the original study. This data further challenges the notion that proinflammatory cytokines directly mediate fatigue in chronic immunological conditions. Validation in an independent international cohort would be necessary to further confirm these results.

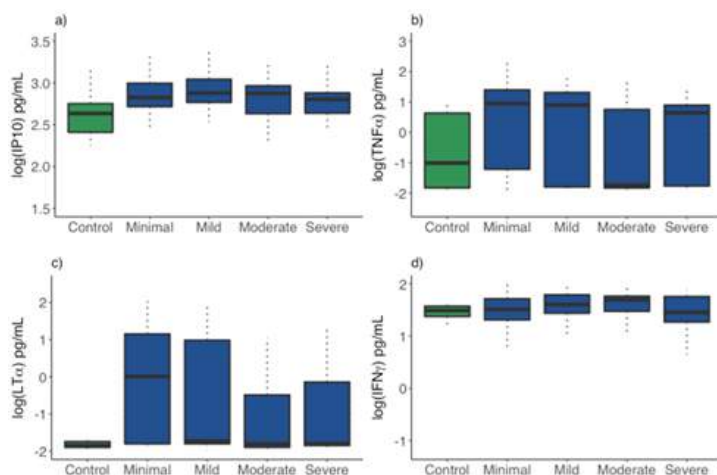

Figure 1: Box plot showing median cytokine levels and IQR for a) IP-10, b) TNF- $\alpha$ , c) LT- $\alpha$  and d) IFN- $\gamma$  in controls and pSS fatigue groups.

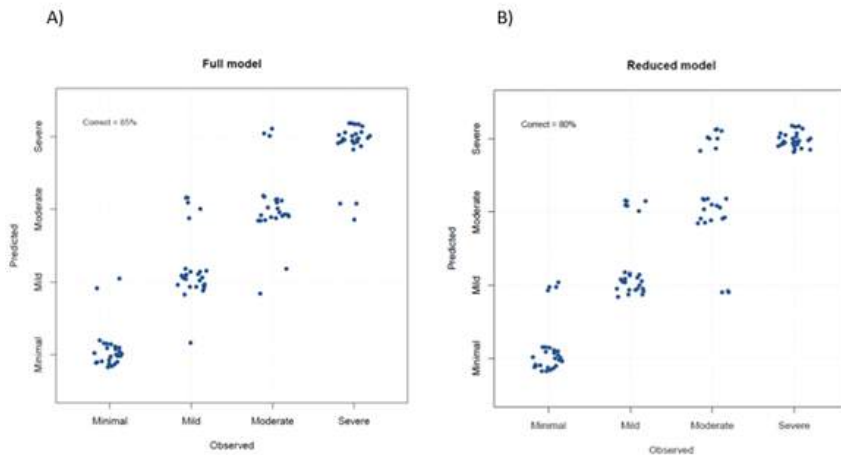

Figure 2: (A) Full ordinal logistic regression model with all parameters. All of these variables predict fatigue correct in 85% of cases. (B) shows that IFN- $\gamma$ , IP-10, depression and pain alone predicted fatigue level with 80% accuracy.

## Immune Response to Seasonal Flu Vaccination in Patients with Primary Sjogren's Syndrome

Albin Björk<sup>1</sup>, Marika Kvarnström<sup>2</sup>, Gudny Ella Thorlacius<sup>2</sup> and Marie Wahren-Herlenius<sup>2</sup>, <sup>1</sup>Department of Medicine, Unit of Experimental Rheumatology, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden, <sup>2</sup>Unit of Experimental Rheumatology, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Vaccination of rheumatic patients has been reported to induce lower antibody titers than in healthy individuals. However, studies have primarily included patients treated with immunomodulatory drugs. Previous data from our group revealed that untreated patients with primary Sjögren's syndrome (pSS) respond with higher vaccine specific antibody titers than healthy controls (HC) following vaccination with a squalene adjuvanted H1N1 vaccine. Whether non-adjuvanted vaccines would also induce higher specific antibody responses in non-treated patients is not known. In the present study, we therefore monitored the vaccination response to the adjuvant-free vaccine for seasonal flu (Fluarix) in HC and untreated patients as well as that in patients receiving hydroxychloroquine (HCQ).

**Methods:** The study included 17 pSS patients without treatment, 8 pSS patients receiving HCQ, and 16 HC. All participants were women and all pSS patients were positive for SSA autoantibodies at the time of diagnosis. All individuals were vaccinated with the Fluarix 2015/2016 vaccine as part of the standard vaccination program. Clinical parameters were recorded using a questionnaire based on ESSPRI. Antibody titers were analysed by ELISA. RNA expression analysis was performed in CD14<sup>+</sup> monocytes and CD19<sup>+</sup> B cells using the Human Immunology v2 CodeSet (Nanostring).

**Results:** Untreated patients with pSS responded with significantly higher vaccine specific IgG titers than HC after immunization. Further, levels of anti-Ro52 autoantibodies increased in untreated patients, but not in HCQ-treated patients after vaccination. Nanostring RNA expression data confirmed the presence of an interferon (IFN)-signature in monocytes and in B cells from pSS patients and an IFN score calculated from B cell expression data could discriminate between high and low vaccine antibody response at day 29. No significant changes in self-reported clinical parameters were registered.

**Conclusion:** Untreated pSS patients display an increased serological responsiveness to the non-adjuvanted seasonal flu vaccine when compared to healthy controls. The increased response is however not mirrored by any clinical aggravation of the patients' rheumatic disease.

Jonsson**<sup>4</sup>, <sup>1</sup>Department of Rheumatology, Haukeland University Hospital, University of Bergen, Bergen, Norway, <sup>2</sup>Broegelmann Research Laboratory, Department of Clinical Science, University of Bergen, Bergen, Norway, <sup>3</sup>Department of Rheumatology, Haukeland University Hospital, Bergen, Bergen, Norway, <sup>4</sup>Department of Clinical Dentistry, Section for Oral and Maxillofacial Radiology, University of Bergen, Bergen, Norway

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Several studies have reported a protective effect of smoking with regard to risk for primary Sjögren's syndrome (pSS) and minor salivary gland inflammation. To our knowledge, there are no studies investigating major salivary gland ultrasonography (SGUS) findings in smokers with pSS. The aim of this study was to investigate the frequency of smokers

in a cohort of pSS, and to determine the possible impact of smoking on minor salivary gland histopathology, major salivary gland ultrasonography, and secretory function of the salivary and lacrimal glands.

## Methods:

Patients with pSS (n=98) were recruited from the Department of Rheumatology, Haukeland University Hospital, Bergen, Norway. All patients had undergone clinical examination and SGUS using a simplified scoring system for glandular homogeneity and hypoechogenic areas. The parotid and submandibular salivary gland scans were graded 0-3; grades 0-1 considered corresponding to normal/non-specific changes and grades 2-3 to SS-like pathological changes. In addition, routine clinical and serological parameters, information regarding focus score, sicca symptoms, secretory function, fatigue, and smoking habits were available for retrospective analysis. All patients fulfilled the 2002 AECG criteria for pSS.

## Results:

The majority of patients in this pSS cohort (n=59) were non-smokers, the remaining consisted of former smokers (n=27) and current smokers (n=12). Pathological SGUS findings were found in 38/59 (64 %) of the non-smokers, 13/27 (48 %) of the former smokers, and in 7/12 (58 %) of the current smokers.

Data on focus score (FS) was available in 83 patients, and correlated with SGUS score ( $p=0.010$ ,  $r=0.283$ ). Interestingly, 49/54 (91 %) non-smokers, 17/21 (81 %) former smokers and 3/8 (38 %) current smokers had  $FS \geq 1$  ( $p<0.010$ ,  $r=0.283$ ). Mean focus score was 2.0 for non-smokers, 2.1 for former smokers, and 0.6 for current smokers; the difference between current and former smokers was significant ( $p=0.023$ ).

Oral sicca symptoms correlated with SGUS score ( $p<0.001$ ,  $r=0.378$ ). Unstimulated salivary secretion was  $\leq 1.5$  ml/15 min in 42/57 (74 %) non-smokers, 18/26 (69 %) former smokers, and 7/12 (58 %) current smokers. Stimulated saliva was  $\leq 3.5$  ml/5 min in 27/57 (47 %) non-smokers, 12/26 (46 %) former smokers, and 4/12 (33 %) current smokers. Schirmer's I-test levels (right and left eye, respectively) for current smokers were 9.3 and 11.3 mm, former smokers 4.9 and 3.8 mm, and non-smokers 7.7 and 7.9 mm. Differences were significant for the left eye when comparing current smokers and former smokers ( $p=0.021$ ), and non-smokers and former smokers ( $p=0.048$ ).

Interestingly, anti-Ro/SSA titers were elevated in 9/12 (75 %) current smokers and 20/27 (74 %) former smokers, compared to 35/58 (60 %) non-smokers. A similar trend was observed for anti-La/SSB titers in 6/12 (50 %) current smokers, 12/27 (44 %) former smokers, and 19/58 (33 %) non-smokers.

## Conclusion:

In this cohort, smokers with pSS had a lower degree of minor salivary gland inflammation and pathological imaging findings in the major salivary glands. The sub-group also presented with better secretory function compared to non-smokers and former smokers.

**Session Time:** 9:00AM-11:00AM

*Complement Consumption as a Predictor of Pulmonary Manifestation in Patients with Primary Sjögren's Syndrome: Results from a Unicentric Observational Study*

**Background/Purpose:** Primary Sjögren's syndrome (pSS) may present with respiratory manifestations ranging from proximal and distal airways impairment to various forms of interstitial lung disease (pSS-ILD), which can affect up to 16% of patients<sup>1</sup>. Studies on factors associated with pulmonary manifestations of pSS are few and of heterogeneous results<sup>2,3,4</sup>. Our main objective was to identify clinical and laboratory elements related to pSS that may be predictors of lung disease.

**Methods:** Retrospective study of pSS patients in follow-up at a university hospital. Patients older than 18 years who met pSS classificatory criteria according to the American-European Consensus of 2002 were included. Patients with other CTD were excluded. Epidemiological, clinical, and laboratory data were extracted from medical records. Chest CT scans were reviewed by a radiologist without knowledge of the patients' clinical data. Data from patients with pSS with and without pulmonary manifestations were compared and Fischer's test was applied for statistical evaluation.

**Results:** Seventy patients with pSS were selected (68% female and mean age  $45.8 \pm 9.5$ ). Fifteen (21.4%) had some form of pulmonary manifestation, 14 (20%) of ILD and 1 of bronchiolitis (1.4%). Among the analyzed variables, a statistically significant association was found between complement consumption (C3 or C4) and presence of pulmonary manifestation (38.4% versus 10.2%;  $p: 0.02$ ). No association was found between autoantibodies such as ANA, RF, Ro/SSA and La/SSB or other forms of extraglandular manifestation (Table 1). No variables were correlated with the presence of pulmonary cysts or pSS-ILD. The radiological findings of patients with pulmonary manifestations are summarized in Table 2.

**Conclusion:** In our series of patients with pSS, we found a high frequency of individuals with pSS and pulmonary impairment. Complement consumption was a predictor of this form of manifestation, an association never seen before.

TABLE 1. COMPARISON OF CLINICAL AND LABORATORIAL FEATURES OF pSS PATIENTS WITH AND WITHOUT LUNG DISEASE

	PATIENTS WITH LUNG DISEASE (N=15)	PATIENTS WITHOUT LUNG DISEASE (N=55)	p
ANTINUCLEAR ANTIBODIES	15 (100%)	51 (96.2%)	0,99
RHEUMATOID FACTOR	10(66,6%)	34(69,3%)	0,99

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Environmental factors involved in the pathogenesis of primary Sjögren's syndrome (pSS) are still largely unknown. The oral cavity is the microbial habitat closest to the salivary glands – the most affected tissue in pSS. Hypofunction of the salivary glands is the major cause underlying symptoms of a dry mouth (xerostomia), occurring in over 90% of the patients with pSS. The aim of our study was to explore whether the oral microbiome, in particular the bacterial composition and/or the presence of bacterial species, is specific for the oral microbiome of patients with pSS.

**Methods:** To assess whether changes in the oral microbiome of pSS patients are a cause of pSS or an effect of oral dryness, we included two control groups: patients with oral dryness not diagnosed as pSS (non-SS sicca patients) and population based controls. We collected a swab from the buccal mucosa of 82 patients with oral dryness referred to our outpatient

clinic for a complete diagnostic work-up for pSS. After completing the diagnostic workup, 32 patients could be classified as pSS according to the 2002 AECG classification criteria and 50 patients as non-SS sicca. The bacterial composition of the buccal mucosa samples was determined with 16S rRNA sequencing. Buccal mucosa swab samples from a population based cohort study were used as population controls (n=118).

**Results:** Mean unstimulated whole salivary flow rates in pSS and non-SS sicca patients were 0.09 and 0.17 mL/min respectively. Significantly less 16S rRNA reads per sample were obtained from the buccal swab samples of patients with oral dryness (pSS and non-SS sicca together) compared to population controls ( $p < 0.0001$ ). Also the diversity of the bacterial composition from the buccal mucosa was significantly lower in pSS and non-SS sicca patients than in population controls ( $p = 0.01$  and  $p < 0.001$  respectively), but no difference was observed between pSS and non-SS sicca patients. Principal coordinate analysis showed no evident separation of the individual samples between the three different study groups, but the buccal mucosa bacterial communities from pSS patients were significantly more dissimilar to those from population controls than non-SS sicca patients from population controls ( $p = 0.028$ ). Multivariate analysis showed highly significant associations between oral dryness and the genera *Olsenella*, *Cryptobacterium* and *Fretibacterium* – all which have been associated with periodontal disease – since these genera were only detected in samples from the buccal mucosa of patients with oral dryness and not in population controls ( $p$ -value  $< 0.005$ ). However, no oral bacterial taxa were specifically associated with pSS.

**Conclusion:** Patients with pSS have a dysbiosis of the oral microbiome, viz. a reduced diversity and increase of pathogenic bacteria. We presume that dysbiosis in the oral microbiome of patients with pSS is largely an effect of oral dryness and not a causal factor in the pathogenesis of pSS. On top of this dysbiosis as a consequence of oral dryness, there might be a specific effect of pSS on the diversity of the oral microbiome.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** : A characteristic feature of Sjögren's syndrome (SS) is the destruction of salivary and lacrimal glands mediated by mononuclear cell infiltration. Adipocytes can also occupy a large portion of the salivary gland (SG) tissue area, although little is known about their significance in SS. We have previously investigated adipose tissue infiltration in SG biopsies from SS patients and non-SS sicca controls. Our findings indicated distinct incidence of adipose tissue replacement in SS patients, where adipocytes were detected in IL6 rich regions. We now aimed to examine the development of adipocytes in the SG microenvironment, and delineate their possible involvement in immune reactions.

**Methods:** A microarray analysis was performed on SG from 6 SS patients and 6 non-SS controls, where the expression levels of genes involved in adipose tissue development were assessed. Real-time PCR was carried out on SG from 14 SS patients and 15 non-SS controls to account for interleukin (IL)-6, IL10 and IL17 mRNA levels. Immunohistochemical staining of frozen SG tissue using IL17 was also conducted.

**Results:** Upregulated signalling pathways identified in SG of SS patients show prominent adipose tissue development and mitochondrial fatty acid beta-oxidation, including the genes ARID5B, OXCT1, BDH1, SOX8, HMGCS2, FTO, ECHS1, PCCA, ACADL and ACADVL. Genes involved in interferon production and signalling were also detected (IRF1, IRF9, IRF7), in addition to IL6, IL10, and IL17 (Figure 1, Table 1). Higher mRNA levels of IL6, IL17 and IL10 were also observed in the SG of SS patients compared to controls. Moreover, IL17+ cells were observed mostly interstitially in the SG and around adipocytes, also within the focal infiltrates.

**Conclusion:** Adipocyte development seems to be more prominent in the SG of SS patients at the site of inflammation, where adipose tissue replacement is also evident. Detection of IL17 positive adipocytes in the target organ suggests their involvement in immune reactions.

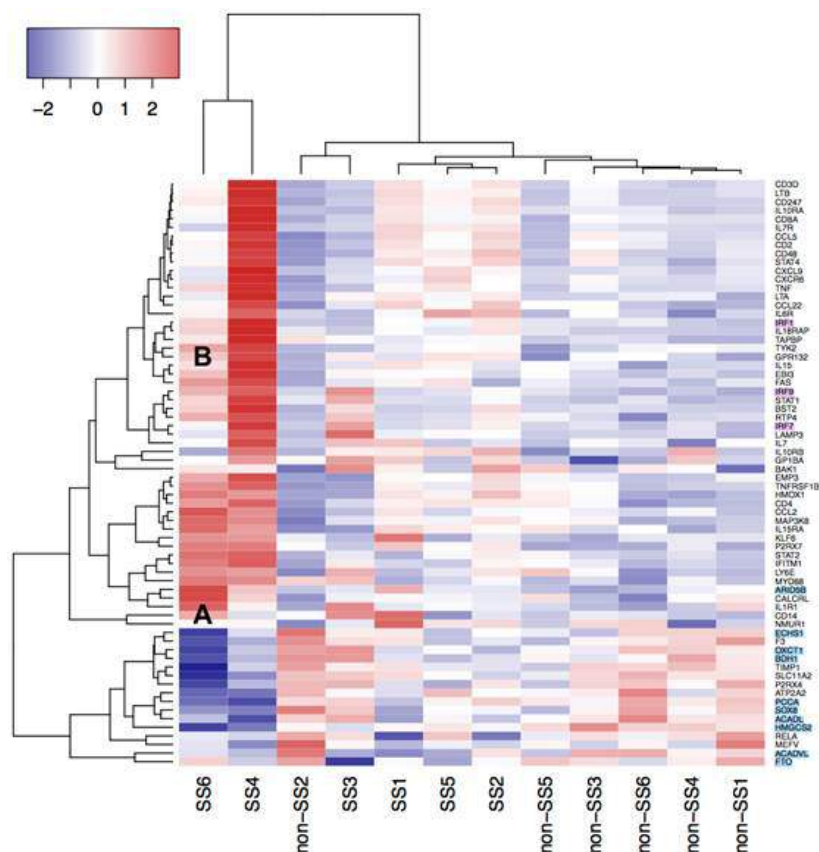

Table 1. Genes identified in clusters A and B (Figure 1), and their function.

A	
Genes involved in adipose tissue development and fatty acid beta oxidation	
Gene	Function
ARID5B	Adipogenesis and expression of adipogenic genes
OXCT1	Key enzyme (CoA-transferase) involved in lipid formation
BDH1	Enzyme (dehydrogenase) involved in fatty acid production
SOX8	Transcription factor regulating adipose tissue development
HMGCS2	Enzyme regulating cholesterol metabolism and lipid biosynthesis
FTO	Control of adipocyte differentiation into brown or white fat cells
ECHS1	Fatty acid beta-oxidation (lipid metabolism)
PCCA	Fatty acid metabolism, biotin binding
ACADL	Cellular lipid production, mitochondrial fatty acid beta-oxidation
ACADVL	Lipid catabolism, mitochondrial fatty acid beta-oxidation
B	
Genes involved in interferon production and signalling	
Gene	Function
IRF1	Type I interferon production, interferon signalling, apoptosis, CD8+ T cell differentiation, innate and adaptive immunity
IRF9	Type I interferon signalling, IFN $\gamma$ -mediated signalling pathway
IRF7	Type I interferon signalling, IFN $\gamma$ -mediated signalling pathway, IFN $\alpha$ - and IFN $\beta$ production, innate and adaptive immunity

ARID5B: AT-rich interactive domain-containing protein 5B  
OXCT1: Succinyl-CoA:3-ketoacid coenzyme A transferase 1 (mitochondrial)  
BDH1: D-beta-hydroxybutyrate dehydrogenase (mitochondrial)  
SOX8: Transcription factor SOX-8  
HMGCS2: Hydroxymethylglutaryl-CoA synthase (mitochondrial)  
FTO: Alpha-ketoglutarate-dependent dioxygenase FTO  
ECHS1: Enoyl-CoA hydratase (mitochondrial)  
PCCA: Propionyl-CoA carboxylase alpha chain (mitochondrial)  
ACADL: Long-chain specific acyl-CoA dehydrogenase (mitochondrial)  
ACADVL: Very long-chain specific acyl-CoA dehydrogenase (mitochondrial)  
IRF1: Interferon regulatory factor 1  
IRF9: Interferon regulatory factor 9  
IRF7: Interferon regulatory factor 7

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Over the last decades, several post translationally modified proteins have been identified as auto-antigens in rheumatoid arthritis (RA). No data regarding Abs against acetylated proteins (AAPA) and very few on Abs against carbamylated proteins (anti-CarP) are currently available in primary Sjögren's syndrome (pSS). Acetylation of lysine/ornithin results from the addition of an acetyl group by the N-acetyltransferase enzyme, while carbamylation is the conversion of lysine residues into homocitrulline. In RA, carbamylation can be induced by cigarette smoke. The aim of our study was to investigate the prevalence and significance of AAPA and anti-CarP Abs in pSS.

### **Methods:**

Eighty-seven pSS patients according to the 2002 American-European Consensus Criteria were enrolled. AAPA and anti-CarP were assessed by ELISA using mutated vimentin acetylated or carbamylated in position 7 as antigen. Acetylation could target either a lysine or an ornithine residue. To assess the possible effect of nearby antigens, acetylation and carbamylation were also alternatively included in position 2 (inverse peptide). Acetylated histone and non histone peptides were also employed as antigens. Clinical and serological records, including glandular and extraglandular manifestations, cardiovascular (CV) risk factors and CV events were retrospectively collected.

### **Results:**

AAPA were identified in 20 pSS patients (23%). Seven patients displayed only one AAPA specificity while 13 displayed 2 or more AAPA specificities. Anti-CarP Abs have been identified in 4 pSS patients (5%) and in all cases the antigen was mutated vimentin carbamylated at position 7 but not the inverse peptide. AAPA<sup>+</sup> patients did not display extra-glandular involvement including renal, pulmonary, gastrointestinal, central/peripheral nervous system manifestations or myositis.

Conversely, binary logistic regression revealed that AAPA positivity was associated with cardiac (namely pericarditis) and cardiovascular (CV) events (heart failure, pulmonary arterial hypertension, pulmonary embolism) (odds ratio=11;  $p<0.0001$ ) but not with smoking or systemic arterial hypertension. pSS patients with anti-CarP Abs displayed more frequently leukopenia ( $p=0.01$ ) and parotid gland swelling ( $p=0.03$ ) but surprisingly none of the anti-CarP<sup>+</sup> patients displayed articular involvement and none of them was a current or former smoker.

### Conclusion:

Our study demonstrated for the first time that AAPA are detectable in pSS. Although preliminary, our results support the evidence of a possible association of AAPA and cardiac/CV manifestations. Likewise, specific anti-CarP Abs against mutated carbamylated vimentin are present in a small proportion of pSS patients and seem to be associated with leukopenia and parotid gland swelling but not with articular involvement and smoking. These results are of particular importance in light of the increased CV risk in pSS and will be assessed in a larger cohort of patients for validation purposes. Furthermore, it might be speculated that carbamylation in pSS may be induced by mechanisms other than cigarette smoking.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Labial salivary gland biopsy (LSGB) is a minimally invasive procedure used in the diagnostic of Sjögren's Syndrome (SS). Objectives: to describe demographic, clinical and histological features of patients submitted to LSGB; to analyze the usefulness of LSGB in diagnosis of primary SS (pSS) and secondary SS (sSS); to assess the association between

histological findings and autoantibodies; to compare the sensitivity (Sn) and specificity (Sp) of the American-European 2002 (AE02) and ACR 2012 criteria.

## Methods:

An observational, analytical, cross-sectional study was performed. A total of 803 patients were included between June 1996 and May 2016. A sub analysis of 674 patients was performed, excluding those with SSs and others without antibodies.

Grades III and IV biopsy of the Chisholm and Mason's (CM) classification were considered positive. Data was analyzed using STATA 17 software.

## Results:

803 patients were included, 90% females. The mean age was 53 years (range 14-86). PSS was diagnosed in 238 (29.6%), and SS in 45 (5.6%), with female predominance in both groups (30.1% and 5.8%, respectively). Table 1 shows the clinical characteristics and complementary studies in patients with nonspecific dryness syndrome (NoSS) and SSP and SS.

Table 1.

Parameters n (%)	NoSS n(%)	PSS n(%)	SSS n(%)	P value
<i>Xerostomía</i>	399 (76.6)	200 (84)	39 (88.6)	<i>0.019</i>
<i>Xerophthalmia</i>	447 (85.8)	220 (92.4)	36 (81.8)	<i>0.018</i>
<i>Abnormal ophtalmic test</i>	209 (67.4)	175 (96.2)	28 (96.6)	<i>&lt;0.01</i>
<i>Abnormal parotid sialography</i>	31 (52.5)	24 (75)	-	<i>0.036</i>
<i>Ro/SS-A</i>	11 (2.4)	73 (32.7)	13 (32.5)	<i>&lt;0.01</i>
<i>La/SS-B</i>	-	31 (14)	3 (7.5)	<i>&lt;0.01</i>
<i>ANA</i>	61 (12.4)	116	20	<i>&lt;0.01</i>
<i>RF</i>	81 (16.4)	(49.6)	(48.8)	<i>&lt;0.01</i>
		96 (41.6)	31 (73.8)	
<i>LSGB G III-IV</i>	8 (1.5)	217 (91.2)	26 (59.1)	<i>&lt;0.01</i>
<i>Pilocarpine</i>	21 (4.04)	57 (24.1)	2 (4.6)	<i>&lt;0.01</i>
<i>Hydroxychloroquine</i>	43 (8.3)	206 (86.9)	26 (59)	<i>&lt;0.01</i>
<i>Prednisone &lt;20mg</i>	68 (65)	68 (29.5)	30 (5.5)	<i>&lt;0.01</i>
<i>Prednisone &gt;20 mg</i>	6 (1.5)	68 (29.5)	6 (13.6)	<i>&lt;0.01</i>
<i>Rituximab</i>	2 (0.4)	3 (1.5)	1 (2.3)	<i>0.27</i>
<i>Other immunosuppressive drug</i>	64 (15.7)	2 (0.9)	38 (86.4)	<i>&lt;0.01</i>
		171 (72.8)		

In the subanalysis of 674 patients, 33.1% were pSS, of which 204 (91.5%) were female. The mean age was 54 years (range 14-86). LSGB was 0, I or II grades in 8.5% patients with PSS, versus 91.5% patients with III-IV grades ( $p < 0.01$ ); Sn 91.5%, Sp 98.5%, positive predictive value (PPV) 96.7, negative predictive value (NPV) 95.9. Table 2 compares the serological characteristics of patients using LSGB as a "gold standard".

Table 2.

Parameters	LSGB (+)	LSGB (-)	p	Sensitivity	Specificity	PPV	NPV	LR
Ro/SS-A	58 (27.5)	26 (31)	<0.01	27.5	94.4	69.1	74.1	4.9
La/SS-B	24 (11.4)	7 (1.5)	<0.01	11.4	98.5	77.4	70.9	7.5
ANA	97 (46.4)	71 (15.4)	<0.01	46.4	84.6	57.7	77.6	3
RF	84 (40.8)	78 (48.2)	<0.01	40.8	83	51.9	75.7	2.4

In multivariate analysis the significance for anti-Ro (OR: 2.0), ANA (OR: 2.9) and RF (OR: 2.5) was maintained.

The AE02 criteria had a Sn of 32.3%, Sp 97.3%, PPV 85.7% and NPV 74.4%.

The ACR 2012 had a Sn of 83.4%, Sp 98.5%, PPV 96.4% and NPV 92.3%.

### Conclusion:

LSGB is a simple, safe, and useful tool for the diagnosis of Sjögren's syndrome. It exhibits an adequate balance between Sn, Sp, PPV and NPV..

Antibodies showed a significant association with a positive LSGB with low Sn for pSS screening but high Sp. The LSGB had a great value in "seronegatives patients".

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Women with primary Sjögren's syndrome (pSS) often experience vaginal dryness. The cause of this symptom is unknown. This study compared the vaginal and cervical health of women with pSS and controls, using clinical and histopathological parameters.

**Methods:** Consecutive premenopausal women with pSS according to the AECG and ACR-EULAR criteria, with symptoms of vaginal dryness, and age-matched controls planned for a risk-reducing salpingo-oophorectomy underwent a vaginal examination. Excluded were women with an inflammatory or infectious gynaecological disease, intra-uterine contraceptive device, or use of hormone therapy or DMARDs. Participants were screened for chlamydia, gonorrhea, and vaginal bacterial and fungal infections. The vaginal health index was recorded, which consists of 5 domains (elasticity, fluid secretion, pH, epithelial mucosa, moisture). Each domain was scored on a scale of 1-5, resulting in a score of 5-25. Low scores correspond to low vaginal health. In pSS patients, vaginal and endocervical biopsies were taken under local anesthesia. In controls, the investigation was performed under general anesthesia, prior to surgery. Formalin fixed and paraffin embedded tissue sections were stained for HE and CD45 (leucocytes) and examined by a dedicated gynaecopathologist. The percentage of area stained for CD45 was calculated with Aperio ImageScope v12.0. Groups were compared using Mann-Whitney U test.

**Results:** A total of 9 pSS patients and 5 controls were included so far. One pSS patient was excluded from the analysis due to presence of Chlamydia trachomatis. Median age was 35 years (IQR 30-46) in pSS patients and 37 years (IQR 36-42) in controls ( $p=0.62$ ). Median vaginal health index was lower in pSS patients (18.5, range 14-23) compared to controls (23.0, range 20-23,  $p=0.019$ ). In the HE staining of the vaginal tissue, a mild ( $n=6$ ) or moderate ( $n=2$ ) infiltrate was seen in all pSS patients. In controls, no infiltrate ( $n=3$ ) or a mild infiltrate ( $n=2$ ) was seen in the vaginal tissue. Infiltrates were mainly located in the subepithelial layer, with aggregates in dermal papillae (figure 1). The median percentage of area stained for CD45 in the vagina was higher in pSS patients (2.0%, range 1.0-5.0%) compared to controls (1.4%, range 0.4-1.4%,  $p=0.03$ ). Endocervical tissue was obtained in 5 pSS patients and in 3 controls. In the HE staining of the endocervical tissue, moderate or severe infiltrates were seen in 3 pSS patients, and a moderate infiltrate in 1 control. The median percentage of area stained for CD45 in the endocervix did not differ between groups (patients 4.4%, range 1.1-28.3%; controls 3.2%, range 2.0-13.0%,  $p=1.00$ ).

**Conclusion:** In this preliminary analysis, pSS patients show a lower vaginal health index and a higher percentage of subepithelial infiltrate in the vagina compared to controls, while endocervical histopathology did not differ. Detailed phenotypic evaluation of the infiltrate will follow.

**Figure 1:** Histopathology of vaginal biopsies from a patient with pSS (A,B) and a control (C,D), stained for HE (A,C) and for CD45 (B,C). Note the subepithelial infiltrate and the CD45<sup>+</sup> aggregates in the dermal papillae in the pSS patient.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Ultrasonography (US) has been developed in salivary glands (SG) and particularly in primary Sjögren syndrome (pSS) for 10 years. However, the training curve is long and the reliability is not completely achieved (1). A new tool procedure has

been developed to study the elasticity of the tissue parenchyma using elastography and could be implemented in the evaluation of SGUS pSS patients. The objective was to evaluate SGUS using grey scale (GS) and the elasticity salivary glands parenchyma using elastography to differentiate pSS from sicca syndrome (SS) patients in a longitudinal consultation of sicca syndrome in Doppler Unit of Brest (France).

**Methods:** 63 patients complaining of sicca syndrome were enrolled in the ELSA study. At inclusion, all patients underwent a standardized workup including a clinical evaluation, laboratory tests, SG histology, SGUS and elastography. Immunological testing included: anti-nuclear antibodies, anti-SSA (recognizing both Ro 52 and 60 kDa), anti-SSB, native anti-DNA, ANCA, rheumatoid factors and anti-CCP. A Toshiba Applio machine was used to evaluate in GS SGUS parenchyma and elastography -elastometry. The 6 main SG were examined in US according to previous scoring (2) elastography (with color map) and elastometry (in cm/sec) and :left parotid gland (USLPG), left submandibular gland (USLSMG), left sublingual gland (USLSLG), right parotid gland, (USRPG) right submandibular gland (USRSMG), right sublingual gland (USRSLG).

**Results:** 15 patients fulfilled the AECG criteria. The clinical characteristics of the patients in terms of ocular dryness and shirmer test were not significant between pSS and Sicca patients. There was a significant difference ( $p=0.04$ ) concerning oral dryness ( $p=0.04$ ), immunological datas: Antinuclear antibodies and anti SSA and minor salivary glands biopsy ( $p=0.007$ ). We found significant differences between the 2 groups in GS for the USLPG ( $p=0.021$ ) and USLSMG ( $p=0.05$ ). Evaluation of sublingual glands using US in grey scale and elastometry of the 6 SG showed no significant differences between the two groups.

**Conclusion:** Grey scale SGUS seems to be more sensitive to differentiate pSS to Sicca patients compared to elastometry. US of sublingual glands showed no involvement in the echostructural damage in pSS patients and suggest not examining these glands in the USpSS evaluation. Elastometry has been described to be a new tool and might be added as a new imaging technique to ultrasonography in pSS patients (3). However, ELSA study results showed no differences between pSS and Sicca patients. We need to follow the evolution of the Sicca population with US in GS and elastometry to detect potential echostrural parenchymal damage which might not yet be present at inclusion.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-centromere antibody (ACA) positive Sjögren's syndrome (SS) is considered as a subtype in SS. Recent international collaborative large scale cohort study highlighted several clinical features such as Raynaud's

phenomenon, sclerodactyly and extra glandular dysfunction (Arthritis Care Res. 2016). Assessment of ACA is potentially valuable for definitive diagnosis of this subtype and medical management in a certain number of patients uncovered by current 2015 ACR/EULAR classification criteria. However, enough information of clinical and immunological features of ACA positive SS has not been accumulated and clinical significance of ACA in SS may not be fully established. The aim of this study is to clarify clinical and immunological features of ACA positive SS.

**Methods:** All patients with primary SS (pSS) who visited to our Division of Rheumatology at Keio University Hospital in Tokyo between May 1995 and December 2016 were enrolled. Clinical information and immunological tests including immunoglobulin (Ig) and serum autoantibodies were collected and statistically analyzed.

**Results:** Five hundred and ninety nine patients were clinically classified as pSS (female: 93%, mean age:  $55 \pm 15$ ). They were divided into 4 groups by serum ACA and anti-SS-A antibody status. Only discrete-speckled pattern in anti-nuclear antibody (ANA) test and/or anti-centromere antibody positive (ACA alone) were detected in 39 patients (6.5%), while only anti-SS-A antibody with no ACA (SS-A alone) were detected in 449 patients (75.0%). Number of patients with both ACA and SS-A (Double positive) was 40 (6.7%), while 67 patients had neither ANA nor SS-A (Seronegative). Then we statistically compared these 4 groups. The proportions of Raynaud's phenomenon or sclerodactyly were higher in ACA alone and Double positive groups ( $p < 0.01$  or  $p < 0.01$ ). The proportion of dryness was no difference among 4 groups. The proportions of increase of serum IgG or IgA were 15% or 7% in ACA alone group, 61% or 20% in SS-A alone group, 50% or 28% in Double positive group and 22% or 4% in Seronegative group ( $p < 0.01$  or  $p < 0.01$ ). Existence of anti-SS-A antibody, not ACA associated to high concentration of IgG or IgA, while there was no difference between 4 groups as IgM ( $p = 0.40$ ). Regarding C3, C4 or CH50, there were no differences among 4 groups. Remarkably, the proportion of leukocytopenia in ACA alone group was significantly higher than the others ( $p = 0.02$ ). As compared with pulmonary, cardiac or articular involvements, no differences were found among 4 groups. Importantly the proportion of patients who had facial erythema was significantly lower in ACA positive SS ( $p < 0.01$ ).

**Conclusion:** Our large-scale study identified distinct characteristics of ACA-positive SS patients different from anti-SS-A/Ro antibody positive or seronegative SS patients in Japanese population.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Sjögren's Syndrome Poster I: Translational Research

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although patient stratification can improve the success rate of clinical trials, efforts to apply this strategy to autoimmune studies such as Sjögren's syndrome are hindered by the nature of this disease area, intra-disease patient diversity, difficulties around diagnostic criteria and response metrics, as well as the lack of clear biological mechanisms to explain drug efficacy. In some of the diseases, the nexus of these variables is B-cell biology.

**Methods:** The ImmunoSignature Technology — the semi-quantitative profile of antibody binding specificity — is designed to enable patient stratification in autoimmune disease trials. HealthTell's unique approach to peptide microarray fabrication, combining silicon wafer-based photolithographic synthesis with optimized peptide coupling chemistry and MALDI-based quality control, permits high-throughput ImmunoSignaturing with exceptional scalability, reproducibility and accuracy, making it broadly-applicable to diagnostic, clinical and discovery applications. In this study, HealthTell's ImmunoSignature platform was applied to key steps in a clinical trial (NCT02149420) with VAY736, an anti-B cell activating factor (BAFF) receptor monoclonal antibody, in patients with primary Sjögren's Syndrome.

**Results:** The ImmunoSignature distinguished Sjögren's patients from healthy volunteers with an AUC of 0.84, with individual peptides showing a correlation to the EULAR Sjögren's syndrome disease activity index (ESSDAI) of up to 0.74 (Pearson's r). Using serum collected prior to treatment, the ImmunoSignature predicted which patients will respond to study drug with a drop in ESSDAI of  $\geq 3$ , yielding an AUC of 0.75 from a small study (18 treated patients with 9 placebo). Response to therapy performance was also measured using sera drawn 12 weeks post treatment and resulted in an AUC of 0.84. Using the 12-week sample, principle component analysis correctly segregated drug-treated responders from drug-treated non-responders, placebo non-responders and the single placebo-responsive patient. Alignment of the peptides that comprise these contrasts to the human proteome yields not only known Sjögren's autoantigens but also potential novel biomarkers.

**Conclusion:** The Immunosignature identified in this study is important for disease diagnosis and explanation of study drug response.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

It has been shown in the past that inflammatory activity (i.e., elevated C-reactive protein) predicts radiographic spinal progression in patients with axial spondyloarthritis (axSpA). Fibrinogen and factor 13 genotypes have been recently identified as factors modifying inflammatory response due to differences in the properties of the fibrin network related to particular genotype constellations [1].

The objective of the current study was to investigate the association between  $\alpha$ -fibrinogen (FGA),  $\beta$ -fibrinogen (FGB) and factor XIII A-subunit (F13A) genotypes with the level of CRP and radiographic spinal progression over 2 years in patients with early (up to 10 years symptom duration) axial SpA.

**Methods:**

Altogether 207 patients with early axial SpA from the German Spondyloarthritis Inception Cohort (GESPIC) were included. Clinical data and CRP level were collected at baseline and every 6 months thereafter. A time-averaged CRP level over 2 years (up to 5 time-points) was calculated. Structural damage in the spine was assessed on spinal radiographs at baseline and after two years according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Significant radiographic spinal progression was defined as the worsening of the mSASSS by  $\geq 2$  points over two years. FGB -455G>A (rs1800790), FGA T312A (rs6050) and F13A V34L (rs5985) genotypes were determined with available samples using allele-specific primer pairs.

**Results:**

No clear association between studied genotypes and the time-averaged CRP or radiographic spinal progression could be found. However, the effect of CRP in the predictive model for radiographic spinal progression was strongly dependent on FGB genotype (table): the odds ratio (OR) for the elevated time-averaged CRP as a predictor of the mSASSS worsening by  $\geq 2$  points over two years was 5.47 (95%CI 1.51-19.79) in FGB -455GG (wild-type) carriers, while there was no such effect of CRP in carriers of the alternative (A) allele, OR=0.99 (95%CI 0.20-4.92). Interestingly, this effect modification was dependent also on F13A genotype: in carriers of the wild-type genotypes of both FGB (-455GG) and F13A (34VV), n=65, the OR for the elevated CRP as a predictor of radiographic spinal progression was 10.8 (95%CI 1.07-108.0), while alternative allele carriers (F13A 34L) showed a weak and non-significant association of CRP with radiographic spinal progression even in the presence of the wild-type FGB genotype (n=59): OR=2.01 (95%CI 0.34-12.04). F13A itself as well as FGA genotypes showed no effect-modifying effects on CRP.

**Conclusion:**

The predictive value of CRP regarding radiographic spinal progression seems to be dependent on FGB and F13A genotypes. This might also suggest that CRP is not a good indicator of inflammation in individuals with a specific genetic background.

## Added Value of Biomarkers Compared to Routine Clinical Parameters for the Prediction of Radiographic Spinal Progression in Axial Spondyloarthritis

Lorraine Tietz<sup>1</sup>, Lien Le<sup>2</sup>, Agnes Hartl<sup>1</sup>, Martin Rudwaleit<sup>1,3</sup>, Joachim Sieper<sup>1</sup>, Ulrich Mansmann<sup>2</sup> and **Denis Poddubnyy**<sup>1,4</sup>, <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Ludwig-Maximilian University, Munich, Germany, <sup>3</sup>Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany, <sup>4</sup>German Rheumatism Research Centre, Berlin, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Structural damage in the spine is an important determinant of the functional status and spinal mobility in axial spondyloarthritis (axSpA). Already present syndesmophytes, elevated C-reactive protein, cigarette smoking, and to a lesser extent male sex are routine clinical parameters predicting radiographic spinal progression in axSpA. In the last years, several biomarkers with a predictive value for radiographic spinal progression were identified. It is, however, not known, if biomarkers have a meaningful added value over clinical parameters in prediction of radiographic spinal progression in axSpA.

The objective of the study was to examine whether adding biomarkers to the routine clinical parameters would improve prediction of radiographic spinal progression in axSpA.

### Methods:

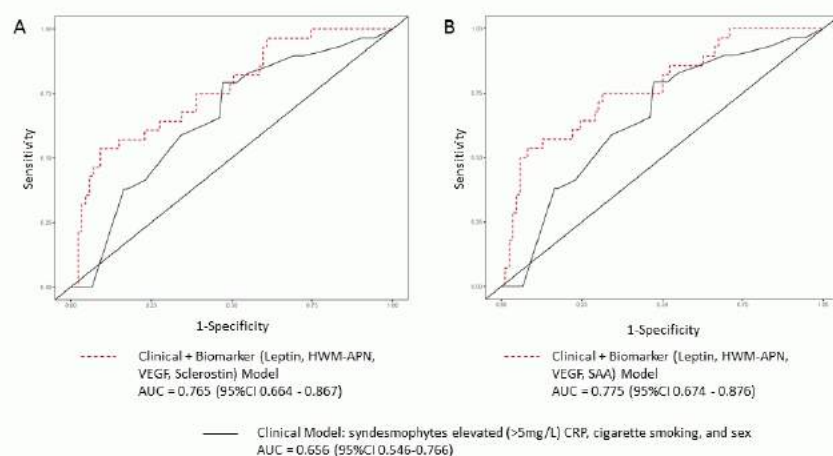

Altogether 120 patients with radiographic axSpA who completed a 2-year clinical and radiographic follow-up in the ENRADAS trial were included. Structural damage in the spine was assessed on spinal radiographs at baseline and year 2 according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Radiographic spinal progression was defined as a worsening of the mSASSS by  $\geq 2$  points after 2 years. Clinical predictors of radiographic spinal progression at baseline included syndesmophytes, elevated ( $>5\text{mg/L}$ ) CRP, cigarette smoking, and sex. Serum biomarkers measured at baseline included: matrix metalloproteinase-3, vascular endothelial growth factor (VEGF), calprotectin, leptin, high molecular weight adiponectin (HWM-APN), oostoprotegerin, sclerostin, N-terminal telopeptide, procollagen type II N-terminal propeptide, and serum amyloid A (SAA).

**Results:** Repeated cross-validation analysis revealed two biomarker combinations: (1) Leptin + HWM-APN + VEGF + Sclerostin and (2) Leptin + HWM-APN + VEGF + SAA with added predictive value compared to the clinical model (syndesmophytes, smoking, elevated CRP, and sex). Adding these biomarker combinations to the clinical model resulted in improvement of the predictive value reflected by the Area Under the Curve (AUC):  $\text{AUC}_{\text{Clinical+Biomarkers(1)}}=0.765$  (95%CI 0.664-0.867) and  $\text{AUC}_{\text{Clinical+Biomarkers(2)}}=0.775$  (95%CI 0.674-0.876) vs.  $\text{AUC}_{\text{Clinical}}=0.656$  (95%CI 0.546-0.766) – figure. The average prediction error (APE) of the Clinical+Biomarker(1) and Clinical + Biomarker(2) models were 0.227 and 0.229, respectively as compared to the APE for the pure clinical model (0.248). These findings were supported by the results of stability analyses.

## Conclusion:

Biomarkers are able to improve prediction of radiographic spinal progression in axSpA if used in addition to the clinical parameters, but the added value seems to be rather small.

**Figure:** The receiver operator curve analyses of clinical vs. clinical + biomarker models for prediction of radiographic spinal progression (mSASSS worsening  $\geq 2$  points after 2 years) in axial SpA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The altered expression of miRNAs contributes to the pathophysiology of inflammatory conditions. In addition, circulating miRNAs may serve as promising therapeutic and prognostic biomarkers. Our aim was to investigate the effect of anti-TNF therapy on the levels of circulating miRNAs in patients with ankylosing spondylitis (AS).

**Methods:** Our study included 19 AS patients. Disease activity scores (ASDAS-CRP, BASDAI) and laboratory parameters of disease activity were obtained at baseline (M0), month 3 (M3) and 12 (M12) after initiation of anti-TNF therapy. Total RNA was isolated from plasma using miRNeasy Serum/Plasma Kit (Qiagen). A comprehensive analysis of miRNAs was performed using TaqMan Low Density Array (TLDA) in 3 patients at M0, M3 and M12. dCt method was used for relative quantification:  $dCt = Ct(miRNA) - Ct(array\ average)$ . Seventeen miRNAs with >1.5-fold change in the expression prior and after the therapy initiation in all 3 samples were selected for next validation using single assays. The levels of miRNAs in validation measurements were normalized to an average of 3 spike-in controls of *C. elegans* origin:  $dCt = Ct(spike-in\ average) - Ct(miRNA)$ . Data were analyzed using ANOVA with Bonferroni corrections and Spearman's correlation coefficient.

## Results:

All AS patients had high disease activity (BASDAI  $6.3 \pm 1.5$ , ASDAS  $4.1 \pm 0.7$ , CRP  $32.5 \pm 28.9$  mg/l, ESR  $40.1 \pm 19.6$  mm/h) prior commencing anti-TNF therapy with a good therapeutic response at M3 (BASDAI  $2.8 \pm 1.2$ , ASDAS  $2.15 \pm 0.65$ , CRP  $9.8 \pm 13.6$  mg/l, ESR  $15.2 \pm 21.3$  mm/h,  $p < 0.001$  for all comparisons) and M12 (BASDAI  $2.3 \pm 1.7$ , ASDAS  $1.9 \pm 0.9$ , CRP  $7.4 \pm 9.6$  mg/l, ESR  $13.7 \pm 12.2$  mm/h,  $p < 0.001$  for all comparisons).

Out of all 380 miRNAs analyzed by TLDA, 125 miRNAs were detected in all samples, 148 miRNAs were detected at M0, 154 at M3 and 151 at M12. Validation of 17 selected miRNAs confirmed significant downregulation of miR-145 at M3 (TLDA 1.59-change; single assays 1.62-change,  $p = 0.024$ ), but the downregulation did not reach statistical significance at M12 (TLDA 1.46-change; single assays 1.11-change,  $p > 0.05$ ).

At baseline, miR-145 positively correlated with VAS ( $r = 0.450$ ,  $p = 0.048$ ). In addition, the decrease in miR-145 expression from M0 to M3 significantly correlated with disease activity improvement over time from M3 to M12 as per BASDAI ( $\Delta$ BASDAI M3/12 =  $-0.50 \pm 1.93$ ,  $r = 0.670$ ,  $p = 0.002$ ) and ASDAS scores ( $\Delta$ ASDAS M3/12 =  $-0.28 \pm 0.70$ ,  $r = 0.614$ ,  $p = 0.005$ ) and VAS at M12 ( $r = 0.528$ ,  $p = 0.020$ ). In line with this observation, high levels of miR-145 at M3 significantly correlated with disease activity worsening based on an increase in ASDAS from M3 to M12 ( $r = 0.595$ ,  $p = 0.007$ ) and higher ASDAS ( $r = 0.535$ ,  $p = 0.018$ ) and VAS ( $r = 0.564$ ,  $p = 0.012$ ) at M12.

## Conclusion:

We propose that an early change in miR-145 levels may be a predictor of future outcome of AS patients as it's early decrease after anti-TNF initiation correlated with further disease activity improvement. These data, similarly to previous studies showing correlation of miR-145 with CRP and pro-inflammatory IL-6 (Cell Biochem Funct. 2015;33(5)), suggest potential use of circulating miRNAs as biomarkers of treatment response in AS.

## **Tenascin-C, a TLR 4 Endogenous Ligand Levels Are Increased in Ankylosing Spondylitis**

**Latika Gupta**, Shruti Bhattacharya and Amita Aggarwal, Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Monocytes of patients with Ankylosing Spondylitis (AS) over-express Toll-like receptor (TLR) 4 on their monocytes. Tenascin-C (TNC) is an extracellular-matrix-glycoprotein and acts as an endogenous TLR4 ligand. Thus we studied the serum and synovial fluid levels of TNC in adults with AS.

### **Methods:**

TNC was measured in serum of 36 AS patients (ASAS 2009 criteria) and 10 healthy controls by ELISA. 22 patients were followed-up after 3 months of standard of care treatment. Five paired serum-synovial fluid samples were also analyzed. Disease activity was assessed by BASDAI, ASDAS, tender and swollen joint count; enthesitis score, ESR and CRP. All values are in median (IQR).

### **Results:**

Median age was 30 (20-35) years and disease duration 5.5(1.3-10) years. 31 were male and 5 female. 25 cases had peripheral arthritis (69.5%). Median BASDAI was 5.3(3.3-6.7). HLA B27 was positive in 34 (94.5%) cases.

Median serum Tenascin C levels were higher in AS [554.6ng/ml] as compared to healthy controls [32.88 ng/ml,  $p<0.00001$ ]. Serum TNC levels correlated with ASDAS ESR [ $r=0.367$ ,  $p=0.028$ ] and ESR [ $r=0.39$ ,  $p=0.035$ ]; but not with other disease activity measures. In patients with disease duration less than 5 years (early disease) serum levels had better correlation with ESR [ $r=0.59$ ,  $p=0.009$ ] and CRP [ $r=0.479$ ,  $p=0.044$ ]. On ROC analysis for active ( $\text{PhGA}\geq 6$ ) vs. inactive ( $\text{PhGA}\leq 4$ ) disease, TNC (AUC=0.60) performed as well as CRP (AUC=0.65) and ESR (AUC=0.73). The synovial fluid levels [11.61(5.99-176.9) ng/ml] were lower than in the serum [627.4 (488.5-779.1) ng/ml,  $p=0.008$ ].

TNC levels fell with treatment [630.8 ng/ml to 376.4 ng/ml  $p=0.0006$ ] in treatment responders ( $n=11$ ) but not in non-responders ( $n=11$ ) [562.3 to 445.6,  $p=0.33$ ].

### **Conclusion:**

Serum TNC levels are significantly raised in AS and can serve as marker of inflammation in early disease. Treatment reduces the TNC levels, probably due to control of disease activity.

## **Diagnostic Value of Anti-CD74 Antibodies in Early Axial Spondyloarthritis: Data from the Spondyloarthritis Caught Early (SPACE) Cohort**

**Janneke de Winter**<sup>1</sup>, Marleen van de Sande<sup>1</sup>, Niklas Thomas Baerlecken<sup>2</sup>, Inger Berg<sup>3</sup>, Roberta Ramonda<sup>4</sup>, Désirée van der Heijde<sup>5</sup>, Floris van Gaalen<sup>6</sup>, Torsten Witte<sup>7</sup> and Dominique Baeten<sup>1,8</sup>, <sup>1</sup>Clinical Immunology and Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, <sup>2</sup>Rheumatology, Private Practice, Cologne, Germany, <sup>3</sup>Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, <sup>4</sup>Rheumatology Unit, Department of Medicine DIMED, University of Padova, Padova, Italy, <sup>5</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>6</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>7</sup>Clinical Immunology and Rheumatology, Medical University Hannover, Hanover, Germany, <sup>8</sup>UCB Pharma, Slough, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Anti-CD74 IgG antibodies are reported to be elevated in serum of patients with axial spondyloarthritis (axSpA). This study aimed to assess the diagnostic value of anti-CD74 antibodies to discriminate between early axSpA and non-SpA in early back pain patients.

### **Methods:**

Using ELISA, we first confirmed the elevation of anti-CD74 IgG and IgA serum antibodies in patients with radiographic axSpA (ankylosing spondyloarthritis, (AS)) (n=138) when compared to healthy controls (n=57). Next, we tested their diagnostic value in patients with early axSpA (n=274) and non-SpA back pain controls (n=319) from the SPondyloArthritis Caught Early (SPACE) cohort.

### **Results:**

Median anti-CD74 IgG antibodies (OD) were higher in AS patients than in healthy controls (0.70 vs. 0.51,  $p<0.0001$ ) and present in 79.7% of AS patients vs. 43.9% of healthy controls ( $p<0.0001$ ). Anti-CD74 IgG antibody levels (OD) did not differ between axSpA patients and non-SpA back pain controls (0.50 vs. 0.52,  $p=0.152$ ) and were present in 46.4% of the axSpA patients vs. 47.9% of the non-SpA back pain controls ( $p=0.713$ ). Median anti-CD74 IgA antibodies (OD) were higher in AS patients than in healthy controls (0.31 vs. 0.20,  $p<0.0001$ ) and present in 28.5% of AS patients vs. 5.3% of healthy controls ( $p<0.0001$ ). In the SPACE cohort, anti-CD74 IgA antibodies (U/mL) were higher in axSpA patients than in non-SpA back pain controls (19.92 vs. 14.02,  $p<0.0001$ ) and present in 54.7% vs. 37.0% of the axSpA patients vs. non-SpA back pain controls ( $p<0.0001$ ), respectively. This resulted in a PPV of 58.8% and a NPV of 59.1%. In a multivariate logistic regression model including anti-CD74 IgA and total serum IgA, total serum IgA was associated with a diagnosis of axSpA (Exp(B) 1.19,  $p<0.0001$ ) whereas anti-CD74 IgA was not (Exp(B) 1.01,  $p=0.332$ ).

### **Conclusion:**

Anti-CD74 IgG and anti-CD74 IgA were elevated in AS versus healthy controls. Only anti-CD74 IgA is elevated in patients with early axSpA versus chronic back pain controls of the SPACE cohort. In the SPACE cohort, these differences disappear in a multivariate analysis with total IgA levels and have limited diagnostic value in these early back pain patients. Other biomarker or biological features of anti-CD74 IgA, including prediction/contribution to radiographic progression, should be investigated.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** A newly developed scoring method for low dose CT (ldCT) of the whole spine, CT Syndesmophyte Score (CTSS), has shown good inter-reader reliability and sensitivity to detect changes in bone formation over 2 years in Ankylosing Spondylitis (AS) patients<sup>1</sup>. Next step in validation is the comparison of assessment of bone formation on ldCT with conventional radiographs (CR).

**Methods :** Patients from the Sensitive Imaging in Ankylosing Spondylitis cohort were analysed. Inclusion criteria: mNY-criteria+, <sup>3</sup>1 syndesmophyte on cervical/lumbar spine CR and <sub>1</sub> inflammatory lesions on MRI-spine. Patients had baseline and two-year CR of the lateral cervical and lumbar spine and whole spine ldCT (approximately 4mSV). Two readers independently assessed CR and ldCT in separate sessions. Images were paired per patient, blinded to time order, patient information, and results of the other imaging technique. CR was assessed using mSASSS. On ldCT, syndesmophytes were scored in coronal and sagittal planes, assessing eight quadrants per vertebral unit (VU). Scores for syndesmophytes according to the CTSS were: absent=0, <50% of intervertebral disc height (IVDH)=1, ≥50% of IVDH=2 or IVDH bridging=3. Formation of new syndesmophytes (CR score 0/1~2/3, CTSS 0~1/2/3) and growth of existing syndesmophytes (CR score 2~3, CTSS 1~2/3, or ≥3) and the combination of new or growing syndesmophytes was calculated per corner/quadrant. Consensus about each outcome was defined by agreement of readers on the same corner/quadrant. The number of syndesmophytes on CR and CT was compared by level. Level 1: upper four quadrants of a VU on ldCT and upper corner on CR. Level 2: lower four quadrants on ldCT and lower corner on CR. Data of CR and ldCT was compared per reader and for the consensus score.

**Results :** Fifty patients (mean age 50 years; 84% male; 86% HLA-B27+) were included in the analysis. In all comparisons, ldCT detected more patients with progression (table 1). This is especially apparent in case of growth and for cut-offs of a higher number of syndesmophytes per patient. E.g. using the consensus score, 30% of the patients showed bony proliferation (new or growing syndesmophytes) at <sup>3</sup>3 sites on ldCT compared with only 6% on CR. ldCT detected more syndesmophytes in all sections of the spine, with most syndesmophytes occurring in the thoracic spine (figure 1).

**Conclusion :** Whole spine ldCT is more sensitive in assessing the formation and growth of syndesmophytes than CR, which is limited to cervical and lumbar spine and is a promising method of assessment for clinical research of AS.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Metrology indices aimed at assessing spinal mobility in ankylosing spondylitis (AS) patients are used in clinical trials and clinical practice to assess disease severity and progression. The purpose of this study was to examine the association between changes in spinal mobility and radiographic disease in AS patients enrolled in a longitudinal outcome study.

## Methods:

AS patients meeting modified New York Criteria with at least 2 sets of radiographs for assessment of modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) spaced at least two years apart were included. Spinal mobility measurements conducted over the same interval as the sets of radiographs included occiput-to-wall distance, cervical rotation, cervical lateral bending, Schober's and lateral lumbar bending (mean number of sets of mobility measurements per patient, 2.7±0.9). Because some patients had cervical spine films not visualizing the lower segments, the cervical and lumbar spine assessments were analyzed separately. Visits were categorized into 3 groups based on changes of their metrology between visits: improving, worsening or no change in spinal mobility. Longitudinal multivariable negative binomial regression analyses using generalized estimating equation accounting for the correlation of repeated measures over time were conducted to assess associations between each of the respective spinal mobility indices and mSASSS progression. We adjusted each analysis for baseline mSASSS, study sites and clinical/demographic variables (gender, education, disease duration, current smoking status, longitudinal Bath Ankylosing Spondylitis Disease Activity scores, baseline CRP levels, and Patient Global Assessment).

## Results:

523 patients met these criteria for the cervical spine analyses and 548 for the lumbar spine analyses. The median patient follow up time was 4.08 years (IQR= [2.17, 6.58]) for the cervical spinal and 4.17 years (IQR= [2.17, 6.67]) for the lumbar spinal measurements. Data summarized in Based on multivariable models, increases in occiput to wall distance were significantly associated with increased cervical mSASSS scores compared to no change (adjusted rate ratio (RR) =1.95; p=0.02) and no change in occiput to wall distance was negatively associated with increasing mSASSS compared to decreased occiput to wall distance (adjusted RR= 0.49; p<0.01). Despite a weak trend, no significant differences were noted when comparing positive vs. negative change in lateral cervical bending, cervical rotation, Schober or lateral lumbar bending assessments and changes in the mSASSS.

## Conclusion:

Significant associations were observed between longitudinal changes in occiput to wall and mSASSS scores but not between cervical (lateral cervical bending, cervical rotation measures) or lumbar spinal mobility measures (Schober's, lateral lumbar bending). The occiput-to-wall analysis suggested any change of this measure, positive or negative, was associated with radiographic progression. This suggests that *concomitant* cervical and lumbar metrology and radiographic disease changes may be measuring different structural phenomena.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The factors associated with “Bamboo spine” occurrence, i.e. the most severe axial phenotype of SpA patients, have been poorly assessed to date. The aim of this study was to clarify the factors associated with the severe type of AS “Bamboo spine” by investigating associations with various demographics, clinical and functional outcomes.

**Methods:** 275 patients with Bamboo spine enrolled by ASAS-COMOSPA study (Cross-sectional international study involving 22 countries and including 3984 SpA patients fulfilling the ASAS SpA criteria) were included in the analysis. Demographic, Clinical, and biological characteristics were compared between Bamboo-spine and non-Bamboo spine patients. Variables with significant difference in univariate analyses were used as dependent variables in multivariable and logistic regression. A logistic regression was used for the analysis to clarify the parameters associated with the Bamboo spine phenotype. Independent variables with a p value less than 0.2 in univariate linear/logistic regression analysis were tested in multivariate regression models. Odds ratio (ORs) with 95% CIs were calculated.

**Results:** Results of the univariate analysis are provided in the table. Multivariate analysis showed that Bamboo spine phenotype was independently associated with NSAIDs intake from first symptom (OR 4.29; 95% CI 1.45-12.71 P<0.02), male gender (OR 4.09; 95% CI 2.37-7.05; P<0.02), HLA-B27 positivity (OR 2.26; 95% CI 1.34-3.83; P<0.02), increased CRP (OR 1.76; 95% CI 1.20-2.60; P<0.02), osteoporosis (OR 1.52; 95% CI 0.99-2.34; P=0.05), with only a trend for smoking (OR 1.38, 95% CI 0.97-1.98; P=0.07).

**Conclusion:** The results of this study confirm parameters that have been previously associated with axial structural severity (longer disease duration, uveitis, smoking, HLA-B27 and male gender). NSAIDs have been reported to have a potential protective effect on the structural progression of the disease. Nevertheless, in this cross sectional study, NSAIDs intake from the first symptoms was associated with the Bamboo spine phenotype, suggesting that severe axial involvement leads to a sustained NSAIDs intake for pain relief. This also suggest that patients evolving to a bamboo spine phenotype have not been under-exposed to NSAIDs treatment and/or that NSAIDs sustained exposure is not sufficient to protect from Bamboo spine phenotype.

# Frequencies of Ligament Ossification in Patients with Ankylosing Spondylitis According to Several Ligaments Around Spine By Whole Spine CT Scan

**Ran Song**<sup>1</sup>, Ji-Young Choi<sup>2</sup>, Yeon-Ah Lee<sup>2</sup>, Seung-Jae Hong<sup>2</sup>, Hyung-In Yang<sup>3</sup> and Sang-Hoon Lee<sup>1</sup>, <sup>1</sup>Rheumatology, Kyung Hee University Hospital at Gang dong, Seoul, Korea, Republic of (South), <sup>2</sup>Rheumatology, Kyung Hee University Hospital, Seoul, Korea, Republic of (South), <sup>3</sup>Kyung Hee University Hospital at Gang dong, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Ankylosing spondylitis is chronic inflammatory arthritis with ligament ossification in spine such as ant. longitudinal ligaments, post. longitudinal ligaments, or other several ligaments around spine joints. We generally use mSASSS to evaluate progression of ossification which method only calculate amount of ossification in ant. longitudinal ligament. But there has not been known which ligaments are ossified most commonly.

We performed whole spine CT scan in patients with ankylosing spondylitis to analyze the frequency of ligaments ossification according to the sites of spine.

## Methods:

This is a retrospective chart review study. We enrolled the patients who were diagnosed as ankylosing spondylitis by modified NY criteria in our hospital. Among these patients, we analyzed the male patients who had been performed by whole spine CT scans in ages between 40 and 45. Total 119 patients were enrolled. We analyzed the frequency of ossification in ant. longitudinal ligaments, post. longitudinal ligaments, ligamentum flavum, ligaments around facet joints, interspinous ligaments, supraspinus ligaments and annulus fibrosus according to C, T and L spine.

## Results:

The most frequent ossification site was lateral side of annulus fibrosus in T spine (68.9%). Even regardless of C, T, L spine, ossification of lateral side in annulus fibrosus was also the most frequent site (157 sites). Second common ligaments ossified were ant. longitudinal ligaments (142 sites) and third common ligaments were ligaments around facet joints (109 sites). According to spine, the ligaments of T spine were the most common ligaments ossified (252). The ligaments in L spine were second common ligaments ossified (177). Interestingly ossification in the ligaments around L spine did not developed, but developed in T spine in 27 patients (22.7%). This is very important finding because ossification in the ligaments around T spine is not included in mSASSS method which method is used to evaluate disease progression in ankylosing spondylitis at present. Ossification in ant. longitudinal ligaments was strongly statistically correlated with ossification in ligaments around facet joints in L spine strongly ( $p=0.00$ .  $r=0.547$ ).

## Conclusion:

Ligaments around T spine were most commonly ossified in ankylosing spondylitis and we need to find new method to evaluate of ossification in T spine.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The appropriate use of imaging-based scoring instruments is usually an ad hoc process based on passive learning from published manuscripts. Moreover, most instruments lack knowledge transfer tools that would facilitate attainment of pre-specified performance targets for reader reliability prior to use in clinical trials and research. We aimed to develop and validate online calibration modules for the SPARCC MRI Scores based on consensus scores from these instrument developers, experiential game psychology, and real-time iterative feedback built into a scoring schematic directly on the DICOM image.

**Methods:** The SPARCC BME inflammation calibration module is comprised of 50 DICOM cases, each with scans from baseline and 12 weeks after the start of tumor necrosis factor inhibitor therapy. The SPARCC structural score is comprised of 40 cases, each with scans from baseline and after 2 years follow-up. Scans are scored in pairs for status and change scores blinded-to-time-point. Continuous visual real-time feedback regarding concordance/discordance of scoring per SIJ quadrant with expert readers is provided by a color-coding scheme. Reliability is additionally assessed by real-time intra-class correlation coefficient with the first ICC data being provided after 20 cases per SIJ coronal slice (calibration-per-slice), and further ICC data after the entire case has been scored (calibration-per-case). Accreditation for SPARCC BME is achieved with a status score ICC of > 0.8 and a change score ICC of > 0.7, and for SPARCC structural, status score ICC of >0.7 is required for fat and ankylosis, >0.5 for erosion and backfill, and >0.5 for change score in all domains. 14 readers scored the SPARCC BME module and 11 the SPARCC structural module, only 2 having prior experience with these scores, and 9 being rheumatology fellows.

**Results:** For the SPARCC BME score and the calibration-per-slice method, all 14 readers completed the scoring and attained the required level of proficiency. For the SPARCC structural scores and the calibration-per-slice method, all 11 readers completed scoring, proficiency for status was attained by 10 for each lesion domain, and proficiency for change

was attained by 11, 5, 6, 8 for fat, erosion, backfill, ankylosis, respectively. All readers rated the modules as easy and intuitive with average time for reading each case for SPARCC BME and Structural being 9 min and 12 min, respectively.

**Conclusion:** Experiential online learning is an effective and feasible calibration tool in the scoring of MRI scans.

SPARCC score	Calibration per SIJ Slice			Calibration per Case

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** At the SI joint (SIJ) level, several methods exist for evaluating structural damage, e.g., MRI, CT scan, radiographs. In EMBARK (NCT01258738) and DESIR (NCT01648907), MRI and radiographs were available at baseline and Week 104. We evaluated: (1) the association between presence/absence of erosion on MRI and presence/absence of erosion or sacroiliitis on radiographs at the SIJ at baseline and Week 104, and (2) the association

between decrease/increase in erosion on MRI and decrease/increase in erosion or sacroiliitis on radiographs at the SIJ between baseline and Week 104.

**Methods:** Patients in both studies had early axial SpA (axSpA). EMBARK included a 12-week double-blind placebo-controlled period, then open-label etanercept for 92 weeks. DESIR patients had no history of biologic therapy and did not receive biologics for 2 years. MRI and radiographs of the SIJ from DESIR and EMBARK were combined and anonymized; readers were unaware of film chronology and original patient cohort. Three experienced readers evaluated T1 weighted MRI images using the SpondyloArthritis Research Consortium of Canada (SPARCC) SIJ Structural Score (SSS), graded radiographic sacroiliitis using the modified New York grading system, and recorded the presence/absence of individual radiographic lesions (erosion, sclerosis, ankylosis) for each SIJ. Presence/absence of lesions at each time point and decrease/increase in lesions was identified for each patient based on agreement of 2 out of 3 readers. Statistical analyses included kappa coefficient of agreement and McNemar's test for asymmetry.

**Results:** 224 patients had MRI and radiographs available. At baseline, concordance for presence or absence of erosion was observed in 162/224 (72.3%) ( $\kappa=0.42$ ) (Table). In cases of discordance, erosion was more frequent on MRI (21.4%) than radiographs (6.3%;  $P<0.0001$ ). Week 104 data were similar to baseline. Decrease in erosion from baseline to 104 weeks was more frequent than increase only when assessed by MRI, and was significantly more frequent on MRI than radiographs. Similarly, decrease in erosion on MRI was significantly more frequent than decrease in sacroiliitis grade.

**Conclusion:** In patients with early axSpA, erosion was present more often on MRI than on radiographs at baseline and Week 104. Decrease in erosion at Week 104 was noted more frequently on MRI than radiographs.

Table. Concordance between MRI and radiographs; baseline, Week 104, and change between baseline and Week 104

	N	Present / Present	Absent / Absent	Absent / Present	Present / Absent	Kappa (95% CI)	P-value for discordance asymmetry*

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** only scarce data are available regarding the prevalence of MRI inflammatory lesions of the sacroiliac joints (SIJ) or the spine suggestive of axial Spondyloarthritis (axSpA) in patients with recent onset mechanical chronic back pain (CBP). The aim of this study was to evaluate the prevalence of MRI (SIJ, Spine) inflammatory lesions suggestive of axSpA in a non-axSpA CBP population and to compare its prevalence to an recent onset axSpA cohort.

### **Methods:**

*Patients:* a) Recent onset axSpA patients: first, a sample of 100 patients representative in terms of imaging abnormalities of the global DESIR<sup>(1)</sup> recent onset axSpA cohort (> 3 months but <3 years), based on the results of the previously published central reading of baseline films of DESIR<sup>(2)</sup> were selected (e.g. 35% of patients fulfilling the ASAS definition of MRI sacroiliitis). b) Recent onset CBP patients: consecutive in- and outpatients consulting for recent (>3months but <5years) mechanical CBP, initiating before the age of 45y and with a maximum age of 50y, in four tertiary care Hospitals were included in the study. Imaging: MRI scans (T2-STIR and T1 sequences) of the SIJ and full spine were performed in both groups with identical protocol. Central reading: an experienced reader (AM) centrally read all MRI scans, blinded for

clinical diagnosis. Statistical analysis: prevalence of MRI inflammatory lesions suggestive of axSpA were compared in both groups. Sensitivity, specificity and positive likelihood ratio of each lesion were calculated.

## Results:

A total of 98 patients with recent onset CBP were included, and compared to 100 recent onset axSpA patients. Age and gender were comparable (mean(SD) 36.2(9.9) vs. 32.2(8.7)y, and 41.8% and 45% males, in the CBP vs. axSpA groups, respectively). MRI inflammatory lesions of the SIJ were quite frequent in the CBP group (25% patients with at least one inflammatory lesion) but were significantly more frequently observed in the axSpA group (Table), with a mean SIJ - SPARCC score of 4.9 (8.8) vs. 0.6 (1.3),  $p<0.001$ . The ASAS definition of MRI sacroiliitis presented a high specificity and a good positive likelihood ratio. Conversely, prevalence of inflammatory lesions of the spine was very frequent in the CBP group and not significantly lower compared to the axSpA group (SPARCC spine 5.6 (13.5) vs. 3.3(5.8), in the axSpA vs. CBP groups, respectively). Regardless the definition of a positive MRI for the spine applied, performances were not good, with positive likelihoods ratios below 2.

		CBP	SpA		p	Sensitivity	Specificity	LR+
		N=98	N=100					
SIJ-MRI	At least one inflammatory lesion of the SIJ	24 (25.3%) n=95	40 (40.0%)		0.028	0.4 (0.3, 0.5)	0.8 (0.7, 0.8)	1.6 (1.0, 2.4)
	ASAS definition of positive MRI sacroiliitis	8 (8.4%) n=95	35 (35.0%)		<0.001	0.4 (0.3, 0.5)	0.9 (0.8, 0.9)	4.2 (2.0, 8.5)
	At least one inflammatory lesions of the spine	44 (44.9%) n=99	52 (52.5%)		NS	0.5 (0.4, 0.6)	0.6 (0.5, 0.7)	1.2 (0.9, 1.6)
	ASAS definition of positive MRI spine $\geq 3$ inflammatory lesions)	33 (33.7%) n=99	44 (44.4%)		NS	0.4 (0.3, 0.6)	0.7 (0.6, 0.8)	1.4 (0.9, 1.9)
Spine-MRI	SPACE (3) definition of positive MRI spine $\geq 5$ inflammatory lesions)	25 (25.5%) n=99	30 (30.3%)		NS	0.3 (0.2, 0.4)	0.7 (0.7, 0.8)	1.2 (0.8, 1.9)

## Conclusion:

ASAS definition of a positive MRI-sacroiliitis performed very well for axSpA recognition; however, definitions proposed for a positive MRI-spine suggestive of axSpA did not seem to perform adequately in this recent disease stage. This supports the idea of not including a positive MRI of the spine in the ASAS classification criteria.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** only scarce data are available regarding the prevalence of MRI structural lesions of the sacroiliac joints (SIJ) or the spine suggestive of axial Spondyloarthritis (axSpA) in patients with recent onset mechanical chronic back pain (CBP). The aim was to evaluate the prevalence of MRI (SIJ and Spine) structural lesions suggestive of axSpA in a non-axSpA CBP population and to compare its prevalence to an recent onset axSpA cohort.

### **Methods:**

*Study design:* Observational cross-sectional national multicentre study. *Patients:* a) Recent onset axSpA patients: first, a sample of 100 patients representative in terms of imaging abnormalities of the global DESIR<sup>(1)</sup> recent onset axSpA cohort (> 3 months but <3 years), based on the results of the previously published central reading of baseline films of DESIR<sup>(2)</sup> were selected (e.g. 21% of patients fulfilling the modified NY criteria (mNY)). b) Recent onset CBP patients: consecutive in- and outpatients consulting for recent (>3months but <5years) mechanical CBP, initiating before the age of 45y and with a maximum age of 50y, in four tertiary care Hospitals were included in the study. *Imaging:* MRI scans (T2-STIR and T1 sequences) of the SIJ and cervico-thoracic and thoraco-lumbar spine were performed in both groups with identical protocol. *Central reading:* an experienced reader (AM) centrally read all MRI scans, blinded for clinical diagnosis. *Statistical analysis:* prevalence of lesions and lesions combinations previously proposed<sup>(3)</sup> to be suggestive of axSpA was compared in both groups. Sensitivity, specificity and positive likelihood ratio (LR+) of each lesion were calculated.

### **Results:**

**Results:** A total of 98 patients with recent onset CBP were included, and compared to 100 recent onset axSpA patients. Age and gender were comparable (mean (SD) 36.2 (9.9) vs. 32.2 (8.7)y, and 41.8% and 45% males, in the CBP vs. axSpA groups, respectively). Prevalence of chronic lesions of the SIJ was significantly greater in the axSpA group but up to 17% patients with CBP presented at least one chronic lesion of the SIJ (Table). The presence of at least 3 subchondral bone erosions at the SIJ performed the best for axSpA discrimination. Prevalence of chronic lesions of the spine was comparable

in the two groups, with high prevalence of fatty lesions across groups; erosions were rare in both groups. The presence of at least 5 fatty lesions was the most discriminant, with a high specificity. Performances of all other structural lesions of the spine were poor.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** only very scarce data is available regarding the prevalence of spine Xrays abnormalities suggestive of axial Spondyloarthritis (axSpA) in patients with recent onset mechanical chronic back pain (CBP).

**Objective:** To evaluate the frequency of spine X-ray abnormalities suggestive of axSpA in a non-axSpA CBP population and to compare its prevalence to an recent onset axSpA cohort.

### **Methods:**

**Methods :** *Study design:* Observational cross-sectional national multicentre study. *Patients:* a) Recent onset axSpA patients: first, a sample of 100 patients representative in terms of imaging abnormalities of the global DESIR <sup>(1)</sup> recent onset axSpA cohort (> 3 months but <3 years), based on the results of the previously published central reading of baseline films of DESIR<sup>(2)</sup> were selected (e.g. 21% of patients fulfilling the modified NY criteria (mNY)). b) Recent onset CBP patients: consecutive in- and outpatients consulting for recent (>3months but <5years) mechanical CBP, initiating before the age of 45y and with a maximum age of 50y, in four tertiary care Hospitals were included in the study. *Imaging:* Full spine Xrays were performed in both groups with an identical protocol. *Central reading:* an experienced reader (AM) centrally read X-ray films, blinded for clinical diagnosis. *Statistical analysis:* Number of lesions suggestive of axSpA were compared in both groups.

**Results:** A total of 98 patients with recent onset CBP were included, and compared to 100 recent onset axSpA patients. Age and gender were comparable (mean (SD) 36.2 (9.9) vs. 32.2 (8.7)y, and 41.8% and 45% males, in the CBP vs. axSpA

groups, respectively). Prevalence of spine lesions was globally very low, and only squaring was significantly more frequent in the axSpA group.

	<b>CBP (N=95)</b>	<b>SpA (N=100)</b>	<b>p</b>
<b>Number of erosions</b>	0.4 (0.8)	0.3 (0.5)	NS
<b>Number of sclerosis lesions</b>	0.4 (1.6)	0.5 (1.4)	NS
<b>Number of squaring lesions</b>	0.01 (0.1)	0.2 (0.8)	0.037
<b>mSASSS*</b>	2.0 (14.5) n=89	2.2 (15.1) n=91	NS
<b>Number of patients with at least one full bone bridge</b>	2 (2.1%)	5 (5.0%)	NS

\*exclusion of patients with more than 75% missing corners per section (cervical and lumbar)

**Conclusion:** Lesions suggestive of axSpA in spine Xrays of patients with CBP are rare; however, even in this recent onset disease patients, squaring lesions were significantly more frequent in the recent onset axSpA patients.

Landewé<sup>3</sup>, Maxime Dougados<sup>4</sup> and Désirée van der Heijde<sup>1</sup>, <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Rheumatology, Department of Rheumatology, LUMC, Leiden, Netherlands, Leiden, Netherlands, <sup>3</sup>University of Amsterdam and Atrium Medical Center, Amsterdam, Netherlands, <sup>4</sup>Paris-Descartes University,, Paris, France

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The effect of local inflammation on structural damage in patients (pts) with axial spondyloarthritis is not well known. We aimed to test the possible effect of inflammation on structural damage both assessed by MRI and at

the level of the spine and SIJ.

**Methods:** Pts with recent onset ( $\leq 3$  years) axSpA (according to the treating rheumatologist) from the DESIR cohort were included. MRI of the SIJ (MRI-SIJ) and spine (MRI-spine) were obtained at baseline (BL), 2 and 5 years and scored by 3 trained central readers. Bone Marrow Edema (BME) at MRI-SIJ was assessed according to ASAS definition and at the MRI-spine by the presence of  $\geq 3$  lesions. Structural damage in the SIJ (MRI-SIJ-STR) and in the spine (MRI-spine-STR) was defined by  $\geq 3$  fatty lesions. The % of structural net progression (number of ‘progressors’ minus the number of ‘regressors’ divided by total number of pts) was assessed according to CRP and BME status at BL. The effect of BME on MRI-SIJ on MRI-SIJ-STR and of BME on MRI-spine on MRI-spine-STR was evaluated using two types of binomial generalized estimating equations (GEE) models: i. effect at BL on 5 years incorporating measurements from all readers (GEE adjusted for reader); ii. effect of BME over 5 years (longitudinal time-lagged models with auto-regression). The final models were adjusted for variables proved to confound the association of interest (variables tested: age, gender, HLA-B27, smoking status, CRP, BASDAI, ASDAS, treatment with NSAIDs and TNFi).

**Results:** In total, 151 and 145 pts had complete 5-year MRI-SIJ and MRI-spine data available from 3 readers, respectively. Of the 151 pts with complete MRI-SIJ data, the net % pts who switched from MRI-SIJ-STR negative to positive ranged from 3.8% to 24% according to the presence of objective signs of inflammation at BL (figure). Low number of pts did not allow for similar analysis in the spine. In the multivariable analysis, both the presence of BME at MRI-SIJ (OR=4.2 [95% CI: 2.4-7.3]), and BME at MRI-spine (OR=8.9 [95% CI: 2.1-38.7]) at baseline were highly predictive of MRI-SIJ and MRI-spine structural progression respectively 5 years later, adjusting for CRP (only factor found to confound the association of interest). Similar positive associations were found in the longitudinal models testing the effect of BME on MRI-SIJ-STR and MRI-spine-STR over 5 years (table).

**Conclusion:** Our results show that local inflammation is strongly associated with the development of structural damage over 5 years both in the SIJ and spine in early axSpA and that this effect is independent of systemic inflammation.

**Figure.** Net progression from MRI-SIJ-STR negative to MRI-SIJ-STR positive ( $\geq 3$  fatty lesions) according to baseline objective inflammatory markers.

**Table.** Effect of inflammation on MRI (ASAS definition of sacroiliitis and BME in the spine) on binary MRI structural outcomes.

	$\geq 3$ fatty lesions on MRI-SIJ	$\geq 3$ fatty lesions on MRI-Spine
Effect of BMI on:	OR (95% CI) (N=144-197)	OR (95% CI) (N=145-197)
By GEE adjusted for reader	4.2 (2.4; 7.3)*	8.9 (2.1; 38.7)*
By longitudinal GEE adjusted for reader and repeated measurements	5.1 (2.7; 9.6)£	15.6 (4.8; 50.3)£

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several imaging outcomes have become available to assess inflammation and structural damage over time in patients with axial spondyloarthritis (axSpA). However, no formal comparison of their sensitivity to change has been made in the early phases of the disease. We aimed to compare the sensitivity to change of different MRI and radiographic scoring methods in patients with early axSpA.

**Methods:** Patients from the DESIR cohort fulfilling the ASAS axSpA criteria were included. Radiographs and MRI of the sacroiliac joints and spine were obtained at baseline, 1 year, 2 years and 5 years. Each film was scored by 2 or 3 readers in 3 ‘reading-waves’ (wave 1: baseline; wave 2: baseline, 1 year, 2 years; wave 3: baseline, 2 years, 5 years). Outcomes measuring inflammation and structural damage both on MRI and radiographs in the spine and SIJ were assessed (Table). The analysis of change captured over time was performed using generalized estimating equations (GEE) longitudinal models separately for each outcome, taking into account data from all readers and waves (‘integrated analysis’). To allow comparisons across outcomes, these were standardized (difference between the individual score and the mean of all scores divided by the standard deviation, per reader, wave and time-point) before running the models. The higher the standardized coefficient the more change in inflammation/damage is captured.

**Results:** In total, 345 patients were included (mean (SD) symptom duration: 1.6 (0.9) years; 53% males; 89% HLA-B27 positive). Inflammation on MRI-SIJ (according to both the ASAS definition of sacroiliitis and the continuous SPARCC score) was more sensitive to change as compared to inflammation on the spine that remained essentially unchanged regardless of the outcome (table). Structural damage on the SIJ was found to increase over time, but with a higher standardized yearly rate of change on MRI-SIJ (range: 0.015-0.274) as compared to X-SIJ (range: 0.043-0.126). Notably,  $\geq 3$  Fatty lesions on MRI-SIJ was the structural outcome in the SIJ with highest sensitive to change (0.274), while  $\geq 3$  erosions was the least sensitive (0.015). Spine structural damage slowly progressed over time but, in contrast to SIJ, radiographic outcomes (i.e.  $\geq 1$  syndesmophytes and mSASSS) were more sensitive to change than MRI structural outcomes.

**Conclusion:** Our data adds to the body of evidence showing that structural damage assessed in pelvic radiographs only has low sensitivity to change. MRI-SIJ is a promising alternative (especially fatty lesions) capturing more structural changes. In contrast, in detecting structural change in early axSpA radiographic outcomes outperform MRI outcomes.

**Table.** Standardized rate of change of imaging outcomes over 5 years of follow-up in early axSpA patients from the DESIR-cohort who fulfil the ASAS axSpA classification criteria.

## Progression of Structural Damage on MRI in Patients with Axial Spondyloarthritis Is Limited: The 5 –Year Results in the DESIR Cohort

Alexandre Sepriano<sup>1</sup>, Sofia Ramiro<sup>2</sup>, Robert B.M. Landewé<sup>3</sup>, Maxime Dougados<sup>4</sup> and Désirée van der Heijde<sup>1</sup>, <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Rheumatology, Department of Rheumatology, LUMC, Leiden, Netherlands, Leiden, Netherlands, <sup>3</sup>University of Amsterdam and Atrium Medical Center, Amsterdam, Netherlands, <sup>4</sup>Paris-Descartes University,, Paris, France

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Reliably detecting radiographic structural change in patients with axial spondyloarthritis (axSpA), especially in the sacroiliac joints (SIJ), is notoriously difficult. Magnetic resonance imaging (MRI) is an alternative for radiographs to assess structural damage. However, so far the utility of MRI in capturing change in structural damage over time has been poorly studied. We aimed to evaluate the change over time of structural lesions on MRI of the SIJ and spine in patients with axSpA.

**Methods:** Patients with recent onset ( $\leq 3$  years) axSpA (according to the treating rheumatologist) from the DESIR cohort were included. MRI of the SIJ (MRI-SIJ) and spine (MRI-spine) were obtained at baseline and 5 years and scored by 3 trained central readers unaware of their chronology. Structural damage in the SIJ (MRI-SIJ-STR) and in the spine (MRI-spine-STR) was defined according to 3 binary rules (A1:  $\geq 5$  fatty lesions and / or erosions; B1:  $\geq 3$  erosions; and C1:  $\geq 3$  fatty lesions) and 3 continuous scores (A2: number of fatty lesions /erosions; B2: number of erosions; and C2: number of fatty lesions). For binary outcomes, structural damage was defined by the agreement of at least 2 out of 3 readers and the % of net progression by subtracting the number of patients that ‘improved’ from those that ‘worsened’ divided by the total number of patients with complete baseline and 5-year data. For continuous outcomes, the mean of the 3 readers was used and the difference between year 5 and baseline was calculated.

**Results:** In total, 151 and 145 patients had complete MRI-SIJ and MRI-spine data available from 3 readers, respectively. The percentages of net progression at SIJ level are summarized in the figure. These were 6.6%, 0.7% and 7.9% for the binary outcomes A1, B1 and C1 respectively. Notably, the percentage of ‘improvement’ (4.6%) was almost as high as the percentage of ‘worsening’ (5.3%) for definition B1 ( $\geq 3$  erosions); while no ‘improvements’ were seen by the 3 readers for definition C1 ( $\geq 3$  fatty lesions). Similar differences were seen for the mean (standard deviation) change of the 3 MRI-SIJ-STR continuous outcomes (A2: 1.02 (2.60); B2: 0.20 (1.39); and C2: 0.83 (2.20);  $p < 0.01$  for all). MRI-spine-STR net change over time was almost absent (A1: -0.7%; B1: 0.0%; C1: 0.7%) considering the binary outcomes, and small (though statistically significant) considering definition A2 (0.18 (0.52);  $p < 0.01$ ) and C2 (0.14 (0.48);  $p < 0.01$ ) but absent for definition B2 (0.03 (0.24);  $p = 0.109$ ).

**Conclusion:** These results suggest that patients with early axSpA only show modest structural progression in the MRI of the SIJ and that fatty lesions are more sensitive to change compared to erosions. In this early axSpA population, MRI-detected structural progression in the spine is very limited/absent.

**Figure.** Changes in different binary MRI-SIJ-STR outcome measures. All outcomes are assessed according to the ‘2 out of 3’ definition in the completers population (N=151). MRI-SIJ-STR, structural damage on magnetic resonance imaging of the sacroiliac joints.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Axial SpA has been reported in 4-16% of patients with Crohn's disease (CD). However, some plain radiograph or magnetic resonance imaging (MRI) studies in Crohn's population suggest presence of sacroiliitis in up to 40% patients. Whether axial SpA is underdiagnosed and hence undertreated is unclear, especially since it does not correlate with CD activity. This study utilizes standardized MRI SI joint (SIJ) imaging to determine prevalence of axial SpA in a cohort of CD patients and investigate its relationship with other clinical and serologic measures. In addition, we compare MRIs from our cohort of CD patients with separate cohorts of patients with known axial SpA with and without inflammatory bowel disease (IBD).

**Methods:** Adult consecutive patients meeting pathological, radiological and/or endoscopic criteria of CD and not currently on any biologic except vedolizumab, were prospectively enrolled from an IBD Clinic. Data collected included length of CD, history of joint/back pain, HLA-B27 status, BASMI, BASDAI, Harvey-Bradshaw Index (HBI) scores- a measure of CD activity, Ankylosing Spondylitis Disease Activity Score-C reactive protein (ASDAS-CRP). All patients underwent T1 and short tau inversion recovery (STIR) sequence MRI of SIJ. 3 expert readers, blinded to clinical history reviewed MRIs for presence of active and/or structural lesions globally indicative of SpA, for ASAS MRI positivity, detailed lesion scores using the SpA Research Consortium of Canada (SPARCC) SIJ inflammatory and structural scoring methods after calibration using validated modules. These images were compared to MRIs from age and sex-matched AS patients with and without IBD.

**Results:** 32 CD patients were enrolled: 76% females, 80% white, median age 36.4 years (IQR 27.2 – 49) with moderate CD activity (mean HBI  $8.8 \pm SD 4.5$ ). 56% had peripheral SpA and only 1 was HLA-B27 positive. 20 reported back pain and 14 (70%) met ASAS inflammatory back pain (IBP) criteria. Mean BASDAI, ASDAS-CRP and BASMI were higher than patients without back pain ( $p < 0.05$ ). Total of 9 SIJ MRIs (35% of all patients with back pain and 16% of those without) showed global evidence of SpA (bone marrow edema BME  $\geq 2$  and/or structural lesions) and 6 out of those were ASAS positive (presence of active inflammation/BME), including 2 asymptomatic patients. Older age (OR 1.4, 95% CI 1.04 - 1.90) and higher BASMI (OR 3.2 95% CI 1.1-9.6) were associated with MRI SpA findings. But presence of IBP, peripheral SpA, CD duration, BASDAI, ASDAS-CRP or HBI did not show association. Compared to historic cohort of AS patients with (n=23) and without (n=24) IBD, CD patients with IBP had similar BASDAI and ASDAS-CRP scores ( $p < 0.05$ ) but they had lower BME and structural lesions ( $p 0.02$  and  $< 0.001$ ) compared to IBD with and without SpA.

**Conclusion:** MRI evidence of axial SpA was 35% and 16% in our cohort of CD patients with and without back pain respectively. MRI is a valuable tool to diagnose axial SpA in CD patients with back pain, especially those who are older and has evidence of restricted spinal mobility on exam. Presence of IBP did not show association, as previously suggested, although these patients experience similar morbidity as our comparator cohort with known AS with or without IBD.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the Phase III ASTRAEA study (NCT01860976), abatacept (ABA) significantly increased ACR20 responses, alleviating musculoskeletal symptoms in patients (pts) with active psoriatic arthritis (PsA).<sup>1</sup> Here we explore the effect of ABA on pt-reported outcomes (PROs) in ASTRAEA. **Methods:** Pts were randomized (1:1) to SC ABA 125 mg weekly or placebo (PBO) for 24 weeks (W). At W16, pts without  $\geq 20\%$  improvement in joint counts escaped to open-label ABA. Adjusted mean changes from baseline to W16 (all pts) and W24 (non-escape responder analysis) in Short Form-36 (SF-36; physical and mental component summary [PCS, MCS] and individual domain scores using spidergrams), HAQ-DI, Dermatology QoL Index (DLQI), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scores were evaluated in total population (prespecified intent-to-treat analysis) and subgroups (*post hoc*) stratified by baseline CRP and prior TNF inhibitor (TNFi) use. Proportions of pts reporting improvements from baseline  $\geq$  minimal clinically important difference (MCID) in SF-36 summary ( $\geq 2.5$ ) and domains ( $\geq 5.0$ ), FACIT-F ( $\leq -4.0$ ), and HAQ-DI ( $\leq -0.35$ ), and scores  $\geq$  normative values in SF-36 summary ( $\geq 50$ ) and individual domains, FACIT-F ( $< 40$ ), and HAQ-DI ( $< 0.5$ ) at W16 were analyzed in the total population. **Results:** In the total population, numerical improvements in most PROs were reported with ABA (n=213) vs PBO (n=211) at both time points (significant for SF-36 PCS at W16, HAQ-DI at W24, and DLQI at both time points; Table). At W16 before escape, improvements in all SF-36 domains were numerically greater with ABA (significant for physical function, bodily pain, and vitality). A higher proportion of pts receiving ABA vs PBO reported improvements  $\geq$  MCID in SF-36 PCS, SF-36 MCS, SF-36 domains, FACIT-F, HAQ-DI (Figure), and DLQI (not shown) at W16. Proportion of pts reporting scores  $\geq$  normative values at W16 was higher with ABA vs PBO for SF-36 PCS, SF-36 MCS, FACIT-F, and HAQ-DI. At W24, improvements in most SF-36 domain scores accrued in responders in both groups; numerical differences favored ABA. Improvements were observed in all PROs in the ABA vs PBO group for TNFi-naïve and -exposed subpopulations at W16. Improvements in all PROs were reported with ABA in baseline CRP  $>$  upper limit of normal (ULN) vs CRP  $\leq$  ULN subpopulation at W16 (Table). Subgroup data at W24 were difficult to interpret due to lower number of pts assessed vs W16.

**Conclusion:** Abatacept treatment improved many PROs in pts with active PsA, with larger benefits in the elevated CRP subpopulation and regardless of prior TNFi exposure. 1. Mease PJ, et al. *Ann Rheum Dis* 2017 [Epub ahead of print]

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). Safety and efficacy were investigated in 2 Phase 3 randomized controlled trials (RCTs: OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]). This analysis evaluated patient-reported outcomes (PROs) in patients with active PsA in OPAL Broaden (N=422), with inadequate responses (IR) to  $\geq 1$  conventional synthetic DMARD, naïve to tumor necrosis factor inhibitors (TNFi); and in OPAL Beyond (N=394), IR to  $\geq 1$  TNFi.

**Methods:** Patients were randomized to tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO) advanced to either tofacitinib 5 or 10 mg BID at Month 3, and, in OPAL Broaden, to adalimumab 40 mg subcutaneously every 2 weeks. Based on a longitudinal model, least squares mean (LSM) changes from baseline were reported for the following: Patient Global Assessment of Disease Activity Visual Analog Scale (PtGA VAS), Pain VAS, Short Form-36 Health Survey Version 2 (SF-36v2), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Dermatology Life Quality Index (DLQI), and Ankylosing Spondylitis Quality of Life (ASQOL). Findings were reported using nominal p values without adjustments for multiple comparisons.

**Results:** Improvements in PtGA and Pain were observed as early as Week 2 (first assessment), and exceeded PBO at Month 3 with both tofacitinib doses in both RCTs ( $p \leq 0.05$  vs PBO) (Table). At Month 3, SF-36v2 Physical Component Summary (PCS), physical functioning (PF), bodily pain (BP), and vitality (VT) domains, and FACIT-F scores, exceeded PBO with both doses ( $p \leq 0.05$ ) in both trials; improvements in PCS, PF, BP, and FACIT-F exceeded minimum clinically important differences (MCID). DLQI and ASQOL scores at Month 3 exceeded PBO with both doses in both RCTs ( $p \leq 0.05$ ), and social functioning (SF) domain with both doses in OPAL Beyond and 5 mg BID in OPAL Broaden ( $p \leq 0.05$ ). PRO improvements reported in OPAL Broaden with tofacitinib were similar to adalimumab. The percentages of patients receiving both tofacitinib doses reporting changes  $\geq$  MCID at Month 3 in SF-36v2 PCS, PF, and BP domains were statistically significant in both RCTs, as were general health (GH) and mental health (MH) domains with 10 mg BID and FACIT-F with both doses in OPAL Broaden, and SF domains with both doses in OPAL Beyond and role physical (RP) with 10 mg BID.

**Conclusion:** Patients with active PsA receiving tofacitinib reported statistically greater and clinically meaningful improvements in PROs compared with PBO at Month 3 in both RCTs.

## Ixekizumab Improves Patient-Reported Outcomes through 52 Weeks in Patients with Active Psoriatic Arthritis and Previous Inadequate Response to Tumor Necrosis Factor-Inhibitors

Arthur Kavanaugh<sup>1</sup>, Helena Marzo-Ortega<sup>2</sup>, Ronald Vender<sup>3</sup>, Julie Birt<sup>4</sup>, David Adams<sup>4</sup>, Olivier Benichou<sup>4</sup>, Chen-Yen Lin<sup>4</sup> and Peter Nash<sup>5</sup>, <sup>1</sup>Medicine, University of California, San Diego, La Jolla, CA, <sup>2</sup>Department of Rheumatology, Chapel Allerton Hospital, Leeds, United Kingdom, <sup>3</sup>Dermatrics Research, Inc., Hamilton, ON, Canada, <sup>4</sup>Eli Lilly and Company, Indianapolis, IN, <sup>5</sup>University of Queensland, Brisbane, Australia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Background/Purpose:** Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets interleukin-17A. Up to 24 weeks, IXE was superior to placebo (PBO) in improving health related quality of life of patients with active psoriatic arthritis (PsA) and previous inadequate response to TNF inhibitors (TNFi) in a phase 3 trial (SPIRIT-P2; NCT02349295).<sup>1</sup> Herein, we report the Week 52 interim patient-reported outcome (PROs) findings of IXE treatment during the Extension Period (EP) of SPIRIT-P2.

**Methods:** All 363 patients entering SPIRIT-P2 had an inadequate response to or were intolerant to TNFi. During the Double-Blind Treatment Period (DBTP; Weeks 0-24), patients were randomly assigned 1:1:1 to subcutaneous administration of either 80 mg IXE every 4 weeks (Q4W; N=122) or 2 weeks (Q2W; N=123) following a 160 mg starting dose at Week 0 or PBO (N=118). Of these, 310 patients completed the DBTP and entered the EP (Weeks 24-156). Patients randomized to IXE at Week 0 continued the same dose regimen in the EP. PBO patients were re-randomized (1:1) to IXE Q4W or Q2W at Week 16 (inadequate responders) or Week 24 and received a 160 mg starting dose. At baseline and Week 52, the following PROs were assessed: Short Form-36 Health Survey (SF-36) Physical Component Summary (PCS) and Mental Component Summary (MCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS; 0-100 scale), Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP; absenteeism, presenteeism, work productivity, and activity impairment), fatigue Numeric Rating Scale (NRS; 0 [no fatigue]-10 [as bad as you can imagine] scale), and the itch NRS (0 [no itch]-10 [worst itch imaginable] scale). The fatigue NRS has not been validated. Itch NRS was assessed in patients with baseline psoriatic lesion involving  $\geq 3\%$  body surface area (BSA; N=175). All analyses were performed on the EP population. Change in PRO measures from baseline at Week 52 were summarized using descriptive statistics. Missing values were imputed by modified baseline observation carried forward.

**Results:** Mean baseline (Week 0) scores of PROs indicated that the EP population had impaired physical and mental function, quality of life, and work productivity (Table). Patients receiving IXE up to 52 weeks reported improvements in SF-36 (PCS and MCS), EQ-5D VAS, WPAI-SHP (presenteeism, work productivity, and activity impairment), and fatigue NRS (Table). For PsA patients with  $\geq 3\%$  BSA baseline psoriasis, improvements in itch NRS were observed for patients receiving IXE up to 52 weeks.

**Conclusion:** In patients with active PsA and previous inadequate response to TNF-i, IXE provided sustained improvement up to 52 weeks in all measured PROs, including physical and mental function, quality of life, work productivity, fatigue, and itch ( $\geq 3\%$  BSA psoriasis).

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the efficacy of ustekinumab (UST) by prior treatment exposure and disease duration in adult PsA patients (pts) in the Phase 3 trials PSUMMIT 1 and PSUMMIT 2.

**Methods:** Pts had active PsA ( $\geq 5$  swollen,  $\geq 5$  tender joints, CRP  $\geq 3.0$ mg/L,) for  $\geq 6$  mos despite treatment with csDMARDs and/or NSAIDs (PSUMMIT 1) or csDMARDs, NSAIDs, and/or anti-tumor necrosis factor (TNF) agents (PSUMMIT 2). In both studies, pts were randomized to SC injections of placebo (PBO) or UST 45mg or 90mg at wks 0, 4 and every 12 wks. PBO pts crossed over to UST 45mg at wk 24. At wk 16, early escape (PBO $\rightarrow$ UST45mg; UST45mg $\rightarrow$ UST90mg; UST90mg $\rightarrow$ UST90mg) was possible. Stable doses of MTX were allowed. Pooled data from both PSUMMIT 1 and 2 were analyzed. Efficacy assessments included ACR response, DAS28-CRP response, DAS28-CRP remission (score  $< 2.6$ ), changes in enthesitis (modified MASES index) and dactylitis scores, and total van der Heijde-Sharp (vdH-S) score for radiographic progression. Pts who were anti-TNF-naïve, MTX- and anti-TNF-naïve, all csDMARD- and anti-TNF-naïve were evaluated. ACR response at wks 4 and 16 to assess for early efficacy was also evaluated for anti-TNF-naïve pts with PsA duration  $< 1$  year,  $\geq 1$  to  $< 3$  years, and  $\geq 3$  years.

**Results:** In the pooled data, 747 pts were anti-TNF-naïve (53.8% were male; mean age=47 years); 179 pts were MTX- and anti-TNF-naïve (63.7% were male; mean age =47 years); 146 pts were all csDMARD- and anti-TNF-naïve (61.0% male; mean age=46 years). In all three prior treatment populations, significantly greater proportions of pts in the combined UST group vs PBO achieved an ACR20, ACR50, or ACR70 at wk 24. (Table). Similarly, greater proportions of pts in the combined UST group had DAS28-CRP response or remission vs PBO across all three prior treatment populations. In anti-TNF-naïve pts, improvements in enthesitis and dactylitis were significantly greater in the combined UST group vs PBO, and mean change in total vdH-S score was significantly greater for pts in the PBO group than the combined UST group; comparable trends were observed for the MTX- and anti-TNF-naïve pts and all csDMARD- and anti-TNF-naïve pts, but did not reach statistical significance due to the smaller sample sizes in both subgroups. Among anti-TNF-naïve pts treated with UST, ACR20/50/70 response rates were similar across different PsA disease duration groups at early time-points (either wk 4 or wk 16).

**Conclusion:** UST-treated patients had greater improvements in signs and symptoms of PsA regardless of prior treatment exposure and disease duration.

**Table. Efficacy at week 24 in PSUMMIT 1 and PSUMMIT 2 combined.**

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The GO-VIBRANT study was designed to evaluate the safety and efficacy of intravenous (IV) golimumab (GLM) in adult patients (pts) with active PsA (biologic-naïve).

**Methods:** GO-VIBRANT is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled trial. Biologic-naïve active PsA pts were randomized (1:1) to IV GLM 2mg/kg at weeks (wk) 0, 4, and every 8 wks thereafter or PBO at wks 0, 4, 12, and 20 with crossover to GLM at wk24. The primary endpoint was ACR20 response at wk14. Multiplicity-controlled endpoints included ACR50, ACR70, PASI 75, change from baseline in HAQ-DI, enthesitis, dactylitis; and ACR50 and change from baseline in total modified vdH-S (structural damage) score at wk24. Efficacy analyses were based on randomized treatment. Adverse events (AE) through wk24 are reported here.

**Results:** 480 pts were randomized (PBO: 239; GLM: 241). The study met its primary and all controlled secondary endpoints. At wk14, significantly greater proportions of GLM pts vs PBO achieved ACR20 (75.1% vs. 21.8%). Also, GLM treatment resulted in significant change from baseline HAQ-DI score (-0.60 vs. -0.12), ACR50 (43.6% vs. 6.3%), PASI 75 (59.2% vs. 13.6%), ACR70 (24.5% vs. 2.1%), and change from baseline in enthesitis and dactylitis scores (-1.8 vs. -0.8 and -7.8 vs. -2.8, respectively) (all p<0.001) at wk14. At wk24, significantly greater proportions of GLM pts vs. PBO pts achieved ACR 50 (53.5% vs. 6.3%, p<0.001). At wk24, there was significantly less progression of structural damage for GLM pts vs PBO as measured by change from baseline in total modified vdH-S score (-0.36 vs. 1.95; p<0.001). ACR20 was significantly higher with GLM than PBO as early as wk2 (45.6% vs. 7.5%; p<0.001). 27.0% of GLM pts (vs. 4.2% PBO) achieved Minimal Disease Activity by wk14. In a post-hoc analysis, the number needed to treat for ACR20 at wk14 was 1.9 (Table). Through wk24, 46.3% of GLM pts and 40.6% of PBO pts had ≥1 AE; 2.9% vs. 3.3% of pts, respectively, had ≥1 serious AE. Two deaths and 2 malignancies, all in PBO pts and 1 demyelinating event in a GLM pt were reported. The most common type of AE was infection (20.0% of GLM pts vs. 13.8% of PBO pts). No opportunistic infection or

tuberculosis was reported through wk24. The rate of infusion reactions in GLM-treated pts was low at <2%; none was serious or severe.

**Conclusion:** In pts with active PsA, IV GLM demonstrated significant and clinically meaningful improvements of disease activity and physical function, skin psoriasis clearance, HRQoL, dactylitis and enthesitis, and inhibition of structural damage progression. GLM was well-tolerated through wk24; the safety profile was consistent with other anti-TNF therapies, including SC GLM.

Table. Clinical Response

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Apremilast (APR), an oral PDE4 inhibitor, was effective in phase 3, randomized, placebo (PBO)-controlled trials assessing treatment of moderate to severe plaque psoriasis (ESTEEM 1 and 2) and psoriatic arthritis (PsA; PALACE 1-3). We report MACE, malignancies, and serious infections (SIs; opportunistic and non-opportunistic) incidences in subjects receiving APR 30 mg BID (APR30) for  $\geq 156$  wks in a pooled analysis of these studies.

**Methods:** Incidence rates and exposure-adjusted incidence rates (EAIR)/100 subject-yrs of MACE, malignancies, SIs, and serious opportunistic infections (SOIs) are reported for 0 to 16 wks, 0 to  $\leq 52$  wks, and the APR-exposure period (0 to  $\geq 156$  wks) for subjects receiving APR30 any time during the studies, through February 2015;  $\sim 30\%$  (n=575) of sbjs received  $>3$  yrs ( $>156$  wks) of APR exposure.

**Results:** 2,242 subjects were included in the safety analysis for 0 to 16 wks (PBO n=913, subject-yrs exposure [sy]=260.2; APR30 n=1,329, sy=377.8); 1,905 subjects received APR30 during the APR-exposure period, representing 3,527.5 sy. Exposure during 0 to  $\leq 52$  wks was 1,524.5 sy. At baseline, 64.2% of APR30 subjects with PsA (PALACE 1-3) were receiving concomitant DMARDs (including methotrexate). Incidence of MACE with APR30 was low and comparable to PBO during 0 to 16 wks. During 0 to  $\leq 52$  wks and the APR-exposure period, incidence of MACE (EAIR/100 subject-yrs) remained low (**Table**). Incidence rates (EAIR/100 subject-yrs) of hematologic malignancies, nonmelanoma skin cancers, and solid tumors were similar with PBO (0.0, 1.2, 0.4) and APR30 (0.0, 1.3, 0.3) during 0 to 16 wks; incidence rates remained low during 0 to  $\leq 52$  wks and the APR-exposure period (**Table**). During 0 to 16 wks, the overall rate of SIs and non-SIs was low and comparable between subjects receiving PBO (20.6%) and APR30 (24.8%). The overall rate of SIs and non-SIs was 42.2% during 0 to  $\leq 52$  wks and comparable to rates during the PBO-controlled period (0 to 16 wks); the majority of reported infections (upper respiratory tract infection, nasopharyngitis, sinusitis) were not serious. During the PBO-controlled period (0 to 16 wks), rates of SIs with APR30 were low and comparable to PBO; no SOIs were reported. During 0 to  $\leq 52$  wks, the overall rate of SIs was low (0.6%; EAIR/100 subject-yrs: 0.7). The rate of SIs remained low (1.8%; EAIR/100 subject-yrs: 1.0) during the long-term cumulative APR-exposure period (0 to  $\geq 156$  wks) (**Table**). No clustering of any particular event was noted with respect to SIs; most events occurred in only 1 subject. No clinical reactivation of tuberculosis was reported with long-term APR30 exposure (0 to  $\geq 156$  wks). The rate of marked hematologic abnormalities remained low with long-term APR exposure.

**Conclusion:** Incidence of MACE, malignancies, and SIs was low in subjects with psoriasis and PsA receiving APR30 for  $\geq 156$  wks. No new safety signals or SOIs were observed over time with APR30.

	Treatment Period	
	0 to $\leq 52$ Wks	APR-Exposure Period 0 to $\geq 156$ Wks Cumulative Events*
	APR30 n=1,905 Subject-Yrs=1,524.5	APR30 n=1,905 Subject-Yrs=3,527.5
	EAIR/100 Subject-Yrs	EAIR/100 Subject-Yrs
<b>Major adverse cardiac events<sup>§</sup></b>		
Acute myocardial infarction	0.1	0.1
Myocardial infarction	0.1	0.1
Subarachnoid hemorrhage	0.1	0.1
Cardiac arrest	0.0	0.1
Cerebral infarction	0.0	0.1
<b>Malignancies</b>

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the immune responses that cause joint inflammation and other manifestations of psoriatic arthritis (PsA), including skin disease. The primary findings from the PALACE 4 study (NCT01307423) demonstrated greater efficacy with APR vs. placebo in disease-modifying anti-rheumatic drug (DMARD)-naïve subjects with active PsA.<sup>1</sup> We describe the long-term efficacy and safety of APR monotherapy in DMARD-naïve subjects in PALACE 4 for up to 208 weeks.

**Methods:** Subjects were randomized (1:1:1) to placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20). At Week 16, subjects were eligible for early escape. At Week 24, all subjects remaining on placebo were switched to APR. Double-blind treatment continued to Week 52, with open-label APR treatment for up to 4 additional years; subjects randomized to APR30 or APR20 continued with their assigned dose during open-label treatment.

**Results:** A total of 527 subjects were randomized and received  $\geq 1$  dose of placebo (n=176), APR30 (n=176), or APR20 (n=175). Of the subjects entering the fourth year of treatment, 92.6% (250/270) completed the Week 208 visit. At Week 52, 58.0% (119/205) of subjects receiving APR30 achieved a  $\geq 20\%$  improvement in modified American College of Rheumatology (ACR20) response. At Week 208, rates of improvement in PsA signs and symptoms and physical function were sustained (Table). Of the subjects still receiving study drug, 68.2%, 43.4%, and 23.1% achieved a modified ACR20, ACR50, and ACR70 response, respectively; 40.5% and 67.6% achieved  $\geq 75\%$  and  $\geq 50\%$  reduction from baseline Psoriasis Area and Severity Index (PASI-75 and PASI-50) responses, respectively (Table). During Weeks  $>156$  to  $\leq 208$ , the most common adverse events (AEs) among APR30-exposed subjects were upper respiratory tract infection (4.3%) and nasopharyngitis (6.5%); serious AEs occurred in 5.8% of APR30 subjects; serious infection was reported by 1 APR30 subject and no opportunistic infections were reported during Week  $>156$  to  $\leq 208$ . In general, no change in the types of AEs and no increase in the incidence and severity of AEs were seen with longer-term exposure. The APR20 safety profile was similar to that of APR30.

**Conclusion:** Over 208 weeks, APR monotherapy demonstrated sustained response and improvements in PsA signs and symptoms, including swollen and tender joint counts, enthesitis, dactylitis, physical function, and psoriasis. APR continued to demonstrate an acceptable safety profile and was generally well tolerated.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with active psoriatic arthritis (PsA) may experience disease manifestations across multiple domains, as well as impaired functioning in daily activities at home and at work. ACTIVE, a phase 3b study, is evaluating the efficacy of apremilast (APR) monotherapy in biologic-naïve subjects with PsA who may have had exposure to 1 prior

conventional disease-modifying anti-rheumatic drug. The ACTIVE work productivity findings through Week 104 are reported.

**Methods:** Subjects were randomized (1:1) to receive APR 30 mg BID or placebo. Subjects who did not improve at least 10% in both swollen and tender joint counts at Week 16 were eligible for early escape. At Week 24, all remaining placebo subjects were switched to APR. Work productivity and activity impairment were assessed at baseline and Week 16 using the 6-item, self-administered Work Productivity and Activity Impairment Questionnaire: Psoriatic Arthritis (WPAI:PsA). The WPAI:PsA includes 4 subscale scores: Absenteeism, Presenteeism, Work Productivity Loss, and Activity Impairment; subscale scores each range from 0% to 100%, with higher scores indicating greater impairment. Work-related subscales were evaluated only among employed subjects, while activity impairment was evaluated among all subjects, regardless of employment. Correlations were examined at Week 16 between WPAI:PsA subscale scores and selected 36-item Short-Form Health Survey version 2 (SF-36v2) domain scores (i.e., Physical Functioning [PF], Bodily Pain [Pain], and Vitality [VIT]). Improvement in work productivity was assessed through Week 104.

**Results:** Baseline characteristics were similar between the APR and placebo subjects with WPAI:PsA scores included in the current analysis. At Week 16, APR significantly improved work productivity and the ability to carry out daily activities compared with placebo, with significantly greater mean improvements observed in the overall Work Productivity Loss score ( $P=0.001$ ) and Activity Impairment score ( $P<0.001$ ) (Table). Estimated mean change in the Absenteeism score was similar with APR vs. placebo ( $P=0.679$ ). By contrast, the Presenteeism score showed significant improvement with APR vs. worsening with placebo ( $-10.8\%$  vs.  $4.1\%$ ;  $P=0.002$ ). At Week 16, statistically significant correlations were observed between WPAI:PsA subscale scores (except Absenteeism) and SF-36v2 domain scores (i.e., PF, Pain, and VIT). Among subjects randomized to receive APR at baseline, Week 16 WPAI:PsA subscale score improvements were generally maintained through Week 104.

**Conclusion:** In biologic-naïve subjects with active PsA, APR monotherapy contributed to an overall improvement in work productivity at Week 16, which correlated with SF-36v2 PF, Pain, and VIT scores; improvements in WPAI:PsA subscale scores were generally maintained to Week 104.

Improvements in WPAI:PsA Subscale Scores (%) at Week 16				
WPAI:PsA Subscale	Apremilast LS Mean (95% CI)	Placebo LS Mean (95% CI)	Treatment Difference (95% CI)	P Value
Presenteeism	n=39 -10.8 (-17.8, -3.8)	n=56 4.1 (-1.7, 9.9)	-14.9 (-24.1, -5.8)	0.002
Work Productivity Loss	n=40 -11.9 (-18.8, -5.0)	n=55 3.5 (-2.4, 9.4)	-15.4 (-24.5, -6.2)	0.001
Activity Impairment	n=87 -11.8 (-16.4, -7.1)	n=103 -0.5 (-4.7, 3.8)	-11.3 (-17.6, -5.0)	<0.001
Absenteeism	n=40 -3.6 (-5.9, -1.3)	n=55 -3.0 (-4.9, -1.0)	-0.6 (-3.7, 2.4)	0.679
Results are from an analysis of covariance model, adjusted with baseline WPAI:PsA subscale score, baseline prednisone use (yes/no), and previous disease-modifying anti-rheumatic drug use (yes/no). LS mean is estimated using the observed margins of the covariates. WPAI:PsA scores were evaluated for subjects with values at both baseline and Week 16. Absenteeism, Presenteeism, and Work Productivity Loss were evaluated only among employed subjects. Activity Impairment scores were evaluated among all randomized subjects with scores at baseline and Week 16, regardless of employment status. CI=confidence interval; LS=least-square.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The PALACE 1, 2, and 3 trials evaluated the efficacy and safety of apremilast (APR) in subjects with active psoriatic arthritis (PsA) despite prior conventional disease-modifying anti-rheumatic drugs and/or biologics. The objective of this analysis is to further characterize the clinical benefits associated with long-term APR exposure in subjects who failed to achieve an ACR20 response at Week 104.

**Methods:** Subjects were randomized (1:1:1) at baseline to receive placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID. Subjects who were randomized to APR30 at baseline and classified as ACR20 non-responders (ACR20NRs) at Week 104 were considered for this analysis. At Weeks 24, 52, and 104, ACR core components were examined as well as the proportions of subjects achieving a low disease activity (LDA) state (Clinical Disease Activity in Psoriatic Arthritis [cDAPSA] score  $\leq 13$ ), PASI-75/PASI-50 response among those with psoriasis involvement  $>3\%$  of the body surface area at baseline, and dactylitis count and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) of 0 among those with dactylitis or enthesitis at baseline. Safety is described for the overall PALACE 1-3 population.

**Results:** A total of 109 subjects randomized to APR30 treatment at baseline were ACR20NRs at Week 104. Lack of improvement in Patient's Global Assessment of Disease Activity, patient's assessment of pain, HAQ-DI, and C-reactive protein outcomes most commonly had an impact on patients' inability to achieve an ACR20 response. Baseline ACR core components were similar for ACR20NRs and ACR20 responders at Week 104. Among these ACR20NRs, several core components of ACR response, including swollen/tender joint counts and static Physician's Global Assessment of Disease Activity (visual analog scale) scores, showed sustained improvements from baseline through Week 104 (Table). Importantly, of the 109 ACR20NRs at Week 104, 27.5% achieved cDAPSA LDA state and 50.0% achieved a PASI-50 response after continued treatment with APR30 through Week 104 (Table). Among ACR20NRs with baseline dactylitis (n=44) or enthesitis (n=74), 68.2% achieved a dactylitis count of 0 and 33.8% achieved a MASES of 0 at Week 104. In the overall subject population, no new safety concerns were identified through 104 weeks.

**Conclusion:** ACR20NRs receiving APR30 demonstrated significant improvements in core PsA domains. The data may explain why subjects who failed to achieve an ACR20 response remained on long-term APR treatment. These findings suggest that some subjects with PsA may experience meaningful clinical improvement that is not completely captured by the assessment of ACR20 response criteria. Outcome measures specifically designed for PsA patients may be more suitable for evaluating treatment response in PsA patients.

	ACR20NRs at Week 104 With APR30 From Baseline (n=109)		
	Week 24	Week 52	Week 104
Swollen joint count (0-76), mean and median % change	-52.2, -71.4	-62.8, -73.3	-58.0, -75.0
Tender joint count (0-78), mean and median % change	-32.5, -47.4	-45.8, -53.5	-41.7, -51.7
sPGA (VAS 0-100 mm), mean and median % change	-37.9, -43.6	-49.8, -54.2	-44.3, -48.7
cDAPSA LDA score ≤13, n/m (%)	35/108 (32.4)	37/109 (33.9)	30/109 (27.5)
Dactylitis=0, n/m (%) <sup>*</sup>	23/44 (52.3)	29/44 (65.9)	30/44 (68.2)
MASES=0, n/m (%) <sup>§</sup>	20/74 (27.0)	27/74 (36.5)	25/74 (33.8)
PASI-75, n/m (%) <sup>‡</sup>	17/50 (34.0)	22/50 (44.0)	18/50 (36.0)
PASI-50, n/m (%) <sup>‡</sup>	31/50 (62.0)	33/50 (66.0)	25/50 (50.0)

Data are as observed at Week 24, Week 52, and Week 104 for all subjects who were randomized to APR treatment at baseline and were ACR20NRs at Week 104 and with a value at the time point indicated.

<sup>\*</sup>Examined among subjects with dactylitis at baseline. <sup>§</sup>Examined among subjects with enthesitis at baseline. <sup>‡</sup>Examined among subjects with ≥3% psoriasis involvement of the body surface area at baseline. sPGA=static Physician's Global Assessment of Disease Activity; VAS=visual analog scale; n/m=number of subjects achieving response/number of subjects with evaluable data at the time point; PASI-75/50=≥75%/≥50% reduction from baseline in Psoriasis Area and Severity Index score.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Apremilast (APR), an oral phosphodiesterase 4 inhibitor, regulates immune activity in psoriatic arthritis (PsA) patients. We evaluated the long-term safety of APR treatment for up to 4 years in subjects with active PsA despite prior conventional disease-modifying anti-rheumatic drugs (DMARDs) and/or biologics. Safety data were pooled from the phase 3 PALACE 1, 2, and 3 studies.

**Methods:** Subjects were randomized at baseline (1:1:1) to receive placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). PBO subjects were re-randomized to APR30 or APR20 at Week 16 (early escape) or Week 24. Double-blind APR treatment continued to Week 52; subjects could continue APR during an open-label, long-term treatment phase for up to 5 years treatment. Visits in years 2, 3, and 4 were scheduled at 13-week intervals. Safety was assessed at each visit throughout the study, and results are summarized here by exposure.

**Results:** A total of 1,493 subjects were randomized and received  $\geq 1$  dose of study medication (PBO: n=495; APR30: n=497; APR20: n=501). At the 4-year data cut, the numbers of subjects receiving APR30 and APR20 in each exposure period were 1,441 in Weeks 0 to  $\leq 52$ , 1,028 in Weeks  $>52$  to  $\leq 104$ , 865 in Weeks  $>104$  to  $\leq 156$ , and 767 in Weeks  $>156$  to  $\leq 208$ . During the 0- to  $\leq 52$ -week APR-exposure period, adverse events (AEs) occurring in  $\geq 5\%$  of APR30-exposed subjects were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis (Table). Most diarrhea and nausea AEs were reported within the first 2 weeks of treatment and usually resolved within 4 weeks; the frequency of gastrointestinal AEs decreased with longer APR30 exposure, and the frequency of other common AEs either decreased or remained stable with prolonged exposure (Table). Most AEs were mild or moderate in severity. During Weeks  $>156$  to  $\leq 208$  of APR exposure, the discontinuation rate due to AEs was 1.7% with APR30, and the rate of serious AEs (SAEs) was 7.0%, consistent with earlier periods; most SAEs occurred in 1 subject each. Rates were very low for major cardiac events, malignant neoplasms, and serious opportunistic infections, comparable to the first year of treatment. Rates of depression remained very low in Weeks  $>156$  to  $\leq 208$ . Marked laboratory abnormalities were infrequent, and most returned to baseline values with continued treatment.

**Conclusion:** APR30 demonstrated a favorable and consistent safety profile and was well tolerated for up to 208 weeks, marked by the lack of an increase in infection rates or a need for specific laboratory monitoring. The incidence of AEs remained stable or decreased with long-term exposure to APR30.

	APR-Exposure Period*			
	Weeks 0 to $\leq 52$	Weeks $>52$ to $\leq 104$	Weeks $>104$ to $\leq 156$	Weeks $>156$ to $\leq 208$

Burmester<sup>2</sup>, Susan Moriarty<sup>3</sup>, Olivier Benichou<sup>3</sup>, Wen Xu<sup>3</sup> and Peter Nash<sup>4</sup>, <sup>1</sup>Swedish Medical Center and University of Washington, Seattle, WA, <sup>2</sup>Department of Rheumatology and Clinical Immunology, Charité - University Medicine Berlin, Free University and Humboldt University Berlin, Berlin, Germany, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>University of Queensland, Brisbane, Australia

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets IL-17A. The objective of this analysis is to report the integrated safety of IXE in 2 pivotal trials in patients with active PsA.

**Methods:** The SPIRIT phase 3 trials consist of patients with active PsA who were bDMARD-naïve (SPIRIT-P1, NCT01695239) or were inadequate responders to TNF-inhibitors (SPIRIT-P2; NCT02349295). Patients were randomized to 80 mg IXE every 4 weeks (Q4W, N=229) or 2 weeks (Q2W, N=225) after a 160 mg starting dose or PBO (N=224). Integrated safety data are presented from the PBO-controlled treatment periods (Weeks 0-24). Safety was assessed for patients who received at least 1 dose of study drug. At Week 16, patients deemed Inadequate Responders received rescue therapy and were included in this dataset only up to Week 16. Data was analyzed using a Cochran-Mantel-Haenszel test stratified by trial.

**Results:** The percentage of patients with  $\geq 1$  treatment emergent adverse event (TEAE) was significantly greater in the IXE compared to PBO treatment groups (Table 1). No clear difference was seen between groups for the percentage of patients with  $\geq 1$  serious adverse event (SAE) or discontinued early from study drug. Infection-related SAEs were reported in a significantly higher percentage of IXE Q2W than PBO patients. Treatment-emergent infections were numerically more frequent with IXE treatment compared to PBO (Table 2); upper respiratory tract infections, nasopharyngitis, and sinusitis were the most common infections. One PBO, 4 IXE Q4W, and 8 IXE Q2W-treated patients had  $\geq 1$  *Candida* infection. Injection site reactions were reported in a significantly higher percentage of patients in the IXE than the PBO treatment groups; most were of mild or moderate severity. Allergic reactions/hypersensitivity events were reported in a significantly higher percentage of IXE Q2W than PBO patients; no case of anaphylaxis was reported. Two cases of malignancy were reported (both IXE Q4W patients): prostate cancer and basal cell carcinoma. There were no major adverse cardiac events (MACE). While there were no reports of Crohn's disease or ulcerative colitis, 1 IXE Q2W patient had SAEs of anal abscess

and anal fistula, considered to represent inflammatory bowel disease; this patient continued study drug. There were no deaths or reports of suicide or suicidal ideation.

**Conclusion:** The safety profile of IXE during the placebo-controlled treatment period was consistent with published findings in patients receiving ixekizumab for moderate-to-severe plaque psoriasis<sup>1</sup>.

## Secukinumab Demonstrates Consistent Safety over Long-Term Exposure in Patients with Psoriatic Arthritis and Moderate to Severe Plaque Psoriasis: Updated Pooled Safety Analyses

**Philip J Mease**<sup>1</sup>, Iain B. McInnes<sup>2</sup>, Kristian Reich<sup>3</sup>, Peter Nash<sup>4</sup>, Mats Andersson<sup>5</sup>, Ken Abrams<sup>6</sup>, Luminita Pricop<sup>6</sup> and Todd Fox<sup>5</sup>, <sup>1</sup>Swedish Medical Center and University of Washington, Seattle, WA, <sup>2</sup>University of Glasgow, Glasgow, United Kingdom, <sup>3</sup>Dermatologikum Hamburg, Hamburg, Germany, <sup>4</sup>University of Queensland, Brisbane, Australia, <sup>5</sup>Novartis Pharma AG, Basel, Switzerland, <sup>6</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pooled safety data from secukinumab psoriasis (PSO) and psoriatic arthritis (PsA) clinical trial programs after ~1 year of exposure have been reported previously.<sup>1, 2</sup> Here, we report updated longer-term safety data of secukinumab exposure from PSO and PsA studies.

**Methods:** The PSO data pool consisted of 9 Phase III studies in moderate-to-severe plaque PSO and PsA pool consisted of 3 Phase III studies in active PsA. Secukinumab doses differed in the studies and included intravenous (up to 10 mg/kg) or subcutaneous (s.c.; 75–300 mg) loading, followed by s.c. maintenance dosing (300, 150 or 75 mg). Placebo patients were re-randomized to secukinumab at 12–24 weeks depending on study design. Exposure adjusted incident rates (EAIR) were used to adjust for differences in treatment exposure and analyses included all patients who received ≥1 dose of secukinumab.

**Results:** A total of 3893 and 1380 patients from PSO and PsA studies representing an exposure of 7769.0 and 2841.3 patient years, respectively, were included in this pooled safety analysis. In both PsO and PsA, the most frequently reported adverse events (AEs) with secukinumab were nasopharyngitis, headache, non-serious infections of the upper respiratory tract and arthralgia (Table). The EAIRs of AEs of special interest with secukinumab including serious infections, *Candida* infections, inflammatory bowel disease, and major adverse cardiac events (Table) were similar in both PSO and PsA indications, and comparable to those reported previously.<sup>1,2</sup> No cases of tuberculosis were reported.

**Conclusion:** Secukinumab demonstrated a favorable safety profile during long term treatment (up to 7769 patient-years of exposure) in patients with moderate-to-severe plaque PSO or PsA consistent with previous reports. Safety was comparable across psoriasis and PsA patients supporting long-term use in these chronic conditions.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Secukinumab (SEC), a fully human monoclonal antibody selectively neutralizing interleukin-17A, exhibits significant efficacy, with a favorable safety profile, in the treatment of psoriatic arthritis (PsA) and moderate to severe psoriasis. SEC has a rapid onset of action and demonstrates sustained responses. PsA and psoriasis patients are at greater risk for psychological distress, including depression and suicidality. Previous analysis, using pooled data from phase 3 studies FIXTURE and ERASURE, reported high and sustained relief from anxiety/depression in psoriasis patients treated with SEC 300 mg up to Week (Wk) 52 (~80% of patients reported not being anxious/depressed) from the EuroQol 5-dimensional (Mobility, Self-Care, Usual Activities, Pain/Discomfort, and Anxiety/Depression) and 3-level questionnaire (EQ-5D-3L). Here, we aim to confirm these results in additional phase 3 SEC trials in patients with PsA and psoriasis.

**Methods: Results** of the 'Anxiety/Depression' dimension ("not anxious/depressed", "moderately anxious/depressed", or "extremely anxious/depressed") of EQ-5D-3L were derived from three phase 3 studies using an approved SEC dose: FUTURE 1 and FUTURE 2, two randomized, double-blind clinical trials, comparing SEC 150 mg to placebo in active PsA; and CLEAR, a multicenter, double-blind, parallel-group study comparing SEC 300 mg to ustekinumab in moderate to severe psoriasis. The proportions of patients reporting as not being anxious/depressed are described as observed for each individual study up to Wk 52.

**Results:** In FUTURE 1, 76/200 (38.0%) of PsA patients treated with SEC 150 mg reported being not anxious/depressed at baseline, increasing to 99/192 (51.6%) at Wk 4 and 109/184 (59.2%) at Wk 52 (Fig. 1). Similarly, in FUTURE 2, 32/100 (32.0%) and 41/99 (41.4%) of PsA patients treated with SEC 150 mg or 300 mg, respectively reported being not anxious/depressed at baseline, increasing to 51/99 (51.5%) and 52/95 (54.7%) at Wk 4 and 49/89 (55.1%) and 55/95 (57.9%) at Wk 52 (Fig. 1). In the CLEAR study, 154/326 (47.2%) psoriasis patients treated SEC 300 mg reported being not anxious/depressed at baseline, and this increased to 238/322 (73.9%) at Wk 4, 263/326 (80.7%) at Wk 16, and was sustained up to Wk 52 (237/292, 81.2%) (Fig. 1).

**Conclusion:** This analysis of the patient-reported EQ-5D-3L anxiety/depression measure from three phase 3 SEC trials showed consistently higher anxiety/depression burden among patients with PsA than among those with moderate to severe psoriasis; however, it also indicates that SEC treatment improves and provides sustained relief from anxiety/depression among all treated patients, regardless of their disease, up to 1 year.

**Figure 1.** Percentages of patients with psoriatic arthritis or psoriasis reporting not being anxious/depressed on EQ-5D following treatment with secukinumab in three phase 3 clinical trials (as observed).

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Abatacept, a selective T-cell co-stimulation modulator, significantly increased ACR20 response and had an overall beneficial effect on musculoskeletal symptoms in patients with active psoriatic arthritis (PsA) in the Phase III Active pSoriaTic athRitis rAndomizEd triAl (ASTRAEA, NCT01860976).<sup>1</sup> Factors that may predict responses to abatacept were explored in this *post hoc* analysis. The aim of this study was to evaluate the relationship between baseline characteristics and abatacept response in a *post hoc* analysis of ASTRAEA. **Methods:** Patients were randomized (1:1) to SC abatacept 125 mg weekly or placebo for 24 weeks in this trial. Patients without >20% improvement in joint counts at Week 16 were switched to open-label abatacept (early escape). ACR20 response rate in patients stratified by baseline variables was investigated in a multivariate analysis and odds ratios (ORs) generated to identify differences in response. Using a cut-off of OR 1.2, indicating patient subgroups in whom abatacept appeared to have a meaningful treatment benefit, baseline variables were further investigated in a univariate analysis and estimated differences calculated.

**Results:** Of 424 patients enrolled, 213 received abatacept and 211 placebo. In abatacept-treated patients, the multivariate model showed a difference in ACR20 response (OR >1.2) for baseline CRP (>upper limit of normal [ULN] vs ≤ULN; OR 1.346 [95% CI 0.668, 2.712]), DAS28 (CRP) (>5.1 vs ≤5.1; 1.489 [0.782, 2.836]), dactylitis (>0 vs 0; 1.372 [0.708, 2.659]), and median baseline erosions (≥3 vs <3; 1.924 [1.032, 3.587]). In placebo-treated patients, the OR was >1.2 for dactylitis only (1.406 [0.619, 3.193]). These factors, which have been identified previously as indicating poor prognosis in PsA, were balanced between treatment arms at baseline. In the univariate model by poor prognostic factors, the differences in ACR20 response rates with abatacept treatment vs placebo in distinct subgroups were numerically greater in patients who were positive for these prognostic factors at baseline than in those who were not (Figure).

**Conclusion:** These findings identified subgroups of patients with PsA with certain baseline characteristics in whom abatacept is most likely to be effective. The predictive factors identified are aligned with poor prognostic factors in the EULAR and Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) guidelines,<sup>2,3</sup> and may indicate patients with the highest unmet medical need.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

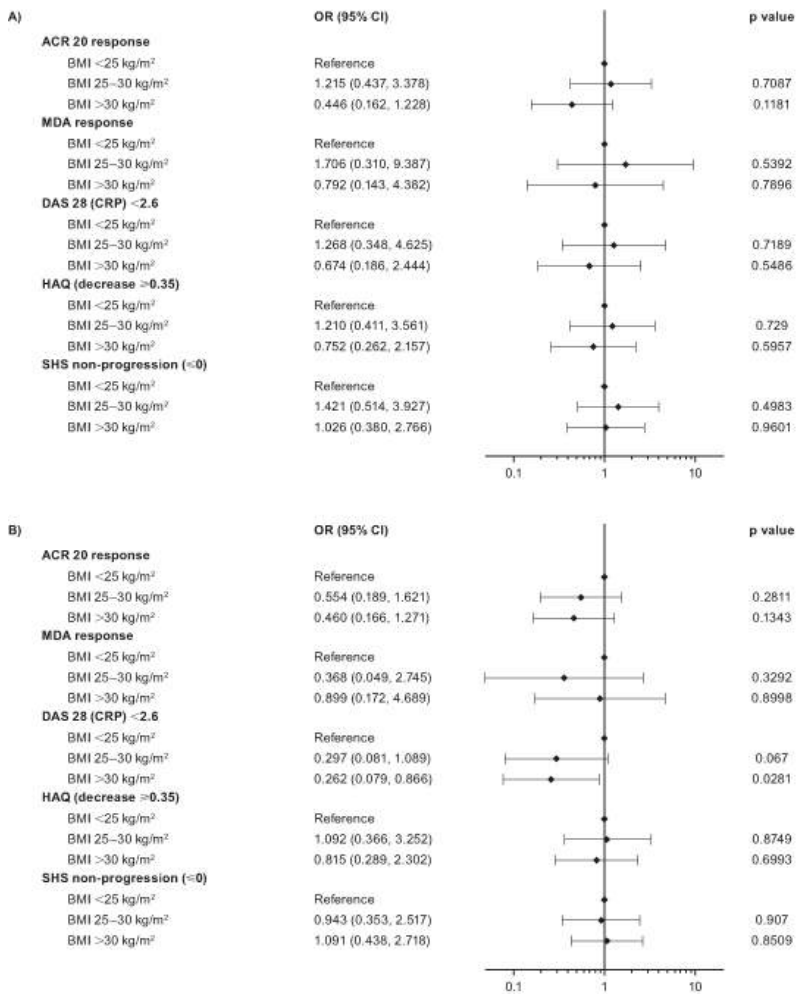

**Background/Purpose:** Obesity is a risk factor for the development and severity of psoriatic arthritis (PsA).<sup>1,2</sup> Patients (pts) with increased BMI (overweight/obese) are less likely to achieve sustained minimal disease activity (MDA) vs those with normal BMI, independent of biologic and non-biologic DMARD use.<sup>3</sup> Moreover, obese pts with PsA respond less favourably to TNF $\alpha$  inhibitors vs normal BMI pts.<sup>4,5</sup> In the Phase III ASTRAEA study (NCT01860976),<sup>6</sup> abatacept (ABA) significantly improved disease activity and was well tolerated; the primary endpoint of ACR20 at 24 weeks (W) was met.<sup>6</sup> We evaluated the relationship between BMI and ABA response in a *post hoc* analysis of ASTRAEA. **Methods:** Pts were randomized (1:1) to weekly SC ABA 125 mg or placebo (PBO) for 24W. Pts without  $\geq 20\%$  improvement in joint counts at W16 were switched to open-label ABA (early escape; EE). Pts designated as EE or with missing data were imputed as non-responders. ACR20/50/70 responses and % of pts with DAS28 (CRP)  $\leq 3.2$  or  $< 2.6$ , MDA, HAQ-DI response (change from baseline [CFB]  $\geq 0.35$ ) and radiographic non-progression (PsA-modified total Sharp/van der Heijde score, CFB  $\leq 0$ ) at W24 were compared for ABA vs PBO between three BMI subgroups (underweight/normal:  $< 25$  kg/m<sup>2</sup>; overweight: 25–30 kg/m<sup>2</sup>; obese:  $> 30$  kg/m<sup>2</sup>) using univariate and multivariate analyses. BMI  $< 25$  kg/m<sup>2</sup> subgroup was the reference and key potential confounding factors for treatment efficacy were included in the multivariate model. Odds ratios (ORs), 95% CIs and p values were calculated for each BMI subgroup comparison.

**Results:** Overall, 212 ABA- and 210 PBO-treated pts had available baseline BMI status. For ABA vs PBO, respectively, 31 (14.6%) vs 39 (18.6%) were underweight/normal, 77 (36.3%) vs 57 (27.1%) were overweight and 104 (49.1%) vs 114 (54.3%) were obese. In the ABA and PBO groups, neither overweight nor obese pts had a significantly lower ACR20 response vs underweight/normal pts in the univariate model. This was confirmed in the multivariate models in overweight and obese pts, respectively, vs underweight/normal pts: ABA: OR (95% CI) 1.215 (0.437, 3.378),  $p=0.7087$  and 0.446 (0.162, 1.228),  $p=0.1181$ ; PBO: OR (95% CI) 0.554 (0.189, 1.621),  $p=0.2811$  and 0.460 (0.166, 1.271),  $p=0.1343$ . Similar results were observed for all other outcomes tested (Figure). **Conclusion:** As in RA, BMI does not appear to affect the

efficacy of abatacept in PsA; this is consistent across both objective and pt-reported outcome measures. Given that 1 in 3 pts with PsA are overweight/obese, these data strongly suggest an advantage of abatacept therapy in this debilitating disease.

## Baseline Structural Damage Predicts Response to Abatacept in Patients with Psoriatic Arthritis: A Post Hoc Analysis from a Phase III Study

Georg Schett<sup>1</sup>, T Lehman<sup>2</sup>, HA Ahmad<sup>2</sup>, A Johnsen<sup>2</sup>, S Banerjee<sup>2</sup> and Philip J Mease<sup>3</sup>, <sup>1</sup>University of Erlangen-Nuremberg, Erlangen, Germany, <sup>2</sup>Bristol-Myers Squibb, Princeton, NJ, <sup>3</sup>Swedish Medical Center and University of Washington, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is a heterogeneous disease in which treatment selection and patient stratification based on clinical domains have recently been proposed.<sup>1</sup> The efficacy and safety of the co-stimulation modulator abatacept in patients with PsA was investigated in the Phase III ASTRAEA study (NCT01860976).<sup>2</sup> The aim of this analysis was to identify baseline factors that predict response to abatacept treatment in patients with PsA in ASTRAEA. **Methods:** Baseline disease and demographic characteristics of patients treated with abatacept (n=213) or placebo (n=211) in the Phase III ASTRAEA study achieving high-level response (ACR50: abatacept n=41, placebo n=26; ACR70: abatacept n=22, placebo n=14) at Day 169 (Week 24) were compared with those of patients not achieving an ACR20 response (abatacept n=129, placebo n=164). Due to the inclusion of an early escape (EE) at Day 114 (Week 16), patients who entered the EE were imputed as non-responders at Day 169 and included in the ACR20 non-responders group. **Results:** For both the abatacept and placebo groups, most baseline demographic and disease characteristics, including age, BMI, disease duration and disease activity at baseline, were similar among ACR50 and ACR70 responders and ACR20 non-responders (Table, abatacept group). Joint-space narrowing, erosion, total PsA-modified Sharp/van der Heijde scores, and the swollen joint count, however, were higher in abatacept ACR50 and ACR70 responders than in ACR20 non-responders. Conversely, placebo ACR 20 non-responders show a higher degree of baseline structural damage than ACR50 and ACR70 responders. Baseline CRP was higher in both abatacept and placebo ACR50 and ACR70 responders than in ACR20 non-responders.

**Conclusion:** These data show that a higher degree of baseline structural joint damage and higher swollen joint count is associated with a greater response to abatacept therapy in PsA. These observations suggest that PsA patients with signs of synovitis-driven osteoclast formation and disease activity including swollen joints and structural damage may be good candidates for abatacept treatment. These results are in accordance with recent data showing that CTLA-4 controls osteoclast differentiation and bone resorption<sup>3</sup> and the known mechanism of abatacept on T-cell co-stimulation mediated inflammation<sup>2</sup>. 1. ### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is a lack of evidence on the effect of biologics in early treatment of psoriatic arthritis (PsA) patients (Pts). Benefit of concomitant use of DMARDs remains controversial in this indication.

**Methods:** To compare clinical outcomes in patients with PsA starting adalimumab (ADA), with short and long disease duration and evaluate the potential effect of concomitant use of DMARDs or corticosteroids (CS), both on PsARC response and persistence on ADA. The analyses included adult PsA Pts who have been registered on Reuma.pt between June 2008 - June 2016 and have received ADA therapy for at least 3 months. PsARC, DAS28, tender and swollen joint count, ESR, CRP, PtGA, PhGA evaluated on a 10 cm VAS, and HAQ were compared between Pts <5 years of disease (early PsA) and those with ≥5 years of disease duration (late PsA) when starting ADA. Time to achieve PsARC response was estimated using Kaplan-Meier method, adjusted with Cox Regression with Efron method for ties with robust estimates of variance for baseline characteristics. Same analyses were repeated to compare patients with and without concomitant use of DMARDs or CS.

**Results:** We included 135 PsA patients who started ADA, 41 of them with early PsA. Pts with early PsA were younger, more frequently males, smokers, had significantly more hypertension. Overall, PsARC response was achieved by 72.9% of the Pts (88% early PsA vs 62.2% late PsA;  $p=0.022$ ) at 3 months, by 85.4% of Pts at 24 months (100% early PsA vs 75.9% late PsA;  $p=0.044$ ) after starting ADA. Patients with early PsA, achieved significantly less painful joints (2.7 vs 6.7;  $p=0.006$ ), lower mean CRP (0.5 mg/dl vs 1.3 mg/dl,  $p=0.011$ ) and PhGA (18.3 vs 28.1;  $p=0.020$ ) at 3 months. In the long term, early PsA Pts showed less swollen joints (0.3 vs 1.7;  $p=0.030$ ), lower PhGA (6.3 vs 21.9;  $p<0.001$ ), CRP (0.4 mg/dl vs 1.0 mg/dl;  $p=0.026$ ) and disease activity evaluated by DAS28 (2.2 vs 3.2;  $p=0.030$ ). Early PsA Pts obtained PsARC response more rapidly than those with late PsA (3.8 and 7.4 months, respectively;  $p=0.008$ ). Concomitant DMARDs, in the long term, showed clinical benefit (PsARC response at 2 years 88.3% vs 60.0%;  $p=0.044$ ). Concomitant CS had no noticeable effect on PsARC response, over 2 years of follow-up. Survival on treatment with ADA was similar in the 2 groups and was not influenced by DMARD or CS therapy.

**Conclusion:** Patients with early PsA had greater chance of improvement after starting ADA, better functional outcome and achieved PsARC response more rapidly than patients with longer disease duration. Our results suggest that comedication with DMARDs may improve PsARC response in the long term.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ustekinumab (UST) is a fully human immunoglobulin monoclonal antibody against interleukin-12 (IL-12) and interleukin-23 (IL-23) that has been proven safe and efficacious for the treatment of PsA in randomized clinical

trials. The aim of the current analysis was to assess the safety and effectiveness of UST among PsA patients treated under Canadian routine clinical care.

**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab or golimumab for rheumatoid arthritis, ankylosing spondylitis, or PsA, or with UST for PsA. Eligible participants for this analysis included UST-treated PsA patients enrolled between 2014-2016. Clinical outcomes assessed at Baseline and the Month 6 visit were: SJC, TJC, pain (100mm visual analogue scale; VAS), PtGA and MDGA (100mm VAS), PASI, HAQ-DI, DAS-28, and joint counts for dactylitis and enthesitis. Safety was ascertained by the incidence of adverse events (AEs), reported per 100 patient years (PY) of follow-up. Descriptive statistics were produced for all variables, and between-visit changes in outcomes were assessed for statistical significance with the paired-samples t-test.

**Results:** A total of 63 UST-treated PsA patients were identified. Mean (SD) age and disease duration at Baseline was 52.8 (11.2) and 5.5 (8.1) years, respectively. A majority of patients were female (63.5 %), and 100.0% were biologic naïve. Changes from Baseline to Month 6 were statistically significant for all clinical outcomes ( $p < 0.05$ ), except for the PtGA (Table 1). With respect to enthesitis and dactylitis, missing data did not permit assessment of improvement from baseline to Month 6. At baseline, 50.9% of patients had some dactylitis and 34.9% had some enthesitis.

Overall, 36 AEs were reported by 21 patients from Baseline to the Month 6 visit. The majority were mild in nature ( $n=26/36$ ; 72.2%); “probable” and “very likely” relation to the study drug was determined for 11.1% ( $n=4/36$ ) and 8.3% ( $n=3/36$ ) of AEs, respectively. The most common AEs included General Disorders and Administration Site Conditions ( $n=7/21$ ; 33.3%) and Infections and Infestations ( $n=8/21$ ; 38.1%). No serious AEs were reported.

Table 1. Clinical outcome parameters over time, and changes from Baseline to Month 6

	Baseline	Month 6	Change <sup>†</sup>	p-value <sup>§</sup>
Parameter, mean (SD)				
<i>SJC-28</i>	3.8 (3.8)	1.6 (2.1)	-2.7 (6.0)	0.014
<i>TJC-28</i>	6.5 (5.6)	3.4 (5.7)	-2.6 (3.6)	<0.001
<i>Pain, mm*</i>	55.1 (22.2)	44.6 (27.7)	-11.3 (22.5)	0.008
<i>PtGA, mm*</i>	58.2 (22.4)	49.1 (28.3)	-9.7 (33.0)	0.101
<i>MDGA, mm*</i>	51.8 (22.9)	23.4 (19.7)	-28.3 (25.5)	<0.001
<i>PASI</i>	4.4 (7.2)	0.7 (1.1)	-3.5 (4.7)	<0.001
<i>HAQ-DI</i>	1.1 (0.6)	0.8 (0.6)	-0.3 (0.7)	0.019
<i>DAS-28</i>	4.0 (1.2)	3.5 (1.2)	-0.5 (0.9)	0.026
* 100 mm VAS; † Based on patients with available Baseline and Month 6 data; § P-value derived from the paired samples t-test				

**Conclusion:** The results of this analysis demonstrate that UST, administered to PsA patients in a routine clinical care setting, is safe and effective in improving clinical outcomes over 6 months of treatment.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). Up to 42% of patients (pts) with psoriasis also have PsA. We examined tofacitinib efficacy and patient-reported outcomes (PROs) in pts with psoriasis and concomitant PsA.

**Methods:** Data were pooled from identical 52-week, randomized, controlled studies: OPT Pivotal 1 (NCT01276639) and OPT Pivotal 2 (NCT01309737). Both studies enrolled pts with moderate to severe psoriasis. This analysis included only those with a medical history of PsA at baseline (prior diagnosis by a rheumatologist). Pts were randomized 2:2:1 to receive tofacitinib 5 or 10 mg twice daily (BID), or placebo (PBO). Pts receiving PBO advanced to tofacitinib at Week 16. The co-primary efficacy endpoints at Week 16 were the proportion of pts achieving a 75% improvement in the Psoriasis Area and Severity Index score (PASI75) and the proportion of pts achieving Physician's Global Assessment (PGA) of "clear" or "almost clear". Secondary endpoints included the proportion of pts achieving Patient's Global Assessment (PtGA) of "clear" or "almost clear" and changes from baseline in Joint Pain Assessment ( $\Delta$ JPA), Nail Psoriasis Severity Index ( $\Delta$ NAPSI), and Short Form-36 Health Survey ( $\Delta$ SF-36) physical component summary (PCS) score, mental component summary (MCS) score, and 8 domain scores.

**Results:** The analysis included 430 psoriasis pts with PsA at baseline; 172, 168, and 90 pts received tofacitinib 5 mg BID, tofacitinib 10 mg BID, and PBO, respectively. At Week 16 a greater proportion of pts achieved PASI75, PGA, and PtGA responses with tofacitinib 5 and 10 mg BID vs PBO (all  $p < 0.0001$  vs PBO; Table). Improvements were observed with tofacitinib 5 and 10 mg BID vs PBO in  $\Delta$ JPA and  $\Delta$ NAPSI (all  $p < 0.0001$  vs PBO; Table). Tofacitinib 5 mg BID significantly improved SF-36 PCS ( $p \leq 0.05$ ) and 5 of 8 domain scores (physical functioning, role limitations: physical, bodily pain, vitality, social functioning [all  $p \leq 0.05$ ]). Tofacitinib 10 mg BID significantly improved SF-36 PCS ( $p < 0.001$ ), MCS ( $p < 0.001$ ), and all 8 domain scores (all  $p \leq 0.05$ ). A dose-response was observed across all endpoints following tofacitinib treatment (Table).

**Conclusion:** Tofacitinib significantly improved clinical endpoints and PROs vs PBO at Week 16 in pts who had concomitant psoriasis and PsA. Details of safety endpoints in pts with psoriasis and PsA in the OPT Pivotal studies will be included in the final presentation.

**Table: Efficacy endpoints at Week 16**

	Tofacitinib 5 mg BID (N=172)	Tofacitinib 10 mg BID (N=168)	PBO (N=90)

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA), which has also been evaluated in other inflammatory rheumatic diseases (IRD) including psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Pain contributes substantial morbidity in patients (pts) with IRD and directly impacts treatment adherence, assessment of disease improvement, and health-related quality of life. We evaluated the effectiveness of tofacitinib in reducing pain in randomized controlled clinical trials in pts with RA, PsA, and AS.

**Methods:** Five pt populations treated with tofacitinib 5 mg twice daily (BID), 10 mg BID, or placebo (PBO) were evaluated: [1] conventional synthetic disease-modifying antirheumatic drug (csDMARD)-inadequate response (IR) RA pts pooled from ORAL Scan (NCT00847613), ORAL Sync (NCT00856544), and ORAL Standard (NCT00853385), [2] tumor necrosis factor inhibitor (TNFi)-IR RA pts from ORAL Step (NCT00960440), [3] csDMARD-IR PsA pts from OPAL Broaden (NCT01877668), [4] TNFi-IR PsA pts from OPAL Beyond (NCT01882439), and [5] AS pts from a Phase 2 study (NCT01786668). Pain outcomes evaluated from baseline to Month (M)6 (Week [W]12 in the AS population) included Pt's Assessment of Arthritis Pain (PAAP) (RA and PsA populations only), Short-Form Health Survey (SF)-36v2 Q7 (bodily pain in the past week), SF-36v2 Bodily Pain Domain (BP), EuroQol Five Dimensions Questionnaire Pain/Discomfort Domain (EQ-5D PD; all populations), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) Q2 (level of AS neck, back, or hip pain) and Q3 (other pain) score (PsA and AS populations only; PsA pts had presence of spondylitis at screening and baseline BASDAI total score >0 in the full analysis set [FAS]). Data were analyzed descriptively.

**Results:** The csDMARD-IR RA, TNFi-IR RA, csDMARD-IR PsA, TNFi-IR PsA, and AS populations comprised a total of 2066, 399, 316, 394, and 155 pts in the FAS, respectively. In each RA or PsA csDMARD-IR and TNFi-IR population treated with tofacitinib, mean PAAP at baseline (5 mg BID, range 55.7–65.7 mm; 10 mg BID, 54.4–60.1 mm) decreased as early as W2 (1<sup>st</sup> post-baseline assessment; 45.8–49.8 mm; 38.9–44.8 mm) and continued to decrease through M6 (30.9–34.4 mm; 28.2–36.7 mm); decreases were numerically greater vs PBO and the magnitude of change in RA and PsA populations was similar (Table). Improvements in SF-36v2 Q7 (Table), SF-36v2 BP (Table), and EQ-5D PD were observed in all 4 RA and PsA csDMARD-IR and TNFi-IR populations, and in BASDAI Q2 and Q3 in the csDMARD-IR PsA and TNFi-IR PsA populations. In the AS population, improvements from baseline in mean SF-36v2 Q7 (Table), SF-36v2 BP (Table), EQ-5D PD, and BASDAI Q2 and Q3 were reported at W12 and were numerically greater vs PBO.

**Conclusion:** Treatment with tofacitinib is associated with a rapid improvement and sustained reduction of pain in pts with RA and PsA who are csDMARD-IR or TNFi-IR, and in pts with AS.

Table. Mean (SE) PAAP score, <sup>a</sup> SF-36v2 Q7 <sup>b</sup> score, <sup>b</sup> and SF-36v2 BP <sup>c</sup> at baseline through M6 (FAS) in RA and PsA cDMARD-IR or TNFi-IR populations, and SF-36v2 Q7 <sup>b</sup> score, <sup>b</sup> and SF-36v2 BP <sup>c</sup> at baseline and W12 (FAS) in the AS population

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA). The efficacy of tofacitinib has been evaluated in 2 Phase 3 studies in patients (pts) with PsA. In this analysis, we describe the efficacy of tofacitinib by background methotrexate (MTX) dose in pts with PsA.

**Methods:** This post hoc analysis utilized efficacy data pooled from 2 Phase 3, randomized, double-blind, placebo-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with a diagnosis ( $\geq 6$  months) of active PsA ( $\geq 3$  swollen and  $\geq 3$  tender joints). Pts in OPAL Broaden were tumor necrosis factor

inhibitor (TNFi)-naïve and had an inadequate response (IR) to  $\geq 1$  conventional synthetic disease-modifying antirheumatic drug (csDMARD). Pts in OPAL Beyond had an IR to  $\geq 1$  TNFi. Pts were randomized to tofacitinib 5 or 10 mg twice daily (BID), placebo, or adalimumab 40 mg subcutaneous every 2 weeks (OPAL Broaden; adalimumab data not shown). All pts received a stable dose of 1 csDMARD (eg MTX, leflunomide, or sulfasalazine) as background therapy. The maximum dose of MTX allowed per protocol was 20 mg/week. Efficacy outcomes for tofacitinib at Month 3 were evaluated by background MTX dose ( $\leq 15$  vs  $>15$  mg/week) and included: ACR20/50/70 response rates ( $\geq 20/50/70\%$  improvement from baseline, respectively), Health Assessment Questionnaire-Disability Index (HAQ-DI) response rate (reduction from baseline  $\geq 0.35$  points), and mean change from baseline in HAQ-DI score. Analyses were based on the full analysis set for pts receiving MTX on Day 1; pts with missing data were considered as having a non-response for binary endpoints. No statistical testing was performed.

**Results:** In total, data from 556 pts who received tofacitinib plus MTX only or placebo plus MTX only (tofacitinib 5 mg BID, n=186; tofacitinib 10 mg BID, n=178; placebo, n=192) were included in this analysis. Most pts were treated with background MTX at doses  $\leq 15$  mg/week (n=371, 66.7%; mean [SD] dose, 12.6 [3.1] mg/week) vs  $>15$  mg/week (n=185, 33.3%; mean [SD] dose, 19.8 [0.8] mg/week). Baseline demographics and disease characteristics were generally similar between arms in MTX dose groups (Table). At Month 3, tofacitinib 5 and 10 mg BID were generally associated with numerically greater ACR and HAQ-DI response rates and greater changes from baseline in HAQ-DI score compared with placebo. The magnitude of tofacitinib effects on efficacy outcomes appeared broadly similar between background MTX dose groups (Table).

**Conclusion:** The results of this pooled analysis suggest that the efficacy of tofacitinib in pts with PsA was greater than placebo and does not differ when evaluated by background MTX dose ( $\leq 15$  vs  $>15$  mg/week), although small pt numbers in some groups may limit the conclusions that can be made. These results are consistent with findings from similar analyses of tofacitinib in pts with rheumatoid arthritis.

Table. Patient demographics and disease characteristics at baseline, and efficacy outcomes at Month 3 by MTX dose

	MTX dose $\leq 15$ mg/week			MTX dose $>15$ mg/week

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA). We describe the safety profile of tofacitinib from integrated Phase (P)3 and long-term extension (LTE) studies.

**Methods:** Data were analyzed for patients (pts) who received  $\geq 1$  dose of tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO), integrated across 2 P3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]) and 1 LTE study (OPAL Balance [ongoing, database not locked; NCT01976364]). Common adverse events (AEs; occurring in  $\geq 2\%$  of tofacitinib pts in any group) were analyzed in the PBO-controlled portion (Months 0–3) of the P3 studies (Cohort 1 [C1]). Serious AEs (SAEs) and discontinuations due to AEs were analyzed over 12 months in pts randomized to tofacitinib 5 or 10 mg BID in P3 studies (Cohort 2a [C2a]); pts randomized to PBO were excluded from this analysis. Deaths and AEs of special interest (serious infections [SI], herpes zoster [HZ], opportunistic infections [OI] including HZ, major adverse cardiovascular events [MACE], malignancies, non-melanoma skin cancer [NMSC]) were evaluated in all tofacitinib-treated pts in the P3 and LTE studies (Cohort 3 [C3]). Incidence rates (IR; pts with events/100 pt-years [PY] and 95% confidence intervals) are reported. Laboratory results will be reported in future publications.

**Results:** C1 included 474 tofacitinib- and 236 PBO-treated pts; C2a included 474 tofacitinib-treated pts; and C3 included 783 tofacitinib-treated pts (exposure: 776 PY). Nasopharyngitis (5.9%) and headache (8.5%) were the most commonly reported AEs at Month 3 in pts receiving tofacitinib 5 and 10 mg BID, respectively (Table). In pts randomized to tofacitinib 5 or 10 mg BID, over 12 months (C2a), the IRs for SAEs were 7.92 (4.09, 13.84) and 8.11 (4.19, 14.17), respectively. Discontinuation due to AEs occurred in 11 (4.6%) and 11 (4.7%) pts randomized to tofacitinib 5 and 10 mg BID, respectively, with IRs of 7.16 (3.58, 12.82) and 7.31 (3.65, 13.08), respectively, over 12 months (C2a). Across all tofacitinib-treated pts in the P3 and LTE studies (C3), SIs occurred in 11 pts (1.4%; IR 1.40 [0.70, 2.50]). HZ was reported in 16 pts (2.0%; IR 2.05 [1.17, 3.33]) receiving tofacitinib. All 3 cases of multidermatomal HZ were adjudicated as OIs; these were the only OIs (0.4%; IR 0.38 [0.08, 1.11]). In C3, 2 deaths occurred (0.3%; IR 0.25 [0.03, 0.91]); all were considered unrelated to the study drug. MACE were reported in 3 pts (0.4%; IR 0.38 [0.08, 1.11]), malignancies (excluding NMSC) in 5 pts (0.6%; IR 0.63 [0.21, 1.48]), and NMSC in 4 pts (0.5%; IR 0.51 [0.14, 1.30]) in C3.

**Conclusion:** Tofacitinib in active PsA demonstrated a safety profile consistent to that seen with tofacitinib in RA; no new risks were identified. Longer-term follow-up and larger pt populations will provide further information on the safety profile of tofacitinib in pts with PsA.

**Table: Common adverse events (≥2% occurrence in any group, all causalities) at Month 3 in patients receiving tofacitinib 5 or 10 mg BID or placebo (Cohort 1)**

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). Two Phase 3 studies have been completed (NCT01877668; NCT01882439) and a long-term extension (LTE) study is ongoing (database not locked; NCT01976364). This analysis compares incidence rates (IR) for adverse events (AEs) of special interest in a tofacitinib cohort from the Phase 3 PsA trials with real-world experience in a comparison cohort from the US Truven MarketScan database.

**Methods:** The tofacitinib cohort included adult patients (pts) from 2 Phase 3 studies with  $\geq 6$  months' PsA diagnosis who met CASPAR criteria, had active plaque psoriasis, and active arthritis ( $\geq 3$  swollen and  $\geq 3$  tender/painful joints). Pts were grouped by those who received tofacitinib 5 (N=238) or 10 mg (N=236) twice daily (BID) in the Phase 3 studies, and all pts who received  $\geq 1$  dose of tofacitinib in the Phase 3 studies or the LTE (tofacitinib all doses, N=783). The comparison cohort (N=5,799) comprised pts with moderate to severe PsA, defined by  $\geq 1$  inpatient or  $\geq 2$  outpatient 696.0 diagnosis codes on 2 unique calendar days ( $\geq 1$  by a rheumatologist) between Oct 2010 and Sep 2015, or initiated therapy with a systemic agent for PsA. Key Phase 3 study exclusion criteria were applied to the comparison cohort. IRs for serious infection events (SIEs), herpes zoster (HZ), malignancies (excluding non-melanoma skin cancer [NMSC]), NMSC, and major adverse cardiovascular events (MACE) were compared.

**Results:** Mean age, gender, and diabetes history were generally similar between the tofacitinib and comparison cohorts (48.7–49.5 years, 42.4–49.2% male, 12.2–15.7% history of diabetes). Overall, more tofacitinib-treated pts had prior experience with corticosteroids (15.7–28.2%), csDMARDs (100%), and tumor necrosis factor inhibitors (48.1–55.9%) vs the comparison cohort (11.9%, 46.6%, and 36.6%, respectively). IRs per 100 PY (95% CI) for SIEs requiring parenteral antibiotics in an outpatient/emergency setting, or resulting in hospitalization were 1.30 (0.16, 4.69) and 2.00 (0.41, 5.83) in the tofacitinib 5 and 10 mg BID groups, respectively (Table). IRs were generally similar between the tofacitinib and comparison cohorts for SIEs resulting in hospitalization only, and for SIEs requiring parenteral antibiotics in emergency settings or resulting in hospitalization (data not shown). In general, the tofacitinib cohort had a higher rate of HZ vs the comparison cohort, and similar IRs for malignancies and MACE between cohorts (Table).

**Conclusion:** IRs of AEs of special interest reported in tofacitinib PsA Phase 3 studies were generally comparable to those in a general PsA population comprising pts receiving a range of biologic agents, except HZ, which was higher for tofacitinib-treated pts but similar to the incidence observed with tofacitinib treatment in other indications.

**Table.** Incidence rates (95% CI)\* [PY exposure] for adverse events of special interest

## Secukinumab Sustains Individual Clinical Responses over Time in Patients with Psoriatic Arthritis: 2-Year Results from a Phase 3 Trial

**Paul Emery**<sup>1</sup>, Iain B. McInnes<sup>2</sup>, Philip J Mease<sup>3</sup>, Michael Schiff<sup>4</sup>, Luminita Pricop<sup>5</sup>, Steven Shen<sup>5</sup>, Zailong Wang<sup>5</sup> and Corine Gaillez<sup>6</sup>, <sup>1</sup>NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, <sup>2</sup>University of Glasgow, Glasgow, United Kingdom, <sup>3</sup>Swedish Medical Center and University of Washington, Seattle, WA, <sup>4</sup>University of Colorado, Denver, CO, <sup>5</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, <sup>6</sup>Novartis Pharma AG, Basel, Switzerland

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Achieving, sustaining, and improving clinical responses to biologics in PsA are important parts of EULAR and GRAPPA recommendations aimed to optimize treatment goals.<sup>1,2</sup> Here we present patient (pt)-level secukinumab data and report the likelihood of improving, sustaining, or worsening an ACR response and disease status (28-joint disease activity score using CRP [DAS28-CRP]) from Week (Wk) 24 to 104 in pts with active PsA from the FUTURE 2 trial.<sup>3,4</sup>

**Methods:** Data from FUTURE 2 trial through Wk 104 have been previously reported.<sup>4</sup> This *post-hoc* shift analysis was performed on ACR responses (ACR non-responders [NR], ACR20, 50, or 70) between Wks 24 and 104 for subgroups of secukinumab-treated pts categorized by their highest ACR response criteria at the earlier time point, by evaluating whether this response was improved, sustained or worsened at the later time point, using mutually exclusive ACR response categories and as observed analyses. Similar shift analyses on DAS28-CRP derived criteria were performed in 4 exclusive categories: high, moderate, and low disease activity (HDA, MDA, and LDA), and remission (REM) only.<sup>5</sup>

**Results:** In total, 86/100 (86%) and 76/100 (76%) pts in the secukinumab 300 and 150 mg groups, respectively, completed the 104-wk treatment. Of which, 73/70 and 81/75 pts in secukinumab 300/150 mg were eligible for ACR and DAS28-CRP shift analysis, respectively, from Wk 24 to 104. Baseline demographics and clinical characteristics were balanced across treatment groups.<sup>3,4</sup> Most secukinumab-treated pts who achieved at least an ACR20, 50, or 70 response at Wk 24, improved or sustained their response at Wk 104 (Figure). Similarly, a majority of pts who were in the MDA, LDA, or REM status at Wk 24 sustained or improved their disease status related to DAS28-CRP score at Wk 104 (Figure). In secukinumab 300 mg group, 53% of pts with LDA improved to REM and a majority (76%) of pts with REM maintained their status from Wk 24 to 104, whereas, in 150 mg group, a majority of pts (75% and 72% with LDA and REM, respectively) improved or maintained their status by Wk 104.

**Conclusion:** In this *post-hoc* analysis, a majority of secukinumab-treated pts who achieved at least ACR20 response or at least MDA at Wk 24 sustained or improved their ACR response or disease status at Wk 104. Numerically higher sustained ACR response and LDA or REM rate was observed for secukinumab 300 mg, thereby extending the sustainability of ACR response and lowering the disease activity that has been previously reported at group level.<sup>2,3</sup>

Figure: Shift Analysis in ACR and DAS28-CRP Responses from Week 24 to 104

#### ACR

#### DAS28-CRP

N = number of patients who completed Week 104 and had ACR or DAS28-CRP response available at both Weeks 24 and 104; n1 = number of patients with no ACR or DAS28-CRP response at Week 24, who completed Week 104 and had ACR or DAS28-CRP response available; n2-n4 = number of patients with ACR or DAS28-CRP response at Week 24, who completed Week 104 and had ACR or DAS28-CRP response available. DAS28-CRP response was calculated with validated cut-offs to indicate HDA (>5.1), MDA (>3.2 and ≤5.1), LDA (<3.2), and REM (<2.6).

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for treatment of psoriatic arthritis (PsA). We examined tofacitinib efficacy in patients (pts) with active PsA.

**Methods:** Data were pooled from 2 placebo (PBO)-controlled, double-blind, multicenter, global Phase 3 studies (OPAL Broaden [N=422; 12 months; NCT01877668]; OPAL Beyond [N=394; 6 months; NCT01882439]). Pts had active PsA and either inadequate response (IR) to  $\geq 1$  conventional synthetic disease-modifying antirheumatic drug (csDMARD) and were tumor necrosis factor inhibitor (TNFi)-naïve (OPAL Broaden), or had IR to  $\geq 1$  TNFi (OPAL Beyond). Pts were randomized to tofacitinib 5 mg twice daily (BID), 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (OPAL Broaden only), or PBO, and a single, stable csDMARD. PBO pts moved to tofacitinib 5 mg or 10 mg BID at Month (M)3. Endpoints included ACR20/50/70 response rates ( $\geq 20\%/ \geq 50\%/ \geq 70\%$  improvement), change from baseline ( $\Delta$ ) in Health Assessment Questionnaire-Disability Index (HAQ-DI), HAQ-DI response (decrease from baseline [BL] of  $\geq 0.35$ ),  $\geq 75\%$  improvement from BL in Psoriasis Area and Severity Index (PASI75),  $\Delta$  Leeds Enthesitis Index (LEI) and enthesitis absence,  $\Delta$  Dactylitis Severity Score (DSS) and dactylitis absence, and  $\Delta$  Dermatology Life Quality Index (DLQI). Tofacitinib 5 mg and 10 mg BID data (to M6) and PBO data (to M3), were pooled. Significance was declared at  $p \leq 0.05$  without correction for multiplicity.

**Results:** In total, 238, 236 and 236 pts received tofacitinib 5 mg BID, 10 mg BID, or placebo, respectively. Pts were white (94.2%) and female (55.4%) with  $\geq 5$  peripheral swollen or tender joints (98.0%), enthesitis (LEI $>0$ ; 67.5%), dactylitis (DSS $>0$ ; 52.5%), psoriatic body surface area  $\geq 3\%$  (67.7%), and C-reactive protein levels  $>2.87$  mg/L (62.5%) at BL. Mean age was 49.1 years; mean PsA duration was 8.0 years. Significant improvements vs PBO at M3 were seen for peripheral arthritis and physical function endpoints for tofacitinib 5 mg and 10 mg BID: ACR20, ACR50, ACR70,  $\Delta$ HAQ-DI, and HAQ-DI response (Table 1). Significant improvements in psoriasis, enthesitis, and dactylitis endpoints vs PBO were seen for tofacitinib 5 mg and 10 mg BID at M3: PASI75,  $\Delta$ LEI, enthesitis absence (using LEI),  $\Delta$ DSS, dactylitis absence (using DSS), and  $\Delta$ DLQI (Table 1). Efficacy was maintained or further improved at M6.

**Conclusion:** In a pooled analysis of csDMARD-IR/TNFi-naïve and TNFi-IR pts, tofacitinib 5 mg and 10 mg BID improved peripheral arthritis and physical function, psoriasis, enthesitis, and dactylitis vs PBO at M3.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA). Interim data up to January 2017 (database not locked) report the safety, tolerability and efficacy of tofacitinib for patients (pts) with active PsA from ≤36 months' participation in an ongoing open-label, long-term extension study (LTE; NCT01976364 OPAL Balance).

**Methods:** Eligible pts from 2 pivotal Phase (P)3 tofacitinib PsA studies (NCT01877668 OPAL Broaden, NCT01882439 OPAL Beyond) could enter a 3-year LTE ≤3 months after completing the qualifying study or discontinuing for reasons unrelated to the study drug. Pts received tofacitinib 5 mg twice daily (BID) for 1 month, after which an increase to 10 mg BID for efficacy reasons or a reduction back to 5 mg BID for safety reasons was permitted. All pts entered on a background of a csDMARD, as was mandated by the qualifying studies. Primary endpoints were incidence and severity of adverse events (AEs) and change from baseline in laboratory values. Efficacy was a secondary endpoint.

**Results:** 686 pts were enrolled and treated in OPAL Balance and 530 pts (77.3%) remained at data cut-off. Mean (range) duration of tofacitinib exposure in the LTE was 448 (1–1,015) days. On Day 1, 676 (98.5%) pts received a csDMARD, of which 56 (8.3%) later discontinued. To Month 36, 1,685 AEs were reported in 502 (73.2%) pts, 72 (10.5%) pts had serious AEs, and 52 (7.6%) discontinued due to AEs. AEs of special interest included 11 serious infections (1.6%), 19 herpes zoster events (2.8%) including 1 serious event of facial herpes zoster, 2 major adverse cardiovascular events (0.3%), and 13 (1.9%) malignancies. No AEs of gastrointestinal perforation or inflammatory bowel disease were reported. One AE of uveitis was reported. There were 4 deaths (not attributed to treatment, as assessed by the investigator) due to metastatic pancreatic carcinoma, acute cardiac failure/hypertensive heart disease, chronic obstructive pulmonary disease, and pulmonary embolism. Four AEs of latent tuberculosis were reported in pts whose previously negative QuantiFERON response became positive. Few pts experienced elevated liver enzyme levels; ALT was elevated ≥3 x ULN in 20 (2.9%) pts, AST ≥3 x ULN in 11 (1.6%) pts. Four (0.6%) pts met discontinuation criteria for laboratory values due to 2 sequential hemoglobin values <8.0 g/dL or decreases >30% from baseline value, 2 sequential platelet counts <75 x10<sup>9</sup>/L, 2 sequential AST or ALT elevations ≥5 x ULN regardless of total bilirubin or accompanying signs or symptoms, and 2 sequential increases in serum creatinine >50% and an increase >0.5 mg/dL over average of screening and baseline. Efficacy was maintained in the LTE (Table).

**Conclusion:** Over 36 months in the LTE, the safety profile of tofacitinib in pts with active PsA was generally similar to that of the pivotal P3 studies. No new safety signals were identified. Efficacy across various PsA disease domains was maintained over time.

Table. Summary of efficacy through to Month 24\*

	Tofacitinib (all patients)			
	Month 6	Month 12	Month 18	Month 24
(N=686)

### SESSION INFORMATION

Session Date: Sunday, November 5, 2017

Session Title: Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

**Background/Purpose:** DAPSA score is a validated tool to measure disease activity states and response criteria, focusing on peripheral joint involvement in patients (pts) with PsA.<sup>1</sup> Secukinumab, a fully human anti-IL-17A mAb, significantly improved signs and symptoms vs placebo (PBO) at Week (Wk) 24, with sustained ACR responses through Wk 104 from the FUTURE 2 study<sup>2,3</sup>. This *post-hoc* analysis assessed DAPSA responses through Wk 104 from FUTURE 2 study.

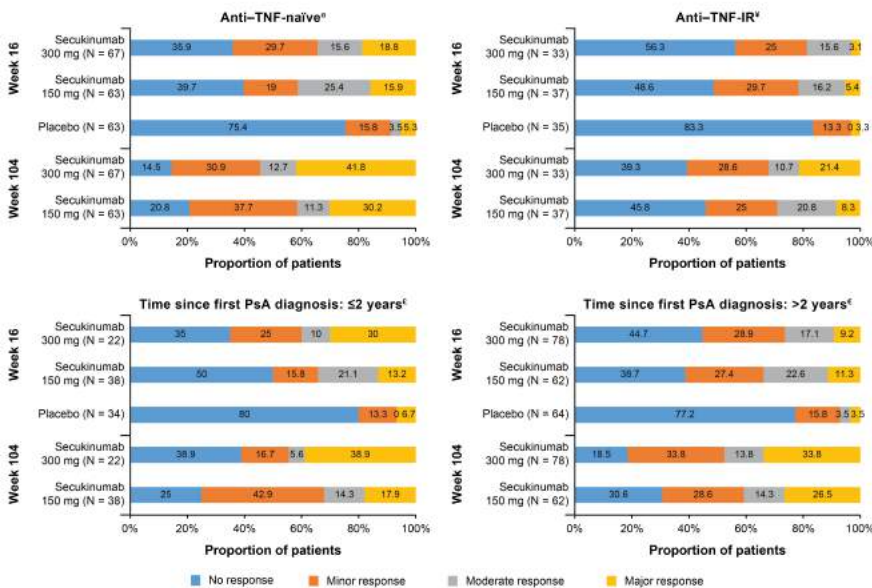

**Methods:** FUTURE 2 study design has been previously reported.<sup>3</sup> DAPSA score was derived as the sum of five variables: tender and swollen joint counts (TJC 68 and SJC 66), pt global and pt pain assessed on a 10 cm visual analog scale, and CRP level (mg/dL). DAPSA responses are presented for secukinumab 300 and 150 mg (approved doses) in overall population and in pts stratified by prior anti-TNF therapy use (anti-TNF-naïve vs inadequate response/intolerance to these agents [anti-TNF-IR]) and time since first PsA diagnosis ( $\leq 2$  vs  $> 2$  years) using observed data.

**Results:** Baseline demographics and clinical characteristics were similar across treatment groups.<sup>3</sup> A total of 96,100, and 87 pts treated with secukinumab 300, 150 mg, and PBO, respectively, were available for the evaluation of DAPSA response at Wk 16. DAPSA response in overall population showed moderate/major response in 16%/14% and 22%/12% vs 2%/5%; minor response in 28% and 23% vs 15%; no response in 43% and 43% vs 78% in secukinumab 300 and 150 mg vs PBO, respectively. DAPSA response rates were higher and sustained at Wk 104 in secukinumab-treated pts. A higher proportion (35% and 23%) of pts showed major response, with moderate response observed in 12% and 14% of pts treated with secukinumab 300 and 150 mg, respectively, at Wk 104. The proportion of pts achieving DAPSA response at Wks 16 and 104 by anti-TNF use and time since first PsA diagnosis is shown in the figure. The proportion of pts in overall population meeting DAPSA core components thresholds and other components of PsA among pts with DAPSA moderate/major response at Wks 16 and 104 is shown in the table.

**Conclusion:** In the overall population, around 30% of secukinumab-treated pts at Wk 16 achieved DAPSA moderate/major response vs  $< 5\%$  in PBO group, with numerical increase in the major response at Wk 104. Moderate/major response at Wk 16 was observed in pts regardless of prior anti-TNF use or time since first PsA diagnosis. Majority of the pts who achieved major response met all core components criteria, in contrast to the pts with moderate response.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Very low disease activity (VLDA) or remission (REM) and alternatively, minimal disease activity (MDA) or low disease activity (LDA) are optimal targets to be achieved by psoriatic arthritis (PsA) patients (pts).<sup>1,2</sup> DAPSA and MDA are validated composite indices used in PsA to measure disease activity states.<sup>3</sup> This exploratory analysis assessed the proportion of pts treated with secukinumab reaching DAPSA REM or LDA and those who reached either MDA or VLDA at Weeks (wks) 16 and 104 in the FUTURE 2 study.

**Methods:** Data through 2 years for the FUTURE 2 study have been reported.<sup>4</sup> DAPSA cut-offs included: REM ( $\leq 4$ ) and LDA ( $>4$  and  $\leq 14$ ).<sup>5</sup> MDA and VLDA are defined as having achieved at least 5 ( $\geq 5/7$ ) or all (7/7) of the 7 pre-specified criteria, respectively.<sup>6</sup> DAPSA-REM, DAPSA-REM/LDA, MDA, and VLDA and their core components were assessed in the overall population and in pts stratified by prior anti-tumor necrosis factor use and time since first PsA diagnosis using as observed data. Only data for secukinumab 300 and 150 mg (approved doses) and placebo are reported.

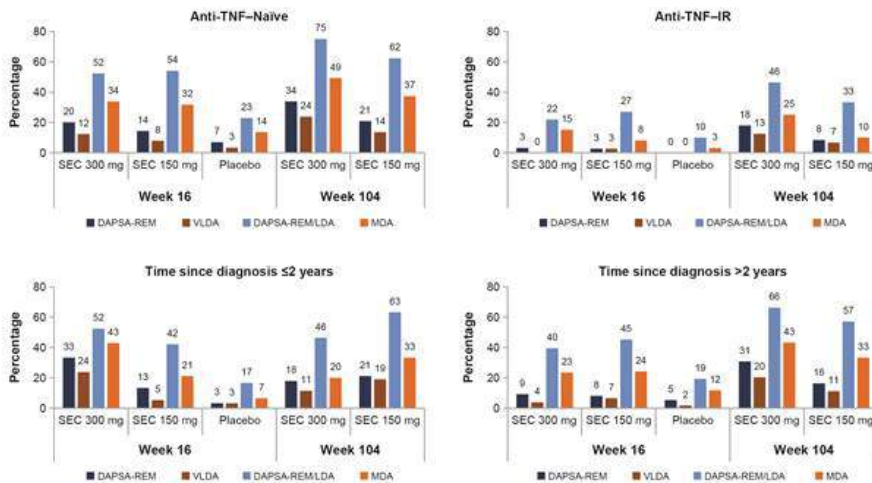

**Results:** Baseline characteristics were similar across treatment groups.<sup>4</sup> At Wk 16, in the overall population, the proportion of pts treated with secukinumab 300/150 mg achieving remission was 14%/10% (DAPSA-REM) and 8%/6% (VLDA) and achieving low disease activity was 42%/44% (DAPSA-REM/LDA) and 28%/23% (MDA). DAPSA and MDA responses by prior TNF-inhibitor status and time since diagnosis are presented in figure. DAPSA and MDA responses with secukinumab were sustained through Wk 104. Secukinumab treated pts who achieved either DAPSA-REM or VLDA at Wk 16 had complete resolution of TJC, SJC, enthesitis and PtGA. Numerically somewhat higher proportion of pts achieved skin clearance, HAQ-DI and PGA with VLDA than DAPSA-REM at Wk 16 and sustained to Wk 104 (Table).

**Conclusion:** In the overall population, a higher proportion of secukinumab treated pts at Wk 16 achieved DAPSA-REM, VLDA, DAPSA-REM/LDA, and MDA than those treated with placebo with a greater number of pts achieving DAPSA-REM or LDA than VLDA or MDA, respectively. These responses were sustained through Wk 104. At Wk 16, a higher proportion of anti-TNF-naïve pts and pts with early diagnosis ( $\leq 2$  years) treated with secukinumab achieved and sustained DAPSA-REM, MDA and VLDA than in the overall population.

Figure: Proportion of pts achieving DAPSA and MDA states by anti-TNF status and time since diagnosis at Wks 16 and 104

Total number of pts providing data to the analysis: secukinumab 300 mg (N=100), 150 mg (N=100) and placebo (N=96). MDA defined as achieving 5 of the following 7 criteria: Tender joint count ≤1, Swollen joint count ≤1, Psoriasis Area and Severity Index (PASI) ≤1, Pt pain VAS ≤15, Pt global VAS ≤20, Health Assessment Questionnaire - Disability Index (HAQ-DI) ≤0.5, Tender enthesal points ≤1. MDA ≥5/7 denotes achieving at least 5 criteria. VLDA ≥7/7 denotes achieving at 7 criteria. DAPSA was derived as the sum of five variables: tender joint and swollen joint counts (TJC 68 and SJC 66); pt global and pain assessed on a 10 cm VAS; and C-reactive protein levels (mg/dl) with disease states defined as follows: REM: DAPSA Score ≤4, LDA: 4 < DAPSA Score ≤14 and DAPSA-REM/LDA includes pts who achieved either of the two states. DAPSA score at baseline (mean [SD]) was 42.0 (17.4), 46.8 (24.3) and 44.9 (25.3) in the secukinumab 300 mg, 150 mg and placebo groups, respectively.

Components, n (%)	Week	Remission								Low Disease Activity

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). PsA is a heterogeneous disease and composite endpoints allow assessment of multiple clinical outcomes in one instrument. We examined the effects of tofacitinib treatment on several composite endpoints in patients (pts) with PsA.

**Methods:** In 2 placebo (PBO)-controlled, double-blind, multicenter, global Phase 3 studies, pts had active PsA and either had an inadequate response (IR) to  $\geq 1$  conventional synthetic disease-modifying antirheumatic drug (csDMARD) and were tumor necrosis factor inhibitor (TNFi)-naïve (OPAL Broaden [N=422; 12 months; NCT01877668]), or had an IR to  $\geq 1$  TNFi (OPAL Beyond [N=394; 6 months; NCT01882439]). Pts were randomized to receive tofacitinib 5 mg BID, tofacitinib 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (OPAL Broaden only), or PBO (advancing to tofacitinib 5 or 10 mg BID at Month 3, OPAL Broaden and OPAL Beyond), in addition to continuing on a single, stable csDMARD. Composite endpoints assessed: Psoriatic Arthritis Disease Activity Score (PASDAS), Disease Activity Score using 28 joints with C-reactive protein, Disease Activity Index for Reactive Arthritis/Psoriatic Arthritis (DAREA/DAPSA), and Composite Psoriatic Disease Activity Index score.

**Results:** Demographics and baseline disease characteristics were generally similar between treatment groups within the 2 studies, except for duration of PsA disease (longer in OPAL Beyond) and geographic distribution (OPAL Broaden having more Eastern EU pts). Baseline values for composite endpoints were generally similar across treatment groups and studies (Table). Both doses of tofacitinib showed improvements in composite endpoints vs PBO at Month 3 in both studies (Table). In OPAL Broaden, the effects of adalimumab were similar to both doses of tofacitinib across composite endpoints. Effect size for the composite endpoints (using a subpopulation of pts who had all available data for all endpoints) was highest for PASDAS and typically lowest for DAREA/DAPSA; this rank order of effect size was similar across treatment arms and studies. At Month 3, effect sizes in pts receiving active treatment ranged from 0.90 (DAREA/DAPSA for tofacitinib 5 mg BID) to 2.40 (PASDAS for tofacitinib 10 mg BID) in OPAL Broaden, and 0.81 (DAREA/DAPSA for tofacitinib 5 mg BID) to 1.84 (PASDAS for tofacitinib 10 mg BID) in OPAL Beyond (Table). Standardized response means generally followed the same pattern as effect size across studies with both doses of tofacitinib (Table).

**Conclusion:** In 2 Phase 3 studies, tofacitinib 5 mg and 10 mg BID improved composite endpoint scores vs PBO over 3 months in pts with PsA. The largest effect size and standardized response means were observed for PASDAS. Effect sizes and standardized response means varied across endpoints but were consistent across studies.

**Table. Summary of mean at baseline, LS mean change from baseline, effect size, and standardized response mean at Month 3 for composite endpoints (PASDAS, DAS28-3CRP, DAREA/DAPSA, CPDAI) in OPAL Broaden and OPAL Beyond studies**

Nominal \*p<0.05; \*\*p<0.01; \*\*\*p<0.001 vs placebo at Month 3.  
<sup>a</sup>For CPDAI, only patients with BL BSA ≥3% were included.  
<sup>b</sup>Based on MMRM model including data from baseline up to Month 3 without imputation.  
N = Number of patients in the FAS.  
N1 = Number of patients evaluable at baseline.  
N2 = Number of patients included in the MMRM model.  
N3 = Number of patients with BL BSA ≥3% in the FAS and with non-missing values of all 4 composite endpoints across visits of baseline, Month 3 (baseline and Month 3 only for placebo groups), Month 6, and Month 12 (for OPAL Broaden only). This subpopulation was used for the calculation of effect sizes and standardized response means across visits.  
Effect size at Month 3 was defined as (mean at baseline – mean at Month 3)/(SD at baseline); standardized response mean at Month 3 was defined as (mean at baseline – mean at Month 3)/(SD of change from baseline at Month 3).  
BID, twice daily; BL, baseline; BSA, body surface area; CPDAI, Composite Psoriatic Disease Activity Index score; CRP, C-reactive protein; DAREA/DAPSA, Disease Activity Index for Reactive Arthritis/Psoriatic Arthritis; DAS28-3, Disease Activity Score using 28 joints; FAS, full analysis set; LS, least squares; MMRM, mixed model for repeated measures; PASDAS, Psoriatic Arthritis Disease Activity Score; Q2W, every 2 weeks; SC, subcutaneous; SD, standard deviation; SE, standard error of LS mean.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets IL-17A. In the SPIRIT-P1 phase 3 study (NCT01695239), IXE was superior to placebo (PBO) in achieving ACR20 response at Week 24 in biologic DMARD (bDMARD)-naïve patients with active psoriatic arthritis (PsA). Here, the efficacy and safety of IXE over 2 years in SPIRIT-P1 is evaluated.

**Methods:** During the SPIRIT-P1 double-blind treatment period (DBTP; Weeks 0-24), 417 bDMARD-naïve patients with active PsA were randomized 1:1:1:1 to 80 mg subcutaneous IXE (160 mg starting dose at Week 0) every 4 weeks (Q4W), every 2 weeks (Q2W), 40 mg adalimumab every 2 weeks (ADA, active reference arm), or PBO. Of these, 381 patients entered the extension period (Weeks 24-52), followed by the long-term extension period (Weeks 52-156). Data presented here are for the combined extension periods (CEP; Weeks 24-108) in patients who completed the initial 24 weeks of treatment and received  $\geq 1$  dose of study drug during the CEP (CEP population). IXE-randomized patients continued on IXE throughout the CEP. PBO and ADA patients were re-randomized (1:1) to IXE Q4W or Q2W at Week 16 (inadequate responders) or Week 24; ADA patients had an 8-week washout period before receiving IXE. Patients failing to demonstrate  $\geq 20\%$  improvement in both tender joint count and swollen joint count at Week 32, or any subsequent visit, were discontinued from the study. Efficacy measures included ACR20/50/70 responses, HAQ-Disability Index (DI) Score, DAS 28 based on C-reactive protein (DAS 28-CRP), 75%, 90%, and 100% improvement in the Psoriasis Area and Severity Index (PASI 75/90/100), Leeds Enthesitis Index (LEI), and Leeds Dactylitis Index-Basic (LDI-B). Missing values were imputed by nonresponder imputation for categorical data and modified baseline observation carried forward for continuous data.

**Results:** Efficacy and safety results for the CEP population are summarized in Table 1. Improvements in ACR and PASI responses, resolution in enthesitis and dactylitis, and improvements from baseline in HAQ-DI, DAS 28-CRP, enthesitis, and dactylitis were observed at Week 108. Frequency of treatment-emergent adverse events (AEs) were similar across treatment arms and the majority were mild or moderate in severity; serious AEs occurred in 46 patients. One death occurred in the CEP population: an ADA/IXE Q4W patient with a history of dyslipidemia, diabetes mellitus, hypertension, and a previous transient ischemic attack, suffered a cerebrovascular accident at Week 108.

**Conclusion:** For patients naïve to biologic treatment, IXE demonstrated clinically significant improvement in the signs and symptoms of PsA across treatment groups up to 2 years of treatment. The safety profile of IXE observed during the CEP was similar to that observed in the DBTP of SPIRIT-P1 and SPIRIT-P2, as well as other phase 3 studies of IXE in patients with plaque psoriasis.

Abbreviations: ACR20/50/70= 20/50/70% improvement in American College of Rheumatology; BSA=body surface area; AE=adverse events; DAS28-CRP= Disease Activity Score 28 based on C-reactive protein; HAQ-DI= Health Assessment Questionnaire-Disability Index; LDI-B=Leeds Dactylitis Index-Basic; LEI=Leeds Enthesitis Index; N=number of patients in the analysis population; n=number of responders; PASI75/90/100= 75/90/100% improvement in the Psoriasis Area and Severity Index; SAE=serious adverse event; SD=standard deviation; TEAE=treatment-emergent adverse event.

Note: Adalimumab was an active reference arm in this trial during the double blind treatment period.

For efficacy analyses, baseline was defined as the last non-missing assessment recorded on or prior to the date of first injection of study treatment at Week 0. For safety analyses, baseline was defined as AEs which started prior to the study drug injection during the Extension Periods (Weeks 24-156).

<sup>a</sup>Only patients with psoriatic lesions ≥3% of BSA at baseline were included in the analysis.

<sup>b</sup>Only patients with enthesitis and LEI=0 at baseline were included in the analysis.

<sup>c</sup>Only patients with dactylitis and LDI-B=0 at baseline were included in the analysis.

<sup>d</sup>The Total IXEQ4W and Total IXEQ2W patient populations include all patients treated with IXEQ4W or IXEQ2W, respectively, during the combined extension, regardless of their treatment group during the double blind treatment period.

## Rapid Onset of Efficacy in Patients with Active Psoriatic Arthritis Treated with Ixekizumab: A Pooled Analysis of Data from Two Phase III Clinical Trials

Atul A. Deodhar<sup>1</sup>, Kim A. Papp<sup>2</sup>, Catherine Shuler<sup>3</sup>, So Young Park<sup>3</sup> and Tore K. Kvien<sup>4</sup>, <sup>1</sup>Oregon Health & Science University, Portland, OR, <sup>2</sup>K Papp Clinical Research and Probity Medical Research Inc, Waterloo, ON, Canada, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>Diakonhjemmet Hospital, Oslo, Norway

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rapid onset of clinical improvement is an important attribute of treatment success for patients with PsA. These analyses evaluate the speed of onset of clinical improvement in patients with active PsA treated with the IL-17A selective monoclonal antibody ixekizumab (IXE) compared with placebo (PBO) and include populations naïve to biologic treatment or with a previous inadequate response to TNF inhibitors.

**Methods:** Data were integrated from two Phase III, multicenter, double-blind, PBO- controlled trials. Patients with active PsA either naïve to biologic disease modifying anti-rheumatic drugs (SPIRIT-P1) or with prior lack of efficacy or intolerance to TNF-inhibitor(s) (SPIRIT-P2) were randomized to placebo (PBO, N=224), 80 mg IXE every 4 weeks (IXE Q4W, N=229) or every 2 weeks (IXE Q2W, N=226), after a 160 mg starting dose. Continuous data were analyzed using mixed-effects model for repeated measures; categorical data, using a logistic regression model with missing values imputed by nonresponder imputation.

**Results:** ACR20 response rates were significantly greater for both IXE doses ( $p<.001$ ) at week 1 (Fig 1). ACR50 response rates were significantly greater by week 2 for IXEQ4W ( $p=.013$ ) and week 1 for IXEQ2W ( $p=.030$ ). ACR70 response rates were significantly greater by week 4 (IXE Q4W,  $p=.039$ ) or week 2 (IXE Q2W,  $p=.002$ ). With the exception of the IXEQ2W ACR70 response rate at week 4 ( $p=.176$ ), response rates for ACR20, ACR50, and ACR70 remained statistically significant compared to PBO through the 24-week, double-blind study period. In patients with plaque psoriasis ( $\geq 3\%$  body surface area) at baseline, both IXE dosing regimens achieved significant improvements in psoriasis area and severity index total score compared to PBO by week 1 (Fig 2). Patients with HAQ-DI  $\geq 0.35$  at baseline demonstrated significantly improved physical function by week 1, as measured by HAQ-DI minimal clinically important difference ( $\geq 0.35$ ) response rates ( $p<.001$ ) for both doses of IXE (Fig 3).

**Conclusion:** Patients achieved significantly greater improvements in PsA, skin conditions, and physical function with both IXE dose regimens compared to PBO. Statistically significant improvements in multiple clinical measures occurred as early as week 1 and remained statistically significant through 24-weeks.

## Radiographic Progression of Structural Joint Damage in Patients with Active Psoriatic Arthritis Treated with Ixekizumab over 52 Weeks

Désirée van der Heijde<sup>1</sup>, Masato Okada<sup>2</sup>, Chin H. Lee<sup>3</sup>, Catherine Shuler<sup>3</sup>, Suchitrita Rathmann<sup>3</sup>, Chen-Yen Lin<sup>3</sup> and Philip J Mease<sup>4</sup>, <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>Swedish Medical Center and University of Washington, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Background/Purpose:** Ixekizumab (IXE), an anti-interleukin-17A monoclonal antibody, was shown to be superior to placebo (PBO) in clinical responses and inhibiting the progression of structural joint damage in patients with PsA treated for 24 weeks (wks).<sup>1</sup> The objective was to assess the progression of structural joint damage in PsA pts with IXE for up to 52 wks.

**Methods:** Biologic DMARD-naïve pts with active PsA (N=417) entered into SPIRIT-P1 (NCT01695239), a double-blind phase 3 trial. Pts must have had  $\geq 1$  joint erosion on the hand and foot x-rays confirmed by central reading or had a C-reactive protein level  $> 6$  mg/L at screening. 417 pts were randomized to IXE 80 mg every 2 wks (Q2W; N=103) or 4 wks (Q4W; N=107) following a 160 mg initial dose, PBO (N=106), or adalimumab 40 mg every 2 wks (ADA; active reference arm; N=101) for 24 wks. In the Extension period (EXT: Wks 24-52), PBO and ADA pts were re-randomized (1:1) to IXEQ2W or IXEQ4W at Wk 16 (inadequate responders) or Wk 24; ADA pts underwent a washout prior to IXE treatment. All pts were assessed for structural joint damage using the van der Heijde-modified PsA Total Sharp Score (mTSS, 0-528 scale). X-rays at Wks 0, 24, and 52 were scored independently by 2 readers blinded to time point and clinical data (average of readers). mTSS was excluded from the pre-specified analysis if the radiograph was taken after the scheduled visit date. In a post hoc analysis, mTSS from a radiograph taken after the scheduled visit date was interpolated and considered as observed data. Any missing data at Wk 52, in either presentation, were imputed using a linear extrapolation if they had at least 1 post-baseline value.

**Results:** Pts had active PsA at Wk 0 (Table). 381 pts (91.3%) entered the EXT, with 374 (98.2%) having radiographs collected during the EXT. Wk 52 mean (SD) mTSS change from baseline were 0.54 (2.11) and 0.09 (1.0) for pts randomized to IXEQ4W and IXEQ2W at baseline, respectively. Similar changes at Wk 52 were obtained with the post hoc analysis (Table). The majority of IXEQ2W or IXEQ4W pts exhibited no structural progression through 1 year of IXE treatment (Figure). In pts who switched from PBO or ADA to IXE, Wk 52 mean change from baseline mTSS values scores ranged from -0.03 to 0.41 (Table).

**Conclusion:** Over a 52-wk period, minimal changes in mTSS were observed in PsA pts entering the EXT and treated with IXEQ2W or IXEQ4W.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many subjects (sbj) with chronic plaque psoriasis exhibit nail and scalp involvement that can markedly affect quality of life and be difficult to treat. The phase 3b LIBERATE study evaluated efficacy and safety of apremilast or etanercept vs. placebo in biologic-naïve sbj with moderate to severe plaque psoriasis. Efficacy assessments included effects on preexisting nail and scalp disease and skin lesions.

**Methods:** In this double-blind, double-dummy study, sbj were randomized (1:1:1) to placebo (PBO), apremilast 30 mg BID (APR), or etanercept 50 mg QW (ETN) through Wk 16; thereafter, all sbj switched to or continued APR (PBO/APR, ETN/APR, APR/APR) through Wk 104. The primary endpoint was achievement of a PASI-75 response at Wk 16 with APR vs. PBO; the secondary endpoint was PASI-75 achievement at Wk 16 with ETN vs. PBO. Physician assessments were conducted for overall psoriatic activity (static Physician's Global Assessment [sPGA]); scalp disease activity (Scalp Physician Global Assessment [ScPGA], limited to sbj with score  $\geq 3$  at baseline [BL], indicating moderate to very severe scalp disease); and nail disease (Nail Psoriasis Severity Index [NAPSI], limited to sbj with active disease [NAPSI  $\geq 1$ ] in the target nail at BL). Responses were assessed through Wk 104 using last-observation-carried-forward methodology.

**Results:** The APR extension phase (Wks 16 to 104) included 226 sbj (PBO/APR n=73; APR/APR n=74; ETN/APR n=79). At Wk 16, PASI-75 response vs. PBO was significant for both APR and ETN; long-term treatment with APR maintained both PASI-75 and sPGA 0 or 1 response levels (**Table**). Improvements were seen in nail and scalp disease at Wk 16, and the proportion of responders continued to increase with APR treatment over 104 wks and in sbj who switched from ETN to APR (**Table**). ScPGA 0 or 1 was achieved by 50.0% to 59.2% of sbj across treatment arms, and mean percent improvement from BL NAPSI score ranged from -48.1% to -51.1% (**Table**); the proportion of sbj achieving NAPSI-50 response ranged from 48.6% to 65.2%. Adverse events (AEs) occurring in  $\geq 5\%$  of sbj during Wks 0 to 16 were diarrhea, nausea, nasopharyngitis, upper respiratory tract infection, headache, and tension headache; long-term assessment by exposure-adjusted incidence rates (EAIR)/100 sbj-yrs showed no increase with longer-term APR exposure. No increase in EAIR/100 sbj-yrs of serious AEs occurred during the APR extension phase (4.01 to 5.49, across groups) vs. Wks 0 to 16 (PBO 0.0; APR 12.57; ETN 7.91). Changes in laboratory parameters were infrequent and transient; EAIR/100 sbj-yrs remained low across groups through 104 wks.

**Conclusion:** APR demonstrated efficacy through Wk 104 in sbj who continued APR and sbj who switched from PBO or ETN to APR at Wk 16. The AE profile remained consistent with prolonged APR exposure; no new safety or tolerability issues were observed through Wk 104 in sbj with moderate to severe plaque psoriasis.

## **Integrated Efficacy Results from Two Phase 3 Trials of Ixekizumab for the Treatment of Psoriatic Arthritis**

**Bernard Combe**<sup>1</sup>, Peter Nash<sup>2</sup>, David Adams<sup>3</sup>, Lisa Kerr<sup>3</sup> and Olivier Benichou<sup>3</sup>, <sup>1</sup>Rheumatology, CHU Lapeyronie and Montpellier University, Montpellier, France, <sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ixekizumab (IXE) is a high-affinity monoclonal antibody that selectively targets interleukin-17A. Here, we present integrated efficacy data at Week 24 from two phase 3 trials of IXE for the treatment of psoriatic arthritis (PsA).

**Methods:** Patients with active PsA (SPIRIT-P1) and with prior lack of efficacy or intolerance to TNF-inhibitor(s) (SPIRIT-P2) were randomized to placebo (PBO, N=224), 80 mg IXE every 4 weeks (IXEQ4W, N=229) or every 2 weeks (IXEQ2W, N=226), after a 160 mg starting dose. All patients considered as inadequate responders at Week 16 received rescue therapy (changes in background therapy), while inadequate responders to PBO were also re-randomized to IXEQ4W or IXEQ2W. Continuous data were analyzed using mixed-effects model for repeated measures; categorical data, using a logistic regression model with missing values imputed by non-responder imputation.

**Results:** At Week 24, significantly more patients treated with either dose of IXE ( $p<.001$ ) compared to PBO achieved the primary endpoint of ACR 20, as well as ACR 50, ACR 70, and HAQ-DI change from baseline. Treatment with either dose of IXE resulted in significantly more patients achieving resolution of enthesitis (LEI;  $p<.05$ ) and dactylitis (LDI-B;  $p<.001$ ) compared to PBO. LDI-B improvements from baseline were also significantly greater ( $p<.05$ ) for IXE-treated patients versus PBO. Finally, greater skin clearance (via PASI improvement) was significantly higher for IXE-treated patients ( $p<.001$ ).

**Conclusion:** Patients treated with either dose regimen of IXE achieved significantly greater improvements in arthritis, physical function, and skin lesions compared to PBO at Week 24.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies have suggested that treating patients earlier with biologics could improve disease outcomes. The aim of this analysis was to assess the impact of disease duration on clinical and patient-reported outcomes in patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS) treated with subcutaneous golimumab (GLM) in Canadian routine practice.

**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab or GLM for rheumatoid arthritis, AS, or PsA, or with ustekinumab for PsA. Eligible patients for this analysis included PsA and AS patients initiating GLM treatment since 2010. Disease duration at entry in the registry was categorized by tertiles as early (PsA: <2 years; AS: <1 year), mid (PsA: 2-5 years; AS: 1-2 years) and long-term (PsA: ≥6 years; AS: ≥3 years) duration. Standard outcomes were assessed; key outcomes of interest were low disease activity (LDA), remission (based on DAS28-ESR <2.6 and CDAI ≤2.8), and minimal disease activity (MDA) achievement for PsA patients, and inactive disease (ASDAS <1.3) for AS patients. In order to determine the impact of disease duration on disease activity at 12 and 24 months, multivariate logistic regression and general linear models adjusted for age, gender, prior biologic treatment, and baseline disease parameters were utilized.

**Results:** A total of 253 PsA patients (54.4% female) and 376 AS patients (58.6% male) were included with a mean (SD) age of 52.7 (13.2) and 44.7 (13.3) years, respectively. Most patients were biologic naïve (PsA: 95.3%; AS: 95.5%). The mean (SD) duration of PsA and AS at baseline was 5.7 (7.7) and of 5.4 (9.8) years, respectively.

In the PsA patient group, significantly greater improvements in MD global assessment (MDGA) and pain from baseline to month 24 were observed amongst patients treated at early term (Table 1). Based on multivariate logistic regression analyses, patients treated at later stage disease were significantly less likely than patients treated early to achieve MDA (OR: 0.10; p=0.025) and CDAI LDAS (OR: 0.06; p=0.002) at 24-month. There was no association between PsA duration and LDA, remission and MDA achievement at 12 months.

Among AS patients treated at early term, significantly greater improvements in BASFI from baseline to month 24 were observed (Table 1). Based on multivariate logistic regression analyses, AS patients treated at mid- and long-term were significantly less likely than patients treated at early term to achieve inactive disease based on ASDAS at 12 months, with odds ratios of 0.21 (p=0.028) and 0.12 (p=0.003), respectively. Disease duration was not associated with AS inactivity at 24-month.

**Conclusion:** The results of this analysis demonstrate that earlier treatment of PsA and AS with GLM in real-world is associated with improved outcomes, particularly in selected patient-reported outcomes at 12 and 24 months.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate physical and mental health functioning, health state, and health-related quality of life (HRQoL) in patients with active psoriatic arthritis (PsA) treated with intravenously administered (IV) golimumab (GLM), an anti-TNF $\alpha$  monoclonal antibody.

**Methods:** In this Phase 3, multicenter, randomized, double-blind, placebo-controlled trial, adult patients (N=480) with active PsA naïve to anti-TNF $\alpha$  therapy (mean age=46 yr) received IV GLM 2 mg/kg (N=241) at Weeks 0 and 4 and every 8 weeks thereafter or placebo (N=239) at Weeks 0, 4, 12, and 20 with crossover to IV GLM at Week 24. Three self-report instruments were included: 1) Short Form Health Survey (SF-36), a generic instrument of physical and mental health functioning: scores for its Physical (PCS) and Mental Component Summary (MCS) and 8 subscales (physical functioning, role-physical, body pain, general health, vitality, social functioning, role-emotional, and mental health) each range from 0 to 100 with higher scores indicating better function; 2) EuroQol visual analog scale (EQ-VAS), a generic measure of current health state (0=worst health you can imagine to 100=best health you can imagine); 3) Dermatology Life Quality Index (DLQI), a disease-specific HRQoL instrument measuring impact of skin disorders on daily living (scores range from 0-30 with lower scores indicating lesser impact). SF-36 PCS and MCS at Week 14 were controlled secondary endpoints. Least square mean differences between the treatment groups were estimated using analysis of covariance controlling for methotrexate use and baseline score.

**Results:** Mean improvements from baseline with IV GLM vs placebo occurred as early as Week 8 in SF-36 PCS (8.0 vs 1.7) and MCS (5.0 vs 1.2) scores (Table 1). Greater mean improvements from baseline in PCS ( $p<0.001$ ) and MCS ( $p<0.001$ ) scores were seen with IV GLM vs placebo at Weeks 14 and 24. Greater mean improvements in all 8 SF-36 subscales at Weeks 14 and 24 were also observed with IV GLM vs placebo ( $p<0.001$  for all). The percentages of patients achieving clinically meaningful change (5 points or greater) in PCS and MCS scores were higher in IV GLM vs placebo at Weeks 14 and 24 (PCS: 67.6% vs 29.7%, 69.7% vs 29.3%; MCS: 51.5% vs 26.4%, 46.9% vs 29.3%;  $p<0.001$  for all). Mean EQ-VAS improvements were observed as early as Week 8 with IV GLM vs placebo (17.2 vs 3.7) and remained greater with IV GLM vs placebo at Weeks 14 and 24 (both  $p<0.001$ ; Table 1). Mean changes in DLQI were observed with IV GLM as early as Week 8 (-7.2 vs -1.7; Table 1). Higher percentages of patients in the IV GLM cohort achieved DLQI scores of 0 or 1 at Weeks 14 (35.3% vs 9.8%;  $p<0.001$ ) and 24 (40.7% vs 9.8%;  $p<0.001$ ) vs placebo.

**Conclusion:** Adult patients with active PsA treated with IV GLM showed marked improvements from baseline vs. placebo in physical and mental health function, health state, and HRQoL as early as Week 8; improvements were maintained through Weeks 14 and 24.

<b>Table 1: Summary of mean (standard deviation) changes in SF-36, EQ-VAS, and DLQI</b>

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies have suggested that concomitant methotrexate therapy may increase the efficacy of biologic treatments. A scarcity of data exists on the benefits of combination therapy with golimumab (GLM) and MTX as well as other DMARDs (oDMARDs). The aim of this analysis was to compare the long-term retention of GLM monotherapy vs. combination therapy with MTX and/or oDMARDs and to explore independent predictors of retention in patients with rheumatoid arthritis (RA) and psoriatic arthritis followed in Canadian routine practice.

**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab or GLM for RA, ankylosing spondylitis, or PsA, or with ustekinumab for PsA. Eligible participants for this analysis included RA and PsA patients treated with GLM. Patients were excluded if they had follow-up <24 months and were not discontinued. Treatment durability was assessed with the Kaplan Meier (KM) estimator of the survival function and Cox regression.

**Results:** A total of 336 RA patients were included; baseline characteristics and disease parameters are summarized by treatment group in Table 1. There were 195 (58.0%) patients who discontinued with a KM-based mean (SE) time to discontinuation of 36.2 (1.7) months. Between group differences were observed with higher treatment durability for

MTX+GLM+oDMARDs [39.8 (2.3)] months, followed by MTX+GLM [37.4 (3.4)], GLM+oDMARDs [27.2 (4.8)] and GLM monotherapy with [25.2 (3.0)] ( $p=0.025$ ). Upon adjusting for potential confounders, higher durability was observed for the MTX+GLM+oDMARDs group vs. GLM monotherapy [hazard ratio -HR- (95% CI): 0.59 (0.36-0.96),  $p=0.032$ ]. Moreover, increased baseline DAS28 [HR (95% CI): 1.17 (1.03-1.32),  $p=0.014$ ] and previous use of MTX [HR (95% CI): 1.73 (1.00-3.00),  $p=0.052$ ], were independently associated with premature treatment termination.

A total of 167 PsA patients were included; baseline characteristics and disease parameters are described by treatment group in Table 1. There were 96 (57.5%) patients who discontinued with a KM-based mean (SE) time to discontinuation of 34.7 (2.3) months. No between group differences were observed for treatment durability. However, upon adjusting for potential confounders, increased baseline MDGA [HR (95% CI): 1.12 (1.01-1.25),  $p=0.038$ ], previous use of MTX [HR (95% CI): 3.54 (1.09-11.45),  $p=0.035$ ], and female gender [HR (95% CI): 1.96 (1.19-3.21),  $p=0.008$ ] were independently associated with premature treatment termination.

**Conclusion:** The results of this analysis have shown that combination therapy with GLM, MTX and other DMARDs is significantly associated with higher treatment durability compared to GLM monotherapy among RA patients. Although gender and MDGA were identified as significant independent predictors of long-term retention among PsA patients, treatment durability was not affected by concomitant MTX and DMARD use.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The efficacy of Golimumab (GLM) treatment in psoriatic arthritis (PsA) patients has been widely documented. The aim of this study was to analyze the long-term retention of GLM and to identify independent predictors of drug retention in patients with PsA including concomitant DMARD.

**Methods:** Prospective monocentric cohort of PsA patients treated with GLM according to clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analyzed with Cox proportional hazard regression model.

**Results:** 48 patients were included, 20/48 (41.7%) oligoarticular, 19/48 (39.6%) polyarticular and 9/48 (18.7%) with peripheral and axial PsA. The baseline characteristics of the patients are shown in Table 1. Mean follow-up time was 22.3 months (SD 19.0). Mean survival time was 40.3 months (95% CI: 32.0-48.5). Age, mean evolution time and previous biological use were significant in the univariate analysis. Concomitant DMARD had no influence on GLM retention rate (HR: 1.3; 95% CI: 0.5-3.2; p: 0.6). Figure 1. Patients with PsA treated with GLM as first or second biological tended to

have a better retention rate of the drug, but did not reach statistical significance. Fig 2. 18/48 (37.5%) withdraw GLM treatment. 13/18 (72.2%) due to lack of efficacy, 1/18 (0.6%) due to adverse events and 4/18 (22.2%) due to other reasons.

Table 1. Baseline demographic and clinical characteristics of the patients.

Age -mean (SD)-years	48.3 (11.1)
Female gender %	52.1%
Mean evolution time (SD) years	8.4 (7.9)
TJC	4.1 (4.1)
SJC	2.9 (2.7)
CRP mg/dl Mean (SD)	0.6 (0.7)
DAS28-CRP	3.7 (1.5)
Concomitant DMARD %	50%
Biological Therapy naïve %	52.1%

**Conclusion:** Real-world Golimumab retention rate in patients with PsA was good and did not depend on concomitant treatment with DMARD. When used as first or second biologic, Golimumab retention rate tend to be better.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Secukinumab, an anti-interleukin 17A monoclonal antibody, showed significant improvement of signs and symptoms of psoriatic arthritis (PsA) in phase 3 studies. Available studies used conventional radiography, not allowing a deeper imaging analysis of the inflammatory changes during application. The aim of this study was to assess short term efficacy of secukinumab on inflammation and structural damage according to change in OMERACT-EULAR ultrasound score, the MRI PsAMRIS score, and HRpQCT scans of the MCP and PIP joints in PsA patients.

### **Methods:**

PsA patients with active disease (TJC and SJC  $\geq 3$ ), were included in the 24 week open label prospective PSARTROS study and treated with subcutaneous secukinumab 300 mg once weekly over 4 weeks, then once every 4 weeks. Baseline 1,5T MRI hand scans, HRpQCT scans of the MCP and PIP joints, and ultrasound imaging of 28 joints were performed at baseline and after 24 weeks of treatment. MRI was scored according to PsAMRIS. HRpQCT scans were evaluated for erosions and osteo-proliferation. Ultrasound was assessed for synovial hypertrophy and Doppler activity according to OMERACT scores. Statistical significance was set at  $p \leq 0.05$ .

**Results:** 20 patients, mean age  $52 \pm 9.9$  years, 60% female, mean disease duration  $6.7 \pm 5.9$  years, 50% naive for biological therapy, were included in the study. Three patients were early discontinued (recurrent pharyngitis, lack of efficacy, withdrawal of consent), and were not included into the longitudinal analysis. Baseline DAS28 was  $5.03 \pm 0.96$ , baseline

DAPSA was  $32.2 \pm 12.1$ . On baseline MRI, all patients had at least one inflammatory sign (synovitis: 90%, osteitis: 20%, periarticular inflammation: 25%, flexor tenosynovitis: 35%, bone proliferation: 30%, erosions: 60%). Baseline composite PsAMRIS score was  $11.6 \pm 12.8$  and baseline PsAMRIS synovitis score was  $3.7 \pm 3.3$ . Baseline ultrasound synovial hypertrophy and Doppler activity were  $6.2 \pm 4.5$  and  $3.5 \pm 4.0$ , respectively. Specific MRI and ultrasound scores were significantly correlated with DAS28 and DAPSA at baseline. Clinical disease activity parameters significantly improved at follow up (DAS28:  $2.94 \pm 0.95$ ,  $p < 0.001$ ; DAPSA:  $8.8 \pm 5.8$ ,  $p < 0.001$ ). PsAMRIS synovitis score ( $2.5 \pm 2.4$ ) as well as composite PsAMRIS score ( $8.8 \pm 10.0$ ) decreased longitudinally with secukinumab treatment ( $p = 0.034$  and  $p = 0.039$ , respectively). There was no progression in erosion or proliferation scores between baseline and follow-up through MRI and HRpQCT imaging. Synovial hypertrophy and Doppler activity in ultrasound also significantly improved with secukinumab treatment ( $2.3 \pm 3.5$ ;  $p = 0.009$  and  $1.8 \pm 2.7$ ;  $p = 0.003$ , respectively). A significant percentage of patients reaching minimal disease activity showed residual signs of synovitis in the MRI and US (66% and 50%, respectively).

## Conclusion:

Secukinumab significantly improves MRI and ultrasound signs of joint inflammation in patients with PsA. No progression in articular damage or osteo-proliferation was observed.

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Psoriatic Arthritis (PsA) is a heterogeneous disease which makes management of PsA a challenge. European League Against Rheumatism (EULAR) and the Group for Research and Assessment of Psoriasis and PsA (GRAPPA) updated their respective recommendations for the management of PsA in 2015. However, these recommendations are primarily based on studies conducted in resource replete countries of Europe and North America; they may not necessarily be applicable to PsA patients in countries in Central and South America, Africa and the Asia-Pacific region. Therefore there is a need to adapt the EULAR and GRAPPA recommendations for each of these regions under the auspices of ILAR.

### **Methods:**

1) The ADAPTE process for guideline adaptation was used to assess and adapt the EULAR and GRAPPA treatment recommendations for PsA. Guideline quality was assessed using the 23 criteria of the Appraisal of Guidelines for Research and Evaluation (AGREE) instrument.

2) A literature search included three databases Medline, Embase, LILACS to identify studies that addressed additional treatment issues in Central and South America, Africa and the Asia-Pacific region.

### **Results:**

The setup phase of the ADAPTE process was completed. Key health professionals in Pan-American League of Associations for Rheumatology (PANLAR) and The African League of Associations in Rheumatology (AFLAR) as well as patient research-partners identified key health issues faced. The adaptation phase of the ADAPTE process was carried out with both EULAR and GRAPPA recommendations assessed for quality and relevance to ILAR regions. Three different categories were assessed in the two guidelines; a) efficacy and safety of pharmacotherapy, b) recommendation for physicians with limited access to other specialists, c) screening and management of tuberculosis (TB), hepatitis B/C, human immunodeficiency virus (HIV), Chagas' disease, leishmaniasis, and leprosy. The consensus (> 75% of votes) was to adapt the GRAPPA guidelines in terms of recommendations regarding efficacy and safety of pharmacotherapy, however, recommendations for combination therapy with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) and biologic (b)DMARDs was not stated and evidence needed to be synthesized from literature review. Similarly, recommendation for biosimilars, biomimics; physicians with limited access to specialists; screening and management of TB, HB/C, HIV, Chagas' disease, leishmaniasis, was lacking and referred to literature review.

The literature search retrieved a total of 634 articles; following exclusion of duplicates and off-topic items and after title and abstract review 26 articles were included for full text review. Results from the literature review suggests lack of recommendation/evidence around use of biosimilars/biomimics, skin treatment in the absence of dermatologist, and issues around screening and management of certain diseases relevant to resource-poor countries.

### **Conclusion:**

New ILAR recommendations have been devised using adaptation from the GRAPPA recommendations where appropriate and additional SLR data to answer specific issues for resource poor settings and devise a research agenda for these regions.

## Short-Term Efficacy and Safety of New Biological Agents Targeting the IL-6, IL-12/23 and IL-17 Pathways for Active Psoriatic Arthritis: A Network Meta-Analysis of Randomised Controlled Trials

Dongze Wu, Jiang Yue and Lai-Shan Tam, Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong

First publication: September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

According to EULAR recommendations, in patients with peripheral arthritis and an inadequate response to at least one conventional synthetic DMARD, biologic DMARDs targeting IL-12/23, IL-17 pathways may be used in patients for whom TNF inhibitors are inappropriate. The objective of this study was to investigate comparative efficacy, safety and tolerability of IL-6, IL-12/23 or IL-17 inhibitors for patients with active psoriatic arthritis (PsA).

### Methods:

Randomized controlled trials (RCTs) evaluating the efficacy, safety and tolerability of IL-6, IL-12/23 or IL-17 inhibitors were identified by a comprehensive systematic literature review. Pair-wise meta-analyses and Bayesian network meta-analyses using the random-effects model were performed to estimate pooled odds ratios (ORs) and 95% credible interval (CrI) of attaining a 20% improvement according to American College of Rheumatology criteria (ACR20) and ACR 50 response across trials.

### Results:

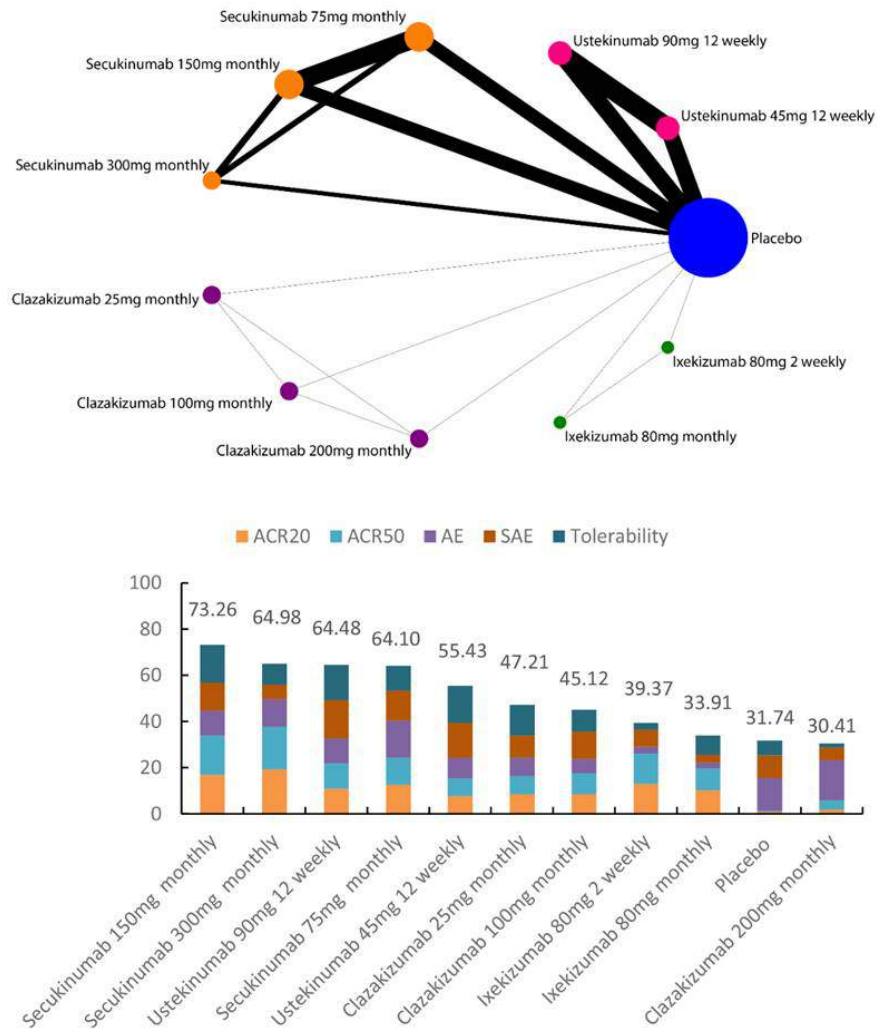

Six trials were identified which included 2,411 participants and 11 treatments. Pair-wise meta-analysis showed that secukinumab, ustekinumab and ixekizumab demonstrated superior efficacy over placebo in achieving ACR 20 and ACR50 response. However, Ixekizumab has a higher incidence of adverse events (AE) than placebo. In contrast, ustekinumab has a higher tolerability (less likely to be discontinued due to AE) than placebo. Network meta-analysis showed that secukinumab (300mg monthly) had the highest efficacy in achieving ACR20 and ACR50; whereas clazakizumab (200mg monthly), ustekinumab (45mg 12 weekly), secukinumab (150mg monthly) had the lowest probability of having AE, serious AE, and intolerability respectively. Considering overall risk-benefit profile, secukinumab (150mg monthly) may offer an optimal balance for active PsA patients.

### Conclusion:

From available evidence, secukinumab was found to be the safest and most efficacious short-term treatments for active PsA amongst all the new biologics targeting the IL-6, IL-12/23 and IL-17 pathways.

## Effect of Adding MTX to TNF Inhibitors on Joint Severity Indices and Skin Scores in Psoriatic Arthritis: A Post-Hoc Meta-Analysis of Randomized, Controlled Trials

**Rochelle Castillo**<sup>1</sup>, **Khushboo Sheth**<sup>2</sup> and **Santhanam Lakshminarayanan**<sup>3</sup>, <sup>1</sup>University of Connecticut, Farmington, CT, <sup>2</sup>Rheumatology, Stanford University, Palo Alto, CA, <sup>3</sup>Division of Rheumatology, University of Connecticut Health Center, Farmington, CT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

Background/Purpose:

Co-medication of MTX with TNF inhibitors (TNFi) has proven superior to TNFi monotherapy in improving clinical outcomes in patients with RA. Whether this holds true in psoriatic arthritis (PsA) remains unclear. We undertook this study to summarize the post-hoc data from randomized, controlled trials (RCTs) on PsA to determine the effect of adding MTX to TNFi on joint severity indices and skin scores.

Methods:

We performed a systematic search of PubMed, Medline, Scopus, and the reference lists of relevant articles for studies published up to April 2017. RCTs containing data on the effect of combination MTX and TNFi versus TNFi monotherapy were included. A random effects model was used to pool extracted data. Heterogeneity was evaluated with  $I^2$ ;  $p$ -values < 0.05 were considered significant. Relative benefit, the equivalent of relative risk in studies that aim to improve outcomes, was used to measure the effect size of dichotomous variables.

Results:

Eight clinical trials consisting of 1,055 subjects were included. Responses were grouped into categories based on duration of treatment (12±4 weeks, 24±4 weeks, 48±4 weeks) and outcome measured. Meta-analysis was performed when at least two studies provided data for the same outcome during the same time frame. In studies measuring ACR 20/50/70 at Week 12, there was no statistically significant difference between combining TNFi with MTX vs. TNFi alone (Figure 1). The same trend of no added benefit to combination therapy was observed in ACR 20/50/70 at Week 24 and ACR 20 at Week 48. In studies that measured PASI 75, there was a non-significant trend toward increased response at Weeks 24 and 48 with combination therapy compared to TNFi monotherapy (Figure 2).

Conclusion:

In contrast to RA, the post-hoc data gleaned from PsA trials has not suggested a benefit to adding MTX to TNFi in improving joint severity indices. This may be attributed to the fact that MTX monotherapy is generally considered less effective in PsA than in RA. However, the non-significant trend toward increase in PASI 75 suggests that combination therapy may be beneficial in the subset of PsA patients with significant skin involvement. An inherent limitation of the included studies is that subjects in the MTX+TNFi group were already on stable MTX doses prior to initiating TNFi therapy. Thus, studies directly comparing TNFi monotherapy with combination therapy with MTX in MTX-naive patients are needed to arrive at definitive conclusions.

Figure 1. ACR 20/50/70 at Week 12 with adalimumab (ADA) and infliximab (IFX)

Figure 2. PASI 75 at Weeks 24/48 with ADA, etanercept (ETN), and IFX.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is a heterogeneous inflammatory arthritis affecting multiple clinical domains. If left untreated, it has the potential for significant morbidity and disability. Prior to the introduction of TNF-alpha inhibitors (TNFi), therapeutic options were limited. Agents that block the IL-17 pathway (IL-17i) were recently FDA-approved, showing remarkable improvement in psoriasis, as well as similar efficacy to TNFi in PsA. Surprisingly, IL-17i are not effective for all autoimmune conditions, and appear to exacerbate Crohn's disease, even leading to *de novo* intestinal inflammation. Because IL-17 plays a physiologic role in maintaining gut epithelial health and fighting extracellular bacteria and fungi, we propose that intestinal inflammation occurs as a result of microbial dysbiosis. The goal of this study was to better understand the interaction between IL-17i and the microbiome in humans and mice.

**Methods:** Fecal samples were collected from subjects with PsA pre- and post-treatment with secukinumab (n=9), an anti-IL-17A monoclonal antibody, and adalimumab (n=10), a TNFi, which served as the control. In parallel, fecal pellets were collected from wild type mice pre- and post-exposure to anti-IL-17 or MOPC isotype control antibodies. Samples underwent DNA extraction, amplification, and 16S rRNA gene sequencing with Illumina MiSeq. Analysis was performed

with Quantitative Insights into Microbial Ecology (QIIME) and R. Additionally, short and medium chain fatty acids (SCFA/MCFA) were measured utilizing liquid chromatography coupled with mass spectrometry (LC-MS/MS).

**Results:** PsA subjects treated with IL-17i did not show differences in overall microbial alpha or beta diversity pre- and post-treatment. However, there was a significant shift in the *Firmicutes* to *Bacteroidetes* ratio after just five weeks of therapy. Subjects clustered into two well-defined groups based on expansion or contraction of the *Clostridiales* taxa. Relative abundance of *Clostridiales* correlated with levels of the SCFA acetate ( $r=0.4$ ,  $p=0.09$ ) and the MCFA hexanoate ( $r=0.4$ ,  $p=0.09$ ). These differences were absent in TNFi-treated controls. Similarly, mice exposed to anti-IL-17 antibody showed parallel perturbations in microbiota composition as demonstrated by alpha ( $p<0.05$ ) and beta diversity ( $p<0.05$ ), with expansion of *Clostridia* and related taxa ( $p<0.05$ ).

**Conclusion:** We characterized the effects of biologic therapies on gut microbiota composition and metabolites in human PsA and in mice. Treatment with IL-17i leads to a gut microbial dysbiosis not seen with TNFi. Further studies to understand the downstream effects of these perturbations may allow for the development of precision medicine approaches to PsA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Tumour necrosis factor (TNF)-blocker tapering has been proposed for patients with psoriatic arthritis (PA) in clinical remission. To evaluate if there are clinical, demographic and ultrasound (US) data predictive of disease recurrence after spacing of anti-TNF therapy in PA patient during a phase of minimal disease activity (MDA)

## Methods:

Patients treated with anti-TNF for at least 12 months and with at least 6 months duration of MDA were consecutively recruited at 6 Italian centers.

In every center, the local rheumatologists provided PA pts to be examined by US. Personal history, demographic and clinical data were recorded. Each patient underwent the following US examinations : metacarpophalangeal (MCP), knee and tibio-tarsal (TT) joint, flexor and extensor tendon of hand digit, flexor and extensor tendon at carpal area, flexor and extensor tendon of foot, and enthesis of common extensor tendon insertion on the lateral epicondyle of the humerus, quadriceps tendon, patellar tendon, Achilles tendon and plantar fascia insertions on the calcaneus.. Each examination were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, flexor tendon tenosynovitis, ext tendon tenonitis, and enthesel involvement using an Esaote MyLabClass with a 5-13 or 6-18 MHz linear probe. US examiners were blind of clinical data of the pts. After the clinical and US examination patients increased the interval between the anti-TNF administration according to a common protocol. The patients were clinically evaluated at three month interval for the maintenance of a state of MDA. Baseline clinical and US data were compared between the group of patients still in MDA at the end of a minimum follow-up period of 6 month vs the group of patient with disease recurrence.

## Results:

Sixty-three pts were recruited (mean age 53+13y, mean PA duration 13+8y, mean. MDA duration 21+11m). At the end of follow-up period 5 patient were lost, 47 (81%) maintained a state of MDA and 11 (19%) had recurrence. At baseline US examination 66.7 % of pts had at least one peripheral joint involved (17.5 % had peripheral active synovitis), 47.6% had acute enthesitis and 95.2% chronic enthesopathy. US bursitis was present in 22.2% of pts, 3.7% had hand extensor finger tendon involvement. No significant difference in any US and demographic data were present between the group in persistent MDA vs the recurred group. Patients with baseline Maastricht enthesitis index (MEI) > 0 had higher risk of recurrences as compared with the group with MEI = 0 (36% vs 10%, p = 0.034).

## Conclusion:

The presence of joint, enthesal and tendon abnormalities at US examination are not predictive of disease recurrence after anti-TNF spacing in PA patients in MDA. Only a value of MEI > 0 is significantly correlated to recurrence.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early diagnosis in psoriatic arthritis (PsA) is mandatory in order to initiate early therapy and prevent disability. Around 20% of patients with Psoriasis (PsO) routinely visited in Dermatology departments have PsA previously undiagnosed. The aim of this study is to evaluate the presence of inflammation by clinical examination and ultrasound in joints and entheses of patients with PsO without musculoskeletal symptoms.

**Methods:** Patients with PsO under topic or PUVA therapy without musculoskeletal symptoms were referred to our Arthritis Unit. Clinical and demographic data were collected. The patients were evaluated for Body Surface Area (BSA), Swollen Joint Count (SJC) (66 joints), Tender Joint Count (TJC) (68 joints) and entheses (MASES). Psoriatic Arthritis Impact of Disease tool questionnaire (PsAID) and Psoriasis Epidemiology Screening tool questionnaire (PEST) were used to assess the impact of the disease. A comprehensive ultrasound evaluation of 46 joints and 12 entheses was made (ESAOTE MylabTwice, 12-18 Mhz probe). Enthesis score was calculated using the Madrid Sonographic Enthesis Index (MASEI) and a total score for synovitis (synovial hypertrophy and Power Doppler) was also calculated.

**Results:** 32 patients were included. 18 patients were female (56.3%), mean age (SD) was 48.3 years (14.6) and disease duration was 17.9 years (15.9). Mean BMI was 24.6 (5.2) and BSA 6.69 (8.7). 8 out of 32 (25%) had severe PsO (systemic treatment or BSA>10% at any time of evolution). 4 patients (12.5%) had Power Doppler signal and 2 (6.3%) fulfilled criteria for ultrasound-defined active synovitis (SH>2+PD) despite no signs or symptoms of musculoskeletal disease. However, although structural alterations such as calcifications and enthesophytes were frequent, no PD was found at any entheses. In the univariate analysis, higher BMI (p=0.013), weight (p=0.010), waist (p=0.033) and hip (p=0.014) circumferences were significantly associated with severe PsO. In the same way, CRP serum levels were also significantly higher in patients with severe PsO (p=0.027).

**Conclusion:** Patients with severe PsO had significantly higher CRP serum levels, BMI, weight, waist and hip circumferences. Of note, 12.5% of PsO patients had subclinical synovitis defined as PD. These patients should be followed in order to confirm if they develop Psoriatic Arthritis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Knowledge of the existence of an epidemiological association between SpA and periodontitis may fuel pathophysiological thinking about SpA and if established, have clinical implications. Currently, it is unclear whether SpA patients have a higher frequency of periodontitis and data in the literature reporting a possible association is limited. . Therefore, the aim of the present study was to compare the frequency and severity of periodontitis in SpA-patients with healthy-control individuals, through the evaluation of clinical, serological and microbiological periodontal condition.

**Methods:** Patients with a diagnosis of SpA (n=78) and bDMARD-naïve fulfilling the ASAS classification criteria as well as 156 healthy-controls matched for age/gender, were included. Two trained and calibrated periodontologists performed the periodontal clinical assessment. The presence of periodontitis and its severity were determined according to the criteria established by the Center for Disease Control and Prevention-American Academy of Periodontology (CDC-AAP). The clinical periodontal variables, IgG1/IgG2 antibodies against *P. gingivalis* and periodontopathic bacterial identification, were also established. Comparisons of periodontal characteristics between the SpA-patients and the control-group were performed using univariable analyses. A logistic regression analyses was performed to calculate the odds ratio (95% CI) for diagnosis of periodontitis in SpA-patients and matched-controls.

**Results:** A diagnosis of periodontitis was established in 56% in SpA patients vs. 69% of healthy-controls ( $p<0.001$ ). Severe periodontitis was found in 3% vs 12% in SpA vs healthy-controls respectively ( $p<0.001$ ). There was no significant increase of frequency of any periodontal variable, IgG1/IgG2 antibodies against *P. gingivalis* or the presence of periodontopathic bacteria between SpA patients and control-group. Periodontitis was not positively associated with a diagnosis of SpA (OR: 0.57 95% CI 0.32-1.00,  $p=0.05$ ) in the logistic regression analyses

### Conclusion:

Our results suggest that –unlike the situation in RA- there is not a positive association between SpA and periodontitis in Colombian patients. We even found a lower prevalence of periodontitis and less severe periodontitis in comparison to healthy controls. Moreover, all periodontal characteristics evaluated including clinical parameters, antibodies anti *P. gingivalis* and bacterial identification were not increased in SpA patients as compared to controls.

**Table 1** Characteristics and periodontal variables in patients with spondyloarthritis (SpA) and healthy controls

Characteristics	SpA (n=78)	Controls (n=156)	p-value
Age (years)	39.6 (11.0)	39.5 (11.1)	†

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prior studies have demonstrated abnormalities in the composition of the gastrointestinal microbiota in pediatric and adult patients with spondyloarthritis (SpA.) In particular, diminished fecal abundance of *Faecalibacterium prausnitzii* and abnormalities in both directions in the abundance of the *Bacteroides* genus have been identified, mirroring results in studies of patients with inflammatory bowel disease.

**Methods:** We obtained fecal specimens from children with treatment-naïve enthesitis-related arthritis (ERA) and healthy controls from multiple geographic locations, as well as specimens from adult patients with long-standing SpA. All of the samples underwent sequencing of the 16S ribosomal DNA (rDNA). A subset of the ERA and healthy pediatric fecal samples were also subjected to shotgun metagenomics sequencing.

**Results:** Children with ERA (n = 30) and healthy controls (n = 19) underwent 16S rDNA sequencing. Clustering of the microbiota based upon diagnosis (p = 0.046) was observed, while among ERA patients, there was no clustering by geographic location. In contrast to previous studies, fecal abundance of *F. prausnitzii* was slightly higher in the patients versus controls (10.0% vs 7.8%, p = 0.192); however strain-level differences were observed, with patients having relatively decreased abundance of the anti-inflammatory A2-165 strain (41% versus 54%, p = 0.084) and an increased abundance of the control L2/6 strain (28% versus 15%, p = 0.038). Similar trends were observed in adults with long-standing SpA (n = 11) and controls (n = 10): total *F. prausnitzii* 10% in patients versus 6.9% in controls (p = 0.427), while A2-165 as percentage of *F. prausnitzii* was 25% in patients versus 41% in controls (p = 0.175).

With respect to *B. fragilis*, opposite trends were seen among the pediatric versus the adult subjects. Specifically, pediatric patients with ERA demonstrated increased abundance of *B. fragilis* compared to controls (2.0% versus 0.45%, p = 0.045), yet adult subjects demonstrated decreased abundance of the *Bacteroides* genus (11% versus 26%, p = 0.036) and specifically of *B. fragilis* (0.2% versus 1%, p = 0.106).

Shotgun metagenomics sequencing of the fecal DNA in the pediatric subjects did not demonstrate any global pathway differences. However, it did reveal diminished coverage of the butanoate pathway (abundance normalized to controls of 1 versus 0.72 in ERA, p = 0.037).

**Conclusion:** Our study supports previous work indicating that decreased fecal abundance of a regulatory strain of *F. prausnitzii* may be at least partly responsible for the pathogenesis of SpA, possibly due to decreased production of butyrate, and suggests that efforts to replenish it in patients with SpA may be a potential therapeutic avenue. In contrast, the mechanism by which *Bacteroides* impacts arthritis may differ in pediatric and adult patients, possibly reflecting altered immunologic development in the former rather than direct pathogenicity or the organism. If this is the case, then enthusiasm for microbial-based interventions to address this organism may be tempered. Instead, our findings may underscore the necessity of prevention efforts, such as avoiding unnecessary use of antibiotics in healthy children.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Apremilast (Otezla) is a PDE4 inhibitor approved for the treatment of psoriasis and psoriatic arthritis, but the mechanisms of action of apremilast are not fully described. The objective of this study was to study the downstream effects of apremilast on cells of the inflamed joint in ex vivo models of immune mediated inflammatory arthritis. Therefore, we tested the ex vivo effect of apremilast on the secretion of several cytokines, chemokines and growth factors by synovial fluid mononuclear cells (SFMCs), fibroblast-like synovial cells (FLSs), osteoclasts, synovial macrophages, and osteoblasts.

### Methods:

SFMCs and FLSs were obtained from a study population consisting of patients with active RA, or peripheral SpA with at least one swollen joint (for obtaining synovial fluid) (n=14). Peripheral blood mononuclear cells (PBMCs) were obtained from healthy controls and osteoblasts were purchased. SFMCs were cultured for 48 hours with and without addition of apremilast measuring the secretion of a large panel of cytokines, chemokines and growth factors by the Olink proseek multiplex interferon panel and commercially available ELISA assays. These effects were compared with the effects of the TNF $\alpha$  inhibitor adalimumab. Further, FLS-PBMC co-cultures were used to study the secretion of metalloproteinases, SFMCs cultured for 21 days were used to study inflammatory osteoclastogenesis and macrophage differentiation, and a mineralization assay was used to study new bone formation.

### Results :

In SFMCs cultured for 48 hours, apremilast decreased the production of IL-12B ( $P<0.00001$ ) CSF1 ( $P=0.009$ ), sCD6 ( $P=0.03$ ), sCD40 ( $P=0.04$ ), and MCP-1 ( $P=0.02$ ), and increased the production of CXCL5 ( $P=0.003$ ) dose-dependently. In sub-analyses, the apremilast induced decrease in cytokine production was greater in cultures with a high lymphocyte count and in cultures from patients with a low C-reactive protein level. Further, apremilast had a very different response signature compared with adalimumab, e.g. with a more robust inhibition of IL-12B ( $P=0.01$ ) and less inhibition of IL-8 ( $P=0.0001$ ) (see figure). In FLS-PBMC co-cultures, apremilast decreased MMP3 production ( $P=0.009$ ). In SFMCs cultured for 21 days, apremilast did not significantly decrease inflammatory osteoclastogenesis ( $P=0.2$ ). However, apremilast increased the secretion of IL-10 ( $P=0.04$ ) without affecting the secretion of MCP-1 ( $P=0.5$ ). Finally, apremilast did not significantly decrease mineralization by human osteoblasts ( $P=0.2$ ).

## Conclusion :

This study reveals the downstream effects of apremilast in ex vivo models of arthritis with a strong inhibition of IL-12B. Further, apremilast induced IL-10 production in synovial macrophages and decreased MMP3 in FLS-PBMC co-cultures. Our findings could explain some of the efficacy of apremilast seen in IL-12/IL-23 driven immune mediated inflammatory diseases such as psoriasis and psoriatic arthritis.

## Mir-10b-5p Is a IL-22 Regulator in CD4+T Cells from Ankylosing Spondylitis

Tae-Jong Kim<sup>1</sup>, So-Hee Jin<sup>2</sup>, Liye Chen<sup>3</sup>, Mohammad Hussein Al-Mossawi<sup>3</sup>, Anna Ridley<sup>3</sup>, Takuya Sekine<sup>3</sup>, Davide Simone<sup>3</sup>, Hui Shi<sup>3</sup>, Frank Penkava<sup>3</sup> and Paul Bowness<sup>3</sup>, <sup>1</sup>Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South), <sup>2</sup>Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South), <sup>3</sup>Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Emerging data suggest that a single microRNA (miR) can profoundly alter the phenotype and outcome of immune responses, offering the prospect of therapeutic use. We recently reported a novel Th17 regulator miR-10b-5p that is present in Th17 cells from patients with Ankylosing Spondylitis (AS). IL-22 is closely related to Th17 cells and also regulated by IL-23, a key cytokine for IL-17A production. Moreover, IL-22 has been implicated in the regulation of new bone formation in experimental models. Therefore, we wonder whether miR-10b-5p affects IL-22 production in AS.

#### **Methods:**

Primary CD4<sup>+</sup> T cells were negatively isolated from PBMCs from AS patients (Miltenyi Biotec). Transfection was performed with the Neon transfection system (Thermo Fisher Scientific, Germany) according to manufacturer's instructions.

The transfection efficiency was evaluated by monitoring FAM (Fluorescein) positive cells using flow cytometry, and qPCR at 24 h after transfection. miR-10b-5p function was determined by overexpression of miR mimic in CD4<sup>+</sup> T cells followed by intracellular cytokine staining, cytokine measurement, and qPCR. Statistical analysis was performed using Prism 5.0 Software (GraphPad Software, San Diego, USA). A  $p < 0.05$  was considered statistically significant.

#### **Results:**

Overexpression of miR-10b-5p reduced both IL-22<sup>+</sup>CD4<sup>+</sup> T cell frequencies and IL-22 production in CD4<sup>+</sup> T cells from patients with AS. To identify the cellular targets of miR-10b-5p, we previously performed RNA-sequencing of CD4<sup>+</sup> T cells transfected with miR-10b-5p together with in silico Target Scan analysis. MAP3K7 was selected as a target gene because of its known role in cytokine regulation. We then silenced MAP3K7 in CD4<sup>+</sup> T cells using siRNA and found the suppression of IL-22 response, mimicking the effect of miR-10b-5p overexpression.

#### **Conclusion:**

Our data suggest that miR-10b-5p suppress IL-22 production by targeting MAP3K7. miR-10b-5p might be a potential therapeutic candidate for regulation of new bone formation in patients with AS.

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A higher incidence of cardiovascular (CV) risk factors and atherosclerosis has been reported in axial spondyloarthritis (axSpA) patients<sup>1</sup>. Since axSpA (particularly AS) is an inflammatory disease characterized by changes in the osteoproliferative process, a dysregulation in the molecules involved in bone remodeling is highly plausible in these patients, also affecting vascular calcification in the context of atherosclerosis. Therefore, we aimed to assess the role of osteonectin (ON), osteopontin (OPN) and osteocalcin (OC), implicated in bone metabolism<sup>2</sup>, in the development of subclinical atherosclerosis and its association with CV risk factors in a large cohort of axSpA patients.

**Methods:** Serum ON, OPN and OC levels were measured by multiplex assays in 171 Spanish axSpA patients (including both non-radiographic axSpA [nr-axSpA] and AS), recruited from Hospital Universitario Marqués de Valdecilla and Hospital de Laredo (Spain) who fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria (for nr-axSpA)<sup>3</sup> and also the 1984 modified New York criteria (for AS)<sup>4</sup>. Patients with history of CV disease, diabetes mellitus, chronic kidney disease, IBD or psoriasis were excluded. Carotid US was performed to evaluate the presence of subclinical atherosclerosis. The association of these molecules with the different variables of study were assessed by ANOVA, partial correlation or Student's t test, where appropriate, using STATA® v. 11.1. The results were adjusted by potential confounding factors.

**Results:** ON and OPN positively associated with ESR at study ( $p=0.01$  and  $0.02$ ). Higher ON levels were observed in men and axSpA patients who smoked ( $p=0.01$ ), and also correlated with CRP levels at study ( $p=0.02$ ). In addition, patients with CRP at diagnosis  $>3$  mg/L showed higher OPN levels. Regarding OC, hypertensive patients displayed higher levels of this molecule ( $p=0.02$ ). No association was found between these molecules and markers of subclinical atherosclerosis.

**Conclusion:** We disclosed an association of ON, OPN and OC with inflammation and CV risk factors, supporting an implication of these molecules in the development and progression of atherosclerotic disease in axSpA.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Th17 cells play an important role in the pathogenesis of ankylosing spondylitis (AS). Tyk2, a member of the Janus Kinase (JAK) family of signaling molecules, was the first JAK to be associated with AS in genome-wide association studies. Tyk2 plays a crucial role in Th17 cell function through mediating IL-23 intracellular signaling, making Tyk2 an attractive target for the treatment of AS. Here we examine the expression of *Tyk2* at the cellular level in human peripheral blood mononuclear cells (PBMCs) for evidence of SNP-mediated changes in expression. We further tested a novel, potent and selective Tyk2 inhibitor, NDI-031407, for therapeutic effect in the SKG mouse model of AS.

### **Methods:**

Flow cytometry on PBMC was carried out on 76 AS patients, 47 healthy controls and 21 RA patients. *Tyk2* mRNA was assessed in unstimulated cells using PrimeFlow and cytokines were assessed in PMA/ionomycin-stimulated cells. SKG mice were gavaged twice daily with NDI-031407 or methylcellulose vehicle from weeks 1 to 8 post-disease induction. Mice were scored weekly for clinical presence of peripheral and axial arthritis, dermatitis and blepharitis. Sacroiliitis was assessed by T1- and T2-weighted MRI. Histology was assessed by H&E staining. Th17 frequency and phenotype were assessed by flow cytometry in popliteal, mesenteric and sciatic lymph nodes.

### **Results:**

*Tyk2* mRNA expression in PBMCs by flow cytometry did not demonstrate significant differences between AS and controls. *Tyk2* expression levels did not stratify by candidate SNPs (rs12720356, rs35164067) and did not correlate with Th17 frequency. NDI-031407 is a small molecule Tyk2 inhibitor that inhibits Tyk2 with a  $K_i$  of 0.2 nM, and is 218-, 148-, and 20-fold selective against JAK1, JAK2, and JAK3, respectively. In SKG mice, therapeutic dosing with NDI-031407 significantly reduced the clinical scores of joint and skin inflammation to normal levels (see figure). MRI of the sacroiliac joint (SIJ) showed joint space narrowing and edema with disease progression and NDI-031407 protected against these SIJ changes. Enthesitis and bone erosion in the ankle and tail were prevented by Tyk2 inhibition. FACS showed that NDI-031407 suppressed the expansion of IL-17A<sup>+</sup> Th17 cells (vehicle vs NDI-031407; 6.04% vs 2.73% of CD4<sup>+</sup> T cells,  $p < 0.001$ ) in addition to reducing IL-17F, IL-22, ICOS and Ki67 expression.

### **Conclusion:**

AS-associated Tyk2 SNPs do not impart a difference in *Tyk2* expression and likely contribute to AS through promoting Th17 cell function. Our findings indicate that Tyk2 inhibition can prevent disease progression in SKG mice by reducing Th17 cells and associated inflammatory cytokines. Future studies aim to unravel the role of Tyk2 in Th17 cell development to better understand the mechanism behind Tyk2 inhibition. This work provides the first evidence that Tyk2 inhibition presents as a viable therapeutic target in AS.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Genetic research in axSpA is performed in patients with longstanding ankylosing spondylitis (AS). Early axial spondyloarthritis (axSpA) is a diverse patient group in which a minority of the patients have AS. Therefore, it is

not known if recently identified genetic risk factors for AS are also risk factors for early axSpA. The aim is to evaluate if ERAP1 and HLA-B\*4001 are susceptibility factors for early axSpA.

**Methods:** Patients with early axSpA meeting the ASAS classification criteria from the SPondyloArthritis Caught Early (SPACE) cohort (inclusion criteria: back pain for  $\geq 3$  months,  $\leq 2$  years, onset  $< 45$  years) and the DEvenir des SPondyloarthrites Indifférenciées Récentes (DESIR) cohort (inclusion criteria: inflammatory back pain for  $\geq 3$  months,  $\leq 3$  years, age  $< 50$ ) were typed for two well established AS genetic risk factors: ERAP1 SNPs (rs30187 (susceptibility), rs17482078 (protective) and rs10050860 (neutral)<sup>1</sup>) and HLA-B\*4001. Subsequently, for ERAP1 SNPs sub analyses were performed for AS and non-radiographic axSpA (nr-axSpA) patients. Analysis of weaker AS risk factors was limited by sample size. For ERAP1, genotyped Dutch healthy controls (n=1085) (data kindly provided by C. Wijmenga and A. Zhernakova (UMCG)) and published French subjects<sup>1</sup> were used as controls. For HLA-B\*4001 healthy blood bank donors from the Netherlands (n=5584) and France (n=10177) were used as controls.

**Results:** In 486 DESIR patients (mean age 32.5 (SD 8.6); 50% male; 84% HLA-B27+; 18% X-SI+) and 144 SPACE patients (mean age 29.5 (SD 8); 51% male; 88% HLA-B27+; 24% X-SI+) ERAP1 SNP rs30187 was more common than in controls (OR 1.2, p=0.01 in meta-analysis; table 1). rs17482078 and rs10050860 were negatively associated with early axSpA (both OR 0.7 (0.6-0.9) p<0.01 in meta-analysis). Minor allele frequencies were similar for AS patients and nr-axSpA patients (table 2). Although both cohorts were sufficiently powered, HLA-B\*4001 was not positively associated with early axSpA (OR 0.6 (0.4-0.9) in meta-analysis).

**Conclusion:** ERAP1 rs30187 is a genetic risk factor for early axSpA patients with and without radiographic sacroiliitis. To our knowledge this is the first report of genetic risk factor research in early axSpA patients meeting the ASAS criteria. Larger cohorts are needed to study additional AS risk factors.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis is an inflammatory musculoskeletal disease which develops in 30% of patients with psoriasis. Our previous peripheral blood microarray study identified CXCL10, NOTCH2NL, HAT1, and SETD2 as differentially expressed between PsA and psoriasis patients without arthritis (PsC). This study aimed to determine gene expression in leukocyte subsets to elucidate their functions in psoriatic disease.

**Methods:** Peripheral blood mononuclear cells were isolated using Ficoll paque separation from PsA and PsC patients not receiving biologic therapy and healthy controls (HC). T cells (CD3+), monocytes (CD14+), and NK cells (CD56+) were separated by positive selection. mRNA was extracted using RNeasy miniprep kits and qPCR performed with 75ng mRNA to determine CXCL10, CXCR3, NOTCH2NL, IL-17A, HAT1, and SETD2 gene expression. A two-way ANOVA with Bonferroni's post-hoc test was used to determine significant differences ( $p < 0.05$ ).

**Results:** Gene expression was measured in 15 PsA (mean age 59, 60% males), 15 PsC (mean age 57, 67% males), and HC (mean age 54, 60% males). Expression of IL-17A in monocytes was 18.42-fold greater in PsA patients than PsC ( $p < 0.0001$ ) and 31.36-fold greater in PsA than HCs ( $p < 0.0001$ ). There were no other significant differences in gene expression between disease groups in each given cell type. However, in T cells, CXCL10 was elevated in PsA compared to PsC (1.42-fold) and HC (2.47-fold). A similar trend was found for the receptor, CXCR3, where expression was higher in PsA than PsC (1.18-fold) and HC (1.13-fold). Finally, SETD2 expression in PsA was higher than PsC (1.65-fold) and HC (1.28-fold) in T cells. CXCL10 expression in monocytes ( $p < 0.0001$ ; 11.1-fold) and NK cells ( $p < 0.0001$ ; 2.04-fold) was higher than in T cells. Expression of CXCR3 was higher in T cells compared to monocytes ( $p < 0.0001$ ; 208.17-fold) and NK cells ( $p < 0.0001$ ; 1.3-fold). HAT1 was more highly expressed in T cells as compared to monocytes ( $p = 0.0003$ ; 3.41-fold) and NK cells ( $p = 0.0274$ ; 1.48-fold). Expression of SETD2 was elevated in T cells compared to monocytes ( $p = 0.0007$ ; 3.2-fold) and NK cells ( $p = 0.0082$ ; 1.22-fold). NOTCH2NL expression was elevated in T cells compared to monocytes ( $p = 0.0154$ ; 2.43-fold).

**Conclusion:** Genes of interest were differentially expressed in leukocyte subsets. The higher expression of these genes in PsA compared to PsC and HCs could provide insight into their role in driving the development of PsA. Knowing which cell types are predominantly involved with expression of certain biomarkers will aid in developing targeted treatments.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is an inflammatory disease affecting the joints and connective tissue and is associated with psoriasis of the skin and nails. In our daily clinical routine, patients often report changes in their disease activity with certain foods, despite the ongoing treatment. Choline metabolism has been recently strongly related to inflammation. Dietary intake of choline, through two circulating metabolites, trimethylamine (TMA), and trimethylamine N-oxide (TMAO), are mechanistically linked to cardiovascular inflammation. The objective of this study was to explore the link between choline metabolites and inflammation in PsA.

**Methods:** Patients with PsA, diagnosed based on the CASPAR criteria, were recruited from the Rheumatology Outpatient Clinic at the University of California, San Diego. A thorough clinical examination, including joint and skin disease evaluations, was conducted. Patients completed a health assessment questionnaire. DAS28, Clinical Disease Index (CDAI) and Simple Disease Index (SDAI) scores and body surface area (BSA) of psoriasis were calculated. Serum concentration of choline metabolites: choline, TMA, TMAO, and betaine were determined by Mass Spectrometry. Inflammatory biomarkers in serum were determined by ELISA. Statistical analysis included means, standard deviation, t-test and Pearson correlation.

**Results:** 38 patients (average age 47.45 years, standard deviation [SD] 10.29) were recruited. The mean (SDs) of DAS28PCR was 2.24 (1.29). 27 patients (71.05%) had active skin disease, with an average BSA of 4.73 (SD, 14.5). 23.68% of patients had enthesitis, 5.26% had dactylitis and 47.36% had nail involvement. 65.11% received biological therapy (46.42% of them in association with a synthetic disease modifying drug DMARD), 13.95% received sDMARD in monotherapy and 20.9% received symptomatic treatment. We found that TMAO, a choline metabolite, correlated with parameters of disease activity for both skin (BSA) and joint (DAS28, CDAI, SDAI) (Table 1). Choline, TMA and TMAO also correlated with inflammatory markers (Table 2). TMAO was higher in patients with active joint disease (CDAI>2.8) versus patients in remission (CDAI<2.8;  $p = 0.01$ ) and in patients with higher severity of skin disease (BSA >5%) versus low severity (BSA <5%;  $p = 0.03$ ).

Table 1. Correlation between choline metabolites and disease activity

Metabolite	DAS28CRP	CDAI	SDAI	BSA	Swollen joints count	Dactylitis

Choline	0.286*			0.367**				0.643***	0.467***
TMA	0.315*			0.709***				0.573***	0.380**
TMAO	0.517***			0.709***	0.416**		0.330*	0.385**	
Betaine									

SAA-Serum amyloid A; CRP-C reactive protein; IL-Interleukin; TNF-RI-Soluble tumor necrosis alpha receptor type I; MMP-Metalloproteinase. \*  $p < 0.1$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

**Conclusion:** In our cohort, choline metabolism was associated with inflammation in PsA patients. Since diet is the main source of choline, modulating choline food intake might help to better control disease activity in these patients. Further studies are needed to explore the mechanistic links between choline and TMAO and inflammation.

# Role of Eicosanoids As Biomarkers in Psoriatic Arthritis

**Roxana Coras**<sup>1,2</sup>, Arthur Kavanaugh<sup>1</sup>, Doquyen H. Huynh<sup>1</sup>, Aladdin Shadyab<sup>3</sup>, Sara Marsal<sup>4</sup>, Oswald Quehenberger<sup>5</sup> and Monica Guma<sup>1</sup>, <sup>1</sup>Medicine, University of California, San Diego, La Jolla, CA, <sup>2</sup>Medicine, Autonomous University of Barcelona, Barcelona, Spain, <sup>3</sup>Family Medicine and Public Health, University of California, San Diego, La Jolla, CA, <sup>4</sup>Rheumatology Research Unit, Vall d'Hebron Hospital, Barcelona, Spain, <sup>5</sup>Pharmacology, Medicine, University of California, San Diego, La Jolla, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is an inflammatory disease affecting the joints and connective tissue and is associated with psoriasis of the skin and nails. There is no reliable biomarker to identify psoriatic patients at risk of joint disease or disease progression. Eicosanoids, including prostaglandins and leukotrienes, are biological lipids that are implicated in various pathological processes including inflammation. We hypothesized that by defining more precisely the eicosanoid profile in PsA patients, we might identify novel diagnostic or prognostic biomarkers for disease activity and PsA pathogenesis.

**Methods:** Patients with PsA, diagnosed based on the CASPAR criteria, were recruited from the Rheumatology Outpatient Clinic at the University of California, San Diego. A thorough clinical examination, including joint and skin disease evaluations, was conducted. Patients completed a health assessment questionnaire. DAS28, Clinical Disease Activity Index (CDAI) and Simple Disease Activity Index (SDAI) scores and body surface area (BSA) of psoriasis were calculated. Serum eicosanoids were determined by mass spectrometry and were classified in groups according to the enzyme that participates in synthesis: cyclooxygenase (COX), 5-, 12- or 15-lipoxygenase (LOX), cytochrome P450, or non-enzymatic pathway. Inflammation markers were determined by ELISA. Statistical analysis included mean, standard deviation and Spearman correlation.

**Results:** 43 patients (average age 49.8, standard deviation 10.88) were recruited. Thirty-two (74.41%) had active skin disease with an average BSA of 4.25 (SD, 13.67). The means (SDs) of DAS28PCR was 2.25 (1.25) and CDAI was 10.69 (11.87). 48.83% of patients had nail disease, 20.93% had enthesitis, and 4.65% had dactylitis. Further, 65.11% received biological therapy (46.42% of them in association with a synthetic disease modifying drug, such as DMARD), 13.95% received sDMARD in monotherapy, and 20.9% had symptomatic treatment. Several eicosanoids, especially those in the 12-15-LOX pathway, significantly correlated with joint disease activity, but not with skin disease activity (Table 1). Several eicosanoids correlated with serum markers of (IL6, Resistin, EGF, IL1 $\beta$  and IL8), but not with CRP (Table 1). Of note, there was a weak correlation between CRP and SDAI that didn't reach statistical significance ( $p=0.06$ ).

Table 1. Correlation of Eicosanoids with clinical and serum parameters of inflammation											
	Eicosanoid	CDAI	SDAI	DAS28	BSA	CRP	IL6	EGF	Resistin	IL1 $\beta$	IL8
COX	PGE2						0.294*	0.319**		0.592***	
15-LOX	15-HETE	0.259*	0.382***	0.333**			0.392**	0.499***	0.428***	0.399***	0.533***

	Tetranor 12-HETE		0.399***	0.365**			0.373**	0.386**	0.530***		0.547***
	HXB3		0.350**	0.284*			0.366**	0.440***	0.485***	0.290*	0.552***
PGE2-Prostaglandin E; HETE- hydroxyeicosatetraenoic acid; HETrE- hydroxyeicosatrienoic acid; HODE-Hydroxyoctadecadienoic acid; HOTrE- hydroperoxyoctadecatrienoic acid; HXB3-Hepoxilin B3.* p<0.1, ** p<0.05, *** p<0.01											

**Conclusion:** Eicosanoids, especially in the 12- and 15- LOX pathways, correlated with joint disease activity better than the CRP, but not with skin disease, suggesting that they may be potential biomarkers of joint activity in psoriatic and PsA patients. Further studies are needed to determine whether 12- and 15-LOX pathways also play a role in the pathogenesis of joint inflammation in PsA.

# Genome-Wide DNA Methylation, Transcriptomics, and Proteomics of Psoriasis and Psoriatic Arthritis in Monozygotic Twins

Angela Ceribelli<sup>1</sup>, Elvezia Maria Paraboschi<sup>2</sup>, Natasa Isailovic<sup>1</sup>, Elena Generali<sup>1</sup>, Michela Robusto<sup>2</sup>, Maria De Santis<sup>1</sup>, Giulia Cardamone<sup>2</sup>, Francesco Sacchini<sup>3</sup>, Antonio Costanzo<sup>3</sup>, Stefano Duga<sup>2</sup> and Carlo Selmi<sup>1</sup>, <sup>1</sup>Rheumatology and Clinical Immunology, Humanitas Research Hospital, Rozzano (MI), Italy, <sup>2</sup>Laboratory of Medical genetics and RNA biology, Humanitas Research Hospital, Rozzano, Italy, <sup>3</sup>Dermatology Unit, Humanitas Research Hospital, Rozzano, Italy  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017  
**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I  
**Session Type:** ACR Poster Session A  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic disease is a chronic inflammatory disorder spanning from skin disease (PsO) to psoriatic arthritis (PsA) without known serum biomarkers. The genetic background is insufficient to explain disease onset as illustrated by monozygotic (MZ) twins and epigenetics may contribute to disease susceptibility modulating gene expression. We analyzed the DNA methylation, transcriptome, and proteomic profile in MZ twins discordant for PsO/PsA.

**Methods:** MZ twin couples discordant and concordant for PsO/PsA were investigated for (1) genome-wide DNA methylation (Infinium MethylationEPIC BeadChip), (2) RNA and transcriptome (Illumina TruSeq Stranded mRNA kit), and (3) proteomics using aptamers (SOMALogic). **Results** observed with aptamers were further validated by ELISA.

**Results:** The epigenetic analysis identified 19 genes consistently differentially methylated and mostly involved in the pathway of TGF- $\beta$  and IFN response. Pathway analysis of integrated DNA methylation and transcriptome demonstrated an enrichment in “transcription regulation”, “innate immunity”, “ATP-binding” and, “Srp-dependent co-translational proteins”, that may be involved in the psoriatic condition. Serum proteomics reported a significant up- and downregulation of 10 and 3 proteins, respectively, largely involved in the innate and adaptive immune response, DNA repair and DNA damage sensors. Validation results showed a significant correlation between the SOMALogic and ELISA tests for 2 proteins (respectively  $r=0.70$ ,  $p=0.02$ , and  $r=0.50$ ,  $p=0.04$ ) and we confirmed that levels of 3 proteins involved in the regulation of UV radiation-induced apoptosis and in the cutaneous inflammatory response were elevated in sera from psoriatic disease patients, albeit not significantly, and one protein involved in hematopoietic and dendritic cell differentiation and apoptosis was significantly more expressed in both PsO and PsA compared to controls (HC  $n=2$ , 20%, PsO+PsA  $n=18$ , 60%,  $p=0.028$ ; PsO  $n=10$ , 66.7%,  $p=0.02$ ).

**Conclusion:** We report the first -omics approach in MZ twins discordant for psoriatic disease and suggest that the observed changes may constitute disease biomarkers and point to biological pathways with a potential pathogenic role.

## Role of Mir-21-5p As a Potential Biomarker of Psoriatic Arthritis and Response to Treatment

**Rohan Machhar**<sup>1</sup>, Justine (Yang) Ye<sup>1</sup>, Vinod Chandran<sup>2</sup> and Dafna D Gladman<sup>3</sup>, <sup>1</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>2</sup>Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>3</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is an inflammatory arthritis occurring in patients with psoriasis. miRNA's are small non coding RNAs whose main function, at a post transcriptional level, is to modulate the expression of target genes via translation inhibition or mRNA degradation. A recent study identified miR-215p to be upregulated in early PsA and early rheumatoid arthritis (RA) and found down regulation post 12 weeks of methotrexate (MTX) treatment. Mir-21-5p was also found to be upregulated in several inflammatory and autoimmune diseases such as systemic sclerosis, systemic lupus erythematosus, RA, type 1 diabetes, and psoriasis. We aimed to determine the role of miR-21-5p as a biomarker for PsA and response to methotrexate.

**Methods:** Whole blood RNA samples collected in Tempus tubes from 40 patients with early PsA (<2 years disease duration and not receiving biologic therapy), 40 patients with PsC who have been confirmed by rheumatologist not to have PsA (>10 years psoriasis duration, not receiving biologic therapy, and matched to PsA patients on age, sex, psoriasis duration, and age of psoriasis onset), and 42 HC (matched to patients based on age, sex). RNA was extracted using the Tempus Spin RNA Isolation Kit with a genomic DNA removal step. miR-21-5p was validated using droplet digital PCR (ddPCR), a novel and sensitive technology for miRNA quantification. miR-21-5p expression was also measured in 10 PsA patients before and after 24 weeks of MTX treatment.

**Results:** The clinical, laboratory and miRNA expression data are presented in Table 1. Significant up regulation of miR-21-5p was seen in both early PsA and in PsC in comparison to HC ( $p<0.001$ ). There was more upregulation in early PsA compared with PsC ( $p<0.001$ ), miR-21-5p was significantly down regulated 24 weeks post treatment in 10 patients ( $p<0.008$ ) (figure 1).

**Conclusion:** We have determined the role of miR21-5p as a biomarker for early PsA and response to methotrexate. Our results support previous work suggesting the potential role of miR21-5P in response to treatment biomarker in early PsA and as in inflammatory disorder marker.

Fig 1: miR 21-5p expression in PsA patients at baseline and after 24 weeks of therapy ( $p<0.008$ ).

# Investigating the Role of Mechanical Stress in Spondyloarthritis Pathogenesis

**Breanna Nguyen**<sup>1</sup>, Robert Colbert<sup>2</sup> and Gerlinde Layh-Schmitt<sup>1</sup>, <sup>1</sup>National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, <sup>2</sup>NIAMS/NIH, Bethesda, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mechanotransduction is a cell's ability to translate mechanical stimuli into biochemical signals and has been implicated in signaling pathways involving differentiation and proliferation. Mechanical stress at entheses and adjacent tissues has additionally been implicated in the pathogenesis of spondyloarthropathies, such as ankylosing spondylitis and psoriatic arthritis, by triggering inflammation. However, the mechanisms underlying these processes remain unclear. This project aims to establish an *in vitro* system to study the effects of mechanical stress on mesenchymal stem cells and osteoblasts, specifically examining mineralization and cytokine production.

**Methods:** Mechanical stress was applied to rat calvarial mesenchymal stem cells (MSCs) using the Flexcell FX-5000 Tension System. This instrument uses a computer-controlled vacuum pump to apply uniform axial strain to cells plated on silicone bottomed Bioflex plates. For osteogenic differentiation, 3% uniform axial strain was applied to the cells. After applying strain for 5 days, cells were cultured in osteogenic medium (OS+) to induce differentiation. Mineralization was measured with Alizarin red stain after 28 days. For measuring cytokine secretion upon stress, MSCs were subjected to 24 hours of 10% strain. ELISA was used to quantify cytokine secretion into cell culture supernatants at 24, 48, and 72h after stimulation. For all experiments, non-stretched cells were used as controls.

**Results:** For MSCs cultured in OS+ for 28d, overall mineralization was 2 to 3-fold higher than MSCs cultured in OS-, as expected. In OS+ conditions, stress resulted in a 12% decrease in mineralization for stretched cells compared to non-treated controls ( $p < 0.05$ ). In addition, stress increased secretion of RANTES and IL-6 from MSCs, as determined by ELISA. For RANTES, stretch led to a 130% increase in production at 24h, a 56% increase at 48h, and a 43% increase 72h after stimulation ( $p = 0.06$ ;  $p < 0.001$ ;  $p < 0.01$ , respectively). For IL-6, stretch led to a 324% increase in production at 24h, an 85% increase 48h, and a 55% increase 72h after stimulation ( $p < 0.01$ ;  $p < 0.05$ ;  $p < 0.05$ , respectively).

**Conclusion:** These results suggest that mechanical stress can alter osteogenic ability and cytokine secretion from MSCs. RANTES and IL-6 have been previously shown to play a positive role in bone formation, so further studies are needed to determine whether these mediators have a biological effect during osteogenesis in this system. Future studies will focus on optimizing the system and then using it to study the role of ankylosing spondylitis risk genes in MSC and osteoblast function.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The HLA class I allele, HLA-B27, is associated with spondyloarthritis (SpA), an immune-mediated inflammatory disease affecting the axial skeletal, skin, gut and eyes. HLA-B27 has a tendency to misfold, and accumulate in the endoplasmic reticulum (ER) and on the cell surface as disulfide-linked dimers. ER accumulation can generate stress resulting in an unfolded protein response (UPR). The UPR upregulates several pathways that promote folding and secretion and/or ER-associated degradation (ERAD) of accumulated proteins, which involves retrotranslocation and ubiquitination of target proteins in the cytosol where they are degraded by proteasomes. Our recent studies suggest that autophagy as well as ERAD contributes to the disposal of misfolded HLA-B27, yet these pathways are still not sufficient to prevent misfolded HLA-B27 from accumulating. Since these pathways of protein degradation require substrate ubiquitination, we asked whether HLA-B27 heavy chains were ubiquitinated using HLA-B7 for comparison.

**Methods:** Bone marrow derived macrophages from HLA-B27 and human  $\beta_2m$  (h $\beta_2m$ ) transgenic rats were examined with and without IFN $\gamma$  and proteasome or autophagy inhibitors. Immunoprecipitation, western blotting, and immunofluorescence were used to measure HLA-B27 heavy chains and ubiquitination amount. Autophagy was activated using rapamycin, or blocked with bafilomycin. ERAD was inhibited by inhibiting proteasome function with bortezomib. HLA-B7/h $\beta_2m$  transgenic rat macrophages were used as controls.

**Results:** Blocking autophagic flux with bafilomycin resulted in the accumulation of misfolded HLA-B27 dimers and oligomers as well as monomers, comparable to blocking ERAD with the proteasome inhibitor bortezomib. HLA-B7 monomers also accumulated after blocking each degradation pathway. The proportion of ubiquitinated heavy chains was ~3-fold lower for HLA-B27 compared to HLA-B7. Immunoprecipitation experiments using anti-ubiquitin antibody followed by blotting for HLA class I heavy chains, further confirmed that HLA-B7 is significantly more ubiquitinated than HLA-B27. Activation of autophagy with rapamycin rapidly eliminated ~50% of misfolded HLA-B27, while folded HLA-B27 or HLA-B7 monomeric heavy chains were minimally affected.

**Conclusion:** These results demonstrate for the first time that both autophagy and ERAD play a role in the elimination of excess HLA class I heavy chains expressed in transgenic rats. Our results suggest that impaired ubiquitination of HLA-B27 may play a role in the accumulation of misfolded disulfide-linked dimers, whose elimination can be enhanced by activation of autophagy. Manipulation of the autophagy pathway should be further investigated as a potential therapeutic avenue in experimental spondyloarthritis.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

CD19+CD24<sup>hi</sup>CD38<sup>hi</sup> B cells demonstrate a regulatory capacity and their frequency is altered in the peripheral blood of patients with various autoimmune diseases. The pathogenic implication of autoinflammatory and/or autoimmune mechanisms has been reported in spondyloarthritis (SpA), and an increased frequency of circulating B cells expressing a regulatory phenotype has been described in SpA (Cantaert T. et al, Arthritis Rheumatol 2012). Therefore our objective was to study the frequency of CD19+CD24<sup>hi</sup> CD38<sup>hi</sup> B cells (Breg) in patients with Ankylosing Spondylitis (AS) naïve for TNF blockers, and the effect of anti-TNF $\alpha$  drugs on this B cell subset in AS.

### **Methods:**

Peripheral blood was drawn from AS patients naïve for TNF $\alpha$  blockers (AS/nb) (n=42), AS patients who were already receiving treatment with anti-TNF $\alpha$  drugs (AS/b) (n=59: 37 infliximab, 10 adalimumab, 10 golimumab, 2 certolizumab) and healthy controls (HC) matched for age and gender (n=101). In addition, six AS/nb patients who were started on anti-TNF $\alpha$  drugs (2 infliximab, 1 adalimumab, 2 golimumab, 1 certolizumab) donated blood at two time points: right before the first dose of anti-TNF $\alpha$  was administered and 6 months thereafter. For each of these 6 patients, the same healthy donor acted as a control on both occasions. After isolation by Ficoll-Hypaque, PBMCs were stained with antibodies to CD3, CD4, CD19, CD24, and CD38, and examined by cytometry.

### **Results:**

When compared with HC, AS/nb patients demonstrated a significantly increased frequency of Breg cells, which did not correlate with ASDAS-CRP, serum calprotectin, CRP or ESR values. In contrast, in AS/b patients, the frequency of circulating Breg cells was not different from HC. The 6 AS/nb patients who started treatment with anti-TNF $\alpha$  drugs demonstrated a significant reduction of circulating Breg numbers, which were no longer elevated after six months of treatment. At the same time, a significant decrease of CRP, serum calprotectin and ASDAS-CRP was observed in all 6 patients; in 4 of them, the  $\Delta$ ASDAS-CRP was  $> 2.0$ .

### **Conclusion:**

An increased frequency of circulating CD19+CD24<sup>hi</sup>CD38<sup>hi</sup> B cells is observed in AS/nb patients, that does not correlate not related with disease activity parameters. Treatment with anti-TNF $\alpha$  drugs is able to downmodulate circulating Breg numbers in AS.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Innate lymphoid cells (ILCs) produce disease-related cytokines including IL-17 and IL-22 and are therefore of substantial interest in PsA. Spreading the disease from the skin to the joints most likely requires trafficking of cells through the circulation. Upon perturbation of immune homeostasis, the pool of resident ILCs is replenished by migration of ILCs into the peripheral blood. Tackling their potential contribution to immunopathology of PsA we quantified circulating ILC subsets in PsA patients in correlation to disease activity and structural tissue damage.

**Methods:** 124 patients satisfying the Classification Criteria for Psoriatic Arthritis (CASPAR) and 26 healthy volunteers were enrolled in the study. Information regarding the tender and swollen joint count of 68 joints, the visual analogue scale (VAS) of pain and global assessment, presence of plaque psoriasis, psoriatic nail dystrophy, enthesitis, history of uveitis/iritis, CRP levels, erythrocyte sedimentation rate, imaging results (MRI and high-resolution peripheral quantitative CT) were collected and disease activity score 28 (DAS28), disease activity in psoriatic arthritis (DAPSA), minimal disease activity score (MDA) were calculated. MRI and high-resolution peripheral CT were taken and PsA MRI score (PsAMRIS) was assessed. Flow cytometric analysis was performed and IFN $\gamma$ -producing ILC1s, IL-4/IL-5-producing ILC2s and IL-17/IL-22-producing ILC3s were identified among ILCs. Multivariate linear regression and Receiver-Operating Characteristic (ROC) Curve analysis was performed using the IBM SPSS Statistics software.

**Results:** Total number of circulating ILCs were increased in PsA patients compared to healthy controls ( $p < 0.001$ ). Linear regression analyses of the relationship between disease activity and circulating ILC counts showed that ILC2 negatively ( $R = -0.3732$ ;  $p < 0.0001$ ) and ILC1 and ILC3 positively correlated with DAPSA score ( $R = 0.2622$ ,  $p = 0.0057$ ;  $R = 0.4092$ ,  $p < 0.0001$  respectively). The strongest correlation was observed when the ratio of ILC2 to ILC3 was analyzed ( $R = -0.5709$ ;  $p < 0.0001$ ). ILC2/3 ratio was also reduced in patients with active psoriatic skin disease, presence of enthesitis or a history of concomitant uveitis. Extend of synovitis or tenosynovitis or presence of bone erosions or osteophytes on MRI was inversely correlated with the ILC2/3 ratio ( $R = -0.6753$ ;  $p < 0.0001$ ,  $R = -0.5828$ ;  $p = 0.0011$  and  $p < 0.001$  respectively). Consistently, presence of erosions and/or osteoproliferation assessed by HR-pQCT was correlated with a significant lower ILC2/3 ratio. Furthermore, ROC Curve was used to test the performance of the ILC2/3 ratio as marker in differentiating between remission and disease activity of PsA. Indeed, a cut-off 0.57 exhibited highest sensitivity (92.9%) and a 84.7% specificity in identifying remission.

**Conclusion:** We show that perturbed ILC homeostasis is correlated with both composite clinical disease activity scores and with imaging signs of inflammation and structural damage suggesting pathogenic impact of ILCs in PsA. Further studies are necessary to validate ILC2/ILC3 ratio as biomarker for immunological disease activity in PsA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Single Nucleotide Polymorphisms (SNPs) in *PTGER4* were found to be associated with Ankylosing spondylitis (AS) in GWAS. *PTGER4* codes for the prostaglandin-E2 receptor EP4. PGE2/EP4 interaction can affect bone formation and inflammation. We studied serum PGE2 levels and SNPs in *PTGER4* in relation to spinal fusion in AS patients. We further evaluated the interaction of smoking, PGE2 and EP4 in driving IL23 production.

**Methods:** Patients diagnosed with AS using the modified New York criteria and followed prospectively using a standardized protocol, were included in this study. Biological samples including serum, gut, synovial and bone marrow (BM) samples, DNA and RNA were stored and radiographs of the spine obtained every two year to assess progression. ELISA for Serum PGE2 and immunohistochemistry tissue expression of Prostaglandin-Endoperoxide Synthase 1 (PTGS1), EP4 and pCREB were performed. Radiographs were scored by modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Patients with an increase of  $\geq 1$  mSASSS unit/year on follow up were deemed progressors. Five *PTGER4* single nucleotide polymorphisms (SNPs) satisfying inclusion criteria (associated with AS or related diseases, call rate above 90%, MAF > 0.1 and not in LD above 0.8) were studied. Immune cell subsets from peripheral blood mononuclear cells (PBMCs) were analyzed for surface expression of the EP4 receptor. Additionally, PBMCs were incubated with nicotin, PGE2, or EP4 agonist to determine cytokine expression by flow cytometry and RT-PCR.

**Results:** Serum PGE2 levels were significantly higher in AS progressors (n=88) than in non-progressors (n = 101) ( $p < 0.001$ ). In multivariable regression analysis, there was significantly more progression in patients with higher baseline mSASSS ( $B = 0.02$ ;  $p = 0.01$ ) and serum PGE2 ( $B = 0.001$ ;  $p = 0.002$ ), but lower progression with longer TNF inhibitor use ( $B = -0.01$ ;  $p = 0.03$ ). There was a trend towards higher progression with higher baseline ESR ( $B = 0.012$ ;  $p = 0.08$ ). 3) A total of 172 AS patients had DNA and X-ray data for analysis. Patients with CC genotype of *PTGER4* SNP rs6896969 were significantly more likely to progress compared to AA/AC (OR: 2.45, 95% CI: 1.3 to 4.6;  $p = 0.006$ ). Progressors tended to more likely be homozygous for the major allele G of the rs4957341 SNP (OR 2.1; 25% CI: 0.98-4.35;  $p = 0.058$ ). Increased expression of EP4, PTGS1 and pCREB were observed in the inflamed gut, BM and synovial samples in AS patients. EP4 expression was upregulated in AS monocytes, especially smokers, and the percentage of EP4<sup>+</sup> monocytes correlated with the disease activity evaluated by BASDAI. Sorted EP4<sup>+</sup>CD14<sup>+</sup> cells showed a higher expression of CREB and IL-23

demonstrating the functional relevance of EP4 expression on monocytes. The expression of EP4 is dependent on the transcription factor AP-2a (TFAP-2a). In vitro stimulation of monocytes with nicotine induced a significant monocyte over-expression of EP4 and TFAP-2a.

**Conclusion:** PGE2 and its receptor EP4 are significant players in AS driving both inflammation and spinal fusion. The complex interaction of smoking, prostaglandin pathway upregulation and Th17 activation via CREB can contribute to the pathogenesis of AS.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is associated with increased cardiovascular (CV) morbidity and mortality. Assessing individual CV risk and achieving the recommended LDL-cholesterol (LDL-C) target could contribute to reduce the burden of CV disease in PsA. Aims: To compare the prevalence of CV risk factors (CVRFs) and history of CV disease (CVD) among French PsA patients and age- and sex-matched controls; to quantify individual CV risk using SCORE, QRISK2 and REYNOLDS risk scores; to assess the proportion of PsA patients or controls achieving the recommended LDL-C target according to their individual CV risk.

**Methods:** Observational case-control single-site study. PsA patients (CASPAR criteria), consulting a rheumatologist or hospitalized in the Rheumatology Department of a French University Hospital between March 2016 and January 2017, were included in the study after informed consent was obtained. Age- and sex-matched controls (2:1) were extracted from the Mona Lisa, general population study. CVRF and history of CVD were collected and compared between PsA patients and controls. Individual CV risk was quantified, using SCORE (with or without using a 1.5 multiplication factor), QRISK2 (with or without including PsA as a CVRF) and REYNOLDS risk scores and compared between PsA patients and controls. The proportion of PsA patients or controls achieving the recommended LDL-C target according to their individual CV risk was assessed.

**Results:** 207 PsA patients and 414 controls were included in this study. CVRF and history of CVD were significantly increased in PsA patients in comparison with controls (Table1). Individual CV risk was higher in PsA patients in comparison with controls using SCORE (p=0.002), QRISK2 (p=0.001) and REYNOLDS (p=0.003) risk scores (data not shown). The proportion of PsA patients or controls achieving the recommended LDL-C target according to their individual

CV risk, quantified using SCORE, was low in both groups (Table 2). Among PsA patients or controls with an individual risk score <sup>3</sup> 10%, quantified using QRISK2, only 22.9% or 35.8% were respectively treated with a statin.

**Conclusion:** Our study confirms that the prevalence of CVRF and history of CVD is higher in PsA patients than in controls. It shows that individual CV risk is higher in PsA patients than in controls, whatever risk score is used for its quantification. It highlights that a low proportion of PsA patients achieve LDL-C target (SCORE) or initiate a treatment with a statin (QRISK2) in spite of high individual CV risk.

## Functionally Active MAIT Cells in Psoriatic Arthritis: A New Member of the IL-23/IL-17 Cytokine Network

Siba P. Raychaudhuri<sup>1</sup> and Smriti K. Raychaudhuri<sup>2</sup>, <sup>1</sup>Rheumatology Section, Sacramento Veterans Affairs Medical Center, Sacramento, CA, <sup>2</sup>Rheumatology/Immunology, VA Sacramento Medical Center, Davis, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The mucosal-associated invariant T (MAIT) cells recently have been implicated in autoimmune diseases. Murine model experiments also suggest that MAIT cells are capable of inducing or exacerbating arthritis. However, their gut origin, effector phenotype and lineage towards IL-23/IL-17 cytokine signatures make them more relevant for spondyloarthritis rather than RA. More so these cells are predominantly CD8<sup>+</sup>; thus altogether this subpopulation of T cells likely to have all the potentials to have a contributing role in the pathogenesis of psoriatic arthritis (PsA). Here we have explored relevance and functional significance of the MAIT cell in PsA.

**Methods:** We collected PBMC and synovial fluid mononuclear cells (SFMC) from age/sex matched active untreated PsA patients (n=10) and normal individuals (n=10). We used two methods to culture and enrich the MAIT cells: (i) the

established method for enrichment of IL-17+ T cell by culturing these cells with rIL-23 for 6 days and (ii) the standard protocol for MAIT cell culture with PMA/Inomycin. Hi-D FACS studies were done to identify the activated memory effector CD11a+CD45RO+IL-17+ T cells. MAIT cells were identified as CD3+Va7.2TCR+CD161<sup>high</sup>. The percentages of each cell population and the mean fluorescence intensity (MFI) were analyzed using FlowJo software.

**Results:** MAIT cells were identified in PBMC and SFMC. In both PsA and controls CD3+IL+17 MAIT cells were identified in PBMC (<2%). Where as in SFMC it varied between 4%-8% ( $5.182 \pm 0.251\%$ , SD). However we have made several important observations- (i) Among the IL-17 producing T cells only the MAIT cells were predominantly CD8+ (~90%), (ii) IL-23R was strongly expressed (~20%), and IL-23R was functionally active (iii) rIL-23 induced significant proliferation of the IL-17+ MAIT cells (Fig 1).

**Conclusion:** MAIT cells produce multiple inflammatory cytokines (IL-17, IFN $\gamma$ , and TNF $\alpha$ ) thus relevant for several T cell mediated autoimmune diseases. However Tc17 CD8+ /MAIT cells obviously are more relevant for PsA because of its MHC class-1 association. Moreover our observation that these cells express functionally active IL-23R brings a new dimension that once these cells migrates to joint tissue IL-23 can independently regulate these critical Tc17 CD8+ MAIT cells and thus these cells likely to become a part of the IL-23/IL-17 cytokine network; and there may not be a need for the MR1 associated presentation of bacterially derived vitamin B metabolites to active these MAIT cells .

**Fig 1-** A representative FACS plot of rIL-23 induced marked proliferation of the CD3+Va7.2TCR+CD161<sup>high</sup>IL-17+ T cells

## IL-17 Producing T Cells and Its Dichotomy: A Mixed Response of the Innate and Acquired Immune System in Psoriatic Arthritis

Siba P. Raychaudhuri<sup>1</sup> and Smriti K. Raychaudhuri<sup>2</sup>, <sup>1</sup>Rheumatology Section, Sacramento Veterans Affairs Medical Center, Sacramento, CA, <sup>2</sup>Rheumatology/Immunology, VA Sacramento Medical Center, Davis, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Background/Purpose:** Source of IL-17 in human has been mainly attributed to ab T cells, more specifically to the Th17 cells. However, some reports suggest that cells of the innate immune system:  $\gamma\delta$  T cells and NKT cells may be the major contributing IL-17 producing cells in psoriatic arthritis (PsA). To have a definite answer; here we have studied arrays of IL-17 producing T cell phenotypes in PsA including the Mucosal associated invariant T (MAIT) cells.

**Methods:**

- PBMC and synovial fluid mononuclear cells (SFMC) from age/sex matched active PsA patients (n=15) and normal individuals (n=15) were collected
- Patients were not on DMARDS or biologics
- rIL-23 induced activated IL-17+ T cells were generated and stained as per our earlier reports (Raychaudhuri SP, etal. Mol Cell Biochem. 2012 ;359:419-29).
- Hi-D FACS studies were done to identify the activated memory effector CD11a+CD45RO+IL-17+ T cells. MAIT cells were CD3+V $\alpha$ 7.2TCR+CD161<sup>high</sup>,  $\gamma\delta$  T cells were CD3+ $\gamma\delta$ TCR+, ab T cells were CD3+abTCR+, invariant CD1d-restricted natural killer (NK) T cells were CD1d/PBS-57 tetramer+CD3+. The percentages of each cell population and the mean fluorescence intensity (MFI) were analyzed using FlowJo software.

**Results:**

The percentage of IL-17+ CD3+ T cells was far higher in both PBMC ( $20.5 \pm 0.5\%$ ) and SFMC ( $43 \pm 0.7\%$ ) in PsA patients compared to  $3 \pm 0.5\%$  in PBMC of healthy persons ( $p < 0.001$ ).

Both PBMC and SFMC in PsA patients demonstrated IL-17+ effector memory T cells (TEM) in the following T cell phenotypes: ab T cells,  $\gamma\delta$  T cells, NKT cells and MAIT cells. The frequency of these CD3+IL-17+ T cells in the PBMC and SFMC in PsA patients are described in the Table-1 (Table 1). An important observation we noticed that IL-17+ MAIT cell in SFMC were enriched (5%) compared to 1 % in PBMC and they were predominantly CD8+ (~ 90%).

**Conclusion:**

- In PsA, pathologic CD11a+CD45RO+IL-17+ T cells are comprised of cells of both the innate and acquired immune response: ab T cells,  $\gamma\delta$  T cells, MAIT cells and NKT cells.
- However, compared to the other phenotypes, the dominant (~ 80%) IL-17+T cells in PsA (both in PBMC and SFMC) were conventional T-helper 17 (Th17) CD4+CD11a+CD45RO+abTCR+ T cells ( $p < 0.001\%$ ) (Table 1).
- MHC class-I association, subclinical colitis and enrichment of Tc17 CD8+/MAIT cells in SFMC in PsA could be of additional pathological significance and needs further evaluation.

**Table 1. IL-17 expression (%) in gated CD3+CD11a+CD45RO+ T cells in different T cell phenotypes in SFMC and PBMC of PsA.  $\alpha\beta$ TCR IL-17+ cells are significantly more than NKT, MAIT and  $\gamma\delta$ TCR,  $p < 0.001$ .**

<b>Table-1</b>	<b>PBMC (% <math>\pm</math> SD)</b>	<b>SFMC (%<math>\pm</math> SD)</b>
<b>NKT</b>	15.155 $\pm$ 1.275	17.012 $\pm$ 2.362
<b>MAIT</b>	1.995 $\pm$ 0.089	5.182 $\pm$ 0.251
<b>dgTCR</b>	2.907 $\pm$ 0.469	1.391 $\pm$ 0.229
<b>baTCR</b>	79.943 $\pm$ 1.112	76.496 $\pm$ 0.224

## **Strain-Dependent IL-17A Secretion By CD4-CD8- DN $\alpha\beta$ T Cells Correlates with Disease Susceptibility in Murine Spondyloarthritis**

Imtiyaz Hossain, Mederbek Matmusaev and **Joerg Ermann**, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hydrodynamic injection of IL-23 minicircles into adult B10.RIII mice induces an inflammatory disease with phenotypic features of human spondyloarthritis. Tissue-resident CD4-CD8- double negative (DN) T cells secreting IL-17A in response to stimulation with IL-23 are thought to be critical in this model. To further dissect disease pathogenesis, IL-23 minicircle injection into genetically modified mice would be informative. C57BL/6, the background strain for most genetically engineered mice, has been shown to be less permissive than B10.RIII in several autoimmune or inflammatory disease models. Here, we tested the susceptibility of C57BL/6 mice to IL-23 minicircle-induced spondyloarthritis and compared number and function of DN T cells between C57BL/6 and B10.RIII mice.

**Methods:** Adult C57BL/6 and B10.RIII mice were injected with IL-23 minicircles and monitored clinically for disease development. IL-23 induction was measured by quantitative PCR (liver tissue) and ELISA (serum). Single cells suspensions were prepared from blood, liver, spleen, skin and the Achilles tendon enthesis. Cells were analyzed by multicolor flow cytometry. IL-17A production was measured by intracellular staining after stimulation with IL-23/IL-1 $\beta$  or PMA/Ionomycin in the presence of Golgi-Stop for 4 hours.

**Results:** In contrast to B10.RIII mice, C57BL/6 mice were resistant to induction of IL-23 minicircle-induced spondyloarthritis. While IL-23 expression did not differ between the two strains, C57BL/6 mice failed to develop paw swelling or psoriasis-like skin changes over the observation period of up to 4 weeks. Frequency and number of DN  $\alpha\beta$  and  $\gamma\delta$  T cells were not different in the five tissues analyzed. However, upon in vitro stimulation, we observed a statistically significantly higher frequency of IL-17A positive DN  $\alpha\beta$  T cells in susceptible B10.RIII mice compared with resistant C57BL/6 animals.

**Conclusion:** C57BL/6 mice in our animal facility are resistant to IL-23 minicircle-induced spondyloarthritis, which limits the utility of this model for mechanistic studies. IL-17A secretion by DN  $\alpha\beta$  T cell but not  $\gamma\delta$  T cells correlated with strain-dependent disease susceptibility.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Recent animal studies have suggested that  $\gamma\delta$ T-cells accumulate at enthesis, secrete IL-17 and are responsible for driving the spondyloarthritis (SpA) phenotype resulting from IL-23 overexpression in mice (1, 2). In humans examination of the immunological profile of enthesis has been hampered by lack of tissue. Recently, we used a novel strategy to show that group 3 innate lymphoid cells are present at the human enthesis (3). Here we extend our methodology to examine the broader immunological profile of human enthesis and to determine if  $\gamma\delta$ T-cells are also present.

### **Methods:**

Human enthesal soft tissue (EST) and peri-enthesal bone (PEB) was harvested from normal spinous process in patients undergoing elective spinal orthopaedic procedures. Interspinous EST was dissected from PEB and enzymatically digested, followed by isolation of mononuclear cells. Flow cytometry was then used to determine the proportion of B-cells (CD45+, CD19+) NK cells (CD45+, CD3-, CD56+) and T-cells (CD45+, CD3+). T-cells were then sub divided based on expression of CD4 (T-helper cells), CD8 (Cytotoxic T-cells) and T-cell receptor (TCR)  $\gamma\delta$  ( $\gamma\delta$ T-cells). For analysis of TCR $\gamma\delta$  isoform cDNA was isolated from peripheral blood, EST and PEB and probed with TCR $\gamma\delta$  isoform specific oligonucleotides. Enthesal data was compared to age-matched peripheral blood from healthy controls.

### **Results:**

Enthesal digests contained on average a lower proportion of T-cells compared to peripheral blood ( $p=0.018$ ). However, the proportion of T-cells not expressing either CD4 or CD8 was greater in enthesal tissues ( $p=0.021$ ). As a proportion of T-cells,  $\gamma\delta$ T-cells were 6-fold more numerous in EST compared to peripheral blood ( $p=0.024$ ), and PEB had 3-fold more. 37% of EST  $\gamma\delta$ T-cells expressed CCR6, this compared to 26% and 34% in PEB and peripheral blood respectively. 46% of EST and 54% PEB enthesal  $\gamma\delta$ T-cells expressed the V $\delta$ 1 isoform of the TCR, and clear differences in TCR isoform expression could be observed between peripheral blood, EST and PEB  $\gamma\delta$ T-cell cDNA.

### **Conclusion:**

$\gamma\delta$ T-cells are present in normal human enthesis and constitute a greater proportion of the T-cell pool compared to peripheral blood. A very similar proportion  $\gamma\delta$ T-cells that expressed CCR6, a functional marker for IL-17 production, as was observed

as reported in mice (2). Flow cytometry and transcript analysis indicate a high proportion of  $\gamma\delta$ T-cells expressing the V $\delta$ 1 isoform of the TCR, which is also associated with homing to the gut and skin. This is the first description of  $\gamma\delta$ T-cells at the human enthesis and offers tentative confirmation of findings in mouse models where these cells play a key role in SpA pathogenesis.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tubulointerstitial inflammation (TI) has been shown to have prognostic significance in renal outcome of lupus nephritis. Considering that the type of protein excreted in urine is different between glomerular disease and tubulointerstitial disease, we aimed to determine whether non-albumin proteinuria is associated with severity of TI in lupus nephritis.

**Methods :** We included patients with biopsy-confirmed lupus nephritis at a tertiary medical center in Korea from January 2000 to February 2017. Patients were included if their urine protein/creatinine ratio (uPCR) and urine albumin/creatinine ratio (uACR) were simultaneously measured. All included patients met the ACR criteria for classification of systemic lupus erythematosus. Clinical and laboratory variables including C3 and C4 levels as well as anti-double strand DNA (anti-dsDNA) antibody titers were collected. Non-albumin proteinuria was calculated by subtracting uACR from uPCR (uPCR –

uACR). Renal pathology including International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification 2003, activity and chronicity indices, and severity of TI was reviewed. Logistic regression analysis was performed to identify the clinical and laboratory parameters associated with TI severity.

**Results:** Of the total 36 patients, 27 (75%) had no -to -mild TI and 9 (25%) had moderate -to -severe TI. 31 (86.1%) had proliferative type glomerulonephritis (class III  $\frac{1}{3}$  V and IV  $\frac{1}{3}$  V) and 5 (13.9%) had non-proliferative type glomerulonephritis (class II and V). In logistic regression analysis, the following factors were significantly associated with moderate -to -severe TI: uPCR (odds ratio [OR] 1.599, 95% confidence interval [CI] 1.025-2.494,  $p = 0.039$ ) and non-albumin proteinuria (uPCR – uACR) (OR 3.558, 95% CI 1.147-11.038,  $p = 0.028$ ).

**Conclusion:** In lupus nephritis, non-albumin proteinuria, as assessed by the difference between uPCR and uACR, was associated with severity of TI, to a more relevant degree than uPCR alone. Thus, measuring non-albumin proteinuria can be a valuable non-invasive method for assessing the severity of TI in lupus nephritis.

Table 1. Factors associated with TI severity

	Odds ratio	95% CI	P value
Age	1.034	0.988-1.082	0.148
Female	4.706	0.511-43.361	0.172

## Urinary Tumor-Necrosis Factor-like Weak Inducer of Apoptosis Is an Important Biomarker for Renal Lupus

Michelle Petri<sup>1</sup>, Daniel Goldman<sup>2</sup>, Linda Burkly<sup>3</sup>, Nicolas Wisniacki<sup>4</sup>, Chris Stebbins<sup>3</sup> and Laurence S Magder<sup>5</sup>,

<sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Biogen, Cambridge, MA, <sup>4</sup>GlaxoSmithKline, London, United Kingdom, <sup>5</sup>Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Background/Purpose:** Tumor-necrosis factor (TNF)-like weak inducer of apoptosis (TWEAK) drives release of proinflammatory mediators from renal tubular and mesangial cells, and has been implicated in the pathogenesis of lupus nephritis, angiogenesis and fibrosis. We examined the utility of urinary levels of TWEAK (uTWEAK) as a biomarker for lupus nephritis activity in patients with systemic lupus erythematosus (SLE).

**Methods:** 296 SLE patients in a longitudinal cohort had urine collected at baseline and analyzed by an ELISA for TWEAK developed by Biogen. Urine TWEAK (uTWEAK) concentration was normalized by dividing by urine creatinine concentration. Patients were subsequently seen at regular intervals of three months. At every visit, assessment of disease activity was recorded using SELENA-SLEDAI, BILAG-2004 and the Physician's Global Assessment (PGA). Standard of care laboratory tests were also performed at each visit.

**Results:** uTWEAK was associated with ethnicity (highest in Asians) and strongly associated with prednisone dose. Table 1 shows the relationship of uTWEAK with organ specific SLE activity. uTWEAK was only associated with renal activity. It was negatively associated with serum creatinine ( $r = -0.25$ ,  $p < 0.00001$ ). The association of uTWEAK with urine protein/cr was mainly seen after uTWEAK/creatinine ratio of approximately 0.12.

Table 1: Risk of specific types of SLE disease activity by urinary TWEAK levels at the same visit.

SLE Disease Activity (SLEDAI descriptors)	Urinary TWEAK / Creatinine Ratio				P-value (trend)
	1 <sup>st</sup> Quartile (n=74)	2 <sup>nd</sup> Quartile (n=74)	3 <sup>rd</sup> Quartile (n=74)	4 <sup>th</sup> Quartile (n=74)	
Renal	7 (9%)	5 (7%)	12 (16%)	14 (19%)	<b>0.030</b>
--Proteinuria > 500 mg	5 (7%)	5 (7%)	10 (14%)	13 (18%)	<b>0.017</b>
--Hematuria	0 (0%)	0 (0%)	1 (1%)	3 (4%)	<b>0.025</b>
--Pyuria	2 (3%)	0 (0%)	3 (4%)	1 (2%)	1.00
Skin	24 (32%)	23 (31%)	19 (26%)	21 (28%)	0.46
Hematologic	1 (1%)	3 (4%)	5 (7%)	3 (4%)	0.29
Musculoskeletal	1 (1%)	2 (3%)	3 (4%)	3 (4%)	0.29
Immunologic	22 (30%)	21 (28%)	22 (26%)	20 (27%)	0.77

uTWEAK at baseline was predictive of renal activity over the next year (Table 2).

Table 2: Risk of specific types of SLE disease activity in visits made in the next year by urinary TWEAK levels.

SLE Disease Activity	Urinary TWEAK / Creatinine Ratio				P-value <sup>1</sup>
	1 <sup>st</sup> Quartile (n=240)	2 <sup>nd</sup> Quartile (n=224)	3 <sup>rd</sup> Quartile (n=228)	4 <sup>th</sup> Quartile (n=239)	
Renal	11 (5%)	18 (8%)	36 (16%)	43 (18%)	<b>0.016</b>
--Proteinuria	10 (4%)	12 (6%)	36 (16%)	40 (17%)	<b>0.011</b>
--Hematuria	1 (<1%)	1 (<1%)	15 (7%)	11 (5%)	<b>0.011</b>
--Pyuria	2 (1%)	9 (4%)	5 (2%)	9 (4%)	0.28
Skin	74 (31%)	69 (31%)	65 (29%)	51 (21%)	0.16
Hematologic	9 (4%)	10 (4%)	10 (4%)	10 (4%)	0.84
Musculoskeletal	8 (3%)	7 (3%)	3 (1%)	15 (6%)	0.35
Immunological	71 (30%)	53 (24%)	72 (32%)	72 (30%)	0.80

<sup>1</sup> Based on a test for trend, imputing scores of 0,1,2,3 for the consecutive quartiles, accounting for repeated measures on the same patient using GEE.

**Conclusion:** In a clinical trial, blocking TWEAK did not improve renal lupus. However, our results show that uTWEAK still has great utility as a lupus nephritis marker, as uTWEAK is only associated with renal activity and does not correlate with non-renal activity. In addition, it predicts renal activity over the next year.

## Low Vitamin D Is Associated with Thrombosis in Systemic Lupus Erythematosus

Michelle Petri<sup>1</sup>, Wei Fu<sup>2</sup> and Daniel Goldman<sup>2</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low vitamin D is common in systemic lupus erythematosus (SLE). It is also found in antiphospholipid syndrome. Vitamin D has effects on tissue factor, PAI-1, thrombomodulin and platelet aggregation that suggest it has an anti-thrombotic role. We asked whether low vitamin D was associated with thrombosis in SLE, adjusting for lupus anticoagulant.

**Methods:** A total of 1,392 SLE patients were included in the analysis. At the first visit when vitamin D was measured, 76.7% had levels of 25-hydroxyvitamin D <40 ng/mL. The SLE patients were: 92% female, mean age 42.9 years, and ethnicity 50% Caucasian, 41% African American. 27% patients had a history of thrombosis; 7% stroke, 4% MI and 14% DVT.

**Results:** Vitamin D, measured either as a continuous variable or as “low” (<40 ng/mL) vs. normal, was associated with any thrombosis and with DVT.

Table 1: Associations of First Vitamin D Measurement with Thrombosis

	Positive for Thrombotic Event		No Thrombotic Event		P-value
	Mean (SD)	N (%)	Mean (SD)	N (%)	
Any Thrombotic Event					
Vitamin D (ng/ml) (Mean/SD)	27.6(15.1)		30.6(14.6)		0.0008
Vitamin D < 40 ng/ml (N/ %)		299(80.4)		759(75.4)	0.064
Stroke					
Vitamin D (ng/ml) (Mean/SD)	28.9(15.2)		29.9(14.7)		0.5408
Vitamin D < 40 ng/ml (N/ %)		79(75.2)		988(76.9)	0.7914
Myocardial Infarction (MI)					
	Mean (SD)	N (%)	Mean (SD)	N (%)	
Vitamin D (ng/ml) (Mean/SD)	30.2(16.9)		29.8(14.7)		0.883
Vitamin D < 40 ng/ml (N/ %)		35(70)		1032(77)	0.3258
DVT					
	Mean (SD)	N (%)	Mean (SD)	N (%)	
Vitamin D (ng/ml) (Mean/SD)	25.9(13.4)		30.4(14.9)		<0.0001
Vitamin D < 40 ng/ml (N/ %)		171(87.2)		895(75)	0.0002

We next adjusted for race, age, sex and lupus anticoagulant. Low vitamin D remained associated with DVT.

Table 2 Summary of Adjusted Odds Ratio for Low Vitamin D (< 40 ng/ml)

Dependent Variables	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Any Thrombosis	1.33 (0.99,1.79)	1.36 (0.99,1.86)
Stroke	0.91 (0.58,1.45)	0.92 (0.57,1.48)
MI	0.7 (0.38,1.29)	0.8 (0.42,1.53)
DVT	2.28 (1.47,3.54)	2.31 (1.47,3.65)

We next looked prospectively: this analysis excluded thrombotic events before the first vitamin D measurement. It allowed for vitamin D to be a time-varying variable, as replacement therapy was given if it was low. After adjustment for race, age and sex, the adjusted hazard ratio remained significant for any thrombosis: 1.75 (1.04,2.92).

**Conclusion:** Low vitamin D was significantly associated with any thrombosis and with DVT (even after adjustment for lupus anticoagulant). In prospective models it remained significantly associated with any thrombosis. As supplementation with vitamin D was proven to reduce thrombosis in an oncology randomized clinical trial, vitamin D replacement should become routine in SLE patients at risk for thrombosis.

## Low Vitamin D Is Associated with End Stage Renal Disease in Systemic Lupus Erythematosus

**Michelle Petri**<sup>1</sup>, Wei Fu<sup>2</sup> and Daniel Goldman<sup>2</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Vitamin D insufficiency/deficiency is common in SLE. Replacement therapy may help renal disease activity. We asked whether low vitamin D predicted later organ damage.

**Methods:** We considered all follow-up after a patient's first measure of vitamin D. The first measure of vitamin D usually occurred in late 2009 or 2010 for existing patients and at the first visit of new patients after that. The patients were categorized based on their first measure of vitamin D as <20 ng/mL versus 20+ ng/mL. A total of 1,392 SLE patients were included in the analysis. At the first visit when vitamin D was measured, 27.3% had levels of 25-hydroxy vitamin D <20 ng/mL. The SLE patients were: 92% female, mean age 47.3 years and ethnicity 50% Caucasian, 41% African American.

**Results:** Risk of lifetime organ damage was calculated, using SLICC/ACR Damage Index.

Table 1: Risk of organ damage adjusted for age, gender and ethnicity.

	Categorical Vitamin D (< 20 ng/ml as abnormal)			
	RR (95% CI)	P-Value	Adjusted RR (95% CI)	Adj. P-Value
Ocular Damage	0.97 (0.76,1.25)	0.83	1.10 (0.86,1.4)	0.4388
Neuropsychiatric Damage	0.95 (0.73,1.24)	0.7222	1.04 (0.79,1.36)	0.7979
Renal Damage	<b>1.87</b> <b>(1.23,2.84)</b>	<b>0.0033</b>	<b>1.66 (1.08,2.54)</b>	<b>0.0206</b>
Pulmonary damage	1.01 (0.74,1.38)	0.9321	1.04 (0.77,1.41)	0.7888
Cardiovascular Damage	1.11 (0.77,1.59)	0.5882	1.20 (0.83,1.74)	0.3396
Peripheral Vascular Damage	1.18 (0.7,2)	0.5346	1.23 (0.75,2)	0.4134
Gastrointestinal Damage	0.91 (0.65,1.26)	0.553	1.04 (0.74,1.46)	0.8093
Musculoskeletal Damage	1.03 (0.82,1.28)	0.8208	1.09 (0.86,1.37)	0.4706
Skin Damage	<b>1.69</b> <b>(1.11,2.57)</b>	<b>0.0145</b>	1.22 (0.8,1.84)	0.3561
Total Damage	1.11 (0.97,1.28)	0.1246	<b>1.17 (1.02,1.33)</b>	<b>0.0245</b>

**Conclusion:** Low vitamin D associated with total damage and with End Stage Renal Disease. As vitamin D supplementation reduces proteinuria, this further suggests that vitamin D supplementation should be part of treatment of lupus nephritis. Surprisingly, low vitamin D did not associate with musculoskeletal damage (including with the subtype of osteoporotic fractures).

**Disclosure:** M. Petri, Anthera Inc, 5, GlaxoSmithKline, 5, EMD Serono, 5, Eli Lilly and Company, 5, Bristol Meyer Squibb, 5, Amgen, 5, United Rheumatology, 5, Global Academy, 5, Exagen, 2; W. Fu, None; D. Goldman, None.

## Vitamin D Deficiency Is Associated with Increased Serum Cholesterol Among Patients with Systemic Lupus Erythematosus

**Michelle Petri**<sup>1</sup>, Daniel Goldman<sup>2</sup> and Laurence S Magder<sup>3</sup>, <sup>1</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Epidemiology and Public health, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Background/Purpose:** Vitamin D insufficiency/deficiency is common in SLE. In other populations, vitamin D has been associated with cardiovascular risk factors such as blood pressure and serum cholesterol. We assessed whether there was an association between serum vitamin D and total serum cholesterol in a large SLE cohort.

**Methods:** Serum 25-hydroxy vitamin D [25(OH)D] was measured at quarterly clinic visits in a large SLE cohort. 1358 different patients were observed from 1 to 40 visits (the median was 11). The patients were 92% female, 50% Caucasian, 41% African American. Age ranged from 17 to 89 years. When the 25(OH)D level was below 40 mg/ml, the patient was prescribed supplemental vitamin D, usually 50,000 IU weekly. We explored the association between serum vitamin D levels and serum cholesterol using longitudinal regression models.

**Results:** Levels of 25(OH)D below 50 ng/ml were associated with a higher mean cholesterol. There was a significantly negative linear relationship between vitamin D and mean cholesterol when 25(OH)D was below 50 ng/ml.

Table 1: Slope of Relationship Between 25(OH) Vitamin D and Mean Cholesterol Over Different Ranges of 25(OH) Vitamin D

Range of 25(OH) Vitamin D	Estimated slope (95% Confidence Interval)			
	Unadjusted	P-value	Adjusted	P-value
0-50 ng/ml	-0.37 (-0.42, -0.32)	<0.0001	-0.30 (-0.35, -0.24)	<0.0001
50+ ng/ml	-0.09 (-0.15, -0.02)	0.014	-0.11 (-0.18, -0.03)	0.0037

<sup>1</sup> Adjusted for age, age-squared, sex, race, proportion of time on hydroxychloroquine use, corticosteroid use, BMI and systolic blood pressure.

**Conclusion:** We observed a decline in total cholesterol as vitamin D increased to the normal range. Vitamin D supplementation significantly reduced cholesterol, even after adjustment for hydroxychloroquine. Vitamin D, like hydroxychloroquine, has benefit beyond immunomodulation, in that it reduces multiple cardiovascular risk factors.

**Disclosure:** M. Petri, Anthera Inc, 5, GlaxoSmithKline, 5, EMD Serono, 5, Eli Lilly and Company, 5, Bristol Meyer Squibb, 5, Amgen, 5, United Rheumatology, 5, Global Academy, 5, Exagen, 2; D. Goldman, None; L. S. Magder, None.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**-Background/Purpose:** Lupus nephritis (LN) represents the main prognostic factor in systemic lupus erythematosus (LES) [1]. The clinical significant classes of LN –due to the need of treatment- are the proliferative (III, IV), membranous (V) and mixed classes (III or IV/V). The aim of the study was to find a urinary metabolomic fingerprint to diagnose classes III, IV and/or V of LN

**-Methods:** Cross-sectional study. Inclusion criteria: lupus patients with and without clinical significant lupus nephritis (classes III, IV, V and mixed classes). Urine samples were screened for metabolites using gas chromatography mass spectrometry (coupled with electronic nose) and principal component analysis for metabolite selection.

**-Results:** We included 29 lupus patients, 11 with LN and 18 without LN. Age between groups were 26 years (IQR 14.5) in patients with LN and 33 (IQR 22.3) in patients without LN ( $p$  0.48). The median SLEDAI score in LN patients was of 13 and 3 in those without NL ( $p$  <0.0001). Class IV nephritis was present in 45% of LN patients, mixed class in 36%, and class V in 18%. The median proteinuria of patients with NL was 1g/L, (IQR 2.7). We observed differences in metabolic fingerprint in patients with and without LN, with an AUC 90%. Metabolic pathway analysis was conducted, and we found several pathways involved, like methane, glycolysis, pyruvate and glycerophospholipid pathways. The most significant metabolites of the PCA that discriminated LN, were 2-nonanone with a sensitivity of 0.87 and specificity of 0.93. Obtaining the ratio of 2-bromopropane with 2-nonanone, the diagnostic accuracy improved, with a positive likelihood ratio (LR) of 14 and a negative LR of 0.1.

**-Conclusion:** We identified a urinary metabolomic fingerprint that involved several metabolic pathways; 2-nonanone and the ratio of 2-bromopropane/2-nonanone had the best diagnostic accuracy in our study.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time: 9:00AM-11:00AM**

**Background/Purpose:** Hyperuricemia has been reported to be associated with chronic kidney disease (CKD) in several clinical conditions, and recent studies also observed an association between increased uric acid (UA) serum levels and renal damage in lupus. However, the predictive value of UA for the development of long-term renal dysfunction in lupus nephritis is unknown. The purpose of this study was to evaluate if the UA level may be considered a predictor of long-term renal outcome in patients with lupus nephritis.

**Methods:** 75 biopsy-proven lupus nephritis patients with more than 7 years follow-up were consecutively selected for this study. Clinical and laboratorial data were obtained using a standardized electronic chart database protocol carried out at 1-6 months interval. UA levels were measured in sera stored at -70°C for all SLE patients at biopsy during nephritis flare and in 31 patients, for whom sera were available, at 6 and 12 months post-biopsy. The renal outcome was addressed after 7 years of follow-up to determine if UA was a predictor of good long-term renal outcome ( $\text{Cr} < 1.5 \text{ mg/dL}$  in 7 years). SLE patients were divided in two groups according to the renal outcome [good outcome ( $\text{Cr} < 1.5 \text{ mg/dL}$  in 7 years) and poor outcome ( $\text{Cr} \geq 1.5 \text{ mg/dL}$  in 7 years)] to assess whether UA levels at different time-points of follow-up were able to differentiate such groups. ROC curves were plotted to assess UA accuracy.

**Results:** At baseline, patients had mean SCr of  $1.7 \pm 1.3$  mg/dl, proteinuria of  $5.7 \pm 4.7$  g/24h, albumin of  $2.4 \pm 0.8$  g/dl, and SLEDAI scores of  $9.5 \pm 5.0$ . Almost two thirds of the patients (66%) patients had positive anti-dsDNA and 28 patients (35%) had SCr  $\geq 1.5$  mg/dl. The distribution of histological classes among studied patients was: class II (6%), class III / IV (53%) and pure class V (36%). Serum UA levels were not able to differentiate good from poor long-term renal outcomes in patients with lupus nephritis at any of the time points analyzed: baseline, 6, 12 months (respectively  $p = 0.96$ ,  $p = 0.76$ ,  $p = 0.77$ ). As expected, the ROC curve with higher AUC (12 months) showed a low accuracy (AUC=0.59). The cut-off for UA was 5.46mg/dL (Sensitivity=0.63, Specificity= 0.65, Positive Predictive Value=0.38, Negative Predictive Value=0.16, 95% CI=0.2-0.7,  $p < 0.05$ ). The AU was only associated with the current creatinine levels: at baseline ( $p=0.01$ ), 6 months ( $p=0.03$ ) and 12 months ( $p=0.01$ ).

**Conclusion:** This study demonstrated that serum uric acid levels in lupus patients reflect solely the current renal function and it is not a good predictor of long-term renal outcome in lupus nephritis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

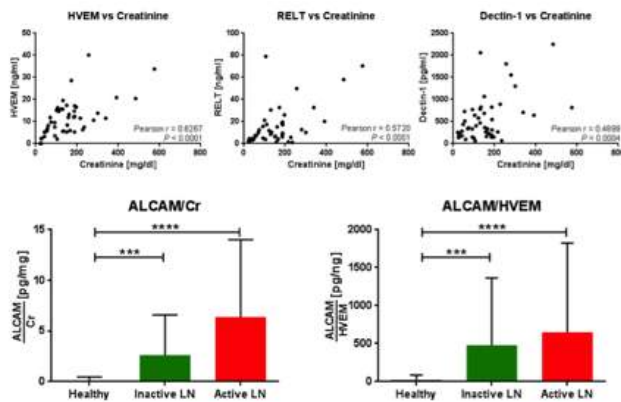

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To account for glomerular filtration rate, urinary creatinine is routinely used for the normalization of urine biomarkers related to disease. Because of the small size of this metabolite, antibodies are difficult and expensive to develop, limiting the applications of disease-specific urine protein biomarkers for antibody-based point of care applications.

**Methods:** An aptamer-based screening of 1129 proteins in 24 human urine samples (8 active lupus nephritis (LN), 8 inactive LN, 8 healthy controls (HC)) was carried out to identify urine proteins that correlated well with urine creatinine but not disease.

**Results:** The screen uncovered 18 proteins that correlated well with urinary creatinine but were similar in patients with or without nephritis. Further validation in an independent cohort of 48 subjects (16 active LN, 16 inactive LN, 16 HC) showed a significant positive correlation of urine HVEM, RELT, and Dectin-1 to urinary creatinine. The most promising marker, urine HVEM, was significantly correlated to urinary creatinine in both white (Pearson  $r = 0.7229$ ,  $P = 0.0001$ ) and black subjects (Pearson  $r = 0.6111$ ,  $P = 0.0009$ ). Finally, normalization of other urinary biomarker proteins against urine HVEM showed comparable fold change and statistical significance as normalization to urinary creatinine.

**Conclusion:** Instead of the metabolite creatinine, proteins such as HVEM, RELT and Dectin-1 can be used for normalization of urine biomarkers. The use of proteins instead of metabolites for normalization paves the way towards novel diagnostic approaches.

Urine HVEM, RELT, and Dectin-1 were validated by ELISA and found to be significantly correlated with urinary creatinine. HVEM, the most promising marker for GFR normalization, was also used to normalize ALCAM, a biomarker for SLE, to have comparable fold change and statistical significance as normalization to urinary creatinine.

## Membrane Attack Complex (MAC) Deposition in Lupus Nephritis Is Associated with Hypertension and Poor Clinical Response to Treatment

**Shudan Wang**<sup>1</sup>, Ming Wu<sup>2</sup>, Luis Chiriboga<sup>3</sup>, Briana Zeck<sup>4</sup> and H. Michael Belmont<sup>5</sup>, <sup>1</sup>Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York City, NY, <sup>2</sup>New York University School of Medicine, New York, NY, <sup>3</sup>Pathology, New York University School of Medicine, New York, NY, <sup>4</sup>Pathology, New York University School of Medicine, New York City, NY, <sup>5</sup>Medicine, New York University School of Medicine, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

LN is characterized by deposition of immune complexes in the kidney. Activation of the classical complement pathway by dsDNA is believed to play a role in its pathogenesis. The relative importance of C5a generation versus MAC involvement in tissue injury remains uncertain. We study immunohistochemistry staining for C9 in renal biopsies as a marker for intensity of kidney damage and clinical response to therapy.

### Methods:

Chromogenic immunohistochemistry was performed on formalin-fixed, paraffin-embedded, 4-μm human renal biopsy sections using unconjugated, murine anti-human Complement C9 (Hycult Biotech, clone X197) from SLE patients who fulfill 4 ACR or SLICC criteria. Positive control is C3 glomerulopathy and negative control is normal kidney. Clinical parameters assessed at time of biopsy and 6 months. Student t-test, Fisher's exact test, and logistic regression were performed in SAS.

## **Results:**

30 renal biopsies were obtained from SLE patients with LN Class II (2), III (5), IV (8), V (5), III+V (8) and IV+V (2). This study included 24 women and 6 men, mean age  $32.9 \pm 12.1$  years, with 4 Asians, 9 Blacks, 11 Hispanics and 6 Caucasians. 13/30 (43.3%) biopsies stained positive for glomerular C9 (Figure 1). Patients with +C9 have significantly higher systolic/diastolic BP, trend towards lower C3, and male gender; known predictors of poor renal outcomes (Table 1). There was no significant difference for ISN/RPN class, activity or chronicity indices between +C9 vs. -C9 groups. Five (45.5%) of 11 patients with +C9 did not respond to therapy at 6 months (defined as <50% reduction in proteinuria), compared with 2/15 (13.3%) patients with -C9. No difference in induction or maintenance therapy and compliance to therapy was found between +C9 and -C9 groups. +C9 patients were significantly more likely to be a non-responder at 6 months (OR=5.3, 95% CI 0.8, 36.4) compared to -C9 patients. After adjusting for systolic BP, compliance to treatment and proteinuria at time of biopsy in a multivariate logistic model, +C9 patients remain more likely to be non-responders (OR=4.3, 95% CI 0.3, 65.2).

## **Conclusion:**

This study demonstrates that MAC deposition is a biomarker for more intense disease and that targeting C5a may be insufficient for controlling inflammation and damage in LN. MAC staining may be useful in routine IF studies of suspected or known lupus renal biopsies to identify patients at risk for aggressive and refractory disease and who may be candidates for novel therapies targeting terminal complement pathway.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

- **Background/Purpose:** The NIH indexes (of activity and chronicity) were proposed by Austin et al., in 1984. At the moment, there are therapies which can modify the histology of lupus nephritis; therefore, the markers of prognosis in the kidney biopsy may have different hazard ratios to the described by Austin et al.
- **Methods:** We evaluated all the patients in whom a kidney biopsy was performed. DKF was defined as a glomerular filtration rate (GFR) of  $\leq 60$  ml/min/m<sup>2</sup> in two determinations in the follow-up. Histology was graded from 0-3 for glomerular or tubular abnormalities weighted by the intensity of damage. Factors associated with the development of DKF according to the different factors were evaluated through Kaplan-Meier curves and multivariate Cox regression analysis. Cox regression analysis was used to evaluate independent factors associated with the development of DKF. Independent factors in the multivariate analysis were used to construct the new index using the hazard ratio of each variable. ROC curves for survival (Heagerty et al, 2000) were used to evaluate the performance of the new index in comparison with the activity and chronicity indexes.
- **Results:** We have followed 186 patients with LN and kidney biopsy, 143 (76.9%) women, mean age at kidney biopsy was  $29.7 \pm 12.9$  years; classes of LN were: 78 patients (41.3%) class IV, 31 (16.4%) class V, 23 (12.2%) class III/V, 23 (12.2%) class IV/V, 19 (10.1%) class III, and other classes 12 patients; 135 patients (79.5%) have a minimum follow-up of 12 months. Table 1 shows the results of the univariate and the final multivariate model that was used to develop the new index. ROC curves showed AUC for detecting DKF at 12 months for activity, chronicity and our new index of 0.59, 0.70 and 0.74 respectively. Figure 1 shows the survival according two groups: low index (new index lower than the median) and high index.

**Table1.**

Histological feature	Univariate HR (CI)	Univariate p-value	Multivariate HR (CI)	Multivariate p-value
<b>Glomerular abnormalities</b>				
Cellular proliferation	1.06 (0.88-1.28)	0.547	NA	NA
Karyorrhexis	0.94 (0.72-1.13)	0.364	NA	NA
Cellular crescents	1.09 (0.96-1.22)	0.364	NA	NA
Hyaline thrombi	0.91 (0.70-1.17)	0.453	NA	NA
Leukocyte infiltration	1.23 (0.97-1.57)	0.059	NA	NA
Glomerular sclerosis	1.64 (1.33-2.03)	< 0.001	1.48 (1.14-1.91)	0.003
Fibrous crescents	1.68 (1.27-2.21)	< 0.001	1.35 (0.99-1.82)	0.051
<b>Tubulointerstitial abnormalities</b>				
Interstitial cell infiltration	1.34 (1.17-1.55)	< 0.001	1.41 (1.02-1.94)	0.038
Interstitial fibrosis	1.30 (0.97-1.75)	0.162	NA	NA
Tubular atrophy	1.35 (1.05-1.74)	0.025	NA*	NA*

\* Tubular atrophy was no included in the final model.

- **Conclusion:** We suggest predicting the risk of DKF with glomerular sclerosis, fibrous crescents, and interstitial cell infiltration. Maybe the other histological characteristics could be modified by the new therapies.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although lupus nephritis is a common and serious manifestation of SLE, there have been few predictive markers for development of lupus nephritis in SLE patients. Serum uric acid level is affected by decreased renal function, besides several factors such as old age, male, menopause, and drugs. However, it is not yet well known whether hyperuricemia is independently associated with lupus nephritis in SLE patients with normal glomerular filtration rate (GFR). The aim of this study was to evaluate the association of baseline serum uric acid level and development of lupus nephritis.

**Methods:** We retrospectively reviewed electronic medical records of 101 female SLE patients whose ages at the time of diagnosis (baseline) were 45 years old or below in a tertiary medical center from January 2000 to March 2015. SLE with renal involvement was diagnosed when patients met the 2015 ACR/SLICC revised criteria for diagnosis of SLE. We compared baseline serum uric acid levels of the SLE patients who had nephritis at the time of diagnosis or later (nephritis group) with the patients who had not developed nephritis (non-nephritis group) during follow-up period.

**Results:** Among 101 patients, 22 (22%) had hyperuricemia at baseline and 45 (45%) had developed lupus nephritis during follow-up period (median 6.1 years). There were significant differences in baseline serum uric acid level, GFR, anti-dsDNA antibody and complement level between non-nephritis group and nephritis group (Table). Interestingly, among 59 patients with normal renal function (baseline GFR  $\geq 90$  mL/min/1.73m<sup>2</sup>), baseline serum uric acid level was also significantly higher in the nephritis group than non-nephritis group (Figure 1). Moreover, the patients with hyperuricemia (uric acid  $\geq 6$  mg/dL) at baseline were more likely to develop lupus nephritis than those without hyperuricemia during follow-up period (64% vs. 39%,  $p = 0.042$ ) (Figure 2).

**Conclusion:** These findings suggest that high serum uric acid level at the time of diagnosis may be independently associated with lupus nephritis even in SLE patients with normal GFR. More careful evaluation would be required for development of lupus nephritis in hyperuricemic patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Background/Purpose:** Patients are often referred to the rheumatologist because of elevated anti-nuclear antibody (ANA) titers. We sought to evaluate the association of cell bound complement activation products (CB-CAPs), low complement (C3 or C4), and anti-double stranded (ds) DNA with systemic lupus erythematosus (SLE) and ANA titers.

**Methods:** The cohort (n=1155 adults) consisted of 498 patients with SLE with established disease (all fulfilling the 1997 ACR criteria, 91% females, mean age 41 years) pooled from prior studies of complement activation products, and a control group of 657 subjects (86% females; mean age 56 years; 314 with rheumatoid arthritis and 343 with other diseases). Abnormal CB-CAPs consisted of C4d bound to erythrocyte or B-lymphocyte levels above the 99th percentile of normal healthy. Low complement (C3 or C4) and anti-dsDNA (all confirmed using Crithidia luciliae) were determined using immunoassays. ANA titers were determined by indirect immunofluorescence, with subjects classified as having negative (<1:80), intermediate (1:80 to 1:320) or high ( $\geq$ 1:640) ANA status. The sensitivity, specificity, and Youden's index (J), a measure of diagnostic effectiveness that combines sensitivity and specificity ( $J = \text{sensitivity} + \text{specificity} - 1$ ) of various markers in distinguishing SLE from non-SLE, were evaluated. J differences were tested using t-tests.

**Results:** The diagnostic effectiveness of abnormal CB-CAPs, low complement, and anti-dsDNA in distinguishing SLE from non-SLE is presented in the Table. Overall, abnormal CB-CAPs had a significantly greater association with SLE ( $J=0.51$ ) than low complement ( $J=0.32$ ) and anti-dsDNA ( $J=0.31$ ) ( $p<0.01$ ;  $n=1155$ ). The greater association of abnormal CB-CAPs in comparison to low complement and anti-dsDNA was statistically significant in the group of subjects with high ANA ( $p<0.03$ ), intermediate ANA ( $p<0.01$ ), and negative ANA ( $p<0.02$ ). This association was also seen among subjects with high ANA ( $J=0.60$ ) compared to intermediate ( $J=0.45$ ) and negative ANA ( $J=0.17$ ) ( $p<0.01$ ). Similar results were observed for low complement and anti-dsDNA ( $p<0.01$ ). In the group of subjects with normal complement (309 SLE and 619 non SLE), abnormal CB-CAPs was 50% sensitive and 89% specific while anti-dsDNA was 20% sensitive and 99% specific ( $J=0.39$  vs  $0.19$ ;  $p<0.01$ ). In the subset of subjects with high ANA and normal complement (117 SLE and 106 non SLE), abnormal CB-CAPs was 68% sensitive and 82% specific and yielded higher diagnostic value than anti-dsDNA (40% sensitive and 93% specific) ( $J=0.50$  vs  $0.34$ ;  $p<0.01$ ).

**Conclusion:** Abnormal CB-CAPs has higher diagnostic performances for SLE than low complement and anti-dsDNA and is a sensitive and specific measure for SLE in patients with high ANA titers and normal complement levels.

**Table 1:** Performance characteristics (Sensitivity [Se], Specificity [Sp], Youden's Index [J]) by ANA status.

	Negative ANA [<1:80] Total=374, 79 SLE	Intermediate ANA [1:80-1:320] Total=430, 181 SLE	High ANA [ $\geq$ 1:640] Total=351, 238 SLE	All ANA [<1:80- $\geq$ 1:640] Total=1155, 498 SLE

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is a heterogeneous disease. Interleukin-1 receptor-associated kinase 4 (IRAK4) activity is predicted to affect multiple pathogenic pathways in SLE<sup>1</sup>. We hypothesized that coordinated expression of IRAK4-regulated genes reflective of toll-like receptor (TLR) and other upstream stimulation will reflect activity of the pathway. We aimed to identify a TLR7/8-induced gene signature to identify SLE patients who are more likely to respond to the inhibition of the IRAK4 pathway.

**Methods:** To determine candidate genes, we first identified those with impaired response to TLR7 or 8 stimulation by R848 in patients carrying loss-of-function mutations in IRAK4 (analyzed from GEO: GSE 25742)<sup>2</sup>. We then selected differentially-expressed genes that also showed elevated baseline expression in SLE blood vs. healthy controls in 2 datasets: PBMC microarray data from an extra-renal SLE cohort (SLE n=61, HC=20) and whole blood (WB) RNA sequencing data from a second extra-renal cohort (SLE n=103; HC= 19)<sup>3</sup>. We then confirmed these genes underwent dose-dependent down-regulation in response to R848 in healthy human WBs treated with selective IRAK4 small molecule inhibitor (SMI) compounds.

**Results:** Our analysis of the GSE 25742 microarray dataset showed 285 genes that displayed significantly lower induction by R848 in the whole blood from IRAK4-deficient patients vs. healthy controls (FDR<0.05; FC>1.25). The IRAK4-deficient patients did not upregulate type I interferons (IFNs) in response to R848. Baseline levels of 44 differentially-expressed genes were up-regulated in blood from SLE vs. healthy controls in both SLE cohorts analyzed. We further observed that 9 genes were down-regulated in a dose-dependent manner by 2 distinct IRAK4 SMI compounds in the human whole blood assay. These genes formed an inter-correlating signature in SLE patient blood, and partially overlapped with the interferon signature. Significant positive correlations were observed between top candidate genes and ISM status, anti-dsDNA status, and levels of BAFF, anti-RNP and anti-Sm, while significant negative correlations were observed between the candidate genes and levels of C3 and C4 in both SLE datasets.

**Conclusion:** We have identified a set of IRAK4-dependent genes with an inter-correlating signature and partial overlap with the interferon signature, that could potentially serve as biomarkers of the IRAK4 pathway in SLE patient blood samples.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cutaneous lupus erythematosus (CLE) is the cutaneous manifestation of SLE, affecting 85% of patients<sup>1</sup>. CLE is subdivided into acute, subacute and chronic/discoid forms. Discoid lupus erythematosus (DLE) can present in the absence of SLE, but up to 28% of DLE subjects will progress to SLE<sup>2</sup>. CLE lesions are characterized by interface dermatitis and a dermal perivascular immune infiltrate consisting largely of lymphocytes and histiocytes, with relatively large numbers of plasmacytoid dendritic cells (pDCs), with or without fibrosis. As robust producers of type I interferon, pDCs may play a central role in the pathogenesis of CLE lesions. To monitor the effect of therapeutic pDC-specific inhibition, we aimed to develop quantitative interlesional measures of immune infiltrate and Type I IFN pathway related proteins.

**Methods:** Patients with lesions consistent with a diagnosis of CLE and treated according to standard of care were recruited by the Perelman Center for Advanced Medicine at the University of Pennsylvania. Enrolled patients presented with subacute, chronic (other than discoid) or discoid forms of CLE with or without systemic lupus erythematosus as defined by  $\geq 4$  out of 11 classification criteria (n=10 subjects who met SLE criteria out of a total of n=19, mean CLASI = 14.21 (range=1-29). At baseline and week 12, 3-5 mm punch biopsies from active CLE lesions were collected and used for immunohistochemistry with anti-MxA (MX dynamin-like GTPase), CD45 (hematopoietic cells) and CD303 (BDCA-2) antibodies. Glass slides were examined, then digitized. Using custom-designed algorithms in Visiopharm (Denmark) software, percent areas were quantified as the portion of immunoreactive area / total tissue area for epidermis, papillary dermis and reticular dermis. R and p represent Pearson correlation and p-values.

**Results:** At baseline (n=19 subjects), CLASI correlated with relative area of epidermal (but not dermal) CD45 (r=0.72, p=0.0005) and MxA (r=0.61, p=0.0056). Also at baseline, relative area of CD303 correlated with MxA in all skin regions. Compared with papillary and reticular dermis, MxA was enriched in epidermis. In contrast, CD45+ and CD303+ cells were most plentiful in papillary and reticular dermis. Biopsies from the second visit (week 12) were available for 14 subjects. When all skin regions were combined, longitudinal change in CLASI correlated with change in CD45<sup>+</sup> (r=0.59, p=0.0255) and MxA<sup>+</sup> relative areas (r=0.61, p=0.0218).

## Conclusion:

At a single time point and as indicators of longitudinal change, relative areas of MxA and CD45 are useful tissue-based biomarkers. They can be used to complement CLASI in the setting of a clinical trial. These findings warrant investigation of tissue-based quantification of CD45 and MxA for stratification of CLE patients and to augment biopsy evaluation in the diagnostic setting.

## **Immunosignature Autoantibody Profiles Provide Mechanistic Insight into Systemic Lupus Erythematosus and Differentiation from Symptomatically Overlapping Diseases**

**Theodore M. Tarasow**<sup>1</sup>, Robert Gerwien<sup>1</sup>, Jonathan Melnick<sup>1</sup>, Scott A. Melville<sup>1</sup> and Chaim Putterman<sup>2</sup>, <sup>1</sup>HealthTell, Inc., San Ramon, CA, <sup>2</sup>Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY  
**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Diagnosis and monitoring of patients with SLE usually requires careful evaluation by a rheumatologist. However, difficulties in accurately quantifying disease and treatment response can make patient care subjective and inconsistent. A quantitative and reproducible test that facilitates SLE differential diagnosis and disease stratification may help decrease time to definitive diagnosis and improve treatment outcomes.

The Immunosignature (IS) technology uses a high-density array of 126,000 unique peptides designed to survey an individual's antibody repertoire. For autoimmune diseases, differential antibody binding profiles have the potential to provide accurate differential diagnosis, disease activity, and progression measures as well as provide more comprehensive autoantigen profiles.

The objective of this study was to use the IS technology to differentiate and characterize the autoantibody profiles in subjects with SLE from healthy controls and subjects with inflammatory and non-inflammatory diseases that share symptoms with SLE patients.

### **Methods:**

A well-annotated cohort of 371 serum samples was prospectively collected and included patients with SLE (n=75), RA (n=95), SS (n=20), OA (n=24), FM (n=22), other disease (OD) (n=76) and healthy controls (HC) (n=59). Subjects with rheumatological diseases were diagnosed based on ACR criteria. There were no significant differences in gender, race or ethnicity across all groups. Antibody (IgG)-peptide binding with significant intensity differences between contrasting groups was identified by Bonferroni adjusted t-test. Support vector machine classifiers were trained using the most distinguishing peptides. Classifier performance was evaluated by a cross-validation routine that included feature selection, model training and testing. Distinguishing peptides were mapped to putative autoantigens using a BLAST routine modified for array amino acid composition.

### **Results:**

The number of peptides significantly different between SLE contrasts and the cross validated classification performance as measured by the area under the curve (AUC) are shown in the Table. Significant peptides associated with SLE were

mapped to known and novel putative autoantigens, including a known immunogenic epitope of SS-B.

Contrast	# Samples	Significant Peptides	cvAUC (95% CI)
SLE vs. HC	134	5,121	0.90 (0.88-0.92)
SLE vs. All Disease*	312	684	0.79 (0.77-0.81)
SLE vs. RA	170	201	0.80 (0.76-0.85)
SLE vs. OA	99	455	0.88 (0.86-0.91)
SLE vs. FM	97	464	0.83 (0.78-0.87)
SLE vs. SS	95	0	0.65 (0.60-0.70)
*All Disease = SLE, SS, OA, FM, and OD (PsA (11), gout (9), scleroderma (7), DM (6), PM (5), other connective tissue disorders (38 total, <5 each)).			

### Conclusion:

Based on these observations, the IS technology can be used to classify subjects with SLE from healthy controls or subjects with diseases that have common symptoms or are similarly characterized by underlying immunological dysregulation. The ability to broadly survey the antibody repertoire within and between diseases allows for the identification of putative autoantigens and may provide additional approaches to subsetting patients. These results need verification in cohorts from other sites and validation in blinded studies.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The urokinase plasminogen activator receptor (uPAR) is expressed on various cell types and plays important roles in proteolysis, migration and adhesion. Receptor shedding yields a soluble form (suPAR) that has emerged as a promising severity biomarker in malignancies, inflammatory and infectious diseases. Previously, suPAR was shown to reflect accumulated organ damage in systemic lupus erythematosus (SLE). Our aim was to investigate suPAR as a potential predictor of future organ damage in well-characterized patients with recent-onset SLE.

### **Methods:**

A total of 345 patients with SLE ( $\geq 4$  ACR criteria) were included in this study. All patients originated from the SLICC inception cohort and were selected based on a minimum of 5-years follow-up and absence of organ damage (SLICC/ACR damage index; SDI $>0$ ) at inclusion. The patients were enrolled within 15 months of SLE diagnosis. Plasma creatinine was available for 180 patients and estimated glomerular filtration rate (eGFR) was calculated according to the MDRD 4-Variable Equation. Serum suPAR levels were measured by ELISA (Virogates, Birkerød, Denmark) at inclusion only, and levels at inclusion were related to SDI after 5-years of follow-up. Age- and sex-matched controls (1:1) were from the Swedish population.

### **Results:**

Baseline suPAR levels were higher in patients who acquired damage (SDI  $>1$ ) over a 5-year period (n=33) compared to patients without damage development (n=246;  $p<0.001$ ) and controls (n=345;  $p=0.007$ ) (Fig. 1). There were no significant differences in suPAR levels with regard to ethnicity (Caucasians vs. non-Caucasians) or sex in patients and controls, but there was a weak correlation between age and suPAR among controls ( $p<0.001$ ,  $r=0.23$ ). No correlations ( $r>0.2$ ) were found between suPAR and disease activity (SLEDAI-2K), corticosteroid dose or eGFR in patients. Logistic regression revealed significant impact of baseline suPAR on future damage (SDI $>1$ ) ( $p=0.014$ ; area under curve, AUC=0.64) and the predictive value became stronger after adjustment for age, sex, ethnicity and corticosteroid dose ( $p=0.008$ ; AUC=0.74). Examining the components of the SDI individually revealed significant impact of suPAR on damage in the musculoskeletal domain (SDI $\geq 1$ ) ( $p=0.018$ ; AUC=0.66) also when adjusting for covariates ( $p=0.020$ ; AUC=0.68).

### **Conclusion:**

Prognostic biomarkers of disease severity in SLE could identify patients in need of tight control and improved treatment strategies. suPAR has become an interesting option for patient triaging and prognostication in various diseases, and here, for the first time, it is shown to have predictive potential of damage accrual in SLE. Continued follow-up of patients could elucidate the association between suPAR and damage in specific organ domains. Furthermore, the possible role of suPAR as a causative agent in SLE organ damage remains to be investigated.

**Figure 1.** Baseline suPAR levels in healthy controls and patients with different damage accrual (SDI; SLICC/ACR damage index) at the 5-year follow-up. One-way ANOVA with Tukey's post hoc test revealed higher baseline levels of suPAR in patients who acquired organ damage (SDI>1) the upcoming 5 years compared to patients who were spared from damage (SDI=0) but also compared to controls. Error bars indicate 95% confidence interval. SDI = Systemic Lupus International Collaborating Clinics/American College of Rheumatology damage index.

## Systemic Hypertension Is Associated with Presence of Vascular Injury on Lupus Nephritis Renal Biopsies: A Retrospective Cohort Study

**Cianna Leatherwood**, Brigham and Women's Hospital, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Vascular injury in lupus nephritis is often described on renal biopsy, but its clinical correlates are not well understood. Recent evidence suggests it may be associated with poorer prognosis. We retrospectively investigated clinical and laboratory characteristics associated with vascular injury on renal biopsy among patients diagnosed with lupus nephritis.

**Methods:** We reviewed initial renal biopsy reports performed at a single academic medical center between 1996 and 2015 showing Class II-VI lupus nephritis. Experienced pathologists interpreted the histologic findings. Vascular injury was defined as arterial or arteriolar thickening of the intima without thrombosis, necrosis or proliferation. The extent of vascular injury was described as absent, mild, moderate, or severe. Clinical variables including i) hypertension (systolic blood pressure  $\geq 140$ mmHg or diastolic blood pressure  $\geq 90$ mmHg), ii) demographics, iii) serum laboratories at the time of biopsy and iv) medications for 30 days prior to the biopsy were obtained from the medical records. We used univariable analyses and multivariable logistic regression to model risk of vascular injury on biopsy.

**Results:** Among 155 initial lupus nephritis biopsies 103 exhibited vascular injury. The average age was 39 years, 84% were female, 42% were African American and dsDNA was positive in 84%. ISSN lupus nephritis biopsy classes overall were 14% II, 26% III, 33% IV and 26% V, and class was not statistically associated with presence of vascular injury. There were no statistically significant differences in duration of SLE at biopsy or prior medications between biopsies with or without vascular injury (**Table**). Vascular injury was associated with older age [39 ( $\pm$ 13) vs. 34 years ( $\pm$ 11),  $p$  0.02], elevated creatinine [1.8 vs 0.97 mg/dL,  $p$  0.0006] and hypertension (36% vs. 19%,  $p$  0.03] in univariable analyses. Presence of antiphospholipid antibodies and treatment with high dose glucocorticoids, immunosuppressants and ACE inhibitors at the time of biopsy did not differ between groups. Hypertension remained a strong correlate of vascular injury in a multivariable model controlling for age, race, sex and creatinine [OR 1.32 (95% CI 1.08, 1.62)].

**Conclusion:** Systemic hypertension was associated with vascular injury on lupus nephritis renal biopsy in this study. Further work in characterizing any differences in vascular lesions among patients with and without lupus nephritis is necessary as understanding the pathogenesis of these lesions may give insight into novel treatment pathways. These findings may support the importance of aggressive blood pressure management in patients with lupus nephritis.

Table. Univariable Analyses of Clinical Factors Potentially Associated with Vascular Injury on 155 Initial Lupus Nephritis Biopsies			
	Vascular Injury (n= 103)	No Vascular Injury (n=52)	p-value*
Age, mean	39 (±13)	34 (±11)	0.02
Duration of SLE at biopsy (years), mean	7.8 (±8)	5.5 (7)	0.16
Female	87 (84%)	45 (87%)	0.73
Race			
White	32 (33%)	18 (35%)	0.11

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Type I interferon (IFN-I) has a crucial role in the pathogenesis and activity of Systemic Lupus Erythematosus (SLE). IFN-I targeted therapies are currently in phase III clinical trials. Early findings suggest that anti-IFN-I therapy responses are superior in individuals with high INF-I signature. In established SLE, the level of IFN-I activity can be measured using an interferon gene expression score. We previously described two independent interferon gene expression scores that we called Score A and B. We also previously described a memory B cell flow cytometric marker (Tetherin) that can be used to measure IFN-I response in B cells. We aimed to describe the clinical phenotype of IFN-high SLE patients and to correlate this with Score A, Score B and Tetherin levels.

**Methods:** IFN gene expression Scores A and B as well as memory B cell tetherin were measured in 156 consecutive SLE patients attending the Leeds SLE clinic. For this preliminary analysis, we selected 59 patients across a spectrum of levels of IFN assays for detailed retrospective notes review.

**Results:**

Characteristic	Internal organ involvement	Previous cyclophosphamide	Cardiovascular Disease	Objective flare 3 months before or after test	Increased glucocorticoid dose 3 months before or after test**
Number of patients					
Yes (n=)	21	13	5	18	15
IFN Score A median (IQR)					
No	0.02 (0.40)	0.04 (0.82)	0.03 (0.40)	0.024 (0.029)	0.02 (0.19)
Yes	0.04 (1.15)	0.03 (0.45)	1.00 (0.96)	0.39 (1.08)	0.33 (1.39)
P	0.124	0.913	0.024	0.042	0.030
INF Score B median (IQR)					
No	0.12 (0.33)	0.15 (0.42)	0.18 (0.35)	0.17 (0.30)	0.17 (0.30)
Yes	0.28 (0.64)	0.22 (0.48)	0.79 (0.74)	0.34 (0.50)	0.34 (0.50)
P	0.037	0.150	0.019	0.343	0.343
Memory B cell tetherin median (IQR)					
No	1318 (2176)	1537 (2787)	1637 (2879)	647 (830)	682 (1174)
Yes	1714 (2866)	1192 (2602)	664 (1186)	3450 (1965)	3419 (1942)
P	0.740	0.666	0.310	<0.001	<0.001

\*numerically there was a stepwise increase in score B comparing 0, 1 and 2 internal organs affected but not statistically significant.

\*\*There were also significant correlations between average dose of prednisolone in over 3 months before and after the sample date and IFN Score A (Rho = 0.402, p=0.014) and memory B cell tetherin (Rho = 0.537, p<0.001)

There was no substantive relationship between interferon assays and number of previous oral immunosuppressants. There was a trend to higher tetherin levels in patients with exposure to 1 or more antimalarials (p=0.068).

**Conclusion:** High interferon is associated with more severe disease. We observed a stronger relationship between Score A and tetherin with parameters that reflect current disease activity, while long term sequelae were more clearly associated with Score B. Interferon assays may allow clinicians to better stratify SLE patients for therapy and severity prediction.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We sought to evaluate the relationships between low complement C3 and C4 proteins, abnormal complement activation (cell-bound complement activation products [CB-CAPs]), and a Lupus Severity Index (LSI) instrument recently developed.

**Methods:** The study was multi-centered and enrolled 500 SLE subjects (mean age  $41.0 \pm 0.6$  [SEM] years; 91% female; mean disease duration  $10.9 \pm 0.4$  years), all fulfilling the 1982 American College of Rheumatology (ACR) criteria revised in 1997. LSI was determined using the ACR criteria and sub-criteria elements collected from medical records as described (Bello *et al.*, Lupus Science & Medicine 2016;3:e000136). Serum C3 and C4 levels were determined using standard immunochemistry techniques. Complement activation was assessed by quantitative flow cytometry, and abnormal activation was defined as levels of C4d bound to erythrocyte (EC4d) or B-lymphocytes (BC4d) above the 99th percentile of a control group of normal healthy individuals ( $>14$  and  $>60$  net mean fluorescence intensity [MFI], respectively). Multivariate linear regression analysis was used to evaluate the contributions of low complement and abnormal CB-CAPs to LSI, with age and disease duration as covariates. Pearson's Chi-Square and Kruskal Wallis ANOVA tests were used as appropriate for group comparisons.

**Results:** In this cohort, median LSI score was 0.596 points (range 0.327-0.938 points, first tertile: 0.544; second tertile: 0.792). Multivariate linear regression analysis revealed that higher LSI scores were associated with abnormal CB-CAPs (estimate= $0.063 \pm 0.015$  points;  $p < 0.01$ ), low complement (estimate= $0.030 \pm 0.015$ ;  $p = 0.048$ ), younger age (estimate= $-0.026 \pm 0.001$  per 10-years increment;  $p < 0.01$ ), and longer disease duration (estimate= $0.027 \pm 0.003$  per 10-years increment,  $p < 0.01$ ) (Global  $R^2 = 0.13$ ). Altogether, subjects presenting with both low complement and abnormal CB-CAPs had higher LSI (median [IQ range]: 0.785 [0.558-0.839]) than those presenting with either abnormality (median [IQ range]: 0.591 [0.526-0.817]) or those presenting with normal complement and normal CB-CAPs (median [IQ range]: 0.546 [0.481-0.703]) ( $p < 0.001$ ). Figure 1 illustrates the higher frequencies of low complement ( $p < 0.01$ ) and abnormal CB-CAPs ( $p < 0.01$ ) by LSI tertiles and shows that abnormal CB-CAPs is more prevalent than low complement at all LSI levels ( $p < 0.01$ ).

**Conclusion:** These data indicate that abnormalities in the complement system are associated with increased LSI.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antibody titers to double stranded DNA (anti-dsDNA) and complement C3 and C4 proteins have clinical utility in the routine monitoring of systemic lupus erythematosus (SLE). We evaluated the performance characteristics of antibody titers to C1q (anti-C1q), and C4d bound to erythrocytes (EC4d) as additional biomarker candidates in the monitoring of SLE disease activity.

**Methods:** SLE patients (total 124 patients, mean age 42 years, 97% females) were enrolled from three different cohorts. The first cohort enrolled 37 subjects, all selected for active disease in the presence of complement activation. The second and third cohorts enrolled 64 and 24 SLE subjects, respectively. Disease activity was assessed longitudinally using the Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA) SLE disease activity index (SLEDAI) without anti-dsDNA and complement components; this modification is referred to as the clinical SELENA-SLEDAI. Also, the Physician's Global Assessment of disease activity (PGA: 0-3-point scale) was collected. Antibody titers, serum C3 and C4 levels were determined using standard immunoassays (low C3/C4 was defined as either C3 or C4 below normal range). EC4d levels were determined using quantitative flow cytometry and expressed as net mean fluorescence intensity (MFI). The relationships between fluctuations in SLE disease activity and biomarkers were analyzed using Spearman rank test and linear mixed effect models with the clinical SELENA-SLEDAI and PGA as the dependent variables and biomarkers as independent predictor of disease activity fluctuations (autoantibody titers and EC4d levels were log normalized for the analysis). Marginal  $R^2$  were calculated to evaluate the proportion of variance explained by independent variables.

**Results:** Overall, a total of 624 study visits were collected in the 124 patients. At baseline, both clinical SELENA-SLEDAI (average 6.0 points) and PGA scores (average 1.0 point) correlated with EC4d levels C3/C4 status, anti-dsDNA and anti-C1q titers ( $p<0.01$ ). Linear mixed effect models revealed that changes in EC4d, C3/C4 anti-dsDNA and anti-C1q titers were all significantly associated with fluctuations in disease activity ( $p<0.01$ ) (Table I). Of the 124 subjects, 97 of them presented with either chronically low C3/C4 ( $n=40$ ) or normal C3/C4 status at all visits ( $n=57$ ). In this subset, changes in EC4d levels were associated with fluctuations in clinical SELENA-SLEDAI (estimate  $1.2\pm0.3$ , marginal  $R^2=8\%$ ) and PGA (estimate  $0.2\pm0.1$ , marginal  $R^2=9\%$ ).

**Conclusion:** These data indicate that anti-dsDNA, antiC1q, low complement and EC4d are associated with disease fluctuations in SLE. EC4d correlates with disease activity among subjects with chronically low or normal complement.

**Table 1:** Linear Mixed effect models for the clinical SELENA-SLEDAI and PGA. Slope estimate and marginal R<sup>2</sup> (p value) are given.

SLE marker	Clinical SELENA SLEDAI Slope estimate $\pm$ SEM	PGA Slope estimate $\pm$ SEM
EC4d (Log Net MFI)	1.2 $\pm$ 0.3 (6%) (p<0.01) <sup>1</sup>	0.17 $\pm$ 0.044 (6%) (p<0.01)
Low C3/C4	1.7 $\pm$ 0.4 (4%) (p<0.01)	0.30 $\pm$ 0.06 (6%) (p<0.01)
Anti-dsDNA (log U/ml)	1.1 $\pm$ 0.2 (18%) (p<0.01)	0.10 $\pm$ 0.02 (8%) (p<0.01)
Anti-C1q (Log U/ml)	1.2 $\pm$ 0.2 (10%) (p<0.01)	0.15 $\pm$ 0.03 (8%) (p<0.01)

<sup>1</sup>One log increase in EC4d levels is associated with 1.2-point increase in the clinical SELENA-SLEDAI. Marginal R<sup>2</sup> in percent of variance explained are given.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Abnormal activation of the complement system is emerging as a useful biomarker in the evaluation of patients presenting symptoms of autoimmune rheumatic diseases. We sought to evaluate the relationships between complement activation and autoantibodies associated with systemic lupus erythematosus (SLE), anti-phospholipid Syndrome (APS) and rheumatoid arthritis (RA).

**Methods:** From May 2014 to November 2016, a cohort of 32,404 patients within the United States (mean 51 $\pm$ 15 [SD] years, 86% females) was tested. EDTA whole blood and serum were collected within 48 hours of patient examination and processed in a CLIA certified/CAP accredited clinical laboratory. C4d bound to erythrocyte or B lymphocyte above the 99th percentile of normal healthy group were defined as abnormal. The panel of 16 autoantibodies (all determined by solid phase immunoassays) consisted of 6 SLE autoantibodies (high ANA, anti-dsDNA confirmed using Crithidia, anti-U1 RNP, anti-C1q, anti-ribosomal P, anti-Smith, all IgGs), 6 APS autoantibodies (anti-cardiolipin, anti- $\beta_2$  glycoprotein 1, anti-phosphatidylserine/prothrombin complex, IgM and IgG) and 4 RA autoantibodies (anti-CCP, anti-MCV, IgM RF, IgA RF). The relationships between abnormal complement activation and the presence of the autoantibodies were analyzed on de-identified patient data using multivariate logistic regression with abnormal complement activation as the dependent variable and the presence of autoantibodies as predictors. Adjusted odds ratio were calculated for each autoantibody.

**Results:** Of the 32,404 patients tested 12% of them presented with abnormal complement activation. The overall incidence of autoantibodies ranged from 1% (anti-Sm) to 22% (ANA). The presence of SLE and APS antibodies were all associated with abnormal complement activation with adjusted OR ranging from 1.40 for anti-C1q (CI95%: 1.24-1.58) to 4.52 for anti-dsDNA (CI95%: 3.95-5.17), and from 1.47 for anti-cardiolipin IgG (CI95%: 1.22-1.77) to 3.2 for anti-PS/PT IgM (CI95%: 3.20-2.92), respectively (p<0.02). Of the 4 RA-associated antibodies, only anti-CCP (adjusted OR=1.25, CI95%:

1.02-1.54) and IgM RF (adjusted OR=1.17, CI95%: 1.04-1.32) were significantly associated with complement activation ( $p<0.05$ ). Figure 1 illustrates the relationship between the cumulative presence of lupus, APS and RA autoantibodies, and abnormal complement activation. Across the cumulative range of SLE and APS associated antibodies, we detected a 319-fold (CI95%: 240-424), and 120-fold (CI95%: 94-153) increased likelihood of abnormal complement. In contrast, the cumulative presence of RA autoantibodies yielded minimum impact of the likelihood of abnormal complement activation (adjusted OR=2.3; CI95%: 2.0-2.7)

**Conclusion:** These diagnostic immunology data suggest that complement activation in peripheral blood is intimately related to SLE and APS antibodies.

## The Presence of Anti-Ro and Anti-La Antibodies Is Associated with Tubulointerstitial Damage in Lupus Nephritis

Alejandra Londono Jimenez<sup>1</sup>, Wenzhu Mowrey<sup>2</sup> and Anna R. Broder<sup>2</sup>, <sup>1</sup>Internal Medicine, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Albert Einstein College of Medicine/Montefiore Medical Center, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Moderate-to-severe tubulointerstitial damage (TID) is associated with poor renal outcomes in lupus-related kidney disease, independent of glomerular pathology<sup>1</sup>. Unlike glomerular damage, TID is not associated with anti-dsDNA or complement levels and no serologic parameters associated with TID in SLE have been identified to date<sup>2</sup>. The presence of anti-Ro/La antibodies in Sjögren's syndrome is associated with extraglandular manifestations, including

tubulointerstitial nephritis<sup>3</sup>. Whether anti-Ro/La antibodies are associated with TID in lupus-related kidney disease has not been studied.

**Objective:** To study an association between anti-Ro/La antibodies and TID in lupus nephritis (LN).

**Methods:** We identified all patients who fulfilled ACR and/or SLICC criteria for SLE at a large urban tertiary care center. Medical history, demographic and laboratory data were ascertained from chart review. Patients were included if they had an index renal biopsy consistent with LN between January 2005 and July 2015 and had complete data on TID and anti-Ro/La. All biopsies were reviewed by 2 experienced renal pathologists and TID was classified as mild, moderate or severe when tubular atrophy and/or interstitial fibrosis involved <25%, 25-50% or >50% of the interstitium, respectively<sup>1</sup>.

**Results:** Of the 157 LN patients, 39 (25%) had moderate/severe TID (Table). Moderate/severe TID was associated with older age, proliferative LN (class III/IV±V) and lower estimated glomerular filtration rate (eGFR) at biopsy. Anti-Ro/La were present in 11/118 (9%) with none/mild TID vs 11/39 (28%) with moderate/severe TID ( $p=0.003$ ), and in 13/114 (11%) with none/mild TII vs. 8/37 (22%) with moderate/severe TII ( $p=0.12$ ). In the logistic regression model adjusted for age, eGFR and LN class, dual positivity for anti-Ro/La antibodies was associated with a 3-fold increase in the odds of TID, OR 3.1, 95% CI (1.1-9.1),  $p=0.04$ .

**Conclusion:** Dual anti-Ro/La positivity is associated with moderate/severe TID in patients with biopsy proven LN after adjusting for age, LN class and eGFR. The presence of only anti-Ro antibodies is not associated with moderate/severe TID. Understanding the role of anti-Ro/La in the mechanisms underlying TID in LN may lead to novel preventive and therapeutic strategies.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Background/Purpose:**

Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by immune system disruption with autoantibodies production. One of the upregulated autoantibodies is the specific to the Ro antigen, a ribonucleoprotein associated to a small RNA, constituted by the 52KDa and 60 KDa polypeptides, whose epitopes are mainly conformational. The routine detection method for anti-Ro is an enzyme immunoassay, however, is possible to obtain false-negatives for anti-Ro and this could be avoided by analyzing both subunits separately. The aim of the present study is to identify false-negatives for anti-Ro by analyzing both 52KDa and 60 KDa subunits separately, as well as to characterize if there are clinical or molecular differences in this subgroup of patients compared to anti-Ro negative cases.

**Methods:**

A cross-sectional, observational study of patients diagnosed of SLE according to SLICC 2012 criteria was performed. In these patients a complete blood-test was made, and clinical data by personal interview was collected. INF1A, Anti-Ro, anti-Ro52KDa and anti-Ro60KDa levels were measured by colorimetric methods. Biostatistical analysis was performed with R 3.3.2.

**Results:**

We selected 69 SLE patients with negative results for anti-Ro ( $2.34 \pm 4.17$  U/mL) out of 142 total SLE patients. A total of 51 patients were negative for both anti-Ro subunits and 18 cases presented positive results (up to 20 pg/mL) for at least one of them.

	<b>Anti-RO52KDa</b>		<b>Anti-RO60KDa</b>	<b>Anti-RO52KDa / Anti-RO60KDa</b>
	<b>NEGATIVES</b>	<b>POSITIVES</b>	<b>POSITIVES</b>	
	<b>N=51</b>	<b>N=8</b>	<b>N=2</b>	<b>N=8</b>
Anti-RO [U/mL] Mean (DS)	1.92 (3.11)	1.65 (3.2)	0.5 (0.71)	6.15 (8.37)
Anti-RO52 KDa [pg/mL] Mean (DS)	1.26 (1.89)	147.24 (74.25)	1.05 (0.89)	196.82 (50.06)
Anti-RO60 KDa [pg/mL] Mean (DS)	1.73 (2.71)	6.3 (7.01)	120.96 (111.78)	145.22 (76.69)

The subgroup of patients that exhibit simultaneously high levels of anti-Ro52KDa and anti-Ro60KDa have higher clinical activity compared to negative anti-Ro cases (75% of active patients against 41.2% in anti-Ro negative patients). However, no differences in the accumulated damage evaluated by SLICC score between negative anti-Ro cases and patients with at least one positive subunit were observed.

We analyze serum levels of INF1A cytokine in the four groups of patients, and anti-Ro and subunits negative cases showed significant lower INF1A levels than the other patients ( $8.26 \pm 14.87$  pg/mL and  $26.62 \pm 40.71$  pg/mL respectively;  $P=0.04$ ). In addition, patients with high levels of anti-Ro52KDa subunit are those with the highest INF1A levels (anti-Ro 52+/anti-Ro60-  $23.5 \pm 47.6$  pg/mL of INF1A; anti-Ro 52+/anti-Ro60+  $36.4 \pm 37.9$  pg/mL of INF1A).

**Conclusion:**

In our anti-Ro seronegative patients, a 26% of false-negative cases were detected. These cases with high levels of almost one anti-Ro subunit showed significantly higher levels of INF1A in contrast to negative cases, supporting the fact that they are indeed a different group from the negative cases. Moreover, the high INF1A levels could be the reason of the observed differences in the clinical activity measured by SLEDAI score in both groups.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

### Background/Purpose:

Anti-C1q antibodies (C1Q Ab) are observed in 30-60% of patients with Systemic Lupus Erythematosus (SLE). A number of studies have shown that the presence of C1Q Ab correlates with disease activity. In particular C1Q Ab is reported to strongly correlate with active renal disease with some studies reporting antibody absence having a negative predictive value of close to 100% for active lupus nephritis (LN) (1). However specificity for active lupus remains controversial and variations may be due to timing of samples, assay used, cut off values and population studied.

Here we undertook a point-in-time measurement of C1Q Ab in a multi ethnic cohort of SLE patients and investigated correlations between this and clinical and serologic parameters of SLE.

### Methods:

SLE patients attending an inner city Lupus Clinic were involved in the study. Disease activity was calculated using the SLE Disease Activity Index (SLEDAI 2K); erythrocyte sedimentation rate (ESR), dsDNA Ab, complement levels (C3, C4), and urine protein creatinine ratio (uPCR) were measured. For patients with biopsy proven LN renal inactivity was defined as a PCR < 50 mg/mmol. C1Q Ab was quantified by ELISA (Orgentec Diagnostika GmbH). A positive test defined by the manufacturer is a level above 10 U/ml. Correlation of C1Q Ab levels with disease activity markers was measured using Pearson's correlation.

### Results:

116 patients were included in the study. All fulfilled the 2012 SLICC criteria for SLE. 103 (89%) were female. There were 38 (32.8%) South Asians (SA), 48 (41.3%) Afro Caribbean (AC) and 25 (21.6%) White Caucasians (WC). C1Q Ab positivity was present in 29% SA patients, 13% AC patients and 28% WC patients (p=0.06).

There was a positive correlation between C1Q Ab levels and dsDNA levels (r=0.358, p<0.01); whilst a negative correlation was observed with C3 levels (r=-0.406, p<0.01). No correlation was found with SLEDAI scores (r=0.18, p=0.053), uPCR (r=0.13, p=0.16) and ESR (r=0.045, p=0.63). Positive C1Q Ab was more common in patients with a history of biopsy proven LN (32.7%); of these patients, 43% (n=12/28) had inactive LN at the time of sampling with a positive C1q Ab. In addition, C1Q Ab was present in 15.5% (n=9) of patients with minimally active disease (SLEDAI≤4).

### Conclusion:

The overall prevalence of C1Q Ab was 23.3% in our lupus cohort, and was present in all ethnic groups. Its presence was correlated with dsDNA but not with SLEDAI score, ESR and PCR. There was a negative correlation with C3 level. C1Q Ab was found more commonly in renal than in non-renal patients. Importantly a positive C1Q Ab level was found in 15.5% of patients with inactive disease defined as SLEDAI $\leq$  4 and in 43% of LN patients with inactive renal disease (defined as PCR $<$ 50). We would therefore caution against use of C1Q Ab as a stand-alone biomarker for active lupus.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** early identification of subclinical cardiovascular disease (CVD) in systemic lupus erythematosus (SLE) patients is mandatory to reduce morbidity and mortality. Endothelial dysfunction (ED) is one of the first steps of the process leading to atherosclerosis and has been associated with further CVD development. Aim of the study was to assess the prevalence of ED by a non invasive procedure in SLE patients with early disease without CVD and risk factors, and correlate ED with nailfold capillary morphology and angiogenic T (angT) cells. AngT cells are a T cell subpopulation, involved in repair mechanisms of the endothelium, cooperating with endothelial progenitors cells.

**Methods:** all the consecutive SLE patients, according to SLICC Classification Criteria, with a disease duration less than 5 years, evaluated from december 2014 to march 2016 were proposed to participate to the study. Exclusion criteria were represented by history of CVD, diabetes, chronic renal disease (creatinine clearance $<$ 60 ml/min), not controlled systemic arterial hypertension, current or past smoking (in the last 3 years), hypercholesterolemia (total cholesterol $>$ 240 mg/dl), obesity (body mass index  $>$  or  $=$ 30), statin or beta-blocker use. Each patient underwent a clinical and serological evaluation, a transthoracic doppler echocardiogram, endothelial function study by endoPAT technique, nailfold

videocapillaroscopy (NVC) and T cell subpopulation study. Characteristics of patients with ED (ED+), defined as reactive hyperemic index  $\leq 2$ , were compared to those of patients without ED (ED-) and normal controls, matched for age, sex and CV exclusion criteria, by Fisher, T student or Mann-Whitney tests as appropriate.

**Results:** Among 46 screened SLE patients, 20 patients were enrolled (100% female, 80% caucasian) with a median disease duration of 14 months (0-68), a mean age of 42 years ( $\pm 15$ ), and a mean age at diagnosis of 40 years ( $\pm 16$ ). Arthritis, cutaneous and hematological features were found in 70%, 55% and 65% of cases, respectively. ANA, anti-dsDNA and anti-ENA were found in 100%, 50% and 50% of cases. Anti-cardiolipin and anti-beta2glycoprotein I antibodies in 20% and 10%. ED was found in 8 patients (40%). ED didn't correlate with any demographic-clinical-serological-echocardiographic features. A significantly higher prevalence of ED ( $p:0.003$ ), vascular stiffness ( $p:0.02$ ), left ventricular concentric remodelling ( $p:0.003$ ), grade I diastolic dysfunction ( $p:0.04$ ) were found in SLE patients compared to controls.

ED+ patients more frequently showed minor NVC abnormalities (i.e. tortuous,/crossed/enlarged) ( $p: 0,007$ ), lower capillary number/mm ( $p: 0,01$ ) and wider intercapillary distance ( $p: 0,06$ ) compared to controls. AngT cells were significantly reduced in SLE patients compared to controls ( $p: 0,045$ ), but they were increased in ED+ SLE compared to ED- ( $p: 0,04$ ).

**Conclusion:** A significant proportion of SLE patients showed signs of ED despite a recent disease and the absence of cardiovascular risk factors. ED correlates with microvascular alterations by videocapillaroscopy and increased ang T cells, as marker of endothelium repair.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Homocysteine level is a predictor of the occurrence of cardiovascular diseases, however, its role as a predictor of damage in SLE has not been studied. The aim of this study is to determine the impact of homocysteine levels on damage accrual in SLE patients.

### Methods:

These analyses were conducted in 145 SLE patient, 136 females and 9 males, followed longitudinally at a single center. Evaluations were done every six months and included interview, medical records review, physical examination and laboratory tests. Disease activity was measured with the SLEDAI (Systemic Lupus Erythematosus Disease Activity Index). Damage accrual was ascertained with the SLICC/ACR damage index (SDI). Univariable and multivariable Cox regression models were performed to determine if homocysteine levels were associated with damage accrual. The multivariable model was adjusted for variables known to be associated with this outcome [age at diagnosis, gender, socioeconomic status, disease duration, SLEDAI, antimalarials and immunosuppressive drugs use, average daily dose and time of exposure to prednisone (PDN)].

## **Results:**

The patients mean (SD) age at diagnosis was 43,70 (12,09) years, nearly all were Mestizo. At baseline, disease duration was 7,55 (6,73) years. The SLEDAI was 5,60 (4,34) and the SDI 0,97 (1,35). The average daily dose of PDN was 7,30 (5,78) mg/d and the time of exposure to PDN was 7,36 (6,73) years. Mean homocysteine levels was 10,07 (3.71)  $\mu$ moles/liter. Patients were followed for 3.54 (1.27) years, and 75 (51.7%) increased at least one point in the SDI. Homocysteine level predicted new damage accrual in the univariable and multivariable models [HR 1.08 (CI95%: 1.03-1.14); p=0.002 and HR: 1.09 (CI95%: 1.02-1.16); p=0.008 respectively.]

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic lupus erythematosus (SLE) affects various body organs making its clinical presentation highly variable. While previous studies have demonstrated associations between lab abnormalities and individual clinical manifestations of disease, our study aimed to be more specific and categorized patients into sub-groups based on their unique presentations. We then investigated associations between immunological/serological abnormalities and exclusive clinical phenotypes of SLE.

### Methods:

Information regarding SLE related clinical symptoms and serological data were collected from 201 patients diagnosed with SLE. Laboratory abnormalities included: anti-nuclear antibody (Ab), anti-Ro Ab, anti-La Ab, anti-Smith Ab, anti-U1-ribonucleoprotein Ab, anti-rheumatoid factor Ab, anti-dsDNA Ab, low C3, low C4, anti-cardiolipin Ab, lupus anticoagulant and beta2-glycoprotein. Patients were classified into clinical subgroups based on manifestation(s) of disease: arthritis alone (A); mucocutaneous disease alone (B); nephritis alone (C); arthritis + mucocutaneous disease (D); arthritis + nephritis (E); nephritis + mucocutaneous disease (F); or all 3 (G). Omnibus chi-square tests evaluated associations between individual lab abnormalities and phenotype with subsequent post-hoc evaluation for significant omnibus tests. Positive and negative predictive values (PPV, NPV) were also investigated.

### Results:

Analyses revealed that anti-Smith, anti-dsDNA antibodies and low levels of C3 and C4 were associated with phenotype G ( $p=0.001$ , Chi-square ( $\chi^2$ )=11.3;  $p=0.004$ ,  $\chi^2=8.3$ ;  $p<0.0001$ ,  $\chi^2=21.4$ ;  $p<0.0001$ ,  $\chi^2=22.5$  respectively) with a PPV of 59.4%, 85.3%, 91.2% and 85.3% respectively, and anti-Sm Ab had a NPV of 71.3%. Anti-dsDNA Ab, low C3 and C4 levels were additionally significantly associated with phenotype F ( $p=0.01$ ,  $\chi^2=6.25$ ;  $0.01$ ,  $\chi^2=6.48$ ;  $p=0.01$ ,  $\chi^2=6.54$  respectively). PPV of anti-dsDNA Ab, low C3 and C4 for F was 93.3%, 91.2%, and 80% respectively and 73.3% combined. Further, anti-dsDNA Ab, low C3 and C4 were negatively associated with phenotype B ( $p<0.001$ ,  $\chi^2=15.3$ ;  $p<0.001$ ,  $\chi^2=12.48$ ;  $p=.014$ ,  $\chi^2=6.1$ , respectively). Low complement levels were also negatively associated with phenotype D (C3:  $p=.038$ ,  $\chi^2=4.3$ ; C4:  $p=.011$ ,  $\chi^2=6.54$ ). While nephritis alone was not significantly associated with any markers, anti-dsDNA Ab, and low complement levels combined had an 80.8% NPV for renal disease.

### Conclusion:

Our results suggest that an expanded epitope including anti-dsDNA and anti-Smith antibodies, along with low complement levels are associated with a broader phenotype in SLE which includes arthritis, nephritis and mucocutaneous involvement.

Anti-dsDNA Ab and low complement levels were also associated with the mucocutaneous disease and nephritis combined but not nephritis or mucocutaneous disease alone. In fact, these serological markers were negatively associated with mucocutaneous involvement. These findings suggest that immunological profiles may reflect unique phenotypes of SLE. Future genetic models that target particular phenotypes of SLE and associated immunologic abnormalities may be useful in developing new drug therapies.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Two Apolipoprotein L1 (APOL1) risk variants (RV), G1 and G2 are enriched in African populations due to a conferred resistance to *Trypanosoma brucei*. This comes with the cost of progressive renal disease by multiple causes including SLE. Despite the high regional allelic frequencies, APOL1 variant phenotypes have never been described in a Sub-Saharan African SLE cohort. Further, it is unclear if SLE nephritis progression in RV carriers is driven by inflammation or intrinsic nephropathy. Accordingly, this prospective longitudinal cohort study evaluated APOL1 genotype-phenotype traits in the context of SLE activity in 72 Ghanaian patients seeking care at Korle bu Teaching Hospital in Accra, Ghana.

**Methods:** All 72 patients met 4 ACR criteria for SLE and were stratified by APOL1 genotype using PCR/sequencing as follows: ancestral (G0/G0), RV heterozygotes (RV/G0), and RV homozygotes (RV/RV). DNA was extracted from saliva, and ancestry informative markers were performed on a subset of 20 patients to confirm heritage. ANAs were confirmed in the NYU clinical lab by multiplex analysis. Endpoints collected at three, 6 month intervals included demographics, ACR criteria, SLEDAI score, vital signs, and lab values as available. To measure SLE serologic activity, dsDNA titers were completed and in 15 subjects (5 per genotype), interferon (IFN) signature was measured by the WISH cell assay.

**Results:** The frequencies of the G0, G1, and G2 alleles were 60%, 25%, and 14.5% respectively (meeting Hardy Weinberg Equilibrium) and principal component analysis confirmed ancestry. Subjects were all female, average age of 32.1 years with SLE duration of 2.3 years. Data were collected on at least one, two, or three time points on 72, 56, and 30 subjects respectively. There were no differences in history of nephritis, diabetes, or age across the genotypes. The RV associated with higher average BPs; 109.9/75.7, 111.3/75.2, and 125.2/85.6 mmHg in the G0/G0, RV/G0, and RV/RV groups respectively (p: 0.04 systolic; 0.02 diastolic). Only 13% of the cohort took anti-hypertensives regardless of genotype. Among those with nephritis, RV/RV had increased creatinine: 0.9, 1.1, and 2.5 mg/dL in the G0/G0, RV/G0, and RV/RV groups respectively (p: 0.03). RV/RV carriers took higher doses of prednisolone (17.2mg) compared to G0/G0 or RV/G0

(11.2mg; 11.8mg respectively), however this did not reach statistical significance and there was no difference in SLEDAI scores. Despite higher creatinine, RV/RV carriers were less likely to ever have had anti-DNA positivity (11% positive) and had lower dsDNA titers (10.7 IU/mL) than G0/G0 (41% positive; 57.1 IU/mL) and RV/G0 (43% positive; 95.6 IU/mL) carriers (p: 0.03). IFN signatures in both G0/G0 and RV/G0 patients were higher than in RV/RV (245.7, 81.3, and 24.3 respectively). G0/G0 or RV/G0 carriers were more likely to have IFN scores above the average value of 109.9 (LR: 4.3; p: 0.04).

## Conclusion:

Taken together, RVs associated with higher BP and creatinine in this Ghanaian SLE cohort. Despite having poorer renal function, RV homozygotes exhibited lower dsDNA titers and lower IFN signatures than G0/G0 or RV/G0 patients potentially suggesting intrinsic renal disease independent of SLE activity in RV homozygotes.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular involvement including pericardium, conduction system, coronary arteries and valvular abnormalities are frequent manifestations of SLE. It is estimated to occur in more than 50% of SLE patients and the prevalence is increasing in the setting of imaging modalities like echocardiogram. Studies have shown approximately 11 times higher risk of any valvular abnormalities in SLE, with mitral valve regurgitation being the most common among them. The mechanism of injury and risk factors are still not completely understood. While association of antiphospholipid antibodies and SLE related valve disease is well known, role of other antibodies like SSA and Anti-Smith remains poorly defined. Recent studies have shown the increased incidence of SSA antibodies in SLE and their positive association with severe mitral valve regurgitation. Though the detection of the early or minor changes by using echocardiography may be limited, these parameters are reliable for all-cause mortality and cardiac morbidity. We sought to test the association between valvular abnormalities and SSA antibodies in SLE patients without clinical cardiovascular disease (CVD).

**Methods:** Adult SLE patients without clinical CVD continuously seen at a University Lupus Center between April 2016 and March 2017, meeting 1997 ACR classification criteria for SLE were studied. Patient characteristics including demographics, SLE-specific features, medication use, traditional CVD risk factors, 12-lead electrocardiogram (EKG) were ascertained. Trans Thoracic Echocardiogram (TTE) was obtained mainly retrospectively from within one year of the date of

enrolment. Univariable and multivariable linear regression models were constructed to test the association of SSA antibodies with valvular abnormalities.

**Results:** Sixty-four SLE patients (baseline characteristics in table 1) were studied. In univariable analyses, presence of SSA antibodies was significantly associated with a higher incidence of any valvular abnormality (OR= 5.8, P = 0.042) , mitral valve regurgitation ( OR= 3.08, p=0.05) and tricuspid valve regurgitation (TVR) ( OR = 4.95, p= 0.018) . Multivariable regression models showed the absence of any confounders. There were a total of 54 (84%) valvular abnormalities with TVR being the most common at 49 (77%).

**Conclusion:** SSA Antibodies are associated with valvular abnormalities with TVR being most common in SLE patients without clinical cardiovascular disease

## Serum Anti-NR2 Has a Better Specificity Than Sensitivity in Diagnosing Neuropsychiatric Systemic Lupus Erythematosus (NPSLE)

**Syed-Foad Ahmadi**<sup>1</sup>, Golar Zahmatkesh<sup>2</sup>, Masoud Majed<sup>3</sup> and Sheetal Desai<sup>4</sup>, <sup>1</sup>Department of Medicine, University of California Irvine, Orange, CA, <sup>2</sup>Department of Psychiatry, Charles Drew University of Medicine and Science/UCLA, Los Angeles, CA, <sup>3</sup>Division of Neuroimmunology, Mayo Clinic, Rochester, MN, <sup>4</sup>Medicine/Rheumatology, University of California, Irvine, Orange, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-NR2, a subclass of anti-NMDA receptor antibodies, is reportedly associated with NPSLE syndromes. However, its diagnostic accuracy is inconsistent across prior studies. Hence, we aimed to quantitatively synthesize the data regarding the sensitivity and specificity of anti-NR2 in diagnosing NPSLE.

**Methods:** We searched PubMed, Embase, CINAHL and the Web of Knowledge. We included the studies of the diagnostic test accuracy of anti-NR2 for diagnosing NPSLE among patients with SLE, in which they used the ACR case definitions or other validated tools as their reference standards. Two investigators (SFA, GZ) independently replicated data extraction by using a standard form, which included an assessment of study quality as well as participant-level data to populate 2×2 contingency tables. For meta-analysis, we used the Hierarchical Summary Receiver Operating Characteristic (HSROC) model by Rutter & Gatsonis (2001) in Stata 13.0.

**Results:** We screened 1583 records and eventually included the data from 8 studies with a collective sample of 984 patients (**Figure 1**). The pooled data represented a wide range of NPSLE manifestations including acute confusional state, seizure disorders, cerebrovascular disease, aseptic meningitis, headaches, cognitive dysfunction, psychoses, mood disorders, movement disorders (chorea), myasthenia gravis, demyelinating syndromes, myelopathy, plexopathy, and mono, poly, and cranial neuropathies. The reported sensitivities fell within a wider range (5% to 100%) compared to the specificities range (64% to 92%) (**Figure 2**). Meta-analysis of the results yielded the following pooled results with their 95% confidence intervals: Sensitivity 53% (24-80%), Specificity 77% (69-83%), -Likelihood ratio (LR) 0.61 (0.30-1.25), and +LR 2.26 (1.07-4.76) (**Figure 3**).

**Conclusion:** Serum anti-NR2 Ab has non-significant sensitivity and -LR, but it has statistically significant specificity and +LR in diagnosing NPSLE. Thus, patients with suspected NPSLE may benefit from checking their anti-NR2 levels. Nevertheless, further analyses are needed before recommending anti-NR2 for routine clinical use.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The transglutaminase Factor XIII (FXIII) stabilizes blood clots through crosslinking fibrin lysine and glutamine residues at the end of the complement cascade. Enzymatic activity and plasma levels of FXIII appear to be tightly controlled, as excess FXIII can lead to increased arterial plaque, yet low or absent FXIII leads to thrombosis due to fibrin instability. In addition, recent data suggest that tissue macrophages could be the main source of plasma FXIII. Anti-FXIII antibodies have been observed in SLE and correlate with brain hemorrhage, although other clinical correlations between plasma FXIII and SLE remain unexplored.

**Methods:** 120 SLE patients were recruited from a pre-existing longitudinal cohort developed to study atherosclerosis in SLE. Anti-dsDNA, C3 and C4 levels were analyzed in the clinical lab of our university hospital. Carotid ultrasound was performed to determine the presence or absence of subclinical atherosclerosis and intima-media thickness (IMT). The Technochrom FXIII kit (Diapharma, West Chester, OH) was utilized to determine plasma FXIII transglutaminase activity. Plasma monocyte subpopulations were identified by flow cytometry using anti-CD14 and –CD16 fluorescent antibodies (Biolegend).

**Results:** 66/120 SLE patients had high plasma FXIII transglutaminase activity (>143% of the mean of the standard curve). SLEDAI was significantly lower in the high FXIII activity group compared to patients with normal FXIII activity (2.08±3.9 versus 4.2±3.1, p=0.006). In addition, anti-dsDNA antibody levels were significantly lower in the high FXIII activity group (87.5±255.7 versus 274.7±323.8, p=0.041). Significantly higher levels of plasma C3 and C4 levels were also observed in the high FXIII activity group. Taken together, these results show that higher FXIII activity might be a biomarker for lower SLE disease activity.

In contrast, percentages of CD14<sup>+</sup>CD16<sup>int</sup> and CD14<sup>+</sup>CD16<sup>hi</sup> plasma monocytes (considered precursors to anti-inflammatory ‘M2’ macrophages) were inversely proportional to FXIII activity (r=-0.54, p=0.008; r=-.064, p=0.005, respectively), although there was no correlation between classical plasma monocyte levels (CD14<sup>+</sup>CD16<sup>-</sup>, ‘M1’ macrophage precursors) and FXIII enzymatic activity. In addition, IMT positively correlated with FXIII activity (r=0.40, p=0.01). No correlations between carotid plaque presence and FXIII activity were noted.

**Conclusion:** High plasma FXIII transglutaminase activity correlates with multiple measures of low disease activity in SLE patients. Conversely, high FXIII activity inversely correlated with low numbers of anti-inflammatory monocytes. Higher

IMT was also observed in patients with high FXIII activity. Careful regulation of FXIII enzymatic activity, and, by extension, its crucial role in fibrin crosslinking and plaque stabilization, could be dysregulated in a subset of SLE patients at risk for accelerated atherosclerosis.

## **The Utility of a Rise in Anti – Double Stranded DNA Antibodies for Predicting Disease Flares in Systemic Lupus Erythematosus. a Meta-Analysis**

**Margrét Arna Víktorsdóttir**<sup>1</sup>, Sæmundur Rögnvaldsson<sup>1</sup>, Þórunn Jónsdóttir<sup>2</sup> and Gunnar Tomasson<sup>3</sup>, <sup>1</sup>University of Iceland, Faculty of Medicine, Reykjavík, Iceland, <sup>2</sup>Landspítali University Hospital, Reykjavík, Iceland, <sup>3</sup>University of Iceland, Faculty of Medicine, Reykjavík, IS

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The ability of predicting disease flares in systemic lupus erythematosus (SLE) by serial measurements of antibodies to double stranded DNA (anti-dsDNA) remains uncertain. Previous studies have found inconsistent results and clinical guidelines provide vague recommendations regarding this aspect of disease management. The objective of this study is to assess the diagnostic value of rise in anti-dsDNA for prediction of a disease flare in SLE.

**Methods:** A MEDLINE search without language restrictions was conducted to identify papers on anti-dsDNA and disease flares in SLE. Papers that could not be excluded by a review of titles and abstracts were subject to a detailed review. The primary inclusion criteria were 1) availability of the data to extract the sensitivity and specificity of a rise in anti-dsDNA for a disease flare and 2) the rise in anti-dsDNA preceded the flare. For each study, the positive and negative likelihood ratios were calculated and information extracted on disease manifestations and laboratory methods of anti-dsDNA measurements. Summary estimates with 95% confidence intervals (CI) were calculated with a random effects model and results expressed with forest plots. Between-study heterogeneity was assessed with  $I^2$ , which takes a value from 0 to 1 and refers to the part of the total variability in the meta-analysis that is due to heterogeneity. Meta-regression was used to assess the impact of the i) publication year, ii) gender proportions, iii) proportion of patients who had renal manifestations, iv) method- and v) frequency of anti-dsDNA measurements on summary estimates and heterogeneity. Egger's test was used to assess for publication bias using p-value of <0.05 as cut-off. The trim-and-fill method was used to adjust the summary estimates for publication bias.

### **Results:**

Literature search identified 1690 papers of which 58 underwent full-text review. Nine studies with a total of 922 patients were included, of them 256 patients had a rise in anti-dsDNA and 243 had flares. Summary estimates for positive and negative likelihood ratios for anti-dsDNA rise and subsequent disease flare were 4.15 (95% CI 2.03-8.47) and 0.47 (95% CI 0.31-0.72) respectively (Figure). There was substantial between-study heterogeneity ( $I^2=0.89$ ). Neither disease manifestations nor the methods anti-dsDNA measurements affected the summary estimates or explained heterogeneity. Findings were consistent with presence of publication bias ( $p=0.021$ ). Adjustment for publication bias substantially

attenuated the summary estimates resulting in positive and negative likelihood ratios of 1.90 (95% CI 0.84-4.33) and 0.72 (95% CI 0.46-1.14), respectively.

Figure. Forest plots of positive and negative likelihood ratios of rise in anti-dsDNA and 95% CIs. Size of the boxes represents the studies' weight to the summary estimates. The upper diamonds represent the summary estimates and 95% CIs and the lower diamonds represent the summary estimates adjusted for publication bias using the trim-and-fill method. (LR+ and LR- = positive and negative likelihood ratios, anti-dsDNA = anti-double stranded DNA antibodies, CIs = confidence intervals).

## Conclusion:

A rise in anti-dsDNA has a limited ability for predicting flares in SLE and publication bias may have exaggerated the utility of serial anti-dsDNA measurements. These findings have direct implications for clinical management of SLE.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Abstract Background/Purpose :** Serum Mac-2-binding protein (M2BP) is elevated in various chronic inflammatory diseases. Recently, the Wisteria floribunda agglutinin positive-M2BP (WFA+-M2BP) immunoassay has shown promise in detection of highly glycosylated M2BP. We aimed to evaluate the clinical utility of serum M2BP for assessing disease activity of systemic lupus erythematosus (SLE), using the WFA+-M2BP immunoassay. **Methods :** Serum M2BP was measured in 203 patients with SLE. The associations between SLEDAI-2K and variables was assessed using multivariate

linear regression analysis. The relationship between serum M2BP and laboratory variables related to the SLE disease activity index (SLEDAI)-2K and inflammatory burdens was evaluated by Pearson's correlation analysis. Multivariate logistic regression analysis was used to compare the odds ratios (ORs) of laboratory variables in predicting active SLE. **Results** : Eighty patients were classified as having active SLE (SLEDAI-2K  $\geq 5$ ) and 123 patients as having inactive SLE. The median serum M2BP was higher in patients with active SLE than those with inactive SLE (2.1 vs. 0.9,  $p < 0.001$ ) (Table 1). In multivariate linear regression analysis, serum M2BP, anti-ds DNA, C3, and erythrocyte sedimentation rate were associated with SLEDAI-2K (Table 2). Serum M2BP was strongly correlated with laboratory variables related to SLEDAI-2K and inflammatory burdens, compared to other significant variables. Multivariate logistic regression analysis demonstrated that serum M2BP was more useful in predicting active SLE than other laboratory variables. **Conclusion** : Serum M2BP can reflect SLE activity and furthermore, it can predict active SLE. We suggest that serum M2BP may be a convenient complementary laboratory tool to SLEDAI-2K in the clinical setting. **References** 1. Nielsen CT, et al. Plasma levels of galectin-3-binding protein reflect type I interferon activity and are increased in patients with systemic lupus

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes**Session Type:** ACR Poster Session A**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Given the heterogeneity of clinical presentations, the diagnosis of Systemic Lupus Erythematosus (SLE) can be challenging, in particular in those patients presenting with early or incomplete disease, or with overlapping or atypical features. Autoantibodies (AABs) are important in aiding the clinical diagnosis of SLE, with some few AABs, anti-double-stranded DNA (dsDNA), anti-Smith (Sm), and anti-ribosomal P (riboP) being highly associated with SLE. As none of the traditional AABs has sufficient sensitivity to achieve diagnosis of SLE, current testing is based on measuring multiple AAB assays either in parallel or serial. We have recently identified novel AABs in SLE, which hold promise for improving diagnostic testing of SLE (1). We have developed quantitative ELISA-prototypes for five new AABs, which were tested in combination with traditional AABs. The objectives of this study were to evaluate the diagnostic value of novel AABs and to screen for an optimized combination of novel and traditional AABs using logistic regression to increase the diagnostic accuracy of SLE testing.

**Methods:** Serum samples were obtained from 156 SLE patients with European ancestry at the rheumatology department of the Heinrich-Heine University (Düsseldorf, Germany), and Hannover Medical School (Hannover, Germany). SLE samples were compared against 126 samples from autoimmune diseases (AID; myositis: n=20; Sjögren's syndrome (SjS): n=31; rheumatoid arthritis (RA) n=36; systemic sclerosis (SSc): n=39), and 77 healthy control samples. Prototype bead based ELISAs were developed for 5 recently identified novel antigens. Traditional diagnostic AABs were measured using IVD ELISAs and included: SSA/Ro60, SSA/Ro52, La/SSB, Sm, RNP, dsDNA, Scl70, CENPB, Jo-1, CCP, phospholipid and dsDNA. Optimized marker combinations of new and traditional markers were tested using logistic regression and receiver operating curve analysis (ROC).

**Results:** When comparing 156 SLE patients with 203 control samples, the area under the curve (AUC) of the five novel SLE ELISAs ranged from 0.63 to 0.75. A cut-off was set at a specificity of 95% and yielded a sensitivity ranging from

13.5% to 21.2% for the five novel assays. The sensitivity and specificity of new ELISAs was comparable to traditional ELISAs, which was in this cohort for anti-dsDNA 35% and 97%, anti-Sm 15% and 97%, and anti-RiboP 26% and 97%. A logistic regression model was used to combine the results of multiple tests. Compared to a logistic regression with traditional assays, a logistic regression with novel markers achieved higher sensitivity by pertaining high specificity. The logistic regression model based on a multimarker IVD assay with ten extracted nuclear antigens (ENA) yielded an AUC of 0.87 and a sensitivity of 58% at a specificity of 95%. By contrast, the optimal combination of traditional and novel ELISAs reached an AUC of 0.92 and a sensitivity of 75% at a specificity of 95%.

**Conclusion:** This study demonstrates the feasibility of combining test results of novel and traditional AABs using logistic regression to increase the diagnostic accuracy for SLE. Further studies are required to assess the impact of different ethnicities on marker selection and algorithm performance.

## **An ANA Screening Assay Containing Multiple Antigens Increases the Sensitivity and Specificity of ANA Testing By Indirect Immunofluorescence**

Thomas Karonitsch, Hans Peter Kiener and **Günter Steiner**, Rheumatology, Medical University of Vienna, Vienna, Austria  
**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Indirect immunofluorescence (IIF) on Hep-2 cells is still considered the gold standard for screening of antinuclear antibodies (ANA), the serological hallmark of connective tissue diseases (CTD). While this method is sensitive it lacks specificity. Moreover, low-titer ANA subspecificities may escape detection by IIF. It was therefore the aim of this study to investigate the diagnostic usefulness of an ANA screening assay containing 13 diagnostically relevant antigens.

### **Methods:**

Sera from 265 consecutive patients presenting with symptoms characteristic of connective tissue diseases (but without a clear diagnosis yet) were analysed by both IIF and the EliA® CTD Screen (Thermo Fisher Scientific) containing the following antigens: dsDNA, U1-snRNP, Sm, Ro60/SSA, Ro52/TRIM21, La/SSB, ribosomal protein P (ribP), topoisomerase I (Scl-70), centromere B, RNA polymerase III, fibrillarin, Jo-1, Mi-2, Pm/Scl.

### **Results:**

Among the 265 patients, 90 were positive in IIF and 78 in the CTD Screen; 61 sera were positive in both systems, 17 only in the CTD Screen and 29 only in the IIF assay. Thus, the CTD Screen increased diagnostic sensitivity of ANA testing by approximately 6%. In all double positive patients at least one diagnostically relevant antibody was detected, with anti-Ro/SSA (n=32), anti-Ro52/TRIM21 (n=21) and anti-dsDNA (n=15) antibodies being the most frequently detected ones. In addition to the antibodies determined by standard routine diagnostics (dsDNA, U1-snRNP, Sm, Ro60/SSA, Ro52/TRIM 21, La/SSB, topoisomerase I, centromere B, Jo-1) antibodies to ribP, RNA polymerase III and Pm/Scl were detected in one

serum each. Importantly, antibodies were also detected in 15 of the 17 patients exclusively positive in the CTD Screen: anti-dsDNA (n=7), anti-Ro60/SSA (n=4), anti-U1snRNP (n=2), anti-La/SSB (n=1) and anti-Jo-1 (n=1). In contrast, among the 29 sera exclusively positive in IIF only two contained a diagnostically relevant antibody (low titwer anti-DNA and anti-Sm). Clinical evaluation suggested that the majority of CTD Screen pos/IIF negative patients were at high risk for developing a CTD, particularly primary Sjogren's syndrome. Most common symptoms were arthralgia (n=13), sicca syndrome (n=12) and Raynaud's phenomenon (n=5). These patients require careful monitoring during clinical follow-up and might have escaped early diagnostic detection due the negative IIF result.

**Conclusion:** CTD screening assays containing multiple antigens seem to be useful and highly specific diagnostic tools that increase sensitivity of ANA testing enabling the detection of disease-associated ANA subspecificities in IIF-negative sera. This may reduce the number of false negative diagnoses enabling the physician to diagnose and treat "ANA negative" connective tissue diseases at an earlier stage.

## **Does Erythrocyte Sedimentation Rate Reflect and Discriminate Flare from Infection in Systemic Lupus Erythematosus? Correlation with Clinical and Laboratory Parameters of Disease Activity**

**Valentin S. Schäfer**<sup>1</sup>, Katharina Weiss<sup>2</sup>, Andreas Krause<sup>2</sup> and Wolfgang A. Schmidt<sup>3</sup>, <sup>1</sup>Immanuel Krankenhaus Berlin, Medical Center for Rheumatology Berlin-Buch, Berlin, Germany, <sup>2</sup>Medical Centre for Rheumatology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin, Germany, <sup>3</sup>Medical Center for Rheumatology and Clinical Immunology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin, Germany

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ESR is applied for monitoring disease activity in SLE. It is known to be influenced by age and infections. We aimed at evaluating how ESR correlates with commonly applied disease activity parameters and how infections influence these results.

**Methods:** Retrospective analysis of laboratory parameters, clinical activity, infection and serositis in consecutive SLE patients between 2006 and 2015. Based on the treating physician's judgement on disease activity and presence of infection, patients were separated into four groups: flare, infection, both and neither. ESR was correlated to CRP, ferritin, anti-dsDNA antibodies, C3, serositis and erythrocyturia with proteinuria. For age, ESR, CRP, ferritin and age- and gender-adapted ESR (ESRp), mean values between groups were compared. ESRp was calculated as the percentage of an ESR cut-off considering age and gender.

**Results:** We identified 203 SLE patients with 371 visits, flare n=147, infection n=48, both n=23 and neither flare nor infection n=153. Correlation coefficients of ESR and other parameters are given in table 1; there was moderate correlation with CRP (r=0.47-0.58) and weak correlation with other parameters (r<0.2). As shown in figure 1, ESR and CRP levels were normal in patients in remission, but did not differ between flare, infection or both. ESRp was higher in patients with flare versus with infection (p=0.01). ESR and CRP lost association to activity in infected patients and, conversely, to

infection in patients with flare. ESRp, serositis and anti-dsDNA antibodies were related to disease activity regardless of infections (table 2).

**Conclusion:** ESR is raised in flares, but also in infected and older patients. CRP levels do not enable discrimination between flare and infection. Both parameters argue against flare and infection when normal. ESRp can help to differentiate between flare, infection or even both.

Table 1: Correlation coefficients of ESR with other laboratory and clinical parameters

	<b>CRP</b>	<b>Ferritin</b>	<b>C3-reduction</b>	<b>Raised anti-dsDNA-antibodies</b>	<b>erythrocyturia + proteinuria</b>	<b>Serositis</b>

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nailfold capillaroscopy (NVC) is a useful, non-invasive, reproducible and cost-effective diagnostic tool, able to assess the shape of capillaries in the nailfold bed. According to the presence of peculiar abnormalities, it is essential in the early differential diagnosis of connective tissue diseases (CTDs), mainly “scleroderma-spectrum disorders” (SSD). Despite its large diffusion, no univocal NVC patterns have been ascribed to undifferentiated connective tissue disease (UCTD) as well as to systemic lupus erythematosus (SLE). The aim of the study was to evaluate the most common NVC pictures in a population of UCTD patients and if selected NVC pictures might be linked to SLE onset in these patients.

**Methods:** We evaluated a cohort of 42 UCTD-affected women, diagnosed according to 2014 criteria proposed by Mosca et al. (age, 38 years $\pm$ 46 months; duration of disease, 71 $\pm$ 54 months) presenting Raynaud's phenomenon. During the observational period (3 years), all of the UCTD patients were evaluated every 6 months. We considered the following NVC parameters/pictures: presence of ectasic capillary loops (diameter  $\geq$ 20  $\mu$ m); giant capillaries (diameter  $\geq$ 50  $\mu$ m); hemosiderin deposits; capillary number reduction; meandering capillaries (tortuosity); elongated capillaries; ramified/bushy capillaries; micro-vascular array disorganization. SLE diagnosis was posed according to the 2012 SLICC/ACR criteria. Qualitative variables were expressed in frequencies; their association, by non-parametric tests; quantitative variables, by analysis of co-variance.

**Results:** Non-specific NVC alterations (for instance, not suggestive of SDD) were detected in 40 (98%) of the UCTD patients during the observational period. On the other hands, the presence of hemosiderin deposits, ectasic loops, elongated and ramified capillaries was found associated to the clinical subgroup of UCTD patients that later developed SLE (4/42 subjects, 10%; OR=10.5).

In particular, the independent variables “hemosiderin deposits” (OR=8.32) and “elongated capillaries” (OR 6.28), were found significantly linked to the SLE onset ( $p<0.05$ ), whereas the independent variables “tortuosity” (OR=12.16) and “ramified/bushy capillaries” (OR 9.47) were, at the opposite, predictive for the prosecution of the status of UCTD patient ( $p>0.05$ ).  $>0.05$ ), whereas the independent variables “tortuosity” (OR=12.6) and “ramified/bushy capillaries” (OR=9.47) were, at the opposite, predictive for the maintenance of UCTD diagnosis ( $p<0.05$ ), whereas the independent variables “tortuosity” (OR=12.16) and “ramified/bushy capillaries” (OR 9.47) were, at the opposite, predictive for the prosecution of the status of UCTD patient ( $p>0.05$ ).  $>0.05$ ).

## Conclusion:

The present study reports NVC pictures that can be more frequently observed in UCTD patients. In addition, the NVC analysis suggests that the presence of typical capillaroscopic microvascular abnormalities seems more frequently observed in those UCTD patients that move to SLE.

# Impact of Anti-RBP Antibodies on Disease Activity and Quality-of-Life in Immunosuppressant Naïve Systemic Lupus Erythematosus

**Rene Bermea**<sup>1</sup>, Tammy Utset<sup>2</sup> and Kichul Ko<sup>3</sup>, <sup>1</sup>Medicine, University of Chicago, Chicago, IL, <sup>2</sup>Medicine, Section of Rheumatology, University of Chicago, Chicago, IL, <sup>3</sup>Medicine, Section of Rheumatology and Gwen Knapp Center for Lupus and Immunology Research, University of Chicago, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

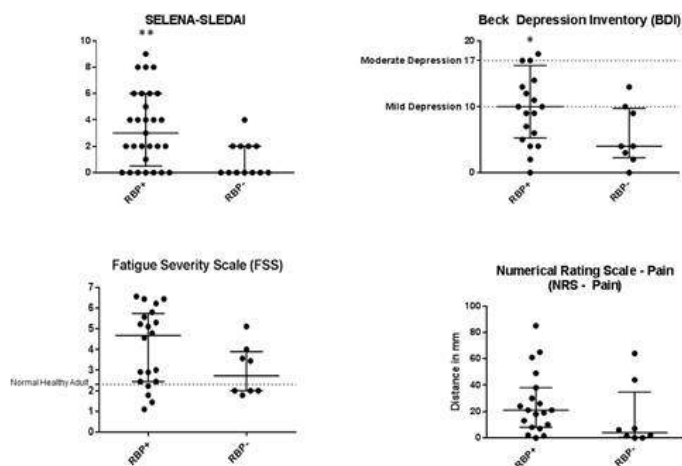

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is a lack of phenotypic data on SLE patients who have never been on immunosuppressive therapy. Anti-RNA binding protein (anti-RBP) antibodies (anti-Smith, anti-RNP, anti-SSA, anti-SSB) in SLE have been linked to an upregulation in transcriptional patterns, some thought to contribute to disease. This study sought to characterize the impact of these autoantibodies on disease activity and quality-of-life in immunosuppressant naïve SLE patients.

**Methods:** Retrospective cross-sectional analysis of subjects meeting ACR Classification Criteria for SLE was performed. Subjects were anti-RBP positive (RBP+) if at least one titer was  $\geq 20$  (units, ELISA); others were classified as anti-RBP negative (RBP-). Subjects ever on non-corticosteroid immunosuppression or currently on corticosteroids were excluded. Baseline characteristics included age, sex, disease duration, anti-dsDNA, C3, C4, and ethnicity (African-American [AA] or European-American [EA]). A measure of all four anti-RBP titers and most baseline characteristics were necessary for inclusion. Disease activity was measured using the SLEDAI and quality-of-life indices included the Beck Depression Inventory (BDI), Fatigue Severity Scale (FSS), Numerical Rating Scale for Pain (NRS-Pain Scale), and the Medical Outcomes Study Sleep Scale (MOS-SS). Both groups were compared using Mann-Whitney U, two-tailed Fisher's Exact tests, and multivariate linear regression.

**Results:** Forty-one subjects met criteria for inclusion, 29 of which were identified as RBP+ and 12 RBP-. There was no difference in age, sex, disease duration, anti-dsDNA, C3, or C4 between groups. There were significantly more AA in the RBP+ group (65.5% vs 16.7%,  $p < 0.01$ ) and EA in the RBP- group (34.5% vs 75.0%,  $p = 0.037$ ). Disease activity and quality-of-life indices between groups is demonstrated in Figure 1. SLEDAI was significantly worse in RBP+ vs RBP- subjects (3 vs. 0,  $p = 0.009$ ), a relationship confirmed with multivariate regression (standardized beta coefficient = 0.515,  $p = 0.017$ ). Similarly, BDI scores were worse in the RBP+ cohort (10 vs. 4,  $p = 0.050$ ). RBP+ subjects trended towards worse fatigue by FSS (4.67 vs. 2.72,  $p = 0.139$ ) and pain by NRS-Pain Scale (21 vs. 4,  $p = 0.087$ ). MOS-SS sleep indices were also worse among RBP+ subjects. To account for the difference in ethnicity between groups, a subgroup analysis of EA patients was conducted and found similar trends in RBP+ patients.

**Conclusion:** Anti-RBP positive SLE subjects showed worse measures of disease activity and quality-of-life. RBP+ subjects were more likely to be African-American, although similar outcomes were seen in a European-American sub-analysis. Our study was limited by sample size given our exclusion of immunosuppressed subjects. Further study is needed to measure these antibodies' impact on clinical outcomes and response to treatment prospectively.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A 2010 American College of Rheumatology position paper designated indirect immunofluorescence assay (IFA) on HEp-2 cells the “gold standard” for ANA testing and that laboratories performing other methods should state the method used and describe its performance parameters. This study was performed to determine laboratory practices in ANA testing.

**Methods:** Supplemental questions were sent to laboratories participating in the College of American Pathologist's proficiency testing program for ANA as part of the Special Immunology S-A Survey 2016 to determine the practice of ANA testing. Of 5847 kits distributed, 1206 (21%) responded to the questionnaire; 942 were in the United States and 264 were international.

**Results:** ANA screening method varied: 56% IFA, 21% ELISA, 12% multi-bead immunoassay, and 18% “other” methods. Ordering test name indicated method used in only 32%; only 39% stated method used on the report. Of 644 laboratories, 80% used HEp-2 substrate, 18% HEp-2000 (HEp-2 cell line engineered to overexpress SSA), and 2% “other.” Slides were prepared manually (67%) or on an automated platform (33%), and examined by direct microscopy (84%) or images

captured by an automated platform (16%). IFA patterns were interpreted by personnel in 95% of laboratories; <1% used automated image capture and analysis solely; 4% interpreted images both by personnel and an automated platform. 97% of 641 laboratories reporting ANA by IFA provided a titer. Only 51% reported a positive result at the traditional 1:40 dilution. Titer was reported to endpoint routinely by 43%, only upon request by 23%, or never by 35%. 8% did not report dual patterns. Of those reporting multiple patterns, 24% did not report a titer with each pattern.

**Conclusion:** Only slightly more than half of testing laboratories utilize the ACR “gold standard” IFA method with HEp-2 cell substrate.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ANA IFA pattern may guide clinical evaluation by directing specific antibody testing. ICAP has defined consensus ANA IFA patterns and the level of competency required to identify and interpret them. This study was performed to determine laboratory practices in interpreting and reporting ANA IFA patterns.

**Methods:** Supplemental questions were sent to laboratories participating in the College of American Pathologist’s proficiency testing program for ANA as part of the Special Immunology S-A Survey 2016 to determine the practice of ANA testing. Of 5847 kits distributed, 1206 (21%) responded to the questionnaire; 942 were in the United States and 264 were international.

**Results:** Of 638 performing ANA by IFA and reporting a pattern, nearly 100% reported nucleolar, 99% homogeneous and speckled, and 96% centromere, all competent-level ICAP patterns. Only 42% reported nuclear dots (competent-level). 53% reporting nucleolar pattern further described expert-level subpatterns. Of 519 reporting speckled patterns, only 29% reported dense fine speckles, a competent-level pattern reportedly found in normals. “Other” speckled was reported by 44%. 4% did not report speckled pattern at all. Of those reporting nuclear dots, 86% differentiated *many* nuclear dots and 84% *few* nuclear dots. Nuclear envelope (expert-level) was reported by 18%. Competent-level cytoplasmic patterns were reported: golgi 69%, mitochondrial 65%, speckles 30%, 17% rods and rings, reticular 12% and polar 10%. Expert-level cytoplasmic patterns were reported: spindle apparatus 59%, centriole 55%, mid body 45%, and lysosomal 32%. Only 54% used an internal fluorescence intensity standard.

**Conclusion:** Pattern reporting practice is variable. Cytoplasmic pattern reporting is limited, possibly reflecting a lack of consensus that cytoplasmic patterns should be reported in an “antinuclear” antibody test. Failure to use an internal fluorescence intensity standard by nearly half of the laboratories may increase inter-assay and inter-observer variation in the threshold for staining positivity and in titer determination.

## **Positive Direct Coombs' Test in the Absence of Hemolytic Anemia Predicts High Disease Activity and Poor Renal Response in Systemic Lupus Erythematosus**

**Hironari Hanaoka**, Harunobu Iida, Tomofumi Kiyokawa, Yukiko Takakuwa and Kimito Kawahata, Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Direct Coombs' test in the absence of hemolytic anemia was newly included in the immunologic criterion of the SLICC/ACR 2012 criteria for SLE. Since erythrocyte complement receptor contributes to the clearance of circulating immunocomplex, the direct Coombs' test in the absence of hemolytic anemia may indicate excessive immunocomplex production. In this study, we determined its clinical significance in Japanese SLE population.

**Methods:** Patients who fulfilled SLICC/ACR classification criteria of SLE and visited St. Marianna University Hospital during Jan to Nov 2016 were prospectively evaluated with direct Coombs' test. Hemolysis was defined as lower haptoglobin concentration than the normal limit. Clinical features including SLEDAI, treatment, and laboratory findings were examined. For patients with lupus nephritis class III or IV, we additionally compared renal pathological features and cumulative complete renal response (CR) rate between patients with positive result for direct Coombs' test in the absence of hemolytic anemia and those with negative.

**Results:** Among 186 patients enrolled, 10 (5.4%) patients were positive with direct Coombs' test in the absence of hemolytic anemia. They had higher SLEDAI ( $p<0.01$ ), lower CH50 ( $p<0.01$ ), higher anti-DNA titer ( $p<0.01$ ) and lower cumulative CR rate ( $p=0.03$ ) (Figure 1) comparing to those who were negative. In the renal pathological analysis, a significantly higher percentage of subendothelial deposit was determined in patients who were positive comparing to those who were negative ( $p=0.02$ ). Multivariate analysis indicated that SLEDAI was the independent factor strongly correlated with the direct Coombs' test (OR 2.44, 95%CI 1.66-4.98,  $p<0.01$ ) (Table 1).

**Conclusion:** Direct Coombs' test in the absence of hemolytic anemia might be correlated with high disease activity and poor renal response in SLE.

Figure 1

Table 1. Multivariate analysis for predicting the Direct Coombs' test in the absence of hemolytic anemia

Parameters	Odds ratio	95% confidence interval	P
Plt (/uL)	2.83	0.98-3.33	0.09
SLEDAI	2.44	1.66-4.98	<0.01
anti-DNA antibody (IU/mL)	1.50	0.96-1.00	0.2
CH50 (U/ml)	4.80	1.00-1.21	0.02
IC-C1q (U/ml)	4.45	1.01-4.42	0.03

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We conducted a systematic review to investigate the clinical value of clinical characteristics and autoantibodies, especially lupus-specific antibodies, for lupus myelitis and its subtypes.

**Methods:** We searched PubMed, EMBASE, and ICHUSHI without language restrictions for case reports or series of lupus myelitis. We focused on cases reported since 1997, when the revised classification criteria for systemic lupus erythematosus were published. Associations between patient characteristics including autoantibodies and functional

outcome, survival, and subtypes of myelitis (grey and white matter myelitis) were examined. We attempted to contact authors to supplement missing information for analysis.

**Results:** Our search identified 224 cases from 105 articles. White matter myelitis predicted favorable function (odds ratio, 15.18; 99% confidence interval, 3.09 to 151.31;  $p < 0.0001$ ). Anti-nuclear antibody also predicted favorable function ( $p = 0.007$ ). Age  $\geq 50$  years was associated with poor survival outcomes ( $p = 0.007$ ). Grey matter myelitis was associated with longitudinally extensive transverse myelitis ( $p < 0.001$ ) and anti-double-stranded DNA ( $p = 0.003$ ), and tended to be associated with anti- $\beta 2$ -glycoprotein I ( $p = 0.011$ ). White matter myelitis tended to be associated with optic neuritis and anti-neuromyelitis optica antibodies. Although our study might be susceptible to under-reporting of original cases and selection bias, we aimed to provide a conservative interpretation by setting the statistical significance threshold at  $p < 0.01$ .

**Conclusion:** This systematic review confirmed that grey matter myelitis predicted poor functional outcome, and was associated with longitudinally extensive transverse myelitis and anti-double-stranded DNA antibodies. White matter myelitis was associated with favorable functional outcomes and may partially represent a complication of neuromyelitis optica.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Antibodies against double-stranded deoxyribonucleic acid (anti-dsDNA) are a useful and valuable serological marker for diagnosis of systemic lupus erythematosus (SLE). Studies suggest strong correlation between increasing levels of anti-dsDNA and subsequent flares, particularly renal disease. The radioactive immunoassay (RIA) by FARR (FARR-RIA) has been utilized as the gold standard in the past for anti-dsDNA determination, detecting mostly high avidity antibodies. Additionally, enzyme-linked immunoassay (ELISA) and immunofluorescence (Crithidia luciliae) (CLIF) both recognize also low avidity anti-dsDNA and ELISA also detects antibodies against ssDNA. There is a need for replacing FARR-RIA with a safer and more environmentally friendly immunoassay. To modify the detection of anti-dsDNA by FARR-RIA, by replacing the radioactive isotope <sup>14</sup>C and other toxic reagents and evaluate the newly developed, environmentally-friendly fluoroimmunoassay (FIA) for daily laboratory and clinical practice.

**Methods:** We tested 759 sequentially collected samples for anti-dsDNA testing, with FARR-RIA and FIA (using Picogreen® as intercalating dye). The group consisted of 146 blood donors, 70 SLE, 25 antiphospholipid syndrome, 28

rheumatoid arthritis, 25 Sjögren's syndrome and 465 patients with unknown diagnoses. Final results of both methods were calculated from difference of signal measured between supernatant (S) and precipitate (P) divided by the sum of signals in S and P.

**Results:** At cut-off value of 0.35, both diagnostic specificity and sensitivity were comparable using FARR-RIA and FIA. Diagnostic specificity in both methods was 100%, while diagnostic sensitivity for FARR-RIA and FIA were 50% and 53%, respectively. Diagnostic accuracy for FIA was slightly lower compared to FARR-RIA, 0.781 vs. 0.887. There was comparable inter-accuracy of both methods in high positive results ( $CV_{\text{FARR-RIA}} = 11\%$ ,  $CV_{\text{FIA}} = 12\%$ ), while low positive results ( $CV_{\text{FARR-RIA}} = 29\%$ ,  $CV_{\text{FIA}} = 18\%$ ) showed greater variation. We confirmed comparable intra-repeatability in high positive results ( $CV = 2\%$  for both methods) and low positive results ( $CV_{\text{FARR-RIA}} = 33\%$ ,  $CV_{\text{FIA}} = 28\%$ ). At high and low positive results comparable analytical accuracy was observed, while analytical sensitivity was higher in FIA. Neither ssDNA nor RNA affected the detection of anti-dsDNA. A correlation of 0.626 ( $p < 0.01$ ) was found between FARR-RIA and FIA positive results.

**Conclusion:** FIA and FARR-RIA showed comparable diagnostic specificity and sensitivity. Therefore, FARR-RIA could be replaced with FIA in daily laboratory routine practice for the detection of anti-dsDNA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Due to the poor specificity of the anti-nuclear antibodies (ANA) indirect immunofluorescence (IIF) assay, enhanced by the huge increase in ANA requests by non-rheumatologists, second line identification of specific anti-double stranded DNA (dsDNA) and anti-extractable nuclear antigen (ENA) is necessary.

Our study aims to objectify a cost-effective diagnostic ANA algorithm, standardizing the work-out of positive ANA IIF tests in a routine, secondary care setting.

### Methods:

The ANA test results reported in our laboratory were retrospectively reviewed over a 9-month period. Positive ANA IIF test results on NOVA View® (Inova, USA) at 1:80 screening dilution (cut off = 49 Light Intensity Units (LIU)) were further analysed by dsDNA- (dsDNA-NcX IgG ELISA, Euroimmun, Germany) and ENA-screen (ANA screen 11 IgG

ELISA, Euroimmun). For positive ENA-screen samples, ANA identification was performed with EUROLINE ANA profile 3 (Euroimmun). Based on ROC-curve analysis of LIU versus ENA/dsDNA identification, the LIU cut off at 95% sensitivity was determined.

## Results:

3276 samples of 2916 patients were tested for ANA, of which 49,8% were from the rheumatology ward. 279 (9,6%) patients had repeated ANA requests. None of the repeated ANA IIF, dsDNA/ENA screen tests had a clinically significant result. 45,9% patients tested ANA IIF positive, with identification of a specific Ab (dsDNA/ENA) in 11,6% of the patients. ROC analysis of LIU in function of ENA/dsDNA identification revealed a specificity of 3,0% (2,1-4,3) for the 49 LIU cut off. A global ANA IIF sensitivity of 94,8% for ENA/dsDNA identification was obtained at a cut off of 88 LIU, with a specificity of 36,1% (33,6-39,5%) (**Table 1**). ROC curve analysis for isolated homogeneous, speckled, centromere and speckled metaphase positive IIF patterns confirmed an acceptable analytical performance and LR's of ENA/dsDNA positivity at LIU of 88 (**Table 2**), in concordance with earlier published LR's for ANA associated rheumatic disease positivity. Using this 88 LIU cut off for second line testing, can result in a yearly cost reduction of 5.060€. Introducing a limitation of the ANA workout to once yearly, if ANA IIF titer and pattern are stable, implies a supplementary cost reduction of 4.290€.

## Conclusion:

Analytical performance analysis reveals a clinical and cost effective cut off for ANA IIF of 88 LIU for the initiation of second-level testing. If the patient is clinically stable and ANA IIF pattern and titer has not significantly changed, a yearly repetition of the diagnostic ANA workout is more than clinically sufficient.

ANA IIF pattern §	ENA/dsDNA+/ ENA/dsDNA-	LIU interval

# Elevated Erythrocyte Sedimentation Rate Among Obese Patients with SLE- Not Always a Marker of Disease Activity

**George Stojan**<sup>1</sup>, Erik Barr<sup>2</sup> and Michelle Petri<sup>3</sup>, <sup>1</sup>Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD, <sup>3</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Obesity is more common in patients with SLE compared to the general population. The prevalence of obesity among SLE patients is between 28 and 50 percent. We hypothesized that a higher body mass index was associated with elevated ESR after adjusting for disease activity, prednisone and immunosuppressive use.

## Methods:

Our analysis is based on 2246 different patients who were observed from 1 to 137 visits. The median number of visits per patient was 15.

The “between-person” association addresses the question of whether those who tend to have high BMI also tend to have high ESR. To assess this, we calculated the person-specific mean ESR values and plotted them against the person-specific mean BMIs. We fit crude and adjusted models to estimate the slope in the expectation of mean ESR per unit difference in mean BMI. The results are shown in Table 1.

The within-person analysis addresses the question of whether a person tends to have higher ESR when his/her BMI is lower than his average BMI. To assess this, for each visit, we calculated the difference between the BMI level at that visit and the person’s average of BMI. Then we modelled the relationship between these differences in BMI and the difference between the person’s ESR at each visit and the person’s average ESR.

## Results:

Table 1: Difference in person-specific mean ESR per 1 unit difference in person-specific mean BMI

Model	Effect	Unadjusted Estimated difference in mean ESR per 1 unit difference in mean BMI (95% CI)	P-value	Adjusted <sup>1</sup> Estimated difference in mean ESR per 1 unit difference in mean BMI (95% CI)	P-value
Model 1	BMI	0.6 (0.4, 0.7)	<0.0001	0.5 (0.4, 0.6)	<0.0001
Pooling across Sex					
Model 2	BMI	0.6 (0.5, 0.7)	<0.0001	0.5 (0.4, 0.7)	<0.0001
Allowing different	Female	5.0 (-12.2, 22.2)	0.57	3.2 (-12.1, 18.5)	0.68
association by sex	BMI*Sex	-0.5 (-1.1, 0.2)	0.14	-0.3 (-0.9, 0.2)	0.24

<sup>1</sup> Adjusted for age, age-squared, race, mean disease activity, mean prednisone dose, proportion of time on immunosuppressant medication.

Table 2: Difference in ESR at each visit per 1 unit difference in between the person's BMI at that visit and the person's average BMI.

Model	Effect	Unadjusted Estimated difference in ESR (relative to a person's average ESR) as a function of differences in a person's BMI (relative to that person's average BMI)	P-value	Adjusted <sup>1</sup> Estimated difference in ESR (relative to a person's average ESR) as a function of differences in a person's BMI (relative to that person's average BMI)	P- value
Model 1: Pooling across Sex	BMI -mean BMI	0.04 (-0.01, 0.10)	0.15	0.09 (0.03, 0.15)	0.004
Model 2	BMI -mean BMI	0.05 (-0.01, 0.11)	0.12	0.09 (0.03, 0.15)	0.004
Allowing different	Females	0.004 (-0.54, 0.54)	0.99	0.26 (-0.30, 0.82)	0.36
association by sex	BMI -mean BMI *Sex	-0.07 (-0.31, 0.16)	0.55	-0.04 (-0.28, 0.21)	0.78

<sup>1</sup> Adjusted for age, age-squared, race, disease activity, prednisone dose, immunosuppressant use.

## Conclusion:

Patients whose mean BMI is 10 points higher have a mean ESR that is 6mm/hour higher ( $p<0.0001$ ). The association between BMI and ESR does not vary by sex and is not affected by adjusting for covariates.

We also found a significant within person association between ESR and BMI: a 1 unit increase in BMI increases the expected ESR by 0.09mm/hour ( $p=0.004$ ).

Careful interpretation of clinical data is necessary in obese patients- an elevated ESR may not be a manifestation of disease activity.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The indirect immunofluorescence (IIF) test for anti-cell or antinuclear (ANA) antibodies on HEp-2 cells (HEp-2-ANA) is considered the gold standard method for ANA detection. However, this is a very sensitive test and detects autoantibodies also in some healthy individuals and patients with non-autoimmune diseases. The establishment of distinctive HEp-2-ANA features in SARD patients and in healthy individuals has proven to be helpful in the daily medical practice. However, the HEp-2-ANA test is not expected to be requested for healthy individuals, but rather for those seeking for medical care due to some health disorder. Therefore, we aimed to determine the frequency and characteristics of positive HEp-2-ANA tests in individuals affected by a variety of non-autoimmune diseases.

**Methods:** This is a cross-sectional observational study comparing HEp-2-ANA results in 588 non-autoimmune disease (NAD) patients, 194 patients with systemic autoimmune rheumatic diseases (SARD) and 1,217 healthy individuals. NAD group comprised 4 subgroups: 95 patients with malignancy, 148 with infectious diseases, 163 with psychiatric diseases and 152 with multiple co-morbidities (diabetes mellitus, arterial hypertension, and metabolic syndrome). Sera were tested at 1:80 dilution and diluted to the end titer. Slides were analyzed by two independent blinded examiners at x400 magnification. We followed the anti-cell (AC) pattern nomenclature according to the ICAP (International Consensus on ANA Patterns) recommendations.

**Results:** A positive HEp-2-ANA result occurred in 102 (18.3%) NAD patients, 170 (87.6%) SARD patients and 150 (12.3%) healthy individuals. The four subgroups of NAD patients did not differ regarding HEp-2-ANA titer or pattern. HEp-2-ANA titer in NAD patients was higher than in healthy individuals and these two groups had lower titer than SARD patients. The nuclear dense fine speckled pattern (AC-2) was more frequent in healthy individuals than in NAD patients ( $p = 0.029$ ) and was not observed in the SARD group. The nuclear homogeneous (AC-1) and nuclear coarse speckled (AC-5) patterns were more frequent in SARD patients than in the other groups ( $p < 0.001$ ). The most common pattern in all groups was the nuclear fine speckled (AC-4) pattern, which presented a gradient in titer across the three groups ( $p < 0.001$ ):

healthy individuals and NAD patients had predominantly low and intermediate titer, respectively, and SARD patients had predominantly high titer.

**Conclusion:** The pattern and titer of HEp-2-ANA positive tests in NAD patients clearly differ from SARD patients. In addition, when compared to healthy individuals, NAD patients present positive HEp-2-ANA tests with slightly higher titer and with lower frequency of the nuclear dense fine speckled (AC-2) pattern.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In a previous study, we identify a potential role of anti-RNP/Sm in combination with LA as risk factor for thrombosis. We aimed to validate this association

**Methods:** Case-control study of patients with SLE who presented thrombosis after SLE diagnosis and controls with SLE without thrombosis. All patients fulfilled <sup>3</sup> 4 American College of Rheumatology revised and updated classification criteria for SLE. Comorbidities, traditional risk factors, clinical variables, disease activity and treatment were evaluated. Also, a blood sample was drawn to determine antiphospholipid (aPL) and anti-RNP/Sm antibodies. **Statistical analysis:** Differences between groups were evaluated with the Student t-test or Mann-Whitney U test for continuous variables; Chi-square or Fisher's exact test for categorical variables. Univariate logistic regression analyses and multivariate analyses were performed. Odds-ratio (OR) and 95% confidence intervals (95% CI) were calculated

**Results:** 63 cases and 63 controls were studied, 88% women, median age of 40 years and disease duration of 135 months at study inclusion. No differences were found between groups regarding age, comorbidities, or clinical characteristics at SLE diagnosis. Patients with thrombosis were more frequently positive for anti-RNP/Sm (83% vs 62%, p=0.001); IgG aCL (29% vs 11%, p=0.02); IgG anti-B2GPI (21% vs 13%, p=0.02); IgM anti-B2GPI (p=0.02); LA (62% vs 19%, p<0.001); the combination of anti-RNP/Sm + LA (52% vs 14%, p<0.001), and aPL triple marker (17% vs 2%, p=0.002), compared to controls. The combination of anti-RNP/Sm + LA (OR 5.98, 95% CI 2.17-16.47, p=0.001); SLEDAI-2K (OR 1.18, 95% CI 1.04-1.32, p=0.007), and prednisone dose (OR 1.08, 95% CI 1.03-1.12, p<0.001) were independently associated with thrombosis.

**Conclusion:** This study confirmed an independent association between the combination of anti-RNP/Sm antibodies and LA with thrombosis. Further studies to identify potential pathogenesis mechanisms of the presence of anti-RNP/Sm and

thrombosis are needed

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by involvement of different organs in the body. The cardiovascular (CVD) involvement in SLE is responsible for high morbidity and is often the leading cause of death. Despite that, little is known about the risks of development of different CVDs in SLE. We aimed to determine the rate of different echocardiographic findings and their risks and clinical correlates in SLE patients.

### Methods:

SLE patients (n=59), fulfilling 4 or more ACR criteria for SLE, attending outpatient Rheumatology clinics, were recruited. Demographic data, disease characteristics and current medication use were gathered from the patients. Clinical evaluation with SLE Disease Activity Index (SLEDAI), echocardiography, anthropometric measurements and routine laboratory tests were done. Mann-Whitney U test, Chi-square test, Fisher exact test and logistic regression analysis were used for statistical analysis as appropriated.

### Results:

The mean age of the patients was 31.4±10.5, and 86.4% of the patients were females. The rate of different echocardiographic findings was as follow: overall valve lesions (47.5%), pulmonary hypertension (PHT) (18.6%), pericardial effusion (13.6%) and pericardial thickening (6.8%). The most common valve abnormalities were: mitral regurge (33.9%), tricuspid regurge (32.2%), mitral thickening (18.6%), and aortic thickening (13.6%) but less common were aortic regurge (6.8%) and pulmonary regurge (5.1%). The least common were pulmonary stenosis, mitral stenosis, and tricuspid and pulmonary thickening representing only (1.7%) each. The frequency of occurrence of different echocardiographic findings with different SLE features is shown in fig1. Univariate and multivariate analyses revealed a significant association of PHT with age (OR=1.095, p=0.023, CI=1.013 - 1.184), mucocutaneous disease was a negative predictor of mitral regurge (OR=0.227, p=0.03, CI=0.059 - 0.868) and mitral thickening, (OR=0.046, p=0.032, CI=0.003 - 0.765), unlike Raynaud phenomenon which is a positive predictor of mitral thickening (OR=14.614, p=0.036, CI=1.199 - 178.1). Levels of HDL were associated with aortic thickening (OR= 0.907, p=0.05, CI =0.823 - 1). The use of prednisolone reduced the risk of developing aortic thickening (OR= 0.054, p=0.012, CI=0.006 - 0.53). Pericardial effusion was

associated with metabolic syndrome (OR=12.4, p=0.025, CI=1.367 - 112.5) and high triglycerides levels (OR=1.012, p=0.028, CI=1.001 - 1.023). The echocardiographic findings showed no association with SLEDAI scores.

## Conclusion:

Different laboratory and clinical correlates with different echocardiographic findings reflect the complexity of CVD mechanisms and warrant further studies to unravel disease pathogenesis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** No early serum marker of accurate diagnosis of lupus mesenteric vasculitis (LMV) contributes to the treatment decision-making process. The study was undertaken to evaluate clinical significance of serum D-dimer level as an early diagnosis marker of LMV patients.

**Methods:** Thirty-eight systemic lupus erythematosus (SLE) patients who presented with acute and subacute abdominal pain were retrospectively analyzed and classified into LMV group (n=15) and Non-LMV group (n=23) between January 2006 and January 2016. The patients were evaluated by serum D-dimer level on the first day after admission, abdominal CT, other laboratory-testing parameters, as well as SLE disease activity index (SLEDAI) during the same period.

**Results:** No significance difference of the SLEDAI, autoantibodies and laboratory profiles at admission was detected between two groups. The D-dimer value on the first day of admission was significantly higher in patients with LMV than those with other causes ( $P<0.05$ ,  $P=0.04$ ). In addition, serum D-dimer level was also significantly higher in patients with long-term ( $\geq 7$ d) gut resting and high-dose steroid therapy ( $P<0.01$ ,  $P=0.003$ ). All LMV patients showed good response to high-dose intravenous steroids and there was no patient required immunosuppressive and surgical therapy.

**Conclusion:** D-dimer level could be an effective and early serum marker indicating the clinical evolution of LMV. D-dimer may also assist the treatment determination and prognostic evaluation.

## **Prevalence and Risk Factors of Depressive Disorders in Chinese Patients with Systemic Lupus Erythematosus (SLE)**

Chi Chiu Mok<sup>1</sup>, Yan Tung Lilian Lo<sup>2</sup>, Chi Wai Cheng<sup>2</sup> and Kam Shan Poon<sup>2</sup>, <sup>1</sup>Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, <sup>2</sup>Psychiatry, Castle Peak Hospital, Hong Kong, Hong Kong

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Depression is common in SLE but most previous studies utilized self-rated scales for evaluation. Formal diagnosis of depression was not established by psychiatric interviews. This study was conducted to determine the prevalence of depressive disorders, severity of depressive symptoms and the associated risk factors in Chinese patients with SLE.

### **Methods:**

Adult patients who fulfilled  $\geq 4$  ACR criteria for SLE were randomly recruited from the rheumatology out-patient clinics and hospital admissions in a 6-month period. Psychiatric disorders were diagnosed through a direct interview by a designated psychiatrist using the Chinese-bilingual Structural Clinical Interview for DSM-IV Axis I disorders, patient research version (CB-SCID-I/P). The severity of depressive symptoms was assessed by the Hamilton Depressive Rating

Scale (HAM-D). Patients were asked to complete the Beck Depression Inventory (BDI), Medical Outcomes Study Social Support Survey (MOS-SSS-C) and the WHO Quality of Life Measure-Abbreviated Version. SLE disease activity (SLEDAI), organ damage (SLICC/SDI) and socio-demographic were collected and correlated with the presence of psychiatric disorders. Logistic regression was used to study the risk factors for psychiatric disorders in SLE.

## Results:

175 SLE patients were studied (95% women, age  $39.2 \pm 12.4$  years, SLE duration  $10.3 \pm 6.7$  years). Twenty-seven (15.4%) and 37 (21.1%) patients were diagnosed as having a current depressive (52% major depressive disorder, 22% dysthymia) and anxiety (35% generalized anxiety, 14% panic, 14% phobia, 8% adjustment disorder) disorder, respectively. Patients with depressive disorders, as compared to those without any psychiatric disorders, had higher SLE activity ( $p=0.03$ ), were more likely to have a history of psychiatric diagnosis ( $p<0.001$ ) and receive financial assistance from the Government ( $p=0.04$ ). Independent factors associated with a current depressive disorder were SLEDAI score ( $1.13[1.02-1.24]$  per point;  $p=0.02$ ), perceived poor social support ( $p=0.03$ ) and a past history of psychiatric disorders ( $p=0.003$ ). On the other hand, being separated/divorced ( $\beta=0.19$ ;  $p=0.02$ ), higher SLEDAI score ( $\beta=0.16$ ;  $p=0.02$ ), shorter SLE duration ( $\beta=-0.18$ ;  $p=0.02$ ) and a history of psychiatric disorders ( $\beta=0.18$ ;  $p=0.01$ ) were independently associated with higher HAM-D scores, which reflected the severity of depression. Depressive disorders and severity of depression were associated with poorer quality of life. ROC analysis showed a cut-off of 14 points of the self-rated BDI had a sensitivity of 89% and a specificity of 83% for providing good psychometric property for differentiating a current depressive disorder from those without.

## Conclusion:

Depressive disorder is prevalent in Chinese patients with SLE. Independent risk factors include more active disease, perceived poor social support and a past history of psychiatric disorders. Patients with more active SLE, shorter disease duration, a past history of psychiatric disorders and being separated are associated with more serious depressive symptoms. The self-rated BDI provides a good screening tool for identifying depressive disorders in SLE patients.

## Novel Electronic Health Record Method Reveals That dsDNA Antibody-Negative Systemic Lupus Erythematosus Is Associated with Pain, Sleep, and Mood Disorders

**April Barnado**<sup>1</sup>, Robert Carroll<sup>2</sup>, Carolyn Casey<sup>3</sup>, Joshua C. Denny<sup>2</sup> and Leslie Crofford<sup>1</sup>, <sup>1</sup>Medicine, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN, <sup>3</sup>Lehigh Valley Health Network, Allentown, PA

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus is a heterogeneous disease with diverse presentations. Studies have shown that dsDNA antibodies associate with renal disease. However, less is known about comorbidities in SLE patients without dsDNA antibodies. Using a large, novel electronic health record (EHR) cohort of SLE patients with a long duration of follow-up, we sought to identify not only ACR SLE criteria that associate with dsDNA antibody status but also other

comorbidities that might not be assessed in cohort studies. We used a technique that scans across EHR billing codes called phenome-wide association study (PheWAS) to compare comorbidities in SLE patients with and without dsDNA antibodies.

**Methods:** We used our validated SLE algorithm of  $\geq 4$  counts of the SLE ICD-9 code (710.0) and ANA positive  $\geq 1:160$  while excluding dermatomyositis and systemic sclerosis ICD-9 codes with an internally validated positive predictive value of 94% and a sensitivity of 86%. We identified SLE cases in a de-identified EHR called the Synthetic Derivative (SD) that contains over 2.8 million subjects with longitudinal data. SLE subjects have on average 9 years of follow-up. dsDNA status was defined as positive if ever positive, negative if there was at least 1 assay and all were negative, and measured via enzyme-linked immunosorbent assays with manufacturer values to determine positivity. Demographics of dsDNA positive vs. negative subjects were compared using chi-square and Mann-Whitney U tests. PheWAS was performed in dsDNA positive vs. negative SLE patients using logistic regression adjusting for current age and race and correcting for multiple testing using Bonferroni ( $p < 1.35 \times 10^{-4}$ ).

**Results:** Of 1097 SLE subjects, 521 had a positive dsDNA, 503 negative dsDNA, and 73 with missing data. dsDNA positive subjects were more likely to be African American vs. Caucasian (61% vs. 45%,  $p < 0.001$ ) and younger at age of first SLE ICD-9 code ( $37 \pm 17$  vs.  $43 \pm 15$ ,  $p < 0.001$ ) with no difference in sex (female 51% vs. male 52%,  $p = 0.58$ ). As expected, dsDNA positive subjects, compared to dsDNA negative, were more likely to have renal codes including nephritis, renal failure, and end stage renal disease (Table 1). dsDNA positive subjects were also more likely to have codes for hematologic and serositis criteria. dsDNA negative subjects were more likely to have codes for sleep, pain, and mood disorders.

**Conclusion:** Using a novel EHR technique in a large SLE cohort with longitudinal follow-up, dsDNA positive subjects were more likely to have codes for renal, serositis, and hematologic involvement. In contrast, dsDNA negative subjects were more likely to have codes related to neuropsychiatric symptoms. Our results demonstrate that PheWAS can expand our understanding of SLE disease heterogeneity by uncovering important clinical differences in subgroups of SLE patients.

**Table 1.**

<b>PheWAS codes</b>	<b>Phenotype present*</b> <b>(≥ 2 or more instances of the code)</b>	<b>Phenotype absent*</b> <b>(0 instances of the code)</b>	<b>Adjusted Odds Ratio for age and race</b> <b>(95% Confidence Interval)</b>	<b>p value</b>
<b>Codes favoring dsDNA positive subjects</b>				
Nephritis and nephropathy in diseases classified elsewhere	162	614	<b>dsDNA positive:</b> 4.66 (3.00 – 7.22)  <b>dsDNA negative:</b> 1.00 (ref)	$5.95 \times 10^{-12}$
Renal failure	261	614	2.33 (1.71 – 3.19)	$1.15 \times 10^{-7}$
Other anemias	275	585	1.87 (1.37 – 2.55)	$7.67 \times 10^{-5}$

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prolonged clinical remission is a desirable, though rare outcome in systemic lupus erythematosus (SLE). We recently showed that low disease activity (LDA) state confers the same risk as complete remission with regard to damage accumulation and flare rate at two years. The aim of the present study was to assess the impact of prolonged LDA (for 10 years) on such outcomes as compared to patients who achieved complete remission.

**Methods:** The inception cohort of a large lupus clinic (patients enrolled within 18 months of diagnosis) was investigated. Patients selected had a minimum follow-up of 10 years and no interval greater than 18 months between consecutive visits. Prolonged clinical remission was defined based on SLEDAI-2K=0 (serology excluded), achieved within the first five years since diagnosis and maintained for  $\geq 10$  years. Prolonged LDA was defined as  $\text{SLEDAI-2K} \leq 2$  (serology excluded) for the same period. Statistical analysis was performed with SAS 9.0 software;  $p < 0.05$  was considered significant.

**Results:** Of the 883 inception patients, 382 fulfilled the inclusion criteria. Twenty-seven patients (7.1%) achieved prolonged clinical remission and 48 (12.6%) prolonged LDA. There were no differences regarding demographic, clinical, and immunological variables at diagnosis and at 10 years. Mean prednisone dose at diagnosis was higher in the patients who achieved remission. Antimalarial usage was higher in patients with LDA both at diagnosis and at 10 years. The two groups had comparable cumulative damage over 10 years, flare rate after 10 years, and mortality throughout follow-up. Details are given in Table 1.

Table 1. Comparison between patients with prolonged remission and LDA						
Variable	At diagnosis			At 10 years		
	CR (n=27)	LDA (n=48)	p	CR (n=27)	LDA (n=48)	p
Age at diagnosis (y)	39±14.1	39.1±14.9	0.976			
ACR criteria (mean±SD)	4.4±1.4	4.9±1.7	0.199			
Time to remission or LDA (y)	1.6±1.3	1.8±1.6	0.656			
SLEDAI-2K (mean±SD)	10.7±11.6	9.5±10	0.642	1.2±1.6	1.6±1.7	0.305
Low complement (n, %)	9 (33.3%)	16 (33.3%)	1.000	8 (29.6%)	13 (27.1%)	0.97
Anti-dsDNA (n, %)	13 (48.1%)	16 (33.3%)	0.206	6 (22.2%)	12 (25.0%)	0.956
Glucocorticosteroids (n, %)	17 (63.0%)	33 (68.8%)	0.61	6 (22.2%)	10 (20.8%)	0.888
Mean prednisone dose (mg/d)	16.8±9.5	10.7±8.4	0.028	5.3 ± 3.2	4.6 ± 1.4	0.576
Cumulative prednisone dose (g)				18.1 ± 12.4	13.4 ± 9.1	0.129
Antimalarials (n, %)	16 (59.3%)	38 (79.2%)	0.065	11 (40.7%)	32 (66.7%)	0.029
Immunosuppressives (n, %)	9 (33.3%)	16 (33.3%)	1.000	3 (11.1%)	8 (16.7%)	0.514
No Medications (n, %)				12 (44.4%)	19 (39.6%)	0.682
SLICC/DI (mean±SD)	0.26±0.53*	0.33±1.04*	0.73	0.96 ± 1.06	1.10 ± 1.32	0.636
Disease flare after 10 years				7 (25.9%)	15 (31.3%)	0.627
Time to flare (median in years)				12 (11-15)	11 (10-13)	0.217
Deceased (n, %)				3 (11.1%)	5 (10.4%)	0.925
* At one year after diagnosis, CR: complete remission, LDA: low disease activity, SLICC/DI: Systemic Lupus International Collaborating Clinics/Damage Index						

**Conclusion:** Patients with prolonged (>10 years) LDA achieved comparable outcomes as those with complete remission in the long term. Differences regarding therapeutic approach were observed but did not affect damage accumulation. Approximately 40% of these patients were able to discontinue all medications 10 years after diagnosis. Prolonged LDA status is an acceptable treat to target outcome in SLE.

## Prolonged Antimalarial Treatment Is Associated with Increased Risk for Elevated Myocardial Biomarkers in Systemic Lupus Erythematosus

**Konstantinos Tselios**<sup>1</sup>, Dafna D Gladman<sup>2</sup>, Paula Harvey<sup>3</sup>, Shadi Akhtari<sup>3</sup>, Jiandong Su<sup>4</sup> and Murray Urowitz<sup>2</sup>,  
<sup>1</sup>Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>2</sup>Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>3</sup>Cardiology, Women's College Hospital, University of Toronto, Toronto, ON, Canada, <sup>4</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antimalarial (AM)-induced cardiomyopathy (AMIC) has been rarely reported in systemic lupus erythematosus (SLE). However, given the large number of patients treated, it seems possible that AMIC is under-recognized and may run undiagnosed as an ill-defined heart failure syndrome. Specific cardiac biomarkers may identify patients at risk. We sought to investigate the prevalence and associated factors for such biomarkers in systemic lupus erythematosus (SLE).

**Methods:** One hundred sixty eight consecutive patients (153 females) attending a large lupus clinic, without past history of cardiac disease (heart failure, coronary artery disease, valvulopathy etc.) and/or pulmonary hypertension, were enrolled. None had chest pain or electrocardiographic (ECG) abnormalities suggestive of acute coronary syndrome. High-sensitivity cardiac troponin I (cTnI) and B-natriuretic peptide (BNP) were measured simultaneously in serum and plasma samples, respectively. Patients were categorized according to normal or abnormal BNP and/or cTnI. For the assessment of the impact of AM duration on abnormal cardiac biomarkers, patients were divided in two groups according to the median duration of use, which was calculated at 5.6 years in the current cohort. Statistical analysis was performed with SAS 9.0 software;  $p < 0.05$  was considered significant.

**Results:** Sixteen patients (9.5%) had elevated BNP and/or cTnI. Compared to subjects with normal biomarkers, they were older, had longer disease and AM use duration and more frequently persistent creatine phosphokinase (CPK) elevation. Details are shown in Table 1.

Table 1. Comparison between BNP/cTnI abnormal and BNP/cTnI normal patients			
VARIABLE (At assessment)	BNP/cTnI abnormal (no history of heart disease or PAH) (n=16)	BNP/cTnI normal (n=152)	P
Age (y)	54.7 ± 15.1	47.83 ± 12.15	<b>0.037</b>
SLE duration (y)	22.54 ± 10.44	15.45 ± 10.05	<b>0.008</b>

Hypertension	10 (62.5%)	54 (35.5%)	<b>0.035</b>
Diuretics treatment	5 (31.3%)	8 (5.3%)	<b>&lt;0.001</b>
Systolic BP at test (mmHg)	118.4 ± 21.7	113.5 ± 16.9	0.28
Diastolic BP at test (mmHg)	71.9 ± 10.1	69.5 ± 11.8	0.444
Abnormal CPK ⌘	7 (43.8%)	24 (15.8%)	<b>0.008</b>
Cumulative years on AM	13.66 ± 9.14	7.88 ± 8.02	<b>0.008</b>
AM duration > 5.6 years	14 (87.5%)	69 (45.4%)	<b>0.001</b>
Corticosteroids	8 (50%)	70 (46.1%)	0.763
Mean prednisone (mg/day)	9.4 ± 4.2	7.53 ± 5.1	0.326
Immunosuppressives	10 (62.5%)	87 (57.2%)	0.685
eGFR: estimated glomerular filtration rate, PAH: pulmonary arterial hypertension, BP: blood pressure, CPK: creatine phosphokinase, AM: antimalarials, CQ: chloroquine, HCQ: hydroxychloroquine, ⌘ Three abnormal measurements during the last two years			

Multivariable regression analysis showed prolonged AM treatment (>5.6 years) and persistent CPK elevation to be important predictors for elevated cardiac biomarkers [HR=5.43, 95%CI=1.14-25.9,  $p=0.034$  and HR=4.62, 95%CI=1.22-17.51,  $p=0.024$ , respectively]. Two patients were diagnosed with AMIC on endomyocardial biopsy; both had CPK and BNP/cTnI elevation.

**Conclusion:** Approximately 9% of SLE patients had elevated myocardial biomarkers, in the absence of prior cardiac disease or pulmonary arterial hypertension. Prolonged AM therapy and persistent CPK elevation conferred an increased risk for abnormal BNP and cTnI, which might predict AMIC.

## Long-Term Outcome of Demyelinating Syndrome in Systemic Lupus Erythematosus: A Longitudinal Study

**Jamal A. Mikdashi**<sup>1</sup> and **Ipolia Ramadan**<sup>2</sup>, <sup>1</sup>Div of Rheumatology, Univ of Maryland Schl of Med, Baltimore, MD, <sup>2</sup>National Institute of Health, Rockville, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Demyelinating syndromes (DS) in systemic lupus erythematosus (SLE) are characterized by inflammation, demyelination and neurodegeneration. Little is known, however, about the tenet of dissemination in time or space of DS in SLE. The aim of this study is to evaluate the long-term outcomes in SLE patients with DS in a large SLE cohort.

**Methods:** Data of patients with DS were obtained from the SLE cohort at the University of Maryland, between 1996 and 2016. Demographic, clinical features, serological studies, SLE-related treatment, and DS treatment-related exposures, Expanded Disability Status Scale (EDSS) score at baseline, were included. SLE patients with DS were classified as Clinically Isolated Syndrome (CIS), [those presenting with optic neuritis, partial myelitis or a brain stem syndrome], and Radiologically Isolated Syndrome (RIS), [those exhibiting radiological disease with T2/fluid attenuated inversion recovery or enhancing magnetic resonance imaging (MRI) typical of demyelination as a biomarker of acute inflammatory activity]. The primary outcomes were DS progression, overall survival, cognitive dysfunction and residual disability. The predictors of DS progression were calculated using multivariable Cox proportional hazards regression analysis models. To avoid bias, patients were included in the analysis regardless of their duration of follow-up.

**Results:** 25 SLE cases with DS were identified [mean age; 41.9 + 12.3 years, 80 % African America, 84% women, with a mean follow up of 6.9 + 1.8 years]. The median baseline EDSS score was 4.5 (range, 1.5-6.5). CIS was observed in 15 cases (60 %) [Optic neuritis n=6 (24%), acute transverse myelitis n=9 (36%)]. Ten patients (40%) had RIS. Two patients (8 %) had neuromyelitis optica syndrome.

Nine patients (36%) had progressive forms of DS, 8 (32 %) had cognitive dysfunction and 9 (36 %) had worsening disability. Three deaths at follow up, were observed and were considered SLE-related mortality.

Factors associated with progression of DS included, SSA antibody [Odds ratio, 10.5 (95% CI: 1.5-72,  $p < 0.005$ )], and presence of oligoclonal bands on spinal fluid analysis. There were lack of association with INF gene expression, DS modifying therapy, phospholipid syndrome, or use of hydroxychloroquine.

Worsening disability overtime was associated with spinal cord lesions {OR 34 (95 % CI: 3.5-93.2,  $p < 0.001$ )}, and CIS [OR 10.3 (95 % CI 1.0-102,  $p < 0.008$ )]. The use of DS modifying therapy tended to be protective, (OR 0.8, 95% CI, 0.6-0.9,  $p < 0.051$ ).

Older age (> 40 years) [OR 3.6 (95% CI: 1.7- 67,  $p < 0.03$ ] and midbrain lesion (OR 2.7, 95 % CI: 1.1-6.5,  $p < 0.05$ )] were associated with cognitive impairment.

**Conclusion:** More than half of SLE patient with DS remained free from neurological progression for 5 years after DS diagnosis. Younger age, relapsing form of DS, prior immunotherapies, and lower baseline EDSS score were factors associated with better outcomes. Identifying novel biomarkers of DS progression in SLE will help develop therapeutic options and engender mechanisms of neurodegeneration.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antiphospholipid syndrome has been shown to be associated with increased cardiovascular mortality, but the role of antiphospholipid antibodies (aPL) on endothelial dysfunction remains elusive. We investigated the association between endothelial dysfunction and aPL in systemic lupus erythematosus (SLE) patients.

**Methods:** 185 SLE patients and 62 controls were enrolled. Endothelial function was measured by flow-mediated dilatation (FMD). Cardiovascular risk factors were assessed and quarterly measurement of anti-cardiolipin (aCL) and anti-b<sub>2</sub> glycoprotein I Ab were used to calculate time-integrated values throughout disease duration. Circulating endothelial progenitor cell (EPC), defined by CD34+/KDR+ mononuclear cells, was quantified by flow cytometry.

**Results:** Median FMD was significantly lower in SLE patient than in controls (6.9 versus 9.3%,  $P<0.001$ ). In univariate analysis, older age, hypertension, and persistent positive lupus anticoagulant (LAC) were associated with decreased FMD in SLE patients ( $P=0.034$ ,  $P=0.020$ , and  $P=0.028$ ). Time-integrated aCL value (TI-aCL), but not a single value, was correlated with decreased FMD ( $P=0.003$ ). Multivariate analysis showed that hypertension and TI-aCL were independent factors for decreased FMD ( $P=0.012$ ,  $P=0.011$ ); addition of positive LAC increased the adjusted probability of decreased FMD ( $P=0.003$ ). FMD was correlated with EPC number ( $r=0.342$ ,  $P=0.005$ ) and TI-aCL was also an independent factor of reduced EPC after multiple adjustment ( $P=0.024$ ). The predicted probability of endothelial dysfunction at median EPC level was higher in group with high TI-aCL than in group with low TI-aCL ( $P=0.004$ ).

**Conclusion:** Cumulative burden of aPL was closely associated with endothelial dysfunction in SLE patients, which was mediated in part by reduction of EPC.

## Risk Factors for Neuropsychiatric Systemic Lupus Erythematosus and Its Recurrence

**Ryusuke Anan**, Yuko Kaneko, Jun Kikuchi and Tsutomu Takeuchi, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neuropsychiatric involvement in systemic lupus erythematosus (NPSLE) is the leading cause of morbidity and mortality in patients with SLE but not well understood. The aim of this study was to identify risk factors for NPSLE and its recurrence.

**Methods:** We enrolled consecutive patients with SLE who had visited Keio University Hospital between 2013 and 2015. The patients were divided according to the presence or absence of NPSLE, and their clinical characteristics, manifestations, findings of cerebrospinal, electroencephalographic and neuroimaging examination, treatment and prognosis were compared. Patients with NPSLE were further divided by the recurrence of NPSLE, and its risk factors were examined.

**Results:** A total of 302 patients with SLE were enrolled. Two hundred seventy (89%) were female, and the mean age was 49.2 years. Forty-two (14%) patients were diagnosed with NPSLE during the course of SLE according to the ACR case definitions. The patients with NPSLE had a history of serositis more frequently than those without (37% vs 20%,  $p=0.03$ ). Anti-Ro/SSA antibody (76% vs 54%,  $p=0.02$ ) and anti-phospholipid antibody (55% vs 35%,  $p=0.03$ ) were more frequently detected in patients with NPSLE while no difference was found in other autoantibodies including anti-DNA, anti-Sm, anti-RNP, and lupus anticoagulant. Among NPSLE patients, 22 (52%) had recurrent central nervous involvement. Serologically, the recurrent group had higher positivity of anti-Ro/SSA antibody than the non-recurrent group (88% vs 59%,  $p=0.02$ ). Patients with focal hypoperfusion in single photon emission computed tomography (SPECT) at the first NPSLE had significantly higher relapse rate than those with diffuse hypoperfusion (86% vs 36%,  $p=0.02$ ). Patients treated with intravenous cyclophosphamide at the first NPSLE were at a lower risk of recurrence (12% vs 46%,  $p=0.01$ ).

**Conclusion:** Anti-Ro/SSA antibody was a risk for recurrent NPSLE. Patients with focal hypoperfusion of SPECT at the first NPSLE had significantly higher risk for NPSLE recurrence. Cyclophosphamide is important for preventing the recurrence of NPSLE.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A large multicentre multinational inception cohort was established to study risk factors for atherosclerosis (AS) in SLE. We aim to describe all vascular events (VE) and determine the predictors of atherosclerotic vascular events (AVE) in this cohort over a 17 year period.

**Methods:** Patients enter the cohort within 15 months of SLE diagnosis ( $\geq 4$  ACR criteria). Clinical and laboratory features of SLE are collected annually in a standardized protocol from 2000-2017. Patients with  $< 3$  years of follow-up or VEs attributed to other causes were excluded. VEs recorded include myocardial infarction (MI), angina, congestive heart failure (CHF), intermittent claudication (PVD), transient ischemic attack (TIA), pacemaker insertion and stroke. Diagnosis of a VE is confirmed using standard clinical criteria, relevant laboratory data and imaging where appropriate. Attribution to AS was made on the basis of lupus disease being inactive at the time of VE, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Factors associated with AVE were analyzed on patients with AVEs that occurred after study enrollment using time to event analysis with time dependent covariates and cox proportional hazard model.

**Results:** 1848 patients entered the cohort (88.7%F, age at SLE  $34.7 \pm 13.4$  years, disease duration  $5.6 \pm 4.2$  months, mean follow-up of  $7.3 \pm 4.5$  years). Thus far, there have been 231 VEs in 159 patients. These include: MI (24), angina (31), CHF (52), pacemaker insertion (9), PVD (20), TIA (29) and stroke (66). 106 VEs were attributed to active lupus and 42 to other causes. 83 VE in 57 patients were attributed to AS including: MI (17), angina (26), CHF (12), pacemaker (5), PVD (9), TIA (7), and stroke (7). 14 patients in the AS group had  $> 1$  AVE. SLE duration at first AVE was  $3.7 \pm 3.5$  years. Of the 57 AVE patients, 47 had an AVE that occurred after study enrollment.

Table 1. Cohort Characteristics at Enrolment			
Characteristic	Patient that had a AVE (N=47)	Patients that did not have a VE (N=1364)	p value
Male	13 (27.7%)	133 (9.8%)	<0.001
Caucasian	34 (72.3%)	663 (48.6%)	0.001
Age at SLE diagnosis (Mean $\pm$ SD)	51.82 $\pm$ 14.89	33.99 $\pm$ 12.93	<0.001
Smoking	25 (53.2%)	466 (34.2%)	<0.001
Hypertension	26 (55.3%)	446 (32.7%)	0.001
Diabetes	3 (6.7%)	46 (3.4%)	0.241
Obese	23 (51.1%)	381 (28.9%)	0.001
Hypercholesterolemia	21 (44.7%)	475 (34.8%)	0.165
Family history of CAD	21 (45.7%)	300 (22.5%)	0.001
SLEDAI-2K (Mean $\pm$ SD)	4.13 $\pm$ 4.83	5.38 $\pm$ 5.33	0.112
Total ACR Criteria (Mean $\pm$ SD)	4.96 $\pm$ 1.21	4.91 $\pm$ 1.05	0.683
Serositis	21 (44.7%)	367 (26.9%)	0.007
Renal Disorder	12 (25.5%)	389 (28.5%)	0.655
Neurologic Disorder	3 (6.4%)	55 (4.0%)	0.425
Immunologic Disorder	39 (83.0%)	1,044 (76.5%)	0.304
Anticardiolipin	7/35 (20.0%)	116/894 (14.5%)	0.198
Lupus Anticoagulant	13/35 (37.1%)	187/926 (20.2%)	0.026
Treated with oral steroids	32 (68.1%)	928 (69.7%)	0.802
Average daily corticosteroid dose (Mean $\pm$ SD)	14.20 $\pm$ 17.58	16.73 $\pm$ 17.39	0.327
Treated with antimalarials	26 (55.3%)	936 (68.6%)	0.251
Treated with immunosuppressives	18 (38.3%)	542 (39.7%)	0.926
Table 2. Predictive Risk Factors – Multivariable Analysis			
Predictor	Hazard Ratio	95% Confidence Interval	p value
Age at SLE diagnosis	1.08	1.06, 1.10	<0.001
ACR Criteria – Serositis	2.47	1.34, 4.54	0.003
Antimalarial treatment	0.52	0.28, 0.95	0.033

The classic risk factors at inception were not predictive, but they do increase over time (Figure 1).

**Conclusion:** Over the follow-up of an inception cohort with SLE there were 83 AVEs in 57 patients of which 47 occurred after enrollment. Only older age and serositis are significant risk factors for AVE and antimalarials were protective. However, traditional risk factors increase over time and may have an impact on the development of AVE in the future.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus nephritis (LN) remains one of the most serious complications of SLE, occurring in up to 50% of patients. Current LN treatments are not sufficiently efficacious, are accompanied by significant off-target toxicities and result in a high percent of patients progressing to end stage renal disease. Thus, additional efforts are needed to understand LN at the molecular level, and to identify clinical responsiveness with specific molecular pathways.

**Methods:** SLE patients with proteinuria and suspected LN (n=105) were enrolled over 15 months by 12 US-based lupus centers to the RA/Lupus Accelerated Medicines Partnership Phase I program. Demographic, clinical, and therapeutic information was gathered using standard case report forms and entered into a study-specific database. ACR and SLICC SLE classification criteria, biopsy information, modified SELENA-SLEDAI, laboratory values and patient reported outcomes (PROMIS29) were collected. Serum, plasma, PBMCs, total blood leukocytes, urine, urine cells, and renal biopsy tissue were collected, with non-lesional, non-sun exposed skin biopsies in 25%. Complete renal response was considered improvement of urine protein to <500mg (or UPCR <0.5) and normal serum creatinine (or up to 125% of baseline) with prednisone taper, while partial response required improvement of urine protein by  $\geq 50\%$ .

**Results:** Of the 105 SLE patients recruited, 93 (89%) were female and most were non-Caucasian (n=84; 80%), including 28% Hispanic, 39% African-American, 11% Asian, 2% mixed ethnicity/not reported. Of the SLE renal biopsies (n=105), 75% were ISN Class III, IV, V or mixed. LN patients were on average 33.7 years of age (range: 14-58) with a baseline urine protein:creatinine ratio of 3.3 (with 34% > 3; n=21), 70% anti-dsDNA positive (n=48), 84% with low complement levels (n=59) and 39% with Hg < 10 g/dL (n=28). The average SLEDAI was 12.3, with 56% of this group presenting with global disease activity (e.g. 2 organ systems active in addition to renal, e.g. arthritis, skin, serositis). Analysis of 30 LN patients with longitudinal information revealed that 33% achieved complete response and 17% partial response to standard of care (SOC) therapy at 6 months. LN patients with extra renal disease activity were twice as likely to be renal non-responders to SOC (n=10 NR; n=5 CR/PR) than those LN patients whose disease activity was limited to renal and immunologic features only (n=6 NR; n=9 CR/PR).

**Conclusion:** These preliminary findings suggest that renal response to current SOC may occur more often in patients without other active manifestations of lupus. Significant clinical heterogeneity exists between LN patients emphasizing a need for deeper molecular phenotyping.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Ambulatory 24-hour blood pressure and nocturnal blood pressure measurements are better predictors of cardiovascular risk than office blood pressure. Patients with systemic lupus erythematosus (SLE) have a high prevalence of hypertension and cardiovascular events. Recent findings indicate that sodium stored in the skin can be measured with  $^{23}\text{Na}^+$  magnetic resonance imaging (MRI) and plays an important role in both blood pressure and immune regulation. Little is known about ambulatory blood pressure in SLE and its relationship to skin  $\text{Na}^+$  is not known.

### **Methods:**

Office blood pressure was measured at study enrollment using standard procedures and ambulatory 24-hour blood pressure measurements were recorded (Meditech, Budapest, Hungary) in 23 patients with SLE and 23 controls frequency-matched for age, race, and sex. Skin  $\text{Na}^+$  content in the lower leg was measured with a 3T  $^{23}\text{Na}^+$  knee-coil with a magnetic resonance imaging scanner (Philips Achieva 3T) in 13 patients with SLE. Phantoms containing aqueous solutions with 10, 20, 30, and 40 mmol/L NaCl were included for calibration. Blood pressure measurements in patients and control subjects were compared using Wilcoxon-rank sum tests and adjusted for age, race, and sex using a linear regression model. Spearman correlations were used to assess the correlation between blood pressure measurements and skin sodium in SLE patients.

### **Results:**

**Results:** Office blood pressure was not significantly different in patients with SLE and controls (Table). However, ambulatory blood pressure measurements, particularly nocturnal measurements, were higher in patients with SLE. In patients with SLE (n=13), skin  $\text{Na}^+$  concentrations were 15.0 (IQR 13.3 – 18.4) mmol/L and were significantly correlated with both office ( $\rho=0.67$ ,  $P=0.023$ ) and mean 24-hour systolic blood pressure ( $\rho=0.62$ ,  $P=0.04$ ).

	SLE (N=23)	Controls (N=23)	p-value	p-value*
Age, years	35 (31-52)	35 (26-50)	0.73	
BMI, kg/m <sup>2</sup>	25.9 (22.7-33.8)	24.3 (22.7-26.8)	0.22	
Sex female	19 (82.61%)	20 (87.0%)	1.0	
Race white	15 (65.2%)	19 (82.6%)	0.31	
Smoker never	17 (73.9%)	17 (73.9%)	1.0	
24 hr Mean SBP, mmHg	128.5 (113-139.1)	115 (110.6-121)	0.05	0.04
24 hr Mean DBP, mmHg	78 (68.9-85.2)	72.4 (66.8-74.9)	0.02	0.04
Awake Mean SBP, mmHg	130.2 (115-139.3)	118.5 (114.7-124.7)	0.07	0.07

Office SBP, mmHg	126 (114-140)	121 (115-127)	0.37	0.43
Office DBP, mmHg	83 (68-90)	82 (73-90)	0.76	0.84
Hypertension, Yes	11 (47.8)	2 (8.7)	0.007	

BMI= body mass index, SBP = systolic blood pressure, DBP = diastolic blood pressure, \*Adjusted for age, sex, and race

\*\* Continuous and categorical data expressed as median (interquartile range) and counts (percent) respectively

## Conclusion:

Despite similar office blood pressure measurements, ambulatory blood pressure, particularly nocturnal blood pressure, was higher in patients with SLE than controls. Skin Na<sup>+</sup> levels were correlated with systolic blood pressure in SLE. Studies to further assess the relationship between skin Na<sup>+</sup> and disease activity, blood pressure, and cardiovascular disease in patients with SLE are needed.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Gaps exist in SLE patient care in monitoring and management of comorbidities, treatment related toxicities, and disease activity, suggesting a lack of well-defined systems of care in SLE. Our hypothesis was that a more time structured, IT enhanced, and QI indicator-driven approach to SLE management would translate to more frequent, comprehensive, and guideline adherent interactions with the lupus patient (“tight” management) that would lead to improved outcomes.

### **Methods:**

To prompt “tight” management of SLE patients at Ochsner main campus (687 patients - 2014 baseline; 644 patients - 2015 interventional; 581 patients – 2016 post-interventional), the following interventions were implemented:

- **Lupus Management Module:** SLE specific dashboard embedded into Epic EHR. Dashboard incorporates automated SLE management specific reminders, alerts (and facilitates ordering appropriate testing/management), test result tracking, and customized assessments (SELENA-SLEDAI, SLICC- SDI). SLICC-DI assessment is prompted 1x annually. SLEDAI assessment prompted every office visit. The occurrence of flare is prompted tabulated and based on change in SELENA- SLEDAI assessment. Clinicians have the ability to override or confirm the tabulated occurrence of flare. Also, clinicians could manually designate the occurrence of flare independently of the automated tracking system.
- **Patient Campaigning:** Identification of patients due for SLE specific testing or management activities. Of primary importance were to prompt an office visit at least 1x/6 months and prompt pre office visit lab testing to enable completion of the SELENA- SLEDAI tabulation at the point of care, thereby enabling and facilitating fully informed management decision making at the point of care.

### **Results:**

These interventions prompted improvement in rate of SELENA-SLEDAI application 1x/6 months (26.35% - 2014 baseline period, 43.79% - 2015 interventional period, 39.93% - 2016 post-interventional period;  $p < 0.0001$ ), rate of SLICC-SDI application 1x/12 months (22.83% - 2015 interventional period, 34.25% - 2016 post-interventional period;  $p < 0.0001$ ), rate of performance of ALL appropriate labs 1x/6 months (28.38% - 2014 baseline period, 44.57% - 2015 interventional period, 43.37% - 2016 post-interventional period;  $p < 0.0001$ ), rate of cardiovascular assessment 1x/12 months (35.95% - 2014 baseline period, 51.71% - 2015 interventional period, 46.30% - 2016 post-interventional period;  $p < 0.0001$ ), rate of influenza vaccination 1x/12 months (18.78% - 2014 baseline period, 29.50% - 2015 interventional period, 37.18% - 2016 post-interventional period;  $p < 0.0001$ ), rate of lupus flare (16.30% - 2015 interventional period, 12.05% - 2016 post-interventional period;  $p = 0.0338$ ), and rate of hospitalization (8.59% - 2014 baseline period, 6.68% - 2015 interventional period, 5.68% - 2016 post-interventional period;  $p = 0.0466$ ).

### **Conclusion:**

Time structured, IT enhanced, and QI indicator driven interventional modalities prompted more frequent, more comprehensive, guideline adherent point of care interaction with SLE patients. “Tighter” management resulted in the improved outcomes of both rate of lupus flare and rate of hospitalization in SLE patients.

## **Differential Diagnosis of Autoimmune Diseases, Outlier Detection Plus Subgrouping in Clinical Trials By High Content Autoantibody Profiling**

**Peter Schulz-Knappe**, Petra Budde and Hans-Dieter Zucht, Protagen AG, Dortmund, Germany

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early diagnosis as well as initiation of successful treatment are two big challenges in the management of patients with autoimmune diseases (AID). Overlap of a plethora of clinical symptoms, ranging from multi-organ involvement, fatigue, inflammation to CNS-involvement make differential diagnosis quite challenging. Especially in early disease these signs are difficult to quantify, hence the lag time from start of disease until clinical diagnosis may be delayed, sometimes for years. With the growing interest in conducting clinical trials in AID, there is a need for new biomarkers that can be used to diagnose individual AIDs to reduce the inclusion of patients not carrying the intended disease, and identify clinical subsets, predict treatment outcome and assess disease activity.

**Methods:** The autoantibody reactivity pattern in serum of AID patients was analyzed using a Luminex bead-based antigen array (SeroTag) and 1,600 – 8,000 selected human protein antigens. We screened over 3,000 serum samples from Sjögren's Syndrome (n= 350), SLE (n= >1000), SSc (n= >250), RA (n= >1000), and several other AIDs and over 1,000 healthy individuals to confirm known and to discover novel autoantibodies, create reduced autoantibody panels for differential diagnosis and disease subgrouping.

**Results:** Apart from clear confirmation of the known benchmark autoantigens known for many years we have discovered over 80 novel autoantibodies, which were detected in frequencies of 10 to >25% in selected AIDs. Some novel autoantibodies are specific for certain diseases, such as the major vault protein in SLE or BICD2 in SSc. Others are present in several diseases, indicating overlap syndromes. Multiplex panels of 50-100 AABs were generated and tested to allow for a subgroup definition of Sjögren's, SLE, and for clear segregation of SjS/SLE overlap syndrome patients. As well, subgrouping of SSc and early RA patients was achieved.

**Conclusion:** A set of 100-150 autoantigens, half of them well established, the other half novel, succeed in differential diagnosis of AID, in some diseases already at early disease stage. This panel has been used in several drug trials to subgroup SLE, Sjögren's or RA into subgroups. Especially in SLE, outliers in the range of 10-15% of the trial population were seen which can be used to curate a trial population, eventually to arrive at a more precise assessment of trials primary objectives.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster I: Biomarkers and Outcomes

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the incidence and variability of traditional coronary artery disease (CAD) risk factors in a cohort of systemic lupus erythematosus (SLE) patients.

**Methods:** 174 women were included (T0) in this prospective study on SLE atherosclerosis. The following traditional CAD risk factors were analyzed: hypertension (blood pressure  $\geq 140/90$  mmHg or antihypertensive medication), diabetes mellitus (DM) (fasting glucose  $\geq 126$ mg/dl on at least two occasions or use of oral hypoglycemic agents or insulin), dyslipidemia (total-cholesterol  $\geq 200$ mg/dl or HDL  $< 40$ mg/dl or LDL  $\geq 130$ mg/dl or use of oral lipid-lowering agents), hypertriglyceridemia (triglycerides  $\geq 150$ mg/dl), obesity (body mass index  $\geq 30$ kg/m<sup>2</sup>), abdominal obesity (waist circumference  $\geq 88$ cm), smoking, positive family history for coronary event. Metabolic syndrome (MetS), according to Third Report of the NCEP/ATP III criteria, and Framingham risk score (FRS) were computed. The cumulative incidence between T0 and T1 for all risk factors was investigated. The incidence rate (person-years) for hypertension, DM, dyslipidemia and hypertriglyceridemia, with a CI95%, were calculated based in the data collected from the medical records. The frequency of risk factor disappearance at T1 (including the absence of treatment in the definition of disappearance), among patients with the risk factor at T0, was also described.

**Results:** The mean (SD) age at T0 of 151 patients reevaluated after 39 (36.5-42.0) months (T1) was 37.8 (11.1) years old, 75.5% non-white. The cumulative incidence, the incidence rate and the disappearance of some risk factors for CAD are presented in Table 1. The cumulative incidence during follow up were zero for smoking, 3.8% for positive family history for premature CAD, 16.5% for obesity, 18.8% for MetS and 39.1% for abdominal obesity. Eleven (11.7%) of 143 patients with low FRS in T0 were classified in high risk category in T1. Considering the risk factors disappearance, 26.0% with MetS at T0, 16.7% with obesity and 6.3% with abdominal obesity presented without the risk factor at T1. Only 1 (12.5%) patient within the higher risk of coronary event in 10 years (FRS $>10\%$ ) at T0 “reduced” the risk to  $<10\%$  in T1.

**Conclusion:** The authors identified a significant increase in the incidence of CAD risk factors in lupus patients with a follow-up of approximately 3 years. Conditions such as hypertension, obesity and DM presented less fluctuation than dyslipidemia between T0 and T1, raising considerations about the importance of statins use in lupus patients over time.

**Table 1. Coronary artery disease risk factors cumulative incidence, incidence rate and disappearance after 39 (37-42) months, in lupus patients**

Risk factor	Cumulative incidence*	Incidence rate 1000 person-years (CI 95%)	Disappearance of risk factor**
Hypertension	18/79 (22.8%)	72.1 (38.8-105.4)	6/72 (8.3%)
Diabetes mellitus	5/143 (3.5%)	10.4 (1.3-19.5)	0
Dyslipidemia	33/89 (37.1%)	133.2 (87.8-178.6)	27/62 (43.5%)
LDL-c $>130$ mg/dl	20/126 (15.9%)	49.9 (28.1-71.8)	9/25 (36.0%)
Total Chol $>200$ mg/dl	27/122 (22.1%)	71.9 (44.8-99.0)	11/29 (37.9%)
HDL-c $<40$ mg/dl	15/111 (13.5%)	44.2 (21.8-66.5)	27/40 (43.5%)
TGL $>150$ mg/dl	16/108 (14.8%)	49.1 (25.0-73.1)	18/30 (41.9%)

\*Incident case/Number of patients without risk factor at T0.

\*\*Number of patients with disappearance of a risk factor/Number of patients with the risk factor at T0.

## Antibodies Against the Chemokine Receptors CXCR3 and CXCR4 Predict Progressive Lung Fibrosis in Systemic Sclerosis (SSc)

**Gabriela Riemekasten**<sup>1</sup>, Elise Siegert<sup>2</sup> and Harald Heidecke<sup>3</sup>, <sup>1</sup>Department of Rheumatology, Universitätsklinikum Schleswig-Holstein, Lubeck, Germany, <sup>2</sup>Rheumatology and Clinical Immunology, University Hospital Charité, Berlin, Germany, <sup>3</sup>CellTrend GmbH Luckenwalde, Luckenwalde, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chemokine receptors CXCR3 and CXCR4 are involved in immune cell migration and in the pathogenesis of inflammatory fibrosis, a key feature of systemic sclerosis (SSc). It is hypothesized that IgG antibodies (ab) against these two receptors are present in patients with SSc and associated with clinical findings.

**Methods:** Anti-CXCR3 and anti-CXCR4 ab levels were measured in 449 sera from 327 SSc patients and in 234 sera from healthy donors (HD) by ELISA. In SSc, ab levels were compared with clinical data in a cross-sectional and longitudinal setting. Protein expression of CXCR3 and CXCR4 on PBMC was analyzed in 17 SSc patients and 8 HD by flow cytometry.

**Results:** Anti-CXCR3 and anti-CXCR4 ab levels were different among SSc subgroups compared to HD and were highest in diffuse SSc patients. The ab levels strongly correlate with each other ( $r = 0.85$ ). Patients with SSc-related interstitial lung disease (SSc-ILD) exhibited higher ab levels, which negatively correlated with lung function parameters (e.g.  $r = -0.5$  and  $r = -0.43$  for predicted vital capacity, respectively). However, patients with deterioration of lung function showed lower anti-CXCR3/4 ab levels compared to those with stable disease. Frequencies and median fluorescence intensities (MFI) of CXCR3+ and CXCR4+ PBMC were lower in SSc patients compared to HD. They correlated with the severity of skin and lung fibrosis (Fig. 1).

Fig. 1: Frequency of CXCR3-positive CD14+ monocytes among CD14+ monocytes (a) as well as CXCR3 density (b) on CD14+ monocytes negatively correlated with the predicted percentages of forced vital capacity (FVC). (c) CXCR4 density on CD4+ T cells correlated with modified Rodnan skin score (mRSS).

**Conclusion:** Anti-CXCR3/4 ab and their corresponding receptors are linked with severity of lung fibrosis. High ab levels could serve as marker for SSc-ILD stability suggesting a protective role of these ab in SSc-ILD.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anabasum (JBT-101) is a selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses and limits fibrosis in animal models of SSc. It is a synthetic, oral, non-immunosuppressive small molecule. Anabasum had acceptable safety and tolerability and showed evidence of clinical benefit in diffuse cutaneous SSc (dcSSc) in Phase 2 trial JBT101-SSc-001 (NCT02465437). The objective of this study was to provide long-term open-label safety and efficacy data in dcSSc subjects who received anabasum in that trial.

**Methods:** Subjects who completed the double-blind placebo-controlled (DBPC) part of JBT101-SSc-001 were eligible to receive anabasum 20 mg BID in an open-label extension (OLE).

**Results:** 36/38 (95%) eligible subjects enrolled in the OLE and 34/36 (94%) were on baseline immunosuppressive drugs. At the time of data cut-off, 1 subject had discontinued from the OLE, the duration of OLE dosing was median 194 days (range 25, 207 days) and total duration of DBPC + OLE dosing with anabasum was median 234 days (range 28, 295 days). All 36 subjects had at least one OLE visit  $\geq$  28 days post baseline. Adverse events (AEs, n = 88) occurred in 28/36 (78%) subjects in the OLE. Most AEs were mild (55/88, 62%) or moderate (30/88, 34%) in severity and unrelated to anabasum (75/88, 85%). The AEs that occurred in  $\geq$  10% of subjects (n, % of subjects) were mild fatigue (5, 14%) and mild/moderate upper respiratory tract infection (4, 11%). Dizziness occurred in 2 (6%) subjects. Only one subject had more than mild or moderate AEs. That subject developed renal crisis 7 days after starting 60 mg/day prednisone prescribed by a non-study physician for suspected temporal arteritis and had 2 severe and 1 life-threatening/serious AEs related to the renal crisis and deemed unrelated to anabasum. In the period between DBPC and OLE off study product (median 50 days, range 5 - 360 days), the modified Rodnan skin score (mRSS) was stable in all subjects, subjects treated with anabasum and

subjects treated with placebo during DBPC dosing (Table 1). After 10 weeks of anabasum treatment in OLE (Visit 3 in OLE), mRSS declined from baseline in these same groups of subjects.

Table 1. Changes in mRSS before and after 10 weeks dosing in OLE

Period	Group	mRSS change from baseline	P, 2-sided paired t test
		Mean (SD)	
Off study drug between DBCP and OLE dosing	All subjects, N = 36	0.1 (4.1)	0.9372
	Subjects previously treated with anabasum, N = 23	0.6 (4.4)	0.5459
	Subjects previously treated with placebo, N = 13	-0.8 (3.6)	0.4106
On anabasum Visit 1 to Visit 3 (10 weeks)	All subjects, N = 29	-3.2 (3.9)	0.0001
	Subjects previously treated with anabasum, N = 20	-2.5 (3.5)	0.0049
	Subjects previously treated with placebo, N = 9	-4.8 (4.5)	0.0128

**Conclusion:** In OLE of Phase 2 trial JBT101-SSc-001, anabasum continues to have acceptable safety and tolerability in dcSSc with no severe or serious AEs or study discontinuations related to anabasum. The mRSS improved, although open-label nature of dosing with anabasum is acknowledged. These data support further testing of anabasum for treatment of dcSSc.

## Performance of the American College of Rheumatology Provisional Composite Response Index in Systemic Sclerosis (CRISS) in the Scleroderma Lung Study-I

**Dinesh Khanna**<sup>1</sup>, Donald P. Tashkin<sup>2</sup>, Holly Wilhalme<sup>2</sup> and Chi-hong Tseng<sup>3</sup>, <sup>1</sup>University of Michigan, Ann Arbor, MI, <sup>2</sup>University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA, <sup>3</sup>Medicine, University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The CRISS has been proposed as a composite outcome measure for trials in systemic sclerosis<sup>1</sup>. CRISS is a 2-step process that assigns a probability of improvement for each individual patient on 0.00 [no improvement] to 1.00. Step 1 assesses clinically meaningful decline in cardio-pulmonary-renal involvement (based on consensus expert opinion) and assigns a probability of 0.00. For remaining subjects who do not experience a clinically meaningful decline, 5 variables are used over 12 months to calculate probability of improvement. These are: FVC%, mRSS, patient and physician global assessments (MD GA), and HAQ-DI. Scleroderma Lung Study-I compared oral daily cyclophosphamide (CYC) vs. placebo (PLA) in subjects with SSc-ILD<sup>2</sup>, which showed modest efficacy favoring CYC at 12-month but greater improvements in patient-reported outcomes. Our objective was to assess if CRISS index can discriminate CYC from PLA in the SLS-I over 12 months.

**Methods:** We used patient-level data for this analysis. For Step 2, MD GA was not assessed in the SLS-I. Therefore, linear regression model was developed to predict MD GA from variables which were similar between the original CRISS cohort and SLS-I. Stepwise regression (using maximum  $R^2$  method) was used to identify the best prediction model for MD GA and applied to the SLS-I data. We compared the CYC vs. PLA for the whole population and for the diffuse cutaneous SSc using the Wilcoxon rank-sum test for CRISS and Student's t-test for individual variables. In addition, we explored the proportion of subjects who had a probability score  $\geq 0.60$ <sup>1</sup> and compared the 2 groups using Chi-square.

**Results:** The mean (SD) baseline disease duration was 3.2 (2.1) years; 59% had diffuse cutaneous SSc. The prediction model for MD GA included the FVC (at baseline and 12 month change), mRSS (at baseline and 12 month change), gender, disease duration, and joint contractures (  $R^2$  of 0.44).

For Step 1, the definition of worsened cardio-pulmonary-renal involvement was met by 9 in CYC vs. 13 in PLA and were given a CRISS score of 0.0. For the remaining subjects, [60 in CYC and 52 in PLA], we applied Step 2. Using the CRISS as a continuous measure, CYC was statistically superior to PLA for the whole group ( $p=0.007$ ) and diffuse SSc ( $p=0.002$ ; Table). Lack of administration of MD GA in the trial is a limitation of this analysis.

**Conclusion:** In this post-hoc analysis using individual data from SLS-I, CRISS is able to discriminate CYC from PLA, supporting its validity in an independent cohort.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic sclerosis (SSc) autoantibodies (aAbs) are invaluable for SSc diagnosis and prognosis. Anti-centromere (ACA), anti-topoisomerase I (ATA) and anti-RNA polymerase III (RNAP) have been incorporated into SSc classification criteria, whereas anti-Th/To is much less commonly tested. Meanwhile, newly discovered anti-BICD2 seems particularly interesting in predicting milder SSc.

Our goal was to characterize the aAb profile in French Canadian SSc patients and its correlation with clinical features, nailfold capillaroscopy (NCM) findings and survival rates.

### **Methods:**

Biobanked sera obtained at first visit from 303 SSc patients were tested for SSc aAbs by indirect immunofluorescence, ELISA and immunoblotting. Clinical data and NCM findings at first visit were compared by aAb subsets. Survival status and causes of death were extracted from a previous study (1). Survival was estimated by Kaplan Meier analysis and additional predictors for mortality were identified.

### **Results:**

In the 303 patients, aAb prevalence was: ACA 35% (n=145), ATA 10% (31), anti-Th/To 7% (21), anti-RNAP 4% (12) and anti-BICD2 8.9% (27). All anti-BICD2+ patients were also ACA+ and 96% had limited cutaneous SSc (lcSSc). Only the presence of puffy fingers was more prevalent in anti-BICD2+ patients compared to other ACA+ patients (37% vs 19% respectively, p=0.04). Diffuse cutaneous SSc (dcSSc) was most prevalent in ATA+ (20%) and anti-RNAP+ (68%) patients. Pulmonary fibrosis was more strongly associated with ATA than other aAbs (26% vs 9%, p=0.01). On NCM, anti-RNAP+ patients presented earlier capillary dilations after disease onset than other SSc patients (median interval 0.8 years vs 2 years, p=0.03).

Overall, 32 SSc related deaths occurred after a mean ( $\pm$  SD) of 9.8 ( $\pm$  4.5) years following diagnosis. Risk factors associated with mortality were dcSSc (OR 2.6, CI 1.3-6.7), lung fibrosis (OR 5.5, CI 2.2-13.6), and anti-SSA/Ro presence (OR 2.5, CI 1.1-5.8). Kaplan Meier analysis of SSc related deaths showed that only ATA+ patients had a significantly lower cumulative 15 year survival rate (58%) (Fig. 1, log rank p=0.03), whereas survival was similar between other aAb subsets, including anti-BICD2.

### **Conclusion:**

These data reaffirm and expand the importance of SSc related aAbs as prognostic markers. ATA are associated with dcSSc, lung fibrosis and worst survival in comparison to other SSc aAbs. Anti-BICD2 was always associated with ACA. The latter were both strongly associated with lcSSc and had similar survival rates. The only difference was an increased prevalence of puffy fingers in anti-BICD2+ patients.

## Symptoms of Autonomic Dysfunction in Systemic Sclerosis Assessed By the Compass-31 Questionnaire

**Brittany Adler**<sup>1</sup>, James Russell<sup>2</sup>, Laura K. Hummers<sup>3</sup> and Zsuzsanna McMahan<sup>4</sup>, <sup>1</sup>Rheumatology, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Neurology, Anatomy and Neurobiology, University of Maryland School of Medicine, Baltimore, MD, <sup>3</sup>Medical and Rheumatology, Johns Hopkins University, Baltimore, MD, <sup>4</sup>Department of Internal Medicine, Johns Hopkins University, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Autonomic dysfunction is a known complication of systemic sclerosis (SSc) and can affect vascular tone, gastrointestinal (GI) motility, and heart rate and blood pressure control. We sought to quantify autonomic symptom burden in a large cohort of patients with SSc and to determine clinical and serologic risk factors that associate with autonomic symptom burden.

### Methods:

Patients with SSc were recruited from the Johns Hopkins Scleroderma Center and completed the Composite Autonomic Symptom Score (COMPASS)-31 questionnaire, which is a validated tool to measure autonomic symptom burden. The COMPASS-31 scores and subdomain scores in orthostatic, secretomotor, vasomotor, gastrointestinal, urinary, and pupillomotor dysfunction were quantified for each patient. Demographic information, clinical and serologic data, and Medsger disease severity scores were obtained from the longitudinal Johns Hopkins Scleroderma Center database. We analyzed the relationship between various features of systemic sclerosis and the total COMPASS-31 scores and subdomain scores using the student's t-test for dichotomous variables and linear regression analysis for continuous variables.

## Results:

104 patients with SSc completed the COMPASS-31 questionnaire. The average COMPASS-31 score among our SSc cohort was  $24.9 \pm 15.5$ , which was comparable to previously published scores in other diseases known to affect the autonomic nervous system such as small-fiber polyneuropathy. There was no relationship between the COMPASS-31 score and SSc subtype or autoantibody status. Patients with severe GI disease reported higher scores in multiple subdomains of the COMPASS-31, including orthostatic intolerance ( $p=0.006$ ) and secretomotor dysfunction ( $p=0.03$ ), compared to patients with mild or absent GI disease. There was also a dose-response relationship between GI disease severity and autonomic symptom burden (see Figure).

## Conclusion:

We determined that patients with SSc have a significant burden of autonomic symptoms across multiple domains of autonomic function. All patients with SSc are at risk for autonomic symptoms regardless of SSc subtype or autoantibody status. We also determined that patients with severe GI disease have more symptoms of dysautonomia, which suggests that some of the GI disease in systemic sclerosis may be a cause or consequence of autonomic dysfunction.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Prospective Registry of Early Systemic Sclerosis (PRESS), an 11 center US cohort study of early diffuse cutaneous systemic sclerosis (dcSSc) patients, was designed to study dcSSc pathogenesis and patient response to treatments. Modified Rodnan skin score (mRSS), used to quantify skin severity, correlates with mortality. The study purpose was to identify a serum signature associated with dcSSc and correlated with mRSS.

**Methods:** Baseline serum samples and clinical data were collected from PRESS subjects at enrollment and healthy matched controls. Subjects met SSc ACR criteria, had early dcSSc (defined as < 2 years duration since first non-Raynaud symptom attributed to SSc; swollen hands or sclerodactyly; PLUS 1 or more of the following: present anti-topoisomerase I or anti-RNA polymerase III serum autoantibodies; proximal skin involvement; tendon friction rubs). Samples were subjected to a custom Multi-Analyte Profiles (MAP) that uses multiplexed ELISA for serum protein quantification. Analytes with >40% missing values were excluded. The fold-change in protein expression between early dcSSc versus control samples was calculated. A t-test was used to test for statistical significance with correction for multiple hypothesis testing using the Benjamini-Hochberg method. mRSS was fitted to a linear model to assess for correlation with protein expression.

**Results:** Characteristics of dcSSc patients and controls were summarized (Table 1). Of 109 analytes, 28 analytes with missing values were excluded, leaving 81 analytes for analysis. 45 proteins were differentially expressed between early dcSSc patients and controls at baseline (q-value <0.05, Table 2). ANG-2, IGFBP-2, MIP-3 beta, TNFR2 and myoglobin had >2 fold-change in dcSSc patients vs. controls (Fig 1). 106 out of 112 (95%) dcSSc patients had baseline mRSS values. C-reactive protein correlated with mRSS (Fig 1).

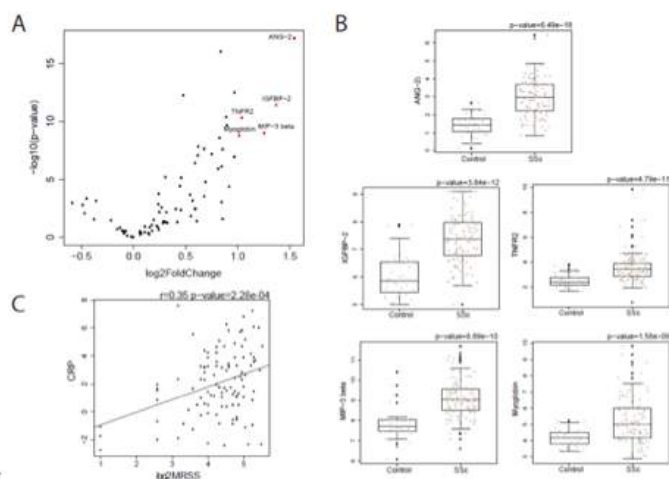

**Conclusion:** We identified 45 proteins with variable expression between early dcSSc patients and healthy controls. Further, we identified that C-reactive protein expression correlates with mRSS severity, which has also been shown to be associated with lung disease progression. Future work includes developing a mRSS-predictive model by studying changes in protein expression in patients with longitudinal mRSS.

**Table 1:** Discovery cohort clinical characteristics.

Mean (SD) or as indicated	Control subjects N=32	Early dcSSc subjects N=112
Age, years	47(14)	49.5 (14.9)
Sex (% female)	65.6	67.9
Ethnicity (% Caucasian)	75	67.9
SSc disease duration(from first non-Raynaud)	NA	15.3
Anti-topoisomerase I (Scl-70), n (% positive)	NA	29 (32.2%)
Anti-RNA Polymerase III, n (% positive)	NA	43 (49.4%)
Baseline mRSS	NA	22.7 (10.4)

Protein analytes	Fold Change	p-value	q-value
<b>Up-regulated</b>			
Angiopoietin-2 (ANG-2)	2.92	6.49E-18	5.26E-16
B cell-activating factor (BAFF)	1.96	3.15E-13	8.51E-12
Insulin-like Growth Factor-Binding Protein 2 (IGFBP-2)	2.59	3.84E-12	6.22E-11
Tumor necrosis factor ligand superfamily member 13 (APRIL)	1.86	4.26E-11	5.54E-10
Tumor necrosis factor receptor 2 (TNFR2)	2.06	4.79E-11	5.54E-10
Matrix Metalloproteinase-7 (MMP-7)	1.87	2.16E-10	2.18E-09
Macrophage inflammatory protein 3 beta (MIP-3 beta)	2.39	9.89E-10	8.90E-09
Myoglobin	2.03	1.58E-09	1.28E-08
Monocyte Chemoattractant Protein 1 (MCP-1)	1.96	1.15E-07	5.47E-07
Interferon gamma Induced Protein 10 (IP-10)	1.89	4.35E-05	1.41E-04
<b>Down-regulated</b>			
Adiponectin	0.67	1.12E-03	2.75E-03
Brain-Derived Neurotrophic Factor (BDNF)	0.78	7.20E-04	1.88E-03
Myeloperoxidase (MPO)	0.72	8.63E-03	1.63E-02
Thrombospondin-1	0.71	1.69E-03	3.90E-03
Vitronectin	0.73	4.71E-04	1.31E-03

**Table 2.** Proteins with differential expression in early dcSSc patients vs. healthy controls. 45 proteins were differentially expressed between early dcSSc patients and controls at baseline (q-value <0.05). Included are the top 10 upregulated and 5 downregulated proteins. Differential protein expression is expressed in terms of fold-change; for example, a fold-change of 1 correlates to protein expression that is two times greater in early dcSSc patients vs. controls whereas a fold-change of 0.5 correlates to protein expression in early dcSSc patients that is half as much as compared to controls.

**Figure 1:** A: Volcano plot demonstrating differential protein expression in early dcSSc patients versus healthy controls. Samples highlighted in red include those with a FDR adjusted p-value <0.05 and a fold change  $\geq 2$ . B: Box plots demonstrating differential protein expression in healthy controls versus early dcSSc patients for proteins with a FDR adjusted p-value <0.05 and a fold change  $\geq 2$ . C: Scatter plot demonstrating the correlation between C-reactive protein and mRSS severity ( $r=0.35$ ,  $p$ -value=0.0002). Black line was fit to the data linearly.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Serum antibodies are used to identify SSc patients who may be at higher risk for SSc-PH. The Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) Registry cohort followed SSc-PH patients. We assessed the validity of prior reports of association between serum antibodies and PH using data from PHAROS and the Northwestern Scleroderma Registry (NW).

**Methods:** Antibody data were compared between PHAROS and NW subjects (mPAP  $\geq$ 25 mmHg on right heart catheterization). World Health Organization PH group (pulmonary arterial hypertension/PAH=Group 1, pulmonary venous hypertension/PVH=Group 2, and PH-interstitial lung disease/PH-ILD=Group 3) was determined. The association between antibodies and PH was studied using two approaches: 1) antibody distribution was compared between PHAROS and NW PH subjects; 2) antibody distribution was compared between combined PHAROS and NW PH (in total and by WHO group) and NW subjects without PH. Chi-square or Fisher's exact tests were used for comparisons.

**Results:** Clinical characteristics were similar for 326 PHAROS subjects and 768 NW Registry subjects, 84 with PH (Table 1). There were significant differences in antibodies between PHAROS and NW subjects,  $p=0.005$  (Table 1). When the PH groups were combined ( $n=410$ ) and compared to NW subjects without PH ( $n=684$ ), the antibodies between the groups were significantly different,  $p<0.0001$  (Table 2). Subjects in the PH group had a higher percentage of isolated nucleolar antibodies (21%) compared to the NW subjects (8%). Similar percentages of ACA were found in both groups (28% for the PH group and 27% for the NW subjects without PH). When the subclassifications of PH groups were examined, the percentage of isolated nucleolar antibodies remained high in all 3 groups.

**Conclusion:** Isolated nucleolar serum antibodies were more prevalent in PH subjects compared to non-PH NW subjects. When the PH groups were examined separately, higher percentages of isolated nucleolar antibodies remained in all 3 groups. Similar percentages of ACA were found in both the PH group and NW subjects without PH, suggesting that isolated nucleolar antibodies may be a more specific marker for PH than ACA. Screening for isolated nucleolar antibodies may help to identify patients with SSc who are at higher risk for developing PH.

**Table 1:** Clinical characteristics and serum autoantibody distribution between PHAROS and NW subjects

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

No data are available to distinguish between progressive and stable patients when mild lung fibrosis is diagnosed in systemic sclerosis (SSc) patients. This study aimed to identify clinical and laboratory parameters that can predict the progression of interstitial lung disease (ILD) within 1 year in patients with mild SSc-ILD.

## Methods:

Data prospectively collected in our local SSc cohort were analyzed in this observational study. Inclusion criteria were: diagnosis of SSc fulfilling ACR/EULAR 2013 criteria, diagnosis of ILD by HRCT, < 20% lung involvement extent on HRCT at the first visit (baseline), available HRCT and pulmonary function tests at baseline and annual follow-up visits (12±3 months), no concomitant with PAH.

The primary endpoint, progression of ILD was defined if any of the following parameters was fulfilled : > 20% extent of lung involvement on HRCT at any follow-up visit, decrease in FVC ≥15% within 1 year, or decrease in FVC ≥ 10% and DLCO ≥ 15% within 1 year.

Candidate predictors for logistic regression were selected by expert opinion based on clinical consideration. Receiver Operating Characteristic (ROC) curve analysis was performed to determine the optimal cut-off value for each significant continuous parameter.

## Results:

From the 81 patients included, 25 (30.9%) had progression of ILD. Differences of parameters between progressors and non-progressors were analyzed by univariate analysis (Table 1).

Three candidate predictors reflecting the overall disease severity including worst SpO<sub>2</sub> during 6-minute walk test (6MWT), arthritis ever and modified Rodnan skin score (mRSS) were selected for logistic regression by expert opinion. The final regression model identified worst SpO<sub>2</sub> (p=0.011, OR: 0.78, 95% CI 0.64 to 0.94) and arthritis ever (p=0.002, OR: 7.15, 95% CI 2.01 to 25.48) as independent predictors. The ROC curve analysis identified the best cut-off value for worst SpO<sub>2</sub> as 94% (area under the curve: 0.78, sensitivity 0.667, specificity 0.857).

By employing combination of both predictors, the prediction model increased the prediction success rate from 30.9% in the whole cohort to 100% in the optimized enrichment cohort (Table 2).

## Conclusion:

Our study identified exercise-induced SpO<sub>2</sub> decline and arthritis ever as independent predictor of progression of mild SSc-ILD within 1 year. The derived evidence-based prediction model might be helpful for the risk stratification of this subgroup in clinical practice and cohort enrichment for future clinical trial design.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Previously, we have identified short disease duration ( $\leq 15$  months) and low baseline modified Rodnan skin score (mRSS) ( $\leq 22/51$ ) as independent predictors of progressive skin fibrosis ( $>5$  mRSS units and  $\geq 25\%$  increment within 1 year) in patients with diffuse cutaneous systemic sclerosis (dcSSc). While this strategy has resulted in recruitment of more patients with progression of skin fibrosis in clinical trials, it might lead to recruitment of patients with less severe internal organ disease. This study was designed to determine whether progression of skin fibrosis is associated with progression of internal organ disease on longitudinal follow-up of patients with dcSSc.

## **Methods:**

This study analyzed prospectively collected data from the EUSTAR cohort. Inclusion criteria were: diagnosis of SSc fulfilling ACR criteria, diffuse cutaneous involvement, mRSS  $\geq 7$  at baseline visit in 2009 or later, valid mRSS with a time interval of  $12 \pm 3$  months after baseline visit, and at least one available annual follow-up visit.

Progression of skin fibrosis was defined as an increase in mRSS  $>5$  units and  $\geq 25\%$  from baseline to  $12 \pm 3$  months later. The outcome was defined as one of the following new events occurring at any follow-up visit based on expert group consensus: 1) renal crisis; 2) decrease in forced vital capacity (FVC)  $\geq 10\%$ ; 3) left ventricular ejection fraction (LVEF)  $<45\%$  or decrease in LVEF by  $>10\%$  for patients with baseline LVEF  $<50\%$ ; 4) pulmonary hypertension (PH) on echocardiography as judged by the investigator; 5) death.

Kaplan–Meier analyses and log-rank tests were used to compare disease progression between progressors and non-progressors for up to 6 years of follow-up.

## **Results:**

A total of 871 dcSSc patients were eligible. The median follow-up period was 3.26 years (IQR: 1.49–5.14). Sixty-seven (7.7%) patients had worsening of skin fibrosis within 1 year (defined as progressors). Cumulatively, 235/666 (35.3%) patients had a decrease in FVC  $\geq 10\%$ , 96/593 (16.2%) had new PH, 22/564 (3.9%) had worsening LVEF, 16/844 (1.9%) had a new renal crisis, and 58/871 (6.7%) died. Mean FVC% at baseline was  $87.2\% \pm 20.4\%$ , while 134 (20.1%) patients had baseline FVC%  $<70\%$ .

Log-rank tests indicated the probability for a decrease in FVC  $\geq 10\%$  was significantly higher for progressors than non-progressors (53.2% vs. 33.9%,  $p=0.004$ ) (Figure). There were non-significant differences in probabilities for new PH (9.5% vs. 16.7%), worsening LVEF (7.3% vs. 3.6%), new renal crisis (0.0% vs. 2.1%) and death (7.5% vs. 6.6%) between progressors and non-progressors.

## **Conclusion:**

Progression of skin fibrosis is associated with a decline in lung function in dcSSc patients over follow-up. Our data indicate that evidence-based criteria for cohort enrichment of progressive skin fibrosis might also be appropriate to recruit more

dcSSc patients at higher risk of lung function decline in future clinical trials.

## Ethnic Variation in Systemic Sclerosis Morbidity and Mortality

**Sindhu Johnson**<sup>1</sup>, Zareen Ahmad<sup>2</sup> and Haifa Al Sheikh<sup>3</sup>, <sup>1</sup>Division of Rheumatology, Toronto Western Hospital, Mount Sinai Hospital, Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Toronto Scleroderma Program, Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is an uncommon connective tissue disease characterized by pathological skin thickening and can involve multiple internal organs. Ethnic variations in SSc have been reported in clinical manifestations, severity of the disease as well as survival. Our aim was to compare the survival and disease manifestations across ethnicity among SSc patients.

**Methods:** The Toronto Scleroderma Program is the largest single-center, multiethnic, longitudinal SSc cohort in Canada. Patients are followed every 6 to 12 months using a standardized protocol. Patients who fulfilled the American College of Rheumatology-European League Against Rheumatism classification criteria for SSc and are 16 years of age or older were included in our retrospective cohort study. The study period was 1970–2017. Ethnicity was self-reported and was categorized as: Caucasian, African-American, Hispanic, Arab, East-Asian, First Nations or Persian. The primary outcome was the time from diagnosis to death from all causes. Secondary outcomes were differences in disease duration, SSc subtype, clinical manifestations, and serology. Survival probabilities and median survival times were determined using Kaplan-Meier survival curves. Cox proportional hazard models were used to estimate adjusted survival.

**Results:** 1005 subjects were evaluated, the majority of whom were Caucasian (n=745 (74%)), African-American n=58 (6%)), South Asian (n=69 (7%)), and East Asian (n=80 (8%)). Compared to Caucasians, East Asians less frequently had calcinosis (29% versus 9%, p=0.002), and esophageal dysmotility (88% versus 69%, p=0.002); African-Americans more frequently had interstitial lung disease (31% versus 53%, p=0.007); and First Nation subjects more frequently had diffuse cutaneous disease (35% versus 56%, p=0.02) and diabetes (5% versus 33%, p=0.03). There were no differences across ethnicities in the prevalence of pulmonary hypertension, renal crisis, or digital ulcers.

We found no difference in the short-term survival across ethnicities. However, in the long-term, there was trend for Hispanic subject to have better survival (81.3% (95%CI 63, 100)), while First Nations (58.3% (95%CI 25, 100)) and South Asian subjects (52.6% (95%CI 32, 87)) had worst survival at 15 years and 20 years, respectively. East Asians appear to have the longest median survival time 43.3 years.

**Conclusion:** Ethnic variations in disease SSc disease manifestations are observed. However, in the setting of a universal health care system, this does not result in significant differences in survival.

**Disclosure:** S. Johnson, None; Z. Ahmad, None; H. Al Sheikh, None.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The CRISS is a composite index of response in diffuse cutaneous systemic sclerosis (dcSSc). It is a 2-step process for the probability of improvement ranging from 0.0 (no improvement) to 1.0. Patients with decline in cardio-pulmonary-renal involvement are assigned score 0.0 in step 1. All remaining subjects are scored for improvement in FVC, mRSS, patient (PT GA) and physician globals (MD GA), and HAQ-DI.

Two independent studies including in total 464 patients from 6 different centres have shown that skin, lung and overall fibrosis correlate with three serum biomarkers (Procollagen III N terminal pro-peptides (PIIINP), Tissue inhibitor of Metalloproteinase I (TIMP-1) and Hyaluronic Acid (HA)), either singularly or combined in the ELF Test algorithm. Here we aimed to determine whether CRISS correlated with the serum concentration of one or more of the ELF biomarkers and explore the scope to build a combined score with better performance in measuring the probability of clinical response in dcSSc.

**Methods:** 31 Consecutive dcSSc patients were included in the study at a single centre. Clinical data and serum were collected at baseline, at 12 and 24 months. CRISS and ELF score were calculated at the same time points. CRISS scores were calculated using the published formula and we assessed correlation coefficients between CRISS scores and biomarkers. Comparison between two groups and correlation were performed using Mann-Whitney and Spearman's tests, respectively.  $P < 0.05$  was considered statistically significant. Statistical analysis was carried out using GraphPad Prism Version 7.

**Results:** Thirty-one dcSSc patients were enrolled (12 M; mean age=50.3  $\pm$  11.5). CRISS at 12 months was 0% in 19 patients, whereas in the remaining 12 patients it ranged from 0.1 to 1.0 (median=0.35). Five out of the 12 CRISS "responders" had a CRISS 24-12  $> 0.0$ , the remaining 7 had no further response (CRISS=0). Overall CRISS 24-0 was  $> 0.0$  in 16 patients (median=0.065, range=0.01-0.93). No clinical features at baseline were significantly different in the responders vs non responders at 12 or 24 months, including mRSS, FVC%, DLCO%, autoantibody profile, age, disease duration, Medsger Severity Score and CRP ( $P > 0.05$  for all). TIMP-1 concentration at baseline was significantly lower in patients with CRISS  $> 0$  vs. CRISS=0 (218.5 vs 265.9 respectively,  $p = 0.03$ ), similar trend was observed for TIMP-1 at 12 months and CRISS 24 months. Accordingly TIMP-1 at baseline or 12 months statistically significant correlation with CRISS 24 months ( $R = -0.389$  and  $-0.374$ , respectively;  $p < 0.05$  for both).

**Conclusion:** This is the first evaluation of CRISS in an observational setting. Although limited by single centre setting and low number, we show that in any 12 months interval a proportion between 38 and 51% of patients show a CRISS >0. Whereas only 6 to 22.5% of patients showed a CRISS>0.10. None of the routinely used clinical parameters can predict CRISS at 12 months whereas TIMP-1 concentration at baseline is significantly lower in the responders. This needs to be explored in additional cohorts and opens the possibility to include serum biomarkers of fibrogenesis within a combined response index for Systemic Sclerosis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Pulmonary arterial hypertension (PAH) is one of the leading death causes in SSc patients. To gain a better prognosis, screening methods are needed to provide an early diagnosis and intervention. The DETECT algorithm is a highly sensitive tool, however it presents a very low positive predictive value. To reduce the number of unnecessary right heart catheterizations (RHC), we evaluated the predictive performance of cardiopulmonary exercise testing (CPET) in a DETECT positive SSc population.

### Methods:

Two-hundred-fifty-eight adult SSc consecutive patients attending our Scleroderma Unit were considered. Among those, the DETECT algorithm was applied to the subjects responding to the application criteria (ACR criteria for SSc, DLco < 60%, disease duration ≥ 3 years). DETECT positive patients underwent CPET and RHC. CPET was performed on a COSMED Quark-B2 equipment, on a cycle ergometer with an incremental work rate between 5 and 15 watts per minute up to the patients' maximum tolerance.

Pearson's correlation was used to evaluate linear associations between CPET parameters and mean pulmonary pressure (mPAP); the difference between PAH vs non-PAH patients for the best parameter was assessed by means of Student's t-test. Finally, the sensitivity/specificity trade-off of this parameter was evaluated by ROC analysis.

## Results:

The enrolment flow chart is reported in Figure 1. Overall 81 patients were eligible for DETECT screening, 39 were positive and underwent CPET and RHC (Figure 1). The patients' clinical characteristics are reported in Table 1. RHC found 12 cases of PAH (30.7%), 1 case of PH due to left heart disease (2.6%) and non-PH in 26 subjects (66.7%).

We found the following significant correlation:

- mPAP-PetCO<sub>2</sub>@lt (r 0.74, p 0.7\*10<sup>-7</sup>)
- mPAP-VE/VCO<sub>2</sub>@lt (r 0.8, p 0.1\*10<sup>-8</sup>)
- mPAP-VE/VCO<sub>2</sub> slope (r 0.85, p 0.7\*10<sup>-11</sup>)

The VE/VCO<sub>2</sub> slope was selected for further investigation.

VE/VCO<sub>2</sub> slope statistically differed between PAH and non-PAH patients (mean ± DS: 45.5 ± 4.95 vs 35.11 ± 5.04; p 0.5\*10<sup>-5</sup>). ROC analysis showed a remarkable performance of the VE/VCO<sub>2</sub> slope in detecting PAH in the DETECT population (AUC 0.955, p 0.7\*10<sup>-5</sup>). A single cut-point value equal to 38.5 of the VE/VCO<sub>2</sub> slope was capable of discriminating PAH and non-PAH patients with a 100% sensitivity and 82% specificity.

## Conclusion:

This study shows that CPET can fruitfully be applied to patients screened with the DETECT improve its specificity. The VE/VCO<sub>2</sub> slope determination allows to significantly reduce the number of useless invasive RHC (from 39 to 17), without increasing missed diagnosis rate.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** N-Terminal pro-brain natriuretic peptide (NT-proBNP) level tends to correlate with myocardial wall stress and/or myocardial damage (fibrosis). Hence, it has been promoted as a potential biomarker to support the diagnosis of pulmonary arterial hypertension (PAH) and help monitor its severity, progression, and response to therapy. A

previous study has noted disproportionately elevated serum NT-proBNP levels among patients with scleroderma associated PAH (SSc-PAH) compared to similar patients with idiopathic PAH (iPAH).<sup>1</sup> Our goal was to (1) verify the above results using a much larger cohort of SSc-PAH and iPAH patients, and (2) to identify possible explanations for this phenomenon.

**Methods:** A retrospective chart-review was conducted comparing demographic, laboratory, and hemodynamic [echocardiographic and right heart catheterization (RHC)] data from a total of 862 patients (686 with iPAH and 176 with SSc-PAH) enrolled in the Cleveland Clinic Pulmonary Hypertension Database. The diagnosis of PAH was confirmed by RHC, and the diagnosis of SSc was confirmed by a rheumatologist. NT-proBNP levels were measured at the time of the patient’s first RHC, which was also considered to be the time of PAH diagnosis. Mean pulmonary artery pressure (mPAP) and pulmonary vascular resistance (PVR) [data from RHC] and estimated right ventricular systolic pressure [data from transthoracic echocardiogram] were collected in both SSc-PAH and iPAH patients. A multivariate linear regression with a disease x log(NT-proBNP) interaction term was performed.

Factor	Total (N=862)	Idiopathic PAH (N=686)	Scleroderma Associated (N=176)	p-value
Pulmonary Vascular Resistance (Wood unit)*	9.3±6.1	9.7±6.3	8.0±5.2	<b>0.002<sup>a</sup></b>
Mean Pulmonary Artery Pressure (RHC)*	49.1±14.7	50.9±14.8	42.3±11.8	<b>&lt;0.001<sup>a</sup></b>
Right Ventricular Systolic Pressure*	75.3±24.6	76.5±24.9	71.1±23.2	<b>0.012<sup>a</sup></b>
NT-proBNP Level*	680.0 [232.0,2621.0]	619.0 [202.0,2513.0]	1079.5 [381.0,4099.0]	<b>0.013<sup>b</sup></b>
log(NT-proBNP)*	6.6±1.7	6.5±1.6	7.1±1.6	<b>0.010<sup>a</sup></b>

\*Data not available for all subjects. Missing values: Pulmonary Vascular Resistance = 89, Mean Pulmonary Artery Pressure = 9, Right Ventricular Systolic Pressure, TTE = 93, log(NT-proBNP) = 557, NT-proBNP Level = 557.  
 Statistics presented as Mean ± SD, Median [P25, P75], Median (min, max) or N (column %).  
 p-values: a=ANOVA, b=Kruskal-Wallis test, c=Pearson's chi-square test, d=Fisher's Exact test.

**Results:** In our cohort, at the time of first RHC, SSc-PAH patients were noted to have significantly higher NT-proBNP levels, yet much lower PVR and mPAP readings compared to similar iPAH patients. Also, there was a significant, positive correlation between NT-proBNP levels, mPAP, and PVR only in SSc-PAH patients, but not in iPAH patients.

**Conclusion:** One plausible explanation for higher NT-proBNP levels in SSc-PAH patients is intrinsic subclinical myocardial damage from SSc-induced fibrosis (which does not occur in early iPAH), in addition to right ventricular wall stress resulting from the occlusive pulmonary vasculopathy.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Pulmonary hypertension (PH) contributes substantially to systemic sclerosis (SSc)-related morbidity and mortality. It tends to develop later in the disease, creating an opportunity for early risk stratification.

Previously published prediction models for PH have been based on cross-sectional data.

We set out to develop a model predicting PH development within 12 months, accounting for disease duration and utilising time-updated clinical characteristics, including serial measurements of lung function. We compare the use of most recent lung function results and serial changes in lung function over the preceding 4 years.

### **Methods:**

We used data from a large unselected longitudinal cohort of SSc patients.

Sequential survival analyses with origins set at 6 consecutive landmark (LM) time-points, 12 months apart, starting at 60 months from disease onset were performed. The predictor variables included time-invariant characteristics (sex, subset and autoantibodies) and LM-specific information (age, presence of organ disease, FVC and DLCO, % predicted). Time to PH from the LMs was calculated with censoring at 12 months. Analyses were combined using a stratified Cox proportional hazards model, with each LM representing a stratum.

### **Results:**

The study cohort consisted of 652 SSc patients. Of those 41.3% had diffuse SSc, 14.9% were male and the average age at disease onset was 48 years. Most patients (96%) either died during follow-up or were followed for over 10 years from disease onset. At the end of follow-up 13.3% of the subjects had developed PH.

The two final multivariable models both included the values at LM of age, presence of pulmonary fibrosis (PF) and antibody specificities (anti-U3RNP and anti-RNA polymerase (ARA)). Model 1 used most recent DLCO values, while Model 2 incorporated patient-specific intercept and slope of DLCO change over the 4 years prior to the LM (Table 1).

Both models were very similar, demonstrating that older age, ARA and anti-U3RNP positivity increase the hazard for PH development. Lower DLCO, both included as most recent measurement and as intercept and slope for the serial change in DLCO over the 4 years prior to LM, predicted increased hazard for PH. This effect was attenuated by presence of clinically-significant PF. None of the estimated effects varied between LM strata.

The two models had very similar fit and discrimination performance with C-index=0.88 for the model with most recent DLCO and C-index=0.87 for the one using intercept and slope for the linear change in DLCO.

### **Conclusion:**

Our results show that comparatively simple models, using only information on age, autoantibodies and serial DLCO assessments could be used for risk stratification and prediction of PH development with good discriminating ability. After validation, this model could be used in clinical practice or for cohort enrichment in clinical trials.

### **Table 1. Comparison of the two prediction models for PH development**

	<i>Model 1</i>		<i>Model 2</i>	
	HR (95% CI)	p-value	HR (95% CI)	p-value
Anti-RNA polymerase antibody	4.9 (1.91, 12.56)	0.001	4.81 (1.87, 12.35)	0.001

## Prospective Validation of the Systemic Sclerosis Skin Symptoms Patient-Reported Outcome (SSPRO) in a Phase 2 Trial of Anabasum (JBT-101) in Diffuse Cutaneous Systemic Sclerosis (dcSSc)

Ada Man<sup>1</sup>, Nancy Dgetluck<sup>2</sup> and Barbara White<sup>3</sup>, <sup>1</sup>Rheumatology, University of Manitoba, Winnipeg, MB, Canada, <sup>2</sup>Biostatistics, Corbus Pharmaceuticals, Norwood, MA, <sup>3</sup>Corbus Pharmaceuticals, Inc., Norwood, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Skin thickening is the defining manifestation of dcSSc. A dcSSc patient's assessment of their skin involvement can provide information about how that patient feels and functions in response to treatment. No skin-specific patient-reported outcome (PRO) measure has been prospectively validated in dcSSc in a clinical trial.

**Methods:** SSPRO is a validated PRO measure that assesses health-related quality of life (HRQOL) related to skin involvement in SSc. It has 18 items representing 4 HRQOL scales: physical effects, emotional effects, physical function, and social effects. All items are scored from 0 (better) to 6 (worse). Anabasum is a preferential cannabinoid receptor type 2 agonist that was tested for safety and efficacy in dcSSc in a double-blind randomized placebo-controlled Phase 2 trial (JBT101-SSc-001). Efficacy outcomes included the SSPRO, Patient Global Assessment (PtGA), HAQ-DI, Physician Global Assessment (MDGA), modified Rodnan Skin Score (mRSS), and FVC % predicted. SSPRO baseline scores were correlated with other baseline outcome scores using Pearson's Correlation Coefficient. Internal consistency was estimated using Cronbach's  $\alpha$ . Effect size (ES, ratio of mean change in SSPRO total score from baseline to 12 weeks, to the standard deviation of the total score at baseline) was calculated to assess the SSPRO's responsiveness to change.

**Results:** SSPRO was administered to 41 subjects with dcSSc. Internal consistency was high for the total (0.87) and for all scale scores (0.92). The SSPRO total and scale scores correlated strongly with PtGA, and moderately with HAQ-DI (except for the emotion scale) showing convergent validity. SSPRO also correlated moderately with MDGA and weakly with mRSS. As expected, SSPRO total and scale scores did not correlate with FVC % predicted, showing divergent validity. The SSPRO total mean score showed a significant difference in anabasum-treated (N = 26) compared to placebo-treated subjects (N = 15) at 12 weeks, LS means difference (SE) = -16.9 (6.0), P = 0.004 ANCOVA. The ES (n = 41) was moderate at -0.51, also demonstrating the SSPRO's responsiveness to change.

Table 1. Correlations of SSPRO with other efficacy outcomes at baseline in a Phase 2 trial of anabasum in dcSSc

Efficacy Outcome	Total Score	Physical Effects	Emotional Effects	Physical Function	Social Effects
PtGA	0.626 <sup>4</sup>	0.506 <sup>3</sup>	0.482 <sup>3</sup>	0.646 <sup>3</sup>	0.573 <sup>4</sup>
HAQ-DI	0.521 <sup>3</sup>	0.500 <sup>3</sup>	0.264	0.592 <sup>4</sup>	0.581 <sup>4</sup>
MDGA	0.514 <sup>3</sup>	0.371 <sup>1</sup>	0.372 <sup>1</sup>	0.543 <sup>3</sup>	0.551 <sup>3</sup>
mRSS	0.445 <sup>3</sup>	0.378 <sup>1</sup>	0.387 <sup>1</sup>	0.338 <sup>1</sup>	0.433 <sup>3</sup>
FVC	-0.315	-0.115	-0.242	-0.165	-0.211

<sup>1</sup> P ≤ 0.05; <sup>2</sup> P ≤ 0.01; <sup>3</sup> P ≤ 0.005; <sup>4</sup> P ≤ 0.0001

**Conclusion:** In this clinical trial dcSSc population, SSPRO showed high internal consistency, construct validity, and responsiveness to change. Moderate and significant correlations of SSPRO scores with PtGA and HAQ-DI scores validate the usefulness of SSPRO as an outcome measure of how the patient with dcSSc feels and functions. Its weaker but still significant and directionally concordant correlations with mRSS shows that the SSPRO may provide additional information on the patient's experience of their skin involvement that the mRSS does not assess. This is the first prospective validation of the SSPRO in a clinical trial.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) represents a heterogeneous autoimmune disease characterized by fibrosis of skin and internal organs. In particular, thickening of the skin, puffy hands, digital ulcers, calcinosis and joint contractures has contributed to disease prognosis by decreasing function of the hand and quality of life. The present study aims to investigate the effectiveness of the hand exercise program and demonstrate its influence on quality of life, as well as anxiety and depression in SSc patients.

**Methods:** Thirty female patients with SSc who fulfilled the 2013 ACR/EULAR classification criteria for systemic sclerosis were included in the study. Patients with neurological disorders, arthritis, myositis, amputation of fingers, serious contracture resisting hand grip and history of undergoing hand surgery were excluded. Patients were randomized into an exercise (n=16) and a control (n=14) group. Each group were informed of their disease and given recommended advice such as avoiding cold and trauma. The exercise group participated in a single hand exercise training applied by a medical doctor. Hereafter, they were given instructions for the home exercise program. The 8-week intervention consisted of isometric hand exercise and self-administered stretching repeated 10 times/2 set of training exercises per a day. Each group's hand functions were assessed by Hand Mobility in Scleroderma (HAMIS) and Duruöz Hand Index (DHI). Additionally, all patients were estimated by Short Form 36 (SF-36), The Health Assessment Questionnaire (HAQ), Beck Anxiety and Beck Depression Inventory. Each group were evaluated at baseline and reassessed after 4 (V1) and 8 (V2) weeks.

**Results:** The baseline demographics and disease characteristics between the groups were similar. When comparing V1 and V2, we established a statistically significant amelioration from baseline measurement of handgrip strength in the exercise group ( $p<0.001$ ). Accordingly, values of HAMIS, DHI, HAQ and Beck Depression Inventory were also significantly improved at V2 ( $p=0.002, 0.001, 0.001, 0.071$ , respectively) (Table). The assessment between the two groups at V1 and V2 indicated significant improvement in the exercise group with respect to the controls.

**Conclusion:** Exercise therapy showed a greater amelioration in the patients' measurements of handgrip strength, quality of life and depression in SSc patients, indicating improvement in their hand function when compared to the control group.

**Table:** Outcome measurement changes in between the two groups at baseline, after 4 week and 8 week.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Altered extracellular matrix (ECM) remodeling leading to fibrosis is a key pathogenic process in systemic sclerosis (SSc). We previously showed that collagen formation and degradation metabolites are deregulated in SSc and that type III collagen turnover could identify progressive patients (1). Here, we report additional longitudinal analysis exploring serological collagen biomarkers potential for diagnosis and prediction of progression of skin and lung fibrosis in SSc.

## Methods:

Patients (n=174) meeting the 2013 ACR/EULAR classification criteria for SSc and age and sex matched healthy controls (HC; n=29) were analyzed. 10% decrease in FVC% predicted or increase in mRSS  $\geq 25\%$  and 5 points at 1 year follow up defined progression. "Stable" were patients not meeting these criteria. Longitudinal clinical assessment and data, and baseline sera collection were conducted by EUSTAR quality standards. Collagen degradation (C3M, C4M2), BGM (MMP-degraded biglycan) and collagen formation markers (P1NP, P4NP7S, PRO-C3, PRO-C5, Pro-C6) were measured in serum by ELISA. Statistical analysis included Mann-Whitney U, Kruskal-Wallis tests, ROC analysis, and binary logistic regression.

## Results:

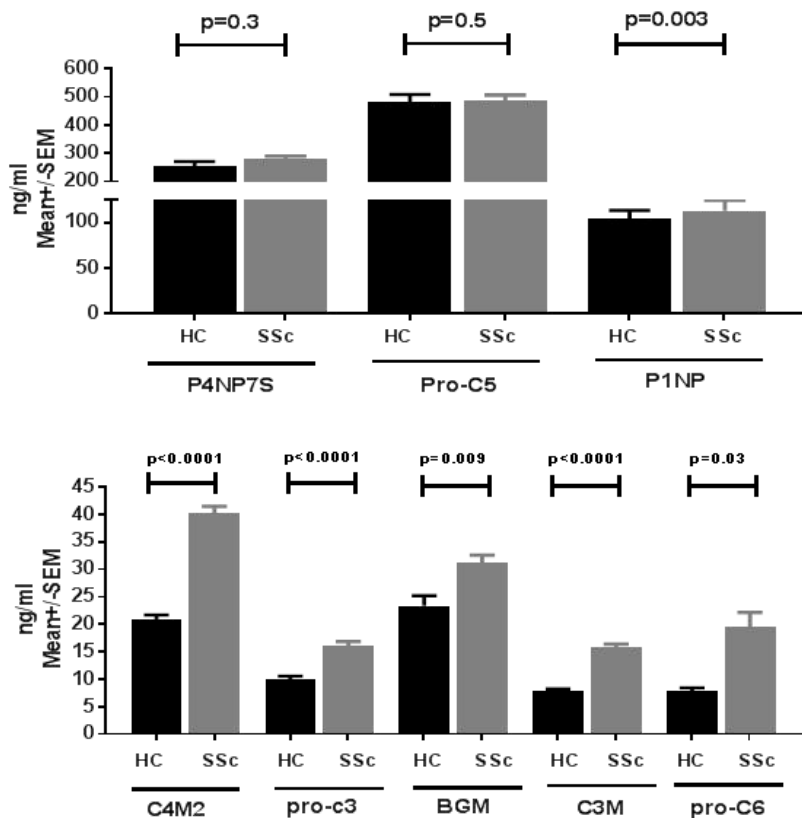

174 patients with SSc as well as 29 HC were analysed. There were 25 (14%) SSc patients who progressed during 1 year. Baseline levels of most collagen biomarkers were higher in SSc compared to HC. C3M, C4M2 and PRO-C3 distinguished well between HC and SSc patients: C3M (AUC 0.90,  $p < 0.001$ , 95%CI 0.85-0.95), C4M2 (AUC 0.90,  $p < 0.001$ , 95%CI 0.85-0.94), PRO-C3 (AUC 0.75,  $p < 0.001$ , 95%CI 0.67-0.83) (Figure 1). In addition to the previously reported ratio of PRO-C3/C3M (1), C3M and C4M2 predicted 1-year progression: C3M (AUC 0.87,  $p < 0.001$ , 95%CI [0.79-0.95]), C4M2 (AUC 0.78,  $p < 0.001$ , 95%CI [0.68-0.88]). A cut-off for PRO-C3/C3M at  $> 1.2$  showed a sensitivity of 84% with a specificity of 78% to predict progressive patients. In logistic regression adjusted for age and sex, PRO-C3M/C3M could predict decrease of  $FVC \geq 10\%$  (OR 3.8, 95%CI [1.5-9.2],  $p = 0.004$ ) and increase of  $mRSS \geq 25\%$  and 5 points (OR=2.1, 95%CI [1.0-4.2],  $p = 0.04$ ). Further, PRO-C3/C3M (OR 2.87, 95%CI [1.8-4.5],  $p < 0.001$ ) and C3M (OR 0.69, 95%CI [0.6-0.8],  $p < 0.001$ ) were identified as significant predictors of progression of skin and lung fibrosis.

## Conclusion:

The dysbalance of collagen turnover suggests decreased collagen degradation in progressive vs. stable patients. Markers of collagen III and IV particularly arise hereby as potential new diagnostic and prognostic biomarkers in SSc.

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Cardiac involvement is a relevant prognostic determinant of outcome in Systemic Sclerosis (SSc). Since the role of cardiac MRI (CMR) is still uncertain, we examined the cardiac involvement in symptomatic SSc patients through CMR, and defined its prognostic role value and its modification over the time.

### **Methods:**

Sixty-two SSc-patients with symptoms of cardiac involvement (dyspnea, palpitations) and/or signs of cardiac failure and elevation of cardiac enzymes (MB-CK and/or troponin T) underwent C-MRI. Patients were followed for  $51.0 \pm 27.2$  months and 23 patients underwent a serial C-MRI studies because of modification and/or a worsening of their symptoms and signs.

### **Results:**

CMR demonstrated abnormalities in 67.7% of patients, in particular T2 hyperintensity in 6 (9.7%) patients, while none of the patients presented early gadolinium enhancement and 20 (32.2%) patients presented late gadolinium enhancement (LGE). We identified 3 different patterns of distribution of LGE: subepicardial, midwall and subendocardial. Fourteen patients presented a single pattern of distribution (22.6%), while 6 patients (9.7%) presented more than one: 20.9% of patients presented a midwall distribution of LGE, 8.1% of patients presented a subepicardial LGE with a linear distribution pattern and 9.7% presented a subendocardial LGE distribution. Twelve patients (19.4%) showed one hypokinetic area and three patients akinetic areas. After a mean follow-up of  $51.0 \pm 27.2$  months, 4 patients (6.0%) died for arrhythmias or heart failure and 75% presented a subendocardial DE distribution pattern ( $p=0.003$ ).

During the follow-up, 23 SSc patients presented a modification and/or a worsening of their cardiac symptoms and signs and they repeated the CMR assessment; CMR abnormalities were partially confirmed in 12 in the subsequent evaluation, 5 CMR demonstrated the development of new areas of T2 hyperintensity, subepicardic and subendocardic DE and ipo/akinesia; finally 7 CMR previously negative remained negative despite new symptoms. Furthermore a statistical significant reduction of the ejection fraction (EF) of left ( $59.4 \pm 10.6$  vs  $56.1 \pm 11.3$ ,  $p<0.001$ ) and right ventricles ( $54.6 \pm 12.0$  vs  $52.1 \pm 12.3$ ,  $p<0.001$ ) was noticed over the time.

### **Conclusion:**

CMR represents a useful tool to assess the cardiac involvement in systemic sclerosis patients with cardiac signs and symptoms. Yet clear-cut links between each CMR finding and cardiac symptoms needs to be better defined Our data suggest that CMR offers the most comprehensive assessment of the extension of myocardial damage and identifies patients with a poor cardiac outcome especially when a subendocardial DE is present. Serial CMR evaluations allow to identify the new cardiac damage and to follow reduction of EF of both ventricles.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The prognosis of patients with scleroderma and interstitial lung involvement (SSc-ILD) can be evaluated by combining data of pulmonary function tests (PFTs) and high-resolution computed tomography (HRCT), but both methods have intrinsic limitations. An automated system able to define the extent and pattern of lung parenchyma involvement could be very useful in clinical practice.

We aimed to evaluate the performance of such an automated system (CALIPER, Imbio LLC, MN) (1-2) in patients with SSc-ILD together with PFTs parameters and visual scoring of HRCT scans according to Goh's visual reader based score (3). Moreover, we aimed to evaluate the prognostic value of CALIPER with respect to PFTs changes over time.

### **Methods:**

Thirty-five scleroderma patients with ILD-SSc were consecutively enrolled. PFTs as well as lung HRCT were performed at both baseline and at latest follow-up. Quantitative analysis of parenchymal involvement on HRCT was performed by using CALIPER, which provided data on the relative volume of 5 different parenchymal patterns: normal, ground-glass, reticular, hyperlucent and honeycombing. Semi-quantitative analysis of the CT scans was performed by two radiologists according to the Goh's visual reader based score.

### **Results:**

Quantitative evaluation by CALIPER was successful in 31/35 patients (88.57%), requiring 20 m' to 30 m' per patient for the software. The two most common patterns were ground-glass (16.64%) and reticular (4.48%), with a mean disease extent of 18.8% and a prevalent distribution at middle and lower zones and in peripheral areas.

The correlations between PFTs and the relative volume of ground-glass were good (FVC:  $r=-0.72$ ,  $p<0.001$ ; TLC:  $r=-0.74$ ,  $p<0.001$ ; DLCO:  $r=-0.40$ ,  $p=0.001$ ), whereas PFTs and the relative volume of reticular pattern showed weaker correlations (FVC:  $r=-0.38$ ,  $p=0.003$ ; TLC:  $r=-0.42$ ,  $p=0.02$ ; DLCO:  $r=-0.31$ ,  $p=0.02$ ). The relative volume of normal lung had good correlations with FVC ( $r=0.63$ ,  $p<0.001$ ) and TLC ( $r=0.42$ ,  $p=0.02$ ).

The concordance between analysis performed by CALIPER and the Goh's visual score was weak either in the ground-glass pattern (ICC:0.67, CI95%: 0.50-0.78) or in the reticular pattern (ICC:0.27, CI95%: 0.03-0.48).

Patients were followed-up for  $26.0\pm15.6$  months. Considering as clinically relevant a decrease in FVC greater than 10% or a decrease in FVC between 5-10% together with a decrease in DLco greater than 15%, reductions of lung volumes higher than -7.2 could predict a functional worsening with a sensitivity of 81% and a specificity of 70% (ROC curve analysis: AUC: 0.74, 0.54-0.93,  $p=0.035$ ).

### **Conclusion:**

Quantitative analysis performed by CALIPER arose as a useful tool to determine the extent and disease pattern in patients with SSc-ILD, correlating with PFT. The discriminatory performance of such an automated program to identify patients who presented a worsening of lung function suggests that quantitative analysis can help in evaluating response to therapy in scleroderma patients with ILD.

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The DETECT calculator has been freely available as a tool for earlier detection and diagnosis of pulmonary arterial hypertension (PAH) in systemic sclerosis (SSc) since 2014. Here, we aimed to evaluate its impact on PAH incidence rates, risk profile and functional class (FC) of patients at time of PAH diagnosis.

**Methods:** The study cohort included all patients in the prospective Oslo University Hospital (OUH) SSc cohort who performed an incident right heart catheterization (RHC) from 2009 and onwards. We grouped the patients in an early cohort with RHC conducted in 2009-2013, and a DETECT cohort with RHC from 2014-17. PH diagnosis was made by an experienced cardiologist according to the updated ESC guidelines with mean (m) PAP  $\geq 25$  mmHg measured by RHC and borderline PH with a mPAP  $>19$  mmHg. Pre and post capillary PHT was defined by PCW above or below 15 mmHg. Risk stratification at time of diagnosis was done using the low, intermediate and high risk grouping system suggested by ESC in 2016. Patients with  $\geq 1$  parameter of poor prognosis were considered at high risk and with  $\geq 1$  parameter of intermediate prognosis, at intermediate risk.

**Results:** An incident RHC was available in 161 patients, 77 from the early cohort and 84 from the DETECT cohort. Clinical and demographic characteristics are shown in Table 1. Absolute numbers of RHC, PAH and borderline PH cases in the years 2009-2017 are shown in Figure 1. At the time of PAH diagnosis, 27% of the DETECT cohort were in the low risk group compared to 19% in the early cohort, while 27% and 47% respectively belonged in the high risk groups (p-value 0.219) (Figure 2). We also observed a trend towards lower functional class in the DETECT cohort (Figure 2).

**Conclusion:** We show that the number of new PAH cases per year has been stable since 2009, with no apparent change following the introduction of the DETECT algorithm. From 2014 and onwards, we observed a, not significant, increase in

amount of newly diagnosed PAH cases with low risk group, and better functional class status. The total number of RHC increased from 2014 and onwards, with a concomitant increase in the number of borderline PH cases.

**Table 1:** Demographics and clinical characteristics

	Total cohort	2009-13	2014-17	p-value

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pulmonary arterial hypertension (PAH) is one of the leading causes of death in systemic sclerosis (SSc). Annual echocardiograms (echo) are recommended to detect PAH at an early stage, potentially improving outcome. We aimed to evaluate the potential of baseline echo parameters to predict PAH progression and all-cause mortality.

**Methods:** The study cohort included all SSc patients from the prospective Oslo University Hospital (OUH) cohort who had an evaluable baseline protocol echo performed between 2003 and 2016. This echo was analyzed regarding left- and right-sided systolic and diastolic function. Right heart catheterization (RHC) was performed in patients suspected of PH. PAH diagnosis was made by an experienced cardiologist with mean pulmonary artery pressure  $\geq 25$  mmHg, pulmonary capillary wedge pressure  $<15$  mmHg, stable forced vital capacity  $>70\%$  and  $<10\%$  lung fibrosis on HRCT. Vital status was available for all patients and PAH progression, defined by occurrence of new PAH related events were calculated. Cox regression analyses were conducted.

**Results:** In total, 337 SSc patients with baseline echo were included. RHC was conducted in 149 (44.2%) patients and 48 (14.2%) were diagnosed with PAH; of those, 34 patients showed PAH progression. Demographic and clinical characteristics are summarized in Table 1. Significant results from univariable and multivariable cox analyses of death are shown in Table 2, and for PAH progression in Table 3. In the final cox regression model for death, age (HR 1.06, 1.03-1.10 95%CI,  $p<0.001$ ), DLCO (HR 0.97, 0.96-0.98 95%CI,  $p=0.001$ ), pericardial effusion (HR 2.24, 1.37-3.63 95%CI,  $p<0.001$ ), left atrium area (HR 1.07, 1.01-1.14 95% CI,  $p=0.024$ ) and tricuspid annular plane systolic excursion (TAPSE) (HR 0.38, 0.19-0.74 95% CI,  $p=0.004$ ) were associated (c-index 0.82). PAH progression was associated with age (HR 1.06, 1.02-1.11 95% CI,  $p=0.005$ ), DLCO (HR 0.97, 0.95-0.99 95% CI,  $p=0.002$ ), and right atrium area (HR 1.17, 1.10-1.25 95% CI,  $p<0.001$ ) (c-index 0.86).

**Conclusion:** In our large and unselected SSc cohort, impaired baseline right heart function, but not left ventricular systolic or diastolic parameters, was predictive for both death and PAH progression. Echo may serve as a tool to stratify patients at risk for PAH and death.

<b>Table 1:</b> Demographic and clinical characteristics of all SSc patients, SSc-PAH patients and deceased patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Raynaud's phenomenon (RP) is consistently ranked highest in patient surveys exploring the frequency and impact of disease related manifestations of systemic sclerosis (SSc). SSc-RP is an episodic phenomenon and not easily assessed in the clinical setting. A thorough understanding of the patient experience of SSc-RP is essential if severity and impact are to be captured using patient-reported outcome (PRO) instruments. We report the findings of an international qualitative research study to investigate the patient experience of SSc-RP.

### **Methods:**

Focus groups (FGs) comprising patients with SSc-RP (fulfilling 2013 ACR/EULAR classification criteria) were conducted across 3 scleroderma centers in the United States and United Kingdom, using a topic guide devised by a steering committee comprising qualitative researchers, SSc patients and SSc experts. Participants were enrolled according to an *a priori* purposive sampling framework ensuring we sought the views of a diverse (geographic, cultural and ethnic) and representative (disease subtype, disease duration, gender and history of digital ulcer disease) cohort of SSc patients. FGs were audio recorded, transcribed, anonymised and analysed using inductive thematic analysis. Additional FGs were conducted until thematic saturation was achieved.

### **Results:**

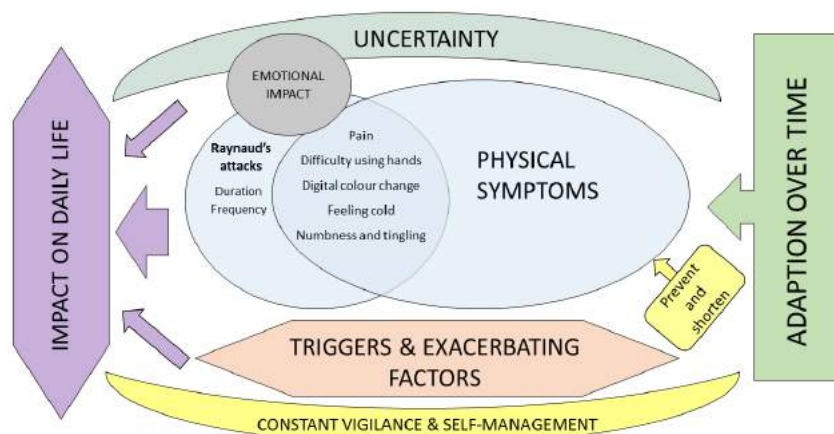

Forty SSc patients participated in 6 focus groups conducted in Bath (n=2), New Orleans (n=3) and Pittsburgh (n=1). The participant demographics are presented (Table). The patient experience of SSc-RP can be described according to 7 major inter-related themes comprising; physical symptoms, emotional impact, triggers & exacerbating factors, constant vigilance & self-management, impact on daily life, uncertainty and adaptation. A conceptual map demonstrating the inter-relationship of the 7 themes is presented (Figure).

### **Conclusion:**

This is the first qualitative study to explore the patient experience of SSc-RP. The multi-center design and purposive sampling framework ensured experiences were obtained from a diverse and representative SSc cohort. SSc-RP comprises a complex interplay of experiences that result in significant physical/emotional distress, disability and altered social participation which adversely affects health-related quality of life. The themes (and subthemes) identified herein are not captured using existing PRO instruments for assessing SSc-RP. Work to develop a novel PRO instrument for assessing the severity and impact of SSc-RP, comprising domains/items grounded in the patient experience of SSc-RP identified in this work is now underway.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Progressive systemic sclerosis (PSSc) has been known to affect mainly adults of 30-50 years of age. Juvenile –onset has been reported to be rare and studies comparing clinical differences between juvenile-onset and adult onset form have been limited (1). One study from North America revealed that there is more skeletal muscle involvement, more severe cardiac disease, whereas improved survival compared with adult onset pSSc cases (1). Recently, one multicenter European study revealed that juvenile-onset PSSc showed scleroderma pattern on the capilleroscopy more frequently than that observed in adult-onset pSSc (2). As there would be also effects of ethnic differences, we aimed to assess clinical differences between the two forms of pSSc of pediatric and adult rheumatology centers of a tertiary center, in Turkey.

**Methods:** Adult onset patients were defined as those who were registered and followed as 'scleroderma' at the departments of adult and pediatric rheumatology at Cerrahpasa Medical Faculty, Istanbul, between 2005 and 2017. Only those with at least 2 follow-up visits were included in the study. Patients's charts were re-evaluated retrospectively for demographic and clinic characteristics.

**Results:** There were 140 patients with scleroderma diagnosis in the adult outpatient clinic records, and 51 in the pediatric clinic records. Of these patients, 3 adults and 25 (49 %) pediatric patients had localized scleroderma ( $p<0.001$ ). We studied the remaining patients (adults:  $n=137$ , juvenile:  $n=26$ ) who had systemic pattern.

As shown in Table, male/female ratio, median follow-up duration, familial history of chronic inflammatory diseases and the frequency of sclerodactyly, digital ulcers, Raynaud phenomenon, arrhythmia/heart failure and gastrointestinal involvement were similar between juvenile and adult onset groups. The frequency of interstitial lung disease, pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas, joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group, on the other hand, the use of vasodilators was more frequent among adults.

**Conclusion:** Our results are online with previous reports: juvenile onset patients seem to have a milder form of disease. Major organ involvement as defined interstitial lung disease and pulmonary artery hypertension was more common among adult onset patients. On the other hand, as expected, joint involvement and myopathy were major causes of morbidity in the juvenile group. Contrary to that previously reported, cardiac involvement was not common in the juvenile group.

**Autoantibodies to Rpp25 (Th/To) are specific markers for systemic sclerosis and are associated with limited cutaneous disease and young age at disease onset**[\[MM1\]](#)

Boyang Zheng<sup>4</sup>, Martial Koenig<sup>4</sup>, Michael Mahler<sup>1</sup>,

<sup>1</sup> Inova Diagnostics, INC. San Diego, CA, USA;

<sup>2</sup> Department of Medicine, McGill University, Montreal, Quebec, Canada

**Background/Purpose:**

Antinuclear antibodies (ANA), present in 80-90% of systemic sclerosis (SSc) patients, are important for disease diagnosis. Of particular utility are those with SSc-specific and SSc-associated antibodies, including anti Th/To amongst others (i.e. antibodies to centromere, Scl-70, RNA Pol-III, PM/Scl, Ro52/TRIM21 and U1RNP). However, in a significant minority of ANA positive SSc patients, no fine specificities are detected using conventional diagnostic protocols. Recently, it was found that anti-Rpp25 antibodies are an important autoantigenic component of the Th/To complex. However, no FDA cleared assay is available for the detection of anti-Th/To antibodies. Consequently, the present study aimed to analyze a large well characterized Canadian SSc patient cohort in comparison to other disease control groups for antibodies to Rpp25 in a standardized assay.

**Methods:**

Sera from 320 Canadian SSc patients [48 diffuse cutaneous (dc) SSc, 223 limited cutaneous (lc) SSc and 49 sine SSc] and various disease controls (n=889) were tested for anti-Rpp25 antibodies by a bead based immunoassay (research use only, Inova Diagnostics, US).

**Results:**

Anti-Th/To antibodies were significantly more common and present in higher titers in SSc patients compared to all controls ( $p<0.05$ ). The prevalence in SSc and in the different control groups is summarized in the figure below.

Receiver operating characteristic (ROC) analysis showed an area under the curve of 0.70 (95% Confidence interval 0.67-0.73). The sensitivity and specificity for SSc was 9.7% (95% CI 6.9-13.4%) and 99.0% (95% CI 98.1-99.5%), respectively. The odds ratio for SSc was 10.6 (95% CI 5.1-22.3). Anti-Rpp25 antibodies were present in 0/48 dcSSc (0.0%), in 27/223 lcSSc (12.1%) and in 4/49 (8.2%) sine SSc patients. The difference between lcSSc and dcSSc was significant ( $p=0.01$ ). In addition, anti-Rpp25 antibodies were associated with a younger age at SSc disease onset (34.3 vs. 39.8 years;  $p=0.048$ ).

**Conclusion:**

Autoantibodies to Rpp25 as part of the Th/To autoantigen show high specificity for SSc and define a subset of SSc with lcSSc and younger age of disease onset.

## Scleromyxedema Phenotype Pre- and Post-Treatment with Intravenous Immunoglobulin

Christopher A. Mecoli<sup>1</sup>, Andrea Fava<sup>2</sup>, Francesco Boin<sup>3</sup> and Laura K. Hummers<sup>4</sup>, <sup>1</sup>Rheumatology, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Johns Hopkins University, Baltimore, MD, <sup>3</sup>Rheumatology, University California, San Francisco, San Francisco, CA, <sup>4</sup>Medical and Rheumatology, Johns Hopkins University, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Scleromyxedema is a rare scleroderma mimic that often responds to intravenous immunoglobulin therapy (IVIG). The clinical and biochemical changes in response to treatment have not been well-characterized.

**Methods:** 15 patients with scleromyxedema were recruited for the study. Clinical information and blood samples were obtained immediately before and again 2-3 weeks after receiving IVIG therapy. Clinical information included the modified Rodnan Skin Score (MMRSS) which includes assessing the patients' back and ears, and visual analog scales to assess patients' pain, itch, flexibility, and softness of their skin. In addition, Health Assessment Questionnaire Disability Index (HAQ-DI) and percent body surface area involved were recorded.

**Results:** Demographic data and disease characteristics can be found in Table 1. Twelve of the 15 patients were receiving maintenance IVIG, and three were treatment-naïve. All patients except for one had a monoclonal gammopathy of undetermined significance (MGUS), 12 of which were IgG lambda, and two were IgG kappa.

Post-treatment, the average MMRSS decreased from 13.6 to 10.3 ( $p=0.003$ ). Skin flexibility, skin softening and skin global all improved as assessed using visual analog scales, and were statistically significant (Table 2). Correlation studies demonstrated that the MMRSS correlated with the Health Assessment Questionnaire-Disability Index (HAQ-DI)  $R=0.47$ ,  $p=0.009$ ). The three treatment-naïve patients had a larger improvement (mean MMRSS  $20 \pm 5.1$  to  $13.3 \pm 4.7$  compared to patients receiving maintenance IVIG,  $11.9 \pm 10$  to  $9.5 \pm 8$ ).

The two patients with a history of neurologic complications relating to scleromyxedema had a markedly lower MMRSS of  $1 \pm 0.8$  compared to patients without neurologic complications,  $13.6 \pm 8.3$ ,  $p=0.006$ . Patients with lambda IgG MGUS had a higher MMRSS compared to those with kappa IgG or no MGUS,  $13.3 \pm 9.8$  compared to  $7.8 \pm 5.2$ ,  $p=0.22$ .

**Conclusion:** Patients with scleromyxedema have clinical improvement to IVIG in several domains, and the extent of skin involvement correlates with their HAQ-DI. Patients with a history of neurologic complications of scleromyxedema or non-IgG lambda MGUS have lower skin scores.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Compared with placebo, treatment with cyclophosphamide (CYC) improved lung function in patients with systemic sclerosis-related interstitial lung disease (SSc-ILD) after 1 year in Scleroderma Lung Study (SLS) I.<sup>1</sup> However, the effects of CYC waned after monitoring patients for an additional year off therapy.<sup>2</sup> In SLS II (comparing CYC and mycophenolate [MMF]), treatment with 1-year of CYC appeared to have a more sustained effect on lung function over 2-years, although SLS II used a different analysis approach than SLS I.<sup>3</sup> To further understand the effects of CYC on SSc-ILD outcomes, the present analysis directly compared outcomes between the CYC arms of SLS I and II.

**Methods:** Participants enrolled in the CYC arms of SLS I (N=79) and II (N=73) were included. SLS I and II randomized participants to oral CYC for 1 year and followed patients for an additional year off therapy (In SLS II, patients received placebo in the second year). Eligibility criteria for SLS I and II were nearly identical. Outcomes included the FVC%-predicted and DLCO%-predicted (measured every 3 months) and quantitative radiographic extent of ILD (QILD) (measured at 1 and 2 years for SLS I and SLS II, respectively). Joint models were created to evaluate the treatment effect on the course of the FVC/DLCO over 2-years while controlling for baseline disease severity.

**Results:** SLS II-CYC participants had similar baseline characteristics compared with SLS I-CYC participants in terms of gender (75% vs. 77% female), disease duration (mean [SD] years: 2.6 [1.8] vs. 3.1 [2.3]), and FVC%-predicted (mean [SD]: 66.9 [9.9] vs. 67.6 [11.4]), respectively. SLS II-CYC patients were slightly older (mean [SD] years: 52.2 [9.6] vs. 48.4 [12.2]; P=0.037) and had a higher DLCO%-predicted (mean [SD]: 54.5 [14.6] vs. 47.2 [13.9]; P=0.0002) than SLS I-CYC participants. After adjusting for baseline QILD and FVC%-predicted, there was no difference in the course of the FVC%-predicted between the CYC arms of SLS I and II (P=0.535), nor the DLCO%-predicted (P=0.172). In both groups, treatment with CYC led to a significant improvement in the FVC%-predicted from 3-12 months, but no significant improvement beyond this point (Figure 1). Treatment with CYC had no effect on the DLCO for either group.

**Conclusion:** Although there are limitations in comparing participants from two trials, the baseline characteristics of the SLS I and SLS II participants were relatively similar. Treatment with 1 year of oral CYC led to similar improvements in lung function in both SLS I and II, although the effects were not sustained following CYC cessation. These results suggest that increasing the duration of ILD therapy may improve outcomes for SSc-ILD patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Assessing the effect of Diltiazem gel on healing process of scleroderma digital ulcers and comparing its effect with Nitroglycerin ointment and placebo.

**Methods:** Ninety scleroderma patients divided to three groups underwent a single blind randomized clinical trial. Experimental group 1 received Diltiazem gel 2%, experimental group 2 received Nitroglycerin ointment 2% and control group received Vaseline as placebo. All interventions were applied 2 times per day for 8 weeks. The mean of maximum diameters of the ulcers was measured for each patient at the beginning and at the end of the study. The site of the ulcers and the number of new ones were, also, determined for each patient.

**Results:**

The mean diameter of the ulcers at the end of the study was significantly lower in three studied groups compared to the beginning of the study (Diltiazem  $P < 0.001$ , Nitroglycerin  $P = 0.002$  and Control  $P = 0.027$ ). However, the difference in size of the ulcers was significantly higher in diltiazem group compared to nitroglycerin and placebo ( $P = 0.04$ ), especially, in ulcers at distal part of digits ( $P = 0.32$ ). In addition, number of new ulcers did not differ significantly between three groups. Moreover, nitroglycerin ointment (42%) was found to induce more complications for patients compared to Diltiazem gel (28%) and placebo (28%).

**Conclusion:** Diltiazem gel can be an effective topical therapy with lower complications for treating scleroderma digital ulcers compared to nitroglycerin ointment and placebo.

## Effect of Probiotics on the Gastrointestinal Symptoms and Immune Parameters in Patients with Systemic Sclerosis: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Thais Marighela<sup>1</sup>, Maria Izabel Arismendi<sup>1</sup>, Milena Brunialti<sup>2</sup> and **Cristiane Kayser**<sup>1</sup>, <sup>1</sup>Rheumatology Division, Universidade Federal de São Paulo, São Paulo, Brazil, <sup>2</sup>Division of Infectious Diseases, Universidade Federal de São Paulo, São Paulo, Brazil

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Abnormalities in the intestinal microbiota have been associated with several autoimmune diseases, including systemic sclerosis (SSc). Recent studies have demonstrated the potential of probiotics in modulating the microbioma and the immune responses in several autoimmune diseases. T cell abnormalities including a predominant T helper type 2 (Th2) profile and increased levels of Th17 cells have been implicated in the pathogenesis of SSc. The objective of this study was to evaluate the effects of probiotics on the gastrointestinal (GI) symptoms and immune parameters in patients with SSc.

### Methods:

In this double-blind, placebo-controlled, randomized clinical trial 73 patients with SSc (EULAR/ACR criteria from 2013) with a moderate-to-severe total score (0.5–3.00) on the University of California Los Angeles Scleroderma Clinical Trial Consortium Gastrointestinal Tract Instrument 2.0 (UCLA GIT 2.0) were randomized to receive probiotics (1 capsule/day of *Lactobacillus paracasei*, *L. rhamnosus*, *L. acidophilus* and *Bifidobacterium lactis*,  $10^9$  colony-forming units per capsule) or placebo (identical capsules containing maltodextrin) for 8 weeks. The primary outcome measurement was improvement in the UCLA GIT 2.0 total score after 8 weeks of treatment. Secondary outcomes included changes in Th1, Th2, Th17 and regulatory T cells serum levels, immunoglobulin A (IgA), scleroderma Health Assessment Questionnaire (SHAQ) score, anthropometric parameters, and dietary intake. The frequencies of Th1 ( $CD3^+CD8^-IFN-\gamma^+$ ), Th2 ( $CD3^+CD8^-IL4^+$ ), Th17 ( $CD3^+CD8^-IL17^+$ ) and regulatory T ( $CD3^+CD4^+CD25^+Foxp3^+$ ) cells in peripheral blood were measured using flow

cytometry. Clinical and immune parameters were assessed at baseline (T0), after four (T4) and eight weeks (T8) of treatment. The trial was registered on ClinicalTrials.com under the identifier NCT 02302352.

## **Results:**

Thirty-seven patients were randomized to probiotics (mean age 47.7 years) and 36 (mean age 46.1 years) to the placebo group. After 8 weeks, there was a significant improvement in UCLA GIT 2.0 total score in both groups ( $p < 0.001$ ), but changes were not different between the two groups ( $p = 0.934$ ). The probiotic group presented a significant decrease in the serum percentage of Th2 (from 2.2% in T0 to 1.5% in T8) and Th17 (from 2.0% in T0 to 1.4% in T8) cells compared with the placebo group (from 2.3% in T0 to 2.5% in T8 for Th2; from 1.9% in T0 to 1.9% in T8 for Th17 cells) ( $p = 0.038$ ,  $p = 0.04$ ; respectively). No significant changes were observed in percentages of Th1 and Treg cells, IgA serum levels, SHAQ score, anthropometric parameters, and dietary intake after treatment between the two groups. No serious adverse events were reported.

## **Conclusion:**

In this first randomized, double-blind trial evaluating the effects of probiotics in SSc, there was no reduction in the GI symptoms with probiotic supplementation compared with placebo. Nonetheless, probiotics showed to reduced the peripheral percentages of Th2 and Th17 cells in patients with SSc. These results indicate that probiotics have immunomodulatory effects and anti-inflammatory properties and might represent an innovative therapeutic approach to SSc patients.

### Title

Role of the Six-Minute Walk Test in Systemic Sclerosis: five years evolution.

**Background/Purpose:** Interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH) are the leading causes of death in Systemic Sclerosis (SSc) patients. Although the six-minute walk test (6MWT) is used for evaluating ILD and PAH in clinical practice, no data are available on the natural evolution of the six-minute walk distance (6MWD) in SSc patients without ILD and PAH.

**Methods:** Prospectively collected data of the first 6MWT (at baseline or at 6-month follow-up) and the 6MWTs at 18-, 30-, 42-, 54-, and 66-month visit of 165 consecutive SSc patients without ILD and PAH, included in the Ghent University Systemic Sclerosis Cohort between May 2006 and December 2016 were analysed.

**Results:** The mean 6MWD during the baseline 6MWT of 165 SSc patients without ILD and PAH (35% limited SSc, 56% limited cutaneous SSc, 9% diffuse cutaneous SSc) was 484.20+/-92.65m with no significant difference in the distance walked at different follow-up visits as compared to baseline. 96-100% of the SSc patients without ILD and PAH performed a 6MWT during the different follow-up visits.

**Conclusion:** In SSc without ILD and PAH, the 6MWT is feasible and the 6MWD is clinically stable over a 66 months period. A 6MWT performed at the time of SSc diagnosis may be used as a reference 6MWD for those SSc patients who develop ILD or PAH during follow-up.

Table 1. Baseline characteristics of 165 SSc without ILD and PAH.

Characteristic	N

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Epigenetic modifications are key drivers of chronic fibroblast activation. Trimethylation of histone 3 at lysine residue K27 (H3K27me3) is a repressive modification, that is implicated in fibroblasts activation. Inhibition of H3K27 trimethylation promotes fibroblast activation. However, the role of H3K27me3 demethylases in fibrosing disorders has not been characterized. The aim of this study is to characterize the role of JMJD3 in as potential drug target in fibrotic disease.

## Methods:

siRNA mediated knockdown and GSKJ4 were used to target JMJD3 *in vitro and in vivo*. Fibroblast activation was analyzed by quantifying collagen synthesis and release, stress fiber formation and by scratch assays. The effects of GSKJ4 on experimental fibrosis were assessed in the Topoisomerase I-mouse model of skin and lung fibrosis and in Bleomycin-induced skin fibrosis. Inflammatory infiltrates in the skin were assessed by immunofluorescence staining. H3K27me3 of target genes was analyzed by ChIP.

**Results:** We demonstrated increased expression of JMJD3 in fibrotic diseases with increased expression of JMJD3 in the skin of SSc patients and in tissue from patients with liver fibrosis and idiopathic pulmonary fibrosis compared to healthy

controls. The overexpression was particularly pronounced in fibroblasts. JMJD3 was also overexpressed in dermal and pulmonary fibrosis in TopoI-induced fibrosis and in bleomycin-induced skin fibrosis. Targeting JMJD3 in vitro ameliorated the activated fibroblast phenotype with decreased collagen release and reduced expression of myofibroblast markers. By screening for several profibrotic pathways, we identified FRA2 as central downstream mediator of JMJD3 mediated fibroblast activation. H3K27me3 at the *FRA2* promoter was reduced by TGFβ stimulation, which resulted in increased expression of FRA2. Treatment with GSKJ4 prevented the TGFβ-induced downregulation of H3K27me3 at the *FRA2* promoter. The functional importance of FRA2 for JMJD3 regulated fibroblast activation was further highlighted by knockdown studies: Upon knockdown of *FRA2*, GSKJ4 loses its inhibitory function on collagen secretion. In vivo, we observed potent antifibrotic effects of JMJD3 inhibition on dermal and pulmonary fibrosis with reduced fibrotic tissue remodeling, decreased collagen content and impaired differentiation of resting fibroblasts into myofibroblasts. As GSKJ4 treatment had no effect on B- cell counts in experimental fibrosis. However, GSKJ4 treatment resulted in a slight reduction of T-cell counts.

## Conclusion:

We present first evidence for a dysregulation of JMJD3 in SSc. JMJD3 regulates fibroblast activation by modulating the levels of H3K27me3 at the *FRA2* promoter. Targeted inhibition of JMJD3 reduces the aberrant activation of SSc fibroblasts and has strong antifibrotic effects in murine models of SSc.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Systemic Sclerosis (SSc) is characterized by severe fibroproliferative vasculopathy, exaggerated deposition of extracellular matrix molecules (ECM) in skin and multiple internal organs, and alterations of humoral, cellular and innate immunity. Vascular changes are responsible for the earliest SSc clinical manifestations; however the mechanisms responsible have not been elucidated.

The goal of this study was to analyze the gene expression differences between normal and SSc lung microvascular endothelial cells (EC) to improve the understanding of SSc vasculopathy pathophysiology.

## Methods:

Pulmonary microvascular EC were isolated employing immunomagnetic procedures from lungs from patients with SSc undergoing lung transplantation. Control EC were isolated from autopsies of individuals who died from non-related pulmonary causes. Following isolation, microarrays were performed in EC from each group. Expression of genes with the highest differential expression was validated with RT-PCR, Western blots and confocal laser microscopy.

## Results:

Interferon-stimulated genes (ISGs) including IFI44L, IFI44, IFI6, IFIH1, IFIT1, displayed the highest differential expression; being overexpressed in EC obtained from SSc donors. Others genes such as those encoding ECM production related proteins, genes associated with post-translational methylation and genes for numerous chemokines were also differentially overexpressed in SSc EC. Increased gene expression and increased protein levels of selected ISGs were confirmed by Western blots and confocal laser microscopy.

## Conclusion:

Numerous ISGs are differentially overexpressed in SSc pulmonary microvascular EC in comparison with normal control EC. These results suggest that events leading to an interferon response in these cells may play a role in the pathogenesis of SSc lung vasculopathy.

Figure 1:  
A: Volcano Plot showing differentially expressed transcripts with 2 fold or more difference (p<0.05) in expression among SSc and normal control ECs (130 transcripts corresponding to 119 genes). Circles show selected genes: 1: IFI44, 2: IFI6, 3: IFIH1, 4: IFI44, 5: OAS-1, 6: IFIT-3, 7: SG15, 8: STAT-1, 9: AADAC, 10: CADM3, 11: TIMP3, 12: TPT1/ITC. B: Detail of the resulting heat map of a dendrogram (hierarchically clustered) reveals groups of genes with high (red squares) expression levels, low expression levels (blue squares) or background expression levels (yellow squares). Interferon related genes are marked with a red dot.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The etiology of systemic sclerosis (SSc) is not clear, but there is evidence suggesting a critical role for epigenetic alterations in disease pathogenesis and clinical expression. We sought in this study to characterize the genome wide DNA methylation signature in SSc Microvascular Endothelial Cells (MVECs).

**Methods:** We performed a genome-wide DNA methylation study in MVECs derived from 7 diffuse cutaneous SSc (dSSc) patients compared to 7 age, sex, and ethnicity-matched healthy controls. Cytosine methylation was quantified across the genome. We divided samples from patients and controls in two groups of matched SSc subjects and controls. Differentially methylated CpG sites between patients and controls were identified by fold difference in methylation level  $\geq 1.2$ , and false discovery rate (FDR) adjusted P value  $< 0.01$ . Moreover, quantitative real-time RT-PCR was performed to assess the correlation between DNA methylation and gene expression levels in selected genes.

**Results:** We identified 71,353 differentially methylated CpG sites in SSc-MVECs using Infinium MethylationEPIC microarray in the first group (0.081% of representative probes), and 33,170 CpG sites in the second group using HumanMethylation 450 microarray (0.073% of representative probes) in dcSSc-MVEC. Among the two groups of subjects, we identified differential methylation of 2,455 CpG sites, representing 1,301 genes. Most of the differentially methylated CpG sites were hypermethylated (1,625 CpG), corresponding to 910 genes. There were 830 hypomethylated CpG sites, representing 485 genes. Common Hypermethylated genes in SSc MVECs include *NOS1*, which encodes for nitric oxide synthase -1, *DNMT3A*, *DNMT3B*, *HDAC4* and *ANGPT2*. We also identified hypomethylation of *IL17RA*, *CTNNA3*, *ICAM2* and *SDK1* in SSc MVECs. Furthermore, we demonstrate significant inverse correlation between DNA methylation status and gene expression in the majority of genes evaluated.

Gene ontology analysis of hypermethylated genes demonstrated enrichment of genes involved in homophilic cell adhesion via plasma membrane adhesion molecules ( $P = 2.10E-07$ ) and angiogenesis ( $P = 0.0006$ ). Pathway analysis of hypomethylated genes includes genes involved in Wnt signaling pathway ( $P = 0.001$ ), vascular smooth muscle contraction ( $P = 0.014$ ) and adherens junctions ( $P = 0.013$ ).

**Conclusion :** Our data suggest the presence of significant genome-wide DNA methylation aberrancies in SSc-MVEC, and identify novel affected genes and pathways in SSc MVECs.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** High-throughput gene expression profiling of skin biopsies from patients with systemic sclerosis (SSc) has identified four “intrinsic” gene expression subsets conserved across multiple cohorts and tissues. These are the inflammatory, fibroproliferative, normal-like, and limited subsets. In order to classify patients in clinical trials or for diagnostic purposes, supervised methods that can assign a single sample to a molecular subset are required. Here, we introduce a novel machine learning classifier which is a robust predictor of intrinsic subset and test it on multiple independent patient cohorts.

**Methods:** Three independent SSc cohorts (Milano *et al.* 2008, Pendergrass *et al.* 2012, Hinchcliff *et al.* 2013) with gene expression data and intrinsic subset assignments were carefully curated and merged to create a training dataset covering a broad set of 297 skin biopsies representing 97 unique patients. Supervised machine learning algorithms were rigorously trained and evaluated using repeated three-fold cross-validation. We performed external validation using two independent SSc datasets: Chakravarty *et al.* 2015, which contains 16 samples/8 patients and Gordon *et al.* 2015, which contains 12 samples/6 patients. Additionally, we validated the classifier on a cohort of SSc patients with gene expression data independently generated by Assassi *et al.* 2015 (102 samples/97 patients). We used weighted gene co-expression network analysis and g:Profiler to identify and functionally characterize gene modules associated with the intrinsic subsets.

**Results:** Repeated cross-fold validation identified gene expression features using multinomial elastic net and incorporated them into the final model which achieved an average classification accuracy of 88%. All molecular subsets were classified with high average sensitivity and specificity, particularly inflammatory (83.3% sensitivity, 95.8% specificity) and fibroproliferative (89.7% sensitivity, 94.1% specificity). Through multiple rounds of external validation, the classifier maintained an accuracy ranging from 70% to 85%. In a re-analysis of gene expression data from Assassi *et al.* study, we identified subsets of patients that represent the canonical inflammatory, fibroproliferative, and normal-like subsets. The inflammatory subset showed upregulated gene modules enriched in biological processes such as inflammatory response, lymphocyte activation, and stress response. Similarly, gene modules enriched for cell cycle processes were increased in the fibroproliferative subset.

**Conclusion:** We have developed a highly accurate and reliable classifier for SSc molecular subsets for single samples trained and tested on diverse cohorts comprised of 427 skin biopsies from 208 independent patients. These analyses show that the intrinsic gene expression subsets are a common feature of SSc found across multiple internal and external validation cohorts. Machine learning methods provide a robust and accurate mechanism for stratifying intrinsic gene expression subsets and can be used to aid clinical decision-making and interpretation for SSc patients and in clinical trials.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Plasmacytoid Dendritic Cells (PDCs) are the key cell type mediating TLR-induced inflammation in several autoimmune diseases such as lupus, dermatomyositis, lichen sclerosus and cutaneous GVHD. In these diseases, PDC infiltrate the skin and produce IFN $\alpha$ , contributing to cutaneous lesions. In lupus, IFN $\alpha$  production was due to TLR7 and -9 recognition of endogenous RNA and DNA respectively. PDCs may also be part of the pathogenesis of systemic sclerosis (SSc). PDCs traffic to the skin in a mouse model of stiff skin syndrome. Moreover PDCs from SSc patients secrete CXCL4 and their levels in the serum correlated with skin and pulmonary disease. Although it is well described that PDC infiltrate the skin following injury or in diseases, little is known about what is controlling PDC trafficking and subsequent activation in the skin or whether PDCs can play a role in promoting/sustaining inflammation-related fibrosis. The aim of our study was to identify the nature of PDC activation in SSc patients, the role of TLRs or the impact of CXCL4 on PDC response.

### **Methods:**

For the human studies, blood was obtained from 87 SSc patients and 23 healthy volunteers (HV), and PBMCs were isolated by density gradient. PDC were then isolated from PBMC by positive selection with BDCA4 magnetic beads or by cell sorting. In mice, fibrosis was induced by sub-cutaneous injection of bleomycin (BLM) in WT and transgenic mice expressing human TLR8 (Tg8).

**Results:** Aberrant expression of TLR8 was observed on SSc PDCs while absent on HV. TLR8 activation in SSc PDCs significantly induced CXCL4 secretion ( $p=0.003$ ) compared to unstimulated PDC while TLR9 induction had no effect ( $p=0.5$ ). TLR8 activation led to an increase secretion of IFN $\alpha$  and pro-inflammatory IL-6 and TNF. CXCL4 further increased TLR8-induced IFN $\alpha$  production by PDC (3-fold) ( $1393\pm153\text{pg/ml}$  for TLR8-induced PDC vs  $5003\pm747\text{pg/ml}$  for CXCL4+TLR8-induced PDC) while it had no effect on IL-6 ( $1390\pm129\text{pg/ml}$  vs  $1365\pm100\text{pg/ml}$ ) and TNF production ( $3404\pm241\text{pg/ml}$  vs  $3251\pm207\text{pg/ml}$ ). In mice, following BLM treatment, a significant increase in skin thickness was observed in WT mice ( $200\pm6\text{mm}$  vs  $357\pm3\text{mm}$ ,  $p<0.0001$ ) and further increased in Tg8 mice ( $396\pm5\text{mm}$ ,  $p=0.04$  vs WT BLM). Moreover, PDCs accumulation was observed in the skin of WT BLM mice as compared to WT PBS as assessed by in situ analysis of SiglecH positive cells. PDCs infiltration were further enhanced in the skin of Tg8 mice ( $p=0.0008$ ) as well as enhanced expression of IFN related genes, IP10 ( $p=0.006$ ), IFIT2 and IFI35 ( $p=0.03$ ).

**Conclusion:** Taken together our data demonstrate that the secretion of CXCL4 is due to the aberrant presence of TLR8 on PDCs of SSc patients, and that CXCL4 contributes to excessive IFN $\alpha$  response by TLRs. In mice, TLR8 exacerbates fibrosis due to an increased PDC infiltration in the skin.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is an autoimmune disease characterized by vascular abnormalities, immune system dysregulation, and fibrosis. Pulmonary arterial hypertension (PAH) affects approximately 10% of SSc patients and is a leading cause of death. We sought to identify cytokines predictive of progression to PAH in SSc.

**Methods:** Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) is a prospective registry that includes SSc patients at high risk for PAH based on pulmonary function test and echocardiographic parameters. Serum was available from 38 high-risk patients for this study. Baseline characteristics were assessed at the time of serum acquisition. Kaplan-Meier estimates were generated for time to PAH from first non-Raynaud's Phenomenon (RP) symptom. The Luminex (eBioscience) immunoassay (Human 62-plex) was used for serum cytokine profiling. Missing data were multiply imputed to generate 60 complete datasets. Using multivariable Cox regression, time to PAH was regressed on a candidate predictor set consisting of all cytokines' preprocessed median fluorescence intensities and four clinical covariates which had previously been shown to be associated with progression to PAH in the PHAROS cohort (exercise induced O<sub>2</sub> saturation, % predicted diffusing capacity for carbon monoxide (DLCO), forced vital capacity/DLCO, systolic pulmonary artery pressure on echocardiogram) (1). Regression coefficients were estimated by five-fold cross-validated, likelihood-based boosting.

**Results:** Baseline characteristics are shown in Table 1. At 1, 5, 10, 15, and 20 years after first non-RP symptoms, the rate of progression to PAH in this high-risk population was 3%, 5%, 15%, 18%, and 31% respectively. Elevated levels of IL-1 $\beta$  (Figure 1) and IL-15 (not shown) correlated with an increased risk of progression to PAH.

**Conclusion:** These preliminary results identified IL-1 $\beta$  and IL-15 as potential biomarkers associated with progression to PAH in SSc. These may be useful in identifying high-risk patients who warrant early referral to right heart catheterization,

and may provide further insight into the mechanism of disease. We plan to validate our findings in an independent cohort.

Table 1. Baseline characteristics of patients at risk for SSc-PAH at the time of serum acquisition	
Clinical features (total no. of patients)	Value
Age, mean $\pm$ SD years (36)	56.5 (11.7)

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Systemic sclerosis (SSc) is an autoimmune disease characterised by excessive fibrosis of skin and internal organs, and vascular dysfunction. Association of T and B cell subsets have been reported in SSc, however there is lack of systematic studies of functional relations between immune cell subsets in this disease. This lack of mechanistic knowledge hampers targeted intervention. In the current study we sought to determine differential immune cell composition and heterogeneity in peripheral blood of SSc patients compared to healthy controls.

## Methods:

SSc patients fulfilling ACR 2013 criteria (n=20, of whom 10 were of diffuse cutaneous subtype; 10 had interstitial lung disease) and healthy controls (n=10) were included. Mononuclear cells from blood were analysed by mass cytometry using a 36 marker (cell-surface and intracellular) panel to aid in identification of major PBMC lineages including T cells, B cells, monocytes and NK cells and their subsets. Unsupervised clustering of mass cytometry data was performed using in-house developed analysis software MARVIS. This software combines dimension reduction and clustering steps to identify all possible cellular subsets. Further, custom R scripts helped in identifying nodes that were differentially expressed between the study groups and also phenotype of these nodes.

## Results:

Unsupervised clustering performed revealed significant differences in the frequencies of T cell and B cell subsets. Most strikingly we identify a 3 fold decrease in frequencies of Va7.2+ CD161+ mucosal associated invariant T cells (MAIT) in SSc patients and 2 fold increase in total B cells, particularly CD19+ CD27- naive cells. A subset of memory CD8+ T cell, expressing CXCR3 was found to be increased in SSc patients as compared to healthy controls. Transcriptome analysis of sorted B cell and T cell subsets showed decrease in genes related to survival and increased expression of apoptotic genes in CD4, CD8 T and MAIT cells from SSc patients. Interestingly, high expression of CXCR3 gene was observed in transcriptome analysis of CD8+ T cells from SSc patients.

## Conclusion:

This study provides an in depth analysis of systemic immune composition in SSc with the potential to delineate mechanisms of pathogenesis and identify diagnostic and/or therapeutic targets. This is the first demonstration of dysfunction of MAIT cells in SSc and further characterisation of their function in this context is required.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Long noncoding RNAs (lncRNAs) represent a class of transcripts longer than 200 nucleotides that are not translated into proteins. In recent years, antisense (AS) lncRNAs have increasingly been recognized as important regulators of their sense genes and they have been found to play key roles in the pathogenesis of several diseases. However, the role of AS lncRNAs in SSc is still unknown. Our previous study identified two AS lncRNAs in SSc skin biopsies namely HAND2-AS1 and OTUD6B-AS1. Here we aim to characterize the functional relevance of these AS lncRNAs.

**Methods:** Sense and AS gene expression was analyzed by qPCR in RNA samples of HC and SSc dermal fibroblasts (Fb). Dermal Fb were stimulated with different profibrotic cytokines and growth factors like TGF $\beta$ , PDGF and IL-4 at physiological concentrations. Function of AS lncRNAs was analyzed by qPCR and Western Blot (WB) in HC dermal Fb and human pulmonary artery smooth muscle cells (HPASMC) transfected with locked nucleic acid antisense oligonucleotides (LNA GapmeRs).

**Results:** RNA sequencing analysis of skin biopsy revealed consistent and significant downregulation of HAND2-AS1 and OTUD6B-AS1 expression. In SSc and HC dermal Fb, no difference was recorded in the basal level of HAND2-AS1, HAND2, OTUD6B-AS1 and OTUD6B expression. However, HAND2 and HAND2-AS1 expression in SSc dermal Fb was significantly downregulated after TGF $\beta$  and IL-4 stimulation (n=4-5,  $p<0.05$ , up to 0.09 fold reduction). HAND2-AS1 expression was also significantly downregulated after PDGF stimulation (n=4,  $p<0.05$ , up to 0.12 fold reduction) and HAND2 expression had the same trend. OTUD6B expression in SSc dermal Fb was significantly downregulated after PDGF stimulation (n=7,  $p<0.05$ , up to 0.16 fold reduction) and OTUD6B-AS1 expression was also decreased. OTUD6B-AS1 expression was significantly downregulated after IL-4 stimulation (n=4,  $p<0.05$ , up to 0.52 fold reduction). Importantly, HAND2-AS1 knockdown significantly reduced collagen 1A1, fibronectin and  $\alpha$ -smooth muscle actin ( $\alpha$ SMA) mRNA in dermal Fb ( $p<0.05$ ). Downregulation of fibronectin expression was also confirmed after HAND2-AS1 knockdown by WB analysis (n=4). In contrast to HAND2-AS1, OTUD6B-AS1 knockdown did not affect extracellular matrix production. However, we observed effects on cell cycle regulation after OTUD6B-AS1 knockdown. OTUD6B-AS1 knockdown in Fb and HPASMC significantly increased OTUD6B, and cell cycle regulators c-MYC, Cyclin D1 and Cyclin D2 mRNA (n=6,  $p<0.05$ ). Upregulation of OTUD6B, c-MYC and Cyclin D1 in HPASMC was also confirmed after OTUD6B-AS1 knockdown by WB analysis (n=2).

**Conclusion:** This is the first report analyzing the functional role of AS lncRNAs in SSc. These results point to an important role of HAND2-AS1 in extracellular matrix production and of OTUD6B-AS1 in cell cycle progression.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The TNF Superfamily member LIGHT (TNFSF14) regulates immune response and angiogenesis. Moreover, recent studies indicate that interactions of LIGHT with its receptor, TNFRSF14, might also play a role in regulation of tissue remodeling. Since autoimmunity, vascular injury and fibrosis are key elements of the pathogenesis of systemic sclerosis (SSc) we hypothesized that LIGHT might be involved in development of SSc. This study was aimed to assess potential role of LIGHT in SSc through evaluation of: 1). expression of LIGHT and its receptor, TNFRSF14, in skin biopsies and 2) associations between serum concentration of LIGHT and clinical features in SSc patients.

**Methods:** Expression of LIGHT and its receptor, TNFRSF14, was investigated by means of immunohistochemistry, and evaluated semiquantitatively (score from 0 to 3), in skin biopsies from 18 SSc patients and 9 healthy controls. Serum levels of LIGHT were measured using commercially available ELISA kits in 320 patients with SSc and 50 control subjects.

**Results:** Expression of both, LIGHT and TNFRSF14 was significantly higher in skin biopsies from SSc patients as compared with healthy controls ( $p < 0.05$ ). Patients with early SSc ( $\leq 3$  years from the first non-Raynaud's phenomenon,  $n = 13$ ) showed significantly higher skin expression of TNFRSF14 ( $p < 0.05$ ) and tended to have greater skin expression of LIGHT ( $p = 0.06$ ) as compared with SSc patients with longer disease ( $n = 5$ ).

The mean serum concentration of LIGHT was significantly higher in SSc patients as compared with the controls ( $p < 0.05$ ). Moreover, mean serum concentration of LIGHT was significantly higher in SSc patients with digital ulcers (DUs) as compared with SSc patients without DUs, patients without anti-centromere antibodies (ACA) as compared with those with ACA, patients with muscle involvement (defined by elevated serum CK levels) compared with patients without CK elevation and in patients receiving steroids, as compared with those without steroid therapy ( $p < 0.05$  for all comparisons). In

addition, the mean concentration of LIGHT was significantly higher in male patients as compared with female SSc patients ( $p < 0.05$ ). There were also statistically significant ( $p < 0.05$ ) although very weak correlations between serum concentration of LIGHT and skin involvement (modified Rodnan skin score (mRSS); R-Spearman = 0.13;), erythrocyte sedimentation rate (ESR; R-Spearman = 0.15), and, inverse, with diffusing capacity of the lungs for CO (DLCO; R-Spearman = -0.22). We could not find any significant associations between serum LIGHT concentrations and other SSc features, including subtype of SSc, disease duration, presence of interstitial lung disease, pulmonary hypertension, or other antibodies. In multivariate regression analysis including, as predictors, DUs, ACA, serum CK elevation, steroid therapy, mRSS, DLCO, ESR, and sex, only presence of DUs and DLCO were independently associated with serum concentration of LIGHT ( $p < 0.05$  for both).

**Conclusion:** These data provide the first evidence of overexpression of LIGHT and its receptor in SSc and suggest that LIGHT-TNFRSF14 axis might contribute to the pathogenesis of SSc. Increased serum concentrations of LIGHT seem to reflect vascular injury in SSc.

## **M10, a Caspase Cleavage Product of the Hepatocyte Growth Factor Receptor, Downregulates Bone Morphogenetic Protein-9-Induced Smad1/5/8 Phosphorylation and Collagen Production in Human Lung Fibroblasts**

**Atsushi Noguchi**, Ilia Atanelishvili, Tanjina Akter, Richard M. Silver and Galina S. Bogatkevich, Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We recently identified M10, a caspase cleavage product of the hepatocyte growth factor receptor, as an anti-fibrotic peptide that interacts with Smad2 and inhibits TGF $\beta$ -induced Smad2 phosphorylation and collagen production in human lung fibroblasts [1]. While Smad2/3 signaling pathway is mainly activated by TGF $\beta$ 1 through type I receptor activin receptor-like kinase (ALK) 5, Smad1/5 signaling pathway is mainly activated by bone morphogenetic proteins (BMPs), which are other members of TGF $\beta$  superfamily, through ALK1/2/3/6 receptors. Recently, BMP9 has been identified as a pro-fibrotic ligand in mouse embryo fibroblasts [2]. In SSc fibroblasts, ALK1/Smad1/5 pathway is suggested to play a pivotal role in the regulation of fibrosis [3]. The aims of this study are to investigate the role of BMP9 in SSc lung fibroblasts and to examine the additional anti-fibrotic mechanisms of M10.

**Methods:** Fibroblasts were derived from lung tissues obtained at autopsy from SSc patients and from age- race-, and sex-matched normal subjects. MRC5 human fetal lung fibroblasts were purchased from Sigma. Potential peptide-protein interactions were modeled *in-silico* using PepSite [4]. Smad phosphorylation, type I collagen, and smooth muscle  $\alpha$ -actin ( $\alpha$ -SMA) expression were determined by immunoblotting and RT-PCR.

**Results:** Using a computational modulation approach available from PepSite, we found a statistically significant ( $p < 0.0001$ ) potential interaction of M10 with the BMP9/ALK1/activin receptor type II B (ActRIIB) complex. The most

probable binding sites are located at  $\beta$ -turn motifs in BMP9. We demonstrate that when recombinant BMP9 is added to the medium, phosphorylation of Smad1/5/8 is rapidly induced in MRC5 cells and SSc lung fibroblasts in a dose-dependent manner. The expression of type I collagen is upregulated after 48 hours treatment with BMP9 in MRC5 cells and SSc lung fibroblasts as well as normal lung fibroblasts. The expression of  $\alpha$ -SMA is increased in normal lung fibroblasts in a dose dependent manner. Intriguingly, the anti-fibrotic peptide M10 significantly downregulated BMP9-induced type I collagen expression and  $\alpha$ -SMA expression as well as Smad1/5/8 phosphorylation in lung fibroblasts.

**Conclusion:** We demonstrate that BMP9 shows pro-fibrotic effects in human fetal lung fibroblasts and in adult lung fibroblasts obtained from SSc patients and matched normal subjects. M10 peptide has a potential to bind to BMP9 and to inhibit BMP9-induced collagen production and epithelial-mesenchymal transition through the Smad1/5/8 signaling pathway.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous work has shown that insulin-like growth factor (IGF)-II is increased in fibrosing lung diseases, including idiopathic pulmonary fibrosis (IPF) and scleroderma/systemic sclerosis (SSc)-associated pulmonary fibrosis. Our goal was to identify the mechanism by which upregulated IGF-II expression contributes to fibrosis in these conditions.

**Methods:** Fibroblasts derived from lung tissues of normal donors (NL), patients with IPF, and patients with SSc-associated pulmonary fibrosis were used. Gene expression, protein expression, phosphorylation, and secretion were analyzed with qRT-PCR, immunoprecipitation, immunoblotting, and ELISA, respectively, in early passage primary fibroblasts. Antibody, siRNA, and inhibitors were used to neutralize, knockdown, or block endogenous IGF-II and the IGF-II receptors: IGF-1 receptor (IGF1R), IGF2R, and/or insulin receptor (IR).

**Results:** The IGF1R, IGF2R, and IR receptors showed lower basal gene expression in SSc fibroblasts. Extracellular matrix (ECM) transcripts, though unchanged in NL, were dramatically increased in IPF and SSc with IGF-II (200 ng/mL) stimulation. Activation of IGF1R, assessed via receptor phosphorylation, occurred 5 min following IGF-II. Phosphorylation decreased by 10 min in NL, but persisted through 10 min in SSc fibroblasts. Phosphorylation was abrogated by antibody-mediated neutralization of endogenous IGF-II. Dual siRNA knockdown of IGF1R and IR decreased ECM components collagen and fibronectin in NL and SSc fibroblasts, as did treatment with an IGF1R tyrosine kinase inhibitor. IGF-II decreased IGF1R and IR transcripts at 6 hr in NL, IPF, and SSc and decreased IGF2R in NL from 1-48 hr. MMP3 transcript was decreased with IGF-II stimulation in IPF and SSc, whereas TIMP1 transcript and secretion were increased.

**Conclusion:** Decreased basal receptor pools, ECM component upregulation, and longer receptor activation render fibroblasts from pathologic lung more sensitive to IGF-II-stimulated fibrosis. Inhibitor studies indicate IGF-II signaling is mediated by IGF1R and IR, which can form a hybrid receptor. IGF-II causes disruption of steady-state ECM deposition and breakdown through altered MMP:TIMP levels, promoting a pro-fibrotic milieu in IPF and SSc.

## **Application of a Novel Computational Approach to Identify New Targets and Pathways for Therapeutic Intervention in Scleroderma**

Elma Kurtagic, Joel Pradines, Anthony Manning and **Ishan Capila**, Research, Momenta Pharmaceuticals, Inc., Cambridge, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic Sclerosis (SSc) is a complex autoimmune disease with chronic progressive course and high interpatient variability. It is characterized by inflammation, vascular dysfunction and fibrosis. Fibrosis of the skin and visceral organs results in irreversible scarring and ultimately organ failure, accounting for high mortality. There is no approved targeted therapy with disease-modifying potential. Several translational studies were published, which focused on transcriptional analysis of samples from SSc patients in order to understand the heterogeneity of underlying disease. We interrogated these datasets using a novel data analysis methodology that leverages the knowledge of protein interaction networks (STRING) for deriving biological insights and identifying intervention points into this heterogeneous disease.

### **Methods:**

Publically available datasets composed of gene expression analysis of patient skin biopsies were identified. Datasets were subjected to sample size and quality assessment. Selected high-quality datasets were analyzed using a novel computational and statistical method. Namely, each gene was scored for both its differential expression and its known protein interactions with top differentially expressed genes (DEGs). This approach led to identification of Well-Associated Proteins (WAPs); gene products that have a significantly large number of known associations to top DEGs, without choosing a threshold for differential expression. The scoring method corrects for the total number of interactions of each gene and is optimally fast,

enabling false discovery rate (FDR) estimates for each WAP via permutation testing, thus taking into account gene co-expression. Furthermore, permutation testing was utilized to identify WAPs that correlated with measurable clinical factors.

## Results:

Four publically available datasets were analyzed. Key biology pathways associated with SSc were identified. More importantly, > 100 potential targets/WAPs were identified with FDR score < 0.01%. ~ 75% of the significant WAPs were not perturbed at the mRNA level and would have been missed via standard statistical methods. Their significant connectedness to top DEGs in the datasets suggests biologically relevant role in SSc. Robustness analysis revealed that WAP scores were ~40% reproducible across pairs of datasets, as compared to only ~10% for DEG scores. Of the top 100 WAPs obtained by combining the two largest data sets, 59 were previously targeted providing drug-repurposing opportunities and 41 were novel targets for drug discovery. Additional analysis identified WAPs (e.g. OSM) that significantly correlated with measurable clinical factors such as MRSS (global skin score), diffuse disease and some auto-antibodies.

## Conclusion:

A novel data analysis methodology was developed, leveraging protein interaction networks to identify WAPs that represent potentially unique targets for therapeutic intervention in SSc. WAPs are unique as they were reproducibly detected across multiple publicly available SSc datasets. Additionally, patient sub-populations that may benefit from targeted therapeutics against selected WAPs were identified.

## Proteomic Analysis of Scleroderma Associated Joint Disease

**Chan Kim**<sup>1</sup>, Julio Mantero<sup>2</sup>, Robert A. Lafyatis<sup>3</sup> and Robert W. Simms<sup>4</sup>, <sup>1</sup>Rheumatology and Clinical Epidemiology, Boston University School of Medicine, Boston, MA, <sup>2</sup>Arthritis Center, Boston University School of Medicine, Boston, MA, <sup>3</sup>Division of Rheumatology and Clinical Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA, <sup>4</sup>Rheumatology, Boston University School of Medicine, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The pathophysiology of joint disease in scleroderma, a heterogeneous multisystem disease mostly characterized by fibrosis, is unknown. We performed proteomic analysis of serum in patients with scleroderma and joint tenderness. Understanding systemic protein expression in scleroderma may help us understand joint disease in scleroderma. Our goal was to characterize protein expression differences between scleroderma patients with joint tenderness and scleroderma patients without joint tenderness.

## Methods:

Patients with scleroderma were recruited from the registry at Boston University Medical Center's Scleroderma Center. Serum (blood) samples were drawn and were analyzed with SOMAscan for 1129 protein biomarkers. As part of the routine examination performed by a senior rheumatologist on all registry participants, tender joint count (0-18) was assessed on physical exam. If a subject had a tender joint count of 2 or more, then that subject had joint disease. If a subject had a tender joint count of 0, then that subject did not have joint disease. For this study, 40 scleroderma subjects had both SOMAscan data and tender joint count assessment. One subject with only 1 tender joint count was excluded, so 39 subjects were analyzed. For analysis, the biomarkers were log2 transformed, and differential expression analyses were performed using the "limma" package using the R statistical software.

## Results:

Among the 39 scleroderma subjects, 9 participants had joint pain (average tender joint count 4.9), and protein expression was compared between scleroderma participants with joint disease and scleroderma participants without joint disease. The top 20 most significant biomarkers are shown in table 1. In previous analyses (not shown), similar biomarkers (such as MMP (matrix metalloproteinase), fibrinogen, tumor necrosis factor), were seen elevated in all scleroderma participants (compared to normal subjects without scleroderma). Notably, IL-6, cadherin-2 (involved in bone and cartilage formation), BRF1 (RNA Polymerase III transcription initiation factor subunit) were expressed higher in scleroderma subjects with joint disease compared to those without joint disease. VEGF-121 (vascular endothelial growth factor) was expressed lower in scleroderma subjects with joint pain compared to those without joint disease.

## Conclusion:

Although scleroderma participants had many protein expression changes due to fibrosis, autoimmunity and vasculopathy, several biomarkers such as IL-6, cadherin-2, BRF1, VEGF-121 were differentially expressed in scleroderma participants with joint disease and could provide insight into the pathophysiology of joint disease in scleroderma.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Our previous study demonstrated that Heat shock protein 90 (Hsp90) is overexpressed in the skin of patients with systemic sclerosis (SSc), in cultured SSc fibroblasts and preclinical models of SSc in a TGF- $\beta$  dependent manner. We showed that Hsp90 is a new regulator of canonical TGF- $\beta$  signalling and its inhibition prevents the stimulatory effects of TGF- $\beta$  on collagen synthesis and dermal fibrosis in three preclinical models of SSc<sup>1</sup>. The aim of this study was to evaluate Hsp90 in the circulation of SSc patients and characterize its potential association with skin changes and SSc-related features.

**Methods:** A total of 91 patients (78 females; mean age 52.7; disease duration 6.0 years; diffuse cutaneous (dc)SSc / limited cutaneous (lc)SSc = 38/53) who met the ACR/EULAR 2013 classification criteria for SSc and 85 age- and sex- matched healthy individuals were included. Plasma Hsp90 levels were measured by ELISA (eBioscience, Vienna, Austria). SSc-related manifestations were obtained from the Czech Registry of SSc patients. Skin changes were assessed using the modified Rodnan skin score (mRSS) and EUSTAR SSc activity score was determined. Data are presented as median (IQR, 25. – 75. percentile).

**Results:** Plasma Hsp90 levels were increased in SSc patients compared to healthy controls [12.5 (9.6–17.9) vs. 9.9 (7.9–12.6) ng/mL,  $p = 0.001$ ], but no difference between (lc)SSc and (dc)SSc were detected [13.1 (9.4–18.1) vs. 11.5 (9.5–17.5) ng/mL,  $p = 0.316$ ]. Hsp90 levels in all patients positively correlated with CRP ( $r = 0.313$ ,  $p = 0.006$ ). Furthermore, Hsp90 concentrations were increased in patients with interstitial lung disease (ILD) compared to those without ILD [12.8 (10.2–17.9) vs. 10.3 (8.6–16.6) ng/mL,  $p = 0.045$ ] and were negatively associated with functional parameters of ILD: FVC ( $r = -0.299$ ,  $p = 0.011$ ), FEV1 ( $r = -0.256$ ,  $p = 0.031$ ), DLCO ( $r = -0.303$ ,  $p = 0.009$ ) and SpO<sub>2</sub> ( $r = -0.317$ ,  $p = 0.038$ ). In addition, only in patients with dcSSc, Hsp90 levels positively correlated with the mRSS ( $r = 0.437$ ,  $p = 0.006$ ). Concentrations of extracellular Hsp90 were not significantly affected by other main clinical parameters of SSc.

**Conclusion:** We demonstrated higher plasma levels of Hsp90 in SSc patients compared to healthy controls. Concentrations of extracellular Hsp90 increase with higher inflammatory activity, with deteriorated lung functions in ILD and also with the extent and severity of the skin involvement in patients with diffuse cutaneous SSc. These data further highlight the role of Hsp90 as a significant regulator of fibroblast activation and tissue fibrosis in SSc.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Sclerosis (SSc) is a multisystem autoimmune connective tissue disorder characterized by vascular injury and fibrosis of the skin and internal organs. Methyl-CpG-binding protein 2 (MeCP2) is a transcription activator or repressor depending on its interacting complexes. Increasing evidence shows that MeCP2 is closely involved in lung, liver, and kidney fibrosis. In this study, we aim to elucidate the role of MeCP2 in dermal fibroblasts from patients with SSc.

**Methods:** Dermal fibroblasts were isolated from healthy controls or patients with diffuse cutaneous SSc (dcSSc). MeCP2 expression was analyzed by qRT-PCR and western blotting. A scratch wound healing assay was used to evaluate fibroblast migration. MeCP2 overexpression was achieved by transfecting fibroblasts with MeCP2 DNA plasmids, while transfection with empty vectors was used as control. MeCP2 knockdown was done using MeCP2 siRNA. RNA isolated from dcSSc fibroblasts after 48hrs of MeCP2 knockdown was sequenced by Illumina HiSeq2500. Gene pathway analysis was performed using GeneMANIA and by searching literatures and GeneCards database.

**Results:** MeCP2 expression was increased by 1.8-fold ( $p=0.02$ ) in dcSSc fibroblasts ( $n=6$ ) compared to normal fibroblasts ( $n=7$ ) at the protein level. However, no change was observed at the mRNA level, suggesting that dysregulation of MeCP2 in dcSSc occurs at the post-transcriptional level. Overexpression of MeCP2 in normal fibroblasts inhibited cell migration ( $n=4$ ,  $p=0.02$ ) while MeCP2 knocked down dcSSc fibroblasts showed higher wound repair ability than controls ( $n=5$ ,  $p<0.01$ ). In addition, the mRNA levels of pro-fibrotic genes such as  $\alpha$ -SMA and COL1A1 were significantly downregulated in MeCP2 overexpressing normal fibroblasts ( $n=6$ ,  $p=0.03$ ) while anti-fibrotic PPAR- $\gamma$  was upregulated ( $n=6$ ,  $p<0.01$ ). Using RNA-seq we identified 51 differentially expressed genes after MeCP2 knockdown in dcSSc fibroblasts ( $n=5$ ,  $\geq 1.2$  fold or  $\leq 0.8$  fold, adjusted  $p$ -value $<0.05$ ). 14 out of 51 differentially expressed genes appeared to be involved in fibrosis, among which 5 downregulated genes including ITGB1 and NID2 were shown to be related to COL1A1, and 4 genes, including ITGB1, PLA2, ADA, and TNFIP1, were involved in cell migration/adhesion. None of the 14 screened genes were differentially expressed between normal and dcSSc fibroblasts, suggesting that MeCP2 might suppress fibrosis via balancing the expression of some of these candidate genes. Moreover, we further confirmed that 9 downregulated fibrosis-related genes identified by RNA-seq were indeed MeCP2-regulated genes, as they were upregulated when MeCP2 was overexpressed in normal fibroblasts.

**Conclusion:** MeCP2 exerts anti-fibrotic effects in dcSSc fibroblasts by reducing cell migration and myofibroblast differentiation. Whole transcriptome profiling reveals that MeCP2 is involved in cell adhesion and controls extracellular matrix (ECM)-related genes. Importantly, MeCP2 overexpression in dcSSc fibroblasts appears to be a defense mechanism to counteract the pro-fibrotic nature of the disease. MeCP2 might be a novel target to restore normal skin function in SSc.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Sclerosis (SSc) is a disease characterized by an increase in the synthesis of extracellular matrix (ECM) components in various organs, including the skin, resulting in increased morbidity. Like most autoimmune diseases, SSc has a female predominance that increases during childbearing years. Interestingly, post-menopausal SSc patients have higher circulating estradiol (E2) levels compared to age-matched controls. E2 exerts pro-fibrotic and pro-inflammatory activity, increasing ECM components and IL-6, both of which are also increased in SSc patients. Aromatase (CYP19) is a cytochrome p450 enzyme active in extra-gonadal tissues, including the skin. It is responsible for the aromatization of androgens into estrogens. Increased activity of aromatase may underlie the increase E2 levels in SSc patients. Since SSc dermal fibroblasts secrete increased levels of IL-6, and increased E2 levels are reported in SSc patients, we hypothesized that there is an interplay between E2 and IL-6 contributing to the pro-fibrotic phenotype.

**Methods:** Human skin in organ culture was stimulated with E2 or IL-6 and its soluble receptor, sIL6R, for 24 or 48 hours. Transcript levels of aromatase, IL-6, and collagen 1A1 were measured using real-time PCR. Aromatase activity was measured using an ELISA-based testosterone conversion assay. Statistical significance was determined using ANOVA, with significance defined as  $p \leq 0.05$ .

**Results:** Human skin stimulated with E2 or IL-6 + sIL-6R *ex vivo* showed increased levels of collagen. E2 stimulation also resulted in increased IL-6 transcript and protein levels. Stimulation of human skin with IL-6 and sIL-6R led to increases in the levels of aromatase mRNA. Skin samples stimulated with IL-6 and sIL-6R also had increased aromatase activity, translating into increased conversion of testosterone into estradiol. The aromatase activity decreased significantly after treatment with anastrozole, an aromatase inhibitor.

**Conclusion:** Our data show that both E2 and IL-6 exert pro-fibrotic effects in human skin. Our findings further establish the existence of a positive feedback loop between E2 and IL-6, supporting a pro-fibrotic cycle that leads to increased ECM production and fibrosis. Our results implicate E2 and IL-6 in dermal fibrosis in SSc. Our results also suggest that effective therapies for SSc may require concomitant inhibition of E2 and IL-6.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic sclerosis (SSc) is a rare autoimmune connective tissue disorder characterized by autoimmunity, vasculopathy and fibrosis. Fibrosis is due to an exaggerated activation of fibroblasts by the transforming growth factor- $\beta$  (TGF- $\beta$ ). In this study we investigated the proteomic response of skin fibroblasts to TGF- $\beta$  in patients with SSc.

### Methods:

Skin fibroblasts from 4 patients with SSc and 3 healthy controls (HC) were cultured in the presence or in the absence of TGF- $\beta$ . Two-dimensional gel electrophoresis and mass spectrometry (MS) were used to identify proteins differentially expressed between groups. Ingenuity Pathway analysis (IPA) and Panther softwares were used to analyse identified proteins. Finally real-time cell analyser (RTCA) was used to assess fibroblast proliferation and viability in order to validate proteins of interest.

### Results:

We identified 687 protein spots differentially expressed between groups. 297 protein spots were analysed by MS. Principal component analysis revealed significant differences between fibroblasts of patients with SSc and HC when cultured in the presence or in the absence of TGF- $\beta$ . IPA revealed specific process networks such as actin cytoskeleton signalling, integrin signalling, and remodelling of epithelial adherens junctions. Panther revealed predominant biological processes such as cellular process, metabolic process and cellular component organization. TGF- $\beta$  enhanced the synthesis of fibroblasts' proteins involved in actin cytoskeleton signalling and integrin signalling. Using IPA and RTCA we identified and validated the involvement of epidermal growth factor receptor (EGFR) and phosphatidylinositol 3 kinase (Pi3K) in the proliferation and the viability of fibroblasts from patients with SSc.

## Conclusion:

In conclusion, we confirmed that the proteome profile of fibroblasts differs between patients with SSc and HC and demonstrated that fibroblasts enhance their proteomic phenotype upon stimulation with TGF- $\beta$ . We finally highlighted that EGFR and Pi3K are proteins of interest in fibroblasts from patients with SSc and should be considered as potential targets to inhibit fibrosis in SSc.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Skin gene expression profiling can distinguish SSc from normal skin and can detect different subsets of disease. Previous studies have reported a cross-sectional relationship between the expression of genes in whole skin and the modified Rodnan skin score (mRSS). We aim to compare gene expression in early versus late dcSSc and define cells responsible for the upregulation of candidate genes.

**Methods:** Total RNA was extracted from forearm skin biopsies of 3 early dcSSc anti-RNA polymerase III positive (ARA+) patients and 3 late dcSSc ARA+ patients. COMP, chemokine ligand 2 (CCL2), PDGF-A, collagen type I  $\alpha$ 1 chain (COL1A1), interferon Induced Protein 44 (IFI44), IL-6, MMP3, SERPINE, TGF- $\beta$  and thrombospondin 1 (THBS1) was measured using quantitative PCR analysis. mRSS was assessed in all patients and correlated with normalized gene expression. RNA in situ hybridization for  $\alpha$ -actin-2 (ACTA2), CCL2, COL1A1, COL3A1, COMP, SERPINE and THBS1 mRNA was performed using RNAScope™ 2.5 LS Reagent Kit in early dcSSc ARA+ patients (n=2) and healthy controls (HC) (n=3). Semi-quantitative scoring criteria were applied (score from 0 to 4).

**Results:** Whole skin relative normalized gene expression of COMP, CCL2, IL-6, SERPINE and THBS1 was significantly ( $p < 0.05$ ) higher in early compared to late SSc skin (COMP mean  $25049.15 \pm 10862.16$  vs  $5256.47 \pm 2380.53$ ; CCL2 mean  $1722.04 \pm 598.93$  vs  $638.25 \pm 279.96$ ; IL-6 mean  $43.98 \pm 40.76$  vs  $11.91 \pm 5.44$ ; SERPINE mean  $1770.32 \pm 704.46$  vs  $184.48 \pm 61.37$ ; THBS1 mean  $7190.75 \pm 309.89$  vs  $1176.81 \pm 235.35$ ) [Figure 1]. There was a positive correlation between

SERPINE and THBS1 and mRSS (SERPINE  $r^2 = 0.493$ ,  $p = 0.09$ ; THBS1  $r^2 = 0.91$ ,  $p = 0.02$ ). Whole skin relative normalized gene expression of all the remaining genes, except for IFI44, was also higher in early compared to late patients although not significantly. RNAscope analysis revealed positive SERPINE staining in subsets of fibroblast-like cells located in the mid-dermis in early dcSSc only (score 3 and 4 in early dcSSc vs score 0 in HCs). An increased number of THBS1+ and COMP+ fibroblast-like cells ( $\alpha$ -smooth muscle actin +) were found in the deep dermis of early dcSSc (score 4 in early dcSSc pts vs score 0, 2 and 3 in HCs).

**Conclusion:** SERPINE, THBS1, COMP, CCL2 and IL-6 are upregulated in early compared to late dcSSc patients. THBS1 and COMP are key genes associated with skin involvement and both are TGF- $\beta$  regulated. RNAscope technology not only confirmed the upregulation of SERPINE, COMP and THBS1 in early dcSSc, but detected the expression of these genes in the dermis of patients in subsets of cells. These findings highlight how specific cells may be responsible for the pro-fibrotic and inflammatory changes typical of the early stages of the disease. Upregulation of fundamental pro-fibrotic and inflammatory genes could be crucial in the early stages of SSc and specific subsets of cells in the dermis could be the responsible for this.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Background/Purpose:** Systemic sclerosis (SSc) is a multisystem, autoimmune disease characterized by immune dysregulation, vasculopathy and excessive fibrosis of the skin and internal organs. Fibrosis is the pathological state where the unbalance in ECM turnover is shifted towards increased formation. The main family of ECM protein is collagen and the excessive fibrosis results in release of ECM fragments to circulation, where they may be quantified as biomarkers. Skin is rich in type I and III collagen, while type IV, V, VI and VII collagen is present to a lesser amount. The objective is to investigate if the level of collagen turnover could aid in describing skin fibrosis in SSc.

**Methods:** SSc patients (n=121) from a cross-sectional study fulfilling the 2013 ACR/EULAR SSc criteria were included together with non-symptomatic controls (n=9). The study included both limited SSc (ln=79) and diffuse SSc (n=42). The mean age of the population was 57.4 (SD 11.6) years, 84% were female, mean disease duration was 11.7 (8.9) years and mean skin score was 11.2 (8.6). Biomarkers of type I, III, IV, V and VI collagen formation (PINP, PRO-C3, P4NP7S, PRO-C5 and PRO-C6, respectively) and type III, IV, V, VI and VII collagen degradation (C3M, C4M, C5M, C6M and C7M, respectively) were assessed in serum by competitive ELISAs. Furthermore, a biomarker of a degraded and citrullinated form of vimentin (VICM) was measured in serum. Statistical differences between non-symptomatic controls and SSc patients was tested by t- test (Mann-Whitney).

**Results:** In SSc patients formations biomarkers of type I, VI and VII collagen was significantly increased compared to non-symptomatic controls (PINP:  $P=0.02$ , PRO-C5:  $P=0.01$ , PRO-C6:  $P=0.03$ ) (Figure 1). Formation biomarkers of type III and VI collagen were not significantly increased. The degradation biomarkers of type III, IV and V collagen were not significantly increased in SSc patients (Figure 2). However, degradation of type VI and VII collagen (C6M:  $P=0.02$  C7M:  $P=0.05$ ) were significantly increased in SSc patients. Furthermore, VICM was also significantly elevated in SSc patients compared to non-symptomatic controls ( $P<0.0001$ ).

**Conclusion:** This pilot study showed that collagen turnover appears to be significantly different between SSc patients and non-symptomatic controls. Even if the collagen formation is increased, the degradation of all collagens are not. These data suggest that serological assessment of ECM turnover could be relevant in SSc, and offers area of investigation of disease pathogenesis.

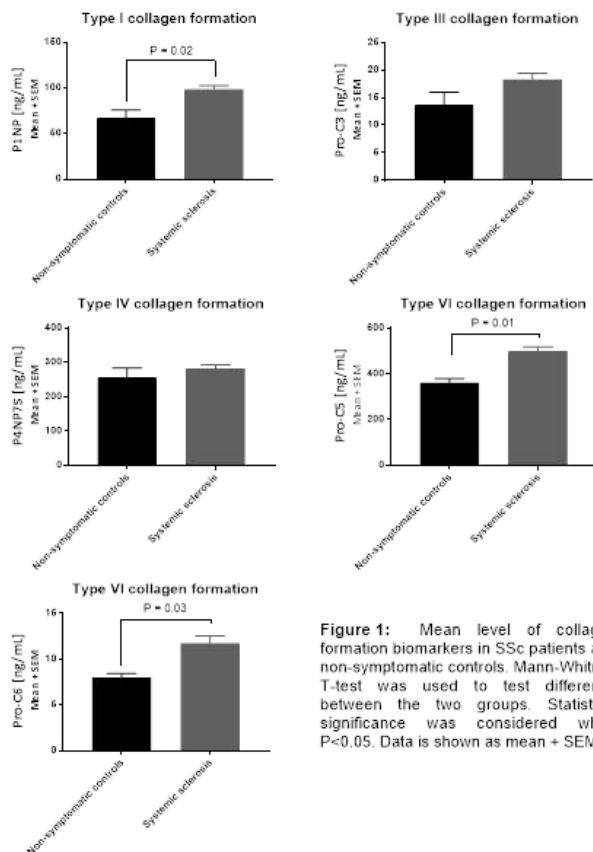

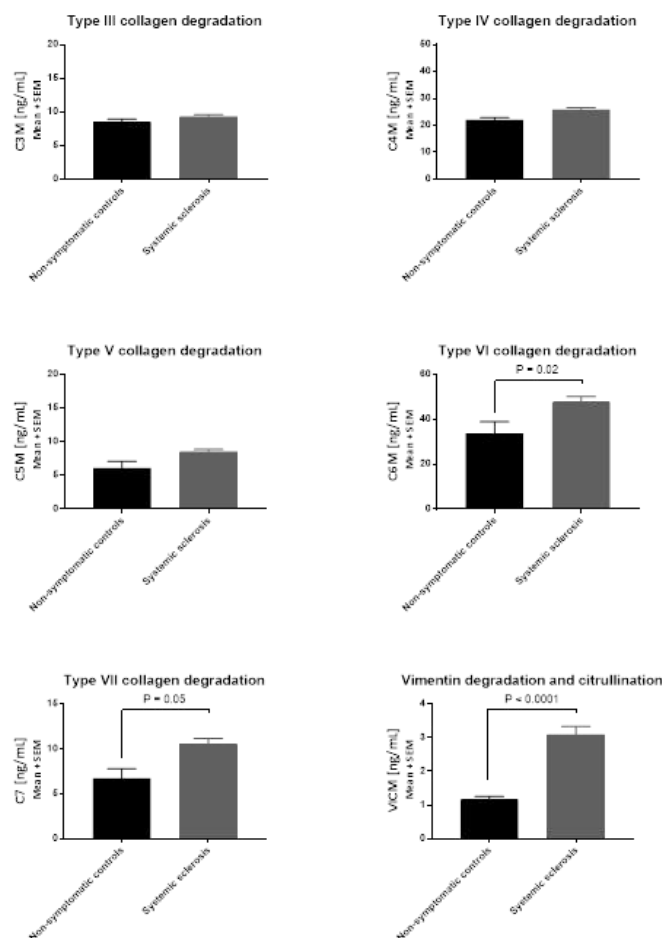

Figure 1: Mean level of collagen formation biomarkers in SSc patients and non-symptomatic controls. Mann-Whitney T-test was used to test difference between the two groups. Statistical significance was considered when  $P<0.05$ . Data is shown as mean + SEM

**Figure 2:** Mean level of collagen formation biomarkers in SSc patients and non-symptomatic controls. Mann-Whitney T-test was used to test difference between the two groups. Statistical significance was considered when  $P < 0.05$ . Data is shown as mean + SEM

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Background/Purpose:** Digital ulcers (DUs) are the most common skin manifestations in systemic sclerosis (SSc). DUs in SSc are not usually caused by vasculitis and are often refractory to conventional immunosuppressive therapies. Extracorporeal shock wave therapy (ESWT) has been used to treat urinary stones since 1980s. The therapy has also been applied to treat various diseases such as chronic tendinopathy, ischemic heart disease, and wound healing disorders. Previously, we reported that the low energy ESWT dramatically improved refractory DUs in SSc (Saito et.al. Tohoku J. Exp. Med. 238:19, 2016). Because ESWT was applied on palms and forearms distant from DUs, we considered that the healing effect of ESWT on DUs may be due to enhanced angiogenesis via some angiogenic factors rather than a direct physical stimulus on ulcers. However, the precise molecular mechanism remains unknown. In this study, we tried to clarify the molecular basis of shock wave (SW) treatment on dermal endothelial cells using *in vitro* SW treatment system. We found that FBJ murine osteosarcoma viral oncogene homolog B (FOSB), which is a component of multipotent transcriptional factor AP-1, was prominently increased after SW treatment. We also examined the functional consequence of FOSB on angiogenesis.

**Methods:** (1) Human Dermal Microvascular Endothelial Cells (HDMECs) were cultured on a cover glass with 2.5% agarose gel (Fig-1) and treated with SW. RNA was extracted from HDMECs 2 h after SW treatment, and gene expression profiling was analyzed using microarray (Agilent). (2) FOSB expression after SW treatment was measured using RT-PCR. (3) FOSB-expressing HDMECs were stimulated with serum, and vascular growth factor A (VEGFA) induction was evaluated using RT-PCR.

**Results:** In the culture system shown in Fig-1, HDMECs were stable without any significant detachment or death of cells after SW treatment. The microarray analysis revealed that FOSB gene expression level was significantly elevated ( $>10$ -fold,  $p < 0.05$ ) after SW treatment in three independent experiments. In RT-PCR analysis, FOSB gene expression level was also increased in proportion to SW energy at 1 h after the treatment. Aberrant expression of FOSB in HDMECs increased VEGFA induction by stimulation with serum (Fig-2)

**Conclusion:** SW treatment elevated FOSB gene expression in HDMECs, which directly led to increased sensitivity for VEGFA induction, suggesting that FOSB may be a master regulator responsible for the angiogenic effect of ESWT. This finding may help in the development of more effective strategies using ESWT for DUs in SSc.

**Fig-1 *In vitro* ESWT treatment system to endothelial cells**

HDMECs were cultured on 12mm coverglass over 2.5% agarose gel.  
The culture plate was also put on 2.5% agarose gel to avoid reflection and interference of shock wave.

**Fig-2 Effect of FOSB expression on induction of VEGFA in HMDECs**

FOSB gene was aberrantly expressed in HDMVECs using retroviral vector (pMX).  
HDMVECs were stimulated with fetal cow's serum (FCS).  
VEGFA induction was quantified with RT-PCR 2 hours after the stimulation.  
Values were expressed as the ratio of copy number of VEGFA to 18SrRNA.

### The immunophenotyping of peripheral blood associates with nailfold microvascular changes in patients with systemic sclerosis

**Background/Purpose:** Systemic sclerosis (SSc) is a complex disease with autoimmunity and vasculopathy, leading to subsequent fibrosis. However, little is known about the relationship between immunological abnormality and microvascular changes. Here, we stratified SSc patients based on peripheral immunophenotyping and investigated the association between immunophenotyping and vasculopathy in SSc.

**Methods:** Ninety patients with SSc were enrolled in this study. Nailfold videocapillaroscopy was performed for qualitative assessment of morphological microvascular. Peripheral blood mononuclear cells were obtained and the phenotype of circulating B, T, NK and dendritic cells was defined based on flow cytometric analysis for human immune system termed "the Human Immunology Project". Based on these results, SSc patients were classified into subgroups by cluster analysis.

**Results:** The proportion of effector T cell was higher in SSc than the healthy control. The proportion of activated Th1 (2.0% vs 1.3%) and activated Th17 (1.2% vs 0.8%), but not Treg and Tfh, was higher in SSc. On the other hand, the abnormalities of B cell differentiation in SSc patients were mild. The proportion of plasmablast was comparable and that of naïve B cell was higher in SSc. However, cluster analysis stratified SSc patients into three subgroups (Figure): patients who showed almost normal immunophenotype (without abnormality group), patients with high percentage of effector T cell and Th17 cells (T cell-dominant group), and patients with high proportion of plasmablast and effector B cell (B cell-dominant group). The majority (81%) of SSc patients belonged to the without abnormality group. In contrast, the percentage of patients who had severe microvascular changes was highest among the T cell-dominant group and the B cell-dominant group.

**Conclusion:** Immune abnormality in peripheral blood was not necessarily found in all cases of SSc. However, our data indicated that there are two types of immunological abnormalities associated with the risk of vasculopathy in patients with SSc. Accumulation of further evidence will not only contribute to elucidate the pathogenesis of SSc but also help the development of targeted therapy.

Figure. Immune cell characteristics based on statistical cluster analysis in patients with systemic sclerosis: Immunophenotypes of the three groups. P values by one-way analysis of variance.

		T cell-dominant group	without abnormality group	B cell-dominant group	p value

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Scleroderma is a progressive fibrotic multi-organ disease characterized by the hardening and tightening of the skin and connective tissues. TGF- $\beta$ 1 is a potent mediator of fibroblast to myofibroblast transition (FMT), which contributes to increased extracellular matrix deposition and is the main driver of disease. There is substantial evidence for crosstalk between  $\alpha$ V integrins and TGF- $\beta$  during these processes. TGF- $\beta$  is secreted in a latent form which contains a Latency Associated Peptide (LAP) region. The LAP of TGF- $\beta$ 1 contains an Arg-Gly-Asp (RGD) motif, which interacts with the integrins  $\alpha$ V $\beta$ 1,  $\alpha$ V $\beta$ 3,  $\alpha$ V $\beta$ 5,  $\alpha$ V $\beta$ 6 and  $\alpha$ V $\beta$ 8 resulting in activation of TGF- $\beta$ 1. Abituzumab is a human antibody specific for  $\alpha$ V and therefore inhibits ligand binding of these five integrins. The goal of this study was to determine if abituzumab can block TGF- $\beta$  activation and FMT in vitro and thus have potential as a scleroderma therapeutic.

**Methods:** Expression of integrins and myofibroblast markers in human lung fibroblasts was analyzed by RT-PCR in the presence and absence of abituzumab. In addition, we examined the ability of abituzumab to block FMT in an epithelial cell (NCI-H358 or Calu3)/fibroblast co-culture, mimicking the potential interaction of epithelial cells and fibroblasts in tissues undergoing fibrosis.

**Results:** Analysis of integrin expression showed that human lung fibroblasts express ITGB1>ITGB5>ITGB8>ITGB3. TGF- $\beta$ -induced FMT caused an increase in the expression of ITGB5, and to a lesser extent ITGB1 and ITGB3. TGF- $\beta$  treatment increased myofibroblast marker genes in lung fibroblasts, and immunofluorescence staining revealed increased  $\alpha$ V $\beta$ 5 and  $\alpha$ -SMA expression. Abituzumab treatment of fibroblast cultures showed a reduction in the increased  $\alpha$ -SMA expression, as well as production of IL-6 and collagen gel contraction, demonstrating an ability for abituzumab to block TGF- $\beta$ -induced FMT. Co-culture of epithelial cells with fibroblasts resulted in induction of  $\alpha$ -SMA and multiple mRNA transcripts that are markers for FMT, as well as increased IL-6 production. In this system, these markers were reduced by abituzumab treatment, demonstrating that  $\alpha$ V integrins play a role in FMT.

**Conclusion:** Results reported here indicate abituzumab has the potential to block TGF- $\beta$ -induced FMT and thus development of fibrosis. It may potentially be an efficacious drug for treatment of scleroderma.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is a complex disease characterized by substantial genotypic and phenotypic heterogeneity. Four molecular gene expression subsets have been identified from SSc skin, including inflammatory, fibroproliferative, normal-like, and limited. Genome-wide association studies have identified genetic variants associated with disease risk. However, these studies were not designed to interrogate genetic changes underlying specific gene expression subtypes. Here, our objective was, by RNA-seq in SSc skin, to identify potential genetic variants associated with specific gene expression subtypes and disease phenotypes.

**Methods:** We generated RNA-seq data from skin biopsies of 42 patients with SSc and 14 healthy controls. Variants were detected and filtered by quality, sequencing depth, minor allele frequency, and potential deleterious effects on gene function. Gene burden tests were used to identify susceptibility loci in cases compared to healthy controls, as well as in healthy controls of a European population from the phase III 1000 Genomes Project (N=503). We further quantitated gene expression and used an additive genetic model to identify gene expression associated variants. Variants enriched in each of the SSc molecular subsets were detected by Fisher's exact test.

**Results:** We identified 267 potentially deleterious variants in 253 genes in patients with SSc, including 30 genes (e.g. *IRF6*, *NCF2*, *IL37*) enriched in immunological processes and 10 genes (e.g. *ITGB4*, *COL5A1*, *LAMA3*) significantly enriched in extracellular matrix-related pathways. We found variants enriched in each of the inflammatory (35 variants), fibroproliferative (7 variants), and normal-like (45 variants) subsets. Potentially deleterious variants in *IL37* were enriched in patients with diffuse skin involvement and were significantly correlated with increased gene expression of *IL6* and *STAT3* in patient samples. Consistently, HapMap B cell lines harboring deleterious *IL37* variants showed increased expression of *IL6* upon immune stimulation.

**Conclusion:** This study demonstrates the value of RNA-seq for identifying genetic variants associated with SSc gene expression subsets. Results indicate genetic variants can be associated with each of the intrinsic gene expression subset and may influence innate immune responses and ECM deposition. The identified *IL37* variant may modulate SSc pathogenesis by increasing expression of the IL-6 pathway.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Circulating fibrocytes seem to exert immunomodulatory effects, expressing class II major histocompatibility complex molecules (HLA-DP, -DQ, and -DR) and could have a role in fibrosing diseases (i.e. systemic sclerosis, SSc), due to the capacity of such cells to migrate into affected tissues (through CXCR4/CXCL12 interaction) and to differentiate into fibroblasts/myofibroblasts, then inducing matrix protein deposition and fibrosis [1-4].

The aim of this study was to isolate fibrocytes from peripheral blood mononuclear cells (PBMCs) of SSc patients and healthy subjects (CNTs) and comparing both after having identified them by fluorescence-activated cell sorter analysis (FACS) (using their specific markers: the leukocyte common antigen CD45, collagen I (COL I), the chemokine receptor CXCR4 and HLA-DR [2]).

### **Methods:**

Blood samples were collected, after signed informed consent, at basal time (T0), from 11 SSc patients (treated only with different vasodilator drugs) and 5 CNTs. In addition, PBMCs, isolated from 9 SSc patients and 5 CNTs, were cultured on fibronectin-coated plates [5]. The non-adherent cells were removed and after 8 days (T8) of culture (standardized time) the adherent spindle shaped cells were lifted through incubation in 0.05% EDTA (ice-cold). Fibrocyte identification was performed by FACS, using anti-CD45, anti-COL I, anti-CXCR4 and anti-HLA-DR monoclonal antibodies.

### **Results:**

FACS analysis revealed that, at T0, among the CD45<sup>+</sup> cells, the percentage of fibrocytes, identified as CD45<sup>+</sup>, COL I<sup>+</sup>, CXCR4<sup>+</sup> was 1.0±1.2 % in SSc patients and 0.5±0.2 % in healthy subjects (CNTs). In addition, the HLA-DR expression on fibrocytes in both CNTs and SSc patients showed low values (22.1±21.1 % and 13.1±4.7 %, respectively).

After 8 days (T8) of culture, fibrocytes presented adherent and spindle shaped morphology and FACS analysis demonstrated that the percentage of fibrocytes CD45<sup>+</sup>, COL I<sup>+</sup>, CXCR4<sup>+</sup> increased up to 52.8±27.1% in SSc patients and up to 61.9±24.4 in CNTs, compared to T0.

Therefore, at T8 of culture, the HLA-DR<sup>+</sup> expression on fibrocytes in SSc patients and CNTs strongly increased (90.1±22.7 % and 97.9±1.9, respectively), compared to T0.

## Conclusion:

Circulating fibrocytes, identified as CD45, COL I and CXCR4 positive cells, resulted in very low percentage in peripheral blood at basal time, but after 8 days of culture in proper conditions, the percentage of differentiated fibrocytes increased up to 50 times in SSc (and CNTs), whereas the HLA-DR expression increased up to 68% in SSc and 85% in CNTs. Data suggest that circulating fibrocytes might be an early cellular targets in presence of fibrosing diseases.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Giant cell arteritis (GCA) is the most common systemic vasculitis in patients aged 50 years or older. The presence of cranial features and an abnormal temporal artery biopsy have historically been the primary focus for diagnosis of this condition. A notable percentage of patients with GCA have negative temporal artery biopsies. Few cohort studies exist comparing the presentation and outcome of patients based on biopsy positivity.

**Methods:** Patients with temporal artery biopsy-negative GCA diagnosed between 1/1/1998 and 12/31/2013 were identified retrospectively. Final diagnosis was confirmed by consensus among two rheumatologists and a physician abstractor. Clinical characteristics, treatment course and outcomes were compared to a cohort of biopsy-positive patients with GCA (n=286) from the same institution.

## Results:

110 patients with temporal artery biopsy-negative GCA were identified. Unilateral biopsies were performed in 73, bilateral-sequential in 10, and bilateral same day in 27 cases. Median duration between steroid initiation and biopsy was 3 days. Median length of first biopsy was 14mm and second biopsy (if performed) was 22mm. Among biopsy-negative patients with advanced imaging within 6-months of diagnosis, 67% (41/61) had evidence of large vessel vasculitis.

Patients with biopsy-negative GCA were younger ( $72.0 \pm 9.0$  vs  $75.0 \pm 7.6$ ;  $p=0.001$ ), met fewer ACR criteria ( $\geq 3$  criteria 64% vs 95%;  $p<0.001$ ) and had a shorter time from symptom onset to diagnosis (median 1.1 vs 2.1 months;  $p<0.001$ ). Vascular risk factors evaluated at diagnosis showed a higher rate of pre-existing hypertension and obesity among patient with biopsy-negative GCA but similar rates of smoking and diabetes mellitus. Frequency of headache and vision loss at time of presentation were similar between groups. However, biopsy-negative GCA patients had more temporal artery tenderness (35% vs 16%;  $p<0.001$ ) and arm claudication (13% vs 2%;  $p<0.001$ ) but less frequent jaw claudication (19% vs 52%;  $p<0.001$ ). Anorexia, fatigue, and arthralgia were also more commonly noted in biopsy-negative patients. Baseline CRP was lower among patients with negative biopsies ( $44.3 \pm 53.6$  vs  $70.4 \pm 63.9$  mg/L;  $p<0.001$ ).

Initial prednisone dose was similar among both cohorts. Although cumulative glucocorticoid (GC) was lower in biopsy-negative patients at 1 year ( $6.3 \pm 2.6$  vs  $7.2 \pm 2.7$  g;  $p=0.004$ ), cumulative GC doses at 2-years and 5-years were equivalent. Biopsy-positive patients (5-years,  $56 \pm 3\%$ ) were able to discontinue GC sooner than biopsy-negative patients (5-years,  $30 \pm 5\%$ ;  $p<0.001$ ). The number of relapses, time-to-first relapse, annual relapse rate and mortality did not differ based on biopsy positivity.

**Conclusion:** While similarities are present, there are notable differences in clinical presentation between biopsy-positive and -negative GCA. Although current ACR criteria underperform in patients with biopsy-negative GCA, imaging studies are often useful for confirmation of diagnosis. Further studies are needed to confirm and understand the observed variability in GC duration.

Stone<sup>3</sup>, Khaled Sarsour<sup>1</sup>, Jinglan Pei<sup>4</sup>, Jennifer H. Best<sup>1</sup>, Christine Birchwood<sup>4</sup> and Shalini Mohan<sup>1</sup>, <sup>1</sup>Genentech, South San Francisco, CA, <sup>2</sup>Roche Products, Ltd., Welwyn Garden City, United Kingdom, <sup>3</sup>Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, <sup>4</sup>Genentech, Inc., South San Francisco, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent clinical trial findings have shown efficacy for tocilizumab (TCZ) in treating giant cell arteritis (GCA).<sup>1,2</sup> TCZ was approved for the treatment of GCA in the US in 2017 and of rheumatoid arthritis (RA) in the EU in 2009 and in the US in 2010, and it has a well-characterized safety profile in RA patients (pts). However, the safety profile of TCZ in GCA pts may differ from that observed in RA pts due to differences in the underlying disease and the higher dosing of glucocorticoids (GCs) used to treat GCA. This study describes the incidence rates (IRs) of safety events in GCA pts or RA pts in a general healthcare claims database and in the TCZ clinical development program to contextualize the observed safety profile of TCZ in GCA.

**Methods:** Adverse events of special interest (AESI) IRs for TCZ in adult GCA and RA pts were estimated from a US-based MarketScan administrative healthcare claims database. GCA pts were  $\geq 50$  years and received  $\geq 2$  prescriptions for oral GCs (the first within 6 months of diagnosis); for comparability, only RA pts who were  $\geq 50$  years were included. AESI included infections, hepatic events, gastrointestinal (GI) perforation, demyelination, cardiovascular events, bleeding events, and malignancies. AESI IRs were also calculated for a pooled population of RA pts who received TCZ in clinical trials and for GCA pts who received TCZ in the GiACTA clinical trial.<sup>1-3</sup> Risks for AESI among GCA pts vs RA pts in the claims database, adjusted for age and oral GC use, were estimated with Poisson regression.

**Results:** The healthcare claims database included 4804 GCA pts (mean [SD] age, 73.4 [9.8] years; follow-up, 3.89 [3.12] years) and 15,164 RA pts (mean [SD] age, 60.3 [8.17] years; follow-up, 4.52 [3.78] years). IRs of myocardial infarction, stroke, GI perforation, and hepatic events in TCZ-naïve GCA pts from the healthcare claims database (Table) exceeded IRs in TCZ-naïve RA pts from healthcare insurance claims. Consistent with this, AESI IRs in TCZ-treated GCA pts (n = 149, ~138 PY) in the GiACTA clinical trial were different from those in TCZ-treated RA pts (n = 7647; mean [SD] age, 52 [12.6] years; ~22,394 PY) in the pooled clinical trial population. GCA pts were at higher risk than RA pts for all AESI in the US claims database after adjusting for age and oral GC use.

**Conclusion:** TCZ-naïve GCA pts from the healthcare claims analysis had higher AESI IRs than TCZ-naïve RA pts. Clinical trial data for TCZ in RA pts and GCA pts reflect these findings and suggest differences in the underlying disease burdens associated with RA and GCA. The higher doses and longer courses of GCs used in GCA may also influence the incidence of AESI. Future analyses are needed to determine how differences in patient demographics may further differentiate the safety profile of TCZ between RA pts and GCA pts. ### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Disease activity in large vessel vasculitis (LVV) is traditionally assessed by clinical and serological (ESR, CRP) parameters. Imaging assessment, including FDG-PET, may also be useful to monitor LVV. The study objective was to determine if currently available therapies for LVV impact disease activity as assessed by clinical, serologic, and imaging-based parameters.

### **Methods:**

Patients with giant cell arteritis (GCA) or Takayasu's arteritis (TAK) were recruited into a prospective, observational cohort. All subjects in this study underwent  $\geq 2$  FDG-PET/CT scans at 6-month intervals. Serologic assessment (ESR, CRP), clinical assessment [physician global assessment (PGA)] and imaging assessment (PETVAS) was determined at each visit. PETVAS is a global summary score of arterial FDG uptake assessed qualitatively relative to liver activity in 9 vascular beds with higher scores indicating more vascular inflammation. Clinical and imaging assessments were performed blinded to each other. Treatment status between visits was categorized as increased, decreased, or unchanged. Treatment change was defined as change in daily prednisone by  $\geq 5$ mg or addition/50% dose change of a DMARD or biologic therapy. Paired Wilcoxon test was used to compare changes in PETVAS, ESR, CRP and PGA with change in overall therapy and with addition/increase in specific medications.

### **Results:**

FDG-PET/CT was performed in 33 patients with LVV (GCA=21; TAK=12) over 98 visits. Interval treatment changes involved glucocorticoids (n=32), methotrexate (n=13), tocilizumab (n=7), TNF inhibitors (n=7), or another DMARD/biologic (n=6). Increased, decreased, or unchanged therapy was recorded over 27, 13, and 23 visit intervals respectively. There was simultaneous glucocorticoid reduction with DMARD increase over 2 intervals, which were excluded from analysis. In the increased treatment group, a significant reduction in PETVAS score ( $p<0.01$ ), inflammatory markers ( $p<0.01$ ) and PGA ( $p=0.01$ ) was noted. In the decreased treatment group, PETVAS scores increased ( $p=0.05$ ) but there was no change in ESR ( $p=0.3$ ), CRP ( $p=0.2$ ), or PGA ( $p=0.28$ ). In the unchanged treatment group, PETVAS ( $p=0.88$ ), ESR ( $p=0.8$ ), CRP ( $p=0.6$ ) and PGA ( $p=0.48$ ) remained unchanged. In terms of specific therapies, addition of tocilizumab, resulted in significant reduction in PETVAS ( $p=0.01$ ), acute phase reactants ( $p=0.01$ ) and PGA ( $p=0.03$ ), whereas TNF inhibitors and methotrexate addition/dose increase had variable effects on clinical, serological, and imaging parameters.

### **Conclusion:**

Similar to clinical and serologic assessment, vascular inflammation assessed by FDG-PET improves with increased treatment and is stable without change in therapy. Unlike clinical and serological assessment, which did not change with reduction in treatment over a 6 month interval, vascular inflammation assessed by FDG-PET worsens with decreased therapy. Specific medications may affect vascular FDG uptake differently. These findings suggest that FDG-PET is useful to monitor treatment response and may be a more sensitive biomarker to detect disease recurrence in the setting of treatment reduction compared to clinical and serologic assessment.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Randomized clinical trial has shown the efficacy of tocilizumab (TCZ) in Giant cell arteritis (GCA). However this data are of selected cases of clinical trial and only a short follow-up have been published. Our aim was to assess the short and long-term efficacy/side effects in clinical practice

**Methods:** Multicenter open-label study on 49 GCA patients treated with TCZ [iv; 8 mg/kg/monthly (n=45), and subcutaneously; 162 mg/week (n=4)]. We assessed the short and long-term efficacy/safety and the optimization of TCZ dose.

**Results:** We included 49 patients (39 women/10 men), mean age 73±9 years. The main clinical features at TCZ onset were: polymyalgia rheumatica (n=31), headache (25), asthenia (17), constitutional syndrome (15), jaw claudication (5), and visual loss (6). Besides corticosteroids and before TCZ, 43 patients had also received several conventional immunosuppressive and/or biologic drugs. 45 of 49 patients achieved a rapid and maintained clinical improvement after TCZ (**Table**). After a median follow-up of 18 [IQR, 7-28] months we observe a reduction of the median of: **a)** C-reactive protein; **b)** ESR; and **c)** prednisone dose. In this follow-up period, the outcome of patients was as follows: **a)** discontinuation of TCZ due to sustained remission(n=8); **b)** dose reduction due to improvement (8) or side effects (4); **c)** withdrawal of TCZ because of side effects (9); and **d)** the same dose that at onset (19). TCZ was discontinued due to: severe neutropenia; recurrent pneumonia; colon adenocarcinoma; cytomegalovirus infection; Alzheimer's disease and atrioventricular blockade; hypertensive crisis during infusion; myelodysplastic syndrome; colon neoplasm and overall health deterioration. The latter patient died because of stroke. Another patient also died after the second TCZ infusion due to stroke in the context of an infective endocarditis. In another one, the dose had to be reduced by recurrent urinary tract infection. In other two patients TCZ was reduced because of moderate neutropenia (one of them also developed cellulitis) and another patient developed diverticulitis.

**Conclusion:** TCZ therapy leads to a rapid and maintained improvement in patients with refractory GCA and/or with unacceptable side effects related to corticosteroids. However, the risk of neutropenia and infection should be kept in mind when using this biologic agent in patients with GCA

**TABLE**

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To test the reliability of recently established consensus-based ultrasound definitions for normal and vasculitic temporal and axillary arteries in patients with giant cell arteritis (GCA) and in controls.

**Methods:** A preliminary one-day meeting was held in Southend, United Kingdom. One year later, a full three-day meeting according to OMERACT ultrasound group guidelines for patient based reliability testing was conducted in Berlin, Germany. This meeting included a 6-hour training session for standardization of examination technique and ultrasound machine settings. In both exercises 6-18 MHz linear ultrasound transducers of high quality ultrasound machines were used. Bilateral common superficial temporal arteries with frontal and parietal branches as well as axillary arteries were examined at two time points by 12 sonographers for normal findings, halo sign and compression sign using consensus-based definitions. In the preliminary meeting, 4 patients had longstanding established GCA, 1 patient had severe arteriosclerosis; and 1 normal control was included. In the second meeting, 4 GCA patients with more recent diagnosis and 2 healthy controls were examined. Inter- and intra-observer reliability was calculated.

**Results:** In the preliminary exercise, inter-reader reliabilities were fair to moderate for the overall diagnosis of GCA (Light's kappa, 0.29-0.51) and poor to fair for identifying vasculitis in the respective anatomical segments (Light's kappa, 0.02-0.46).

Intra-reader reliabilities were moderate (Cohen's kappa, 0.32-0.64). In the main exercise, inter-reader reliability was good to excellent (Light's kappa, 0.76-0.86) for the overall diagnosis of GCA and moderate to good (Light's kappa, 0.46-0.71) for identifying vasculitis in the respective anatomical segments. Intra-reader reliability was excellent for diagnosis of GCA (Cohen's kappa, 0.91) and good (Cohen's kappa, 0.71-0.80) for the anatomical segments.

**Conclusion:** The patient based reliability for ultrasound definitions of halo and compression sign of temporal and for halo sign of axillary artery is good to excellent in recent onset GCA. Training of a standardized examination protocol is crucial for achieving specific results and good inter- and intra-observer reliabilities. The reliability in established disease requires further study.

## **Serum IL-6, SAA and Calprotectin As Biomarkers in Giant Cell Arteritis and Polymyalgia Rheumatica**

**Yannick van Sleen**, Marjolein Hoekstra, Johan Bijzet, Wayel H. Abdulahad, Annemieke M.H. Boots and Elisabeth Brouwer, Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** GCA and PMR are closely related inflammatory diseases. The diagnostic criteria of both disorders depend on a combination of clinical features and elevated ESR or CRP levels. ESR and CRP are also used to monitor disease activity. These biomarkers, however, are not disease specific and not consistently elevated in all GCA and PMR patients. Previously, serum levels of IL-6, SAA and calprotectin were found to be increased in small scale cross-sectional GCA and PMR studies. Calprotectin expression was also found in neutrophils and macrophages in temporal artery biopsies (TABs) of GCA patients. The aim of this study was to identify and compare the values of IL-6, SAA and calprotectin as biomarkers for diagnosing GCA and PMR, monitoring disease activity and predicting disease course.

**Methods:** Serum concentrations of IL-6, SAA and calprotectin were determined by ELISA in 36 newly diagnosed GCA patients (C-GCA (TAB+) or LV-GCA (PET/CT+)) and 27 newly diagnosed PMR patients (fulfilling the Chuang-Hunder criteria), before start of glucocorticoid treatment. Thirty age- and sex matched healthy controls were included as well. Follow-up sera from patients were tested again 3 months (n= 21 for GCA and n= 21 for PMR) and 1 year (n= 23 for GCA and n= 16 for PMR) after the start of treatment. TABs (n=17) from GCA patients were stained with anti-calprotectin and anti-CD15 by immunohistochemistry.

**Results:** Baseline levels of IL-6, SAA and calprotectin in GCA and PMR patients were higher compared to healthy controls. Treatment decreased the levels of IL-6 and SAA in both GCA patients and PMR patients, but serum levels of calprotectin

decreased in PMR patients only. Relapse free survival between the groups with relatively low and high levels of the serum markers did not differ. IL-6 correlated with CRP, and SAA correlated with both CRP and ESR. Calprotectin did not correlate with IL-6, SAA, CRP or ESR, suggesting an IL-6 independent pathway. Interestingly, calprotectin levels were also elevated in GCA and PMR patients with normal ESR or CRP levels. Immunohistochemical staining of TABs showed calprotectin expression in all TABs (Fig. 1). Only a minority of calprotectin positive cells were CD15+ neutrophils.

**Conclusion:** Serum levels of IL-6, SAA and calprotectin discriminate GCA and PMR patients from healthy controls at the group level. In addition, serum levels of IL-6 and SAA decrease with treatment induced remission in GCA and PMR patients. None of the biomarkers tested at baseline predicted future relapse. Serum calprotectin could be a potential marker for silent ongoing vascular inflammation in GCA patients. The diagnostic value of serum IL-6, SAA and especially calprotectin as biomarkers should be further examined and validated.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Modern imaging modalities including ultrasound, magnetic resonance imaging (MRI), computed tomography (CT) and <sup>18</sup>F-FDG positron emission tomography (PET/CT) have been increasingly used in primary large vessel vasculitis (LVV) including giant cell arteritis (GCA) and Takayasu arteritis (TAK). However, there is still significant controversy and uncertainty about when to use which imaging technique, and whether imaging might be helpful during follow-up to assess disease activity and damage. We aimed to develop EULAR recommendations for the use of imaging modalities in LVV in clinical practice.

**Methods:** The EULAR Standardised Operating Procedures have been followed. A systematic literature review was conducted to retrieve data on the role of imaging in LVV. Based on evidence and expert opinion, the task force consisting of 20 experts (physicians, a health care professional and patients) from 12 EULAR countries developed recommendations, with consensus obtained through informal voting. The final level of agreement was voted anonymously.

**Results:** A total of 12 recommendations have been formulated (Table). The task force recommends an early imaging test in patients with suspected LVV, assuming high expertise and prompt availability of the imaging technique. Ultrasound has been suggested as the first choice imaging modality in GCA, because of a good performance of the test, easy access, absence of radiation and other procedural risks, and low resource use. MRI, and in case of predominant large vessel (LV)-GCA, PET and CT, might be alternatives to ultrasound. For TAK, MRI is the preferred imaging modality, because of the absence of radiation exposure and the possibility to assess simultaneously the vessel wall and luminal changes of the aorta and its proximal branches. PET, CT and ultrasound can be used as alternatives.

In patients with a suspected flare of LVV, imaging might be helpful to assess disease activity. The frequency and choice of imaging modalities for long-term monitoring of structural damage remains an individual based decision. All imaging should be performed by a trained specialist using appropriate equipment, operational procedures and settings.

**Conclusion:** These are the first EULAR recommendations providing up-to-date guidance on the role of imaging in the diagnosis and monitoring of patients with (suspected) LVV.

Statement	LoE	LoA
1. In patients with suspected GCA, an early imaging test is recommended to complement the clinical criteria for diagnosing GCA, assuming high expertise and prompt availability of the imaging technique. Imaging should not delay initiation of treatment.	1	9.2 (2.1) 90% ≥8
2. In patients in whom there is a high clinical suspicion of GCA and a positive imaging test, the diagnosis of GCA may be made without an additional test (biopsy or further imaging). In patients with a low clinical probability and a negative imaging result, the diagnosis of GCA can be considered unlikely. In all other situations, additional efforts towards a diagnosis are necessary.	2	9.4 (1.0) 90% ≥8
3. US of temporal ± axillary arteries is recommended as the first imaging modality in patients with suspected predominantly cranial GCA*. A non-compressible 'halo' sign is the US finding most suggestive of GCA.	1	9.7 (0.6) 100% ≥8
4. High resolution MRI of cranial arteries† to investigate mural inflammation may be used as an alternative for GCA diagnosis if US is not available or inconclusive.	2	9.2 (1.1) 90% ≥8
5. CT and PET are not recommended for the assessment of inflammation of cranial arteries.	5	9.5 (1.2) 95% ≥8
6. US, PET, MRI and/or CT may be used for detection of mural inflammation and/or luminal changes in extracranial arteries to support the diagnosis of LV-GCA. US is of limited value for assessment of aortitis.	3 (PET, CT) -5 (US, MRI)	9.8 (0.6) 100% ≥8
7. In patients with suspected TAK, MRI to investigate mural inflammation and/or luminal changes should be used as the first imaging test to make a diagnosis of TAK, assuming high expertise and prompt availability of the technique.	3	9.1 (1.4) 90% ≥8
8. PET, CT and/or US may be used as alternative imaging modalities in patients with suspected TAK. US is of limited value for assessment of the thoracic aorta.	3 (CT) – 5 (PET, US)	9.4 (0.8) 100% ≥8
9. Conventional angiography is not recommended for the diagnosis of GCA or TAK as it has been superseded by the previously mentioned imaging modalities.	5	9.8 (0.6) 100% ≥8
10. In patients with LVV (GCA or TAK) in whom a flare is suspected, imaging might be helpful to confirm or exclude it. Imaging is not routinely recommended for patients in clinical and biochemical remission.	5	9.4 (0.8) 100% ≥8
11. In patients with LVV (GCA or TAK), MRA, CTA and/or US may be used for long-term monitoring of structural damage, particularly to detect stenosis, occlusion, dilatation and/or aneurysms. The frequency of screening as well as the imaging method applied should be decided on an individual basis.	5	9.3 (1.2) 95% ≥8
12. Imaging examination should be done by a trained specialist using appropriate equipment, operational	5	9.8 (0.6)

procedures and settings. The reliability of imaging, which has often been a concern, can be improved by specific training. Suggestions for technical and operational parameters are depicted in Box 1.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Information regarding the degree and the predictors of damage in patients with Takayasu's arteritis (TAK) is limited. This study aimed to characterize damage and identify predictors of damage in patients with TAK.

**Methods:** Patients with TAK enrolled in a multicenter, longitudinal study were included. Measures of disease damage, including the Vasculitis Damage Index (VDI) and the Large-Vessel Vasculitis Index of Damage (LVVID), were assessed at baseline and follow-up visits. **Results** from patients with a diagnosis of TAK made within 6 months prior to entry to the cohort were also separately analyzed. Kaplan-Meier survival curves were used to analyze development of new damage.

Univariate statistics and multivariate Cox regression modeling was used to analyze clinically-relevant baseline predictors of new damage.

**Results:** The study included 128 patients with TAK: 94% female, 89% Caucasian, and median duration of follow-up 3.5 years (1.9, 6.2). At entry into the cohort, 113 patients (88%) had at least one damage item recorded on VDI and LVVID [VDI median score 3 (IQR: 1-5)] and [LVVID median score: 2 (1-4)]. 31/128 (24%) of patients had a diagnosis of TAK made within 6 months prior to study entry, 81% of whom had at least 1 item documented on VDI and LVVID. During the follow-up period 96 patients (75%) accrued at least one new damage item, most of which occurred in the first year of follow-up (**Figure 1**). The cardiac and peripheral arterial systems accounted for most of the damage captured at baseline and follow-up. Results of univariate and multivariate analysis of clinically-relevant baseline predictors are shown in **Table 1**. Patients with new-onset disease (diagnosed  $\leq 6$  months within study entry) had a higher risk of new damage than patients with longer disease duration. The use of glucocorticoids was not associated with development of new damage.

**Conclusion:** Damage predominantly related to disease rather than treatment is present in the majority of patients with TAK, even within 6 months of diagnosis. Although damage accrues more commonly early in the disease course, the majority of patients with TAK continue to accrue new damage, mostly related to disease, even after several years of follow-up. Future research should address the question of whether treatment of TAK during the early stages of the disease reduces accumulation of disease-related damage.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Longitudinal data on the type, progression, and predictors of arterial lesions in patients with Takayasu's arteritis (TAK) is limited. This study aimed to characterize lesions of large arteries in patients with TAK and identify predictors of new lesions.

**Methods:** Clinical, laboratory, and imaging data from patients with TAK enrolled in a prospective, multicenter, longitudinal study and/or a randomized clinical trial were included in this study. Lesions were defined as “new or worse” or “improved” arterial aneurysm, stenosis, or occlusion as determined by angiography (83% Magnetic Resonance Angiogram, 23% Computerized Tomography Angiogram, and 4% Conventional Angiogram). Clinical features were defined as the presence of any symptom or sign attributed to vasculitis. Logistic regression was used to analyze the association of baseline (visit 1) variables with new/worse or improved lesions.

**Results :** The study included 175 patients with TAK: 93% female, 85% Caucasian, mean ( $\pm$ SD) age at diagnosis =  $34.4 \pm 13.4$  years, and mean ( $\pm$ SD) follow-up =  $3.8 \pm 3.1$  years. At baseline, the most frequently affected arteries were subclavian (73% of patients), abdominal aorta (44%), thoracic aorta (42%), and common carotid (37%) (**Figure 1**). In 123 patients with serial imaging, new or worse arterial lesions were noted in 35 patients (28%) predominantly in the subclavian, common carotid, renal, and iliac territories. 96 % of patients with new lesions were either on prednisone and/or other immunosuppressive agents. Improved stenotic lesions, mostly of the subclavian and common carotid arteries, were noted in 16 patients (13%) at follow-up. Clinical features of active disease were absent in 40% of visits at which a new lesion was detected. The mean levels of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) did not differ between the immediate prior visit versus the visit at which a new lesion was detected (ESR mean  $\pm$  SD=  $24.6 \pm 4.0$  and mean CRP  $\pm$  SD =  $12.2 \pm 2.8$  mg/L at prior visit vs. ESR=  $23.5 \pm 3.9$  and CRP=  $9.5 \pm 2.8$  mg/L at lesion visit,  $p = 0.63$  and  $0.12$  for ESR and CRP respectively). There were no differences in age, sex, ethnicity, presence of a flare prior to the onset of new lesion, or disease duration in patients with or without new/worse lesions and with or without improved lesions.

**Conclusion :** Among patients with TAK, large arterial abnormalities are common both at presentation and follow-up. One in 3 patients will continue to develop new or worsening arterial lesions while on treatment with 40% exhibiting no clinical or laboratory changes. Lesions involving the subclavian and carotids are more likely to improve during follow-up. These findings raise concerns about the current definition of active disease in TAK and have implications for the management of patients with TAK and the design and conduct of clinical trials in TAK.

## **Smoking As a Risk Factor for Giant Cell Arteritis: A Systematic Review and Meta-Analysis**

**David Brennan**<sup>1</sup>, Patompong Ungprasert<sup>2</sup>, Kenneth J. Warrington<sup>2</sup> and Matthew J. Koster<sup>2</sup>, <sup>1</sup>Internal Medicine, Mayo Clinic, Rochester, MN, <sup>2</sup>Rheumatology, Mayo Clinic, Rochester, MN

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tobacco smoking is a well-established risk factor for the development of several autoimmune diseases such as rheumatoid arthritis and systemic lupus erythematosus. A similar association between smoking and giant cell arteritis (GCA) has been suspected but remains unclear due to limited study size and conflicting epidemiologic data. In order to further investigate the association between smoking and the development of GCA we conducted a systematic review and meta-analysis.

**Methods:** Two investigators (D.B. and M.K.) independently searched published studies indexed in MEDLINE and EMBASE from inception to February 2017 using the terms “giant cell arteritis,” “temporal arteritis,” “cranial arteritis,” and “Horton disease.” Recent conference abstracts available online were also reviewed. The following inclusion criteria were used: 1) original observational study comparing patients with GCA to healthy controls; 2) inclusion of smoking history; 3) provision of absolute numbers and/or statistical comparisons with 95% confidence intervals. Study eligibility was independently determined by the two investigators, with disagreements reviewed by a third investigator (P.U.) and resolved by consensus. RevMan 5.3 software was used for the data analysis. Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. Given the high likelihood of between-study variance, we used a random-effect model rather than a fixed-effect model. Statistical heterogeneity was assessed using the Cochran's Q test.

**Results:** The initial search yielded 3312 articles. Of these, thirteen studies (8 prospective and, 5 retrospective case-control studies) with unique cohorts were identified and included in the primary analysis (ever vs. never smoking history). Patients in the GCA cohort were more likely to have a history of smoking with an odds ratio of 1.19 (95% CI, 1.01 – 1.39) [Figure 1A]. Considerable heterogeneity was present ( $I^2 = 85\%$ ). Five of these studies included information on current smoking status. One additional study, which only reported current smoking status, was also included. The GCA cohort showed an association with current tobacco use with an odds ratio of 1.18 (95% CI, 1.01 – 1.38) [Figure 1B].

**Conclusion:** Our study demonstrated a statistically significant increased risk of GCA among smokers compared to non-smokers.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The relapse rate of giant cell arteritis (GCA) in the patients treated by corticosteroids (CS) varied widely in observational series and randomized trials. The purpose of this systematic review was to (i) estimate the prevalence of relapse and (ii) explain the heterogeneity of relapse rate in patients receiving CS alone.

**Methods:** We searched from PubMed up to April 2017. Two investigators independently extracted data. The prevalence of relapse was pooled by random effect model. Heterogeneity ( $I^2 > 50\%$ ) was explored by meta-regression.

**Results:** A total of 37 cohorts (6 trials) totalizing 16839 patients were selected. The overall prevalence of relapse was 43% (95% confidence interval [CI] 0.37-0.50) with a high heterogeneity ( $I^2 = 90\%$ ). The year of publication was positively associated with relapse (37 studies, rate increase of 6.1% for one decade,  $p = 0.02$ ) (Figure 1). The length of CS administration was negatively correlated with the relapse rate (15 studies, rate decrease of 1.1% for one additional month,  $p = 0.04$ ) (Figure 2), but not with the initial CS dose at diagnosis ( $P = 0.46$ ) or time of follow-up ( $p = 0.12$ ). The patients included in the control arms of randomized trials testing immunosuppressive drugs relapsed more frequently (62%, CI 47-75) compared to those in observational studies (40%, CI 33-47) ( $p = 0.006$ ).

**Conclusion:** The relapse rate of GCA remains high without improvement across decades. The relapse rate might be related to the duration of CS administration rather than initial dose at induction. Our results challenged the schedules of CS administration used in randomized trials as standard of care and questioned the size of estimated efficacy of methotrexate and tocilizumab.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In forms of large vessel vasculitis (LVV) systemic IL-6 has been shown to follow disease activity. Furthermore, IL-6 inhibition is an effective treatment for giant cell arteritis, a form of LVV. Our group has demonstrated that systemic mast cell degranulation results in inhibition of LPS-induced systemic IL-6 production. Further studies

demonstrated that this effect may be mediated through stimulation of histamine-1 receptor (H1R). The purpose of this study was to determine if mast cell degranulation could inhibit systemic production of IL-6 in a mouse model of vasculitis (*Candida albicans* water-soluble fraction induced model or CAWS).

**Methods:** Two month old male C57Bl/6J mice were randomized to 4 groups (n=4/group). Mice were given intraperitoneal injections of either: a) normal saline (controls), b) CAWS extract, c) compound 48/80 (C48/80, systemic mast cell degranulation agent), or d) CAWS + C48/80. Injections were given on five consecutive days. Animals were sacrificed at 30 days for measurements of systemic TNF- $\alpha$ , INF- $\gamma$  and IL-6 by ELISA as well as aortic expression of messenger RNAs coding for IL-6, suppressor of cytokine signaling-1 (SOCS1), INF- $\gamma$ , IL-10 and TNF- $\alpha$ . Two tailed student's T-test were used for comparisons with  $p < 0.05$  considered significant.

**Results:** CAWS mice had significantly higher systemic IL-6 levels compared to controls ( $345.2 \text{ pg/ml} \pm 132.9$  vs  $56.4 \text{ pg/ml} \pm 19.3$ ,  $p < 0.001$ ). Mice injected with C48/80 + CAWS had significantly lower IL-6 compared to CAWS alone ( $177.3 \text{ pg/ml} \pm 113.6$  vs  $345.2 \text{ pg/ml} \pm 132.9$ ,  $p = 0.02$ ). There was significantly higher systemic INF- $\gamma$  in both the CAWS and CAWS+C48/80 compared to controls. No difference in TNF $\alpha$  was observed between the groups. No significant differences were observed in aortic IL-6 expression between groups. Comparing CAWS+C48/80 to CAWS alone, there was significantly higher aortic expression of both SOCS1 ( $p < 0.001$ ) and TNF- $\alpha$  ( $p = 0.03$ ).

**Conclusion:** The results demonstrate that systemic mast cell degranulation inhibits systemic IL-6 levels in a mouse model of LVV. This was not accompanied by reduced aortic expression of IL-6 suggesting that this effect is occurring in other tissues, possibly the liver. Mast cell degranulation was also associated with increased aortic expression of SOCS-1, a negative inhibitor of IL-6 signaling, suggesting that mast cells may play a direct role in IL-6 signaling as well. Since our prior studies suggest mast cells mediate IL-6 production through H1R stimulation, future research will be devoted to determining if H1R inhibition can inhibit the formation of LVV in a mouse model.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The significance of increasing erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) in clinically asymptomatic individuals with giant cell arteritis (GCA) is controversial. Patient-reported outcomes may be useful in distinguishing disease states but have not been well studied in GCA. This study evaluated the association of changes in ESR, CRP, and patient-reported measures as predictors of subsequent relapse in patients with GCA.

**Methods:** Data from patients with GCA enrolled in a multicenter, longitudinal cohort and/or a clinical trial were included. Subjects were followed with standardized clinical assessments including symptoms attributed to vasculitis, patient global assessment (PtGA) on an 11 point numerical scale (0-10) and The Short Form Health Survey (SF-36). Physical component scores (PCS) and mental component scores (MCS) were calculated from SF-36 and normalized to the general population (mean  $\pm$  SD=50  $\pm$  10) with lower scores indicating poorer outcomes. Relapse was defined as presence since the last visit of any symptom attributable to vasculitis by the treating physician. Robust generalized estimating equations in logistic regression models were used to evaluate the association between change in PtGA, PCS, MCS, ESR, CRP from the visit prior to relapse with subsequent relapse.

**Results:** The study included 202 patients; 149 (74%) women; mean age at diagnosis = 71.6 $\pm$ 8.3 years. All subjects met ACR classification criteria modified to include subjects with angiographic evidence of large-vessel vasculitis. Temporal artery biopsy was positive in 135/163 (82%) in whom it was performed. In the multivariable model, increase in PtGA (OR 1.18, 95% CI 1.08, 1.28), decrease in PCS (OR 1.05; 95% CI 1.02, 1.08), and increase in ESR (OR 1.03, 95% CI 1.00, 1.05) were all associated with relapse (**Table 1**). Change in MCS or CRP were not associated with relapse (**Table 1**). Increase in ESR or CRP was not associated with relapse in subjects when there was no change in PtGA from prior visit (change in PtGA <1) (**Table 1**).

**Conclusion:** In GCA increases in ESR are not associated with relapse if PtGA is unchanged. Where patient-reported measures worsen compared to a prior visit, a change in ESR is significant and is associated with an increased risk of relapse. Changes in PtGA are more strongly associated with relapse than ESR or PCS. Changes in CRP are not associated with relapses, regardless of patient-reported measures. Patients' self-reports are important in the clinical assessment of disease activity in GCA and in predicting relapse as currently defined. These results support the incorporation of patient-reported outcomes into disease assessment in clinical trials and practice for GCA.

<b>Table 1. Multivariate analysis evaluating predictors of relapse in 202 patients with giant cell arteritis</b>		
<b>Variable</b>	<b>Model 1 with all variables OR (95%CI)</b>	<b>Model 2 with no change in PtGA OR (95% CI)</b>
Age, years	1.0 (1.0, 1.0)	1.0 (1.0, 1.0)

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Background/Purpose:** Tuftsin-PhosphorylCholine (TPC) is a novel bi-specific molecule which has shown immunomodulatory effects in experimental mouse models of lupus, colitis and arthritis but data in human autoimmune diseases are lacking. The present study aimed to investigate the effects of TPC *in vitro* on samples from patients with a suspicion of giant cell arteritis (GCA), an inflammatory disease of large- and medium-sized arteries.

**Methods:** Effects of TPC were determined *in vitro* on peripheral blood mononuclear cells (PBMCs) and temporal artery biopsies (TABs) obtained from six patients who underwent TABs because of a suspicion of GCA. Patients were naïve from therapy. 3 patients had inflamed TABs (GCA). 3 patients had normal TABs and received a different diagnosis (controls). GCA patients satisfied the ACR criteria for GCA. TPC was provided by TPCera (Jerusalem, Israel). Treatment with dexamethasone was included as standard of care. To model *in vitro* the inflammatory state, PBMCs were activated with CD3/CD28 beads for 48 hours and with phorbol 12-myristate 13-acetate (PMA) plus ionomycin for 4 hours in presence of different doses of TPC or dexamethasone. T helper (Th) cell subsets were analyzed by intracellular flow-cytometry. Cell viability was assessed by the WST-1 assay. To analyze the effects at tissue level, TABs were cut in fragments, placed in culture medium with TPC or dexamethasone in matrigel drops for 5 days. Levels of 18 cytokines in supernatants of TABs and CD3/CD28 activated PBMCs were quantified with the Procarta Plex Th1, Th2, Th9, Th17, Th22, Treg cytokine panel. Data were calculated relative to untreated cells. Column statistics, one-sample *t* test with an hypothetical value of 100 was used.

**Results:** Supernatants of PBMCs activated through CD3/CD28 and treated with TPC showed significant lower concentrations of IL-1beta, IL-9, IL-12(p70), IL-13 (>80% decrease), IL-2, IL-5, IL-6, IL-17A, IL-21, IL-23, IFNgamma, TNFalpha, GM-CSF (60-75% decrease) and to a lesser degree of IL-18, IL-22, IL-27. Treatment with TPC had no significant effects on IL-10. It had similar effects on PBMCs from GCA and control patients with the exception of IL-17A which was down-regulated only in PBMCs from GCA patients. IL-1beta, IL-13, IL-17A, IL-18 were detected only in supernatants from inflamed TABs and were significantly down-regulated by TPC treatment. IL-2, IL-5, IL-6, IL-10, TNFalpha were detected in supernatants both from inflamed and normal TABs: IL-6 was down-regulated by TPC treatment while no differences were found in IL-2, IL-5, IL-10 and TNFalpha. TPC and dexamethasone treatments had similar effects on cytokine production by CD3/CD28 activated PBMCs and TABs. Neither TPC nor dexamethasone treatments modified the percentage of Th1, Th17 and Th22 cell subsets induced by PMA plus ionomycin. Both TPC and dexamethasone treatments slightly reduced viability in unstimulated PBMCs while did not have any effects on viability of CD3/CD28 activated PBMCs.

**Conclusion:** TPC treatment *in vitro* remarkably down-regulated the production of several cytokines by CD3/CD28 activated PBMCs and TABs, similarly to dexamethasone, supporting further studies to validate the potential use of TPC in autoimmune diseases.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate aortic diameter and predictors of aortic dilatation using FDG-PET/CT in a longitudinally followed cohort of patients with large vessel vasculitis (LVV) compared with controls.

**Methods:** All consecutive patients with LVV who underwent at least 2 PET/CT scans between January 2008 and May 2015 were included. The first and last PET/CT study of each patient was independently evaluated by a radiologist and a nuclear medicine physician. The diameter of the aorta was measured at 3 different levels: ascending, descending thoracic and infrarenal aorta. Aortic dilation was defined as a diameter of >4 cm in the ascending, ≥4 cm in the descending thoracic and ≥3 cm in the infrarenal aorta. Aortic FDG uptake was graded at the same levels using a 0-3 semiquantitative scale and was reported as negative (score 0 or 1) or positive (score 2 and 3). Patients younger than 50 years at symptoms' onset were classified as Takayasu arteritis (TAK), while those older than 50 years as giant cell arteritis (GCA). 29 age- and sex-matched patients with lymphoma who underwent at least 2 PET/CT in the same time interval without evidence of aortic FDG uptake were selected as controls.

**Results:** 93 patients with LVV were included in the study. 53% of patients were newly-diagnosed; the remaining 47% had a median disease duration of 34 months. At first PET/CT, the mean (SD) diameter of descending thoracic aorta was significantly higher in LVV patients compared with controls [28.07 (4.40) vs 25.60 (3.59) mm,  $p=0.012$ ]. At last PET/CT, after a median time of 31 months, patients with LVV compared with controls had higher diameter of ascending [35.41 (5.54) vs 32.97 (4.11) mm,  $p=0.029$ ] and descending thoracic aorta [28.42 (4.82) vs 25.72 (3.55) mm,  $p=0.007$ ] and more frequently had aortic dilatation [19% vs 3%,  $p=0.023$ ]. Significant predictors of aortic dilatation were male sex [OR 7.27,  $p=0.001$ ], and the diameter of ascending [OR 2.03,  $p<0.001$ ], descending thoracic [OR 1.57,  $p<0.001$ ] and infrarenal [OR 1.25,  $p=0.005$ ] aorta at first PET/CT study. Positive aortic FDG uptake, disease activity and elevated inflammatory markers at first PET/CT were not associated with an increased risk of aortic dilatation. Results remained unchanged when the analysis were restricted to the 48 newly-diagnosed LVV patients.

According to age at symptoms onset, 56% of patients were classified as GCA and 44% as TAK. At first PET/CT, GCA compared with TAK patients had shorter disease duration, more frequent positive aortic FDG uptake and higher level of inflammatory markers. Compared with TAK, GCA patients had higher aortic diameter at all 3 levels evaluated in both first and last PET/CT study. However there were no differences in the proportion of patients with aortic dilatation (at last PET/CT 23% in GCA vs 15% in TAK,  $p=0.306$ ). Results remained unchanged when the analysis were restricted to the newly-diagnosed patients.

**Conclusion:** Patients with large vessel vasculitis are at increased risk of aortic dilatation compared with age- and sex-matched controls. Significant predictors of aortic dilatation are male sex and aortic diameter at first imaging study. Positive aortic FDG uptake at first PET/CT is not associated with increased risk of aortic dilatation.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

To investigate the use of glucocorticoids (GC) and related adverse events (AE) in a long-term, geographically-defined cohort of patients with polymyalgia rheumatica (PMR).

## Methods:

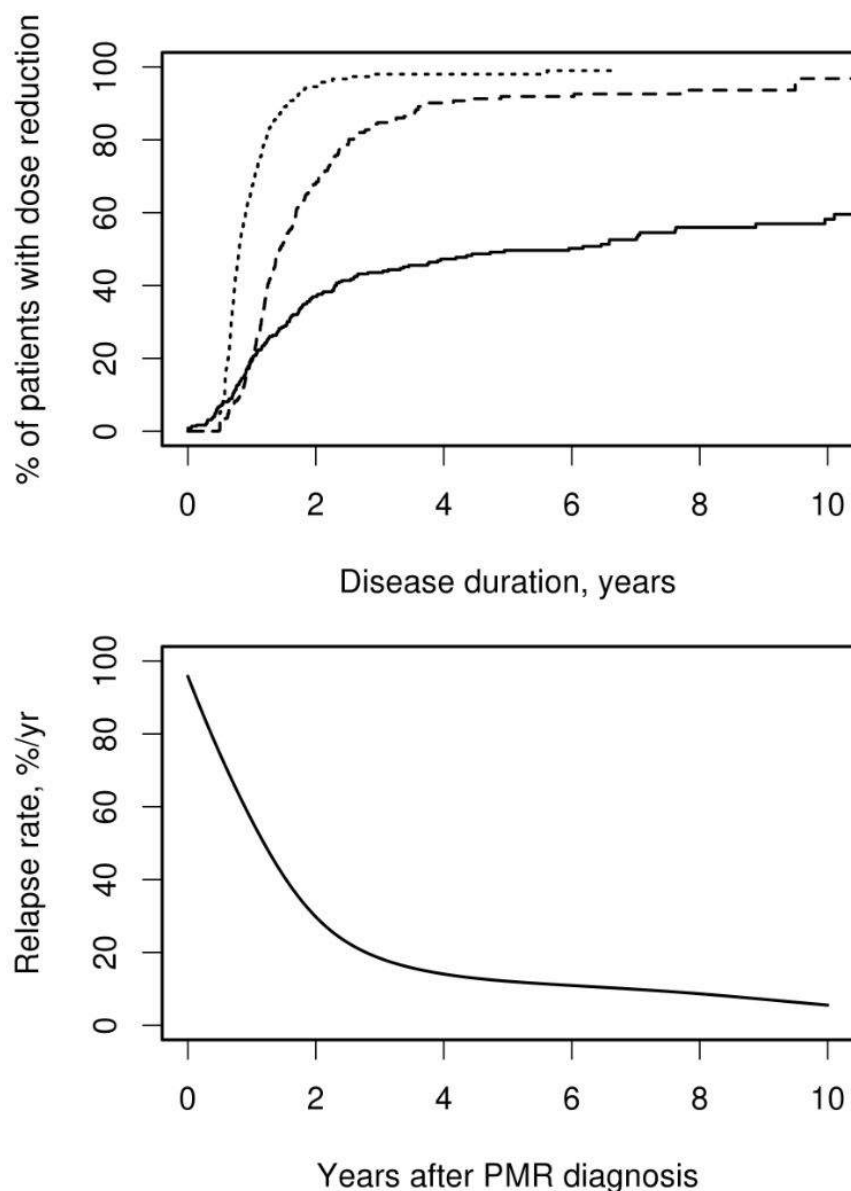

Using a population-based inception cohort, details of GC therapy were abstracted from medical records of all patients diagnosed with PMR in 2000-2014. Age- and sex-matched comparators without PMR were identified from the same underlying population. Cumulative and daily dosage of GC, rate of disease relapse, occurrence of GC-related AE, and rate of GC discontinuation were analyzed.

## Results:

The study included 359 patients with PMR and 359 comparators. The median time to taper below 5mg/day for 6 months was 1.44 years (95% confidence interval [CI]:1.36-1.62), while the median time to permanent discontinuation was 5.95 years (95%CI:3.37-8.88). GC dosage permanent discontinuation (solid line), reaching <5 mg/day for 6 months (dashed line), and reaching <10 mg/day for 6 months (dotted line) are depicted in Figure 1, top panel. Relapse rates according to time after PMR diagnosis are shown in Figure 1, bottom panel. The mean cumulative dose of GC at 2 and 5 years was 4.0 grams (g) (standard deviation [SD] 3.5g) and 6.3g (SD 9.8g), respectively. The mean daily dose of GC at 2 and 5 years was 6.1 mg/day (SD 7.6) and 7.2 mg/day (SD 9.5), respectively. There were no differences in rates of AE between patients with PMR and comparators for diabetes mellitus, hypertension, hyperlipidemia, or hip, vertebral or Colles fractures ( $p>0.2$  for all). Cataracts were more common in patients with PMR than comparators (hazard ratio:1.72; 95%CI:1.23-2.41).

## Conclusion:

The duration of GC therapy in patients with PMR is often protracted. Relapse rates are highest in the early stages of therapy. GC-related AE are not more common in PMR than comparators, except for cataracts.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Background/Purpose:**

The high-dose glucocorticoids (GCs) are the mainstay of treatment in Giant Cell Arteritis (GCA). Patients treated with greater GC dosages are at the greatest risk of morbidity. Immunosuppressive agents have been trialled in an effort to reduce toxicity from GCs and to improve efficacy of treatment. The results of one meta-analysis with the three trials that included methotrexate (MTX) showed a weak benefit in those patients receiving MT, but the results were heterogeneous, with one trial showing significant benefit, while the other two did not (1). In this sense, our main objective was to study the efficacy and safety of MTX adjunct to GCs in the treatment of GCA.

**Methods:**

New-onset giant-cell arteritis initiating treatment of the disease was included in a retrospective observational study to compare treatment efficacy and safety. According to the treatment received the patients were divided two groups: a) GCs alone and b) MTX and GCs. To avoid bias, in group b, only patients who started MTX in the first trimester of treatment were included. As efficacy outcome the number of relapses and the cumulative dose of GCs at 6, 12 and 24 months were collected. For safety, the number of emergency room visits, hospitalization admissions and treatment related side adverse events were investigated in the follow-up.

**Results:**

Among the 147 patients included in the study, 64 (43.5%) received GCs alone (mean age  $78.6 \pm 7.5$  years) and 83 (56.5%) received GCs and MTX as an adjuvant treatment at some time during follow-up. 52 of these 83 patients (mean age  $78.5 \pm 8.0$  years) received MTX in the first trimester after diagnosis (group b). In the MTX group 43 patients received a dose of 7.5-15mg/week and 9 patients received a dose  $\geq 15$ mg/week. Compared with only GCs treatment, MTX introduced in the first three months therapy did not reduce the rate of relapses, 51% in MTX group vs. 37.7% in the GCs group ( $p < 0.09$ ). The mean cumulative dose of prednisone was higher in the MTX group than in prednisone alone group (table). Patients in the MTX group, at any dose, presented a higher incidence of hospital admissions and hospital admissions by infections ( $p < 0.05$ ).

<b>Methotrexate (MTX) vs. Glucocorticoids (GCs) groups: Cumulative GCs doses</b>					
		6 months	12 months	24 months	Relapse Yes/NO (%)
<b>MTX</b>	Mean	4726,50	6312,50	8168,18	25/24 (51%)
	Std. Deviation	1447,06	1776,33	2347,28	
	n	50	48	44	
<b>GCs</b>	Mean	3724,31	5096,10	6825,16	37/61 (37.7%)
	Std. Deviation	2024,89	2626,29	3718,70	
	n	108	100	96	
<b>p value</b>		.002	.004	.029	.087

**Conclusion:**

Whilst MTX have been used in an effort to reduce toxicity from GCs and to improve efficacy of treatment our observational study shows that there is no benefit from adjunct MTX in GCA either in terms of efficacy or toxicity.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Temporal artery biopsy (TAB) plays a key role in diagnosis of giant cell arteritis (GCA). However, approximately 15-20% of patients ultimately diagnosed with GCA have negative biopsies. Among patients with negative TAB, it is often challenging to identify patients with GCA from those with an alternate (non-GCA) diagnosis. Therefore, we sought to compare TAB-negative GCA with patients receiving a non-GCA alternate diagnosis.

**Methods:** Two cohorts were retrospectively identified through direct medical record review. The first cohort consisted of patients with TAB-negative GCA diagnosed between 1/1/1998 and 12/31/2013. The second cohort included all patients with a negative TAB performed between 1/1/2009 and 12/31/2010 in which a non-GCA alternate diagnosis was provided after a minimum of 6 months of follow up. Final diagnoses were confirmed by consensus among two rheumatologists and a physician abstractor. Baseline characteristics were compared between the two cohorts using chi-square and rank sum tests.

**Results:** 110 patients with TAB-negative GCA and 195 non-GCA patients with a negative TAB were identified. Alternate diagnoses for non-GCA patients are listed in Table 1. Age, sex, number of days on glucocorticoids prior to biopsy, and biopsy length were similar in both groups. Time from first symptom to diagnosis was longer in non-GCA patients [mean (SD); 2.6 (2.5) vs 1.5 (2.1) months;  $p<0.001$ ] and fewer non-GCA patients fulfilled  $\geq 3$  ACR criteria for GCA (27% vs 64%;  $p<0.001$ ). Although headache was the primary symptom in both cohorts (66% TAB-negative GCA; 68% non-GCA), patients with biopsy-negative GCA had more frequent anorexia, fatigue, fever, polymyalgia rheumatica, temporal artery tenderness and claudication (jaw, arm, or leg). Baseline transient (5% TAB-negative GCA; 6% non-GCA;  $p=0.58$ ) and permanent (3% TAB-negative GCA; 3% non-GCA;  $p=0.86$ ) vision loss were infrequently observed. ESR was higher in TAB-negative GCA patients [64.0 (35.1) vs 55.2 (67.4) mm/hr;  $p=0.002$ ] compared to non-GCA patients but CRP did not differ [44.3 (53.6) vs 43.8 (61.9) mg/L;  $p=0.39$ ].

Table 1:  
Non-GCA alternate diagnoses among patients with negative temporal artery biopsies

Alternate diagnosis, n (%)	Negative biopsy with alternate diagnosis (N=195)
Neurologic condition	75 (38%)
Isolated PMR	38 (19%)
Rheumatic disease other than PMR or GCA	26 (13%)
Non-arteritic AION	10 (5%)
Fever of unknown origin	9 (5%)
Infectious disease	7 (4%)
Non-malignant hematologic condition	7 (4%)
Malignant disease	6 (3%)
Other vasculitis	6 (3%)
Cervical arthritis	5 (3%)
Systemic disease of unknown etiology	5 (3%)
Other	1 (1%)

AION: anterior ischemic optic neuropathy; GCA: giant cell arteritis; PMR: polymyalgia rheumatica

**Conclusion:** In this cohort, neither headache nor vision loss at presentation were associated with an ability to discriminate between diagnosis of TAB-negative GCA compared to patients without GCA. ACR criteria may be helpful in identifying

patients with TAB-negative GCA. Among patients with negative TAB, constitutional symptoms and claudication (jaw/limb) were more frequently associated with an ultimate diagnosis of TAB-negative GCA.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Giant cell arteritis (GCA) often affects aorta or its branches, but it is unclear whether the large-vessel (LV) lesions are associated with treatment outcomes. The objective of this study was to evaluate clinical features of GCA with LV lesions and their associations with treatment outcomes in Japanese patients with GCA.

**Methods:** From a retrospective, multi-center, nationwide registry of GCA and Takayasu arteritis (TAK), we selected 137 newly diagnosed GCA patients who were treated with glucocorticoids (GCs) and 4 relapsed patients who were treated with GCs between 2007 and 2014. Differential diagnosis of GCA and elderly-onset TAK was made by the discretion of the site

investigators, while 110 out of the 141 patients satisfied the ACR classification criteria for GCA. The primary outcomes were achievement of remission (disappearance of clinical symptoms with normal C-reactive protein) and remission at low dose GCs (prednisolone (PSL)  $\leq 7.5$ mg/day).

**Results:** Imaging examinations were performed in 100 of the 141 GCA, and 69 of them had LV lesions. Stenosis and aneurysm of the aorta or its branches were detected in 18 (26%) and 9 (13%) of the 69 GCA patients, respectively. On the other hand, inflammatory lesion of arterial wall was detected in 51 (74%) patients with enhanced CT, MRI or PET-CT. Of the 69 GCA patients with LV lesions, 34 had inflammatory lesions in left subclavian artery (a.), 29 in right subclavian a., 29 in left carotid a., 23 in right carotid a., 21 in ascending thoracic aorta, 31 in aortic arch, 32 in descending thoracic aorta, and 35 in abdominal aorta. We compared GCA patients with LV lesions by imaging (LVL group, n=69) and the others (non-LVL group, n=72) for clinical features and treatment response. Headache, abnormal temporal artery, jaw claudication, visual disturbance, and musculoskeletal manifestations were observed in 39%, 39%, 25%, 12% and 52% of the LVL group and in 81%, 75%, 47%, 38% and 65% of the non-LVL group. Initial PSL doses (mean  $\pm$  standard deviation) were  $0.78 \pm 0.21$  and  $0.75 \pm 0.25$  mg/kg/day, and concomitant immunosuppressive drugs were used in 48% and 33% throughout observational period of two years, for the LVL group and the non-LVL group, respectively. Remission was achieved in 94% and 96% of the LVL group and the non-LVL group, and relapse-free survival rates were not significantly different between the two groups. The log-rank test showed cumulative rate of remission at low dose GCs was significantly lower in the LVL group compared to the non-LVL group.

**Conclusion:** LV lesions in Japanese patients with GCA were mostly limited to inflammation of arterial wall without stenosis or aneurysm formation, but were associated with poorer treatment outcomes.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary large-vessel vasculitis (LVV) include giant cell arteritis (GCA) and Takayasu arteritis (TA). Age at onset is commonly used to distinguish GCA and TA. TA usually occurs before 50 years, whereas GCA occurs after age 50. However, GCA onset before age 60 remains very rare, reason why LVV between age 50 and 60 could be difficult to classify.

**Methods:** We conducted a national, retrospective study including patients with LVV, defined by histological (temporal artery biopsy) and/or imaging (circumferential thickening and/or hypermetabolism on FDG PET/CT) evidence of inflammatory vascular disease, and aged between 50 and 60 years at onset (LVV<sub>50-60</sub>). Cases were compared to controls with GCA aged over 60 years (LVV<sub>>60</sub>), and matched on gender with a ratio of 1:1.

## Results:

We included 183 patients (136 women). Initial symptoms of LVV were: constitutional symptoms in 144 (79%) cases, cephalic symptoms in 133 (73%), *polymyalgia rheumatica* in 55 cases (30%), peripheral limb ischemic manifestations in 42 (23%), ocular signs in 32 (17%), stroke in 4 cases (2%) and mesenteric ischemia in 2 cases (1%). Temporal artery biopsy showed evidence of vasculitis in 78 (43%) cases.

Computed tomography (CT) angiography was performed in 102 (56%) cases and was abnormal in 74%, involving aorta in 83% (thoracic 29%, abdominal 8% and both 63%), subclavian artery in 26%, iliofemoral artery in 18% and carotid artery in 14%. Isolated aortitis was observed in 38%.

FDG PET/CT scan was performed in 105 (57%) cases, showing hypermetabolism in 90%. Overall, aortitis was noted on CT angiography and/or FDG-PET/CT in 113 (78%) cases, without any cephalic symptoms in 22%.

All patients received glucocorticoids. After a median follow-up of 43.8 months, 78 (31%) patients required second-line therapy, 27 (18%) three-line, and 14 (9%) more lines. Overall, 35% received methotrexate and 12% biological agent (anti-TNFα and/or IL-6 blockade). Fifteen patients required surgery (bypass surgery or angioplasty). At the end of follow-up, only 45% had discontinued glucocorticoids.

Case-control comparison showed that LVV<sub>50-60</sub> had more frequent peripheral limb ischemic manifestations (23 vs 5%,  $P<0.0001$ ), and less frequent cephalic symptoms (72 vs 90%,  $P<0.0001$ ) and ocular signs (17 vs 27%,  $P=0.04$ ). CT angiography and FDG PET/CT scan were more frequently abnormal in LVV<sub>50-60</sub> (41 vs 23%,  $P<0.0001$ ; and 51 vs 27%,  $P=0.007$ , respectively), with aorta being more frequently involved (78 vs 47%,  $P<0.0001$ ). LVV<sub>50-60</sub> received a median of 2 lines of treatment compared to one in LVV<sub>>60</sub> ( $P=0.0002$ ). LVV<sub>50-60</sub> had more frequent surgery (10 vs 0%,  $P<0.0001$ ), received more frequent biological agents (12 vs 3%,  $P=0.003$ ), and had at last follow-up higher median prednisone dose (8.8

vs 6.5 mg/d, P=0.048) and lower frequency of patients with prednisone <7.5 mg/d (71 vs 83%, P=0.01) compared to LVV<sub>>60</sub>.

**Conclusion:** Primary LVV onset between 50 and 60 years identifies a subset of patients with more frequent aorta and peripheral limb vascular involvement compared to patients with LVV onset after 60. LVV between 50 and 60 were also characterized by more refractory disease requiring more methotrexate and/or biological agent.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Giant cell arteritis (GCA) is a non-necrotizing granulomatous arteritis involving large vessels, whereas antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitides (AAV) are a group of necrotizing vasculitis involvement small and medium-size vessels. AAV can be revealed by temporal arteritis (TA) leading to cephalic symptoms and misdiagnosis of GCA, whereas therapeutic management and prognosis strongly differ between these two entities.

**Methods:** We conducted a retrospective multicenter study including patients with symptomatology of TA revealing AAV. We compared these cases (TA-AAV) to controls with GCA randomly selected with a ratio of 1:2.

**Results:**

Fifty patients (26 women, mean age 70 years) were included. Initial symptoms of TA were: cephalic symptoms suggesting GCA in 44 (88%) cases, *polymyalgia rheumatica* symptoms and cough in 15 (30%) each, and ocular manifestations in 8 (16%). All patients without cephalic symptoms had inflammation on TAB consistent with GCA. However, 33 (66%) patients presented at initial presentation atypical symptoms for GCA: ENT involvement in 16 (32%), renal involvement (haematuria, proteinuria or acute renal failure) in 13 (26%), pulmonary involvement (nodule, alveolar condensation or alveolar hemorrhage) in 9 (18%), peripheral neuropathy in 8 (16%), abdominal pain and cutaneous manifestations in 5 (10%) each, episcleritis in 3 and cardiac involvement in 2. ANCA were screened at initial presentation in 33 cases, and were found in 88%, targeting MPO in 62% and PR3 in 38%.

Overall, diagnosis of AAV was made after a median time of 15.2 months (range 1.1-201), after initial flare in 20 (40%), after refractory disease in 13 (26%) and after vasculitis relapse in 17 (34%). AAV diagnoses were GPA, PAM and EGPA in 31, 16 and 3 cases, respectively. Manifestations leading to AAV diagnoses by physicians were common, including pachymeningitis in 4 cases. Once AAV diagnosis was made, all patients received glucocorticoids, in combination with immunosuppressive agents in 84% (cyclophosphamide, rituximab, azathioprine or methotrexate). After median follow-up of 43.2 months, 14 patients presented a relapse of the AAV and 5 patients died.

To identify AAV in patients with TA manifestations, we compared TA-AAV with GCA patients. AAV patients were slightly younger than GCA (70 vs. 74 years,  $P=0.01$ ), and had more frequently: peripheral neuropathy (16 vs. 0%,  $P<0.001$ ), lung involvement (40 vs. 16%,  $P=0.002$ ), ENT (34 vs. 0%,  $P<0.001$ ) and renal involvement (37 vs 0%,  $P<0.001$ ). Histologically, TAB from AAV had significantly more fibrinoid necrosis (23 vs. 0%,  $P<0.001$ ) and adventitial vasculitis (23 vs. 0%,  $P<0.001$ ) and less frequently granulomatous inflammation (13 vs. 40%,  $P=0.01$ ), disruption of the internal elastic membrane (45 vs. 69%,  $P=0.04$ ) and giant cells (29 vs. 60%,  $P=0.01$ ).

**Conclusion:** Diagnosis of AAV should be considered in patients presenting with cephalic symptoms, especially in case of unusual manifestations and in case of necrosis or adventitial vasculitis on TAB. ANCA testing should also be performed in all patients with TA manifestations before retaining GCA diagnosis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neutrophils play an important role in the pathogenesis of necrotizing vasculitis, and activation of neutrophil is one of important triggers of the disease process. Recent reports suggest that platelets can stimulate neutrophils

directly via aggregation by these cells or indirectly via chemokines produced by platelets. Thus, we hypothesized that activation of neutrophils by platelets may contribute to the progression of vasculitis. Our aim of this study is to clarify the phenotype alteration of circulating platelets and neutrophils toward aggregation in patients with vasculitis.

**Methods:** Untreated patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and large vessel vasculitis (LVV) who visited Keio University Hospital between 2015 and 2017 were consecutively involved and compared with 33 healthy controls (HC). Patients with AAV and LVV fulfilled 2012 Revisited International Chapel Hill Consensus Nomenclature or American College of Rheumatology 1990 criteria. Platelet-rich plasma and neutrophils were isolated from heparinized whole blood using gradient centrifugation. Expression levels of CD62P on platelets and CD41a on neutrophils which involved in platelet-neutrophil interaction were analyzed by FACS. The correlation between expression levels of CD62P and CD41a on these cells and clinical parameters of the patients were also analyzed.

**Results:** Four microscopic polyangiitis (MPA), 2 granulomatosis with polyangiitis (GPA) as AAV, and 5 giant cell arteritis (GCA), 3 Takayasu arteritis (TAK) as LVV were involved. As of AAV, mean age was  $67 \pm 8$  years, 62% male, mean BVAS  $15 \pm 2$ , mean neutrophil counts  $6,654 \pm 1,262$  / $\mu$ L, and mean platelet counts  $34 \pm 6 \times 10^4$  / $\mu$ L. As of LVV, mean age  $66 \pm 4$  years, 53% male, mean neutrophil counts  $5,507 \pm 600$  / $\mu$ L, and mean platelet counts  $36 \pm 5 \times 10^4$  / $\mu$ L. The treatment was started with 1 mg/kg/day of prednisolone for all patients. Proportion of CD62P<sup>+</sup> platelets was remarkably higher in AAV ( $2.5 \pm 0.09$  versus  $1.7 \pm 1.0$ ,  $p = 0.05$ ) and LVV ( $3.2 \pm 1.1$  versus  $1.7 \pm 1.0$ ,  $p = 0.005$ ) compared with HC. Moreover, proportion of CD62P<sup>+</sup> platelets was tended to be decreased by immunosuppressive treatment ( $2.6 \pm 0.7$  versus  $2.0 \pm 0.6$ ,  $p = 0.1$ ) along with improvement of disease activity. In addition, proportion of CD41a<sup>+</sup> neutrophils also tended to be higher in AAV and LVV compared with HC ( $27 \pm 8.8$  versus  $20 \pm 5.8$ ,  $p = 0.07$ ), and decreased by the treatment ( $29 \pm 9.2$  versus  $18 \pm 6.8$ ,  $p = 0.07$ ). Interestingly, proportion of CD41a<sup>+</sup> neutrophils was significantly and positively correlated with CD62P<sup>+</sup> platelets ( $r^2 = 0.8$ ,  $p = 0.04$ ) and ANCA titer ( $r^2 = 0.9$ ,  $p = 0.003$ ) in AAV patients.

**Conclusion:** Phenotype of circulating platelets and neutrophils are altered toward cell to cell contact and associate with disease activity. These results suggest that platelet-neutrophil interaction is involved in the disease process of vasculitis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The temporal artery biopsy (TAB) remains the gold standard in the diagnosis of giant cell arteritis (GCA). However, TABs are false-negative in 40% of cases. Cellular studies have shown that activated immune cells upregulate the expression of acetylcholinesterase (AChE). If AChE is upregulated in the active GCA vessel wall, it may potentially improve the TAB as a diagnostic tool. The purpose was to investigate the *in-situ* expression of AChE in the vessel wall of patients with TAB-positive GCA and compare to non-GCA patients. **Methods:** In this histological case-control study, TABs from a total of 24 TAB-positive GCA and 44 TAB-negative non-GCA patients were retrospectively included from the period 2012-2015. Only positive TABs showing clear transmural inflammation were included. Clinical data were obtained from electronic patient records to confirm or dismiss clinical diagnosis. Immunohistochemical methods were used to determine the AChE expression and verified using positive/negative controls. The histological inflammation and AChE expression were assessed and graded on 0-1-2 scale by a pathologist, blinded to clinical data. Solitary AChE staining of the media was not included in the assessment. **Results:** All positive TABs showed ACHE expression, 10/24 showed high AChE expression (grade 2) and 14/24 showed moderate AChE expression (grade 1). No non-specific AChE expression was observed outside the media in any of the negative TABs from non-GCA patients (i.e. grade 0). The AChE expression was in 79% agreement with the histological inflammation. Prednisolone treatment did not suppress the AChE expression. Neither the AChE expression, nor the histological inflammation showed correlation with any clinical findings. Clinical characteristics of included patients are shown in table 1. **Conclusion:** High to moderate AChE expression was observed in all 24 biopsies from TAB-positive GCA patients, and the AChE expression was in good agreement with the histological inflammation. No false positive staining was observed in any of the 44 TABs from TAB-negative non-GCA patients. This indicates that AChE could be a potential biomarker in GCA and may play a significant role in the inflammatory process in GCA.

Table 1: Baseline characteristics

Variables	Positive biopsy diagnosed with GCA N=24	Negative biopsy diagnosed with PMR N=21	Negative biopsy diagnosed with other disease <sup>1</sup> N=23	p value
Age (mean (95% CI), years)	70.1 (67.5-72.8)	71.6 (67.5-75.6)	68.7 (64.1-73.3)	0.565
Females - no. (%)	16/24 (67)	11/21 (52)	13/23 (57)	0.613
Time from symptoms to hospital admission (median (95% CI), days)	41 (27-63)	70 (37-132)	83 (40-170)	0.198
Cumulative prednisolone dose before biopsy (median (95% CI), mg)	204 (136-308)	136 (81-231)	197 (73-535)	0.672
Fulfilled ACR criteria for GCA - no. (%)	23/24 (96)	2/21 (10)	7/23 (30)	0.000*
Localized headache <sup>2</sup> - no. (%)	17/22 (77)	2/18 (11)	9/20 (45)	0.000*
Abnormal temporal artery <sup>3</sup> - no. (%)	14/23 (61)	4/18 (22)	9/19 (47)	0.047*
ESR (mean (95% CI), mm/hour)	73.9 (62.2-85.5)	39.1 (25.6-52.6)	40.3(25.0-55.6)	0.000*
CRP (median (95% CI), mg/l)	65.8 (44.8-96.5)	33.3 (20.9-53.0)	8.0 (3.8-16.6)	0.000*

Continuous variables are expressed as mean (95% CI); in cases of logarithmic transformation, data are expressed as median (95% CI). Binomial variables are expressed as number (percentage). \* Statistical significant

<sup>1</sup> Cancer, osteo arthritis, infection, or ischemic vascular disease.

<sup>2</sup> New unilateral headaches localized in either the occipital, frontal or temporal region.

<sup>3</sup> Tenderness, thickening or decreased pulse of the temporal artery.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Vasculitis Poster I: Large Vessel Vasculitis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The definition of remission in Takayasu arteritis (TA) is a challenge in clinical practice, since smoldering arterial inflammation may occur without overt signs and symptoms of disease activity in TA. There is an unmet need for biomarkers in TA to predict disease progression in patients considered in remission. Thus, this study aims to evaluate serum cytokines in TA patients and to analyze associations with disease phenotypes and therapy during the remission state.
