

# Arthritis & Rheumatology

AN OFFICIAL JOURNAL OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

## ABSTRACT SUPPLEMENT

2017 ACR/ARHP Annual Meeting

November 3–8, 2017

San Diego, CA

**Accreditation Statement:** The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

**Designation Statement:** The ACR designates this live educational activity for a maximum of *54.25 AMA PRA Category 1 Credits™*. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

**International Physicians:** International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)™* must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit™* to EACCME credit should contact the UEMS.

**Health Professionals:** Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)™*. For non-CME sessions, attendees may also request a certificate of participation.

### Disclosure Policy

As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships that occurred in the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content. Relevant relationships include, but are not limited to:

- None: Has no relevant financial relationship to disclose.
1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan;
  2. Research grants;
  3. Employment (full or part time);
  4. Ownership or partnership;
  5. Consulting fees or other remuneration;
  6. Non-remunerative positions of influence, such as officer, board member, trustee or public spokesperson;

7. Receipt of royalties;
8. Speakers' bureau; or
9. Other.

Abstract author disclosures are published [online](#). Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

### Abstract Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, [Arthritis & Rheumatology](#). Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the [ACR/ARHP Annual Meeting Abstract website](#). However, the ACR continues to require that information that goes beyond what is contained in the abstract (e.g., discussion of the abstract done as part of a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until **4:30 PM PT on November 4, 2017**.

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying financial and other sponsors about this policy. If you have questions about the ACR abstract embargo policy, please contact the Annual Meeting abstract staff at [abstracts@rheumatology.org](mailto:abstracts@rheumatology.org).

### Copyright Policy

The Annual Meeting is a private event. Programs presented at the meeting are for the education of attendees and purchasers of recorded presentations as authorized by the American College of Rheumatology. The information and materials displayed and presented during this meeting are the property of the ACR and the presenter and cannot be photographed, copied, photocopied, transformed to electronic format, reproduced, or distributed without written permission of the American College of Rheumatology and the presenter. Any use of the program content for commercial purposes, which includes, but is not limited to, oral presentations, audiovisual materials used by speakers, and program handouts, without the written consent of the ACR is prohibited. This policy applies before, during and after the meeting. The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

### Media

Credentialed media attend the Annual Meeting to cover stories for consumer, trade and other media outlets and are easily identified by their black press ribbons. Media has access to all general sessions and limited access (at the discretion of speakers) to Meet the Professor and Workshop sessions. Media may use handheld audio recorders and still cameras (assuming that intellectual property copyrights are respected); moving video recording is also permitted with the permission of the presenter(s). **The exception to this policy is that no photos or video are allowed in the Exhibit Hall, or in the Poster Hall without permission from the poster presenter.** Press who would like general photos of the Exhibit Hall can obtain these after the meeting from the ACR. Attendees who have questions about the ACR's media policies should contact the public relations department at [pr@rheumatology.org](mailto:pr@rheumatology.org).

### Photographs and Video Recording Policy

As a courtesy to our presenters, ACR policy does not permit photographs or recordings during educational sessions, including poster sessions. The only exception to this is for registered media, who should review their registration materials for more information.

### Abstract Reprint (Reproduction) Policy

Copyright law covers all Annual Meeting abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act.

For the purposes of this statement, the term **ACR Abstracts** refers to all Annual Meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARHP sessions and the late-breaking category.

For the purposes of this statement, the term **ACR Posters** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during the Annual Meeting. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR and the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

- For the purposes of this statement, the term "reproduce" includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.
- For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during the ACR/ARHP Annual Meeting, as identified through the abstract submission process.

### Approval Process for ACR Abstracts

- Excerpts or the entirety of **ACR Abstracts** may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

#### Permissions Department

c/o John Wiley & Sons, Inc.  
111 River Street  
Hoboken, NJ 07030  
Fax: 201-748-6008  
[wiley.com/go/permissions](http://wiley.com/go/permissions)

- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

### Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must be submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to [abstractreprints@rheumatology.org](mailto:abstractreprints@rheumatology.org).
- Poster reproduction requests must include the following:
  - Abstract ID Number
  - Abstract Title
  - Presenting Author's Name
  - A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)

### Reproducing ACR Abstracts and Posters for Dissemination Prior to the Annual Meeting

- Requests to reproduce abstracts for dissemination prior to the Annual Meeting *will not be approved*.
- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the ACR Embargo Policy; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR public relations department at [pr@rheumatology.org](mailto:pr@rheumatology.org).

## Reproducing ACR Abstracts and Posters for Dissemination During the Annual Meeting

Following approval (see approval process above), an exhibiting organization may:

- Following approval (see approval process above), an exhibiting organization may disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Following approval, an exhibiting organization may disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to [abstractreprints@rheumatology.org](mailto:abstractreprints@rheumatology.org).
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time. Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a [QR code](#) generated by the presenter and included on the poster.

## Reproducing ACR Abstracts and ACR Posters for Dissemination After the Annual Meeting

### ACR Abstracts

#### ACR Abstracts

Following approval from Wiley (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following the Annual Meeting.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet:  
*Abstract(s) reprinted from the ACR/ARHP Annual Meeting held November 5-8, 2017. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).*
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

#### ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., images from the poster presentation hung in the poster hall) may be reproduced.

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must be submitted to Wiley (see approval process above).

- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:  
*Reprinted from the ACR/ARHP Annual Meeting held November 5-8, 2017. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).*

### Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARHP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

### Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

- None: Has no relevant financial relationship to disclose.
1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan;
  2. Research grants;
  3. Employment (full or part time);
  4. Ownership or partnership;
  5. Consulting fees or other remuneration;
  6. Non-remunerative positions of influence, such as officer, board member, trustee or public spokesperson;
  7. Receipt of royalties;
  8. Speakers' bureau; or
  9. Other.

### Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during the Annual Meeting is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the prior written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

# Table of Contents

## ACR/ARHP ABSTRACT SESSIONS

### SUNDAY, NOVEMBER 5, 2017

8:30 AM - 4:00 PM

#### ACR Poster Session A

(#1-825)

11:00 AM - 12:30 PM

#### ACR Plenary Session I: Discovery 2017

(#826-830)

2:30 - 4:00 PM

#### ACR Concurrent Abstract Sessions

(#831-836) B Cell Biology and Targets in Autoimmune Disease

(#837-842) Epidemiology and Public Health I: Lung, Bone, and Infection Outcomes

(#849-854) Muscle Biology, Myositis and Myopathies

(#855-860) Pain – Basic and Clinical Aspects Oral

(#861-866) Rheumatoid Arthritis – Animal Models

(#867-872) Rheumatoid Arthritis – Clinical Aspects I: Cardiac Comorbidities

(#873-878) Sjögren's Syndrome I: Clinical Assessment and Trial Outcomes

(#879-884) Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment I

(#885-890) Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Novel and Current Therapies

(#891-896) Vasculitis I: Clinical Trials and Outcomes

#### ARHP Concurrent Abstract Session

(#843-848) ARHP Psychosocial Impact on Rheumatic Disease

4:30 - 6:00 PM

#### ACR Concurrent Abstract Session

(#897-901) 2017 Rheumatology Research Foundation

Edmond L. Dubois, MD Memorial Lecture

(#902-906) Biology and Pathology of Bone and Joint

(#907-912) Education

(#913-918) Epidemiology and Public Health II: Non-Genetic Risk Factors for Incident Disease

(#919-924) Healthcare Disparities in Rheumatology

(#931-936) Osteoarthritis – Clinical Aspects I: Pain and Functional Outcomes

(#937-942) Pediatric Rheumatology – Pathogenesis and Genetics

(#943-948) Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics I

(#949-954) T Cell Biology and Targets in Autoimmune Disease

#### ARHP Concurrent Abstract Session

(#925-930) ARHP Clinical Practice/Patient Care/Health Services Research

## MONDAY, NOVEMBER 6, 2017

8:30 AM - 4:00 PM

#### ACR/ARHP Poster Session B

(#955-1783)

11:00 AM - 12:30 PM

#### ACR Plenary Session II: Discovery 2017

(#1784-1789)

2:30 - 4:00 PM

#### ACR Concurrent Abstract Sessions

(#1790-1795) Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis: Unexpected Effects from

(#1796-1801) Measures and Measurement of Healthcare Quality

(#1802-1807) Patient Outcomes, Preferences, and Attitudes I

(#1808-1813) Reproductive Issues in Rheumatic Disorders

(#1814-1819) Rheumatoid Arthritis – Clinical Aspects II: Treatment Patterns

(#1820-1825) Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy I: Outcomes Therapy

(#1826-1831) Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment II

(#1832-1837) Systemic Lupus Erythematosus – Animal Models

(#1838-1843) Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Clinical Trial Design and Outcome Measures

(#1844-1849) Vasculitis II: Biomarkers and Disease Activity

#### ACR/ARHP Combined Abstract Session

(#1850-1855) ACR/ARHP Combined: Orthopedics and Rehabilitation Science

4:30 - 6:00 PM

#### ACR Concurrent Abstract Sessions

(#1868-1873) Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes

(#1874-1879) Imaging of Rheumatic Diseases I: Novel Imaging and Scoring Systems

(#1880-1885) Miscellaneous Rheumatic and Inflammatory Diseases I

(#1886-1891) Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis

(#1892-1897) Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Autoinflammatory Diseases

(#1898-1903) Rheumatoid Arthritis – Clinical Aspects III: Obesity and Other Comorbidities

(#1904-1909) Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy II: Trials Therapy

(#1910-1915) Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology

(#1916-1921) Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers

(#1922-1927) Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I

#### ARHP Concurrent Abstract Session

(#1856-1861) ARHP Education/Community Programs

## **ACR/ARHP Combined Abstract Session**

(#1862-1867) ACR/ARHP Combined: Epidemiology and Public Health: Prevention, Recognition, and Treatment

## **TUESDAY, NOVEMBER 7, 2017**

8:30 AM - 4:00 PM

in numeric order instead of presentation order.

## Anti-Phosphatidylserine/Prothrombin Antibodies (aPS/PT) As Potential Diagnostic Markers and Risk Predictors of Venous Thrombosis and Obstetric Complications in Antiphospholipid Syndrome

Hui Shi<sup>1</sup>, Qiongyi Hu<sup>2</sup>, Hui Zheng<sup>2</sup>, Jialin Teng<sup>2</sup>, Gary Norman<sup>3</sup>, Jinfeng Zhou<sup>4</sup> and Chengde Yang<sup>2</sup>, <sup>1</sup>Department of Rheumatology and Immunology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China, <sup>2</sup>Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China, <sup>3</sup>INOVA Diagnostics, Inc, San Diego, China, <sup>4</sup>Werfen China, Shanghai, China

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose: , Methods: , Results: and Conclusion:

#### Background/Purpose:

The antiphospholipid syndrome (APS) is a thrombophilic disorder characterized by clinical manifestations of vascular thrombosis and obstetric complications associated with the presence of specific antiphospholipid antibodies (aPLs). Most patients with APS can be identified using the conventional laboratory assays for LAC, IgG/IgM anti-cardiolipin (aCL), and IgG/IgM anti-β2glycoprotein I (β2GPI) antibodies. Some patients with clinical manifestations highly suggestive of APS however are negative for these classic biomarkers and new biomarkers are needed to identify these “seronegative APS or SNAPS) patients. Anti-Phosphatidylserine/Prothrombin (aPS/PT) antibodies are positive in many SNAPS patients. In the present study we assessed the prevalence and significance of aPS/PT, as well conventional APS biomarkers, in a large cohort of well-characterized patients with APS from the Shanghai region of China.

#### Methods:

186 Chinese patients meeting the criteria for the classification of APS using the Sydney criteria (67 primary and 119 secondary APS), 48 with SNAPS, 176 disease controls ((79 systemic lupus erythematosus (SLE), 29 Sjogren's syndrome (SS), 30 ankylosing spondylitis (AS), 38 rheumatoid arthritis (RA)), and 90 healthy donors were examined. IgG and IgM aPS/PT, IgG, IgM, IgA anticardiolipin (aCL), and IgG, IgM, IgA anti-β2-glycoprotein I (anti-β2GPI) antibodies were tested by QUANTA Lite® ELISA kits (Inova Diagnostics, San Diego, CA). Statistical analyses were performed using SPSS 23.0 (IBM, Chicago, IL, USA) or Analyze-it ver 4.6 (Analyze-it Software, LTD). T-test, Mann-Whitney U test, Kappa test, Fisher's exact or Chi-square tests were applied.

#### Results:

160(86.0%) of APS patients were positive for at least one aPS/PT isotype. 135(72.6%) were positive for IgG aPS/PT, 124/186(66.7%) positive for IgM aPS/PT, and 99(53.2%) positive for both. Approximately half of the SNAPS patients were positive for IgG and/or IgM aPS/PT. Highly significant associations between IgG aPS/PT and venous thrombotic events (OR 6.72) and IgG/IgM aPS/PT and pregnancy loss (OR 9.44) were found. Levels of IgM aPS/PT were significantly different in APS patients with thrombotic manifestations and those with fetal loss (p=0.014). The association between IgG/IgM aPS/PT and LAC was highly significant (p<0.001), when both were positive the OR for APS was 101.6. Notably, 91.95%(80/87) of LAC positive specimens were positive for IgG and/or IgM aPS/PT suggesting aPS/PT is an effective option when LAC testing is not available.

#### Conclusions:

Anti-PS/PT antibody assays demonstrated high diagnostic performance for Chinese patients with APS, detected some APS patients negative for criteria markers, and may serve as potential risk predictors for venous thrombosis and obstetric complications.

# Identifying “Second Hit” Risk Factor(s) Associated with Thrombosis and Pregnancy Morbidity in Ethnically Diverse Antiphospholipid Antibodies Positive Patients

Yu Zuo<sup>1</sup>, Jennifer Fan<sup>2</sup>, Ravi Sarode<sup>1</sup>, Song Zhang<sup>2</sup>, Una E. Makris<sup>1</sup>, David Karp<sup>3</sup> and Yu-min Shen<sup>2</sup>, <sup>1</sup>University of Texas Southwestern Medical Center, Dallas, TX, <sup>2</sup>University of Texas Southwestern Medical Center, Dallas, TX, <sup>3</sup>Rheumatology, UT Southwestern Med Ctr, Dallas, TX

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The evaluation of thrombotic and pregnancy risks associated with antiphospholipid antibodies (aPL) in individual patients without APS clinical manifestation is challenging. Our aim is to identify potential predictors of thrombosis and pregnancy morbidities among aPL positive patients.

**Methods:** This study included 229 consecutive persistent aPL positive patients who attended clinic at University of Texas Southwestern Medical Center. All patients had persistent high titer (99 percentiles) aPL. The aPL profiles were assessed with commercial assay. Hypertension (HTN) was classified based on 8<sup>th</sup> Joint National Committee guidelines. Hyperlipidemia (HLD) was defined as fasting total cholesterol >200 mg/dl. When assessing risk factors associated with pregnancy morbidities, only reproductive age (age<45) female controls were used. Pearson Chi-squared analysis and multivariable logistic regression were used to evaluate correlation between different risk factors and clinical manifestations.

**Results:** Of the 229 aPL positive patients, 130 (56.8%) patients had criteria APS clinical manifestations and 99 patients did not. 46% were Caucasian, 26% of African descent, 18% Hispanic, 2% Asian, and 8% were unspecified. Among traditional risk factors and signs of endothelial injury, only hypertension demonstrated an independent association with arterial thrombosis (OR=3.826, 95%CI 1.597 – 9.167, P=0.0026), and LA demonstrated an independent association with venous thrombosis (OR=3.308, 95%CI 1.544 – 7.085, P=0.0021). Fisher's exact test showed a marginally significant association between Caucasian race and thrombosis (P=0.045); however, multivariable analysis did not confirm an independent association. Age, diabetes, hypercholesterolemia, smoking, Raynaud's phenomenon, livedo reticularis, and triple positive aPLs were not significantly associated with either arterial or venous thrombosis. None of the evaluated risk factors demonstrated a significant association with pregnancy morbidity.

**Conclusion:** HTN is a potential predictor of arterial thrombosis and the presence of LA is a potential predictor of venous thrombosis in aPL positive patients.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prevalence of antiphospholipid antibodies in general population has been reported in about 5%. Impact of different thrombophilias in clinical thromboembolic disease is difficult to estimate. Our objective was to assess prevalence (global and in patients < 40 years) of Antiphospholipid Syndrome (APS) in a prospective Institutional Registry of Thromboembolic Disease at a tertiary university hospital

**Methods:** A prospective cohort study evaluated all consecutive incident cases of pulmonary thromboembolism (PTE) and deep vein thrombosis (DVT) confirmed in patients over the age of 18 between January 1st 2011 and December 31st 2014 at a university hospital. All patients with venous thromboembolic disease (VTED), confirmed by venous doppler ultrasound and/or multislice computed tomographic angiography and/or angioMRI and/or ventilation/perfusion scan and/or angiography, were included in the registry after given informed consent. A personal interview was performed and clinical (risk factors, comorbidities, etc) and laboratory data were collected. Patients were contacted annually after incident event in order to assess clinical status, treatments, adverse events, recurrence or death. Electronic medical records of all patients included in the registry were reviewed. APS prevalence was estimated and patients' characteristics were compared with other VTED etiologies

**Results:** 1294 patients with VTED were included in the registry in this period [females 54.9%, mean age 68.8 years (SD 15.7)]. VTED was attributed to APS in 23 patients [females 73.9%, mean age 59.6 (SD 18.2)], representing 1.8% of all patients and 3.8% of patients ≤ 40 years (Table 1). APS was associated with other autoimmune diseases in 7 patients (30.4%) (4 SLE, 2 RA, 1 overlap). Patients with APS and other thrombophilias were younger than patients with other etiologies ( $p < 0.001$ ) (Table 2). Type of event and event mortality were similar across groups (Table 2). Having a prior/recurrent event was more frequent in patients with APS and other thrombophilias. In a multivariate logistic regression analysis, younger age (OR 1.03, CI 1.01-1.06), female sex (OR 1.64, CI 1.06-1.86) and a prior VTED event (OR 6.3, CI 2.5-16.1), were significantly associated with APS as the cause of the event.

Table 1. Registry patients' characteristics

	All patients (n=1294)	Patients ≤ 40 years (n=79)
Females, n (%)	713 (54.9)	46 (58.2)
Mean age at diagnosis, years(SD)	68.8 (15.7)	30.2 (6.6)
Main cause of DVT/PTE, % (CI 95%)		
- Cancer	34.2 (31.6-36.8)	22.8 (14.8-33.4)
- Immobility	15.6 (13.7- 17.6)	5.1 (1.9-12.8)
- Major surgery	14.8 (13-16.8)	20.2 (12.7-30.6)
- Thrombophilias (other than APS)	5.6 (4.5-7)	12.7 (6.9-22)
- Antiphospholipid syndrome	1.8 (1.2-2.6)	3.8 (1.2-11.2)
- Recent journey	1.3 (0.8-2.1)	2.5 (0.6-9.6)
- Oral contraceptives/hormonal replacement	1.2 (0.7-1.9)	10.1 (5.1-19)
- Pregnancy/puerperium	0.5 (0.2-1)	6.3 (2.6-14.4)
- Thrombocytosis	0.4 (0.2-0.9)	0
- Multiple causes	10.3 (8.7-12)	7.6 (3.4-16)
- Unknown	14.5 (12.7-16.5)	8.9 (0.4-17.5)

Table 2. APS patients' characteristics in comparison with other etiologies

	APS patients (n=23)	Other Thrombophilias (n=73)	Other causes of VTED (n=1201)	P value
Female, n (%)	17 (73.9)	42 (57.5)	654 (54.5)	0.2
Mean age at diagnosis, years (SD)	59.6 (18.2)	61.3 (17.6)	69.4 (15.4)	<b>&lt;0.001</b>
Event type, n (%)				
- DVT	12 (52.2)	46 (63.1)	687 (57.3)	0.55
- PTE	6 (26.1)	16 (21.9)	344 (28.7)	0.44
- DVT + PTE	5 (21.7)	11 (15.1)	167 (13.9)	0.55
Event mortality, n (%)	0 (0)	4 (5.5)	110 (9.2)	0.18
On anticoagulation at event time, n (%)	7 (30.4)	14 (19.2)	129 (10.8)	<b>0.002</b>
Prior event, n (%)	11 (47.8)	24 (32.9)	140 (11.7)	<b>&lt;0.001</b>
Type of prior event, n (%)				
- DVT	6 (26.1)	18 (24.7)	105 (8.8)	<b>&lt;0.001</b>
- PTE	2 (8.7)	3 (4.1)	12 (1)	<b>0.001</b>
- DVT + PTE	3 (13.1)	3 (4.1)	23 (1.9)	<b>0.001</b>
Follow-up after event, years, median (IQR)	1.9 (0.1-4.5)	3.2 (0.8-4.5)	1.1 (0.1-3.1)	<b>&lt;0.001</b>
Recurrence of any thrombotic event during follow up, n (%)	4 (17.4)	14 (19.2)	40 (3.3)	<b>&lt;0.001</b>
Comorbidities, n (%)				
- Hypertension	15 (65.2)	36 (49.3)	780 (65.1)	<b>0.02</b>
- Diabetes	5 (21.7)	10 (13.7)	190 (15.9)	0.6
- Dyslipidemia	12 (52.2)	27 (36.9)	483 (40.3)	0.4
- Active Smoker	6 (26.1)	28 (38.4)	379 (31.6)	0.4
- Major cardiovascular event	5 (21.7)	6 (8.2)	144 (12.1)	0.2
- Heart failure	2 (8.7)	3 (4.1)	93 (7.8)	0.5

**Conclusion:** APS- related VTED events represented 1.8% of total events in this registry. Younger age, female sex and having had a prior event were significantly associated with APS

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The most prominent alteration in the immune system of patients with SLE is a type I interferon (IFN) signature, which we recently also reported in patients with primary APS (PAPS). In SLE and APS, this signature is related to disease activity and vascular disease. Plasmacytoid dendritic cells (pDC) are considered key players in the pathogenesis of SLE and APS as they are major producers of type I IFN. MicroRNAs (miRNAs) are short non-coding RNAs that modulate gene expression through RNA interference and have been implicated in the dysregulation of immune cells in autoimmune diseases. Here we investigated miRNA expression in pDC of patients with SLE and APS in relation to the IFN signature.

### Methods:

RNA was extracted from pDCs isolated from the peripheral blood of patients with SLE (n=20), SLE+APS (n=10), PAPS (n=10) and HC (n=12). pDC miRNA and transcriptome profiles were assessed by RT-qPCR by OpenArray and RNA-sequencing (RNAseq) respectively. Patients were stratified by the presence (IFN-high) or absence (IFN-low) of an IFN signature on the basis of RNAseq. pDC stimulated with TLR7 agonists were analyzed for changes in miRNA expression. The frequency of circulating pDC was determined by flow cytometry in patients with SLE (n=49), SLE+APS (n=34) and PAPS (n=27) and healthy controls (HC, n=22).

### Results:

Among 131 expressed miRNAs, 36, 17 and 21 miRNAs were differentially expressed ( $p < 0.05$ ) in patients with SLE, SLE+APS and PAPS, respectively, as compared with HC. All but one of these miRNAs were downregulated in the patients versus HC. Only 1 miRNA was differentially expressed when comparing between SLE and SLE+APS patients and between SLE+APS and PAPS patients. No changes in expression of genes related to the biogenesis of miRNAs were observed in the pDC of the patient groups. RNAseq data revealed an IFN signature in pDC, which was strongest in SLE and SLE+APS patients. IFN-high (n=23) patients showed a stronger downregulation of miRNAs as compared with IFN-low (n=17) patients. Activation of pDCs by TLR7 agonists induced a downregulation of miRNAs in pDC, resembling the miRNA expression pattern seen in patients, in particular those with a high type I IFN signature. Pathway enrichment on the overlap of the targets of the top three miRNA ( $p < 0.001$ ) and differentially expressed genes from RNAseq between IFN-high and -low patients indicated that these miRNAs are potentially regulating pathways relevant for pDC function such as TLR signaling, endocytosis and pDC survival. In line with that, the numbers of circulating pDC were reduced in peripheral blood of patients with SLE, SLE+APS and PAPS, in particular in patients with a high type I IFN signature.

### Conclusion:

Reduced numbers of circulating pDC and downregulation of miRNAs in pDC are shared between SLE, SLE+APS and PAPS patients and are related to the IFN signature. Our data suggest that the reduced expression of a subset of miRNA underlies pDC dysregulation in SLE, SLE+APS and PAPS patients.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Recently, our group conceived a risk score for clinical manifestations of APS [the global APS score or GAPSS] that takes into account the combination of independent cardiovascular risk factors and the aPL positivity profile. These include hyperlipidemia, arterial hypertension, aCL, anti-b2GPI, aPS/PT and the LA. A complementary version, the adjusted GAPSS or aGAPSS, which excludes aPS/PT, was also designed.

## **Methods:**

We pooled data from available cohort studies, including a total of 10 studies, counting for a total of 2273 patients in which the GAPSS score has been applied. A search strategy was developed a priori to identify available cohort that reported findings that investigated the clinical utility of GAPSS or aGAPSS score.

## **Results:**

When pooling together available data, GAPSS/aGAPSS was applied in a total of 2273 patients. Studies characteristics and patients enrolled are summarized in Table 1.

Seven studies used the GAPSS in their cohort, whether three studies used the aGAPSS. In brief, we found a statistically significant difference in the cumulative GAPSS and aGAPSS scores between patients that experienced arterial and/or venous thrombotic event (Cumulative GAPSS  $10.6 \pm 4.74$  and aGAPSS  $7.6 \pm 3.95$ ), patients without any thrombotic manifestation (Cumulative GAPSS  $7.01 \pm 5.46$  and aGAPSS  $4.9 \pm 4.33$ ) and patients with pregnancy morbidity (Cumulative GAPSS  $8.79 \pm 2.59$  and aGAPSS  $6.7 \pm 2.8$ ).

The highest levels of GAPSS were found in patients that experienced arterial thrombosis (mean GAPSS  $12.2 \pm 5.2$ ) and patients that experienced any recurrences of clinical manifestations of APS (mean GAPSS  $13.7 \pm 3.1$ ).

## **Conclusion:**

GAPSS may represent a useful tool to assess the thrombosis or pregnancy loss risk in aPL positive patient, switching from the concept of aPL as a sole diagnostic antibody to aPL as risk factors for clinical events. A risk assessment, using appropriate tools as GAPSS, should be implemented to identify and monitor those patients at a higher risk of recurrences and those needing a strict control of all modifiable risk factor for cardiovascular events; in agreement with the above, in the future the management of APS should also modulate according to the GAPSS values.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The goal of this long-term project was to investigate the course of pregnancy in patients with APS (primary or secondary with SLE) in 1993-2017, to describe the type and severity of it and to explore their relationship with disease-related characteristics. To find specific histological changes in maternal tissue in a subgroup of patients.

**Methods:** During more than 25 years of systematic observation 80 pregnant women with APS were observed and examined. Secondary APS was in our cohort common with systemic lupus erythematosus (SLE). Patients were evaluated every 3 months by a rheumatologist and gynaecologist. Basic demographic data were assessed, as well as the duration and type of therapy, autoantibodies, organ involvement and its activity, the number and type of disease flares, thrombosis, the number of abortions and premature labours, new-born weight and presence of complications such as gestational diabetes, hypertension and preeclampsia. In a subgroup of 13 patients (5 with primary APS, 7 with sec.APS/SLE a macroscopic and histological examination of maternal tissue was performed in comparison with a healthy control group.

**Results:** The group comprised 65 pregnant women with APS, out of which 57% had secondary APS/SLE and 33% primary APS. In the group of primary APS 90% pts were treated with low molecular heparin and/or salicylates. In pts. with sec.APS/SLE 90 % of patients were treated with oral corticosteroids, 8% with cyclosporine A and 16% with azathioprine and 95% with low molecular weight heparin and/or salicylates. 7% of pregnancies were terminated in the first trimester due to missed abortion. 6% of abortions in patients with sec. APS/SLE in second trimester were observed. 57 APS patients delivered 58 newborns, 16% of them before the 37th week of pregnancy and 7% before the 34th week. Out of this group 75% patients delivered prematurely due to hypertension or preeclampsia, 10% due to growth retardation of fetus. Newborn weight was 3020g on average. AV heart block of 3rd degree was observed in 1 newborn with sec.APS/SLE. No congenital malformations were observed in our group. In the group sec.APS/SLE higher number of gestational diabetes was found: 38% of patients, all of which were treated with corticosteroids. Hypertension was found in 33% patients, preeclampsia in 12 % and 60% of patients with preeclampsia had a history of lupus nephritis. Higher score of maternal infarcts and decidual pathological changes with deposits of immunocomplexes were found in microscopic examination in patients with APS in comparison with healthy controles. Rate of weight placenta/fetus was lower. Signs of accelerate aging, nodules and inflammatory infiltration was found in light microscopy and higher score of deposits of immunocomplexes were found.

**Conclusion:** In spite of the fact that women with APS have a high risk during the course of pregnancy, the results of our long terms study showed a good outcome of pregnancy. Higher rate of complications was found in the group with sec. APS with SLE.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The lupus anticoagulant (LAC) is individually the antiphospholipid antibody (aPL) most associated with thrombotic risk in both primary and secondary APS. Anticardiolipin (aCL) and anti-beta2 glycoprotein 1 may further increase the risk. We investigated the risk for thrombosis in SLE of double or triple positivity for these different aPLs.

**Methods:** The analysis is based on 1508 SLE patients, (92% female, 51% white, 40% black, and with a mean age at end of follow-up of 46.4 [SD=14.2]). Thrombosis was defined as: arterial thrombosis (CVA, MI, other arterial thrombosis or digital gangrene); and venous thrombosis (DVT, PE or other venous thrombosis).

**Results:** We looked at the risk of lifetime occurrence of thrombosis as a function of the history of LAC (RVVT confirm), aCL, or anti-beta2 glycoprotein 1 (anti-Beta2). The OR's in the tables are adjusted for age.

Table 1. History of thrombosis by history of APS.

	Specific Components	Proportion (%) of patients with a history of any thrombosis	Odds Ratio (relative to those without any APS components)	P-value
<b>Any Thrombosis</b>				
No aPL	None	100/488 (20%)	1.0 (Ref Group)	
Single Positive	aCL alone	66/369 (18%)	0.8 (0.6, 1.2)	0.31
	LAC alone	26/74 (35%)	2.1 (1.2, 3.6)	<b>0.0063</b>
	anti-Beta2 alone	10/82 (12%)	0.6 (0.3, 1.1)	0.095
Double Positive	Any double positive	105/315 (33%)	1.9 (1.4, 2.6)	<b>0.0002</b>
	aCL + LAC	61/138 (44%)	2.9 (1.9, 4.4)	<b>&lt;0.0001</b>
	aCL + anti-Beta2	29/147 (20%)	0.9 (0.6, 1.5)	0.71
	LAC + anti-Beta2	15/30 (50%)	4.1 (1.9, 8.8)	<b>0.0002</b>
Triple positive	All three	89/180 (49%)	3.7 (2.6, 5.4)	<b>&lt;0.0001</b>
<b>Arterial Thrombosis</b>				
No aPL	None	55/488 (11%)	1.0 (Ref)	
Single Positive	aCL alone	40/369 (11%)	0.9 (0.6, 1.5)	0.78

	LAC + anti-Beta2	12/30 (40%)	5.5 (2.5, 12.0)	<b>&lt;0.0001</b>
Triple positive	All three	60/180 (33%)	3.9 (2.6, 6.0)	<b>&lt;0.0001</b>

The findings in the table confirm that there can be an increase in the point estimate from single, to double positivity. However, it clearly depends on which components are considered, and whether it is arterial or venous thrombosis. The strongest finding is that LAC is the most important component. For arterial thrombosis, however, double positivity with LAC and aCL leads to increased risk.

**Conclusion:** In SLE, lupus anticoagulant is the most important single antiphospholipid test predictive of any thrombosis and venous thrombosis. For arterial thrombosis, aCL and LAC together outperform single tests. For venous thrombosis, the point estimates increase for double positives containing LAC, and for triple positive, although the confidence intervals overlap. In SLE, double, and possibly triple, positivity show promising results. However, different combinations of “double positive” aPLs are important, and differ in arterial vs. venous thrombosis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adhesion of leukocytes to the endothelium is an initiating event in the thrombosis inherent to antiphospholipid syndrome (APS). Over the years, a number of groups have demonstrated that antiphospholipid antibodies (aPL) upregulate both selectins and integrin receptors on endothelial cells, thereby increasing the adhesive potential of the endothelium. Here, we posit that factors intrinsic to leukocytes may also play a pivotal role in adhesive interactions. For example, transcriptome analysis of APS patient neutrophils has revealed an activated, adhesive signature. Furthermore, leukocyte adhesion in our mouse model of aPL-mediated large vein thrombosis is regulated by leukocyte (more so than endothelial) factors. In this study, we functionally characterize leukocyte adhesion in APS, with the goal of ultimately testing the therapeutic potential of putative targets.

**Methods:** Patients had primary APS (classified by Sydney criteria), while healthy controls were matched for age and gender. Freshly-isolated human umbilical vein endothelial cells (HUVECs) were used. Anticoagulated whole blood (or purified cellular components) was introduced into a flow channel via a programmable syringe pump, and perfused across an unstimulated HUVEC monolayer in a pulsatile flow profile with wall shear rate set to 1000 s<sup>-1</sup>. After 15 minutes of perfusion, the chamber was flushed to remove nonadherent cells, and images were captured with an inverted microscope.

**Results:** Perfusion of APS blood across unstimulated HUVECs resulted in significantly more leukocyte adhesion as compared with control blood (mean 5.0-fold increase;  $p < 0.0001$  with  $n = 18$  patients). To assess the role of leukocytes themselves (versus plasma factors that might activate HUVECs), leukocytes were washed free of plasma, resuspended in buffer, and then perfused across HUVECs. In this plasma-free context, there was still significantly more adhesion of APS leukocytes (mean 2.2-fold increase;  $p < 0.01$  with  $n = 10$  patients), suggesting an intrinsic increase and/or activation of leukocyte adhesion factors. Furthermore, treating control leukocytes with APS patient plasma (which was then washed away before perfusion) resulted in increased adhesion of the control leukocytes (mean 2.5-fold increase;  $p < 0.0001$  with  $n = 12$  plasma samples). Experiments are underway to delineate the factors on the leukocyte surface that dictate the increased adhesive potential (as well as the factors in APS plasma that mediate their upregulation). In particular, we are characterizing both selectin ligands and beta-2 integrins on leukocytes, as even unstimulated HUVECs demonstrate baseline expression of potential binding partners (selectins and ICAM-1, respectively). We are also determining the relative adhesive potential of different leukocyte subpopulations (i.e., monocytes versus neutrophils).

**Conclusion:** While there is a known role for aPL in increasing the adhesive potential of endothelial cells, we now report that leukocytes themselves have an intrinsic increase in their adhesive potential. The ultimate goal of this work is to identify the most relevant pharmacologic targets on the leukocyte surface.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

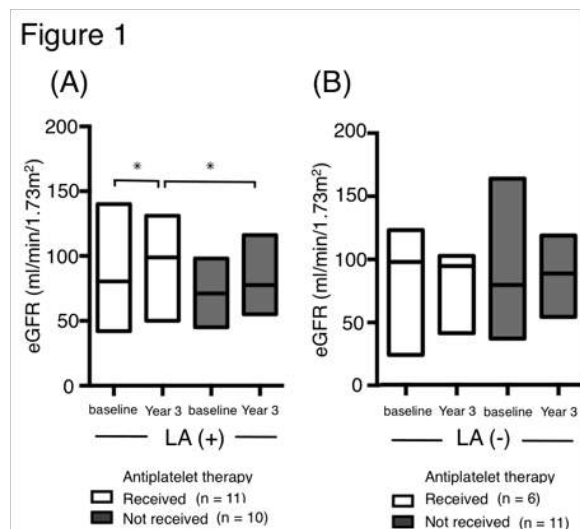

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus nephritis (LN) class III or IV is associated with a poor prognosis for both patient and renal survival. Since antiphospholipid syndrome (APS) is reported to worsen the prognosis of LN, LN patients with APS should be treated with conventional immunosuppressive treatment plus antiplatelet or anticoagulation therapy according to the recommendations for LN management. However it has been unclear whether these therapies would benefit antiphospholipid antibodies (aPL)-positive LN patients not meeting the diagnostic criteria. Here, we evaluated the effect of antiplatelet therapy in addition to conventional immunosuppressive therapy for LN patients positive for aPL without definite APS.

**Methods:** Patients with biopsy-proven LN class III or IV who did not take hydroxychloroquine were retrospectively evaluated. We selected patients positive for anticardiolipin antibody (aCL) or lupus anticoagulant (LA) who did not meet the criteria for a diagnosis of APS. The patients were divided into two subgroups according to whether antiplatelet therapy was received. The cumulative complete renal response (CR) rate, relapse-free rate, and change in estimated glomerular filtration rate (eGFR) over 3 years after induction therapy were calculated.

**Results:** We identified 17 patients who received antiplatelet therapy and 21 who did not. Baseline clinicopathological characteristics and immunosuppressive therapy did not show a statistically significant difference between the two groups except for a significantly higher incidence of LN class IV in the treatment group ( $p = 0.03$ ). There was no significant difference in cumulative CR rate, relapse-free rate, or eGFR change between these subgroups. However, when data on LA-positive patients were assessed, a significant improvement in eGFR was found ( $p = 0.04$ ) in patients receiving antiplatelet therapy (Figure 1).

**Conclusion:** Addition of anti-platelet therapy was associated with an improvement of eGFR in LA-positive patients with LN class III or IV. There may be a wider indication for antiplatelet therapy in LN, in addition to its use in patients with a definite APS diagnosis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The adjusted Global AntiPhospholipid Syndrome Score (aGAPSS) was described as a tool to estimate the risk of thromboses in patients with APS. The aim of this study is to evaluate if higher values of aGAPSS correlate with the presence of arterial or venous thromboses in thrombotic primary APS patients.

**Methods:** A cross-sectional study was performed in a group of 72 outpatients who fulfilled thrombotic pAPS classification criteria (Sydney). Clinical and serologic features were collected during visits and by chart review. aGAPSS was calculated for each patient and correlated to arterial and venous thromboses. Statistical analysis was performed using chi-square, Mann-Whitney U and Spearman's R when applicable. Multivariate regression analysis included age, sex, race and variables with  $p < 0.10$  in the bivariate analysis.

**Results:** Thirty-seven (51.4%) patients had arterial events and 51 (70.8%) had venous thromboses. The mean number of episodes of arterial and venous thromboses was 1.65 and 1.4 per patient, respectively. The median aGAPSS of the 72 patients included in the analysis was 9 (7-13); this was used to divide two groups of patients: low aGAPSS ( $< 10$ ) and high aGAPSS ( $\geq 10$ ). Patients with or without arterial thromboses were compared regarding the presence of high aGAPSS. In a bivariate analysis, higher aGAPSS correlated with the presence of arterial thromboses ( $p = 0.018$ ). In a multivariate regression analysis, higher aGAPSS remained as a risk factor for the presence of arterial thromboses (OR 3.4, 95%CI 1.26-9.2,  $p = 0.016$ ). Demographic and clinical characteristics of this group of patients are shown in Table 1. Regarding venous thrombosis, there was a tendency towards higher levels of aGAPSS ( $p = 0.063$ ). To avoid contamination of data, a new different analysis was performed. Patients who presented both arterial and venous thromboses were excluded, and 2 groups were created, one with arterial exclusive events ( $N = 19$ ) and another with venous exclusive events ( $N = 35$ ). The group with arterial exclusive thromboses had higher values of aGAPSS ( $p = 0.007$ ). In the multivariate analysis, high aGAPSS was associated with increased risk of arterial events (OR 4.95, 95%CI 1.49-16.47). Patients with both arterial and venous thromboses did not have higher aGAPSS ( $p = 0.677$ ).

**Conclusion:** The presence of arterial events was associated with higher values of aGAPSS. aGAPSS seems to be a tool capable to detect high risk thrombotic patients, particularly arterial events.

Table 1: Demographic and clinical characteristics (N=72).

Variable	Arterial thromboses (N=37)	No arterial thromboses (N=35)	P value
Age	46.9±13.5	42.1±11.9	NS
Female gender	29 (78.4)	31 (88.6)	NS
Caucasian	23 (62.2)	24 (68.6)	NS
Time first manifestation (mo)	180 (96-240)	108 (69.5-192)	NS
<b>aGAPSS</b>			
High aGAPSS (value $\geq 10$ )	20 (54.1)	9 (25.7)	0.013
Hypertension	17 (45.9)	10 (28.6)	NS
Dyslipidemia	20 (54.1)	9 (25.7)	0.018
Lupus anticoagulant	34 (91.9)	32 (91.4)	NS
Anticardiolipin	15 (40.5)	13 (37.1)	NS
Anti- $\beta 2$ -glycoprotein I	24 (64.9)	15 (42.9)	NS

Values showed as N(%) for categorical variables, Mean± SD for normal distribution and Median (interquartil range) for asymmetrical distribution.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite the pro-thrombotic nature of antiphospholipid antibodies (aPL), thrombocytopenia is frequently observed in patients with antiphospholipid syndrome (APS) or in non-APS patients with aPL. The management of the thrombocytopenia with aPL (aPL related thrombocytopenia; APAT) is often deductive, due to the paradoxical risks of thrombosis and hemorrhage. We have been striving to clarify the mechanisms of APAT and reported its high prevalence of arterial thrombotic events (Nakagawa I, et al. ACR 2014, Abstract #2). In the present study, along with the reconfirmation of the clinical importance of APAT, we aimed to evaluate the efficacy of therapeutic regimes in APAT through a systematic review of the literature with the objective of elaborating a clinical practice guideline for APAT on a consignment project from the Japanese Ministry of Health, Labor and Welfare.

**Methods:** Four clinical questions were selected for systematic review and redefined using the PICO (Patient, Intervention, Comparison, Outcome) format and prioritized. The four clinical questions were to evaluate the effects of possible therapeutics for APAT; antiplatelet agents, glucocorticoids, splenectomy and thrombopoietin receptor agonists. Systematic reviews were performed using electronic databases (MEDLINE, EMBASE and CENTRAL) by the Cochrane Japan Centre. Cochrane Collaboration Review Manager software was used to manage and analyze the data collected.

**Results:** The initial search yielded 1407 citations of which nine were included in our final analysis. There was no randomized controlled trial on treatment for APAT. We identified four case-controlled studies for splenectomy, one for antiplatelet agents and four observational studies for glucocorticoids. Meta-analysis of quantitative data (17/23) showed evidence of an increase in platelet count in patients who underwent splenectomy compared with the patients without splenectomy (mean difference  $22.6 \sim 10^4$  /mL,  $P = 0.007$ ) (Figure). Complete remissions of the thrombocytopenia were observed in 18/23 (78%) patients with splenectomy versus 0/23 (0%) without splenectomy. The relapses were occurred in 3/23 (13%) patients with splenectomy. There was no complications due to splenectomy. None of the configured outcomes were susceptible to the antiplatelet and glucocorticoid therapy.

**Conclusion:** Although splenectomy for APS was previously reported to be a risk of portal vein thrombosis, our systematic review and meta-analysis revealed that it may be performed rather safely and effectively in APAT patients. However, there was no clear evidence to support applications of antiplatelet agents, glucocorticoids, or thrombopoietin receptor agonists as therapeutics of APAT. Further clinical trials are required to establish therapeutic recommendation for APAT.

**Figure:** Forest Plot: Effect on platelet count on splenectomy, in aPL-related thrombocytopenia patients.

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** APS ACTION Clinical Database and Repository (“Registry”) was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL) positive patients with/without other systemic autoimmune diseases. Our objective was to describe the new pregnancy outcomes of the aPL-positive patients since the inception of the registry.

**Methods:** A web-based data capture system is used to store patient demographics, history, and medications. The inclusion criteria are positive aPL based on the Updated Sapporo Classification Criteria at least twice within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection. For this analysis, we identified all patients who were recorded as “pregnant” during the prospective follow-up.

**Results:** Since the inception of the registry in 5/2012, 45 pregnancies were recorded in 36 aPL-positive patients (mean age 33.4 ± 4.9 y; lupus: 5 [14%]; LA-positive alone: 16 [44%]; triple aPL-positive: 11 [31%]; double aPL-positive: 7 [19%]; obstetric APS [OAPS]: 5 [14%]; thrombotic APS [TAPS]: 10 [28%]; OAPS+TAPS: 12 [33%]; and no history of OAPS/TAPS: 9 [25%]). Of 45 pregnancies (28 patients had one pregnancy, seven had two, and one had three), 23 (51%) resulted in term live birth (preeclampsia [PEC]: 1; and small for gestational age [SGA]: 2), eight (18%) preterm live birth (mean delivery week [w] 33.5 ± 1.7; PEC: 4; and SGA: 1), 12 (27%) (pre) embryonic loss < 10w, one (2%) fetal death > 20w, and one was ongoing at the time of data lock (Table). *Term live birth* occurred in 12/21 (57%) of pregnancies of patients with history of OAPS (no treatment: 1; Aspirin [ASA]: 1; low-molecular-weight-heparin [LMWH]: 2; and ASA+LMWH: 8), compared to 11/24 (46%) of pregnancies of patients without history of OAPS (no treatment: 1; ASA: 1; LMWH: 2; and ASA+LMWH: 7). (p: 0.38). *Pre-term live birth* occurred in 3/21 (14%) of pregnancies of patients with history of OAPS (no treatment: 1; and ASA+LMWH: 2), compared to 5/24 (21%) of pregnancies of patients without history of OAPS (ASA+LMWH: 5) (p: 0.70). Similarly, term and preterm live birth rates were not different between patients with and without TAPS.

**Conclusion:** Fifty percent and 20% of pregnancies in our multi-center international aPL-positive cohort resulted in term and preterm live births, respectively. While 80% of the pregnancies were treated with low dose aspirin +/- LMWH, only 60% had had a history of pregnancy morbidity fulfilling the Updated Sapporo Classification Criteria. Term and preterm live birth rates were similar between patients with and without history of obstetric APS or thrombotic APS; no pregnancy was complicated with fetal loss between 10-20 weeks; and only one with fetal loss after 20 weeks.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The epidemiology of definite antiphospholipid syndrome (APS) in the general population has not been described. A recent meta-analysis (Andreoli L, *et al.* Arth Care Res 2013;65:1869-73) concluded that it was difficult to determine the frequency of a “clinically significant antiphospholipid (aPL) profile” in patients with aPL-related clinical outcomes due to the lack of robust data; only 4%

of the studies had the current cutoff values for anticardiolipin antibodies (aCL) and less than one fifth of them had confirmation after 6-12 weeks. This study aimed to characterize the epidemiology of definite APS based on the 2006 updated international consensus (Sydney) classification criteria.

**Methods:** An inception cohort of patients with incident APS in 2000-2015 in a geographically well-defined population were identified based on comprehensive individual medical record review. All cases met the definite 2006 Sydney consensus APS criteria, including the laboratory and clinical criteria as well as laboratory confirmation after 12 weeks. Lupus anticoagulant, IgM and IgG aCL and anti-β2 glycoprotein-1 antibodies were tested in a centralized lab (cutoff >40 GPL/MPL). Incidence rates were age and sex adjusted to the US white 2010 population. Prevalence estimates were obtained from the incidence rates assuming no increased mortality associated with APS and assuming migration in/out of the area was independent of disease status.

**Results:** In 2000-2015, 33 cases of incident APS were identified (mean age 54.2 years, 55% female; 97% Caucasian). The annual incidence of definite APS was 2.0 per 100,000 population aged ≥ 18 years (95% confidence interval [CI]: 1.1-3.1 per 100,000). Incidence rates were similar in both sexes (2.1 per 100,000 population in females and 2.0 per 100,000 population in males). The peak incidence was observed in those who were older than 75 years. Significant changes in incidence rates over time were not observed. Six (18%) of the patients had a concurrent diagnosis of systemic lupus erythematosus. Three (17%) patients had obstetric manifestations. During a median follow-up of 8.8 years, 7 patients died (84% survival at 10 years after APS incidence; 95% CI: 69-100%). The overall mortality of patients with APS was not significantly different from the general population (standardized mortality ratio: 1.14; 95% CI, 0.46-2.64). The estimated prevalence of APS adjusted to the US white 2010 population was 50 per 100,000 (95% CI: 42-58) and was similar in both sexes (51/100,000 for females and 48/100,000 for males). Based on this and US census data, an estimated 119,300 persons in the US were affected by APS in 2015.

**Conclusion:** Results from this first ever population based study revealed that definite APS occurred in about 2 persons per 100,000 per year. The estimated prevalence is 50 per 100,000. Overall mortality was not different from the general population. The prevalence of APS in the same population was at least as common as SLE (Jarukitsopa, *et al.* Arth Care Res 2015;67:817-28).

## Abnormalities in Th1, Th2 and Th17 Lymphoid Subpopulations in Long-Term Evolution Primary Antiphospholipid Syndrome

Gabriela Medina<sup>1</sup>, Oscar I Florez-Durante<sup>2</sup>, Laura Arcelia Montiel Cervantes<sup>3</sup>, Rubiraida Molina Aguilar<sup>2</sup>, Elba Reyes Maldonado<sup>2</sup> and Luis J. Jara<sup>4</sup>, <sup>1</sup>Clinical Research Unit, Hospital de Especialidades Centro Medico La Raza, IMSS, Mexico City, Mexico, <sup>2</sup>Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Mexico City, Mexico, <sup>3</sup>Hematology Laboratory, Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico, <sup>4</sup>Direction of Education and Research, Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary antiphospholipid antibody syndrome (PAPS) is characterized by recurrent thrombosis and pregnancy morbidity in the presence of antiphospholipid antibodies (aPL). Lymphoid subpopulations and innate and adaptive immune responses have not been fully studied in long-term evolution PAPS.

**OBJECTIVE:** To analyze the lymphoid subpopulations, Th1, Th2 and Th17 immune response in long-term evolution PAPS patients.

**Methods:** Patients with PAPS >18 years of age, of both genders and a group of healthy blood donors matched for age and sex were included. All patients were receiving oral anticoagulants (Coumadin type). No patient had a recent episode (six months) of thrombosis or other manifestation of APS at the time of the study. Peripheral blood was obtained and lymphoid subpopulations were determined by flow cytometry in order to identify with specific immunological markers, for Treg cells we used: CD4+/CD25+/FoxP3+ and CD8+/CD25+/FoxP3+. The dendritic cells analyzed were: type 1: Lin1-/HLA-DR+/CD11c+; Type 2: Lin1-/HLA-DR+/CD123+; B lymphocytes with CD19+; Monocytes with CD14+; NK: CD3-/CD16+/56+ and NKT: CD3+/CD16+/56+ lymphocytes. Th1 cells were identified by IFN-γ+ positivity; Th2: positivity for IL-4+; Th17: positivity for IL-17+. Parametric statistics and Mann-Whitney U-test were

used.

## Results:

A total of 50 patients with PAPS were included, age:  $51.9 \pm 12.8$ , evolution time:  $12.8 \pm 8.9$  years and 35 healthy controls. In patients with PAPS there was a decrease in the total CD3 ( $p < 0.001$ ), CD4 ( $p < 0.005$ ) CD8 ( $p < 0.05$ ) count, Monocytes ( $p < 0.03$ ) B lymphocytes ( $p < 0.002$ ), iNKT ( $p < 0.001$ ), DC1 ( $p < 0.001$ ) and DC2 ( $p < 0.001$ ) count cells compared to the control group (Table 1). We found significant decrease in Th1, Th2 and Th17 cytokines basal and after activation compared to healthy controls.

	<b>Patients</b> <b>N=50</b>	<b>Controls</b> <b>N=35</b>	<b>p</b>
	<b>Median</b>	<b>Median</b>	
CD3/uL	962	1351	0.001
CD4/uL	587	786	0.005

DC2/uL	1	5	0.001
Treg CD4/uL	17	13	0.5
Treg CD8/uL	11	13	0.5
Mann Whitney U test			

## Conclusion:

This study shows profound alterations in innate and adaptive immunity in patients with long-term PAPS, characterized by a decrease in lymphocyte subpopulations and Th1, Th2, and Th17 cytokines with a possible prevalence of other proinflammatory cytokines and inflammasomes. These abnormalities can become new therapeutic targets in order to restore immune imbalance. Our findings may explain in part, the development of thrombosis, accelerate atherosclerosis and other complications, in PAPS patients with long term disease evolution.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Catastrophic antiphospholipid syndrome (CAPS), a rare disease, is characterized by the rapid onset of widespread thrombosis associated with multi-organ failure in patients meeting the serological criteria for antiphospholipid syndrome. To date, the diagnosis and treatment for CAPS has been based on expert consensus and case-series, not evidence-based guidelines developed with rigorous methodology. One of the main obstacles to guideline development in rare diseases is the sparsity and very low certainty (or quality) of the available evidence. As a prototypical rare disease, CAPS was selected to pilot the application of a guideline development process to a rare disease.

### **Methods:**

The RARE-BestPractices project group in partnership with McMaster University developed a clinical practice guideline on diagnosis and management of patients with CAPS, bringing together a panel of international experts, and using the GIN-McMaster Guideline Development checklist. The evidence for the CAPS guideline was summarized using the GRADE methodology framework. Two novel methods, systematic observation reporting forms and ad hoc registry data analysis, were implemented to supplement the available evidence.

Systematic observation reporting involved collecting standardized contributions from each panel member prior to the panel meeting regarding characteristics and clinical course of previous CAPS patients. The goal was to systematize the process of expert input based on actual experience rather than opinions or anecdotes. Ad hoc analysis of registry data involved calculating raw data for survival estimates for each therapy question from the 'CAPS Registry', an international database that has over 500 CAPS patients enrolled.

### **Results:**

Question generation yielded 47 questions, which were prioritized. The top 10 questions were selected by the panel for the guideline process, 3 diagnosis and 7 therapy. The therapy search identified 671 references, of which 8 articles were included in the systematic reviews. The diagnosis search identified 519 references, of which 1 article was included. All of the included studies were considered to be at high risk of bias. Eleven of the 20 panel members submitted systematic observation forms, representing 55 patient cases. The CAPS registry was used to calculate raw mortality for 7 recommendations and impacted the panel's decision for a treatment recommendation related to rituximab.

### **Conclusion:**

The CAPS guideline initiative met the objective of successful development of a clinical practice guideline in a rare disease using GRADE methodology. The novel methodology was found to be useful for complementing literature-based evidence in informing the recommendations.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several studies have showed conflicting results regarding the presence and meaning of anti-phosphatidylserine/prothrombin (aPS/PT). However aPS/PT antibodies seem to be a risk factor for thrombosis. Nevertheless, most of the studies have focused on patients with SLE and secondary antiphospholipid syndrome (APS). We assessed the prevalence of aPS/PT antibodies, as well as their association with other antiphospholipid (aPL) antibodies (specially lupus anticoagulant [LA]) and thrombosis, in a well-established cohort of primary APS from a single center.

**Methods:** We included 96 consecutive patients with primary APS according the Sydney classification criteria and/or patients with hematological features (thrombocytopenia and hemolytic anemia) attending a referral center in Mexico City. Patients from both groups fulfilled the Sydney laboratory criteria for APS. We registered demographics, disease duration and type of manifestation. aCL (IgG and IgM), antibodies to purified human anti-β2GP-I (IgG and IgM) and aPS/PT antibodies (IgG and IgM) were assessed by ELISA (INOVA Diagnostics). LA was determined by LA/1 screening reactant and a confirmatory test LA/2 according to published guidelines. We used chi-square ( $\chi^2$ ) test, Spearman correlation analysis and logistic regression.

**Results:** Most patients were females (69.7%), mean age  $44.5 \pm 14.6$  and median disease duration 7.3 years. The main clinical features were thrombosis (n=74, 77%), hematologic involvement (n=49 patients, 51%) and obstetric events (n=24, 25%) (non-exclusive groups). The prevalence of LA was 69.8%, aCL-IgG 56.8%, anti-β2GP-I IgG 43.1%, aCL-IgM 31.5% and anti-β2GP-I IgM 21%. The frequency of aPS/PT antibodies was 61.2% and 61.6% for IgG and IgM isotype, respectively. When we compared patients with LA+ (n=58) vs. LA- (n=25), the first group had a higher prevalence of aPS/PT-IgG (79.3% vs. 16%,  $p=0.0001$ ) and aPS/PT-IgM antibody (81.5% vs. 31.8%,  $p=0.001$ ), as well as higher titers (aPS/PT-IgG 130.5 U vs. 8.2 U and aPS/PT-IgM 58.5 U vs. 16.6 U,  $p=0.0001$ ). aPS/PT-IgG antibodies correlated with aPS/PT-IgM ( $p=0.59$ ,  $p=0.0001$ ), aCL-IgG ( $p=0.62$ ,  $p=0.0001$ ), anti-β2GP-I IgG ( $p=0.63$ ,  $p=0.001$ ) and anti-β2GP-I IgM ( $p=0.35$ ,  $p=0.001$ ). On the other hand, aPS/PT IgM antibodies correlated with aCL-IgG ( $p=0.57$ ,  $p=0.0001$ ), aCL-IgM ( $p=0.42$ ,  $p=0.001$ ), anti-β2GP-I IgG ( $p=0.48$ ,  $p=0.001$ ) and anti-β2GP-I IgM ( $p=0.59$ ,  $p=0.0001$ ). We found moderate agreement between the presence of LA and both aPS/PT isotypes ( $k=0.58$   $p=0.0001$  for IgG, and  $k=0.47$   $p=0.001$  for IgM). Thrombosis was associated with aPS/PT-IgG antibodies (87.7% vs. 61.1%,  $p=0.003$ ) but not with aPS/PT IgM (73.6% vs. 81.8%,  $p=0.37$ ). At the logistic regression analysis, the aPS/PT IgG antibodies remained associated with thrombosis after adjusting by all other aPL antibodies, OR 8.6 95% CI 2.1-33.8,  $p=0.002$ .

**Conclusion:** In this cohort of patients with primary APS, aPS/PT antibodies were highly prevalent, correlated with other aPL antibodies and were associated independently with thrombosis.

## Thrombotic Events in Pediatric Systemic Lupus Erythematosus: A Preliminary Analysis of a Large, Single-Center Cohort

Jennifer Rammel<sup>1</sup>, Martha Curry<sup>2</sup> and Marietta M. de Guzman<sup>3</sup>, <sup>1</sup>Department of Pediatrics, Division of Immunology, Allergy and Rheumatology, Baylor College of Medicine, Houston, TX, <sup>2</sup>Pediatric Immunology, Allergy and Rheumatology, Baylor College of Medicine, Houston, TX, <sup>3</sup>Immunology, Allergy and Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While pediatric systemic lupus erythematosus (pSLE) represents only 20% of all SLE cases, pSLE patients often have more aggressive disease with multi-organ involvement. These patients can be at significant risk for thrombotic events due to systemic

inflammation, vasculopathy, antiphospholipid antibodies (aPLs) and nephrotic features. Data detailing the timing and nature of thrombotic events in pSLE patients are limited. The objective of this study was to further characterize thrombotic events in a pSLE patient cohort at a large academic medical center.

**Methods:** A retrospective chart review was completed for patients with pSLE who had a documented thrombotic event. All patients fulfilled the American College of Rheumatology (ACR) classification criteria for SLE. Descriptive statistics were utilized for this preliminary analysis.

**Results:** Of the 402 patients in this pSLE cohort, there were a total of 45 thrombotic events in 28 patients. The cohort was 89% female, 50% African American, Non-Hispanic and 43% Caucasian, Hispanic. Mean age at pSLE diagnosis was 12.9 years, range was from 6.7 to 17.8 years. 71% (20) had positive APLs at pSLE diagnosis: 60% lupus anticoagulant (LA), 70% anticardiolipin (aCL), and 45% anti $\beta$ 2glycoprotein1 (a $\beta$ 2GP1). Mean age at first thrombotic event was 14.9 years, range was from 7.8 to 22.9 years. There was a mean difference of 2.0 years from pSLE diagnosis to thrombotic event, with a range of -4.4 to 10.3 years. Fifteen patients (54%) were diagnosed with pSLE at the time of the initial thrombotic event. Of the 45 thrombotic events, 33% (15) were arterial and 66% (30) were venous. Arterial events included 10 cerebrovascular accidents and 4 transient ischemic attacks. Venous events included 16 deep vein thromboses (DVT), 2 pulmonary emboli (PE) without radiographically identified DVT, and 3 combined DVT/PEs. Seven patients (25%) had multiple thrombotic events. At the time of the thrombotic event, 56% were aPL positive (60% LA, 72% aCL, and 40% a $\beta$ 2GP1), 11% were negative, and 33% were either not tested or the data was not available.

**Conclusion:** The majority of the thrombotic events in this cohort were venous, and a single occurrence. More than half of the patients were diagnosed with pSLE as a result of the presenting thrombotic event. Most patients had positive antiphospholipid antibodies both at pSLE diagnosis and at the time of the thrombotic event. Further research plans for this dataset include further analysis of predictive factors for thrombosis and characterizing the variation in establishing initial thrombotic risk, surveillance and management.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Antiphospholipid Syndrome Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary antiphospholipid syndrome (PAPS) is characterized by venous and arterial thrombosis, obstetric morbidity and the presence of antiphospholipid antibodies. The utility of nailfold videocapillaroscopy in conditions such as scleroderma (SSc) and primary Raynaud's phenomenon is well known. Whether patients with PAPS have specific findings in nailfold videocapillaroscopy is not well established. Our aim was to evaluate nailfold videocapillaroscopy findings in PAPS patients and their association with clinical and serological features.

**Methods:** We included 32 PAPS patients according to the modified Sidney criteria and the Alarcón-Segovia criteria for haematologic antiphospholipid syndrome, who regularly attend a tertiary referral center in Mexico City, and 17 healthy controls. We performed nailfold videocapillaroscopy according to the Cutolo technique (Optilia 200x) and obtained: capillary morphology, abnormalities (tortuosity, crossed and dilated capillaries, capillary haemorrhages, neo-angiogenesis) and mean vascular density on 32 images per patient. We collected demographic, clinical (thrombosis, obstetric morbidity, non-criteria manifestations and comorbidities), serological (anticardiolipin antibodies, anti- $\beta$ 2 glycoprotein 1 antibodies and lupus anticoagulant) and treatment information. Analysis was performed using SPSS v.22,

Chi square test was used to compare frequencies and Student's t test was used to compare means.

**Results:** PAPS patients had higher frequency of at least 1 abnormal finding on videocapillaroscopy (78% vs 12%,  $p<0.009$ ,  $OR=26$ ,  $95\%CI=5-146$ ), higher frequency of dilated capillaries (69% vs 0%,  $p=0.0001$ ,  $OR=3.2$ ,  $95\%CI=1.9-5.3$ ), lower frequency of "perfect normal" pattern (12% vs 59%,  $p=0.002$ ,  $OR=0.1$ ,  $95\%CI=0.02-0.4$ ) than controls, and 8 patients (25%) showed changes compatible with the "early" SSc Cutolo pattern ( $<4$  dilated capillaries/mm,  $<4$  haemorrhages/mm, preserved architecture and no avascular areas). In PAPS patients, capillary haemorrhages were associated with neurologic manifestations (75% vs 14%,  $p=0.02$ ,  $OR=19$ ,  $95\%CI=1.4-248$ ) and with comorbidity with hypertension (75% vs 14%,  $p=0.02$ ,  $OR=19$ ,  $95\%CI=1.4-248$ ), while alterations compatible with "early" pattern were not associated to any clinical or serological variable.

**Conclusion:** PAPS patients frequently show at least one abnormality on videocapillaroscopy. The most frequent abnormalities are dilated capillaries, microhaemorrhages and the presence of an "atypical normal" pattern. Capillary haemorrhages are frequently found in patients with neurologic involvement of PAPS. The coexistence of hypertension or other comorbidities may contribute to the development of capillary abnormalities in PAPS patients.

## The Transcription Factor Specificity Protein 1 up-Regulates IL-21 Receptor Expression on B Cells in Rheumatoid Arthritis Leading to Altered Cytokine Production and Maturation

Elizabeth Dam<sup>1</sup>, Alison Maier<sup>1</sup>, Anne Hocking<sup>1</sup>, Jeffrey Carlin<sup>2</sup> and Jane H. Buckner<sup>1</sup>, <sup>1</sup>Benaroya Research Institute at Virginia Mason, Seattle, WA, <sup>2</sup>Rheumatology, Virginia Mason Medical Center, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Growing evidence suggests that IL-21 has a role in B cell dysfunction in rheumatoid arthritis (RA). Previous studies have reported that IL-21 levels are increased in the serum and synovial fluid of RA subjects and correlate with the 28-joint count disease activity score. While an increase in the percent of IL-21R positive B cells in RA has been described, the significance of this finding in B cells with respect to signaling, B cell differentiation and function has not been investigated. The goal of this study was to address this gap in knowledge and determine the mechanism that leads to increased IL-21R expression on B cells in RA.

**Methods:** We analyzed IL-21 receptor expression in B cells isolated from whole blood and synovial fluid from a cohort of RA subjects and healthy controls matched for age, gender and race. The RA subjects all met the ACR classification criteria and none of the subjects were on biologics at the time of the draw. Flow cytometry was used to quantify protein and mRNA levels of IL-21R, specificity protein 1 (SP1) and to determine cytokine production (IL-6) and maturation status of B cells. IL-21 signaling was assessed by measuring pSTAT3 levels following IL-21 stimulation. IL-21R levels were correlated to serum levels of rheumatoid factor (RF) IgM which was assessed by ELISA. SP1 binding to the *IL21R* promoter region in B cells was assessed with ChIP-qPCR.

**Results:** We demonstrate an increase in IL-21R expression in total and memory B cells from RA subjects, which correlated with responsiveness to IL-21 as measured by phosphorylation of STAT3. IL-21R expression on memory B cell also correlated with serum rheumatoid factor IgM levels. There was comparable levels of IL-21R expression between memory B cells from peripheral blood and those from synovial fluid in the same subject. In addition, stimulation of naïve B cells from RA subjects with IL-21 and CD40L resulted in an increase in differentiation into plasmablasts. Further investigation showed that IL-21R expression correlated with an increase in the level of the SP1 transcription factor. Mechanistic experiments showed increased binding of SP1 to the *IL21R* promoter region in B cells in RA.

**Conclusion:** Our results suggest a mechanism by which IL-21 enhances B cell development and function in RA through an SP1 mediated increase in IL-21R expression on B cells. This suggests that therapies for RA may be more efficacious if targeted to memory B cells and/or target SP1.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have reported that soluble BAFF (sBAFF) robustly increased IL-6 production by peripheral monocytes of patients with primary Sjögren's syndrome (pSS) and that the expression level of a BAFF receptor (BR3) was significantly elevated in pSS monocytes. In our previous study, we have also demonstrated that the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the serum IgG level of pSS patients. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in IgG overproduction by B cells and that BAFF signaling via BR3 is a possible therapeutic target to treat autoimmune diseases, such as pSS. In addition, we have successfully discovered two pyrrolopyrimidine derivatives, which inhibit BAFF binding to BR3, by a high throughput screening of a low molecular weight compound library. These compounds inhibited not only IL-6 and IL-10 production by BAFF-stimulated monocytes, but also IgG production by B cells *in vitro* co-cultured with monocytes in the presence of sBAFF possibly by impairing differentiation of B cells. Notably, these compounds suppressed the serum level of an anti-dsDNA antibody in autoimmune disease model mice. In this study, we investigate the effects of these compounds on infiltration of B cells into organs of the model mice.

**Methods:** A pyrrolopyrimidine derivative, BIK-13, which inhibits BAFF binding to BR3, was administered intraperitoneally to MRL/lpr mice three times a week at a dose of 0.2 mg/kg for 6 months. Serum levels of an anti-dsDNA antibody, IL-6 and IL-10 were measured by ELISA. The proportion of B cell in peripheral blood of the mice was analyzed by FACS. Infiltration of lymphocytes into organs was analyzed by immunohistochemistry.

**Results:** Administration of BIK13 to MRL/lpr mice for 16 weeks decreased the serum level of an anti-dsDNA antibody. Moreover, serum levels of IL-6 and IL-10, both of which induce B cell activation, in the mice were concomitantly declined as compared to control mice. Notably, immunohistochemistry revealed that infiltration of B lymphocytes was remarkably suppressed in salivary and lacrimal glands and kidney of the mice. In addition, the proportion of B cells in peripheral blood was also decreased in BIK-13-treated mice as compared to the control mice.

**Conclusion:** These data collectively suggest that BIK-13, a low molecular weight BR3 antagonist, suppress the B cell activation and resultant infiltration into organs *in vivo*. Suppression of cytokine production by monocytes may be directly or indirectly involved in the molecular mechanism of the suppression of the B cell activation. The compound may provide a novel therapeutic possibility to treat autoimmune diseases.

## Reciprocal Regulation of B Cells on Bleomycin-Induced Scleroderma Model: IL-6-

# Producing Effector B Cells Play a Pathogenic Role, While IL-10-Producing Regulatory B Cells Play a Protective Role

Takashi Matsushita<sup>1</sup>, Yasuhito Hamaguchi<sup>1</sup>, Minoru Hasegawa<sup>2</sup>, Manabu Fujimoto<sup>3</sup> and Kazuhiko Takehara<sup>4</sup>, <sup>1</sup>Department of Dermatology, Kanazawa University, Kanazawa, Japan, <sup>2</sup>Department of Dermatology, University of Fukui, Fukui, Japan, <sup>3</sup>Department of Dermatology, University of Tsukuba, Tsukuba, Japan, <sup>4</sup>Department of Dermatology, Kanazawa University, Kanazawa, Japan

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IL-10-producing regulatory B (Breg) cells negatively regulate autoimmune diseases. We reported that Breg cells play a protective role in a mouse model of systemic sclerosis (SSc) and in patients. Recent studies indicate that IL-6-producing effector B (Beff) cells have pathogenic effect in autoimmune diseases. IL-6 plays a critical role for the pathogenesis of SSc, and a phase III trial of anti-IL-6R antibody (tocilizumab) is ongoing in patients with SSc. However, the phenotype and function of IL-6-producing Beff cells remains unclear. In this study, we investigated the phenotype of IL-6-producing Beff cells and their role in SSc pathogenesis.

**Methods:** B cell subsets were sorted and cytokine production was measured by intracellular cytokine staining. We generated mixed bone marrow chimeric mice with a B cell-specific deficiency in IL-6 or IL-10 production (B-IL-6<sup>-/-</sup> or B-IL-10<sup>-/-</sup>), together with control chimeras (B-WT). Skin fibrosis was assessed 4 weeks after the initiation of bleomycin treatment in mixed bone marrow chimeric mice.

**Results:** Most splenic IL-6 producing Beff cells were detected within the marginal zone (MZ) B cell subset, while IL-10-producing Breg cells were detected within the MZ B and B1 B cell subsets, but not within the follicular B cell subset (Fig 1). Serum IL-6 levels gradually increased with the development of fibrosis in bleomycin-induced scleroderma mice, while serum IL-10 levels did not. In addition, the frequency of splenic IL-6-producing Beff cells in bleomycin-treated mice was significantly increased. The bleomycin-induced skin fibrosis was attenuated in B-IL-6<sup>-/-</sup> mice compared with that in B-WT mice. In contrast, B-IL-10<sup>-/-</sup> mice showed more severe skin fibrosis than B-WT mice (Fig 2).

**Conclusion:** IL-6-producing Beff cells play a pathogenic role in bleomycin-induced scleroderma model, while IL-10-producing Breg cells play a protective role (Fig 3). Thus, B cells have reciprocal roles in SSc pathogenesis, presenting pathogenic and protective functions.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a systemic autoimmune disease that often leads to joint damage, a process mediated by an imbalance between bone resorption and bone formation. B cells play a role in bone homeostasis in RA, and evidence suggests that B cells can affect function of both osteoblasts (OB) and osteoclasts (OC). In mouse models of RA, B cells were enriched in the subchondral bone marrow (BM) and synovium, and were adjacent to the bone surface. These B cells produce the inflammatory cytokines TNF $\alpha$  and CCL3, which drive dysregulation of bone homeostasis via their OB inhibitory and OC stimulatory effects. In vitro, synergistic production of these cytokines results from co-activation of the B cell receptor (BCR) and toll-like receptor 9 (TLR9). Therefore, we investigated the mechanisms underlying synergistic TNF $\alpha$ /CCL3 production by B cells in response to BCR and TLR9 co-activation.

**Methods:** Isolated B cells from peripheral blood of healthy controls (HC) were stimulated with 10  $\mu$ g/mL anti-Ig (A+M+G) and CpG2006 for 4 hours, and production of TNF $\alpha$  and CCL3 was assessed by ELISA and qPCR. Multiple specific inhibitors were used to test the involvement of BCR, TLR9, and NF- $\kappa$ B signaling, as well as autophagy. Data is presented as mean $\pm$ SEM. Statistical significance was determined by student's t-test.

**Results:** Stimulation of B cells with  $\alpha$ -Igs and CpG2006 induced significant production of TNF $\alpha$  and CCL3 compared to unstimulated B cells at mRNA and protein levels. Furthermore, cytokine production was significantly higher than levels from  $\alpha$ -Igs or CpG2006 stimulations alone, suggesting a synergistic effect (CpG+ $\alpha$ -Igs vs. CpG vs.  $\alpha$ -Igs (ng/mL): TNF $\alpha$ : 2.71 $\pm$ 0.42 vs. 0.33 $\pm$ 0.04 (P<0.0001) vs. 0.70 $\pm$ 0.23 (P=0.0008), CCL3: 3.69 $\pm$ 1.00 vs. 0.77 $\pm$ 0.29 (P=0.0031) vs. 0.64 $\pm$ 0.18 (P=0.0037)). This synergistic production was dependent on TLR9 and BCR signaling, as blocking B cells with hydroxychloroquine (TLR inhibitor) or PP2 (Src kinase inhibitor) reduced cytokine production to non-synergistic levels. Additionally, blocking BCR internalization with MDC also reduced TNF $\alpha$  and CCL3 production. To investigate signaling downstream of BCR/TLR9 synergy, we tested inhibitors against classical NF- $\kappa$ B (TPCA-1), non-classical NF- $\kappa$ B (NIK inhibitor) and AP-1. We found that BCR/TLR9 synergy was classical NF- $\kappa$ B dependent (CpG+ $\alpha$ -Igs vs. CpG+ $\alpha$ -Igs+TPCA-1 (ng/mL): TNF $\alpha$ : 2.5 $\pm$ 0.44 vs. 0.33 $\pm$ 0.14 (P=0.009), CCL3: 1.9 $\pm$ 0.3 vs. 0.83 $\pm$ 0.08 (P=0.027)). Finally, we inhibited autophagy using class III PI3K inhibitor 3-methyladenine which reduced TNF $\alpha$  and CCL3 production to non-synergistic levels, suggesting that BCR/TLR9 synergy depends on autophagy (CpG+ $\alpha$ -Igs vs. CpG+ $\alpha$ -Igs+3-MA (ng/mL): TNF $\alpha$ : 1.5 $\pm$ 0.25 vs. 0.4 $\pm$ 0.04 (P=0.0058), CCL3: 4.1 $\pm$ 1.15 vs. 0.82 $\pm$ 0.35 (P=0.033)). Investigation of the specific autophagy pathway involved is currently underway.

**Conclusion:** Dual activation of B cells through the BCR and TLR9 synergistically enhanced TNF $\alpha$  and CCL3 production in a classical NF- $\kappa$ B, and autophagy-dependent manner. These results characterize key mechanistic events in the synergistic production of bone regulatory

cytokines by B cells, a process that contributes to the dysregulation of bone homeostasis in RA.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

While extensive studies have been performed to characterize ANCA, little is known about the auto-reactive B cells that produce these autoantibodies. Indirect evidence previously suggested the presence of circulating PR3-specific B cells in patients with PR3-ANCA-associated vasculitis (AAV). Our objectives here were to develop a method to detect circulating PR3-specific B cells in patients with PR3-AAV, to study their proportion among the different B-cell subsets and to assess their relationship with disease activity.

### **Methods:**

A recombinant PR3 (rPR3) was tagged using FITC or biotin, and we studied its ability to bind specifically to two hybridoma cell lines, MCPR3-2 (producing an anti-human PR3 monoclonal antibody) and MCPR3-13 (producing an anti-mouse PR3 monoclonal antibody, with no cross-reactivity with human PR3). We measured the proportion of PR3-FITC positive B cells among PBMCs in 13 patients with PR3-AAV and 14 healthy controls (HCs) by flow cytometry. We then developed a multi-color flow cytometry including CD19, IgD, CD27, CD38, CD24 and biotinylated rPR3 to measure the proportion of PR3-specific B cells among different B-cell subsets in an independent group of 13 patients with PR3-AAV and 11 HCs.

### **Results:**

rPR3 efficiently bound MCPR3-2 hybridoma cells but not MCPR3-13. Specificity of the staining was confirmed by competition experiments: pre-incubation of MCPR3-2 cells with untagged human rPR3 totally abrogated rPR3-FITC staining, whereas pre-incubation with mouse rPR3 had no effect. Dose-ranging experiments defined the optimal concentration of rPR3 to stain cells expressing anti-PR3 immunoglobulin. The mean (SEM) proportion of rPR3-FITC-stained B cells was higher in patients with PR3-AAV compared to HCs: 2.10% (2.33) vs 0.45% (0.19) respectively,  $p < 0.001$ . Patients with active disease had numerically higher proportions of PR3-specific B cells than patients in remission: 3.66% (3.28) vs 1.10% (0.52),  $p = 0.09$ . In HCs, the proportion of PR3-specific B cells was highest among the transitional B-cell subset, and decreased along with the maturation of B cells (figure). Conversely, in patients, the proportion of PR3-specific B cells progressively increased with the maturation of B cells (median 1.9% of naïve B cells, 2.30% of IgD+ memory B cells, 2.37% of IgD-memory B cells, and 3.68% of plasmablasts,  $p < 0.05$  for all comparisons with the naïve subset).

### **Conclusion:**

This study describes an original method to detect and study circulating auto-reactive B cells in patients with PR3-AAV, and suggests that PR3-specific B cells are associated with disease activity and may represent a promising biomarker to predict relapse risk in patients in clinical remission. The progressive enrichment in PR3-specific B cells during the B-cell maturation steps in patients suggest that auto-reactive B cells are actively selected and escape peripheral tolerance checkpoints.

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lung is involved in up to 50% patients with SLE. Among manifestations of pulmonary lupus, pneumonitis, vasculitis and diffuse pulmonary hemorrhage (DPH) carry a high mortality rate, and are without any effective treatment. Advances in the pathogenesis of pulmonary lupus have been hampered because of the heterogeneity of clinical findings, paucity of access to the affected tissue, and the lack of suitable model systems. Hydrocarbon oils, such as 2,6,10,14-tetramethylpentadecane (TMPD), induce lupus-like autoantibodies, nephritis, arthritis, pneumonitis, and DPH depending on the animals' genetic background. Previous studies have used this model to show that animals that lack B cells (Igu<sup>-/-</sup>) have a reduced prevalence of DPH. Here, we examined the role of innate B1 B cells in the pathogenesis of pulmonary lupus using the TMPD-DPH model.

**Methods:** We injected TMPD to induce pulmonary lupus in C57BL/6 (B6) mice and analyzed B cells and B cell subsets in the lungs and peritoneal cavity. To determine the role of innate B cells, we injected CD19<sup>-/-</sup> mice (deficient in B1a B cells) and wild-type B6 mice with 500 µl TMPD intraperitoneally. Furthermore, we adoptively transferred wild-type peritoneal fluid cells which are enriched in B1 B cells into CD19<sup>-/-</sup> and in Igu<sup>-/-</sup> mice (have no B cells). We assessed disease using weight-loss, a semi quantitative scoring system for lung inflammation and hemorrhage, and a quantitative measurement for lung hemorrhage.

**Results:** 73% of 62 TMPD-injected wild-type B6 mice exhibited weight-loss, pneumonitis, vasculitis, and/or DPH compared to none of controls injected with control hydrocarbon oil hexadecane or with PBS or sham. Immunophenotyping revealed abnormalities of all immune cells tested in the diseased lungs. At earlier timepoints prior to histopathological changes, while both hexadecane and TMPD caused myeloid cell abnormalities, only TMPD caused lung-infiltration with B-cells that expressed B1 B cell subset markers: CD19<sup>+</sup>CD11b<sup>+</sup>/CD19<sup>+</sup>CD5<sup>+</sup>. Such B1 B cells were simultaneously reduced in their usual location (peritoneal cavity). CD19<sup>-/-</sup> mice that have less B1a B cells developed less DPH, and less B cell infiltration in the lungs than wildtype mice. The adoptive transfer of wildtype peritoneal fluid cells that are

abundant in B1 B cells into the peritoneum of CD19<sup>-/-</sup> or Igu<sup>-/-</sup> mice induced more DPH/pneumonitis than the respective knockout recipients reconstituted with CD19<sup>-/-</sup> B-cells. The adoptive transfer of CD45.1<sup>+</sup> wildtype peritoneal fluid cells into the peritoneum of CD45.2<sup>+</sup>CD19<sup>-/-</sup> recipients led to lung-infiltration with CD45.1<sup>+</sup> B cells. Furthermore, TMPD induced in the lungs a differential expression of a set of immune/inflammatory genes including chemokine *Cxcl13* that are known to drive B1 B-cells' migration.

**Conclusion:** Exposure to TMPD induces B1 B cells to traffic from the peritoneum into the lungs and cause pneumonitis/DPH. Our observations have implications for pulmonary complications of lupus, vasculitis and other rheumatic diseases by identifying a specific B cell subset as a potential target for therapy. Furthermore, humans can be exposed to hydrocarbon oils present in crude oil and in mineral oils used in cosmetics, laxatives, and food-coatings.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antibodies are important in protection against pathogens, but also harbor the potential to cause autoimmune disease when directed against self-antigens. Systemic lupus erythematosus (SLE) is an autoimmune disease where antibodies recognizing nucleic acids and associated proteins form immune complexes that drive inflammation and disease progression. Consequently, targeting B cells and antibody production is a main focus in SLE drug development and we have endeavored to discover new targets in this pathway.

**Methods:** Here we show results from screening a secreted protein library for effects on Ig secretion by primary human B cells.

**Results:** We identified galectin-3 binding protein (G3BP) as a soluble factor that enhances antibody production induced by a variety of stimuli in vitro. In an orthogonal translational study we found that the G3BP gene (LGALS3BP) was one of the most upregulated genes across 14 different immune cell types isolated from lupus nephritis (LN) patient blood. LGALS3BP contains an IRF7 binding site in its promoter and we observed increased expression in TLR7-stimulated PBMCs. SLE is characterized by RNAs that induce type I interferon (IFN) inflammation through the innate receptor TLR7. LGALS3BP expression in LN patients correlated with type I interferon-inducible genes indicating that G3BP is part of this pathological process. Indeed, in support of this hypothesis, other investigators have documented upregulated LGALS3BP in active IFN high SLE patients versus healthy controls (Merrill, J.T. et al., ACR abstract 1809, 2013). We found the same LGALS3BP upregulation and correlation with type I IFN in a mouse model of LN. Moreover, upregulation in mouse kidneys correlated with nephritis development. In in vitro studies we found that antibodies against G3BP led to defects in human B cell survival and loss of antibody production.

**Conclusion:** We hypothesize that targeting G3BP may be a novel approach to inhibit autoantibody production and may benefit patients suffering from antibody-mediated autoimmune diseases, including lupus nephritis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Recent studies have indicated that B cells play critical roles in systemic autoimmunity and disease expression through various functions such as induction of the activation of other immune cells in addition to autoantibody production. Indeed, rituximab, a B cell depleting antibody, can ameliorate some autoimmune diseases including systemic sclerosis (SSc). However, the role of autoreactive B cells is still not clear, because the number of autoreactive B cells is too small to study their functions directly. Although several studies have revealed that B cells play crucial roles in SSc development, autoreactive B cell functions remain totally unclear. In this study, we investigated the role of autoreactive B cells directly using our original micro-ELISA system, which integrates immunoassay into a microchip in order to detect extremely small amounts of analytes and can study autoreactive B cells at a single cell level.

### Methods:

Peripheral blood mononuclear cells (PBMCs) were obtained from topoisomerase (topo) I positive SSc patients and healthy controls. Each of topo I-specific B cells was sorted into individual wells of 96 well plates. Their mRNA levels were assessed by single cell PCR. In addition, their cytokine production was analyzed by the micro-ELISA system which realized the analysis of cytokine production in single cells. In mouse studies, we assessed antibody affinities and cytokine production of topo I-specific B cells using topo I and complete Freund's adjuvant-induced SSc model mice. Furthermore, topo I-specific B cells from topo I and complete Freund's adjuvant-induced SSc model mice were adoptively transferred to these model mice and then skin and lung fibrosis was assessed.

### Results:

Topo I-specific B cells from SSc patients produced higher amounts of IL-6 compared with topo I-non-specific B cells. In addition, IL-10 production of topo I-specific B cells was lower than those of topo I-non-specific B cells.

To reveal the relationship between B cell affinity to the autoantigen and their cytokine production, we analyzed single topo I-immunized SSc model mice and fourth immunized SSc model mice. Single immunized mice had higher frequencies of IL-10-producing topo I-specific B cells than fourth immunized mice, while fourth immunized mice had higher frequencies of IL-6-producing topo I-specific B cells than single immunized mice. The affinity of topo I-specific B cells from fourth immunized mice was higher than those from single immunized mice. Adoptive transfer with high-affinity topo I-specific B cells aggravated skin and lung fibrosis. By contrast, that with low-affinity topo I-specific B cells ameliorated skin and lung fibrosis.

### Conclusion:

These results suggest that distinct B cell cytokine production is determined by B cell autoantigen affinity. Autoantigen-reactive B cells with higher autoantigen affinity can be a novel therapeutic target in SSc.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Monoclonal antibodies (MoAbs) are highly successful in treating various immunological disorders. The development of anti-drug antibodies (ADA) against the therapeutic MoAb is relatively common. In recent years, knowledge of how to assess immunogenicity of biological drugs has improved. ADA are thought to form immune complexes with the MoAb, leading to accelerated MoAB clearance and low decrease levels in the blood stream. Several reports showed an inverse relationship between MoAb levels and anti MoAb antibody formation. Further, patients who develop ADA are more likely to present with infusion-related adverse effects. Acute infusion reactions, including anaphylaxis, develop in a close temporal relationship to MoAb infusion.

Among the others MoAbs, Rituximab (RTX), an anti-CD20 monoclonal antibody, often results in the production of human anti-chimeric antibodies (HACA).

In this study, we aimed to evaluate the presence of HACA in patients with poor response to treatment with RTX

### Methods:

We assessed the incidence of anti-drug antibodies (ADA) in patients with autoimmune diseases treated with the RTX and determine the potential relationship with trough drug concentration, efficacy, and patient-reported outcomes.

### Results:

When investigating 37 patients treated with RTX, we found very high-titer of HACA (> 1,000 AU) in 5 patients (13.5%): 2 with Systemic Lupus Erythematosus (SLE), 2 with Membranous Nephropathy (MN) and 1 patient with Mixed Cryoglobulinemia (MC). Details are given in table 1. In 4 of them, high titers of HACA were clearly related to unresponsiveness to RTX treatment. In the other case the appearance of high HACA titers was consonant with a severe hypersensitivity reaction during RTX re-treatment.

### Conclusion:

HACA detection and monitoring, especially in the cases of RTX re-treatment, could not only assure a safer administration, but also support a more rational strategy of treatment.

Case	Disease	# of cycles with RTX	steroid-therapy	HACA-Titer (AU)	RTX-level
1	SLE	1	Yes	15,720	ND
2	SLE	1	Yes	3,719	ND
3	MC	3	No	14,670	0
4	MN	1	No	1,007	0
5*	MN	2	No	10,363	0

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** B cell compartment plays a key role in the pathogenesis of rheumatoid arthritis (RA). Activation and survival of B cell largely rely on the BLYS-APRIL system, including ligands and receptors, both expressed as membrane (m) and soluble (s) forms. The main aim of this study was to analyze the role of the BLYS-APRIL system in RA, with a special focus on its clinical relevance.

**Methods:** sBLYS, sAPRIL, sBCMA, sTACI, IFN $\alpha$ , MIP1 $\alpha$ , TNF $\alpha$ , IL-10, IFN $\gamma$ , IL-8, IL-37 and GM-CSF levels were measured by immunoassays in serum samples from 104 RA patients (EULAR/ACR 2010 criteria) and 33 healthy controls (HC). The membrane BLYS (mBLYS) expression was assessed on B cells, monocytes (M $\phi$ ), myeloid (mDC) and plasmacytoid (pDC) dendritic cells and neutrophils (N $\phi$ ) by flow cytometry in blood samples. A group of biological-naïve RA patients was prospectively followed for 3 months upon TNF $\alpha$ -blockade.

**Results:** RA patients exhibited increased sAPRIL ( $p < 0.001$ ) and sBCMA serum levels ( $p = 0.002$ ) than HC. sBLYS was higher in patients with early arthritis (recruited at onset) compared to those with long-standing disease ( $p = 0.051$ ) and HC ( $p = 0.024$ ). Levels of sTACI did not differ between patients and controls ( $p = 0.462$ ). mBLYS expression was increased on B cells ( $p = 0.002$ ), M $\phi$  ( $p < 0.001$ ), mDC ( $p < 0.001$ ) and N $\phi$  ( $p = 0.014$ ) in RA. By means of an unsupervised cluster analysis based on sBLYS, sAPRIL, sBCMA and sTACI, two clusters were identified (clusters I and II), cluster II being hallmarked by increased sAPRIL and sBCMA serum levels. Cluster II was found in 26 (25.0%) RA patients but was not observed in the HC group ( $p = 0.001$ ). Cluster II RA patients showed increased RF ( $p = 0.002$ ) and ACPA ( $p = 0.001$ ) positivity and were less likely to be treated with methotrexate ( $p = 0.028$ ) but more likely with anti-TNF $\alpha$  agents ( $p = 0.013$ ) compared to their cluster I counterparts. Cluster II was associated with higher DAS28 ( $p < 0.050$ ) but no difference in disease duration was observed ( $p = 0.159$ ). Additionally, higher IL-10 ( $p = 0.060$ ), IFN $\alpha$  ( $p = 0.005$ ), MIP1 $\alpha$  ( $p = 0.042$ ), TNF $\alpha$  ( $p = 0.006$ ) and GM-CSF ( $p = 0.008$ ) levels were registered in cluster II. Further analyses revealed that sTACI was negatively associated with DAS28 score ( $r = -0.283$ ,  $p = 0.014$ ) and positively with IL-10 serum levels ( $r = 0.233$ ,  $p = 0.040$ ) in patients within cluster I. On the contrary, in cluster II, APRIL was positively correlated with mBLYS expression on B cells ( $r = 0.786$ ,  $p = 0.036$ ), whereas sBLYS was associated with DAS28 ( $r = 0.281$ ,  $p = 0.016$ ). Also, IFN $\alpha$  serum levels paralleled those of sTACI ( $r = -0.636$ ,  $p < 0.001$ ) in these patients. Finally, increasing sBLYS ( $p = 0.043$ ) and sBCMA levels ( $p = 0.019$ ) upon TNF $\alpha$ -blockade were associated with poor clinical outcome.

**Conclusion:** APRIL and sBCMA identify a subset of patients with a more severe disease, probably linked to a B cell hyperactivation status. APRIL and sBCMA may be promising biomarkers for patient stratification to B-cell targeted therapy in RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The importance of macrophages in the pathogenesis of cutaneous and neuropsychiatric systemic lupus erythematosus (SLE) is well established. Additionally, autoantibodies produced by autoreactive B cells are implicated in both the skin and brain disease associated with lupus. Bruton's tyrosine kinase (BTK) plays an important role in several key macrophage and B cell functions; therefore, we used a novel BTK inhibitor, BI-BTK-1, to target both macrophage and B cell dependent disease pathways in the MRL/lpr murine model of SLE.

### Methods:

Starting at 8-9 weeks of age, female MRL/MpJ-Faslpr/J (MRL/lpr) mice were treated with BI-BTK-1, a highly selective BTK inhibitor, via medicated or control chow (Control mice, n=8; BI-BTK-1 treated, n=12). We quantified the development of skin lesions, and additionally assessed neuropsychiatric disease manifestations via comprehensive behavioral testing and immunohistochemical analysis of brain tissue.

### Results:

Treatment with BI-BTK-1 significantly attenuated the skin inflammation and cognitive deficits associated with disease in the MRL/lpr strain. Specifically, BI-BTK-1 treated mice had less macroscopic (Fig. 1) and microscopic skin lesions, and reduced cutaneous cellular infiltration. Furthermore, skin from treated mice had significantly diminished inflammatory cytokine expression, including reduced protein levels of TNF, IL-6, IL-17, MCP-1, and GM-CSF. BTK inhibition also significantly improved memory function ( $p<0.05$ ), and dramatically decreased accumulation of T cells, B cells, and macrophages within the brain, specifically in the choroid plexus (Fig. 2).

### Conclusion:

Targeted therapies may improve the response rate in lupus driven target organ involvement, and decrease the dangerous side effects associated with more global immunosuppression. Overall, our results suggest that inhibition of BTK with BI-BTK-1 may be a promising therapeutic option for cutaneous and neuropsychiatric disease associated with SLE.

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time: 9:00AM-11:00AM**

**Background/Purpose:** Sjögren's syndrome (SS) is a rheumatic autoimmune disease characterized by focal lymphocytic infiltrations in the lacrimal and salivary glands, autoantibodies to the ubiquitous Ro and La nuclear antigens, severe dry mouth and eyes, arthritis, fatigue, pain and debilitation. In this project we used human proteome arrays to identify potential non-Ro/non-La autoantigens targeted by salivary gland plasmablasts from SS patients.

**Methods:** Recombinant human monoclonal antibodies (mAbs) derived from minor salivary gland plasmablasts of five individuals meeting the 2016 ACR/EULAR classification criteria for primary Sjögren's syndrome were tested for binding to human proteome microarrays containing >15,500 GST- and 6xhis-tagged recombinant human proteins representing >75% of the human proteome spotted in duplicate (HuProt 3.0 arrays, CDI Laboratories). Each of six arrays was probed with a mAb pool (5 to 10 mAbs/pool) derived from one or two subjects. As controls, separate arrays were probed with secondary antibody alone (AlexaFluor 647 Affinipure F(ab')<sub>2</sub> Goat Anti-Human IgG (H+L)) and pools of mAbs specific for rabies, anthrax, and *S. pneumoniae* vaccines. The foreground to background ratio (F/B) was calculated for each array spot then transformed to fit a normal distribution for analyses. Significant binding was defined as normalized F/B

ratios  $\geq 2.0$  SD above the mean value across all arrays and lack of binding by secondary antibody alone. Literature connectivity (IRIDESCENT), interactome and pathways (Ingenuity) bioinformatics analyses were conducted to investigate relationships among the bound antigens.

**Results:** A total of 201 proteins were found to be significantly bound by salivary gland mAbs, including Ro60, La, and Ro52 antigens. These were bound by patient mAbs but not by irrelevant mAbs or secondary antibody alone. Furthermore, of 199 novel non-Ro/non-La antigens identified, 16 were shared between 2 or more subjects on at least 2 arrays. Bioinformatics analyses revealed literature connectivity to the terms “salivary gland” or “Sjögren’s syndrome” among many of the bound antigens. The interactome showed multiple connections between several of the novel antigens; however, the most significant pathway among the shared antigen interactome was the proteasome/ubiquitination pathway.

**Conclusion:** Sixteen novel, non-Ro/La antigens shared between two or more patients were identified as possible targets of autoantibodies in SS. Pathway analysis of the shared interactome supports immune targeting of the proteasome/ubiquitination pathway by SG plasmablasts in SS.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis of several organs. SSc-associated interstitial lung disease (ILD) is a frequent and severe complication of SSc. SSc-ILD declines the quality of patients' lives and sometimes determines their prognosis. Despite the severeness of SSc-ILD, the treatment for SSc-ILD is still debated. The cyclophosphamide (CYC) treatment is the only therapy found to be effective in stabilizing or improving lung function of SSc-ILD in randomized clinical trials, which contained abundant numbers of patients. However, not every SSc-ILD patients treated with CYC recover. We need to know the difference between the responders and the non-responders against CYC. Recent studies indicate that B cells play a critical role in SSc through their function of cytokine production. Indeed, some studies have reported that the B cell depletion therapy with rituximab can be effective for SSc-ILD. However, the relationship between response to CYC therapy and B cell function remains unknown in SSc-ILD. We hypothesized that cytokine-producing effector B cells determine the effectiveness of the CYC treatment in SSc-ILD patients. In this study, we assessed the role of interleukin (IL)-10-producing regulatory B cells and IL-6-producing pathogenic B cells in the responders or non-responders of the CYC treatment.

**Methods:** We cultured human lung endothelial cells (LECs) in a microchannel. Sequentially, B cells from responders or non-responders against the CYC treatment were loaded into the microchannel. After each of B cells which adhered to LECs had produced cytokines, we measured IL-6 and IL-10 production from single B cells by our original micro fluidic-ELISA system. Similarly, we assessed B cells from topoisomerase (topo) I and complete Freund's adjuvant-induced SSc model mice.

**Results:** In SSc-ILD patients, the number of B cells adhering to LECs significantly increased relative to healthy controls. B cells adhering to LECs from CYC-responders produced significantly higher amounts of IL-10 and lower amounts of IL-6 than those from CYC-non-responders. After the CYC treatment, the frequency of B cells which adhered to LECs significantly decreased in responders but did not decrease in non-responders. Regarding the cytokine profile of B cells adhering to LECs, the frequencies of IL-10 producing regulatory B cells after the CYC treatment increased in responders and decreased in non-responders. Those of IL-6-producing pathogenic B cells after the CYC treatment decreased in responders and increased in non-responders. In the mouse study, the number of topo I-specific B cells which adhere to LECs significantly increased compared to non-specific conventional B cells. Topo I-specific B cells also showed significantly higher production of IL-6 and lower production of IL-10 than conventional B cells.

**Conclusion:** These results suggested that the effectiveness of CYC to SSc-ILD patients is associated with the cytokine profile of B cells which interact with LECs. It is likely that IL-6-producing pathogenic B cells which survived the CYC treatment damage the lung function of non-responders.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Positive rheumatoid factor (RF) and/or anti-citrullinated protein antibodies (ACPA) identify a major rheumatoid arthritis (RA) subgroup, characterized by greater propensity to erosive joint damage and extra-articular disease manifestations as compared to seronegative patients. The purpose was to determine the associations between RF/ACPA and changes in functional immune response signatures over 5 years in patients with RA.

### **Methods:**

A longitudinal analysis was performed of baseline and 5-year follow-up data from a prospective study of adult RA patients in a population-based incidence cohort. Data were available for 324 patients at baseline and for 155 patients at 5 years. Peripheral blood leukocytes (PBL) were freshly collected from patients and isolated by Ficoll density gradient centrifugation at both time-points. PBLs were stimulated at 37°C for 48 hrs under six separate conditions: anti-CD3/anti-CD28 monoclonal antibodies (CD3/CD28); phytohemagglutinin (PHA), staphylococcal enterotoxins A and B (SEA/SEB); phorbol myristate acetate and ionomycin (PMA); CpG oligonucleotides (CpG ODN2006); and medium alone. A panel of 17 cytokines and chemokines was analyzed using multiplexed immunoassays (Meso Scale Discovery). RF was measured using the nephelometry (CSL Behring), and ACPA was measured by Quanta Lite CCP3 IgG (Inova Diagnostics). Factor analysis of normalized data was performed using baseline data on 324 patients to make inferences about underlying cell types based on cytokine profiles. Among the 155 patients with follow-up, Spearman methods were used to assess correlations between RF and/or ACPA seropositivity and longitudinal changes in the factor scores for each stimulus, adjusting for age and sex.

### **Results:**

A total of 109 (70%) of the 155 patients were seropositive at baseline (median age: 57.7 yrs; median disease duration: 9.7 yrs). RF/ACPA

positively associated with CpG factor 1 ( $r = 0.28$ ,  $p < .001$ ), factor 2 ( $r = 0.21$ ,  $p = .011$ ), and factor 3 ( $r = 0.20$ ,  $p = .015$ ). Based on loadings  $> 0.5$ , CpG factor 1 comprised IL-1 $\beta$ , G-CSF, TNF- $\alpha$ , MIP-1 $\beta$ , and IL-6; factor 2 comprised IFN $\gamma$ , IL-2, and IL-13; and factor 3 comprised IL-12, and IL-5. Previous studies have shown that the type of CpG used in this study mainly activates B cells. Responses to medium alone paralleled those to CpG, as RF/ACPA positively correlated with medium alone factor 1 ( $r = 0.27$ ,  $p < .001$ ) and factor 3 ( $r = 0.29$ ,  $p < .001$ ) responses. Medium alone factor 1 comprised GM-CSF, MCP-1, IL-17A, IL-6, MIP-1 $\beta$ , TNF- $\alpha$ , and G-CSF; factor 3 comprised IL-1 $\beta$  and TNF- $\alpha$ . Based on this profile, multiple Toll-like receptor (TLR) ligands present in the medium fetal calf serum could have stimulated monocytes or other antigen presenting cells. In contrast, RF/ACPA negatively correlated with CD3/CD28-induced IL-5 ( $r = -0.21$ ,  $p = .008$ ), IL-17A ( $r = -0.22$ ,  $p = .005$ ), and GM-CSF ( $r = -0.20$ ,  $p = .013$ ).

### Conclusion:

Our findings suggest that sustained stimulation of RF-containing immune complexes increases monocyte and B-cell activation states with increased expression of TLR. This could inform the development of functional assays for CpG and other TLR immune responses as predictors of response to B-cell directed therapy in RA.

## B Cell Abnormalities in Patients with Chronic Cutaneous Lupus Erythematosus

Chungwen Wei<sup>1</sup>, Aisha Hill<sup>2</sup>, Kira Smith<sup>3</sup>, Ignacio Sanz<sup>1</sup>, S. Sam Lim<sup>4</sup> and Cristina Drenkard<sup>4</sup>, <sup>1</sup>Medicine, Emory University School of Medicine, Atlanta, GA, <sup>2</sup>Medicine, Emory University School of Medicine, Atlanta, GA, <sup>3</sup>Emory University School of Medicine, Atlanta, GA, <sup>4</sup>Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus is a spectrum of disease with cutaneous lupus (CLE) without systemic features on one end and systemic lupus erythematosus (SLE) on the other. Among CLE subtypes, chronic cutaneous lupus (CCLE) is deemed less likely to be associated with systemic features. However, 10-20% CCLE will develop SLE throughout their disease course. Little is known regarding the immunological correlates to the disease progression, which we postulate may be accompanied by the emergence of SLE-associated B cell abnormalities. As an initial test for our hypothesis, we compared the B cell phenotypes in a cross-sectional analysis among patients with CCLE, SLE with or without CCLE.

**Methods:** Patients met SLICC and ACR criteria for the classification of CCLE and SLE. Frozen PBMCs were analyzed by flow cytometry from healthy controls (HC) ( $n=23$ ) and patients with primary CCLE ( $n=60$ ), SLE ( $n=58$ ) or CCLE with SLE ( $n=42$ ). B cell subsets were identified using the following markers: CD19, IgD, CD27, CD38, CD24, CD21, CD11c, 9G4, in addition to CD3 and live/dead staining as exclusion markers. Frequencies of the various B cell subsets were compared among the groups using ANOVA followed by Tukey's multiple comparison statistical tests. To gain a global view of the changes in B cell homeostasis, an unsupervised hierarchical clustering analysis of the B cell profiles was carried out.

**Results:** Several B cell abnormalities have been shown in SLE patients compared to the healthy controls, including a contraction of IgD<sup>+</sup>CD27<sup>+</sup> unswitched memory (USM) and an expansion of IgD<sup>-</sup>CD27<sup>-</sup> double negative (DN) cells. These observations are replicated in this study as well. Furthermore, within the DN population, a subset of cells with an activated phenotype (CD11c<sup>+</sup>CD21<sup>-</sup>, termed DN2) is significantly expanded in SLE compared to HC. Its counterpart in the IgD<sup>+</sup>CD27<sup>-</sup> naïve and transitional (N+T) compartment – the CD11c<sup>+</sup>CD21<sup>-</sup> activated naïve (aN) B cells – is also expanded in SLE, though not statistically different from HC. Interestingly, CCLE patients share with SLE the characteristic contraction of USM also seen in Sjogren's and other autoimmune diseases, yet they do not exhibit the expansion of DN, activated DN2 and aN subsets. Instead, CCLE patients show an expansion of the early transitional (T1+T2) cells. Globally, an unsupervised hierarchical clustering analysis demonstrates the segregation of HC from SLE (with or without CCLE) on the basis of their B cell profiles. On the other hand, B cell profiles of CCLE patients are heterogeneous and interspersed between HC and SLE patients.

**Conclusion:** Cross-sectional analysis at baseline reveals that CCLE patients share some SLE abnormalities including contracted USM and expansion of early transitional B cells, but do not display expansions of activated mature B cells (both naïve and isotype switched DN cells), a phenotype that is frequently observed in SLE patients. Moreover, our study demonstrates that from a B cell standpoint, CCLE is a heterogeneous condition thereby opening the door to investigations of correlations between distinct B cell profiles and clinical variables and in particular, with progression to systemic disease. Confirmation awaits the longitudinal follow-up of these patients over the next years.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Targeting IL-23 to treat autoimmune disease and chronic inflammation is currently in development based on its pro-inflammatory function via regulating the activation of Th17 cells. IL-23 was previously shown to be important for promoting pathogenic autoantibody production in Fas deficient B6-Fas<sup>lpr/lpr</sup> mice, suggesting the positive role of IL-23 in mediating Fas-independent germinal center (GC) responses. In contrast, the lack of IL-23 did not influence conventional GC formation and IgG anti-CII autoantibodies in type II collagen immunized DBA/1 mice. We determined if IL-23 could regulate development of GCs and pathogenic autoantibody production in BXD2 mice.

**Methods:** The BXD2-IL-23 *p19*<sup>-/-</sup> mice were generated by 10 generation crossing the B6-*p19*<sup>-/-</sup> with the BXD2 mice. Serum autoantibodies were determined by ELISA. GC development was measured by FACS (GL-7 and Fas) and confocal imaging analyses. Autoantibody class switching was enumerated by the percentage of (IgM<sup>-</sup>IgD<sup>-</sup>) in GL-7<sup>+</sup> B cells. Immune complex deposition (IgM and IgG) in kidney was detected by confocal imaging.

**Results:** There was lower induction of *Il17a* in subpopulations of spleen cells from BXD2-*p19*<sup>-/-</sup> mice compared to WT BXD2 mice. However, unlike BXD2-*Il17ra*<sup>-/-</sup> mice, which developed lower levels of both IgM and IgG autoantibodies, BXD2-*p19*<sup>-/-</sup> mice exhibited significantly elevated titer of total IgM and IgM anti-DNA and RF autoantibodies but significantly lower levels of total IgG and IgG anti-histone, compared to WT BXD2 mice. Despite the lower circulating IgG autoantibodies, IgG staining was significantly increased in the glomerulus of BXD2-*p19*<sup>-/-</sup> mice compared to BXD2 and normal B6 mice with both an immune complex and linear staining pattern. The number and size of PNA<sup>+</sup> GCs and the percent of GL-7<sup>+</sup>Fas<sup>+</sup> GC B cells were increased in BXD2-*p19*<sup>-/-</sup> mice comparable to WT BXD2 mice. Abnormal GC development kinetics was confirmed by increased conventional isotype switched IgM<sup>-</sup>IgD<sup>-</sup> GL7<sup>+</sup>Fas<sup>+</sup> B cells in BXD2-*p19*<sup>-/-</sup> mice compared to BXD2 WT mice.

**Conclusion:** The present findings provide a potential link to consolidate previous findings on the importance of IL-23 in mediating IgG autoantibody development in B6-Fas<sup>lpr/lpr</sup> mice and the lack of effects in development of IgG anti-CII antibody in CII immunized IL-23 deficient mice. These results extend the paradigm of IL-23 disease beyond the classical IL-23-Th17 axis and suggest IL-23 exhibits a negative effect on development of classical GC B cells that produce highly pathogenic autoAbs.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Targeting humoral immunity has been proved effective in several inflammatory rheumatic diseases (IRD). Though clinical trials have shown some efficacy of B-cell depletion in ankylosing spondylitis (AS), results are less convincing. Other studies have revealed an association between mutations and expression of immune regulatory genes suggesting a B-cell dysfunction in the development and progression of AS. Yet, there is still lack of data describing B-cell subsets in AS. The study purpose is to assess and compare the immature, naive and antigen differentiated subsets of peripheral B-cell compartment in AS with those in healthy controls (HC) and other IRD

**Methods:** Patients with AS, RA and SLE according to respective classification criteria were included. Patients under biologic DMARDs were not included. Sociodemographic and clinical variables were recorded and blood samples were collected for quantification of inflammatory markers, immunoglobulin levels and assessment of B-cell immature transitional stages and mature subsets by flow cytometry. Mann-Whitney and Fisher's exact test were used for statistical analysis

**Results:** Overall, 60 patients and 12 HC were included. All patient groups presented similar and rather low levels of inflammation, as measured by CRP, ESR and immunoglobulins, in addition to a decreased lymphocyte count. There were no differences in the B-cell counts between AS patients and HC, and both groups had higher B-cell counts than RA and SLE patients. Regarding B-cell subsets, the immature transitional compartment of AS patients was found in normal range, but not in RA and SLE. The latter presented a significant decrease in all transitional cell maturity stages (T1-T3). The next step in B-cell differentiation is mature naïve cells, also found to be normal in AS and decreased in RA and SLE. AS patients presented slightly higher counts of CD27+IgD+ MZ-like and class able to switch memory cells with reference to HC and these cell numbers were found to be low in RA and SLE patients. Switched memory CD27+IgD- B-cells were reduced in all patient groups, however, only SLE patients presented highly decreased cell levels

**Conclusion:** We found that while a severe dysfunction is present in the homeostasis of the B-cell compartment in RA and in particular SLE pts, which are lymphopenic in both immature and mature B-cell compartments, it appears that AS patients are not affected in the same way. At this stage, functional studies appear to be necessary in order to identify differences in key mechanisms of B cell development and differentiation that play a role in the aetiology and progression of these inflammatory rheumatic diseases. Our first results, however, establish that pathophysiological mechanisms involving B-cells clearly differentiate AS from RA and SLE

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic sclerosis (SSc) is a T helper type 2 (Th2)-driven autoimmune disease characterized by vasculopathy and fibrosis. There are still unmet needs in the management of SSc, however B-cell depletion therapy has recently been reported to be effective for this disease. Intriguingly here there is no significant correlation between autoantibody titers and the improvement of clinical symptoms, thus highlighting a novel antibody-independent function of B cells, particularly cytokine production, involved in the pathogenesis of SSc. Granulocyte-macrophage colony-stimulating factor (GM-CSF) exerts a wide range of biological effects mainly on myeloid cells, and B cells has recently been reported as another cellular source of GM-CSF that is induced by a Th2 cytokine IL-4. Given a pathological relevance of Th2 cytokines in SSc and association of GM-CSF with fibrotic processes in various rodent models, in the present study we have sought to elucidate a role of GM-CSF-producing B cells in this disease.

**Methods:** B cell subsets in peripheral blood from healthy donors and patients with SSc were enriched by cell sorting and subjected to the analysis of GM-CSF transcripts and proteins (intracellular staining and ELISA). The relationship between GM-CSF-producing B cells and the clinical features of SSc was also evaluated. To determine the functional impacts of GM-CSF-producing B cells on myeloid cells, B cells cultured under Th2 conditions were co-cultured with CD14<sup>+</sup> monocytes.

**Results:** Among a panel of CD4<sup>+</sup> T cell-derived cytokines, Th2 cytokine IL-4 most significantly induced the generation of GM-CSF-producing memory B cells, while T follicular helper (Tfh) cytokine IL-21 remarkably abrogated this process. Intriguingly TGF- $\beta$  further potentiated IL-4-induced GM-CSF production in memory B cells. GM-CSF-producing effector B cells were positive for CD30, a distinct phenotype from Ab-producing cells induced by IL-21. GM-CSF production in B cells from patients with SSc was more pronounced than that from healthy donors. This trend was also observed in both naïve and memory B cell subsets. A subpopulation of SSc patients with the diffuse type and concomitant IP, in particular, represented enhanced GM-CSF production in memory B cells. Moreover, B cells cultured under Th2 conditions along with TGF- $\beta$  facilitated the differentiation from CD14<sup>+</sup> monocytes to DC-SIGN<sup>+</sup>CD1a<sup>+</sup>CD14<sup>+</sup>CD86<sup>+</sup> cells, a novel DC subset previously reported in skin of SSc patients and SSc model mice.

**Conclusion:** Together, these findings suggest that GM-CSF-producing effector B cells is a novel B cell subset and play a critical role in the pathogenesis of SSc by Ab-independent mechanisms.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**  $\beta$ 2-glycoprotein I ( $\beta$ 2GPI), a phospholipid-binding protein, binds to apoptotic cells and serves as an antigenic target for autoantibodies from patients with systemic lupus erythematosus (SLE). Here, we determine whether this paradigm can be extended to necroptotic cells. Like apoptotic cells, necroptotic cells express phosphatidylserine on their surface and provide a “scaffold” of cellular self-antigens. We hypothesized that  $\beta$ 2GPI should bind to necroptotic cells and serve as a target for anti- $\beta$ 2GPI autoantibodies from patients with SLE.

**Methods:** We established conditions for inducing necroptotic or apoptotic cell death in murine L929 fibroblast cells. L929 cells treated with vehicle served as the viable cell control. Cells were incubated with human  $\beta$ 2GPI and murine monoclonal anti- $\beta$ 2GPI IgG antibody (or isotype control), and bound antibody detected with fluorescently conjugated anti-murine IgG. Similarly, binding of anti- $\beta$ 2GPI autoantibodies from human sera (or IgG isolated from these sera) was detected using fluorescently conjugated anti-human IgG. Human sera were from healthy controls and patients who satisfied the ACR classification criteria for SLE. Antibody binding was analyzed by flow cytometry and confocal microscopy.

**Results:** Using murine monoclonal anti- $\beta$ 2GPI antibody, we demonstrate that  $\beta$ 2GPI binds to necroptotic cells in a similar manner as to apoptotic cells, but not to viable cells. Cells treated with an irrelevant antigen (serum albumin) or isotype control showed little or no antibody binding. Confocal microscopy confirmed monoclonal anti- $\beta$ 2GPI antibody staining of the cell surface of both necroptotic and apoptotic cells. SLE sera positive for anti- $\beta$ 2GPI autoantibodies bound to necroptotic cells and apoptotic cells. In contrast, sera negative for anti- $\beta$ 2GPI autoantibodies behaved similarly to healthy control sera, and showed little or no binding to necroptotic or apoptotic cells. Binding of purified IgG from the sera replicated the findings observed with sera.

**Conclusion:** Our data demonstrate that  $\beta$ 2GPI binds to necroptotic cells and can serve as a target for SLE autoantibodies recognizing  $\beta$ 2GPI. Based on these findings, we propose that the paradigm of apoptotic cells serving as a “cellular scaffold” of self-antigens in SLE may be extended to necroptotic cells.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** B cells contribute to disease pathophysiology through several mechanisms, including cytokine secretion. A wide variety of stimuli can activate B cells to produce cytokines including B cell receptor and Toll-like receptor engagement. Recently, numerous

observations have established the role of metabolic pathways in the diverse array of immune cell functions. It is unknown though how these metabolic pathways influence B cell cytokine production. We sought to elucidate the metabolic programs required for B cell cytokine production

**Methods:** B cells were isolated from the spleens of C57Bl/6J mice and activated overnight individually by anti- $\mu$  antibody, anti-CD40 agonist antibody, poly(I:C), LPS, R484, and CpG. Supernatants were analyzed for the quantification of cytokines using the Milliplex cytokine kit (EMD Millipore). Real-time analysis of extracellular acidification rates and oxygen consumption rates of activated B cells were performed using the XF-96 Extracellular Flux Analyzer (Seahorse Bioscience). To assess 3-carbon sources for oxidative phosphorylation, inhibitors to fatty acid oxidation (etomoxir), pyruvate transfer to mitochondria (UK-5099), and glutamine usage (BPTES) were used. Amino acids, organic acids, and acylcarnitines were extracted using methanol for targeted metabolomics studies using mass spectroscopy.

**Results:** CpG stimulation of mouse splenic B cells increased both glycolysis and mitochondrial respiration to a larger extent than by other stimuli such as LPS or B cell receptor alone. These processes are highly dependent on glutamine, as inhibition of glutaminolysis with BPTES significantly reduced both processes. Furthermore, glutaminolysis activated mTOR, which was required for glycolysis, mitochondrial respiration, and ATP production in CpG-activated B cells. Quantitative targeted metabolomic studies confirmed CpG-stimulation drove increases in intracellular amino acid levels, aerobic glycolysis and TCA cycle intermediates, all of which were reversed in the presence of BPTES. Production of TNF- $\alpha$ , IL-6, and IL-10 by CpG-stimulated B cells also relied on glutaminolysis and mTOR activation. Interestingly, inhibition of glycolysis alone selectively decreased IL-10 production.

**Conclusion:** B cells undergo metabolic reprogramming when stimulated with CpG, requiring glutaminolysis and mTOR activation, which drove aerobic glycolysis, TCA cycling, and ATP production. Cytokine production is intrinsically linked with this reprogramming, although glycolysis was required for B cell IL-10 production suggesting the possibility that various B cell cytokines differentially rely on specific metabolic pathways. These data are the among first to demonstrate a relationship between B cell effector function and metabolic reprogramming, and suggest that B cell cytokine secretion can be manipulated by altering the local metabolic environment. Manipulating metabolic pathways may represent an interesting therapeutic approach for modulating B cells in autoimmune diseases.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rituximab (RTX) has shown clinical efficacy but up to 40 % of RTX treated rheumatoid arthritis (RA) patients are poor responders (Ann-Rheum-Dis. 2005 Feb;64(2):246-52) and the commonly used RA biomarkers (RF/ACPA) are poor predictors for therapy response. In this study the autoantibody repertoire analysed on protein microarrays from RA patients under RTX treatment was correlated to clinical DAS28 response.

**Methods:** Screening of RA sera was conducted on 37,830 unique human proteins on protein microarrays with sera taken before and 24 weeks after treatment. The autoantibody response of different immunoglobulin classes IgD, IgA, and IgG was recorded and bioinformatically evaluated. Response was determined according to DAS28 criteria. DAS 28 scores in the responder group before treatment was from 5.4 – 7.8 and in the non-responder group 5.6 – 6.8. We analyzed 26 RA patient sera (9 responder, 7 non-responder and 10 patients with blinded response classification) investigated the data of found autoantigens in silico and by hierarchical clustering.

**Results:** In the cohort of 26 patients 1292 different autoantigens (IgD, IgA, IgG) were detected. Using protein array we investigated clusters of

autoantigen responses that disappeared or developed during RTX treatment of RA patients. RA autoantigenic patterns before and 6 month after RTX treatment were patient-specific and no relevant autoantigenic cluster was found that was shared between patients or associated with response. However, RTX reduced the repertoire of autoantibodies after 24 weeks of treatment in the tested RA patient cohort on average by 60%. RA patients which do not respond are generating on average 63% new autoantibodies. In good responders to RTX only 5,5% (+/-3%) new autoantibodies can be detected. The IgA and IgG autoantibody repertoire in the serum after 24 weeks of RTX treatment is reduced (IgA: 41%, IgG :31%) in good responders whereas it is increased (IgA: 1,3%, IgG: 24%) in non responders to RTX.

**Conclusion:** After 6 month of RTX treatment the autoantibody repertoire in all good responding RA patients is reduced and non-responders to RTX change their autoantibody repertoire directed against new but patient specific antigens. The fast rebuilding of functional B cells is only detected in non-responders to rituximab.

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** B cells are recognized as key players in the pathogenesis of rheumatoid arthritis (AR) through the production of autoantibodies, the local production of proinflammatory soluble factors and, when acting as antigen-presenting cells, the regulation of T-cell functions. Experimental evidence suggests that B cells should migrate to and accumulate within the synovial microenvironment to exert their pathogenic action in RA. However, little is known about the driving force responsible for the recruitment of B cells in the rheumatoid synovium. Chemokines and their receptors expressed in leucocytes help to control the selective migration and activation of inflammatory cells in the inflamed synovium. Objective: to determine the chemokine or chemokines responsible for the recruitment of B cells in the rheumatoid synovium.

**Methods:** Surface expression levels of CD27, CCR1, CCR2, CCR3, CCR4, CCR5, CCR6, CCR7, CXCR2, CXCR4, CXCR5 and CXCR7 were assessed by double- or triple-staining flow cytometry analysis in CD20+ mononuclear cells isolated by Ficoll-gradient from the peripheral blood (PB) and synovial fluid (SF) of 15 RA patients. In a sample of patients, the total expression (intra- and extracellular) of specific chemokine receptors was analyzed by flow cytometry in CD20+ cells PB and SF permeabilized mononuclear cells from PB and SF. Transwell experiments were used to study the synergism and migration capabilities of negatively immunoselected PB B-cells from normal donors or in CD20+ mononuclear cells from PB and SF of RA patients in response to a single chemokine or a mix of two chemokines.

**Results:** B cells from the SF of RA patients showed a significant increase in the surface expression of CCR1 (2.1 $\pm$  0.1-fold), CCR2 (2.4 $\pm$ 0.2 fold), CCR4 (6 $\pm$ 2 fold), CCR5 (2 $\pm$ 0.1 fold) and CXCR4 (2.5 $\pm$ 0.8-fold) with respect to PB. Remarkably, SF B cells expressed consistently lower amounts of CXCR5 (0.15 $\pm$ 0.05 fold, p<0.01), CXCR7 (0.7 $\pm$ 0.1 fold, p<0.05) and CCR6 (0.75 $\pm$ 0.1 fold, p<0.05) with respect to PB. This differential pattern of chemokine receptor expression was not modified by the previous contact of B cells with antigen, as assessed by CD27 expression levels. Flow cytometry results showed a relative increase in the expression of CXCR5 and CCR6 in permeabilized CD20+ cells from SF compared to those from PB, which suggests that both receptors undergo cell internalization in B cells that migrate to the

rheumatoid synovium. In Transwell experiments, MIP-3 $\alpha$  and BCA-1, ligands of CCR6 and CXCR5, respectively, caused a significantly higher migration on B cells from PB than in those from the SF of RA patients. Together, the two chemokines synergistically increased B cells migration from PB but not from SF.

**Conclusion:** B cells present in the synovial microenvironment of patients with RA down-regulate the surface expression of CXCR5, CCR6 and CXCR7 via an internalization mechanism. Individually, BCA-1 and MIP-3 $\alpha$  show higher chemoattractant effects in B cells from PB versus those from SF, while together they exert a synergistic effect in B cells from PB, but not from SF. These results suggest that BCA-1 and MIP-3 $\alpha$  might play major roles in RA pathogenesis by acting synergistically in the accumulation of B lymphocytes within the inflamed synovium.

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** We investigated 194 individuals with SADs (38 primary Sjögren's syndrome (pSS), 47 rheumatoid arthritis (RA), 46 systemic lupus erythematosus (SLE), 42 systemic sclerosis (SSc) and 21 undifferentiated connective tissue disease (UCTD) patients) and 53 healthy controls (HCs) to determine whether a fine flow cytometry analysis of T and B cell distribution in whole blood could cluster individuals according to disease diagnosis.

**Methods:** Two flow cytometry panels were designed. The first panel was dedicated to T cells and combined CD57, CD45RA, CD62L, CD27, CD38, CD3, CD4 and CD8 mAbs. The second panel was dedicated to B cells and combined IgD, TACI, CD27, CD5, CD38, CD19 and CD24 mAbs. A classical manual gating strategy and the Flow-clustering without K (FLOCK) investigation, a density-based clustering approach to algorithmically identify relevant cell populations from multiple samples in an unbiased fashion, were used.

**Results:** The manual gating strategy allows the identification of 17 distinct lymphocyte subsets. The prediction of the different SADs was determined by discriminant function analysis (DFA). No clustering was found. The FLOCK exploration of the merged HCs identifies 85 distinct subsets of lymphocytes used as reference when compared to SADs . The DFA analysis clearly clusters the HCs and the patients according to each SAD (see figure below).

When compared to HCs, the pSS signature was discriminated by an increase in IgD<sup>hi</sup>CD24<sup>hi</sup>CD38<sup>hi</sup>CD27<sup>-</sup>TACI<sup>-</sup>CD5<sup>hi</sup> transitional B cells, and an increase of CD45RA<sup>+</sup>CD27<sup>-</sup>CD62L<sup>lo/-</sup>CD57<sup>hi</sup> effector CD8<sup>+</sup> T cells.

The SLE signature was discriminated by an increase in IgD<sup>-</sup>CD24<sup>lo</sup>CD38<sup>-</sup>CD27<sup>-</sup>TACI<sup>+</sup>CD5<sup>-</sup> memory like B cells, an increase in CD45RA<sup>-</sup>CD62L<sup>+</sup>CD38<sup>hi</sup> activated central memory CD4<sup>+</sup> T cells.

The RA signature was discriminated by an increase in IgD<sup>hi</sup>CD24<sup>lo</sup>CD38<sup>-</sup>CD27<sup>-</sup>TACI<sup>+</sup>CD5<sup>-</sup> unactivated mature naïve B cells and a decrease in CD45RA<sup>+</sup>CD62L<sup>+</sup>CD38<sup>hi</sup> naïve CD8<sup>+</sup> T cells.

The SSc signature was discriminated by a decrease in CD45RA<sup>+</sup>CD62L<sup>+</sup>CD38<sup>hi</sup> naïve CD8<sup>+</sup> T cells.

Interestingly, patients with UCTD were distributed among the different clusters (28% with HC, 29% with SLE, 29% with SSc, 9% with RA and 5% with pSS clusters).

**Conclusion:** A fine bioinformatical flow cytometry analysis of T and B cell subsets clusterizes patients and HCs suggesting that each SAD can be associated with abnormal specific phenotypical distributions that could be helpful in the diagnosis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a multi-systemic autoimmune disease characterized by B cell hyperactivation and the production of autoantibodies. Histone deacetylase, Sirtuin1 (Sirt1) has been shown to play a role in regulation of inflammation. Sirt1 deficiency results in the development of lupus-like disease in mice, including the production of anti-nuclear antibody. Resveratrol (trans-3,4',5-trihydroxystilbene), a natural polyphenolic phytoalexins, is a potent activator of Sirt1. Our study was conducted to determine the expression of Sirt1 in B cells in SLE patients and further test the effects of resveratrol on B cell activation and auto-Ab production in pristane-induced mouse lupus model.

**Methods:** Flow cytometry and real-time PCR were used to analyze the expression of Sirt1. Sirt1 signaling was modulated with the Sirt1 agonist resveratrol. BALB/c mice were given 0.5 ml of pristane on day 1 by intraperitoneal injection to induce the lupus-like disease and on day 2 the mice received various doses of resveratrol. CD19+ B cells were isolated from the spleen mononuclear cells of the pristane-induced lupus mice and cultured with or without resveratrol in vitro for 3-5 days and B cell activation, plasma B cell differentiation and *Prdm1* gene expression were assessed by flow cytometry or real-time PCR.

**Results:** The expression of Sirt1 in CD19<sup>+</sup>B cells of SLE patients was significantly decreased when compared to healthy donors ( $p=0.0071$ ). The expression of Sirt1 negatively correlated with CD19<sup>+</sup> B cell frequencies ( $p=0.0008$ ). In pristane-induced lupus mice, Sirt1 activator-resveratrol dramatically decreased the expression of CD69, CD80, CD86 expression of B lymphocytes in a dose-dependent manner. Resveratrol significantly inhibited CD138<sup>+</sup> plasma cell differentiation of B lymphocytes after stimulation with LPS plus anti-CD40 antibody. Finally, resveratrol significantly inhibited the expression of PRDM1 (gene encoding Blimp-1) mRNA in B-cells.

**Conclusion:** Sirt1 is downregulated in SLE patients. The use of resveratrol, Sirt1 agonist may present a novel approach for treatment of SLE by inhibiting B cell activation and plasma cell differentiation.

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

A single risk haplotype spanning *UBE2L3* is strongly associated with SLE and multiple autoimmune diseases. The E2 ubiquitin-conjugating enzyme UBE2L3 regulates TNF $\alpha$  and CD40 induced NF- $\kappa$ B activation via regulation of the Linear Ubiquitination Chain Assembly Complex (LUBAC). We have shown that the *UBE2L3* risk allele correlates with plasmablast and plasma cell expansion in SLE individuals by regulating NF- $\kappa$ B activation in B cells. Dimethyl Fumarate (DMF), a current oral therapy for multiple sclerosis and psoriasis, has been recently identified as a UBE2L3 inhibitor. Given the known role of excessive TLR7 signalling in SLE, we aimed to determine the effect of UBE2L3 and linear ubiquitination on TLR7 signalling and to explore whether UBE2L3-mediated plasmablast differentiation can be inhibited by DMF.

### Methods:

Transient overexpression and shRNA silencing were used in TLR7-HEK293 NF- $\kappa$ B reporter cell line to investigate the effect of UBE2L3/LUBAC on NF- $\kappa$ B activation, gene expression by qPCR and IL-8 secretion by ELISA. Western blot was used to measure linear ubiquitin chain polymerisation, confirmed by confocal microscopy. DMF was administered to CD19<sup>+</sup> peripheral blood human B cells cultured in the presence of resiquimod, IFN $\alpha$ , or both for up to 7 days. B cell viability, activation, differentiation and proliferation were analysed by flow cytometry. Immunoglobulin secretion was quantified by ELISA and ANA detected by Hep2 immunofluorescence assay.

## Results:

Overexpression of catalytically active LUBAC components increased TLR7-induced NF- $\kappa$ B activation by reporter assay. NF- $\kappa$ B activation, NF- $\kappa$ B target gene expression by qPCR and IL-8 secretion were further enhanced by co-overexpression of UBE2L3 with LUBAC, basally and after TLR7 stimulation, but was abolished by dominant negative mutant UBE2L3(C86S) or HOIP(C885S), and in UBE2L3 silenced cells. TLR7 engagement triggered accumulation of linear ubiquitin chains comparable to TNF $\alpha$ . DMF exerted a dose-dependent suppression of NF- $\kappa$ B activation following TLR7 engagement. DMF reduced human primary B cell survival, and suppressed proliferation of switched and unswitched CD27<sup>+</sup> memory B cells. DMF inhibited TLR7 stimulated immunoglobulin secretion by in vitro differentiated B cells. Co-stimulation of B cells with TLR7 ligand resiquimod and IFN $\alpha$  induced anti-nuclear autoantibody production which was suppressed by DMF.

## Conclusion:

Our results establish that linear ubiquitination and UBE2L3 regulate TLR7 activation of NF- $\kappa$ B. Silencing UBE2L3/LUBAC, use of dominant negative mutant UBE2L3 or HOIP, or use of the UBE2L3 inhibitor DMF suppressed TLR7 driven NF- $\kappa$ B activation. Excessive TLR7 signalling has been linked to SLE development by impaired checkpoint permissiveness in autoreactive B cells, leading to autoantibody production in the context of type I interferon. DMF demonstrated potent suppression of CD27<sup>+</sup> memory B cell differentiation and inhibited TLR7 and IFN $\alpha$  induced autoantibody production. These results suggest that there may be a role for repositioning DMF in the treatment of SLE and autoantibody driven autoimmune diseases.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We previously showed that up to 40% of RA synovial recombinant monoclonal antibodies (RA-rmAbs) generated from germinal center-like structure (GC-LS+) RA synovium recognize citrullinated antigens contained in neutrophils extracellular traps (NETs) (1). The cellular source of other potential autoantigens targeted by the majority of locally differentiated B cells remains undefined. Recently, RA-fibroblast-like synoviocytes (RA-FLS) have been implicated in the release of citrullinated antigens (2, 3). However, whether these cells are targeted by RA-rmAbs is still unknown. Here, we aimed to define i) the RA-rmAbs immunoreactivity towards RA-FLS and ii) identify potential stromal-derived autoantigens.

**Methods:** 67 RA-rmAbs were generated from single CD19<sup>+</sup> B cells FACS-sorted from fresh synovial cell suspensions following IgV<sub>H</sub>+V<sub>L</sub> genes cloning (1). RA-rmAbs were tested by means of i) cell-based immunofluorescence assays with FLS of RA patients and controls (osteoarthritis (OA)-FLS and RA-dermal fibroblast (RA-DF)), ii) co-localization with stromal specific markers and iii) immunoenzymatic tests with co-localizing antigens. Control rmAbs were also used (Sjögren's syndrome/healthy donor-IgG rmAbs).

**Results:** Immunofluorescence on RA-FLS demonstrated reactivity of 22.4% of RA-rmAbs (15/67 rmAbs) towards FLS. Only 4 rmAbs out of 15 were binding both FLS and NETs components. For some RA-rmAbs this reactivity was not specific to RA-FLS since it was also observed for OA-FLS (3% rmAbs). Interestingly, strong co-localization was observed with calreticulin (CRT) which has been shown to bind the RA shared-epitope (SE) ligand and to increase the signalling pathway activated by the SE ligand in its citrullinated form (3). When tested

in ELISA for native vs cit-CRT, 20% (14/67 rmAbs) of the FLS-reactive RA clones showed binding to CRT with 6 out of 14 RA-rmAbs displaying increased immunoreactivity towards cit-CRT. Controls rmAbs showed no reactivity to either FLS or CRT. RA-rmAbs binding to CRT was further confirmed in western blot immunoassays.

**Conclusion:** Here, we provide novel evidence that a subset of locally differentiated B cells within RA synovial GC-LS can react towards RA-FLS derived antigens. Preliminary data suggest that part of this reactivity is directed towards CRT. Identification of immunodominant epitopes within CRT is under investigations.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

CD40/CD40L is a cornerstone pathway for both innate and adaptive immune responses and a suitable target for autoimmune diseases including Sjogren's. BIIB063 is a high affinity MAb, engineered to reduce Fc effector function and avoid half antibody formation *in vivo* (IgG4P). BIIB063 has the potential to inhibit germinal center formation, immunoglobulin class switching, T cell activation and cytokine release with a potent inhibition of inflammation and autoimmunity. The results of the first in human and the GLP-toxicology findings are presented.

### **Methods:**

In the single ascending dose (SAD) study, 58 healthy volunteers (HV) subjects were assigned to 8 cohorts. Seven cohorts of 4, 6, or 8 subjects were planned to receive increasing single IV doses of BIIB063 (0.003, 0.03, 0.3, 1, 3, 10, and 20 mg/kg) or placebo. One cohort of 8 subjects was planned to receive a single 150 mg SC dose of BIIB063 or placebo. Staggered dosing was used within each cohort to ensure subject safety. Blood samples were analyzed by ELISA for PK and ADA, and flow cytometry for the PD measure of CD40 receptor occupancy (RO). Safety data, including adverse events (AEs) and laboratory tests, were collected. A 26-Week SC and IV Toxicity Study in Cynomolgus Monkeys with a 16-Week Recovery Period was conducted; animals received 10, 30 or 150 mg/kg BIIB063 twice monthly.

### **Results:**

In the SAD study, a total of 29 subjects had been enrolled when the study was voluntarily put on hold due to findings from the ongoing 26-week toxicology study where 4 unscheduled terminations occurred. A thorough investigation revealed Immune complex (IgM-IgG4) deposits in multiple organs of affected animals, consistent with a type 3 hypersensitivity. This reaction occurred in 44% animals irrespective of the dose level and no NOAEL could be established. .

In the SAD, BIIB063 serum concentrations for the lowest two doses (0.003–0.03 mg/kg), were below the LLOQ. BIIB063 C<sub>max</sub> and AUC<sub>inf</sub> ranged from 3.7 to 22 ug/mL and 100 to 1880 hr\*ug/mL following doses of 0.3 and 1 mg/kg, respectively. BIIB063 showed nonlinear PKs

and a dose-dependent CD40 RO and RO duration. There was no significant RO of CD40 at dose levels of BIIB063 <0.3 mg/kg, while full CD40 RO was observed at doses of 0.3 and 1 mg/kg. CD40 RO declined within 96 hr for the 0.3mg/kg dose while CD40 RO lasted 8 days for the 1 mg/kg dose. BIIB063 was generally well tolerated.

No ADA was observed in the 0.003-0.03 mg/kg cohorts where serum concentrations of drug were undetectable, while 67% - 100% subjects had positive ADA in the 0.3-1 mg/Kg cohorts. Interestingly, ADA responses were typically detected several weeks after BIIB063 drug clearance, and in the absence of CD40RO. Hence, the potential impact of ADA on PK and PD was undeterminable.

#### **Conclusion:**

BIIB063 administered to HV exhibited a PK profile consistent with an IgG4 molecule. Target engagement as measured by CD40 RO was clearly demonstrated and its duration was dose dependent. ADA response was present in the higher doses cohorts in the SAD. The preclinical toxicology findings and the high immunogenicity of BIIB063 led to the voluntary discontinuation of the trial.

**Session Date:** Sunday, November 5, 2017

**Session Title:** B Cell Biology and Targets in Autoimmune Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Heavy and light chain gene usage and mutational analyses of the Ig variable regions (V-regions) enable the identification of gene usage within B cell populations. Within the context of antibody secreting cells (ASC) isolated from the minor salivary glands of Sjogren's syndrome (SS) patients it may give clues to the loss of tolerance that leads to the genesis of autoreactive cells described in these patients.

#### **Methods:**

Fourteen subjects were included in this study. Each had symptomatic dry eyes and mouth; 8 subjects met American/European Consensus Group (AECG) primary SS criteria and 1 subject also met the American College of Rheumatology criteria for SLE. Six subjects that did not meet the SS classification criteria (DNMC) served as sicca controls. Labial salivary glands were collected, ASCs were isolated and single-cell sorted using a new method that allows for probing of both kappa and lambda light chains within in the same single cells in rare populations. Cells were sequenced and analyzed for V-region gene usage.

#### **Results:**

We identified a total of 83 unique heavy/light chain pairs from the SS patient group and 21 from the DNMC control group. No significant differences in the VH- or JH- gene-family usage were noted between SS or DNMC. The Ig VH family usage in both the SS patient and DNMC control groups was dominated by the VH3 and VH4 gene families and JH4 was the predominant JH gene family used by both groups. The light chain analysis revealed that kappa variable region (Vk) gene families, Vk1 and Vk3, were the most frequently used in both groups. The kappa joining (Jk) gene analysis revealed that J-genes, Jk-1 through Jk-5, were represented in sequences from both groups. The light chain sequence analyses also revealed the incidence of secondary light chain editing in the sequences from 2 pSS subjects and one DNMC, indicated by clonally related heavy chains with different light chain usage. These light chain sequences were unique and not found in any of the other pairs utilized by any of the other subjects. In addition, allelic inclusion, or 1 heavy chain with 2 distinct light chains within the same cell, was identified in 2 instances from the ASCs isolated from one pSS patient. In each case, both a kappa and a lambda light chain sequence were amplified from the same cell.

#### Conclusion:

In summary, we have developed an improved method for the isolation, characterization and mAb production for rare B cells populations, which has provided data suggesting ASC light chain editing and allelic inclusion not previously reported in SS.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Claudins (Cldns) are well-established components of tight junctions (TJs) that play a pivotal role in the modulation of paracellular permeability. Several studies have explored the physiologic aspects of Cldn family members in bone metabolism. However, the effect of Cldn11, a major component of central nervous system myelin, on bone homeostasis has not been reported. This study was performed to identify the effects of Cldn on bone metabolism via regulation of osteoclast and osteoblast differentiation and their function

#### Methods:

We performed various in vitro and in vivo studies using gain- and loss-of function of Cldn11 that is belong to the Cldn group. Osteoclast formation from bone marrow cells (BMC) and Osteoblast formation was evaluated in specific condition with over-expression or down-regulation of Cldn11. The expression of osteoclast associated gene and osteoblast related gene mRNA were assessed by RT-PCR. The levels of c-fos and NFATc1 protein were assessed by western blot. Also the mitogen-activated protein (MAPK)s and important signal pathways were measured using Western blot analysis. Osteoclast function was evaluated with resorption pit assay and osteoblastic effects of Cldn11 was evaluated with new bone formation of mouse calvaria. With LPS and co-treated Recombinant protein of Cldn11 on mouse calvaria, we evaluated the effects of Cldn11 on LPS induced bone loss by using histologic analysis.

#### Results:

We found that Cldn11 played a negative role in receptor activator of nuclear factor kappa B ligand dependent osteoclast (OC) differentiation by downregulating the phosphorylated form of extracellular signal-regulated kinase (ERK), Bruton's tyrosine kinase, and phospholipase C gamma 2, in turn impeding c-Fos and nuclear factor of activated T cells c1 expression. Osteoblast (OB) differentiation by positive feedback of Cldn11 was achieved through the phosphorylation of Smad1/5/8, ERK, and c-Jun amino-terminal kinase. Importantly, this Cldn11-dependent dual event arose from targeting EphrinB2 ligand reverse signaling into OC and EphB4 receptor forward signaling into OB. In agreement with these in vitro effects, subcutaneous injection of Cldn11 recombinant protein exerted similar effects on local calvarial regions in mice.

#### Conclusion:

These findings suggest that Cldn11 is a novel regulator in bone homeostasis.

## Modulation of Subchondral Bone Turnover Is Associated with Alteration of Cartilage Tissue Quality

Cedric Lavet, Isabelle Badoud and **Patrick Ammann**, Division of Bone Diseases, Geneva, Switzerland

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteochondral unit is a bio composite responsible for an optimal distribution of load during movements and axial compression of a joint. Any alteration of tissue mechanical properties (cartilage or bone) could interfere with an optimal function. One obvious question is to understand whether alteration of subchondral bone turnover (i.e. quality) could affect cartilage quality and thus represent a potential risk of OA development.

#### Methods:

To verify this hypothesis, 15 adult female rats where ovariectomized (OVX, n=10) or SHAM operated (n=5). One group of OVX rats was treated for 8 weeks with pamidronate (APD) at dose of 0.6 mg/kg, 5 days/mo SC to inhibit the increase of bone turnover, and the other two groups received the solvent. At the end of the study, distal femurs were harvested. Bio-indentations (CSM, Switzerland) were performed at the level of the medial condyle at three different area submitted physiologically to different mechanical loading. Elastic modulus (MPa) and indentation depth (mM) were recorded, using different load from 0.05 to 8 mN. Indentation depths were located in the upper third of the hyaline cartilage. Cartilage thickness was evaluated by contrast enhanced computed tomography with ionic contrast agent using (Hexabrix®) at the site of indentation as well as subchondral bone micro architecture. Blood and urine were collected to evaluate bone turnover using measurement of osteocalcin and deoxypyridinoline excretion. Values are mean±SEM; significance of differences was obtained using an ANOVA.

#### Results:

	SHAM (n=5)	OVX (n=5)	OVX+APD (n=5)
Pyridinolines/Creat	23.81 ± 3.03°	68.63 ± 11.02*	26.8 ± 2.83°
BV/TV (%)	48.0 ± 3.0°	35.0 ± 1.7*	48.7 ± 3.4°
Tb.Th (mm)	0.074 ± 0.003°	0.063 ± 0.002*	0.079 ± 0.004°
Modulus (MPa)	2.72 ± 0.22°	1.58 ± 0.14*	3.19 ± 0.32°
Indentation Depth (mm)	15.87 ± 1.12°	23.7 ± 1.22*	12.5 ± 0.88*°

\* versus sham, ° versus OVX (ANOVA)

An increment of markers of bone turnover was observed in OVX rats and was fully prevented by APD administration. OVX resulted in alteration of bone microarchitecture of the subchondral bone as demonstrated by a reduce bone volume (BV/TV) and trabecular thickness (Tb.Th); all these alterations were fully prevented by APD administration. Hyaline and mineralized cartilage thicknesses were not affected by OVX nor by APD treatments. OVX was associated with alteration of cartilage tissue quality as indicated by a decreased of modulus and increased indentation depth. All these alterations were fully prevented by APD treatment preventing the increment in subchondral bone turnover.

#### Conclusion:

All together these results demonstrate that in rat, an increment of subchondral bone turnover and/or alteration of the local micro architecture is associated with degradation of the cartilage tissue quality independently of the estrogen deficiency. These results underline the crucial role plays by subchondral bone as “regulator” of cartilage quality.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mesenchymal stem cells are multipotent stromal cells that can differentiate into tissue-specific lineages, such as osteocytes and chondrocytes. Their multipotency has made them an intriguing candidate for potential cellular therapy for rheumatic and musculoskeletal diseases; however, a substantial improvement in the understanding of the intracellular signaling, function, and regulation of mesenchymal stem cells is warranted before therapeutic use. Our data suggest G protein-coupled receptor kinase 3 (GRK3) functions as a negative regulator of G protein-coupled receptor (GPCR) signaling of sphingosine-1-phosphate receptor (S1PR) on bone marrow-derived mesenchymal stem cells (BmMSCs) and lack of such regulation alters BmMSC functionality.

**Methods:** BmMSCs were isolated from GRK3-deficient (*Grk3*<sup>-/-</sup>) and wildtype mice for evaluations of differentiation (chondrogenic, adipogenic, and osteogenic), CXCL12 secretion (ELISA), and proliferation (CCK8 assay). To better understand the functional differences noted with *Grk3*<sup>-/-</sup> BmMSCs, we investigated GPCR signaling through S1PR stimulation (ERK1/2 western blot). GRK3 β-arrestin recruitment to S1PR1 was demonstrated by TANGO, and S1PR1 internalization was determined by flow cytometry quantification of surface receptor expression.

**Results:** *Grk3*<sup>-/-</sup> BmMSCs have enhanced proliferation and osteogenic differentiation *ex vivo* compared to wildtype BmMSCs in identical culture conditions and passages. *Grk3*<sup>-/-</sup> BmMSCs also secrete more CXCL12, an essential chemokine for hematopoietic stem and progenitor development, and *Grk3*<sup>-/-</sup> mice have increased hematopoietic cell numbers isolated from the bone marrow. However, *Grk3*<sup>-/-</sup> mice do not show enhanced trabecular or cortical bone density, which suggest GRK3 deficiency in BmMSCs may have more pronounced effects on hematopoiesis as opposed to mature bone development *in vivo*. Both *Grk3*<sup>-/-</sup> BmMSC proliferation and osteogenic differentiation were reduced to wildtype level upon sphingosine kinase inhibitor treatment, and *Grk3*<sup>-/-</sup> BmMSCs have sustained ERK1/2 signaling upon stimulation of S1PR with S1P ligand. In addition, we report GRK3 recruits β-arrestin to the C-terminus of S1PR1, and we demonstrate

BmMSCs lacking GRK3 regulation have impaired S1PR1 internalization.

**Conclusion:** Our work suggests GRK3 regulates S1PR on BmMSCs and lack of such regulation induces increased cellular proliferation and osteogenic differentiation, indicating GRK3 may serve as a potential therapeutic target to alter BmMSC functionality.

## **Quality Controls Monitoring As Indicator of Stability in Bone and Cartilage Turnover Markers for Clinical Trials**

**Yannick Lhoste**, Vanessa Di Cataldo, Philippe Vergnaud and Tanja Schubert, Bioclinica Lab, LYON, France

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Protein biomarkers are widely used in clinical studies to assess drug efficacy, such as bone and cartilage turnover markers in osteoarthritis or rheumatoid arthritis clinical studies. In most of these clinical studies it is highly recommended to analyze as many visits, including all follow-up visits, at the same time, often requiring sample storage below -70°C for an extended period of time. Thus, determination of long-term stability of the biomarkers upon storage is critical.

Typically, long-term stability is measured in samples with a baseline assessment before storage in order to determine the nominal value. Subsequently, samples are assessed in the same condition at frequent intervals, covering different storage periods. However, this method requires numerous samples with a large volume, which is often challenging to obtain. Thus, we suggest an alternative approach by monitoring in-house quality control (QCs) as indication of analyte stability.

### **Methods:**

We investigated the long-term stability of the most widely analyzed serum biomarkers in musculoskeletal related clinical trials: carboxyterminal of type 1 collagen (S-CTX-I), osteocalcin (S-OC), aminoterminal propeptide of type 1 collagen (S-PINP), and metalloproteinases 3 and 9 (S-Total-MMP-3 and S-MMP-9). At least 12 serum samples were assayed at baseline and re-assayed after a storage period. Subsequent results were compared to baseline.

Additionally, we monitored the performance of our in-house QC samples for the same biomarkers and compared the data with the stability data previously determined. Urinary carboxyterminal telopeptide of type 2 collagen (U-CTX-II) long-term stability was assessed in samples after QC monitoring to validate our approach. QC monitoring was also performed for serum cartilage oligomeric matrix protein (S-COMP), another cartilage turnover marker.

An analyte is considered stable when the coefficient of variation (CV) and the accuracy (variation from target value) of the QC results are inferior to  $\pm 15\%$ .

### **Results:**

<b>CV (%)</b>	8.4	9
<b>Accuracy (%)</b>	-1.5	-2.6
<b>Stability indication</b>	Stable until 19 months	

#### Conclusion:

Assay analysis of protein biomarkers for clinical trials require a very stringent and robust quality process, which is based on the use of independent, endogenous QC samples throughout the complete duration of the clinical trial. We proved that long-term stability for biomarkers can be assessed by monitoring in-house QCs as confirmed by the U-CTX-II results.

Thus, based on the data obtained during QC monitoring for S-COMP we suggest that this marker is stable up to 19 months below -70°C. However, these data should be confirmed by a standard validation stability test.

## Irisin Ameliorates Infrapatellar Adiposity in Knee Osteoarthritis Pathogenesis By Orchestrating Adipokine Signaling

Feng-Sheng Wang<sup>1</sup>, Yi-Chih Sun<sup>1</sup> and Jih-Yang Ko<sup>2</sup>, <sup>1</sup>Core Facility for Phenomics & Diagnostics, Department of Medical Research, Core Facility for Phenomics & Diagnostics, Department of Medical Research, Kaohsiung Chang Gung Memorial Hospital, Taiwan, Kaohsiung, Taiwan, <sup>2</sup>Department of Orthopedic Surgery, Department of Orthopedic Surgery, Kaohsiung Chang Gung Memorial Hospital, Taiwan, Kaohsiung, Taiwan

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Aberrant infrapatellar fat metabolism is a prominent feature that exacerbates inflammation and fibrosis relative to joint deterioration during osteoarthritis (OA). Irisin, a secretory subunit of fibronectin type III domain containing 5 (FNDC5), is found to regulate adipose morphogenesis, energy expenditure, skeletal muscle, and bone metabolism. This study is undertaken to investigate the association of Irisin expression and end-stage knee OA and verify whether Irisin signaling changed infrapatellar fat remodeling and joint homeostasis in the progression of OA.

**Methods:** Injured articular specimens were harvested from 19 patients with end-stage knee OA and 11 patients with femoral neck fracture (non-OA) who required total hip arthroplasty. Knee joints in mice that overexpressed FNDC5 were subjected to suprapatellar injection of collagenase to provoke OA. Expressions of Irisin, adipokines, and MMPs were probed with RT-quantitative PCR. Infrapatellar adiposity, cartilage damage, and synovial integrity were verified with histomorphometry and immunohistochemistry. Irisin recombinant protein was produced for the treatment of collagenase-affected knees.

**Results:** Infrapatellar adipose and synovial tissues instead of articular cartilage exhibited distinguishable Irisin immunostaining. Injured specimens from the end-stage OA group showed 40% decline in Irisin expression compared with those in the non-OA group. In vitro, a gain of Irisin function enabled synovial fibroblasts but not chondrocytes to display minor responses to the IL-1 $\beta$  provocation of MMP3 and MMP9 expression. Of note, Irisin signaling enhancement resulted in 85% decrease in adipogenic gene expression and 65% reduction in adipocyte formation of mesenchymal progenitor cells. In collagenase-mediated knee OA pathogenesis, the FNDC5-overexpressing mice showed moderate responses to infrapatellar adipose hypertrophy concomitant with slight synovial hypercellularity and membrane hyperplasia within the affected joints. These adipose-regulatory actions warded off the affected knees from cartilage destruction and gait aberrance. Likewise, administration of Irisin recombinant protein mitigated the development of infrapatellar adiposity and synovitis, a remedial effect that slowed down the progression of articular cartilage erosion and walking profile irregularity. Affected joints and adipocytes responded to the Irisin recombinant protein treatment by reducing the expressions of cartilage-deleterious adipokines IL-6, leptin, and adiponectin through regulating PPAR $\gamma$  function.

**Conclusion:** Irisin dysfunction is relevant to the occurrence of end-stage knee OA. Irisin signaling protects from excessive adipogenesis of mesenchymal precursor cells and diminishes inflammation and cartilage catabolism actions aggravated by adipocytes and synovial cells. This study sheds an emerging new light on the Irisin signaling stabilization of infrapatellar adipose homeostasis and the prospective of the therapeutic potential of Irisin recombinant protein for deescalating knee OA development.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Opticin (OPTC) is a small leucine-rich proteoglycan (SLRP) that has been previously demonstrated to be produced and degraded in osteoarthritic (OA) human cartilage. Here, we further investigated the *in vivo* effect of OPTC deficiency in OA cartilage.

**Methods:** OA was induced in 10-week-old *Optc*<sup>-/-</sup> (knock-out) and *Optc*<sup>+/+</sup> (wild type) mice by destabilization of the medial meniscus (DMM). Ten weeks post-surgery, cartilage was processed for histology, and immunohistochemistry. SLRP expression was determined in non-operated mouse cartilage at day 3 (P03) and 10 weeks of age. Collagen ultrastructure was analyzed by transmission electron microscopy in 10-week-old non-operated mouse cartilage.

**Results:** OA *Optc*<sup>-/-</sup> mice demonstrated significant protection against cartilage degradation. Data revealed that in non-operated *Optc*<sup>-/-</sup> mouse cartilage, the SLRPs lumican and epiphykan were significantly up-regulated at P03 ( $p \leq 0.010$ ) and 10 weeks old ( $p \leq 0.007$ ), and fibromodulin down-regulated at 10 weeks of age ( $p \leq 0.001$ ). Immunohistochemistry of OA mice showed a similar pattern. In OA *Optc*<sup>-/-</sup> mouse cartilage, markers of cartilage degradation and complement factors C5b-9 and CCL2 were all down-regulated ( $p \leq 0.050$ ). In *Optc*<sup>-/-</sup> mouse cartilage, collagen fibers were thinner and better organized ( $p = 0.038$ ) than in OA *Optc*<sup>+/+</sup> mouse cartilage.

**Conclusion:** This work demonstrates a protective effect of OPTC deficiency during OA, resulting from an overexpression of lumican and epiphykan, known to bind and protect collagen fibers, and a decrease in fibromodulin, contributing to a reduction in the complement activation/inflammatory process. This work suggests that the evaluation of the composition of the different SLRPs in OA cartilage could be applied as a new tool for OA prognosis classification.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Rheumatoid arthritis (RA) is an inflammatory disease that is characterized by chronic inflammation and bone destruction. Osteoclasts, which are bone-resorbing cells, are generally known to play a pivotal role in the pathogenesis of bone destruction in RA. Poly- $\gamma$ -glutamic acid ( $\gamma$ -PGA), a natural polymer derived from *Bacillus subtilis*, has anti-inflammatory activity. It is mediated by suppressing differentiation of Th17 cells in asthma model. However, the effects of  $\gamma$ -PGA in RA osteoclast differentiation is unclear. Therefore, we evaluated whether  $\gamma$ -PGA prevents inflammation and joint damage of RA by regulating osteoclast differentiation in human and mice.

## Methods:

We tested the inhibitory effect of  $\gamma$ -PGA on osteoclastogenesis in healthy human peripheral blood monocytes, RA synovial fluid macrophages, and mouse bone-marrow-derived macrophages (BMMs). The osteoclastogenesis was assessed by generation of TRAP-positive multinucleated cells and actin ring formation. We analyzed the expressions of essential genes and proteins for osteoclast differentiation by real-time PCR and western blot analysis. We observed whether treatment of  $\gamma$ -PGA efficiently reduces osteoclast formation and bone destruction in animal model of rheumatoid arthritis (collagen-induced arthritis [CIA] in DBA/1J mice).

## Results:

Firstly, we showed that  $\gamma$ -PGA strongly inhibits osteoclast differentiation in normal PBMC-derived osteoclast precursors and RA synovial fluid macrophages.  $\gamma$ -PGA suppressed RANK mRNA and protein level by down-regulating of M-CSF receptor protein, which is required for RANK expression. Furthermore, we found that *in vitro*, treatment with  $\gamma$ -PGA suppressed osteoclastogenesis in wild-type (WT) mice, but the inhibition mechanism of  $\gamma$ -PGA was not TLR4-dependent since  $\gamma$ -PGA still inhibited osteoclast formation in TLR4-deficient mouse BMMs. Reflecting on these *in vitro* effects, oral administration of  $\gamma$ -PGA markedly reduced bone destruction in CIA mice. Histological analysis confirmed that  $\gamma$ -PGA prevented bone destruction and osteoclast formation in the bone tissues. In addition, treatment with  $\gamma$ -PGA also suppressed the expressions of IL-1 $\beta$  and TNF- $\alpha$ .

## Conclusion:

Our results show that  $\gamma$ -PGA markedly suppresses osteoclastogenesis in human and mice.  $\gamma$ -PGA also reduces bone destruction, osteoclast formation, and inflammatory cytokines in animal model of RA. Thus, these data suggest that  $\gamma$ -PGA can be a good candidate for the therapeutic application of joint destruction in RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Atraumatic osteonecrosis (ON) results from reduced bone vascularity. Glucocorticoids (GC) are a major risk factor for ON, as GCs reduce vascular endothelial growth factor, vascular density, and bone mass [Mohan et al CTI 2017]. Mice treated with GCs and either PTH or LLP2A-Ale, a bone targeted therapy that directs mesenchymal stem cells to bone surfaces, showed significantly less GC-induced bone mass changes. The aim of this study was to determine if PTH or LLP2A-Ale co-treatment could prevent or reduce the severity of GC-induced ON.

**Methods:** Seven-week-old male BALB/c mice were randomized into placebo (PL), PL+GC (4 mg/L dexamethasone in drinking water),

GC+250 µg/kg or GC+500 µg/kg LLP2A-Ale (subcutaneous (SC), 1X/2 wks), or GC+40 µg/kg PTH (hPTH(1-34), 5x/wk, SC) (n=8 for PL and 16 for all GC groups). Mice were sacrificed on Day 30 or Day 45. Both distal femurs (DF) from each mouse were decalcified, and coronal sections were made and stained with H&E. ON was identified in the DF epiphysis (DFE) using modified criteria [Yang et al., JOR, 2009] (presence of empty osteocyte lacunae, nuclear pyknosis, ghost osteocytes in bone trabeculae, bone marrow/stromal necrosis, > 30% fat in marrow, and fibrin thrombi in blood vessels). ON was diagnosed when three or more of the above features were seen, by three independent, blinded observers, with >80% agreement. Immunohistochemical staining for blood vessels was performed on the DFE using CD31 and endomucin antibodies.

**Results:** PL+GC mice had 15-20% lower body weight than PL ( $p<0.05$ ). At Day 30, ON prevalence was 18%, 6%, 0% and 6%, respectively, in PL+GC, GC+LLP2A-Ale (250), GC+LLP2A-Ale (500) and GC+PTH groups. At Day 45, ON prevalence was 81%, 25%, 18% and 12%, respectively, in PL+GC, GC+LLP2A-Ale (250), GC+LLP2A-Ale (500), and GC+PTH. Blood vessels (anti-CD31/endomucin) appeared more intact in GC+LLP2A-Ale and GC+PTH groups than in PL+GC at both times ( $p<0.05$ ). At Day 45, both GC+LLP2A-Ale and GC+PTH groups had 50% greater sinusoid density, and 50% lower adipocyte density at the DFE compared to PL+GC alone ( $p<0.05$ ).

**Conclusion:** Co-treatment of murine GC-induced ON with PTH or LLP2A-Ale reduced the prevalence of ON after 45 days. Additional studies to ascertain the mechanism by which these agents prevent GC-induced ON are warranted.

## Nrf2 Inhibits Apoptosis and Suppresses Oxidative Stress By Activating NOX4/ERK1/2/ELK1 Signaling Axis in Human Chondrocytes

Mohammad N. Khan<sup>1</sup>, Imran Ahmad<sup>1</sup>, Mohammad Y Ansari<sup>2</sup> and Tariq M Haqqi<sup>1</sup>, <sup>1</sup>Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH, <sup>2</sup>Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nrf2 is a redox sensitive transcription factor that regulates the expression of phase II antioxidant enzymes and cytoprotective genes and is crucial for maintaining the cartilage integrity. However, mechanisms underlying the cartilage/chondroprotective effects of Nrf2 remains largely unknown. Here, we examined the critical role of Nrf2 in protecting human OA chondrocytes against oxidative damage and induction of apoptosis under pathological conditions.

## Methods:

Deidentified and discarded OA cartilage was obtained at the time of total joint arthroplasty and chondrocytes were prepared by enzymatic digestion. qRT-PCR and immunoblotting with validated antibodies were used to assess the gene and protein expression respectively. Nrf2 activation was determined by luciferase reporter assay. Chondrocytes were transfected with Nrf2 overexpression plasmid, ARE reporter vector or siRNAs using nucleofection. ROS levels were measured by H<sub>2</sub>DCF-DA staining. Apoptosis was measured by TUNEL assay. Agarose gel electrophoresis was used to analyze DNA fragmentation.

## Results:

Expression of Nrf2 and its downstream targets HO-1, NQO1, and SOD2 was significantly higher in damaged OA cartilage compared with the smooth cartilage of the same patient. A luciferase reporter assay demonstrated that IL-1 $\beta$ -stimulation was a potent inducer of Nrf2 activity in OA chondrocytes. Interestingly, pretreatment of OA chondrocytes with antioxidants significantly inhibited the IL-1 $\beta$ -mediated activation of Nrf2/ARE signaling indicating that the activity was due to oxidative stress. Over-expression of Nrf2 in OA chondrocytes significantly suppressed the IL-1 $\beta$ -mediated generation of ROS, production of H<sub>2</sub>O<sub>2</sub> and expression of NOX4 whereas Nrf2 knockdown significantly enhanced the basal as well as induced levels of ROS and expression of NOX4. OA chondrocytes with overexpression of Nrf2 showed inhibition of both the extrinsic and intrinsic apoptotic pathways as IL-1 $\beta$ -induced DNA fragmentation, activation of Caspase-3, cleavage of PARP, cleavage of Caspase-8,-9, release of cytochrome-c, suppression of mitochondrial ROS production and mitochondrial dysfunction were not observed. Further, enhanced expression of Nrf2 stimulated the expression of anti-apoptotic proteins-Bcl2, Bcl-xl and Mcl-1 and significantly suppressed the expression of pro-apoptotic proteins-Bax, Bad and Bid in IL-1 $\beta$  stimulated OA chondrocytes. Nrf2 overexpression enhanced the phosphorylation of ERK1/2 and its downstream target proteins-Elk-1, P70S6K and P90RSK in OA chondrocytes, whereas pharmacological inhibition of ERK1/2 activation enhanced the ROS generation and increased apoptosis in IL-1 $\beta$ -stimulated OA chondrocytes.

**Conclusion:** Taken together, these results show that Nrf2 is a stress response protein in OA chondrocytes with an anti-apoptotic function. IL-1 $\beta$ -induced stress causes activation of Nrf2 which activates the ERK1/2/ELK1-P70S6K-P90RSK signaling pathway to inhibit apoptosis of OA chondrocytes. These activities of Nrf2 make it a promising candidate for the development of novel therapies for the management of OA.

## Baicalein, a Plant-Derived Small Molecule, Activate Nrf2/Autophagy Signaling Axis Via MEK1/2-ERK1/2-Elk1 Pathway to Suppress the Expression of IL-6 in Human Osteoarthritis Chondrocytes

Mohammad N. Khan<sup>1</sup>, Imran Ahmad<sup>1</sup>, Mohammad Y. Ansari<sup>2</sup> and Tariq M Haqqi<sup>1</sup>, <sup>1</sup>Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH, <sup>2</sup>Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inflammation is an important component of osteoarthritis (OA) pathogenesis. IL-6 is implicated in OA pathogenesis as it suppresses anabolic factors and upregulate the expression of catabolic proteins. Here, we used an *in vitro* model of inflammation in OA to investigate the potential of Baicalein, a natural flavonoid found in root extract of *Scutellaria baicalensis*, to suppress the expression of IL-6 and determined the molecular mechanism by investigating the role of Nrf2 and autophagy activation in human OA chondrocytes.

**Methods:** Primary human OA chondrocytes were prepared by enzymatic digestion of deidentified and discarded cartilage from donors with OA who underwent total knee arthroplasty. Autophagy activation was investigated by immunoblotting for LC3-I and LC3-II, ATG5, autophagic flux and immunofluorescence staining for LC3 puncta. Expression and activation of Nrf2 was determined by immunoblotting and by a luciferase reporter assay, respectively. mRNA and protein expression of Nrf2 regulated genes HO-1, NQO1, SOD2 was studied by qPCR and immunoblotting, respectively. Total protein levels and activation of ERK1/2 and its upstream and downstream signaling molecules was assayed by immunoblotting. For molecular docking studies using the Glide tool in Schrödinger Maestro suite, the crystal structure of

Keap1 protein in complex with a small chemical compound K67 (PDB CODE: 4ZY3) was extracted from the Protein Data Bank and used as docking structure template.

## Results:

OA chondrocytes showed high levels of IL-6 expression upon stimulation with IL-1 $\beta$ . However, pre-treatment of OA chondrocytes with Baicalein, in a dose dependent manner, abolished the IL-1 $\beta$ -induced upregulation of IL-6 expression. Baicalein induced macro-autophagy in OA chondrocytes *in vitro* as indicated by significantly ( $p < 0.05$ ) increased expression of LC3, ATG5, ATG3, enhanced autophagy flux and increased number of autophagic puncta in OA chondrocytes. Baicalein treated OA chondrocytes also showed enhanced activity of Nrf2/ARE as revealed by a Nrf2/ARE reporter assay. Molecular docking studies indicated that Baicalein activates Nrf2 by disrupting the Keap-1/Nrf-2 interaction by blocking the Nrf-2 binding site in the Keap-1 protein. Additionally, OA chondrocytes treated with Baicalein, and in a dose dependent manner, showed enhanced expression, both at mRNA and protein levels, of Nrf2 target genes HO-1, NQO1, and SOD2. We next determined the molecular events involved in Baicalein mediated activation of Nrf2 and it was found that treatment of OA chondrocytes with Baicalein activated MEK1/2-ERK1/2-Elk-1 signaling in a time dependent manner. Inhibition of ERK1/2 activation or inhibition of autophagy using small molecules or siRNA mediated depletion of target genes expression abolished the protective effects of Baicalein in OA chondrocytes under pathological conditions.

**Conclusion:** The present study indicates that Baicalein act, at least in part, by activating Nrf2/autophagy axis and increased expression of HO-1, NQO1 and SOD2 in OA chondrocytes. This property indicates that Baicalein could be developed as an effective adjunct therapy for the suppression of OA pathogenesis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

12/15-Lipoxygenase (12/15-LOX) catalyzes the generation of various anti-inflammatory lipid mediators, and has been implicated in several inflammatory and degenerative diseases. However, there is currently no evidence that 12/15-LOX has a role in osteoarthritis (OA). The aim of this study was to investigate the role of 12/15-LOX in the pathogenesis of OA.

### Methods:

The development of aging-associated and destabilization of the medial meniscus (DMM)-induced OA were compared in 12/15-LOX-deficient (12/15-LOX<sup>-/-</sup>) and wild-type (WT) mice. The extent of cartilage damage was evaluated by histology. The expression of OA markers was evaluated by immunohistochemistry and RT-PCR. Cartilage explants were stimulated with IL-1 $\alpha$  in the absence or presence of the 12/15-LOX metabolites, 15-HETE, 13-HODE or LXA4, and the levels of MMP-13, NO and PGE<sub>2</sub> were determined. The effect of LXA4 on the progression of OA was evaluated in WT mice.

### Results:

The expression of 12/15-LOX in cartilage increased during the progression of DMM-induced OA and with aging in WT mice. Cartilage degeneration was more severe in 12/15-LOX<sup>-/-</sup> mice compared to WT mice in both models of OA, and this was associated with increased

expression of MMP-13, ADAMTS5, iNOS, and mPGES-1. Treatment of cartilage explants with 12/15-LOX metabolites, suppressed IL-1 $\alpha$ -induced production of MMP-13, NO and PGE<sub>2</sub>, with LXA4 being the most potent. Intra-peritoneal injection of LXA4 reduced the severity of DMM-induced cartilage degradation.

#### Conclusion:

These data suggest an important role of 12/15-LOX in the pathogenesis of OA. They also suggest that activation of this pathway may provide a novel strategy for prevention and treatment of OA.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cartilage lesions due to traumatic or pathological conditions slowly grow over the time and may lead to osteoarthritis (OA). As a prospective treatment for such lesions, it has been shown that human-derived induced pluripotent stem cells (iPSCs) can be 3D bioprinted and directed to form cartilage-like tissue (Nguyen *et al.* 2017). The advantages of using an established iPSC line are unlimited cell source with regeneration capacity and chondrogenic differentiation potential. The aim of this study was to improve the generation of cartilage-like tissue when 3D bioprinting of iPSCs by using molecularly modified nanocellulose/alginate bioink to resemble natural environment found in the tissue.

**Methods:** In this study the chondrocyte-derived iPSC line “A2B” was used (Borestrom *et al.* 2014). These cells were bioprinted in combination with a modified bioink composed by nanocellulose and alginate. One week after bioprinting, the constructs were cultured in chondrogenic medium in order to stimulate cell differentiation towards chondrocytes. Cell number and viability was studied. Histological analyses of the 3D printed constructs were performed. Furthermore, expression of pluripotency and chondrogenic specific genes was assessed by Taqman qPCR before and after differentiation.

**Results:** High viability of the iPSCs inside the constructs was found after bioprinting. 3D printed constructs were positively stained for alcian blue van gieson staining, showing proteoglycans presence inside the prints. Molecular analyses showed high relative expression levels of the pluripotency-related gene Oct4 before initiating the differentiation protocol. Cells inside the constructs express chondrogenic specific genes, such as collagen type 2 and Sox9 after 6 weeks of differentiation. Moreover, 3D printed constructs showed cartilage-resembles (Figure 1).

**Conclusion :** Modified Nanocellulose/alginate bioink allowed 3D printing of the iPSCs and the *in vitro* generation of cartilage-like tissue. This approach could be used in the future to model OA disease or to perform screenings of different therapeutic compounds.

## Abaloparatide, a Novel PTHrP Analog, Increased Bone Mass and Density at Cortical and Trabecular Sites in an Orchiectomized Rat Model of Male Osteoporosis

Heidi Chandler<sup>1</sup> and Gary Hattersley<sup>2</sup>, <sup>1</sup>Research, Radius Health Inc, Waltham, MA, <sup>2</sup>Radius Health, Inc., Waltham, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Male osteoporosis, a disease of reduced bone mass leading to an increased risk of fragility fractures, often results from androgen deficiency caused by hypogonadism or androgen deprivation therapy. Abaloparatide (ABL) is an anabolic PTHrP analog that reduced the incidence of new vertebral and nonvertebral in postmenopausal women with osteoporosis at a high risk for fractures by increasing bone formation and bone mineral density (BMD)<sup>1</sup>. These attributes suggest ABL may have utility for increasing bone mass and strength in men with osteoporosis. The effects of ABL on bone mass were studied in orchiectomized (ORX) rats, a commonly used preclinical model of male osteoporosis.

**Methods:** 40 Male SD rats underwent sham or ORX surgery at 4 months of age. After an 8-week bone depletion period, ORX rats received vehicle (VEH) or ABL at 5 (ABL5) or 25 (ABL25) µg/kg/d by daily sc injection for 8 weeks (n = 10/group), while sham controls (n = 10) received VEH. Animals underwent dual X-ray absorptiometry (DXA) and peripheral quantitative computed tomography (pQCT) scans after 0, 4, and 8 weeks of treatment, followed by necropsy.

**Results:** DXA conducted 8 weeks after surgery showed the VEH group had significantly lower areal bone mineral content (aBMC) and density (aBMD) at the whole body, lumbar spine, total femur, and proximal femur (including the hip) vs Sham controls, indicating ORX-induced osteopenia at the treatment baseline (BL). Between BL and week 8, whole body aBMD increased by 13.8% and 17.3% in the ABL5 and ABL25 groups, respectively, versus 6.3% in VEH controls (both  $P < 0.001$ ). Lumbar spine aBMD increased from BL to week 8 by 24.5% and 29.1% in the ABL5 and ABL25 groups, versus 7.6% in VEH controls (both  $P < 0.001$ ). Total femur aBMD increased by 19.3% and 26.0% from BL to week 8 in the ABL5 and ABL25 groups, versus 7.2% in VEH controls (both  $P < 0.001$ ). Proximal femur aBMD (including the hip) increased from BL to week 8 by 16.9% and 23.2% in the ABL5 and ABL25 groups, vs 5.0% in VEH controls (both  $P < 0.001$ ). By treatment week 8, aBMD values for all four of these sites in the ABL5 and/or ABL25 groups were fully restored to the levels of Sham controls. pQCT of the tibial diaphysis showed significantly greater gains from BL to week 8 in cortical thickness for the ABL5 (7.3%) and ABL25 (7.1%) groups compared with VEH controls (0.9%; both  $P < 0.05$ ). Tibial diaphysis cortical volumetric BMC (vBMC) was also significantly increased from BL to week 8 in the ABL5 (11.7%) and ABL25 (13.2%) groups compared with VEH controls (6.3%; both  $P < 0.05$ ). pQCT of the proximal tibial metaphysis showed greater gains in trabecular vBMD in the ABL5 (96.4%) and ABL25 (163.0%) groups from BL to week 8 compared with VEH controls (6.9%; both  $P < 0.05$ ).

**Conclusion:** Androgen deficiency via ORX led to significant deficits in bone mass for the whole body and for axial and appendicular sites in mature male rats. Abaloparatide fully reversed the ORX-related deficit in whole body bone mass by promoting the accrual of cortical and trabecular bone. These data provide preclinical support for investigations into the effects of abaloparatide in men with osteoporosis.

## Low and Moderate Intensity Exercise Suppresses Inflammatory Responses in an Acute Mouse Model of Gout and Suggests Therapeutic Efficacy

Nicholas A. Young<sup>1</sup>, Kyle Jablonski<sup>2</sup>, Juhi Sharma<sup>1</sup>, Evelyn Thomas<sup>1</sup>, Brian Snoad<sup>1</sup>, Jeffrey Hampton<sup>3</sup>, Wael Jarjour<sup>1</sup> and Naomi Schlesinger<sup>4</sup>, <sup>1</sup>Department of Internal Medicine, Division of Immunology and Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH, <sup>2</sup>The Ohio State University Wexner Medical Center, Columbus, OH, <sup>3</sup>Immunology and Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH, <sup>4</sup>Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

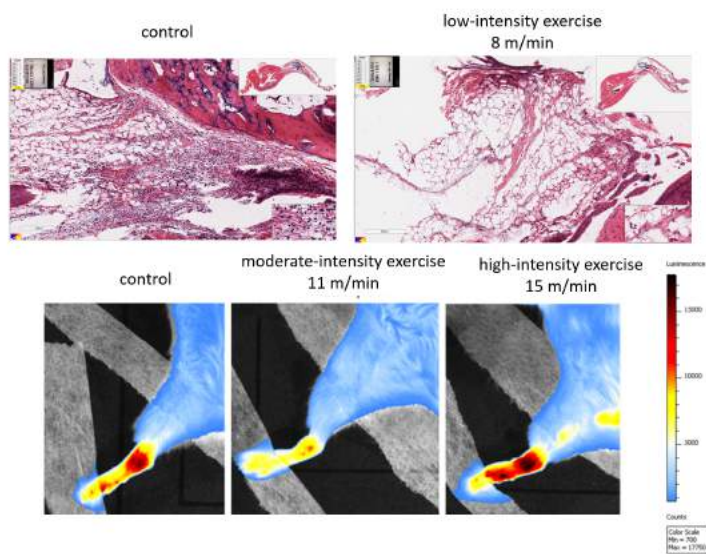

**Background/Purpose:** Little is known regarding the potential benefits of exercise on managing acute gout. Consequently, recent clinical practice guidelines released by the American College of Rheumatology (2012) and the American College of Physicians (2016) contain no recommendations regarding exercise in gout patients. Currently, many rheumatologists recommend resting the involved joints during an acute attack based on animal studies performed nearly a half century ago. Since the potential for exercise to suppress gouty inflammation is an area of study that has yet to be researched sufficiently, the aim of this study was to determine the efficacy of exercise in an acute mouse model.

**Methods:** BALB/C-Tg(NFκB-RE-luc)-Xen mice, which contain a firefly luciferase cDNA reporter gene under the regulation of NFκB, were exercised by daily treadmill walking (45 min/day for 2 weeks) at low intensity (35% VO<sub>2</sub>max; 8 m/min), moderate intensity (55% VO<sub>2</sub>max; 11 m/min), and high intensity (75% VO<sub>2</sub>max; 15 m/min). At the end of the 2 week conditioning period, monosodium urate (MSU) crystal-induced arthritis was induced by intra-articular injection of MSU (0.5 mg) into the tibio-tarsal joint (ankle) under anesthesia. Localized NFκB activity was measured using the Xenogen *in vivo* imaging system (IVIS 200). Serum was collected to measure cytokine expression and tissue was collected for histological analysis.

**Results:** Histopathology of feet/ankle regions demonstrated a decrease in cellular infiltrate into the joint spaces by H&E staining and a marked decrease in macrophage and neutrophils, as indicated by immunohistochemistry and quantification in mice exercised at low intensity (8 m/min) when compared to non-exercised controls. Low intensity exercise also significantly suppressed serum expression of IL-12, KC/GRO, TNF-α, and IL-6 in MSU-induced gout mice relative to non-exercised and wild-type controls. Caliper measurements of foot pads revealed a significant reduction in swelling with both low and moderate exercise when compared to non-exercised controls, while no difference was observed with high intensity exercise. Additionally, IVIS measurements of the injected ankles demonstrated that NFκB activity was significantly reduced with low and moderate exercise, but slightly elevated following the high intensity regimen relative to non-exercised control mice.

**Conclusion:** Our results from an acute gout mouse model suggest that low and moderate exercise may be effective in decreasing gouty inflammation. Thus, these data could support a change in the conventional exercise recommendations provided by Rheumatologists in gout patients. Further studies are needed to more comprehensively evaluate this potentially important observation and to elucidate the mechanism responsible for this observation.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

To use *in vivo* multimodal [<sup>18</sup>F]FDG (fluoro-D-glucose, tracer for inflammation) and [<sup>18</sup>F]Sodium Fluoride (bone tracer) positron emission tomography/computed tomography (PET-CT) imaging for the monitoring of systemic inflammatory and bone remodeling processes as well as colocalized bone destructions before and after TNF blockade in human tumor necrosis factor transgenic (hTNFtg) mice, an established mouse model of chronic inflammatory, erosive polyarthritis.

### Methods:

8 week-old hTNFtg mice were treated with anti-TNF antibodies (Infliximab, i.p., 3x times per week, 10mg/kg body weight) for 4 weeks. Before and after the treatment period mice received [<sup>18</sup>F]FDG or [<sup>18</sup>F]Sodium Fluoride (~25MBq) static PET scans (45min post injection) followed by whole-body and high resolution leg CT scans (800kV, 500μA, 800ms, 360 projections) using an Inveon PET/CT/SPECT multimodality system (Siemens Medical Solutions). PET reconstructions were conducted with OSEM3D/MAP, FBP algorithm. Standard uptake values (SUV) were calculated using PMOD software. Radiographic damage score was evaluated by *in vivo* CTs using InveonResearchWorkplace software. Joints were further analyzed by *ex vivo* μCT scans (Scanco μCT35) and H&E, TRAP and TB stained paraffin-sections.

**Results:** Before therapeutic intervention, we observed an increased accumulation of [<sup>18</sup>F]FDG in various joints of hTNFtg mice including knees, ankles and shoulders compared to wt littermates indicating ongoing systemic inflammatory processes. Moreover, existing bone destructions were detected by *in vivo*CTs. However, [<sup>18</sup>F]SodiumFluoride was equally accumulated within bone tissues such as long bones, in particular at growth plates, and vertebrae between both genotypes. After four weeks, placebo-treated hTNFtg animals showed significantly increased [<sup>18</sup>F]FDG SUVs as well as progressive bone destruction in knees, ankles and shoulders as shown by *in vivo*CTs. In contrast, TNF-blockade led to a significant decrease in [<sup>18</sup>F]FDG SUVs supposing complete resolution of inflammatory processes in those individuals. Comparison of repeated *in vivo*CT images demonstrated a significant reduction in radiographic bone damage score and reversal of existing bone destructions upon TNF blockade. Histological analysis demonstrated regeneration processes of former bone erosion sites present as refillings of cartilaginous or fibro-cartilaginous tissue as well as signs of endochondral ossifications or even intact bone surfaces upon TNF blockade. Surprisingly, we found no marked changes in [<sup>18</sup>F]Fluoride SUVs in joints between both hTNFtg groups and wt mice suggesting that age-related high [<sup>18</sup>F]Fluoride accumulations in growth plates interfere, thus preventing to monitor inflammatory bone damage.

**Conclusion:** *In vivo* small animal multimodal [<sup>18</sup>F]FDG, but not [<sup>18</sup>F]Fluoride, PET-CT imaging provides an objective, non-invasive imaging tool for the longitudinal monitoring of (I) reversibility of ongoing inflammatory processes in various joints and (II) regeneration of existing bone erosions during therapeutic intervention in TNF-driven experimental arthritis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Nerve growth factor (NGF) is a key regulator of pain and anti-NGF therapy reduces osteoarthritis (OA) associated pain. However, anti-NGF therapy is associated with rapidly progressive OA (RPOA) [1]. In hip OA there is a 5-fold increase in mesenchymal stem cells (MSCs) from MRI bone marrow (BM) lesions, areas associated with OA progression [2]. MSCs in such lesions are uniformly positive for the NGF receptor, p75, which is also linked to chemotaxis and proliferation in other stromal cell compartments [3]. We therefore sought to evaluate anti-NGF treatment in monoiodoacetate (MIA) induced OA and test whether NGF influences human BM- MSC function.

## Methods:

Human tibial plateau (TP) bone was isolated from patients undergoing total knee replacement. OA was induced in male Wistar rats (n=6) by intra-articular injection of 0.3 mg MIA. Each animal was treated with subcutaneous injection of control human IgG or anti-NGF (3 mg/kg) on Days 30, 35, 39, 45 and 50. Human and animal tissues sections were prepared for histological analysis using H&E staining and immunohistochemistry (IHC) using anti-p75 and anti-NGF antibodies. BM-MSCs were isolated from iliac crest aspirates and cultured under normal conditions. Expression of p75 was induced following overnight incubation with 400mM ethanol (EtOH) and confirmed by flow cytometry. Proliferation and chemotaxis was assessed with and without induction of p75 and in the presence of 0-1 µg/ml NGF.

## Results:

Regions adjacent to cartilage loss in human TP showed abundant stromal proliferation, NGF and p75 immunoreactivity. In the MIA model, by Day 28 there was substantial loss of cartilage, bone remodelling and stromal proliferation mimicking human disease and animals demonstrated unequal weight-bearing ( $p<0.05$ ). Anti-NGF provided sufficient analgesia to normalise weight-bearing by Day 42. Features associated with joint damage and MIA treatment such as fibrogranular reactions and palisading osteoblasts were strongly p75 immunopositive. NGF positive staining was widespread in naïve and MIA-injected knees. To investigate increased p75 positivity in knee OA, we restored p75 expression loss in expanded cell, to 97% of BM-MSCs (n=3) using EtOH. Increased MSC proliferation was seen at Days 6 and 9 (26%,  $p=0.03$  and 30%,  $p=0.01$  increase respectively, n=7) for 1 µg/ml NGF in the presence of EtOH compared to control (no NGF). In cultures without EtOH induction (absent p75) NGF had no effect. NGF was not chemotactic for MSCs with or without the induction of p75.

## Conclusion:

TP bone from OA patients and rat MIA-treated subchondral bone contains p75 positive staining in regions of cartilage destruction and associated NGF positivity. In vitro, NGF increased BM-MSC proliferation, suggesting NGF may be involved in the stromal proliferation seen at sites of OA damage. Thus, NGF may regulate MSC function. Complete blockade represents a novel mechanism for accelerated joint destruction in OA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Micro RNAs (miRNAs) play a crucial role in the regulation of bone metabolism. MiR-146a, an important anti-inflammatory miRNA, was found to negatively impact osteogenesis and bone regeneration *in vitro*, by controlling the differentiation of mesenchymal stem cells. But to date the role of miR-146a in bone remodelling, its influence on bone stability and development of osteoporosis is not known.

## Methods:

Systemic bone, tibiae and femur, of wt and miR-146a deficient animals was assessed histologically and via  $\mu$ CT analysis, over a period of 3 to 18 months of age. Serum cytokine levels were analysed by Elisa. MRNA expression levels in bone were analysed by qPCR. To induce osteoporosis, ovariectomy (OVX) induced bone loss was performed.

## Results:

When we analysed bone volume of long bones histologically as well as with  $\mu$ CT analysis we detected significantly increased trabecular bone mass in miR-146a deficient compared to wt animals, starting at an age of 6 months. However, cortical thickness of systemic bones from miR-146a knock out animals was significantly reduced compared to control mice. Analysis of serum in aged miR-146a deficient animals displayed elevated activity of bone resorbing osteoclasts as amounts of CTX I in miR-146a<sup>-/-</sup> mice were significantly increased compared to wt animals. Q-PCR analysis of important osteoclast as well as osteoblast marker genes in bones *ex vivo* displayed elevated expression of signature molecules of both cell types in aged miR-146a deficient mice, suggesting a regulatory role of miR-146a in both osteoclasts as well as osteoblasts. When we induced osteoporosis using the OVX disease model, histological analysis of long bones showed significant trabecular bone loss in ovariectomized wt mice. In contrast, we detected no trabecular bone loss in ovariectomized miR-146a knock out animals, suggesting that loss of miR-146a deficiency protects bone loss induced by estrogen deficiency.

## Conclusion:

MiR-146a seems to control bone turnover and miR-146a deficient mice accrue bone over time. Moreover this miRNA has a negative influence on bone loss occurring during oestrogen loss induced osteoporosis. Therefore miR-146a could be possibly used as a therapeutic target in the treatment of osteoporosis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis (OA) is the most common form of arthritis, affecting nearly 10% of the US population. There is no therapy to prevent the progression of or reverse OA pathology. Endogenous adenosine 2A receptor (A2AR) stimulation is crucial for chondrocyte viability and cartilage homeostasis as its downstream signaling mediates inflammation. In recent preliminary studies we have found that mice lacking the A2AR or ecto-5' nucleotidase (CD73, an ectoenzyme critical for extracellular adenosine production) develop spontaneous OA. These findings suggest that diminished extracellular adenosine levels promote the development of OA. Since human OA chondrocytes have been found to have diminished mitochondrial content, we propose to test the hypothesis that OA pathogenesis deregulates A2AR signaling at least in part by affecting the cell's capacity for ATP production via reduced number or functionality of mitochondria.

**Methods:** A human chondrocyte cell line, TC28a2, was used to determine the effects of IL1B-induced inflammation and A2AR stimulation *in vitro*. Cells were treated with IL1B (5ng/mL) and with the A2AR-specific agonist, CGS21680 (CGS; 1uM). Mitochondrial content was measured by mtDNA to nDNA ratios and MitoTracker mean cellular intensity. Mitochondrial health and functionality was assessed by mean pixel intensity (MPI) of a fluorescent probe for monitoring mitochondrial membrane potential, TMRM, and by measuring oxygen consumption rates (OCR) on Seahorse Mito Stress Kit Assays. The role of A2AR ligation on mitochondrial health was also studied by histology for 8hydroxyguanosine (8OH-G) residues as a marker for reactive oxygen species (ROS) in A2ARKO mice and Sprague Dawley rats that underwent ACL rupture (post-traumatic OA model) and subsequently received CGS-filled liposomal injections.

**Results:** A2AR agonism increases mitochondrial content *in vitro*. IL1B incubation for 3 hours followed by A2AR ligation increases mitochondrial membrane potential ( $2867 \pm 165.5$  MPI) compared to control ( $1582 \pm 183.9$  MPI), IL1B alone ( $1483 \pm 120.6$  MPI) and CGS alone ( $1788 \pm 137.8$  MPI) as measured by TMRM staining ( $p \leq 0.0001$ ). IL1B incubation for 4 hours with a last hour of A2AR stimulation increases basal oxygen consumption rate and maximal respiratory rate. IL1B+CGS treated cells had significantly increased ATP production ( $113.04 \pm 13.44$  of OCR) than the control ( $83.86 \pm 11.89$  of OCR), IL1B ( $81.00 \pm 12.80$  of OCR) and CGS ( $76.04 \pm 23.52$  of OCR) treated cells as measured by one-way ANOVA ( $p$  values =  $0.0088$ ,  $0.0128$ , and  $0.0259$  respectively). A2ARKO mice exhibit increased 8OG-G staining in histology as early as 8 weeks. A2AR stimulation after ACL rupture in rats, results in preserved cartilage volumes, improved OARS scores ( $p < 0.001$ ) and reduced ROS as seen by reduced 8OH-G staining in histology.

**Conclusion:** A2AR ligation improves mitochondrial functionality during inflammation and OA progression. Increased mitochondrial function is not seen when the chondrocytes are treated with IL1B or CGS alone; perhaps suggesting that A2AR stimulation is necessary to maintain homeostasis when cells are already under physiological or pathological stress.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Some but not all antibodies against citrullinated modified proteins (ACPA) promote osteoclastogenesis and bone destruction *in vitro* and *in vivo*. We aimed to investigate the ACPA specificity pattern that is related to this effect and if this effect is limited to ACPA or encompasses also other RA-associated antibodies.

### Methods:

Polyclonal ACPA IgG and IgGs others than ACPA were obtained from the peripheral blood of RA patients by purification on a G column followed by an anti-CCP2 column. Monoclonal ACPA, anti-MDA and rheumatoid factor (RF) IgGs were generated from either single plasma cells isolated from the synovial fluid or tetramer-positive sorted single B-cell isolated from the plasma of RA patients. Osteoclasts were generated from CD14<sup>+</sup> monocytes of healthy individuals or bone marrow cells of Fc gamma III or Fc gamma chain knockout mice, in the presence or absence of polyclonal ACPA, monoclonal antibodies (ACPA, and anti-MDA antibodies and RF) and IgG controls. TRAP positive multinucleated cells were counted and bone erosion assay was done in parallel.

### Results:

Polyclonal ACPA increased osteoclastogenesis, by a fold of  $1.6 \pm 0.03$ . One out of 4 tested plasma cell derived monoclonal ACPAs and one out of the five tested tetramer positive B-cell derived monoclonals have similar effects (with a fold increase of  $1.63 \pm 0.15$  for the plasma cell derived antibody and  $1.4 \pm 0.16$  for the tetramer positive B-cell derived) have similar OC effects. Two additional tetramer positive B-cell derived monoclonals inhibited osteoclastogenesis while the remaining had no significant effect. All monoclonal ACPA were relatively highly cross-reactive to several citrullinated epitopes but not to native arginine peptides. Anti-MDA monoclonal antibodies displaying somatic hypermutations and low reactivity had significant *in vitro* functional properties and enhanced osteoclastogenesis (fold increase of for

one antibody  $4.0 \pm 0.76$  and fold increase of for the second one  $2.3 \pm 0.2$ ), while the natural antibody related high-reactivity anti-MDA antibody did not. Anti MDA antibodies had no cross reactivity to other antigen modifications such as citrullination or carbamylation. Monoclonal RF had no direct effect on osteoclastogenesis but were able to significantly increase ACPA-mediated osteoclastogenesis (fold increase of  $1.68 \pm 0.03$  for ACPA alone and for the combination of ACPA and RF  $3.15 \pm 0.24$ ). Dimeric Fab fragments of polyclonal ACPA increased OC numbers by a fold of 1.78, suggesting that epitope recognition is involved in the observed osteoclastogenic effect of ACPA. Interestingly however while ACPA increased osteoclastogenesis from bone marrow precursors of wild type mice, it had no effect on the bone marrow precursors of the Fc gamma chain knockout and Fc gamma III mice bone marrow samples, implying a more complex mechanism than epitope recognition alone that involves Fc receptors.

#### Conclusion:

We demonstrate that RA-associated antibodies targeting different post translational modifications have the capacity to increase osteoclastogenesis while others have not. The mechanism is mediated through both Fc dependent and independent mechanisms.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Extensive evidence has correlated epigenetic alterations in articular tissues with both the presence and progression of human osteoarthritis. A recent study demonstrated that accelerated DNA methylation aging was present in OA cartilage compared to controls but not in peripheral blood samples from a mixed population of knee, hip, and hand OA patients. To further clarify epigenetic age changes specifically in knee OA, we examined the DNA methylation aging rate in peripheral blood mononuclear cells (PBMCs) at baseline from knee OA patients with rapid radiographic progression compared to well-matched nonprogressors enrolled in the Osteoarthritis Initiative (OAI).

**Methods:** Peripheral blood mononuclear cell (PBMC) DNA was obtained from baseline blood draws of 64 OA patients enrolled in the Osteoarthritis Initiative (OAI) longitudinal study. 32 rapidly-progressive OA patients, defined as  $\geq 1.0$ mm radiographic joint space loss or joint replacement within the first 24 months of follow-up were compared to 32 non-progressive OA patients defined as  $\leq 0.5$ mm radiographic joint space loss over 48 months of follow-up. There were no differences in age, sex, race, BMI, baseline K/L grade, or calculated PBMC subset composition between rapid- and non-progressors. DNA methylation was quantified with Illumina HumanMethylation 450k arrays. Epigenetic age was estimated with the algorithm described by Horvath et. al., using 353 age-associated CpG sites. This epigenetic age was compared to chronological age to calculate epigenetic-chronological age discordance ( $\Delta$ Age) and group differences compared with a Student t-test.  $\Delta$ Age was correlated with individual CpG methylation sites of rapid progressors, and Pearson values calculated. Correlation was considered significant if Pearson's  $r$  values were  $\leq -0.55$  or  $\geq 0.55$  ( $p \leq 0.001$ ). Pathway analysis of correlated genes was performed with the Ingenuity Pathway Analysis (IPA) system.

**Results:** The baseline DNA methylation aging rate in rapidly progressive (RP) knee OA patients was decelerated compared to nonprogressors (NP) and to chronological age ( $\Delta$ Age-RP:  $-4.9 \pm 1.4$  vs.  $\Delta$ Age-NP:  $-0.071 \pm 1.3$  mean  $\pm$  SEM years less than chronological age,  $p = 0.015$ ). 1165 CpG sites were correlated with  $\Delta$ Age in rapid progressors, corresponding to 755 genes. Ontologic analysis of highly correlated genes showed association of the STAT3 pathway ( $p = 6E-4$ ), Notch signaling ( $p = 1E-3$ ), axonal guidance signaling ( $p = 7E-3$ ), CREB signaling ( $p = 2E-2$ ), NFAT signaling ( $p = 2E-2$ ), and autophagy ( $p = 4E-2$ ) among others. Associated upstream regulators included FGF2

( $p=3E-5$ ), SMAD4 ( $p=9E-4$ ), SMAD5 ( $p=1E-3$ ), TNF ( $p=4E-3$ ), and TGFB1 ( $p=4E-3$ ), among others.

**Conclusion:** Our data reveal that a decelerated peripheral blood differential DNA methylation age epigenotype is present at baseline in rapidly progressive knee OA patients, but not in nonprogressive knee OA patients. The genes correlated with this methylation age deceleration cluster in pathways previously associated with OA in articular tissues. Our data reinforce the notion that OA is a heterogeneous disease composed of distinct subgroups, and suggests that future epigenetic investigation of immune cell subsets may be beneficial in unraveling OA pathogenesis.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Oxygen supply is a fundamental requirement for all living tissues. Some tissues such as articular joints are characterized by a physiological state of hypoxia. Interestingly, under conditions of inflammation such as in arthritic disease, this level of hypoxia is even further enhanced. However, the functional significance of these observations and the molecular mechanisms involved remain poorly characterized to date. We therefore examined the role of 3 known oxygen sensors, prolyl hydroxylase domain (PHD) proteins: PHD1, PHD2 and PHD3. They are enzymes whose function is essentially controlled by oxygen. Their expression pattern varies between either of them and all of them have been ascribed specific roles in a myriad of biological processes. Our goal was to examine the role of oxygen sensors PHD1, PHD2 and PHD3 in preclinical models of rheumatoid arthritis, and to delineate the cellular source involved.

**Methods:** We subjected the collagen antibody induced arthritis (CAIA) model (resembling rheumatoid arthritis) to hypoxic (10% O<sub>2</sub>) and normoxic conditions (21% O<sub>2</sub>), respectively. Furthermore, the CAIA-model was induced in mice with germline deficiency of the specific PHD's and in mice with a myeloid cell-specific PHD1 deficiency versus controls. Arthritis development was assessed by clinical scoring of paw swelling, histopathology of knee joints and  $\mu$ CT.

**Results:** Mice kept in hypoxic conditions during CAIA experiments showed markedly less arthritis (both by clinical and histopathological assessment) compared to mice in normoxic conditions. Furthermore, we demonstrated that PHD1 knock-out (KO) mice had significantly less joint inflammation compared to wildtype mice. PHD1 KO mice were also protected against inflammation induced bone loss as evidenced by  $\mu$ CT. By contrast, no differences were found between PHD2 heterozygous (PHD2 KO mice are not viable) or PHD3 KO mice and littermate controls. Because myeloid cells are considered critical effector cells upon passive transfer of arthritogenic antibodies in the CAIA model we also generated myeloid cell specific ko mice (PHD1myelKO). Of interest, PHD1myelKO mice developed less arthritis compared to wildtype mice and were protected against inflammation induced bone loss.

**Conclusion:** Our data are consistent with a new paradigm that the oxygen sensor PHD1 is a critical regulator of myeloid cell function in arthritic disease. Overall, the data suggest that PHD1 is a potential target in the treatment of arthritis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tankyrase is a poly (ADP-ribose) polymerase that leads to ubiquitination and degradation of target proteins. Since tankyrase inhibitors increase Axin protein, a negative regulator of Wnt pathway, they are widely used as Wnt inhibitors. Tankyrase inhibitors have attracted the attention as a promising drug candidate for cancer and fibrotic diseases, in which Wnt pathways are critical in the pathogenesis. Tankyrase has recently been reported to degrade an adaptor protein SH3BP2 (SH3 domain-binding protein 2). We have previously shown that SH3BP2 gain-of-function mutation enhances RANKL-induced osteoclastogenesis in murine bone marrow-derived macrophages (BMMs). Though the interaction between tankyrase and SH3BP2 has been reported, it is not fully elucidated whether tankyrase is involved in bone metabolism. In this study, we investigated the effect of tankyrase inhibition in bone metabolism in vitro and in vivo.

**Methods:** Primary murine BMMs from wild-type (WT) mice and SH3BP2 knockout (KO) mice and human peripheral blood mononuclear cells (PBMCs) were treated with tankyrase inhibitors (IWR-1 or G007-LK) in the presence of RANKL. Osteoclasts formation, function and intracellular signaling were analyzed by TRAP staining, resorption assay and western blotting, respectively. Primary calvarial osteoblasts from WT mice and SH3BP2 KO mice were also cultured with tankyrase inhibitors. Osteoblast differentiation and intracellular signaling were analyzed by qPCR, Alizarin red staining and western blotting. To examine in vivo effect of the tankyrase inhibitor, 7-week-old WT male mice were treated with G007-LK for 4 weeks, and then tibias and lumbar vertebrae were analyzed by micro-CT.

**Results:** In murine BMMs and human PBMCs culture, both tankyrase inhibitors enhanced osteoclast formation and function. Tankyrase inhibitors increased SH3BP2 protein and augmented phosphorylation of Syk and nuclear localization of NFATc1 in response to RANKL. Moreover, in SH3BP2 KO BMMs culture, tankyrase inhibitors did not promote osteoclast formation, indicating that the osteoclast-inducing effect is mediated by SH3BP2. Next, in primary calvarial osteoblasts culture, tankyrase inhibitors significantly increased osteoblast-associated genes expression and enhanced mineralization even though they have Wnt inhibitory effect. The osteogenic effect of tankyrase inhibitors were diminished by SH3BP2 deficiency, suggesting increased SH3BP2 expression enhanced osteoblastogenesis by surpassing the Wnt inhibitory effect. Finally, in vivo experiment, the administration of G007-LK significantly decreased trabecular bone volume of both tibias and vertebrae.

**Conclusion:** Tankyrase inhibition upregulates both osteoclastogenesis and osteoblastogenesis through the accumulation of SH3BP2. Our findings highlight the role of tankyrase as the novel regulator of bone metabolism. Also, we demonstrated that in vivo administration of the tankyrase inhibitor induces bone loss. This indicates that we should carefully evaluate the potential adverse effect on bone when tankyrase inhibitors are applied to patients with cancer or fibrotic diseases.

## The Effect of Myostatin Inhibition on Bone Loss in Murine Osteoporosis Models

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Biology and Pathology of Bone and Joint Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Myostatin, also called as growth differentiation factor-8 (GDF-8), is a secreted member of TGF- $\beta$  superfamily. Myostatin is a negative regulator of skeletal muscle mass as shown by increased muscle mass in myostatin-deficient mice. A recent study reported the regulatory role of myostatin on bone metabolism (Dankbar B, et al. Nat Med 2015). The study showed that myostatin directly regulates osteoclastogenesis and its inhibition reduces inflammatory joint destruction in murine arthritis models. In contrast to this, another group reported that myostatin inhibition by the administration of anti-myostatin antibody did not affect bone mass of femur and vertebra in wild-type mice (Bialek P, et al. Bone 2014). Therefore, it is still controversial whether myostatin inhibition could regulate bone mass. Here, we report the effect of genetic inhibition of myostatin on bone loss in murine osteoporosis models.

### Methods:

We used mutant myostatin transgenic (Mstn<sup>Pro</sup>) mice, in which myostatin prodomain, an endogenous myostatin suppressor, is excessively expressed and subsequently inhibits myostatin activity. For a RANKL-induced osteoporosis model, 1 mg/kg of RANKL was injected intraperitoneally at day 0 and 1, and the sera and bones were collected at day 2. For a tail-suspension unloading model, the tails of mice were suspended for 2 weeks. At the end of the period, the sera and bones were collected. Serum TRAP5b and P1NP levels were measured by ELISA. Bone properties of vertebra and tibia were determined by micro-CT. For cell culture experiments, bone marrow cells were isolated from long bones of wild-type (WT) and Mstn<sup>Pro</sup> mice. Bone marrow-derived macrophages (BMMs) were treated with RANKL, and then osteoclast differentiation and function were determined by TRAP staining and resorption assay.

### Results:

Mstn<sup>Pro</sup> mice exhibited increased muscle mass similarly to the previously reported myostatin null mice. RANKL injection induced severe bone loss in Mstn<sup>Pro</sup> mice to the similar extent to that seen in WT mice (WT: 31.0  $\pm$  10.0% reduction, Mstn<sup>Pro</sup>: 42.8  $\pm$  9.6% reduction compared to control mice of each genotype). Serum TRAP5b and P1NP levels were also comparable between RANKL-treated WT and Mstn<sup>Pro</sup> mice. In the tail-suspension model, genetic inhibition of myostatin did not also prevent bone loss. In WT BMMs culture, myostatin stimulation slightly enhanced RANKL-induced osteoclastogenesis. Osteoclast formation and resorbed area in response to RANKL were comparable between WT and Mstn<sup>Pro</sup> BMMs.

### Conclusion:

Genetic inhibition of myostatin did not alleviate bone loss in the osteoporosis models we tested. The role of myostatin inhibition might vary in different pathological conditions (e.g. inflammatory or non-inflammatory conditions). Further research will be required to clarify the clinical implications of myostatin inhibition in various disease settings.

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

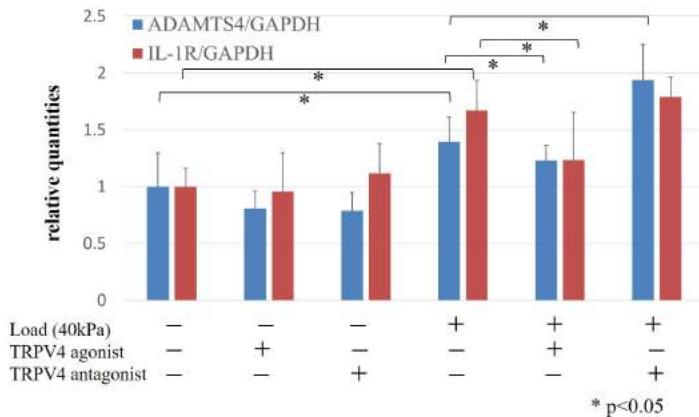

**Background/Purpose:** The mechanism of chondrocyte mechanotransduction is not fully understood. Recently, transient receptor potential vanilloid 4 (TRPV4) has been reported to transduce dynamic compressive loading in articular chondrocytes. The expression of the IL-1 receptor 1 (IL-1R1) on the surface of chondrocytes can be stimulated by compressive stress, and such increment of IL-1 susceptibility has been implicated in the OA pathology. The purpose of this study was to examine mechanical induction of IL-1R1 by chondrocytes in three-dimensional (3D) culture, and the effects of TRPV4 channel regulation on IL-1R1 expression. **Methods:** Mouse embryonal carcinoma-derived clonal cell line (ATDC5) was used and cultured in alginate beads with the growth medium for 6 days. These cells were collected and seeded in collagen gels and scaffolds, which maintained chondrogenic phenotype in 3D environment (Fig.1). Cyclic compressive loading of 40 kPa at 0.5Hz was applied to this 3D constructs using a cyclic load bioreactor for 3 hours. Thereafter, the PGE2 concentration and mRNA expressions of Col-II, ADAMTS4 and IL-1R1 were measured in real-time PCR. The effects of subtle amount of IL-1beta (1pg/ml) was determined with or without compressive stress, and the effects of TRPV4 agonist/antagonist on IL-1-induced ADAMTS4 was determined. **Results:** The PGE2 production in culture media and mRNA levels of ADAMTS4 and IL-1R1 were substantially increased by the excessive compressive stress. Compressive stress plus IL-1beta (1pg/ml) upregulated ADAMTS4 and IL-1R1 expressions by 3-fold and 8-fold, respectively, but IL-1beta alone failed to do so (Fig.2). TRPV4 agonist suppressed upregulation of ADAMTS4 and IL-1R1 mRNAs by cyclic compressive stress, conversely, TRPV4 antagonist rather accelerated these mRNA expressions (Fig.3). **Conclusion:** In chondrogenic 3D environment, the cells gained IL-1 susceptibility under excessive cyclic compressive stress. In this context, the cells would produce ADAMTS4 and MMPs in response to subtle level of IL-1 derived from synovia or cartilage itself, whereas TRPV4 downregulated expression of IL-1R1 and control IL-1 susceptibility to maintain cartilage homeostasis. To control IL-1 susceptibility is a key to prevent the development of OA, when excessive mechanical stress is applied on the articular cartilage.

### Background/Purpose:

Large vessel vasculitis (LVV) include Takayasu arteritis (TA) and giant cell arteritis (GCA). Arterial lesions in LVV result from chronic inflammation and neoangiogenesis. IL-33, a cytokine involved in angiogenesis and vascular permeability has been previously found overexpressed in arteries of large vessel vasculitis. We aimed at assessing its effects on the regulation of immune response and angiogenesis.

### Methods:

In vitro studies on angiogenesis were performed by using human endothelial cells to assess migration, proliferation and angiogenesis. Vascular permeability was assessed in vivo, using Miles assay. The effects of IL-33 on immune response were determined by assessing the production of cytokines by Multiplex in cultures of peripheral mononuclear cells (PBMC) with or without IL-33 stimulation and the proportion of regulatory T cells in cultures of mast cells and CD4+ T cells with or without IL-33 stimulation.

### Results:

We identified increased IL-33 levels in serum and in inflammatory lesions of TA and GCA patients as compared to controls. Sera from TA patients have angiogenic properties by promoting HUVECs proliferation, tube and sprout formation and were also able to induce vessel permeability *in vivo*. The addition of neutralizing anti-IL-33 antibody inhibits neoangiogenesis, migration of endothelial cells *in vitro* and vascular permeability *in vivo*. As mast cells are one of the main targets of IL-33, we repeated these experiments in mast-cells deficient mice in which *in vivo* effects were abolished. Significant increased number of mast cells was observed in aorta lesions of both diseases as compared to non-inflammatory aorta controls. IL-33 overexpression was accompanied by an increased expression of Th2-related cytokines by enhancing the secretion of IL-5 and IL-4. IL-33 also promoted the regulatory immune response by increasing the proportion of regulatory T (Tregs) cells. Consistently, IL-33 and mast cells dramatically increased the proportion of Tregs and the activity of indoleamine 2 3-dioxygenase (IDO).

### Conclusion:

IL-33/ST2 axis, through its interaction with mast cells, has a critical role in the pathogenesis of LVV.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tumor-necrosis factor (TNF)- $\alpha$  plays a key role in the pathophysiology of rheumatoid arthritis (RA) and membrane bound TNF $\alpha$  is sufficient to induce arthritis in mice [1]. Zhang [2] demonstrated membrane bound TNF $\alpha$  on extracellular vesicles (EVs) derived from RA synovial fibroblasts. EVs are stable in body fluids and mediate intercellular communication over short and long distances. In this study we want to determine whether TNF $\alpha$  is also present on circulating EVs from RA patients and not in healthy individuals.

**Methods:** pEVs were obtained from 28 RA patients and 24 healthy controls (HC) by size exclusion chromatography. Protein content was measured by micro-BCA, size and concentration by Nanoparticle Tracking. TNF $\alpha$  was detected by bead-based multiplex immunoassays (BBI) and flowcytometry (FC). To control for specificity, pEVs were preincubated with anti-TNF $\alpha$  (etanercept and certolizumab pegol). Immunoglobulin M rheumatoid factor (IgM-RF) was measured in pEVs by ELISA. RF+ and RF- pEVs were preincubated with Protein L beads to bind RF-IgM before TNF $\alpha$  was measured by FC.

**Results:** Particle size and protein content per particle were significantly higher in RA-pEVs as compared to HC (154nm, 484fg and 116nm, 216fg, resp) while particle concentration was not statistically different between RA patients and HC (0.89, 2.59 x10<sup>10</sup>/ml, resp). In 13 out of 28 RA patients TNF $\alpha$  (220 pg/ml) was detectable in pEVs by BBI whereas in HC TNF $\alpha$  was undetectable. Presence of TNF $\alpha$  on RA-pEVs was confirmed by FC. Preincubation of pEVs with anti-TNF $\alpha$  antibodies (etanercept) fully blocked TNF $\alpha$  detection. Unexpected, after preincubation with anti-TNF $\alpha$  Fab fragments (certolizumab pegol) TNF $\alpha$  was still detectable which suggested aspecific binding of the TNF $\alpha$  detection antibody. By ELISA IgM-RF was detectable on pEVs in 9 out of 13 RA patients. By preincubation with Protein-L coupled magnetic beads, to scavenge RF, TNF $\alpha$  levels on pEVs isolated from RF<sup>+</sup> RA patients were reduced to background.

**Conclusion:** This study shows for the first time that IgM-RF is present on pEVs in a subpopulation of RA patients and this impedes with immunodetection of TNF $\alpha$ . To obtain conclusive evidence for the presence of TNF $\alpha$  other laboratory techniques are needed. However, the presence of RF on EVs could be important in the immunopathophysiology of RA by directing putative immunoregulatory and potentially inflammatory EVs to sites of immune-complex formation.

## Regulation of Th17 Cell Responses By IL-25

Sophie Archer, Ash Maroof, Meryn Griffiths and Stevan Shaw, UCB Pharma, Slough, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

IL-17A is a Th17 proinflammatory cytokine that contributes to the pathophysiology of several immune-mediated inflammatory diseases including PsA; while previously underestimated, there is increasing evidence supporting a similar proinflammatory role for IL-17F. IL-17E (IL 25), another IL-17 cytokine, is implicated in Th2 responses, and signals via the IL 17RA/RB receptor complex, sharing the IL-17RA subunit with IL-17A and IL-17F. Extending upon previous work, we hypothesized that IL-25 indirectly regulates production of Th17 cell cytokines,<sup>1</sup> and a broad range of other inflammatory mediators through effects on polyfunctional T cells. Consequently, selectively targeting IL-17A and IL-17F may offer a therapeutic alternative, in the treatment of immune-mediated inflammatory diseases, to targeting broader

signaling pathways by interfering with IL-25. The aim of this study was to investigate the effects of IL-25 on Th17 and polyfunctional T cell responses.

## Methods:

Isolated human Th17 cells or peripheral blood mononuclear cells (PBMCs) were either stimulated with Th2 cytokines (IL-4, IL-5 and/or IL-13, IL-25) or Th2-cytokine neutralizing antibodies (10 µg/mL) for 72 hrs, to assess their modulatory effect on Th17 cells in addition to other Th cell subsets. Cytokines in cell supernatant and intracellular cytokines were measured using ELISA and flow cytometry, respectively. To investigate how IL-25 or IL-4 affected polyfunctional T cell responses, PBMCs were stimulated with these cytokines for 72 hrs and intracellular cytokine production was assessed by mass cytometry.

## Results:

While IL-25 did not effectively inhibit IL-17A production in stimulated PBMCs, IL-25 did elevate levels of IL-4 in treated versus untreated PBMCs. In contrast to IL-25, IL-4 effectively reduced the percentage of PBMCs expressing IL-17A and IL-17F and inhibited the secretion of IL-17A; the opposite effect was observed using anti-Th2-cytokine antibodies. Both IL-25 and IL-4 inhibited polyfunctional T cell production of the proinflammatory molecules IL-17A, IL-17F, TNF, and IFN $\gamma$  (Figure 1).

**Conclusion:** Taken together these data show that IL-25, via IL-4, indirectly modulates IL-17A and IL-17F production, as well as production of a variety of other proinflammatory molecules (including TNF and IFN $\gamma$ ), through effects on Th17 and polyfunctional T cells. Targeted dual neutralization of IL-17A and IL-17F may therefore produce optimal inhibition of inflammatory signaling responses in immune-mediated inflammatory diseases, without interfering with the regulatory role of IL-25.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Ankylosing spondylitis (AS) is a chronic inflammatory bone disease mediated by proinflammatory cytokine secreted by specialized T cells population. The mechanism by which the development of and function of Th17 cells and emerging IL-23/IL-17 axis may be involved in the pathogenesis of AS. However, the effect of IL-17 and IL-23 in osteoblast remain to be elucidated.

#### Methods:

AS patients satisfying the modified New York criteria were recruited for the study. Healthy donor, rheumatoid arthritis patients and osteoarthritis patients were included as controls. TNF $\alpha$ , IL-17, and IL-23 level were quantized by ELISA in the serum and synovial fluid. Bone tissues were obtained at surgery from facet joints of 10 patient with AS and 26 patients with noninflammatory spinal disease from traffic trauma or spinal compression disease, who served as controls. Immunohistochemistry and RNA level of bone tissue and isolated primary osteoprogenitor cells were performed to identify dominant JAK2 expression. IL-17 cytokine or patient serum with AS stimulated primary osteoprogenitor cells was analyzed by intercellular alkaline phosphatase (ALP) activity, mineralization, real-time PCR, and immunoblotting.

#### Results:

IL-17 and IL-23 basal level were significantly elevated in serum and synovial fluid of AS patients compared to those of the controls. Expression of JAK2 was enriched in bone tissues and isolated primary osteoprogenitor cells of AS patient. An addition of IL-17 cytokine in osteogenic differentiation exhibited an increase in ALP activity and calcium deposit in cellular level and sustained phos-JAK2 and phos-STAT3, and C/EBP $\beta$  in molecular level. Furthermore, adding IL-17A blockade in presence of patient serum with AS upon differentiation exhibited reduced intercellular ALP activity, mineralization, and phos-JAK2 expression in both control and AS osteoprogenitor cells. Intriguing, AG490, a JAK2 specific inhibitor, suppressed ALP activity despite the presence of patient serum with AS.

#### Conclusion:

This study supports a role of IL-17A in the pathogenesis of AS and attempts to provide a link between proinflammatory cytokine and osteoblast activity in an unexplored cellular system. Blocking of IL-17 could attenuate bony ankyloses in AS.

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tumor necrosis factor- $\alpha$  (TNF $\alpha$ ) is involved in the pathogenesis of RA and is increasingly being studied as a biomarker of cardiovascular disease (CVD). While TNF receptor 2 (TNFR2) and TNF $\alpha$  levels are correlated, TNFR2 is used more frequently as a biomarker in studies because of its stability in stored blood samples. We investigated whether TNF inhibitor (TNFi) use may influence measured TNFR2 levels. Since the mechanism of action for TNFi is binding TNF $\alpha$ , a component of these drugs is a TNF receptor. Thus, we hypothesize that there may be cross-reactivity between specific TNFi's and the TNFR2 assay.

**Methods:** All subjects were part of a CVD sub-study performed in a large prospective RA cohort study with blood samples collected annually, data on treatment and C-reactive protein (CRP). TNFR2 was measured using a commercial ELISA kit (R&D Systems, Minneapolis, MN). We categorized TNFR2 levels into 3 groups: (1) >46 and  $\leq$ 10,000 pg/mL, typical range; (2) >10,000 pg/mL and  $\leq$ 100,000 pg/mL, samples requiring 200-fold dilution; (3) >100,000 pg/mL, levels exceeding measurable values. We examined the

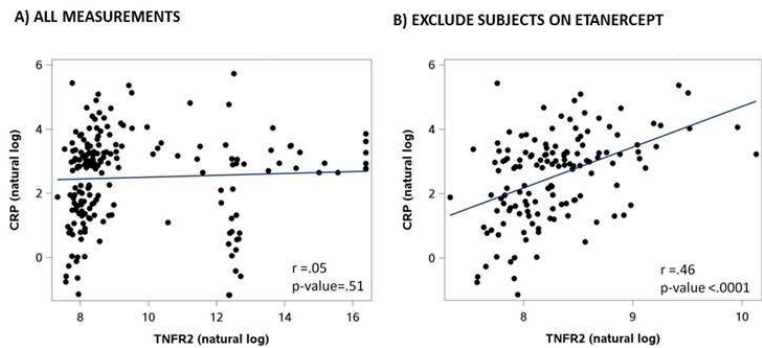

association individual TNFi's and having a TNFR2 level in group 3. Additionally, we assessed the correlation between natural log transformed CRP and TNFR2.

**Results:** We studied 190 RA subjects, mean age 60 years, 84% female, 73% anti-CCP positive and CRP ranged from 0.31-310 mg/L. Subjects on TNFi comprised 47% of the study: 14% on adalimumab, 26% on etanercept, and 8% on infliximab (no subjects on certolizumab or golimumab). All subjects with TNFR2 exceeding measurable levels (group 3) were on etanercept (Table). Samples that required 200-fold dilution (group 2) not on etanercept therapy had higher levels of CRP compared to those on etanercept (Table). We observed no significant correlation between CRP and TNFR2 for all subjects,  $r=0.05$ ,  $p=0.51$ . After excluding subjects on etanercept, the correlation was significant,  $r=0.46$ ,  $p<0.0001$  (Figure). We observed no significant changes in the correlation between CRP and TNFR2 after excluding patients on adalimumab or infliximab.

**Conclusion:** Our data suggest cross-reactivity between etanercept and the TNFR2 assay, as 100% of subjects on etanercept had levels of TNFR2 above measurable levels. Of the TNFi's, only etanercept has a TNF binding domain modeled after TNFR2. Thus, it is plausible that the TNFR2 assay has a high affinity for the TNFR portion of etanercept. These data should be considered when designing studies using TNFR2 in populations where etanercept is a treatment option.

Table. TNFR2 levels stratified by etanercept use.

TNFR2 category	Total, n	Etanercept (%)	No etanercept (%)	CRP mg/L, median (IQR)
<b>Group 1</b> Typical range ≤10,000 pg/mL	134	0	100	17.3 (4.7, 26.8)
<b>Group 2</b> 200-fold dilution 10,000 to ≤100,000 pg/mL	13	54	46	Etanercept: 30.2 (21.5, 35.6)  No etanercept: 57.3 (32.1, 170.1)
<b>Group 3</b> Exceeds measurable level values >100,000 pg/mL	43	100	0	15.8 (2.2, 26.5)

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is an inflammatory arthropathy due to the deposition of uric acid (monosodium urate: MSU) crystals in synovial tissue. MSU leads to activate nucleotide-binding oligomerization domain-like receptor family pyrin domain containing 3 (NLRP3) inflammasome and following IL-1 $\beta$  secretion via caspase-1 activation in human monocytes. Synthesis of mature IL-1 $\beta$  is a 2-step processes. In the 1<sup>st</sup> step, microbial-derived signals (binding of bacterial products such as LPS) up-regulate pro-IL-1 $\beta$ , resulting in synthesis of pro-IL-1 $\beta$ . However, priming signals for NLRP3 inflammasome pathway had not been completely elucidated in sterile inflammatory arthritis including gout. In this study, we investigated the role of TNF-alpha on MSU-mediated IL-1 $\beta$  induction in human neutrophils.

**Methods:** Venous peripheral blood was collected from healthy volunteers. Human neutrophils were stimulated with MSU (200  $\mu$ g/ml), in the presence or absence of TNF-alpha priming (2 to 50 ng/ml). The cellular supernatants were analyzed for IL-1 $\beta$ , IL-18 and caspase-1 by ELISA. Pro-IL-1 $\beta$  mRNA expressions in human neutrophils were analyzed by real-time PCR.

**Results:** TNF-alpha stimulation induced pro-IL-1 $\beta$  mRNA expression, however, MSU stimulation alone did not induce pro-IL-1 $\beta$  mRNA expression in neutrophils. TNF-alpha alone or MSU stimulation did not result in efficient IL-1 $\beta$  secretion. Whereas MSU stimulation to TNF-alpha-primed neutrophils resulted in a marked IL-1 $\beta$  (Figure 1) as well as IL-18 secretion. TNF-alpha-primed neutrophils secreted cleaved caspase-1 (p20) with MSU stimulation.

**Conclusion:** These results indicate that priming of human neutrophils with TNF-alpha promotes uric acid-mediated NLRP-3 activation and IL-1 $\beta$  secretion in the absence of microbial stimulation, that provide new insights into the neutrophils-mediated inflammatory processes in gouty arthritis.

Figure 1. MSU induces IL-1 $\beta$  synthesis from TNF-alpha-pretreated neutrophils.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Inter cellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent studies have revealed that platelets play pivotal roles in inflammation in addition to hemostasis. The thrombus induces subsequent local inflammation and reversely the local inflammation results in the formation of thrombus. Therefore, to suppress activation of platelets is important for preventing tissue damages. In this study, we aim to reveal effects of activated platelets on IL-1b production in human PBMCs and to clarify the mechanism.

**Methods:** We investigated whether IL-1b production is enhanced by co-culture of PBMCs and platelets compared to PBMCs alone. We analyzed the production of IL-1 b in co-culture of each fraction of PBMCs, T cells, B cells, NK cells and monocytes with platelets. NLRP3, or caspase-1 was knocked down by shRNA in THP-1 monocytes, and IL-1b production induced by co-culture with platelets were compared among shRNA-cell lines and scramble controls. We investigated mediators derived from platelets that induced IL-1 b production from monocytes, using inhibitors and neutralization antibodies. Furthermore, we compared CD16 positive monocytes with CD16 negative monocytes, regarding IL-1b productivities, expression levels of NLRP3 and caspase-1 mRNA, and platelets-monocytes-aggregates (PMA) ratios. Activation of platelets in inflammatory diseases, rheumatoid arthritis (RA) and Behcet's disease (BD) were analyzed using CD62P and PMA ratio.

**Results:** IL-1b production was enhanced by co-culture of PBMCs with platelets compared to PBMCs alone. Among PBMCs, monocytes showed the most prominent IL-1b production by co-culture with platelets. NLRP3- and caspase-1-knockdown THP-1 cells showed significantly lower IL-1b production in co-culture with platelets than scramble controls. CCR5 inhibitor and ATP inhibitor significantly attenuated IL-1b production of monocytes co-cultured with platelets. CD16-positive monocytes produced more IL-1b in co-culture with platelets than CD16-negative monocytes. CD16-positive monocytes showed higher NLRP3 mRNA expression and higher PMA ratio than CD16-negative monocytes. Platelets were activated in patients with active RA and BD compared to health controls.

**Conclusion:** Platelets stimulate monocytes and have the ability to enhance IL-1b production via CCL 5 and ATP. They activate NF-kB pathway and NLRP3 inflammasomes in monocytes and enhance IL-1b production. Among monocytes, CD16-positive monocytes are highly bound to platelets and produce IL-1b. Activated platelet may be involved in disease progression of inflammatory diseases.

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Inter cellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interleukin-37 (IL-37) is one of few anti-inflammatory cytokines belonging to the IL-1 cytokine family. It is mainly produced by immune cells of innate immunity such as monocytes and dendritic cells. Recent data suggest its role in several autoimmune and cardiovascular diseases. The aim of this study was to analyse the expression of IL-37 in synovial tissue, synovial fluid (SF) and serum of patient with established rheumatoid arthritis (RA) and osteoarthritis (OA) and to analyse its potential role in the pathogenesis of RA.

**Methods:** Serum and synovial fluid levels of IL-37 were determined in 52 patients with established RA and 49 control subjects with osteoarthritis (OA) by ELISA. All RA patients fulfilled the 2010 ACR/EULAR criteria for RA. Disease activity was assessed based on the Disease Activity Score of 28 joints (DAS28-ESR). For *in vitro* studies, fibroblast-like synoviocyte (FLS) were obtained from patients with RA and OA (n=6-9). Serum C-reactive protein (CRP) and lipid profile were determined. Immunofluorescence and immunohistological staining was used to localize IL-37 protein expression in synovial tissue cells (n=4-6) and FLS.

**Results:** The expression of IL-37 was upregulated in synovial tissue of patients with RA compared to OA, and co-localized with B-lymphocyte, T-lymphocyte, fibroblast-like synoviocyte (FLS) and macrophage specific markers. Further, stimulation with lipopolysaccharide (LPS) increased the nuclear expression of IL-37 in synovial fibroblasts cell cultures. The serum levels of IL-37 were significantly higher compared to synovial fluid levels of RA and OA patients ( $77.50 \pm 56.73$  vs.  $51.50 \pm 43.17$ ,  $p < 0.001$ ;  $57.00 \pm 73.25$  vs.  $27.00 \pm 38.38$ ,  $p < 0.001$ , respectively). Further, the synovial fluid levels, but not the serum levels, of IL-37 were significantly higher in RA patients compared to OA patients ( $77.50 \pm 56.73$  vs.  $57.00 \pm 73.25$ ,  $p < 0.01$ ) and there was a significant correlation between serum and synovial fluid IL-37 levels in RA patients ( $r = 0.55$ ,  $p < 0.001$ ). Although, neither serum nor synovial fluid IL-37 levels were associated with disease activity, synovial fluid IL-37 levels positively correlated with a leukocytes count in SF ( $r = 0.33$ ,  $p < 0.05$ ) and serum levels of CRP ( $r = 0.31$ ,  $p < 0.05$ ). Interestingly, serum levels of IL-37 negatively correlated with high density lipoprotein (HDL) levels ( $r = -0.33$ ,  $p < 0.05$ ) and positively with atherogenic index ( $r = 0.34$ ,  $p < 0.05$ ), but not with low density lipoprotein (LDL)-cholesterol, triacylglycerol (TAG) or total cholesterol levels.

**Conclusion:** Our data suggest possible role of IL-37 in accelerated atherosclerosis and increased cardiovascular burden in patients with RA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mutations in the *TNFRSF1A*, which encodes tumor necrosis factor receptor 1 (TNFR1), are associated with the autosomal dominant disease TNF Receptor- Associated Periodic Syndrome (TRAPS). TRAPS is an autoinflammatory disease characterized by intermittent self-limited inflammatory episodes of fever. More than 100 heterozygous *TNFRSF1A* mutations associated with TRAPS or TRAPS-like clinical phenotype have been reported. T50M mutation and cysteine mutations are reported to cause intracellular accumulation of TNFR1 and exhibit a severe disease phenotype. Single nucleotide polymorphism in TNFR1, such as T61I and R92Q mutations, occurs in

1-5% of the general population and can be associated with a TRAPS-like phenotype. Therefore, there are multiple responsible mechanisms to induce inflammation in patients with TRAPS, and the molecular pathogenesis is not yet fully understood. Recently we have identified a novel mutation, G58V (p.G87V) in *TNFRSF1A*, in two individuals in a family. They also had T61I mutation, and had suffered from recurrent episodes of intermittent fever and abdominal pain. In this study, we functionally characterized this novel G58V *TNFRSF1A* mutation.

**Methods:** The possible pathogenicity of the G58V mutation was analyzed using the four online prediction tools (SIFT, Polyphen2, PROVEAN and PANTHER). Wild-type (WT) or mutated *TNFRSF1A* (T50M, G58V, T61I, R92Q) constructs were generated by cloning the individual cDNAs into the pcDNA3.1 vector. The TNFR1 constructs were transfected into HEK-293 cells. Expression levels of the TNFR1 were examined by western blotting. To evaluate the NF- $\kappa$ B promoter activity, HEK-293 cells were transfected with the TNFR1 constructs along with NF- $\kappa$ B promoter-driven luciferase plasmid and the secreted alkaline phosphatase control vector pSEAP. NF- $\kappa$ B activation levels at 24 hours after the transfection were measured by the dual-luciferase reporter assay.

**Results:** The novel G58V mutation was predicted to be a highly damaging amino acid substitution that could cause a disease. The result is similar to those of pathogenic T50M and cysteine mutations. Expression levels of the WT and mutated TNFR1 proteins are comparable in the whole cell lysates of HEK-293 cells. NF- $\kappa$ B promoter activities in the T50M or the G58V TNFR1-expressing cells were significantly decreased compared to those in WT TNFR1-expressing cells (mean $\pm$ SD; T50M 29.6 $\pm$ 7.5% vs. WT 100 $\pm$ 11.5%,  $p$ <0.001; G58V 40.1 $\pm$ 0.9% vs. WT,  $p$ <0.001). The T61I mutation showed a small but significant reduction in NF- $\kappa$ B promoter activity (67.4 $\pm$ 18.8%,  $p$ <0.05 vs. WT). In contrast, the R92Q mutation did not suppress NF- $\kappa$ B promoter activity (93.2 $\pm$ 18.4%).

**Conclusion:** Consistent with a previous report (Blood 2006;108:1320-1327), the T50M mutation suppressed spontaneous NF- $\kappa$ B promoter activity, in spite of the clinical inflammatory features of TRAPS. The newly identified G58V mutation developed the similar phenotype to the pathogenic T50M mutation. These findings indicate that G58V could be a responsible mutation causing TRAPS.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IFN $\epsilon$  and IFN $\kappa$  are members of the type-I IFN family that also consists of 12 IFN $\alpha$  subtypes, IFN $\beta$ , and IFN $\omega$ . IFN $\epsilon$  and IFN $\kappa$  share approximately 35% sequence identity with each other and the other 14 IFN proteins. In contrast, IFN $\alpha$  subtypes and IFN $\omega$  share 60%-95% sequence identity. The role of human IFN $\epsilon$  and human IFN $\kappa$  in autoimmune disease in general, and SLE in particular, is unknown. However, the unique expression of IFN $\epsilon$  in vaginal tissues, and IFN $\kappa$  in the skin, are consistent with the sex bias and extensive cutaneous manifestations of lupus. Work to understand the role of IFN $\epsilon/\kappa$  in SLE has been hampered by a paucity of quality reagents for biochemical and biological analysis. To overcome this problem, we have produced and purified human IFN $\epsilon$  and IFN $\kappa$  from *E. coli* for biochemical and functional studies.

**Methods:** The IFNs were expressed, refolded, and purified from *E. coli*, and characterized using SDS-PAGE gel electrophoresis, mass spectrometry, surface plasmon resonance, gene expression using reporter cells lines and PCR, and ELISAs performed using serum for Lupus

patients.

**Results:** Purified IFN $\epsilon$  and IFN $\kappa$  bind to the IFNAR receptors and induce reporter cell gene activation. Gene expression induced by IFN $\epsilon$ , or IFN $\kappa$ , was neutralized by anti-IFNAR neutralizing antibodies, but not by the anti-IFN $\alpha$  neutralizing antibodies examined. IFN $\epsilon$  and IFN $\kappa$  both induced a type-I IFN gene signature in human whole blood. ELISA studies suggest serum from some SLE patients contain antibodies that recognize IFN $\epsilon$  or IFN $\kappa$ .

**Conclusion:** Taken together, these data suggest IFN $\epsilon$  and IFN $\kappa$  may be contributing to the dysregulated type-I IFN environment observed in some lupus patients, making them putative targets for anti-IFN therapy.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The proteasome inhibitor (PI) PR-957/ONX 0914 blocks cytokine production in vitro and attenuates disease progression in experimental models of rheumatoid arthritis (RA) (*Nature Medicine* 2009 15;781-788). While these anti-inflammatory effects were demonstrated to be due to inhibition of the immunoproteasome versus the constitutive proteasome, there remained a question as to which immunoproteasome subunits, LMP7, LMP2, or MECL-1, were necessary and sufficient for these effects. Here we utilize subunit-selective PIs to address this question.

### Methods:

Proteasome subunit inhibition was measured in mice following administration and/or in MOLT-4 cells (human leukemia) and human PBMCs following exposure to the immunoproteasome subunit-selective inhibitors, ONX 0914 (LMP7, LMP2, MECL-1), KZR-329 (LMP7), KZR-504 (LMP2), and KZR-082 (MECL-1), via a subunit active site occupancy assay (ProCISE). Cytokine release (TNF- $\alpha$ , IL-6, IL-12/23p40 [p40], and IFN- $\gamma$ ) was measured in human PBMCs stimulated with either endotoxin (LPS) or antibodies to CD3 and CD28 (anti-CD3/CD28) via Meso Scale Discovery electrochemiluminescent detection (MSD). Cell viability was measured by CellTiter-Glo. The therapeutic effect of selective inhibitors alone or in combination was evaluated in the Collagen Antibody-Induced Arthritis (CAIA) mouse model of RA.

### Results:

Consistent with previous studies, at a concentration that inhibited multiple immunoproteasome subunits, ONX 0914 blocked secretion of all cytokines tested in stimulated PBMCs. KZR-329 partially blocked secretion of p40 following LPS stimulation and IFN- $\gamma$  following anti-CD3/CD28 stimulation, but had minimal effect on TNF- $\alpha$  and IL-6. KZR-504 and KZR-082 had no effect on cytokine production. A combination of KZR-329 and either KZR-504 or KZR-082 resulted in a blockade of cytokine release similar to that of ONX 0914. Blockade of all 3 immunoproteasome subunits resulted in enhanced cytokine inhibition compared to the combination of any 2 selective inhibitors, although the triple combination also resulted in a slight decrease in cell viability. In the CAIA model, KZR-329 resulted in a slight attenuation of disease progression, while KZR-504 treatment had no effect. However, in combination, these two inhibitors prevented disease

progression at a level similar to ONX 0914.

#### Conclusion:

Selective inhibition of individual immunoproteasome subunits resulted in minimal decreases in cytokine production in vitro, and was not sufficient to prevent disease progression in a mouse model of RA. Combined inhibition of LMP7 and LMP2, comparable to that achieved with ONX 0914, blocked multiple inflammatory cytokines in vitro and attenuated disease progression in mice. These data suggest that development of selective inhibitors of the immunoproteasome that target multiple subunits will be necessary in order to achieve a therapeutic benefit in rheumatic diseases such as RA.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoimmune disease such as rheumatoid arthritis (RA) and inflammatory bowel disease (IBD) is a chronic inflammatory disorder, significantly limiting quality of life. Even though the dramatic improvement with the new therapeutics had appeared over the past decades, there is still huge unmet medical needs. Recently, it was reported that epigenetic regulation is deeply involved in the development of autoimmune disease and that the inhibition of histone deacetylase showed significant immunomodulation. Herein, we introduce highly potent and selective histone deacetylase 6 inhibitor CKD-506 as a novel therapeutic drug for RA and IBD.

**Methods:** The inhibitory activity and selectivity of CKD-506 for HDAC6 were determined by enzyme assay. The acetylation of tubulin in PBMCs by CKD-506 was determined by western blot. The *in vivo* efficacy of CKD-506 in RA or IBD was evaluated in adjuvant (AIA)- and collagen (CIA)-induced arthritis or DSS- and CD4<sup>+</sup>CD45RB<sup>hi</sup> T cell adoptive transfer-induced colitis animal model respectively. To test the effect of CKD-506 on T cell function, CFSE-labeled effector T cells (T<sub>eff</sub>) from mouse splenocytes were co-cultured with T<sub>reg</sub> in the presence of CKD-506 and T<sub>eff</sub> proliferation was analyzed by flow cytometry. The *ex vivo* anti-inflammatory effect of CKD-506 was tested with peripheral mononuclear cells (PBMCs) or synoviocytes from RA patients. The effect of CKD-506 on inflammatory mediators in T cell adoptive transfer colitis was screened by real time RT-PCR.

**Results:** CKD-506 had a potent and selective inhibitory activity on HDAC6 with an IC<sub>50</sub> of 5 nM. CKD-506 highly induced acetylation of tubulin a substrate for HDAC6 in human PBMCs and lymphoid tissue collected from normal rat. In the arthritis animal models, CKD-506 inhibited severity of arthritis in a dose dependent manner and showed strong synergistic efficacy with methotrexate combination. The proliferation of T<sub>eff</sub> was suppressed by CKD-506. Interestingly, the CKD-506 significantly inhibited TNF but induced IL-10 production in PBMCs. CKD-506 inhibited IL-1b induced CCL-2, CXCL-8, CXCL-10 production in fibroblast-like synoviocytes from RA patients. In IBD animal models, CKD-506 significantly repressed disease progression and highly inhibited the expression of inflammatory mediators in colon tissues of T cell adoptive transferred colitis animal. (Current status: Phase I in EU, EudraCT number: 2016-002816-42)

**Conclusion:** The novel HDAC6 inhibitor, CKD-506 had a therapeutic potential in autoimmune disease such as RA and IBD through the inhibition of inflammatory mediators and the regulation of T cell functions.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is characterized by loss of immune tolerance to self-antigens and periods of waxing and waning disease. The clinical aspects of SLE differ significantly from individual to individual and are altered during periods of heightened disease activity. Activation of innate and adaptive signaling pathways, such as endosome expressed TLR3, TLR7 and TLR9, are linked to SLE development, yet differences in innate and adaptive immune signaling and responding cytokine production during variable disease activity remains unclear.

**Methods:** Peripheral whole blood samples of 10 African American healthy controls and 12 SLE patients with either high (SLEDAI<sup>3</sup>4) or low (SLEDAI<4) disease activity were stimulated with T-cell receptor (TCR), B-cell receptor (BCR), and Toll-like receptor (TLR) ligands for either 4 minutes (TLR and BCR) or 30 minutes (TCR) for phospho-protein analysis, and 24 hours for cytokine analysis of cell culture supernatants. Phospho-protein analysis was assessed by mass cytometry and analyzed using Cytobank. Plasma cytokine and soluble mediator concentrations of stimulated cell culture supernatants were determined by 37-plex assay and by ELISA. Spotfire (version 6.0.1) and GraphPad Prism 5.04 for Windows (GraphPad Software, San Diego, CA) was used for analysis and Mann-Whitney test was used to compare non-normally distributed data. All SLE patients met ACR classification criteria.

**Results:** SLE patients with high disease activity had a significantly increased fold change in T cell associated cytokines following overnight stimulation, namely sCD40L (p=0.045), IL-2 (p=0.041), and IL-13 (p=0.045) in response to TLR4, TLR7/8 and PMA-Ionomycin compared to patients with low disease activity. In general, most SLE patient cytokines had a decreased fold change in response to stimulation compared to healthy controls (p<0.05). CD4<sup>+</sup> T cells and CD8<sup>+</sup> T cells exhibited no significant differences in immune signaling following CD3/CD28 stimulation between SLE patients with high and low disease activity. TLR3, TLR4 and TLR9 stimulation drive heightened phosphorylation of STAT5 (p<0.0061) and PLC $\gamma$ 2 (p<0.045) in granulocytes of high SLE disease activity patients compared to low disease activity following Poly I:C, LPS, and CpG, respectively. In contrast, dendritic cells had a reduced signaling response to TLR7/8, TLR9 and BCR stimulation with lower pSTAT3 (TLR7/8) (p=0.0427), pp38 (TLR9) (p=0.0285), and Syk (p=0.0080), pSTAT1 (p=0.046) and pSTAT5 (p=0.0106) (BCR) in high disease activity patients compared to low disease activity. B cells also had reduced phosphorylation of p38 (p=0.0427) in response to TLR4 stimulation of high disease activity patients compared to low disease activity patients.

**Conclusion:** Our results suggest that altered signaling in response to TLRs in granulocyte and antigen presenting cells may contribute to elevated SLE disease activity by driving T cell proliferation and cytokine production.

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

G protein-coupled receptors (GPCRs) are a family of integral membrane proteins mediating cell trafficking and cellular homeostasis. In the last decades, several functional autoantibodies (ab) against GPCR have been described to be involved in the pathogenesis of various diseases including systemic sclerosis. As suggested by our studies for the autoantibodies against angiotensin and endothelin receptors, anti-GPCR ab may also be present in healthy individuals. However; the role of autoantibodies in physiology is under debate.

### **Methods:**

Antibodies against 10 different GPCR were analysed in 198 healthy donors, 249 patients with SLE, 376 patients with SSc, 47 patients with rheumatoid arthritis, and 128 patients with granulomatosis with polyangiitis (GPA) by ELISA. In patients with SSc, we also have analysed the ab levels against 31 targets including GPCR, growth factors, and signalling molecules. Possible functional interactions of the 31 autoantibody target molecules were studied by STRING, DAVID, and enriched Gene Ontology. Migration assays were performed as well as cell culture experiments stimulating PBMC with IgG from healthy donors. C56Bl/6 mice were immunized with ETAR and the cellular homeostasis was studied by flow cytometry, histology, and compared with the ab levels against anti-ETAR ab.

**Results:** The detection of antibodies against 10 different GPCR revealed either increased or decreased antibody levels in a disease-specific manner when compared to healthy donors. Antibodies against ETAR were increased in patients with SSc and SLE and decreased in patients with GPA. In addition to the disease-specific ab signatures, we identified SSc-specific correlations between the 31 target antibodies. Possible functional interactions of the 31 autoantibody revealed a network of GPCR, growth factors, and signalling molecules with endothelin receptor type A (ETAR) in the centre. Migration and locomotion were suggested to be the most significant functions regulated by an assumed antibody network. Accordingly, IgG from healthy donors induced both IL-8 expression in PBMC as well as, depending on the anti-ETAR ab levels, migration of neutrophils and lymphocytes, which was specifically diminished by the ETAR blocker sitaxentan. In vivo, increased anti-ETAR ab levels were associated with an altered homeostasis of innate and adaptive immune cells in different tissues.

**Conclusion:** As indicated for anti-ETAR antibodies, anti-GPCR antibodies reveal physiological levels in healthy donors and specific alterations in different autoimmune diseases. The antibodies are involved in the homeostasis of immune cells and could contribute to disease pathogenesis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Type I (IFN- $\alpha$ ) and type II (IFN- $\gamma$ ) interferons are important mediators of autoimmunity. However, there is conflicting evidence regarding the contribution of IFN- $\gamma$  to the pathogenesis of RA. We recently showed a strong association of IFN- $\gamma$  receptor 1 (*Ifngr1*) expression and of IFN- $\gamma$  receptor 2 (*Ifngr2*) expression in peripheral blood mononuclear cells (PBMC) with the presence of RA and its radiographic severity, respectively (*Arthritis Rheumatol.* 2015 67:1165). IL-2 has essential regulatory function in inflammatory diseases and is considered as a potential therapy for autoimmune disease. In this study, we tested the hypothesis that RA is associated with alterations in IFN- $\gamma$  and IL-2 STAT signaling within certain subsets of PBMCs.

## Methods:

We used a high-definition phospho-flow approach to evaluate the activation of STAT1 (assessed using antibody to phosphorylated tyrosine at position 701 [pY701]), STAT3 (pY705) and STAT5 (pY694) after stimulation with IFN- $\gamma$  or IL-2. We analyzed subsets of PBMCs from 35 RA patients and 12 healthy controls (HC) as shown in Table.

Subset	Markers
CD4 T cells	
Naïve	CD45RA+CCR7+
Central Memory	CD45RA-CCR7+
Effector Memory	CD45RA-CCR7-
Follicular Helper T cells (Tfh)	CD4+PD1+CX3CR5+
Regulatory T cells (Treg)	CD4+CD25hiCD127lo
CD8 T cells	
Naïve	CD45RA+CCR7+
Central Memory	CD45RA-CCR7+
Effector Memory	CD45RA-CCR7-
B cells	CD20+
Monocytes	CD14+CD11b+

Table. Subsets of PBMCs analyzed in this study.

## Results:

We found that IFN- $\gamma$  induced STAT1 activation was significantly greater in naïve, central memory, Tfh and Treg subsets of CD4+ T cell populations from RA patients compared to HC ( $p < 0.05$ ). IFN- $\gamma$  induced STAT1 activation in RA was similar to HC in effector memory CD4 T cells, all CD8 T cell populations, B cells and monocytes. Phosphatases dephosphorylate STATs to regulate the activation of cytokine induced signals. We found that phenyl-arsine oxide (PAO), a broadly active phosphatase inhibitor, had no effect on IFN- $\gamma$  induced STAT1 activation in any T cell population from RA or HC. This result indicates that IFN- $\gamma$  induced acute activation of STAT1 is not regulated by a phosphatase in RA or HC. IFN- $\gamma$  did not activate STAT3 any mononuclear cell population among RA or HC. IL-2 very efficiently activated STAT5 in all T and B cell populations in RA and HC. The activation of STAT5 in RA was significantly greater than HC in only one population: effector memory CD4 T cells ( $p < 0.01$ ). Remarkably, treatment with PAO greatly enhanced IL-2 induced activation of STAT5 in RA, but not HC CD4 T cell populations (naïve, central memory effector memory, Treg, Tfh). PAO had no effect on STAT5 activation in CD8

T cell populations from RA and HC. This result suggests that the regulatory activity of IL-2 in RA CD4 T cell populations is attenuated by a STAT5-specific phosphatase.

#### Conclusion:

Our results indicate that CD4 T cell subpopulation dependent enhanced IFN- $\gamma$  STAT1 signals and attenuated IL2-STAT5 signals (possibly due to a phosphatase inhibitor) contribute to the pathogenesis of RA. Future studies will focus on stratifying patients by disease activity and other covariates.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** O-GlcNAcylation is an important post-translational modification of nuclear and cytosolic proteins involved in the cytokine signaling networks. Studies show both pro- and anti-inflammatory roles of O-linked N-acetyl glucosamine (O-GlcNAc) depending on different cell types and diseases. However, the role of O-GlcNAcylation in chronic inflammatory diseases such as rheumatoid arthritis (RA) is yet to be explored.

**Methods:** Human normal SFs (NLSFs) and RASFs were isolated from healthy synovial tissues and RA synovial tissues, respectively, under the IRB-approved protocol. Cell lysates and tissue homogenates were used to determine the differences in the expression of the O-GlcNAcylation in NLSFs and RASFs by Western immunoblotting. Effects of IL-1 $\beta$  (10 ng/ml) on O-GlcNAcylation and two enzymes that control glycosylation (O-GlcNAc transferase, OGT and O-GlcNAcase, OGA) in human RASFs were studied. The effect of OGT inhibitor (OSMI-1; 5-50  $\mu$ M) or OGA inhibitor (Thiamet-G; 1-10  $\mu$ M) was evaluated on IL-1 $\beta$ -induced IL-6 and IL-8 production and the underlying mechanisms were studied. In rat adjuvant-induced arthritis (AIA) model, ankle, liver, and spleen homogenates from naïve and AIA rats were analyzed to determine the temporal expression pattern of O-GlcNAcylation.

**Results:** The expression of O-GlcNAc is upregulated in RA synovial tissues compared with healthy synovial tissues, and also showed a similar trend in SFs isolated from these tissues. We also observed IL-1 $\beta$  stimulation resulted in the upregulation of O-GlcNAc levels in RASFs *in vitro*. Interestingly, pretreatment of RASFs with OGA inhibitor (Thiamet-G) inhibited IL-1 $\beta$ -induced IL-6 and IL-8 production, whereas OGT inhibitor (OSMI-1) had no inhibitory effect, suggesting that OGA inhibition may be of potential therapeutic value in RA. Evaluation of the IL-1 $\beta$  signaling proteins (TAK1, TAB1, or NF-kBp65) that are critical in relaying downstream signaling showed a marked increase in O-GlcNAc levels upon IL-1 $\beta$  stimulation. Thiamet-G pretreatment showed a protective role of OGA inhibition in regulating inflammation. Similarly, in rat AIA model, we observed a higher O-GlcNAc expression pattern in rat joint homogenates, whereas no change in O-GlcNAcylation expression was observed in liver. Surprisingly, O-GlcNAcylation in spleen homogenates elicited differential expression at the onset of arthritis (day 8) and at the established arthritis (day 18) compared to naïve, which correlated with the clinical scores and splenomegaly in arthritic animals. Interestingly, O-GlcNAc levels of protein such as NF-kBp65 was found to be downregulated in spleen microenvironment whereas that of NF-kBp50 remained the same.

**Conclusion:** Our findings point to an important mediatory role of O-GlcNAc in stabilizing IL-1 $\beta$  signaling proteins to activate downstream inflammatory proteins. OGA inhibition may serve as a potential therapeutic target in regulating synovial inflammation in RA.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Cytokines, Mediators, Cell-Cell Adhesion, Cell Trafficking and Angiogenesis Poster I: The Variable World of Intercellular Signalling

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by bone and cartilage destruction with leukocyte infiltration and activation at synovial tissue. Recently, upregulated histone deacetylase (HDAC) activity has been reported in peripheral blood mononuclear cells (PBMCs) from RA patients. In addition, it has been reported that HDAC inhibitor (HDACi) improved cancers, neurological diseases and inflammatory diseases by suppressing pro-inflammatory cytokines such as TNF- $\alpha$  and IL-6. Previously, we reported that a novel histone deacetylase 6 inhibitor (HDAC6i), CKD-M808 (M808) decreased clinical score in adjuvant induced arthritis (AIA) rat model. Here, we investigated the effect of M808 on cell adhesion, migration and suppressive function of regulatory T cells (T<sub>reg</sub>) derived from RA patients.

### **Methods:**

Fibroblast-like synoviocytes (FLS) were isolated from synovial tissues of RA patients, and treated with HDAC6i such as tubastatin A and M808 under IL-1 $\beta$  stimulation. The expression of  $\alpha$ -tubulin, acetylated tubulin, intracellular adhesion molecule (ICAM)-1 and vascular cell adhesion molecule (VCAM)-1 were measured in RA FLS by western blotting. The levels of CCL2, CXCL8 and CXCL10 were measured in culture supernatant. Wound healing assay were performed to confirm cell migration ability. The adhesion of U937 or Jurkat cells onto RA FLS was measured by cell adhesion assay. CD4+CD25- T cells (effector T cells, T<sub>eff</sub>) were isolated from RA PBMCs, and differentiated into induced T<sub>reg</sub> (iT<sub>reg</sub>) under differentiating media. After the differentiation, Foxp3 and CTLA-4 were analyzed by flow cytometry. iT<sub>reg</sub> were also co-cultured with carboxyfluorescein succinimidyl ester (CFSE)-labeled T<sub>eff</sub> derived from healthy donor. The proliferation of T<sub>eff</sub> was analyzed by flow cytometry.

### **Results:**

M808 increased the acetylation of tubulin in RA FLS. The number of migrated cell was decreased in M808-treated RA FLS without the change in cell viability. The expression of ICAM-1 and VCAM-1 were decreased in HDAC6i-treated groups in a dose-dependent manner. M808 reduced the levels of chemokines including CCL2, CXCL8 and CXCL10 in RA FLS. In addition, M808 attenuated the adhesion of U937 and Jurkat cells on RA FLS. The suppressive function of iT<sub>reg</sub> were significantly increased in M808-treated groups.

### **Conclusion:**

M808 increased the acetylation of tubulin, and decreased the migration of RA FLS. M808 also decreased the expression of ICAM-1, VCAM-1 and chemokines such as CCL2, CXCL8 and CXCL10. The adhesion between RA FLS and U937 or Jurkat cells was decreased in the presence of M808. M808 increased the suppressive function of iT<sub>reg</sub> derived from RA PBMCs. The novel HDAC6i, M808, may provide a new therapeutic option in RA patients.

## Mind Map Use in Rheumatology Education

**Alex Papou**, Rheumatology, Consultant Rheumatologist, North West Anglia NHS Foundation Trust, Peterborough City Hospital, Peterborough, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Medical knowledge is a constantly expanding and changing field. One of the challenges for healthcare professionals, including doctors in training, is to be able to find the most relevant source of reliable information with minimal reasonable efforts. Search for information is often time-consuming and each educational resource has limitations. Traditional forms of study such as textbooks are often out-of-date and inaccessible at work; internet-based information is often too abundant, and can be disorganized, not relevant to clinical practice, and inaccurate; direct learning from seniors is limited in a busy hospital environment; ward experience learning can lead to mistakes. There is an unmet need for a unified resource that will serve the purpose of being accessible wherever you are, comprehensive, reliable, up-to-date, and easily searchable.

**Methods:** A simple way to organize information is to use mind maps. A mind map is a tree-like structure that consists of radial nodes when the next level can be expanded or collapsed by a mouse click or a tap. Within a few clicks you can reach any information you need, visual hierarchical approach is intuitive and allows easy search, associated topics can be linked, and a web-based application offers easy modification and update of the mind map or its adjustment according to the needs of a trainee.

**Results:** We have developed a free mind mapping educational resource for health care professionals ([www.rheumatologymindmap.com](http://www.rheumatologymindmap.com), [www.rheumatologymindmap.co.uk](http://www.rheumatologymindmap.co.uk), images 1-3). It is based on current rheumatology practice in the United Kingdom and is being updated in accordance with the new information and feedback received from the UK trainees. The mind map has direct online links to appropriate British, European, and American guidelines, incorporates downloadable templates, has hyperlinks to online calculators and to websites providing advice for doctors and patients. The mind map works in desktop and mobile browsers and can be transferred to other platforms including Android and iOS.

**Conclusion:** Mind mapping can offer a new structured approach in medical training and clinical practice, with fast access to the relevant information. The rheumatology mind map can become an important practical tool and its main benefits are accessibility, intuitive interface, easy search, and modifiability.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Understanding epidemiology and biostatistics (epi/biostats) is crucial for rheumatologists to interpret literature and make appropriate data-driven clinical decisions. Based on retrieval-enhanced learning theory, we developed CLASS-Rheum, a cloud-based modular assessment tool to support learning of epi/biostats relevant to rheumatology fellows. In this study we test whether sequential administration of isomorphic Question Sets is associated with sustained learning.

### **Methods:**

CLASS-Rheum Question Sets are organized into 10 modules, each focused on a concept in epi/biostats, framed in rheumatologic context. Administration via Learning Catalytics® allows access on web-enabled devices. With IRB-exemption, 6 rheumatology programs of varying size across the US participated in sequential administration of 2 Question Sets. Question Set 2 (QS2) was comprised of 56 unique questions assessing the same content and learning objectives as Question Set 1 (QS1). We examined face and construct validity, item difficulty, psychometrics, and change in knowledge with sequential administration of Question Sets. Fellows providing individual responses to > 50% of questions were included in the quantitative analysis. Mean change in percent correct and change in Likert-scale ratings were compared with paired-t tests and Wilcoxon Signed-Rank tests, respectively. Mixed effects modeling was used to examine whether year of fellowship impacted percent correct (SAS v9.4).

### **Results:**

From 2/2016-5/2017, 51 rheumatology fellows enrolled in CLASS-Rheum. 39 provided individual responses to >50% of questions and were included in the quantitative analysis. 67% of participating fellows were women. At enrollment, 10% had degrees in epi/biostats, 61% reported being very interested in epi/biostats, and 65% considered their understanding of epi/biostats average compared to other rheumatology fellows. 28 fellows' data were analyzed in QS1 (all first time takers), and 25 fellows' in QS2 (11 first time takers). 14 fellows completed both Question Sets, with mean interval between pairs of isomorphic modules of 260 days (SD 70.7).

Difficulty was similar between modules. Mean percent correct for first time takers was 64.4% (SD 15.1%) for QS1 vs. 64.8 (SD 11.9%) for QS2 ( $p = 0.93$ ). Point biserial correlations were positive for 93% of questions from QS1 and QS2, suggesting strong psychometrics. Based on data from QS1 and QS2, 3<sup>rd</sup> year fellows had statistically higher average scores than 1<sup>st</sup> year fellows ( $p=0.032$ ).

Among the 14 fellows completing QS1 and QS2, mean percent correct increased from 61.8% to 67.9% ( $p = 0.036$ ). 14% of fellows' scores increased >20%. Upon completing QS1, 14/14 fellows described CLASS-Rheum as "very useful/useful" in learning epi/biostats, as did 13/14 after completing QS2 ( $p=0.75$ ).

### **Conclusion:**

Two psychometrically sound modular Question Sets ("CLASS-Rheum") covering important concepts in epi/biostats, framed in a rheumatologic context, were successfully administered to fellows in diverse rheumatology training programs. Sustained increases in knowledge were demonstrated with sequential administration of isomorphic Question Sets over 15 months. CLASS-Rheum will be evaluated in additional programs.

## **Developing a Pediatric Rheumatology Curriculum for Pediatric Residents**

Miriah Gillispie<sup>1,2</sup> and Amanda Brown<sup>3</sup>, <sup>1</sup>Texas Children's Hospital, Houston, TX, <sup>2</sup>Pediatrics, Department of IAR, Baylor College of Medicine, Houston, TX, <sup>3</sup>Allergy, Immunology and Rheumatology, Texas Children's Hospital, Houston, TX

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The purpose of this project was to develop a curriculum to teach residents these skills. Due to a paucity of pediatric rheumatologists and the growing patient population, pediatricians must be able to recognize and begin a basic work up for suspected autoimmune disease. The project includes 30-minute case based lectures on the topics of systemic lupus erythematosus (SLE), juvenile idiopathic arthritis (JIA), periodic fever, aphthous stomatitis, pharyngitis, adenitis (PFAPA), Kawasaki Disease (KD), juvenile dermatomyositis (JDMS), and Henoch Schonlein purpura (HSP).

There are 300,000 children in the US with rheumatic conditions and the incidence is increasing with better recognition of this subset of chronic diseases. This makes rheumatic disease one of the most common chronic illnesses in pediatrics. Most recent estimates from 2015 show that there are 407 pediatric rheumatologists in the country and of those, many have very little clinical time are involved more heavily in research. Sadly, most recent estimates suggest that up to 10% of pediatric rheumatologists will be retiring within the next several years and that demand exceeds supply by 25-50%. Many children who do have access to a pediatric rheumatologist travel >4 hours to see a subspecialist and wait times at many centers are several weeks to months. As a result, the practicing pediatric rheumatologists often must rely heavily on generalists and those in other subspecialties to help manage these patients. However, 40% of residency programs do not have access to an onsite pediatric rheumatologist and 11 states are still without a board certified/eligible pediatric rheumatologist. Even within institutions who have access to a pediatric rheumatologist, exposure is limited with estimates of approximately 5 hours of teaching time for the residents who do not rotate with rheumatology as an elective at our institution. This is similar to exposure in other institutions who have pediatric rheumatology.

**Methods:** All pediatrics and med-peds residents at our institution were anonymously surveyed to get their opinion on which topics in rheumatology they thought were most important and also on their preference for content delivery. Based on responses, a series of six lectures were composed in a case based, interactive format. Second year pediatrics and third year med-peds residents rotate through the inpatient rheumatology service and received this curriculum. Pre and post surveys were used to evaluate improvement in comfort level with rheumatology topics.

**Results:** Per self-assessment from the residents' comfort level with laboratory work up, musculoskeletal exam, and referrals improved after working through cases in the curriculum while on the inpatient rotation.

**Conclusion:** Although exposure to pediatric rheumatology is limited in our institution, we were able to effectively increase comfort level with regards to work up and diagnosis of autoimmune diseases. Ideally, exposure to patients in both the inpatient and outpatient setting would also help increase comfort level with this subset of patients, but ACGME guidelines for residency training do not require exposure to pediatric rheumatology during residency training.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Musculoskeletal (MSK) physical exam checklists for a Veterans Affairs (VA) continuing professional development (CPD) course were developed and validated in a broad educational effort for primary care providers (PCPs). These tools were introduced to national leaders in MSK education in the VA National Simulation, Learning, Education and Research Network (SimLEARN) MSK Master Educator course. The aim of this project is to further enhance these through a statistically guided consensus effort.

### Methods:

Twenty MSK educators attending the 2017 MSK Master Educator course were invited to participate in a 3-step Delphi process. Step 1 involved review of current versions of the 21-item shoulder and 26-item knee checklists with invitation to suggest additional items. In step 2, each educator rated every item's importance to be included in a curriculum for PCPs, using a 5-point Likert scale (1 = not at all important; 5 = extremely important). In the 3<sup>rd</sup> step, educators were given the groups' average rating for each item, reminded of their own initial rating, and asked to make a final 5-point rating. Individual responses to each step remained anonymous. After the final step, items meeting the predetermined criteria of mean <sup>3</sup>4 and standard deviation  $\leq 1$  were retained; these items defined the consensus checklists.

### Results:

Eighteen educators (90%; 16 physicians, 1 physician assistant, 1 nurse practitioner) completed the project. Nine educators' practice area was primary care; 9 were in specialty care, of which 7 were rheumatologists.

In step 1, 11 items were added to the shoulder and 14 to the knee checklists. There were no significant differences in ratings from step 2 to step 3, though standard deviations were significantly smaller for both shoulder and knee ( $p < 0.005$ ) in step 3, after respondents were provided with the groups' mean ratings from step 2.

Final ratings for the shoulder and knee are listed in the figures below:

Rating of Items' Importance to be Included When Teaching the Shoulder Physical Examination to Primary Care Providers						
1 Not at all important for primary care	2 Slightly important for primary care	3 Somewhat important for primary care	4 Very important for primary care	5 Extremely important for primary care		
			Final Rating Mean (SD)		Item Retained Mean $\geq 4$ SD $\leq 1$	
			Primary Care	Specialty Care		All Participants
Item	Original Examination Maneuvers					
1	Adequate exposure		4.8 (0.4)	4.9 (0.3)	4.8 (0.4)	Yes
2	General observation – symmetry/atrophy/lesions		4.8 (0.4)	4.9 (0.3)	4.8 (0.4)	Yes
3	Observe for scapular winging		4.1 (0.9)	4.1 (0.3)	4.1 (0.7)	Yes

9	Palpation – temperature evaluation	3.7 (0.9)	4.3 (0.4)	3.9 (0.8)	No	
10	Palpation – effusion specify ballotment vs. bulge sign	3.7 (1.5)	4.4 (0.5)	4.0 (1.2)	No	
11	Medial collateral ligament – valgus stress with knee straight	2.0 (0.8)	3.8 (0.7)	2.8 (1.1)	No	
12	Lateral collateral ligament – varus stress with knee straight	2.0 (0.8)	3.8 (0.7)	2.8 (1.1)	No	
13	Alternative meniscus testing for larger patients	2.9 (0.9)	3.5 (0.9)	3.2 (0.9)	No	
14	Add % sensitivity and specific of exam components	2.4 (1.1)	2.9 (0.6)	2.6 (0.9)	No	
Total items retained					1 (7%)	

When stratifying ratings by practice area, significant differences were seen between ratings by those in primary care and those in specialty care, for both shoulder ( $p = 0.03$ ) and knee ( $p = 0.004$ ).

## Conclusion:

This is a feasible method for a national group of experts to create statistically guided educational tools. The differences between specialist and primary care educators' ratings of item importance suggest these groups may have different expectations for CPD programs. These findings should inform future educational initiatives, ensuring that both subject matter experts and those familiar with the clinical duties of target learners are included in consensus projects.

## Hospital for Special Surgery Academy of Rheumatology Medical Educators: 5 Year Outcomes Demonstrate the Value of Supporting Education Research in the Academic Environment

Jessica R. Berman<sup>1</sup>, Juliet Aizer<sup>1</sup>, Anne R. Bass<sup>2</sup>, Edward Parrish<sup>1</sup>, Laura Robbins<sup>3</sup>, Michael D. Tiongson<sup>4</sup> and Stephen A. Paget<sup>1</sup>,

<sup>1</sup>Rheumatology, Hospital for Special Surgery Weill Cornell Medical College, New York, NY, <sup>2</sup>Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, <sup>3</sup>Education & Academic Affairs, Hospital for Special Surgery, New York, NY, <sup>4</sup>Hospital for Special Surgery, New York, NY

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It has been previously demonstrated that educators do not receive the same recognition as their colleagues in clinical and basic science, and financial support for education research is often inadequate. With this in mind, in 2011 the Academy of Rheumatology Medical Educators was founded at Hospital for Special Surgery (HSS) in order to: 1) create a stimulating academic environment for educators that enhances the quality of teaching and 2) award pilot grants to educators interested in research.

**Methods:** Directed fund-raising was earmarked specifically for annually awarded education grants to serve as a hospital wide impetus for the development of new teaching programs and curricular change through new or improved opportunities for teaching and learning. A request for proposals (RFP) was sent out yearly from 2011-2016 to the HSS rheumatology faculty. One year the RFP was extended to the entire hospital offering matching funds with departments such as nursing and anesthesia. Grants of up to \$50,000 a year were awarded to applications with merit that met the requisite funding priorities. All grants were reviewed and scored according to Glassick's criteria for scholarship by individuals nationally recognized for their education expertise and reviewed by the HSS Education Council, which provides ongoing oversight of the Academy's activities.

**Results:** To date, 23 grants have been awarded for a total of \$ 690,695 in funding. The awardees have produced 19 national meeting abstracts, given 24 presentations (11 posters, 13 oral) at national meetings and written 7 manuscripts (5 published, 2 submitted) and 2 editorials. Funding has resulted in the creation of 8 unique curricula and two iBooks. Diverse topics have been represented such as the assessment of professionalism, new pedagogical techniques for teaching epidemiology to fellows, use of technology in education, an inter-professional gout education program for patients and a hospital based mentorship program.

**Conclusion:** The HSS Rheumatology Academy aims to create a stimulating academic educational environment that enhances the quality of teaching and promotes teaching careers and education research. The formation of the education research funding pilot highlights the talents of heretofore unsupported and unrecognized teaching faculty by allowing them to distinguish themselves academically. This emphasizes the clear advantages of such a formalized structure to achieve the hospital's heightened educational goals and demonstrates the importance of recognizing the quality of education research as equivalent with clinical and basic science research.

## Peer-Developed E-Learning Resource Can Address Rheumatology Knowledge Gaps in Junior Learners

Larissa Petriw<sup>1</sup>, Tabitha Kung<sup>2</sup> and Mala Joneja<sup>2</sup>, <sup>1</sup>Internal Medicine, Queen's University, Kingston, ON, Canada, <sup>2</sup>Rheumatology, Queen's University, Kingston, ON, Canada

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The symptoms related to Rheumatologic diseases are responsible for one third of visits to general practitioners, yet medical students and residents remain inadequately prepared to approach and manage Rheumatologic problems (Freedman and Bernstein, 2002). There are few resources available to junior learners in Rheumatology. Several handbooks written by Canadian Rheumatologists exist, though none combine clinical images, interactivity and case-based learning in an electronic format. Electronic learning (e-learning) provides a highly flexible medium for information presentation, multimedia and self-assessment in a mobile, searchable, user-friendly platform. Evidence suggests that peer-generated e-learning adds value, though most residents do not have extensive software expertise in developing e-

resources. Here we present an interactive, peer-developed case-based Rheumatology iBook produced by residents for learners in Rheumatology aimed to address these gaps.

**Methods:** Our iBook was written in the free, easy-to-use program “iBooks Author”. The target audience was medical students and residents completing a rotation in Rheumatology. Key learning objectives for a Rheumatology rotation were identified and addressed as the main sections of the iBook. Sections include approaches to common rheumatologic presentations, case presentations of rheumatologic conditions commonly encountered over a rotation or general practice, and appendices, including approaches to serology, medications and joint aspiration. Clinical images and self-assessments add interactivity. The iBook was evaluated in a survey of learners rotating through Rheumatology at Queen’s University, with pre- and post-rotation surveys.

**Results:** The survey is ongoing, however preliminary data shows high satisfaction with our resource and improvement in learners’ knowledge. All learners surveyed agree or strongly agree the iBook is user-friendly (75% strongly agree), well organized (75% agree, 25% strongly agree), and has an appropriate level of material and cases (75% strongly agree). All participants found the iBook useful for rotation preparation (50% agree, 50% strongly agree) and would recommend it to a colleague (57% agree, 43% strongly agree). All participants improved their comfort with Rheumatology topics on a Likert scale pre- and post-assessment. Pre-intervention global comfort level was 2.3/4 and post-intervention was 3/4, with similar trends of improvement in the specific topics surveyed. The iBook itself was free and easy to create without additional training in computer programming.

**Conclusion:** We present the first peer-developed e-learning resource of its kind in Rheumatology that can be used as a rotation resource for junior learners across the country. Although content writing remains labour-intensive, the iBook modality allows easy updating and minimal knowledge of programming by the writers. Conversion to non-iBook format is possible for further distribution across platforms. The iBook structure can easily be adapted to other medical education topics and is a user-friendly method of e-publication for busy residents interested in medical education.

## Validity Evidence for an Objective Structured Clinical Examination Station to Assess Knee Arthrocentesis Skill

Tawnie Braaten<sup>1</sup>, Andrea Barker<sup>2</sup>, J. Peter Beck<sup>3</sup> and Michael J. Battistone<sup>2</sup>, <sup>1</sup>University of Utah, Salt Lake City, UT, <sup>2</sup>Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, <sup>3</sup>Orthopaedics, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

We developed an objective structured clinical examination (OSCE) station to guide preceptors’ observations of trainees’ performance of simulated knee arthrocentesis and to organize feedback in preparation for performing these procedures in patient care. The aim of this project was to examine the evidence for validity of this OSCE.

### Methods:

#### Content:

An orthopedic surgeon, a rheumatologist, and a primary care provider with expertise in musculoskeletal (MSK) medicine developed a checklist to guide rater observations in evaluating arthrocentesis technique. Content was proposed by faculty, supplemented by literature review, and finalized through consensus.

#### Response Process

A multi-disciplinary cohort of 71 learners (53 postgraduate trainees, 12 physician assistant students, 5 advanced practice nursing students, and one university undergraduate student) participated in the OSCEs in 2016-2017. To promote accuracy of the simulated patient (SP) responses to assessment prompts, one faculty member served as the SP and another as rater; ratings were recorded in real time.

#### Internal Structure

Two faculty members independently rated a portion of the cases. Percent agreement was calculated and Cohen's kappa corrected for chance agreement on binary outcomes.

#### Relations to other variables

Relationship to self-assessment of confidence and competence to perform knee arthrocentesis was explored by written surveys utilizing a 5-point Likert scale. Response scores were compared with OSCE scores through Pearson's correlation coefficient.

#### Results:

Checklists were developed for knee arthrocentesis (19 items). The checklist was scored by assigning one point for each error observed, in order to capture multiple errors; thus a score of 0 indicated no errors were noted. Mean score was 3.7 (range = 0-8; s.d. = 1.9). Frequency distribution of scores is reported in the Figure:

Inter-rater agreement was near perfect at 93% ( $k = 0.8$ ), as shown in the Table:

		Rater 1		Total
		No Error Noted	Error Noted	
Rater 2	No Error Noted	116	5	121
	Error Noted	6	31	37
	Total	122	26	158

Observed Agreement =  $(116 + 31)/158 = 0.93$

Chance Agreement = 0.64

Cohen's kappa = 0.8

Pearson's coefficient indicated no correlation between self-assessment and OSCE performance (-0.002).

#### Conclusion:

Validity evidence supports use of this OSCE in educational programs preparing learners for clinical settings where MSK procedures may be performed. Evidence for validity includes systematic development of content, response process control, and demonstration of acceptable interrater agreement. Lack of correlation with self-assessments suggests that the OSCE measures a construct different than self-perceived ability.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** paediatric musculoskeletal matters' (PMM—[www.pmmonline.org](http://www.pmmonline.org)) is a free, evidence-based and peer reviewed open e-resource for paediatric musculoskeletal (MSK) medicine targeting non-MSK specialists. Since launch (Nov-2014) PMM has reached 183 countries with >57,000 users, >194,000 hits. Users who have declared their training background on the website are mainly non-MSK specialists. Feedback from users has requested further content to reflect international healthcare systems. PMM India was developed in collaboration with the Indian Academy of Paediatrics (IAP; Sept-2015, >2,200 users, 14,000 hits to date) and showcases successful partnership with local clinicians in developing PMM with local context. Further 'internationalisation' is now ongoing with additional global partners to develop 'PMM International'. Here, we describe the process for international development.

**Methods:** Paediatric rheumatologists in countries around the world were approached to identify additional PMM content to reflect MSK medicine in their health care systems (e.g. case mix, clinical presentations, care pathways), with the focus on maintaining the level of knowledge relevant for non-MSK specialists. New content was developed by local teams identified by the paediatric rheumatologist(s) who then collated and provided expert overview before submission for editorial review. All contributions were provided in English. Additional cases and images were included with appropriate consent.

**Results:** PMM International additions to the original website brings new content predominately focused on infections / infection-related disease with MSK features or as differential diagnoses for rheumatic disease. Most content is in English with requests for translation of some content (e.g. pGALS which will be available in >7 languages). PMM International will be further peer reviewed with open access to all. A PMM app is planned to facilitate access where internet capacity is limited.

**Conclusion:** Rapid globalisation necessitates appropriate e-resources with content that reflect international health care contexts. PMM International targets non-MSK specialist audiences to raise awareness and early recognition of MSK pathology. Our work reflects strong collaborative global partnerships within the paediatric rheumatology community. PMM has been endorsed by PReS as an educational resource to aid teaching and learning. Implementation of PMM International has yet to be formally evaluated, but PMM data so far, supports wide reach and positive uptake from the target audience user groups.

## Impact of a Student Led Rheumatology Interest Group on Medical Student Interest in Rheumatology

Sonia Silinsky Krupnikova<sup>1</sup>, Adey Berhanu<sup>2</sup>, Sean McNish<sup>3</sup>, Derek Jones<sup>1</sup> and Victoria K. Shanmugam<sup>2</sup>, <sup>1</sup>The George Washington University, Washington, DC, <sup>2</sup>Rheumatology, The George Washington University, Washington, DC, <sup>3</sup>Division of Rheumatology, The George Washington University, Washington, DC

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Based on data from the Rheumatology Workforce Study, there are currently insufficient rheumatologists to serve the needs of the population. The purpose of this longitudinal observational study is to investigate the impact of developing a student-led Rheumatology Interest Group on medical student interest in rheumatology at a single institution. We report updated longitudinal follow-up data on the impact of this intervention at the two year follow-up stage.

**Methods:** A student-led Rheumatology Interest Group was established at our institution in April 2015. The Interest Group runs several meetings per year, including a session on careers in rheumatology, finding research projects and mentors, and joint injection workshops. To assess the impact of the Interest Group on medical student interest in rheumatology we collected data prior to and subsequent to development of the Interest Group based on three parameters: the number of medical student abstract submissions to the University Research Day, the number of medical students enrolling in the rheumatology elective, and the number of manuscripts published by faculty with medical students. The mean number of student-rheumatology interactions per 6 months in the pre and post intervention periods was assessed for each parameter. Data lock for the current analysis was in April 2017 and analysis was performed using GraphPad Prism version 5.00 for Windows (GraphPad Software, San Diego, CA).

**Results:** Analysis of the two years of follow up data indicates that there continues to be a significant increase in medical student enrollment in the rheumatology elective following the Interest Group development, with a mean number of students per 6 months of  $2.0 \pm 0.89$  in the pre-intervention period and  $5.25 \pm 2.06$  in the post-intervention period ( $p=0.0083$ ). The number of abstract submissions also significantly increased from  $0.5 \pm 0.84$  to  $6.5 \pm 4.65$  ( $p=0.0131$ ). Finally, the number of manuscripts submitted by student-faculty dyads increased from  $0.17 \pm 0.41$  to  $1.5 \pm 0.58$  ( $p=0.0026$ ).

**Conclusion:** Based on data at two years of follow-up, a simple and low cost intervention of developing a student-led interest group has dramatically increased ongoing student engagement with rheumatology at a single institution.

## Medical Student Interest in Rheumatology As a Career

Peter Berger<sup>1</sup>, Adey Berhanu<sup>2</sup>, Derek Jones<sup>1</sup>, Sean McNish<sup>3</sup> and Victoria K. Shanmugam<sup>2</sup>, <sup>1</sup>The George Washington University, Washington, DC, <sup>2</sup>Rheumatology, The George Washington University, Washington, DC, <sup>3</sup>Division of Rheumatology, The George Washington University, Washington, DC

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Based on data from the Rheumatology Workforce Study, there are insufficient rheumatologists to serve the needs of the population. Little is currently known about factors that contribute to career choices of graduating medical students. The purpose of this study was to investigate medical student interest in rheumatology at the time of graduation, and to assess factors which drive career choices.

**Methods:**

This prospective survey study was IRB approved and conducted at a single center. A web-based REDCap survey was sent to graduating medical students via listserv approximately 1 month prior to graduation. Students self-reported demographics, information on whether and when they decided on their career specialty, how likely they were to consider a career in rheumatology, and what factors appealed to them about rheumatology as a specialty.

**Results:**

From the graduating class of 208 students, 52 matched into internal medicine or pediatrics. The survey was completed by 28 students (response rate 13.5%). Respondents were 64% female and 36% male; 57% Caucasian and 28% of African American descent. All respondents reported that they had decided on a specialty at the time of survey completion, with 78.5% reporting that they decided during their third or fourth year of medical school. While only one respondent reported planning a career in rheumatology, factors which appealed to the students about rheumatology as a specialty included: favorable work hours (78.5%), work-life balance (78.5%) and interest in complex medical care (54%). Of the experiences that stimulated their interest in rheumatology as a specialty, the most frequent response was the exposure to rheumatology teaching during their second year musculoskeletal block (36%). Interest in a specialty was the primary driver of career choice (85.7%) while earning potential, student debt, and length of training did not play a role.

**Conclusion:**

In this survey of medical students at a single US medical school, the majority of respondents decided their specialty during their clinical years. Interest in the specialty was the most important factor that drove career choice for this graduating class. Rheumatology teaching during the second year module was the most frequently reported exposure during which interest in rheumatology as a specialty was stimulated.

## **Impact of a Lung Ultrasound Course for Rheumatology Specialist (IMPACT-2)**

**Christopher Gasho**<sup>1</sup>, Karina Torralba<sup>2</sup>, David Chooljian<sup>3</sup>, Cong-Bin Wang<sup>4</sup> and Vi Dinh<sup>4</sup>, <sup>1</sup>Pulmonary and Critical Care Medicine, Loma Linda Medical Center, 12354 Anderson St, CA, <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Loma Linda University, Loma Linda, CA, <sup>3</sup>Loma Linda Veteran Affairs Hospital, Loma Linda, CA, <sup>4</sup>Loma Linda University Medical Center, Loma Linda, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although much emphasis is focused on lung ultrasonography(US) within the critical care field, there is a growing interest in the use of lung US and its role in diagnosis and monitoring of Interstitial Lung Disease(ILD). A large burden of ILD is attributed to connective tissue disorders(CTD) and often presents symptomatically after irreversible fibrosis has ensued. With increasing use of point-of-care musculoskeletal US among rheumatologists, translation of this expertise towards lung US places the rheumatologist in a unique position to screen for asymptomatic lung involvement among patients with CTD. Despite recent evidence of the feasibility and utility of using lung US in screening of patients with CTD-ILD, the field is relatively immature and standardized training curriculum for the rheumatology community is lacking. The aim of this study is to determine the effectiveness of a formalized lung US training course for Rheumatology fellows and attending physicians in incorporating and improving skills and attitudes in lung US.

**Methods:** Four rheumatology fellows and four board-certified rheumatologists were enrolled in a 4-hour training session including didactics, live models and simulation experience. Pre-course, post-course and 6-month follow-up surveys evaluated participant perceptions towards

previous US experience, training, clinical utility and attitudes toward dedicated lung US. Written exams (21 multiple-choice questions) were completed before, after training, and at 6 months to evaluate basic knowledge in ultrasound physiology, lung US anatomy, artifact and pathology recognition. In addition, a 30-point practical exam using live models and simulation, evaluated competency in machine setup, anatomical, artifact and pathology recognition

**Results:** The results of this study show overall improvement in written test scores ( 43% v 66% p<0.001) Considerable improvement was also noted in overall practical skill score following training course. ( 16.8% v. 93.4% p<0.001). Sub category improvements were seen in ultrasound setup and anatomical landmark identification (18.8% v 94.4% p<0.001 ) identification of pulmonary artifact (15.6% v 91% p<0.001) and pulmonary pathology identification (29% v. 91% p<0.001). 6 month retention rate was excellent for: Written Scores ( 92.3%) , Practical Skills (93%) , Setup/Landmark Identification (88%) Artifact Identification (100%).

**Conclusion:** Dedicated lung ultrasonography training can be integrated into a rheumatology fellowship program for potential screening of CTD-ILD.

## A Pilot Study of the Use of a Validated Gout Script Concordance Test Assessment in an Interdisciplinary Musculoskeletal Education Program

Bernadette C. Siaton<sup>1</sup>, Andrea Barker<sup>2</sup> and Michael J. Battistone<sup>2</sup>, <sup>1</sup>Rheumatology, University of Maryland School of Medicine, Baltimore, MD, <sup>2</sup>Veterans Affairs Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A validated script concordance assessment (SCT) for gout was created for use in the internal medicine residency program at the University of Maryland Medical Center (UMMC). The assessment demonstrated high reliability and large effect size in a population of 143 learners.<sup>1</sup> The aim of this pilot study was to explore the feasibility of using this tool with interprofessional, multilevel groups of learners at the Center of Excellence in MSK Care and Education (MSK COE) at the Salt Lake City Veterans Affairs Medical Center (SLC VAMC), to inform full implementation of the SCT in July, 2017.

**Methods:** A convenience sample of 19 learners (14 students or trainees; 5 practicing primary care providers (PCPs)) participating in programs at the SLC VAMC MSK COE, were asked to complete the SCT before and after a didactic session on gout. They were then sent emails containing the URL to access the SCT before and after the didactic. Time to complete the survey was not provided during the course. SCT was scored using an aggregate scoring method based on the results of an expert panel. Average pre- and post-test scores were calculated. A one-way ANOVA was used to compare pre- and post-test scores.

**Results:** Nine learners (47%) completed both the pre- and post-didactic SCT. The maximum possible SCT score was 50.16 points. For reference, the average score of the expert panel was 40.65 (SD=1.72) points. The average pre- and post-test scores for the UMMC population were 31.32 (SD=3.12) points and 33.98 (SD=2.72) points, respectively. The average pre-test score for the SLC VAMC population was 29.71 (SD=5.08) points. The average post-test score was 32.04 (SD=2.73) points. SLC VAMC learners did not show a statistically significant increase in scores after didactics,  $p=0.243$ . Individual learner demographics, pre-test scores, and post-test scores are below.

Learner Type	Pre-test Score	Post-test Score
Nurse Practitioner Student	31.74	35.72
Physician Assistant Student	31.86	30.99
Medicine Resident	30.84	34.95
Medicine Resident	17.18	28.67
Medicine Resident	30.12	32.12
Physician	32.95	33.76
Nurse Practitioner	26.87	31.60
Physician	32.65	33.05
Nurse Practitioner	33.16	27.48

**Conclusion:** This pilot study demonstrates feasibility of implementing a validated SCT to assess knowledge of gout in a different institution, across an interprofessional and multilevel group of learners. The response rate was low, indicating that different methods of interfacing with this instrument, including confirmation of participation, are needed with our learner groups. The larger pre-course variance, relative to the reference population, may reflect the comparative diversity of our learners, but the small sample size and response rate limit the validity of statistical inferences. We will continue to use the SCT assessment in the MSK Education Week curriculum and accrue additional learners in order to better understand its use as an assessment.

## Improving Internal Medicine Resident's Knowledge through a Web-Based Musculoskeletal Educational Module

Uzma Haque<sup>1,2</sup>, Clifton O. Bingham III<sup>3</sup> and Allan C. Gelber<sup>4</sup>, <sup>1</sup>Rheumatology, Johns Hopkins School of Medicine, Lutherville, MD,

<sup>2</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Rheumatology, Johns Hopkins University, Baltimore, MD, <sup>4</sup>Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Musculoskeletal (MSK) complaints account for 15-30% of the ambulatory care visits in the United States. MSK training during Internal Medicine (IM) residency remains suboptimal, and residents report low self-confidence in managing MSK conditions. To address this gap, we developed an internet-based MSK module to improve IM residents' knowledge and skills in evaluation and management of ambulatory MSK complaints. We examined the effectiveness of this educational intervention using data from the first 150 residents who completed this module.

**Methods:** The MSK module was disseminated on Physician Education and Assessment Center (PEAC), a web-based extramural ambulatory curriculum, currently used by 50% (194 out of 389) of the accredited IM Programs in the US and available to 11,000 IM residents as a key component to their ambulatory curricula. The module "Approach to a Patient with a Joint Complaint" was based on pretest-case based didactics-posttest format. The goal of this module was to give IM residents foundational knowledge and a systematic initial approach to a patient with a joint complaint, which leads to an appropriate initial diagnostic differential and work-up. Didactics and content was written to address the specific cognitive/knowledge objectives of the module, such as "to distinguish arthralgia from arthritis". MSK knowledge was assessed using pre-tests and post-tests. We compared scores between first (PGY-1), second (PGY-2) and third year (PGY-3) residents to assess baseline knowledge, pretest and posttest scores among different years of training. Analyses were performed using SPSS v24.

**Results:** Of 151 residents completing the module, 32% were program year (PGY)-1, 32% were PGY-2, and 36% were PGY-3. The programs were 23.2% university training programs, 59.6% were community training programs, 7.3% were "other" training programs, and 9.9% were unknown training programs. Baseline mean (SD) pre-test scores were 59.4% (23.4). Pre-test scores were significantly higher when comparing PGY3 to PGY1 ( $p=0.02$ ) only, but not between other years. The mean post-test score was 91.2% (11.2). Completion of the MSK module led to significant improvement from pre- to post-test scores (mean improvement =31.84% (SD=24.53)). There was no difference in the post-test scores among the three years of trainees.

**Conclusion:** Web-based modules can be effective in augmenting and disseminating MSK knowledge to IM trainees. Additional modules and topics are being implemented. Further studies are required to evaluate whether knowledge gained from this intervention translates into improved care for patients with MSK complaints.

## Rime (Reporter-Interpreter-Moderator-Educator) Evaluation Tool to Assess Fellows in Rheumatology

**Micheline Hearth-Holmes**<sup>1,2</sup>, Amy C. Cannella<sup>3</sup> and Alan R. Erickson<sup>4</sup>, <sup>1</sup>Internal Medicine/Rheumatology Division, Univ. of Nebraska Medical Center, Omaha, NE, <sup>2</sup>Internal Medicine/Rheumatology Division, University of Nebraska Medical Center, Omaha, NE, <sup>3</sup>Section of Rheumatology, University of Nebraska Medical Center, Omaha, NE, <sup>4</sup>Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Rheumatologists in academic settings strive to be excellent teachers and educators. The ACR reinforces this perspective by bestowing yearly education awards for outstanding clinician educators who assist in maintaining and increasing the workforce. The RIME method of evaluation is a teaching tool used to gauge medical students and residents in multiple clinical settings, focusing on whether a student has mastered the subjects of reporting and interpreting data followed by the ability to teach medical information. The ability to teach medical information enhances a student's ability to recall information during standardized testing. The purpose of this study is to assess if rheumatology fellow performance on RIME evaluations can predict improvement in in-service examination scores from year 1 to year 2 of their fellowship.

#### **Methods:**

An evaluation tool using RIME format was adapted to assess four domains (presentation quality, presentation skills, analysis, critical thinking). Fellows were given a number score for each domain as well as a total score (1-does not meet expectations; 2-meets expectations; 3-exceeds expectations). Seven teaching faculty were trained on the use of the tool to determine a RIME designation of reporter, interpreter, moderator, or educator. Every presentation given during the two-year fellowship was evaluated. The in-service scores were from first and second year rheumatology fellow examinations. All fellows' ITE scores improved in absolute numbers and percentile rank from year 1 to year 2. RIME scores for each domain were tabulated and compared to the in-service scores. The RIME score was calculated as the mean of the 4 separate domains using a 1-3 scale. The overall RIME score was calculated as the mean of the four sections scored. These scores were compared against the year 1, year 2, and the mean ITE scores for years 1 and 2. All presentations were completed and evaluated prior to the year 2 ITE. Statistical models used were generalized estimating equation models with an exchangeable variance structure to account for repeated measurements within fellows.

#### **Results:**

Data was collected on eight fellows over four years. There were a total of 34 encounters with an average of four encounters per fellow. This data was compared to in-service examinations from years 1 and 2. Year 1 ITE scores and mean year 1 and 2 ITE scores were not significantly associated with RIME scores ( $p=0.194$ ;  $p=0.083$ ). Year 2 ITE scores were significantly associated with RIME scores ( $p=0.036$ ). RIME designations noted that of the 29 completed encounters, 21 presentations were marked as educator, 4 each as interpreter or moderator and none were marked as reporters. Five encounters were not completely scored and were excluded from the analysis.

#### **Conclusion:**

- (1) Only the 2<sup>nd</sup> year ITE scores were significantly associated with RIME scores.
- (2) RIME scores for year 1 and the combined years 1 and 2 ITE scores did not correlate.
- (3) This data would suggest that RIME feedback to the fellows during their training program prior to year 2 ITE (approximately 19 months), reinforces the skills needed to master, retain, and communicate medical knowledge.
- (4) RIME, as well as ITE, is an important tool in the training and evaluation of rheumatology fellows.

## **Incorporating Temporal Artery Ultrasound in a UK District General Hospital with No Prior Colour Doppler Sonography Service: An Encouraging Preliminary Analysis**

Othman Kirresh<sup>1</sup>, Chintu Gademsetty<sup>2</sup> and Charles Li<sup>1</sup>, <sup>1</sup>Rheumatology, NHS Royal Surrey County Hospital, Surrey, United Kingdom,

<sup>2</sup>Radiology, NHS Royal Surrey County Hospital, Surrey, United Kingdom

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Temporal Arteritis (TA) is the most common large vessel vasculitis, affecting adults over the age of 50. It is associated with significant morbidity due to ischemic manifestations such as blindness and stroke.<sup>1</sup> The gold standard for diagnosis has always been temporal artery biopsy (TAB) and although highly specific (98%) it lacks sensitivity, and can yield false-negative results in up to 60% of cases. The emergence of CDS in the diagnosis of GCA has now been widely acknowledged, further supported by meta-analyses confirming its validity.<sup>2</sup> Prospective postulate a better sensitivity compared to TAB.<sup>3</sup> For hospitals with no prior experience in TA-CDS a common validity concern lies in the procedures intra-operator reliability.

## Methods:

A temporal arteritis (TA) pathway incorporating CDS was introduced into a small UK district general hospital serving a population of 200,000. It was presented at a local hospital medical meeting attended by all doctors to raise awareness. Subsequently the pro forma was distributed throughout the trust including medical wards, Accident and Emergency (A&E) and the Medical assessment unit (MAU).

As part of the pathway every patient who was referred for a TAB (performed by the Maxillofacial surgeons), also underwent a CDS. The latter was performed by one musculoskeletal (MSK) Consultant Radiologist who was blinded in terms of patient symptoms i.e. side of headache. Crucially the radiologist although experienced (n= 20,000 MSK Ultrasound studies) has not been trained specifically in temporal artery ultrasound. Patients would then be followed up in Rheumatology Outpatients with the results of the investigations within 4 weeks.

## Results:

**Table 1:**

<b>Referrals</b>	N= 20	
<b>Treated for TA</b>	13/20	
<b>Gender</b>	Male: 10/20 Female: 10/20	
<b>Age Range</b>	56- 85	
<b>Mean Age</b>	71	
<b>Mean time prior to TAB on GC</b>	10.2 Days	Range: 48 hours - 17 days
<b>Mean time prior to CDS on GC</b>	5.1 Days	Range: 24 hours - 11 days
<b>Mean duration of GC Neg for TA</b>	5.7 weeks	
<b>Average initial GC dosage</b>	42.3mg	Range: 40 - 60 mg
	<b>TAB positive</b>	<b>TAB Negative</b>
<b>CDS Positive</b>	3/12 (3/13)	7/20 (7/13)
<b>CDS Negative</b>	0/20 (0/13)	2/20 (2/13)
<b>Positive TAB</b>	3/20 (3/13)	
<b>Positive CDS</b>	11/20 (11/13)	
<b>McNemar Test (CDS vs TAB)</b>	<b>P = 0.023</b>	

TAB had a specificity of 100% in contrast the sensitivity was 23% (Sensitivity 84% for CDS).

## Conclusion:

TA can be a challenging diagnosis for clinicians to make; hence diagnostic investigations are important. Our results demonstrate the critical role and value of CDS in the diagnosis and management of TA. When clinical suspicion is high for TA our data shows CDS as specific as TAB, but more importantly even when a radiologist is new to the procedure significantly higher sensitivity when compared to TAB (84%, P<0.023). Despite non familiarity of the operator the procedure adds to the diagnostic process. Our study data is line with existing data,<sup>2,3</sup> and highlights the necessity to incorporate CDS in the diagnosis of TA.

## Teaching Musculoskeletal Examination to Internal Medicine Residents in Digital Age

Sonam Kiwalkar and Odunayo Olorunfemi, Internal Medicine, Rochester General Hospital, Rochester, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The resident-run internal medicine clinic at our community hospital caters to an inner city population. Lower back pain and knee pain are among the top 5 presenting complaints. We have a heterogeneous group of residents who graduated from medical school from different parts of the world, who vary in experience of practicing medicine before residency, many of whom were exposed to a minimal or unstructured musculoskeletal (MSK) curriculum in medical school affecting their confidence in performing MSK exam. Our objectives were to improve resident knowledge, skills and engage a heterogeneous group of residents in an active learning classroom activity designed to improve MSK exam skills.

**Methods:** We designed a MSK workshop incorporated into our mandatory ambulatory curriculum. There were 2 sessions (upper & lower extremity), 2 hours each, that all 58 residents completed. Based on a flipped classroom design, pre-classwork was assigned including review articles and short videos. Classwork comprised of case discussions and peer led MSK skill demonstration and practice sessions. A pretest multiple choice questions was conducted 5 weeks prior to the first session, a post test immediately after and another after 6 months. Pre and post surveys measured levels of confidence and engagement in this active learning experience compared to passive learning. T-test and Chi was used to analyze data.

**Results:** Residents did better on posttest compared to pretest ( $p < 0.0001$ ). PGY3 sustained their scores even after 6 months. Mean increase in scores were higher for PGY 1 compared to seniors ( $p < 0.0081$ ). Self-reported confidence in MSK exam increased across the board ( $p < 0.004$ ). Those who practiced medicine before joining residency and those who demonstrated MSK skills to their peers sustained this confidence even after 6 months. Use of smart phone during this active workshop compared to traditional classroom passive teaching is shown in Figure 1 & 2, which was used as a marker of resident engagement.

**Conclusion:** The data suggests that a flipped classroom based MSK curriculum improves medical knowledge and skills of performing a MSK exam in a heterogeneous group of Internal Medicine residents. Moreover, it was successful in capturing attention of residents in a digital age. The reason that PGY 3 did better on knowledge component after 6 months may be attributed to their preparation for boards. Compared to similar endeavors in the past, we had a 100% retention rate because our sessions were mandatory. We hope to enhance our curriculum by embedding standardized patients and observed structured clinical assessments.

**Figure 1:** Likelihood of use of smart phones during active and passive learning.

**Disclosure:** S. Kiwalkar, None; O. Olorunfemi, None.

## Utility of a Virtual Rheumatology Clinic for Community Based Internal Medicine Residency Program

Sonam Kiwalkar<sup>1</sup> and Bethany A. Marston<sup>2</sup>, <sup>1</sup>Internal Medicine, Rochester General Hospital, Rochester, NY, <sup>2</sup>Rheumatology, University of Rochester, Rochester, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** At our mid-sized community hospital, internal medicine residents have little routine access to subspecialty rheumatology faculty clinical and didactic teaching, which has been reflected in below-average in-training exam scores in recent years. We needed an active learning resource to disseminate practical aspects of rheumatologic diagnoses and management. Hence, we partnered with the University of Rochester, and collaborated to further develop the 'Virtual Rheumatology Clinic' Tool. University residents had found the online tool as an engaging, interactive and user friendly series of virtual patients, which we felt would benefit residents and students at Rochester General. Our primary outcome was to improve confidence in diagnosis and treatment of rheumatologic conditions. Our secondary outcomes were to improve knowledge base in rheumatology and obtain user feedback for these modules.

**Methods:** We had a total of 58 participants (19 PGY 1, 20 PGY 2, 19 students) using the tool. Login instructions were sent via email. 6 modules (lupus, lower back pain, gout, myositis, giant cell arteritis and osteoporosis) were completed over 3 months. Knowledge was assessed by a pretest and posttest covering a broad range of rheumatology topics. Confidence and usefulness of the tool was determined by pre and post surveys. Data was analyzed by T test and Chi square test.

**Results:** Self-reported confidence in diagnosis and treatment of rheumatologic diseases was below average to average among students and residents before using the modules ( $P=0.560$ ). Students gained more confidence compared to residents after completing the modules ( $P=0.04$ ). There was no difference in pretest and posttest scores across the board ( $P=0.08$ ). Improvement was greater in those concepts covered by the modules compared to those which were not ( $P=0.001$ ). Residents had a greater mean increase in scores compared to students ( $P=0.001$ ). Perceived usefulness of modules is shown in Figure 1.

**Conclusion:** The modules seem to be more appropriate for residents than students, based on overall improvement in objective test scores. Students and residents both acknowledged the usefulness of the modules. Improvement in global post-tests were not detected, likely in part because these were not limited to topics covered; sub scores on covered diagnoses did improve. Our future goals would be to expand the range of topics covered to include rheumatoid arthritis and psoriatic arthritis, expand access to other trainee groups such as family medicine residents and compare utility among groups, and compare the in-training exam scores for cohorts who used this tool to historic cohorts.

**Disclosure:** S. Kiwalkar, None; B. A. Marston, None.

## Tweeting the Meeting: Analysis of Twitter Use during the American College of Rheumatology 2016 Annual Meeting

Mosaab Mohameden<sup>1</sup>, Victoria Malkhasyan<sup>2</sup>, Baker Alkhairi<sup>3</sup>, Najla Aljaberi<sup>4</sup> and Candice Yuvienco<sup>5</sup>, <sup>1</sup>Internal Medicine, University of California San Francisco - Fresno Medical Education Program, Fresno, CA, <sup>2</sup>University of California San Francisco - Fresno Medical Education Program, Fresno, CA, <sup>3</sup>Internal Medicine, Blake Medical Center, Bradenton, FL, <sup>4</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>5</sup>Internal Medicine, Division of Rheumatology Director, University of California San Francisco, Fresno Medical Education Program, Fresno, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The American College of Rheumatology (ACR) annual meeting is the premier rheumatology research and education event of the year. The ACR adopted the use of social networks to spread medical knowledge. Twitter is a popular social network site with hundreds of millions of users and over 500 million Tweets being sent each day, there is a great opportunity for ideas to reach a global audience of new and existing professionals and patients. The ACR has specifically used and encouraged the use of twitter for such purpose and to promote its events and disseminate news and educational tweets from the annual meeting. In this study, we aim to analyze the use of twitter at the 2016 ACR annual meeting.

**Methods:** The Sympular Signals, a specialized healthcare social media analytics platform was used to analyse the hashtag #ACR16, the official hashtag of the ACR 2016 meeting. The analysis was conducted on tweets during the meeting days November 11th-16th of 2016. The number of tweets, participants, impressions, average tweets per hour and average tweets per participant was determined. Advanced search on Twitter was also conducted using the hashtag #ACR16 with timeframe between November 11th-16th. The resulted tweets were sorted by category "top tweets" which are the most popular tweets according to Twitter. The top 50 tweets were categorized by content to scientific, social, administrative, industry promotion, or irrelevant.

**Results:** The 2016 ACR annual meeting had over 16,000 attendees from around the world. The number of people who participated in the hashtag #ACR16 was 3,298 (about 20% of the attendees) sending 16,796 tweets during the meeting days, with an average of 5 tweets per participant and 117 tweets per hour, leaving 50,302 million impressions. The hashtag activity reached a peak of 4146 tweets on the 4th day of the meeting, November 14th. Seventy percent of the top tweets were by physicians, 10% by medical journals, 10% by patient advocate groups, and 10% by non-medical patient advocate individuals.

Forty two percent of the top 50 tweets had scientific content ranging from disease progression to treatment options. Whereas 28% had social content such as selfies and group photos to commemorate the event. Irrelevant tweets were mostly appreciation tweets addressed to some of the presenters at the meeting and represented 26%. Surprisingly, only 2% of content was industrial promotions and 2% were administrative tweets.

**Conclusion:** Twitter has facilitated communication between attendees and helped in delivering valuable information to them and to the public efficiently and free of cost. Most of the tweets were posted by physicians and the posts were mostly scientific. A more targeted approach can be implemented to increase tweets generally and scientific posts specifically by attendees, and to encourage industrial companies to tweet about their products. This is a useful and cost-effective way to deliver valuable information and knowledge to a much further audience than just attendees.

## **Rheumatology Fellows Teaching in a Consult Setting: Pilot Project at Two Training Hospitals**

Holly Smith<sup>1</sup>, Sarah Kazzaz<sup>1</sup>, Anju Mohan<sup>2</sup> and Jammie Barnes<sup>1</sup>, <sup>1</sup>Rheumatology, UT Health, McGovern Medical School Houston, Houston, TX, <sup>2</sup>Internal Medicine, UT Health, McGovern Medical School Houston, Houston, TX

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

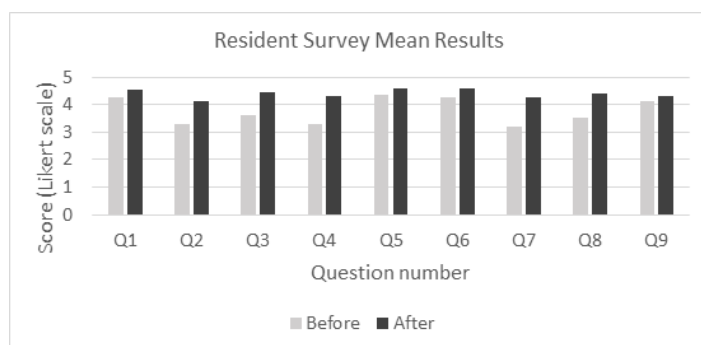

Subspecialty consults in a hospital setting often contribute to disjointed patient care and frustrated providers. Miloslavsky et al (1) previously demonstrated improvement in rheumatology fellows' ability to teach in a consult setting in a standardized learner environment. We sought to perform a similar intervention in a pilot real-world setting at our two teaching hospitals. Our goals were to improve fellows' ability to teach, create interest in the field, and facilitate more collaborative patient care.

### **Methods:**

A 10-question pre-intervention survey was administered to residents on internal medicine teams at each of the 2 training hospitals. The survey utilized a 5-point Likert scale to address 7 aspects of rheumatology fellows' ability to teach, overall effectiveness and approachability, as well as quantifying percentage of time recommendations were shared in person. Our intervention included: a workshop for fellows on adult learning theory and self-directed learning; provision of pocket card containing medicine team locations, contact numbers, and prompt questions; monthly email reminders of the project goals to attendings and fellows. Rheumatology attendings standardized consult rounds by visiting teams following patient evaluations to relay our recommendations; fellows were instructed to lead the discussion. We employed this strategy for four months, after which the same survey was administered to residents on medicine teams. There was no randomization or blinding due to the nature of the study.

### **Results:**

There were 33 pre-intervention and 15 post-intervention completed surveys. Mean scores on each of the 10 questions improved from pre- to post-intervention. Overall teaching effectiveness improved from mean of 3.55 to 4.4 (on 5-point scale). Prior to the intervention, 9% of respondents reported receiving in-person recommendations at least 50% of the time compared to 60% of respondents after the intervention.

## Conclusion:

The findings of our pilot project are similar to the “Rheumatology Fellows as Teachers” project by Miloslavsky et al (1). With a simple teaching intervention and standardization of the workflow, we improved perceived teaching skills in all areas measured. Our limitations included few survey respondents and inability to control for improvements in fellow teaching due to increased experience. Despite these limitations, our findings suggest that having a standardized process for consultation that fosters a positive teaching interaction and collaboration can have far reaching effects on resident fellow interactions as well as patient care. Future studies could include other consult services, and a paired pre- and post-intervention analysis.

## A Blended Learning Approach to Clinical Skills Teaching: E-Learning for Paediatric Gait, Arms, Legs and Spine Examination (pGALS)

Sarah Cope<sup>1</sup>, Sharmila Jandial<sup>2</sup> and Helen E. Foster<sup>3</sup>, <sup>1</sup>Paediatric Rheumatology, Great North Children's Hospital, Royal Victoria Infirmary, Newcastle upon Tyne, Paediatric Rheumatology, Great North Children's Hospital, Newcastle upon Tyne, United Kingdom, <sup>2</sup>Department of paediatric rheumatology, Great North Children's hospital, Royal Victoria Infirmary, Newcastle upon Tyne, Department of paediatric rheumatology, Great North Children's hospital, Royal Victoria Infirmary, Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom, <sup>3</sup>Institute of Cellular Medicine and Paediatric Rheumatology, Newcastle University and Great North Children's Hospital, Newcastle Upon Tyne, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Musculoskeletal (MSK) presentations in childhood are common and often present initially to clinicians who are not specialists in paediatric MSK medicine.

Many doctors report lack of confidence and competence in paediatric MSK clinical skills relating to lack of teaching both at undergraduate (1) and postgraduate levels (2). The paediatric Gait, Arms, Legs and Spine (pGALS) examination is a clinical skill targeting non-specialists and is widely taught (3).

One of the ongoing challenges in paediatric MSK education is the reliance on MSK specialists to deliver teaching yet often this resource is limited. Blended learning combines face-to-face with digital resources, and allows greater reach to learners. Using an evidence-based approach, we have developed an e-learning module focused on paediatric MSK clinical skills to complement pGALS teaching, and describe the development and evaluation process.

## Methods:

Identification of the learning needs for this module came from previous research with medical students and family medicine clinicians, alongside curriculum review and qualitative work with medical students. In conjunction with web-developers we developed an interactive, case-based module using key e-learning strategies such as question & answer, click and reveal, and reiteration of key learning points. The module focused on key elements; MSK history, pGALS manoeuvres and common abnormalities found, red flags, next steps (investigations and management) and links to Paediatric Musculoskeletal Matters website ([www.pmmonline.org](http://www.pmmonline.org)) for more information.

The evaluative strategy focused on qualitative methods including pre-testing and focus groups to allow a greater understanding of the user experience of both the module and perceptions of e-learning in general. Focus groups were audio-recorded, transcribed and underwent thematic analysis.

## Results:

The final e-module had 22 pages, taking 30 minutes to complete. Emergent themes from the focus groups were positive and related to navigation and usability, content and language, application and reach, learning styles and use of technology. An iterative approach to the module development gave greater clarity to the case and presentation of key learning points. The students valued case based learning and the use of questioning to re-inforce learning. They deemed the variety of modalities useful for their learning.

## Conclusion:

Iterative development of this e-learning module, in conjunction with learners, has led to a well-received resource as part of blended learning to complement face-to-face teaching. The module will be openly available to support teaching and learning of paediatric MSK clinical skills. Further e-module development is planned.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** *iBooks*, a free electronic book application by Apple, is well-suited for publishing interactive medical texts. To date, no *iBook* on Antiphospholipid Syndrome (APS) exists, and the utility of an Apple *iBook* for medical students as a teaching method in APS has never been assessed. Our objective was to assess medical students' improvement of knowledge and satisfaction with an interactive APS *iBook*, in comparison with conventional teaching methods.

**Methods:** The APS *iBook* was developed both in French and English by a professional *iBook* developer (LP) with the guidance of a medical team. Second year medical students, who were naïve of lectures regarding APS, were enrolled from two institutions (Nancy University, France; Weill Cornell Medicine, New York, NY). For the “teaching intervention”, following IRB approvals, participants were randomly distributed to three groups: a) APS *iBook* with interactive capability (Group A); b) printed copy of the material contained in the interactive APS *iBook* (Group B); and c) classroom presentation of the material contained in the APS *iBook* (Group C) by a physician (SZ or DE). A standardized medical questionnaire about APS (total score: 10 points) was filled by the participants before and after teaching interventions. Furthermore, participants were asked to fill out a standardized satisfaction survey (max: 10). Recall capability of students was tested four months after the intervention (score: 10 pts).

**Results:** 233 second-year medical students were enrolled (*iBook* group: 73; print group: 79, and lecture group: 81). Mean improvement of knowledge was significantly higher in the lecture group in comparison to the *iBook* group. Satisfaction was significantly higher in both the lecture and the *iBook* groups, compared to the print group on several dimensions including overall quantitative satisfaction, subjective enhanced knowledge, interactivity, quality of content, comprehensibility, and pleasure of learning. Recall capability of students (n=109) was not significantly different among groups (Table).

**Conclusion:** Based on our international two-center randomized control study of medical students, a classroom APS lecture is the most effective method in improving medical students' knowledge, when compared to self-learning methods, i.e., APS *iBook* or APS printed material. Among these two self-learning methods, medical students were more satisfied with the APS *iBook*, although both resulted in the same degree of improvement of knowledge. Given the complexity of the spectrum and the management of aPL-related clinical manifestations, we hope that our APS *iBook* will help medical students in their curriculum and increase the awareness of APS among the community.

**APS *iBook*:** <https://itunes.apple.com/fr/book/antiphospholipid-syndrome/id1185542915?mt=11>

	Group A (iBook)	Group B (Print)	Group C (Lecture)	p
Improvement of Knowledge*	3.65±2.47	4.19±3.21	5.06±3.21*	A vs B: 0.54 A vs C: 0.003
Satisfaction Score	5.7±3.0	4.0±2.6	6.4±4.0	A vs B: <0.0001
Recall Capability**	7.9±2.0	7.8±2.1	7.6±2.0	A vs B vs C: 0.86

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatology practices are expanding to include non-physician healthcare providers, such as nurse practitioners and physician assistants (NP/PAs). To date, there has not existed a structured curriculum for NP/PAs for the acquisition of rheumatology knowledge. The Association of Rheumatology Health Professionals (ARHP), a division of the American College of Rheumatology (ACR), charged a task force (TF) to recommend ways to facilitate the preparation of NP/PAs to work in a rheumatology practice setting.

**Methods:** The TF, consisting of private practice and academic rheumatologists, NPs and PAs, including those in adult and pediatric settings, assimilated information from many sources and resources to develop mechanisms for NP/PAs to acquire rheumatology knowledge. Through face-to-face and webinar meetings, the TF designed a Rheumatology Curriculum Outline (RCO), incorporating stakeholder's feedback, to provide a framework for the training of NP/PAs new to rheumatology practice.

**Results:** The core competencies, from the Accreditation Council for Graduate Medical Education (ACGME) Core Competencies, Nurse Practitioner Core Competencies, and Competencies for the Physician Assistant Profession, of patient care, medical knowledge, systems-based learning, practice-based learning and improvement, professionalism, and interpersonal and communication skills, served as a framework for the RCO creation. (Table 1) Informed by stakeholder's feedback, a NP/PA RCO was developed, endorsed by the ACR Board of Directors and is ready for use by community-based and academic rheumatology practices, whether pediatric or adult, who desire to add a NP/PA to their practice. The RCO includes a Rheumatology Toolbox for Suggested Learning Activities and Assessments to facilitate the development of a robust learning environment for the NP/PA new to rheumatology practice. The Toolbox is an amalgam of resources that were identified by the task force as important and useful for the development and experience of the early NP/PA rheumatology provider. Foundational knowledge, skills and attitudes embodied in the RCO are generally believed to be attainable within one year for NP/PAs. Realizing the needs of individual practices vary, foundational and aspirational expectations are included in the RCO, allowing for flexibility in the application of the RCO to specific practice settings.

**Conclusion:** The ACR/ARHP NP/PA Rheumatology Curriculum Outline is a valuable tool to facilitate efficient and effective training of a NP/PA new to rheumatology and incorporate him/her proficiently as a patient care provider. Increasing the number of NP/PAs trained in rheumatology assists in closing the workforce gap, thus providing access to care for more persons with rheumatic disease.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Musculoskeletal ultrasound (MSUS) is currently taught at 95% of adult United States Rheumatology fellowship programs. Only 30 (41%) programs have a formal curriculum. MSUS curriculum development for rheumatology fellowship programs is ongoing with ACR support. In 2011, at Rochester NY, a group of rheumatology MSUS experts developed a document on documentation, scanning conventions, and tier designations (1, Rheumatology sonographers need to know and need to perform routinely; 2, Rheumatology sonographers need to know but do not need to perform routinely; 3, Rheumatology sonographers may know about & may perform based on individual practice focus) for each view of the major joints. The objective of this study is to update consensus of the 2011 Rochester document to serve as the foundation for the development and implementation of a rheumatology MSUS curriculum for fellowship training programs.

**Methods:** A 96-item IRB-approved survey was developed for use in a Delphi study. Apart from demographics (8), there were 86 questions testing for agreement/disagreement on documentation (5), scanning conventions (5), and tier designations for 8 peripheral joint-specific areas (76). 108 lead faculty at 113 rheumatology fellowship programs were identified based on prior surveys. 101 respondents (including the 38 who developed the 2011 document) were selected based on selected criteria including lead MSUS faculty experience, course instruction, ACR-RhMSUS certification, or publication in MSUS. The survey was disseminated via Qualtrics<sup>®</sup>. Survey initiation and completion indicated consent for study participation.

**Results:** 55 (55%) rheumatologists responded: 39 (71%) were full time academic faculty, 40 (73%) had certification, with a third of the respondents certified via ACR-RhMSUS pathway. 51 (59%) questions achieved high (>85%) agreement. Questions with less than 85% agreement all concerned tier designations. 13 questions with 30-60% disagreement favored tier 1 designation over 2011 tier 2. Table 1 lists areas of disagreement.

**Conclusion:** Initial phase of consensus-building reveals 41% disagreement on areas related to anatomic-region tier designation. Many respondents favored Tier 1 over Tier 2 for many of those items, indicating a shift in overall expert opinion towards including more views in the MSUS mastery requirements. Further clarification through subsequent rounds of this Delphi study is needed to resolve areas of disagreement, and facilitate development of a standardized MSUS fellowship curriculum.

**Table 1. Delphi Study Round 1: 2011 vs 2017 Consensus, Joint Views**

## Focused Musculoskeletal Ultrasound Teaching: Effect on Medical Students' Physical Examination Skills

**Bhavna Seth**<sup>1</sup>, Lorraine Stanfield<sup>2</sup> and Eugene Y. Kissin<sup>3</sup>, <sup>1</sup>Internal Medicine, Boston University Medical Center, Boston, MA, <sup>2</sup>Internal Medicine, Boston University, Boston, MA, <sup>3</sup>Boston University, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Musculoskeletal ultrasound provides instant feedback for spatial understanding and the evaluation of abnormalities with great precision and accuracy, and may aid in developing physical examination skills.

### Methods:

We framed a teaching exercise to develop examination skills in medical students using ultrasound imaging as an aid in order to assess ultrasound utility in improving these skills. Of 158 second year medical students, 63 volunteered to participate in a 2-day musculoskeletal exercise. Students who were not able to commit to both days were excluded. On day one, all students were taught examination of the knee and shoulder in 1 hour. We randomized 24 students for inclusion of ultrasound demonstration of key joint landmarks (Ultrasound aided group-USG) within the same 1hr period.

Student performance was evaluated in a 20-minute OSCE on day 2 with standardized patients. Students were graded by an observer blinded

to instruction group using a standardized checklist, that included key inspection, palpation, and maneuvers for joint exams. The study was exempted from review by the local IRB. Participant confidentiality was maintained with anonymized codes. The Mann-Whitney-Wilcoxon test was used to analyze the results given the small sample and non-normal distribution of the scores.

## Results:

The maximum score for knee and shoulder examinations were 14 and 15 respectively. For the knee examination, the mean score of the USG ( $10.38 \pm 2.35$ ) was significantly higher than the non-USG group ( $8.95 \pm 2.14$ )  $p=0.013$ . There was a non-significant trend towards improved performance of shoulder examination in the USG ( $12.58 \pm 1.82$ ) compared to non-USG ( $11.59 \pm 2.49$ ) group ( $p=0.11$ ).

Since ultrasound visualization is more likely to improved inspection and palpation components, we analyzed them separately. For knee examination, the USG group fared significantly better ( $7.5 \pm 1.72$  vs.  $6.10 \pm 1.67$ ,  $p=0.003$ ); a similar trend towards improved performance in the shoulder examination, did not reach significance in the USG group ( $4.96 \pm 0.99$  vs.  $4.49 \pm 1.12$ ,  $p=0.075$ ).

In sub-components of the knee exam, significant improvement was seen in the USG-aided group in palpation of the lateral collateral ligament ( $p=0.016$ ), popliteal space for Baker's cysts ( $p=0.017$ ), and the patellofemoral shrug test ( $p=0.004$ ). For sub-components of the shoulder exam, improvement was significant in the USG-aided group for shoulder inspection ( $p=0.043$ ), palpation of the sternoclavicular joint ( $p=0.008$ ), acromioclavicular joint ( $p=0.043$ ), and shoulder range of motion ( $p=0.045$ ).

## Conclusion:

Incorporation of ultrasound into musculoskeletal exam curriculum demonstrated short-term improvement in knee examination performance, with a trend toward improvement in shoulder exam in second-year medical students.

Table: Knee and Shoulder Exam- ultrasound vs. non-ultrasound group scores

Subcomponent (maximum score)	USG group (mean scores)	Non-USG group (mean scores)	P value
Knee Examination - Ultrasound dependant skills			
Inspection (2)	1.71	1.51	0.43
Palpation			
Quadriceps, patellar tendon, tibial tuberosity (1)	0.92	0.89	1
Pes anserinus (1)	0.79	0.72	0.51
Lateral & Medial joint line (1)	0.58	0.56	0.88
Lateral collateral ligament (1)	0.79	0.49	0.016
Popliteal/ Bakers cyst (1)	0.87	0.59	0.017
Demarcation of lateral suprapatellar injection site for knee joint injection (1)	0.58	0.54	0.72
Total (8)	$7.5 \pm 1.72$	$6.10 \pm 1.67$	0.003
Knee Examination - Ultrasound independent skills			
Manoeuvres			
Patellofemoral shrug sign (1)	0.71	0.33	0.004
Bulge sign (1)	0.58	0.33	0.05
Ballotment (1)	0.66	0.46	0.14
Extension- Flexion (1)	0.83	0.82	0.84
Anterior Cruciate Ligament (1)	0.66	0.82	0.52
Posterior Cruciate Ligament (1)	0.62	0.87	0.07
Total Knee exam (14)	$10.38 \pm 2.35$	$8.95 \pm 2.14$	0.013
Shoulder Examination - Ultrasound dependant skills			
Inspection (1)	1	0.84	0.043
Palpation			
Sternoclavicular joint (1)	0.83	1	0.008
Acromioclavicular joint (1)	1	0.84	0.04
Biceps tendon (1)	0.83	0.64	0.10
Coracoid process (1)	0.92	0.87	0.56
Glomerohumeral Injection site (1)	0.35	0.28	0.44
Total (6)	$4.96 \pm 0.99$	$4.49 \pm 1.12$	0.075
Shoulder Examination - Ultrasound independent skills			
Range of Motion (3)	2.92	2.4	0.045
Motor-Resisted internal/external rotation, Empty can (3)	2.29	2.4	0.62
Hawkins Test (1)	0.87	0.69	0.35
Neer's Test (1)	0.87	0.77	0.29
Yergeson's Test (1)	0.66	0.85	0.09
Total Shoulder Exam (15)	$12.58 \pm 1.82$	$11.59 \pm 2.49$	0.11

## **A Qualitative Assessment of a CME “City Rounds” Workshop Educational Program to Meet the Educational Needs of Rheumatologists**

**John J. Cush**<sup>1</sup>, Leonard H. Calabrese<sup>2</sup>, Greg Salinas<sup>3</sup> and Sergio Schwartzman<sup>4</sup>, <sup>1</sup>Baylor Scott & White Research Institute, Dallas, TX, <sup>2</sup>Rheumatic & Immunologic Disease and Infectious Disease, Cleveland Clinic Foundation, Cleveland, OH, <sup>3</sup>CE Outcomes, Birmingham, AL, <sup>4</sup>Hospital for Special Surgery, New York, NY  
**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** : An Annual Rheumatology & Therapeutics Review for Organizations & Societies (ARTHROS) initiative called “City Rounds” was created to meet the educational needs of rheumatologists with regard to advances in therapeutic s in Rheumatoid arthritis. The program was designed to introduce and assess advances in diagnosis, therapeutic s and safety through an interactive roundtable, small-group format wherein rheumatologists would interact and discuss case based issues with local and national RA experts .

**Methods:** These, roundtable programs were delivered in 16 US cities and attended by 5-15 rheumatologists using a case-based workbook covering three topics: Targeted Therapies in RA, Immunopathogenesis of RA, and Safety Issues in RA Management. ARTHROS partnered with CE Outcomes to qualitatively evaluate the impact of the City Rounds on rheumatologists using structured interviews with 12 randomly chosen participants. Transcripts of the interviews were analyzed to identify common themes and compare practices reported by interviewees to evidence-based guideline recommendations and learning objectives of the City Rounds program.

**Results:** The findings of the qualitative analysis demonstrate the City Rounds program enabled rheumatologists to provide more thorough patient education. Participant interviews showed the following: 94% of participants believed that these educational objectives impacted their knowledge; 98% of the participants indicated that this activity enhanced their effectiveness in treating; 91% of participants indicated that this activity will change in their practice behavior; 24% of participants indicated they will create or revise policies for patient care; 55% of participants indicated they will change their management and treatment of RA; 38% of participants indicated that they have no barriers in implementing changes learned in this education. Several interviewees reported greater confidence in managing hard-to-treat patients after participating in the education. The City Rounds program also reinforced rheumatologist use of evidence-based care in several key areas, including: selection of tests and exams for diagnosis and monitoring; active use of evidence-based guidelines; and selection of treatments for patients with high RA disease activity who have failed methotrexate. The findings of the assessment also suggest that, despite the positive impact of the program, educational gaps in these same areas persist among some rheumatologists.

**Conclusion:** Small group, workshop or roundtable style educational programs are highly impactful as they: a) well attended by a wide variety of practitioners (from trainees to professors; urban and suburban); b) allow for intense, impactful interactions between colleagues and experts on important teaching points and practice issues; and c) are a conduit for the introduction and integration of guidelines and standards of care into daily practice.

## **A Primer on Exercise: An Interactive, Online Educational Module Incorporating Spaced Education to Supplement the ACR Core Curriculum Outline for Rheumatology**

# Fellowship Programs

**Amit Patel** and Kenneth O'Rourke, Department of Internal Medicine, Section on Rheumatology and Immunology, Wake Forest School of Medicine, Winston-Salem, NC

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The 5 topics in rehabilitative rheumatology (RR) included in the ACR Core Curriculum Outline include exercise, adaptive equipment, orthotics, thermal modalities and splinting. A 2004 survey of Program Directors (PD) led to a subsequent increase in RR clinical symposia at ACR Annual Meetings. Fellowship program instruction in RR is still felt to be under-represented.

## Methods:

An online needs assessment survey of PD (107), therapy providers (34), and physicians with an interest in RR (31) yielded response rates of 37%, 27% and 16%, respectively. For PD respondents, 56% did not offer a RR rotation, 71% had no one interested in leading a group teaching session, but 93% said self-study could be part of teaching resources. There was consensus among all respondents that exercise should be the first RR content to be addressed. Using certain software, we created a two-part, interactive, online educational module on exercise. The first part addresses exercise modalities, CDC exercise recommendations and creating an exercise prescription, and the second part presents current literature for self-directed study on exercise applications in selected rheumatic diseases.

An educational trial of the content in the first part of the exercise module was completed with fellows in the Carolina Fellows Collaborative as our study participants. Fellow level of confidence in, and frequency of, prescribing exercise, as well as providing an exercise prescription for a simulated patient, was assessed during a rheumatology OSCE (ROSCE) station. Fellows were then asked to provide an exercise prescription immediately after, and 6 weeks after completion of the exercise module. In a randomized subset of fellows, spaced education by email was used as a means to improve retention during the 6 weeks between the second and third prescription assignments. All prescriptions were scored using the same metrics applied during the ROSCE station.

## Results:

18 fellows (85.7%) participated in the ROSCE. 4 of 21 fellows (19.0%) completed the exercise prescriptions immediately following completion of the module and 5 fellows (23.8%) completed the prescriptions 6 weeks after completion of the module, 1 of which had participated in the spaced education program. Only 2 fellows (9.5%) completed all 3 sets of prescriptions, none of which had completed the spaced education program. The average correct responses paralleled level of training, overall increasing from 70.94% to 85.42% with the introduction of the module content. At 6-week follow-up, the average score had fallen to 67.91%. Fellow confidence in prescribing exercise, assessed on a 6-point Likert-type scale, increased over the study from an average rating of somewhat unconfident to somewhat confident.

## Conclusion:

We have created an online primer on exercise for use as part of a mini-curriculum on RR. In a pilot trial, completion of the module led to an immediate improvement in the completeness of an exercise prescription, but this improvement was not durable in the short-term, most likely due to the low participation rate and small sample sizes. A larger study including the effect of faculty supervision of learner participation is warranted.

## Early Diagnosis and Treatment of RA: Clinical Performance and Economic Outcomes from a Continuing Education Initiative

**David Gazeley**<sup>1</sup>, Michael Weinblatt<sup>2</sup> and Stephen Bender<sup>3</sup>, <sup>1</sup>Medicine, Medical College of Wisconsin, Milwaukee, WI, <sup>2</sup>Rheumatology,

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The CME initiative RAPID® (Rheumatoid Arthritis: Primary Care Initiative for Improved Diagnosis and Outcomes) is a 7-year series of activities that used national-scope aggregated healthcare claims data to identify primary care clinicians who diagnose and refer patients for RA at a low frequency. Medical claims data have been used since 2008 to measure the implementation of the diagnostic and referral clinical strategies resulting from the RAPID activities by analyzing performance changes of participants. Since its inception, over 65,516 physicians have completed the RAPID educational activity. We have reported statistically significant improvements in the participants' diagnostic and referral performance (Bender S, et al. *CE Measure*, 2016;10:10-15).

### Methods:

Rates of increased RA diagnoses and referral among providers were determined for a sample of the RAPID initiative (RAPID III) using a national-scope administrative healthcare claims database representing over 870,000 US clinicians. New RA diagnoses were defined as the number of unique patients with a diagnosis of RA (ICD-9 codes 714.X) who had a claim from both a primary care provider and a rheumatologist (shared patients) in the time period prior to, or after the CME activity date [2011] and who had been prescribed (and filled) a prescription for an appropriate RA therapy. Comparisons were made among highly matched controls of non-participants, with approximately 40 non-participant controls for every participating clinician. The follow period was approximately 2.5 years. An exploratory predictive model was used to estimate the economic impact of earlier diagnosis and treatment of RA. The model estimated how many patients with moderate/high disease activity were likely to transition to remission and the associated costs averted by decreased healthcare utilization and productivity losses. Prevention of joint arthroplasty was also predicted. Deterministic and probabilistic sensitivity analyses were performed to evaluate the influence of model parameters on the estimated outcomes of the model.

### Results:

A sample of 3,919 RAPID III participants (n=1,691) was evaluated. These participants managed 265,834 patients and had 1,837 newly diagnosed patients with RA. There was a statistically significant 11% increase in the proportion of RA diagnoses by learners following participation in the CME initiative. All referred patients received appropriate therapy for RA. There was no change in the proportion of RA diagnoses among the control group. The estimated costs averted when newly diagnosed patients underwent treatment leading to remission were \$11,618,483 (95% CI: \$3,954,798 to \$24,547,314).

### Conclusion:

A CME initiative improved the post-activity performance of targeted learners significantly more than non-targeted providers. Analysis of medical claims data is a useful tool for assessing performance change in CME initiative participants. Earlier diagnosis and treatment of RA may be associated with decreased costs.

## Training the Next Generation of Investigative Rheumatologists: Results of the Usbji's Young Investigator Initiative for Academic Rheumatologists

Nancy E. Lane<sup>1</sup>, Ann Rosenthal<sup>2</sup>, Howard Hillstrom<sup>3</sup> and Edward Puzas<sup>4</sup>, <sup>1</sup>Center for Musculoskeletal Health, University of California, Davis School of Medicine, Sacramento, CA, <sup>2</sup>Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, <sup>3</sup>orthopedics, Hospital for special surgery, New York City, NY, <sup>4</sup>Orthopedic Surgery, University of Rochester School of Medicine, Rochester, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The success of a physician scientist in academic rheumatology requires effective skills to obtain peer-reviewed funding. The number of NIH-funded junior investigators is low in proportion to the prevalence of musculoskeletal (MSK) diseases. As well-conceived and structured research is more likely to be funded, in 2005 the U.S. Bone and Joint Decade/Initiative (USBJI) and Bone and Joint Canada initiated a grant mentoring and career development program for junior faculty in all fields of MSK research in the US/Canada who had not obtained an Independent Peer Reviewed Research Grant (RO1/equivalent) in order to foster the next generation of investigators. The purpose of this study was to determine the outcomes of Rheumatologists who attended the program 2005-2016.

**Methods:** The Young Investigator Initiative (YII) program included two 2-day workshops held 12-18 months apart with training in specific aspects of the development of well-founded research studies and grantsmanship (specific aims, experimental design, budget, collaborations), benefitting from multi-disciplinary perspectives on their proposed studies. Each mentee was assigned 2-4 experienced external mentors from the YII faculty to complement their institutional mentors until the Young Investigator obtained funding. Mentors made themselves available to assigned mentees for review of specific aims, evaluating grant drafts, and discussing research strategies. External mentors' research expertise across the MSK disciplines included rheumatology, epidemiology, orthopaedics, bioengineering, biology, PTs, OTs.

**Results:** The YII is a competitive, peer-reviewed program. Of 736 applicants 2005-2016, 364 (49.5%) were accepted, including 59 Rheumatologists developing studies in common and less common forms of Rheumatic disease. Program metrics are tabulated in Table 1. Total external funding obtained by YII Rheumatology participants 2005-2016 is \$48.5 million, from a combination of NIH/Canadian Institutes of Health Research/Foundations/Granting Agencies/Institutions, including the ACR-RRF; 34/59 (58%) received peer-reviewed funding.

**Conclusion:** The YII program has been successful in assisting junior investigators in academic rheumatology obtain peer-reviewed funding by providing education and external mentoring on grant structure and writing until funding is obtained.

## Immunotherapy-Induced Rheumatic Disease: How Prepared Are Rheumatologists to Address This Emerging Condition?

Laura Cappelli<sup>1,2</sup>, Cassandra Calabrese<sup>3</sup>, Leonard H. Calabrese<sup>3</sup> and Clifton O. Bingham III<sup>4</sup>, <sup>1</sup>Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Medicine/Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Rheumatic & Immunologic Disease, Cleveland Clinic Foundation, Cleveland, OH, <sup>4</sup>Rheumatology, Johns Hopkins University, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cancer immunotherapy targeting immune checkpoints represents a major advance in oncology, yet has been associated with immune-related adverse events (IRAEs) affecting many organ systems, including an expanding range of rheumatic manifestations. Rheumatologists are new to this field, and we sought to examine their awareness, experience, clinical confidence, and educational needs regarding IRAEs by surveying rheumatology practitioners.

**Methods:** In the 2<sup>nd</sup> quarter of 2016, questionnaires were sent via email to health care provider cohorts at Johns Hopkins University (JHU) and Cleveland Clinic (CC). The survey population came from their Continuing Medical Education (both) and Rheumatology Website (JH) databases. Both cohorts had physicians and advanced practitioners. Survey questions addressed domains of awareness, clinical experience, and interest in IRAE-specific medical education.

**Results:** Response rates were 114/2198 (5.2%) at CC and 39/789 (5.0%) at JHU. Male physicians from private practices and academic institutions predominated (table 1). Only 24.1% reported familiarity with IRAEs, with most unaware of IRAEs or lacking sufficient knowledge on the topic (table 2). Only 14.8% had seen a patient with an IRAE, with inflammatory arthritis the most common. Most (60.7%) did not feel confident managing IRAEs. All but one participant indicated interest in educational activities on IRAEs, with description/recognition of IRAEs perceived as the biggest educational need.

**Conclusion:** We conclude that most respondents 1) had limited experience with rheumatic IRAEs, 2) lacked confidence in clinically addressing IRAEs, and 3) had a strong expressed desire for targeted education. Although limited by response rate, responder bias, and the timing of the survey shortly after the approval of these drugs, the results suggest a considerable need for rheumatology-specific education around this topic.

Table 1. Demographic Variables (N = 153)	
Sex: N (%)	Male: 93 (61%)
	Female: 60 (39%)
Age: mean (SD)	55.0 (12.4)
Degree: N (%)	MD/DO: 127 (83%)
	NP: 8 (5.2%)
	PA: 4 (2.6%)
	RN: 9 (5.9%)
	Other: 5 (3.3%)
Years in medical practice: mean (SD)	22.1 (12.9)
Practice Setting: N (%)	Academic: 43 (28.1%)
	Private Practice: 68 (44.4%)
	Hospital-based Practice: 25 (16.3%)
	Industry: 5 (3.3%)
	Other: 9 (5.9%)

<b>Table 2. ICI/IRAE provider experience</b>	
Familiarity with ICIs (N= 133)	I am unaware: 29 (21.8%)  I have heard of them, but am not knowledgeable: 68 (51.1%)  Familiar: 32 (24.1%)  Very familiar: 2 (1.5%)  Unsure: 2 (1.5%)
Awareness of IRAEs (N= 130)	I am unaware: 54 (41.5%)  I have heard of them, but am not knowledgeable: 33 (25.4%)  Familiar: 32 (24.6%)  Very familiar: 8 (6.2%)  Unsure: 3 (2.3%)
Have seen a patient with an IRAE (N = 122)	Yes: 18 (14.8%)  No: 104 (85.2%)
Types of IRAEs seen	Inflammatory arthritis: 17  Sicca syndrome: 6  Myositis: 4  Vasculitis: 3  Colitis: 7
Confidence in management of IRAEs (N = 122)	Not confident: 74 (60.7%)  Somewhat confident: 30 (24.6%)  Moderately confident: 14 (11.5%)  Very confident: 4 (3.3%)

## Using Goutpro to Make Medical Trainees Gout Pros- a Single Blinded Randomized Control Study

Linh Ngo<sup>1</sup>, Eric Miller<sup>2</sup>, Peter A. Valen<sup>3</sup> and Alisa Duran<sup>4</sup>, <sup>1</sup>Division of Rheumatology, University of Minnesota, Minneapolis, MN, <sup>2</sup>Medicine, Hennepin County Medical Center, Minneapolis, MN, <sup>3</sup>Rheumatology/ Dept of Medicine, University of Minnesota/Minneapolis VAMC, Minneapolis, MN, <sup>4</sup>Department of Medicine, University of Minnesota, Minneapolis, MN

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Education Poster

**Session Type:** ACR Poster Session A  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is the most common type of inflammatory arthritis in the U.S., affecting 4% of the population. Despite modern advancements and the availability of reference tools, the current care from primary care providers is felt to be suboptimal in the U.S. One barrier to improving care in gout includes limited education during medical training.

To address limited education during training, we developed a digital adjunctive teaching tool, GoutPro, on the topic of gout. Utilizing a clinically integrative model proposed by *Khan et al*, it takes into consideration different learning styles, current guidelines on gout, interactive activities and clinical problem solving. In our pilot study, we obtained positive subject feedback through survey. To assess objective trainee improvement of gout knowledge, a single-blinded randomized controlled study assessing knowledge prior to and after GoutPro intervention was conducted.

**Methods:** We recruited a total of 19 medical trainees from Hennepin County Medical Center to participate in our study. Trainees included medical students of MS 3-4 training levels and residents of PGY 1-4 training levels. All trainees registered via an online registration form and consent forms were signed digitally. Registered participants were randomized proportionally according to level of training into the control and the study group via a novel automated cloud based system to keep the investigators blinded. Correspondence with participants was also managed by the automated system. All participants were sent an e-mail with a link to a pre-test of 14 questions on crystalline arthropathy based on recommendations from the 2012 ACR Gout Guidelines and MKSAP 17. The study group was instructed to attend a live session led by the investigators that utilized GoutPro. The control group was provided both the ACR Guidelines and UpToDate reference articles on crystalline arthropathy for review. All participants received an identical post-test 27 days later to avoid coinciding with trainee change of rotations. 15 out of 19 subjects completed the post-test. Our primary outcome was difference in pre- and post-quiz scores between the control and study group. The Student's t-test was used for analysis.

#### Results:

Average Scores	Control Group (n=10)	Study Group (n=5)
Pre-Quiz	38%	52%
Post-Quiz	41%	59%
% Improvement	3%	7%

#### Conclusion:

- 1) The study group had a slightly higher percent improved test scores (7%) compared to those in control group (3%). The results did not reach statistical significance due to the small study size ( $P=0.99$ ).
- 2) At baseline, medical trainees in the study demonstrated low knowledge on gout demonstrating the need for improved gout curriculum.
- 3) Future GoutPro studies with larger sample size from multiple centers will be needed.
- 4) Utilization of a novel cloud-based automated system to randomize and communicate with study subjects was an effective cost-efficient way to recruit, organize and manage study subjects while maintaining investigator blindness.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Education Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Providing social support is an important component in the management of chronic diseases. In rheumatoid arthritis (RA), peer support is particularly important for coping with the psychosocial aspects of the disease. The aim of this study was to assess the participation, experiences, and perceptions of patients in an online support group for patients with RA using social media.

**Methods:** A private online support group was created on Facebook including 105 participants who were 18 years or older, residing in the United States or Canada and had been diagnosed with RA for less than 10 years. Each week, a moderator posted a topic for discussion, however, participants could also share other disease-relevant information not directly related to the discussion of the week. We analyzed participants' posts in the first 5 weeks, their reaction to responses of other participants, and how often and what information was being shared outside the main discussion topics.

**Results:** Most participants were female and non-Hispanic white (94% and 87.6%, respectively). Nearly two-thirds (65%) were married or lived with a significant other or partner and 62 (59%) had a Bachelor's or higher degree. The mean age was 52.7 years. Although nearly all participants visited the forum, only an average of about 50 (48%, range 42-62) actively participated in the discussions each week, with the most and least participation recorded respectively in the first and fifth weeks. About 10 percent of participants never contributed to the discussions. Topics discussed included physical challenges, emotional health, self-care, exercise, and socializing. Discussion on physical challenges attracted the highest number of posts (n=311) while self-care had the least (n=120). Other information shared by participants outside the discussion topics included their disease experiences, medications, social lives, other websites on RA, frustrations and messages of encouragement. They also shared pictures of themselves, their families, pets and satirical depictions of their disease experience. Many participants expressed excitement and thankfulness for the social support provided by the group.

**Conclusion:** Participants were generally enthusiastic about the online support group. Social media based groups may provide an alternative means of facilitating education and peer support that is so often lacking in traditional models of care. However, more research is needed to find better ways to encourage more participation and to sustain participant interest.

## Occupational Exposure to Asbestos and Risk of Rheumatoid Arthritis

Anna Ilar<sup>1</sup>, Per Gustavsson<sup>1</sup>, Pernilla Wiebert<sup>1</sup>, Camilla Bengtsson<sup>1</sup>, Lars Klareskog<sup>2</sup> and Lars Alfredsson<sup>1</sup>, <sup>1</sup>The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Rheumatology unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Due to the known association between silica dust and rheumatoid arthritis (RA), we wanted to study the association between RA and another

silicate mineral; asbestos. The aim was to estimate the risk of seropositive or seronegative RA from ever occupational asbestos exposure as well as years with exposure.

#### Methods:

The study base consisted of men and women living in Sweden between 2006 and 2013. RA patients were identified from the Swedish Rheumatology Quality Register (SRQ). We matched ten controls from the national population register per case on age, county and sex. Data on occupational histories were collected from the national population and housing censuses carried out in 1960, 1970, 1975, 1980 and 1990. A job-exposure matrix (JEM) containing historical exposure estimates from 1955-1995 to asbestos was applied to the study participants' occupational histories. We used conditional logistic regression to assess the odds ratios (ORs) and 95 % confidence intervals (CIs) of RA associated with ever exposure and years of exposure to asbestos. ORs were adjusted for ever exposure to respirable crystalline silica dust and household disposable income divided into quartiles.

#### Results:

9 704 cases and 90 271 controls were included in the analysis. Ever vs. never asbestos exposure resulted in an OR of 1.35 (95 % CI: 1.22-1.48) among men and 1.10 (95 % CI: 0.94-1.29) among women for seropositive RA. The ORs decreased to 1.12 (95 % CI: 1.01-1.25) and 1.02 (95 % CI: 0.86-1.22) for men and women respectively after adjusting for silica exposure and household disposable income. Asbestos exposed men were more likely than women to have worked with asbestos for a longer period of time and their risk of seropositive RA increased with years with the exposure. Male participants with more than 20 years of asbestos exposure at work had an adjusted OR of 1.27 (1.06-1.53, p for trend: 0.008).

#### Conclusion:

Asbestos exposure is associated with seropositive RA among men. The increased risk remained after adjustments for potential confounding from silica exposure and household disposable income.

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Occupational exposure to silica dust has been associated with increased risk of developing ACPA positive Rheumatoid arthritis (RA)<sup>1,2,3</sup>. Little is known about non-occupational exposure, as there are no available tools to assess it in clinical practice.

The *Dust Exposure Life-Course Questionnaire (DELCO)* longitudinally quantifies lifetime occupational and non-occupational (e.g. body care; hobbies such as DIY, woodworking, stone cutting etc..).

The DELCQ, developed within a European Research Council Advanced Grant, provides clinical research with a tool derived from social sciences. In the DELCQ, the identification of situations likely to put people at risk of exposure is grounded on an extensive list of products and activities summed up by the International Agency on Research on Cancer IARC<sup>4</sup> and on a wide overview of the literature that in medicine, epidemiology and industrial hygiene has been addressing silica exposure and silica-related (or suspected-to-be-related) diseases.

The aim of this study was to use this novel tool to explore occupational and non-occupational silica exposure in a series of consecutive RA patients and to explore the association of quantified silica dust exposure with major disease features (ACPA positivity) or outcomes (erosive disease).

### Methods:

The *DELCQ* was administered to 97 consecutive RA patients (77F, 20M, mean age 59.1±13.3 yrs., 75 ACPA positives, 66 with erosive disease) attending the department of rheumatology of the Avicenne teaching Hospital (Bobigny, FRANCE). The *DELCQ* scores of patients were compared to those of 261 controls, matched for sex, age and smoking status, from a 825-subject national cohort, representative of the general French population (ELIPSSilice). Within RA subjects, the association of the scores with ACPA positivity and with erosive disease was assessed after adjustment for tobacco exposure.

### Results:

RA patients had higher scores of total (median [Q1, Q3]: 25 [13, 36] vs. 9 [4, 19]), occupational (10 [0, 17] vs. 0 [0, 4]) and non-occupational (15 [8, 20] vs. 7 [0, 15]) exposure vs. controls ( $p<0.0001$  for all comparisons). Amongst RA patients, male vs. female patients had higher occupational scores of exposure (12 [2, 18] vs. 0 [0, 3]  $p<0.005$ ), while non-occupational exposure was not significantly different (12 [3, 25] vs. 8 [4, 15]). After adjusting for smoking (ever smokers vs. nonsmokers), neither professional or non-professional scores were associated with erosive disease, despite a strong negative interaction with tobacco exposure.

### Conclusion:

By using a tool developed in collaboration of social sciences, this work shows for the first time that RA patients have higher nonprofessional lifetime exposure to silica dust compared to age and sex-matched subjects from the general population. Moreover, higher occupation exposure in RA is confirmed, in accordance with previous literature. Neither occupational nor non-occupational exposure was associated with ACPA positivity or erosive disease, likely due to the high prevalence of ACPA positivity and severe disease in the patient series.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The underlying risk factors for the development of Rheumatoid Arthritis (RA) remain poorly understood; however, prospective studies have demonstrated that individuals with elevated Tumor Necrosis Factor alpha (TNF $\alpha$ ), a pro-inflammatory cytokine, are at increased risk of subsequently developing RA. It remains unknown whether elevated TNF $\alpha$  by means of a different disease process can subsequently increase the risk of developing RA. Recently, major depressive disorder (MDD) has been identified to have a direct effect on

cytokines, including increased serum concentrations of TNF $\alpha$  relative to healthy controls independent of underlying inflammatory disease. Based on this, our hypothesis is that exposure to MDD may increase the risk of subsequently developing RA. In this study using a large population-based cohort, we assessed if patients with MDD were at increased risk of subsequently developing RA compared to the general population without MDD.

**Methods:** A retrospective cohort study was conducted using The Health Improvement Network (THIN) Database between the years 1986-2012 for up to 26 years of follow-up. The MDD cohort comprised patients with a diagnostic (Read) code for MDD and the remainder of patients formed the referent cohort. Both cohorts were followed until patients developed RA or were censored. Cox proportional hazards models were used to determine the risk of developing RA among patients with MDD, as reported using Hazard Ratios (HRs) and 95% confidence intervals (CIs) ( $\alpha=0.05$ ). A backward elimination procedure was used to determine the presence of effect modification (using a Wald test) or confounding by age or sex.

**Results:** A cohort of 403,932 patients with MDD and a referent cohort of 5,339,399 patients without MDD were identified in THIN. A total of 2,192 (0.54%) patients with MDD developed RA, and 24,021 (0.45%) patients without MDD developed RA over this period. Cox proportional hazards models identified a confounding effect by sex and a significant interaction by age ( $p<0.0001$ ), whereby younger patients with MDD (age $<40$ ) had a 42% increased risk of developing RA (sex-adjusted HR=1.42, 95%CI: 1.31 – 1.53). In older patients (age $>40$ ), the risk of developing RA among those with MDD was lower but demonstrated a 14% increased risk (sex-adjusted HR=1.14, 95%CI: 1.08-1.21).

**Conclusion:** MDD was found to be a risk factor for the development of RA. This risk was highest among younger patients with MDD, and the risk was only somewhat increased among older patients with MDD. These results provide support the hypothesis that MDD may be associated with the development of RA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** As anti-citrullinated protein antibody positivity (+), RF+ and erosions are independently associated with poor outcomes in patients (pts) with RA, clinicians may use these prognostic factors in treatment decisions. However, it is not known whether pts with these poor prognostic factors respond equally well to conventional synthetic DMARD therapy. The aim of this analysis was to compare clinical and pt-reported outcomes (DAS28 [CRP], HAQ) of pts with RA with poor prognostic factors (RF+ and/or anti-cyclic citrullinated peptide antibody 2+ [anti-CCP2+] and erosions) vs those without over 1 year. **Methods:** Pts with RA in the UK starting MTX therapy were recruited to the Rheumatoid Arthritis Medication Study (RAMS), a 1-year, prospective cohort study. RF was determined from baseline blood samples, and data about anti-CCP status and erosions were obtained from medical notes. Pts who were anti-CCP2+ and/or RF+ and had erosions were classified as having poor prognosis (PP), while those not were classified as not having poor prognosis (NPP). For this analysis, pts were excluded if they were recruited  $>2$  years following symptom onset or had missing data for any of the three prognostic factors. At baseline, 6-month and 12-month demographic and clinical data were recorded by a research nurse and pts completed the HAQ. The association between prognosis group and DAS28 (CRP) and HAQ at 6 and 12 months was assessed using linear and negative binomial regression, respectively. The association between prognosis group and longitudinal DAS28 (CRP) and HAQ was assessed using linear and negative binomial random effects models, respectively. Baseline age, sex and symptom duration were included in the models as covariates. **Results:** In total, 545 pts with RA were included (PP, n=79 [14.5%]; NPP, n=466 [85.5%]). At baseline, PP pts were older, but other characteristics were similar (Table). DAS28 (CRP) and HAQ scores were similar between groups at 6 months (median [interquartile range (IQR)] DAS28 [CRP]: PP, 3.03 [2.4, 4.1] vs NPP, 3.2 [2.3, 4.3], coefficient -0.11, 95% CI -0.52, 0.29; HAQ: PP, 0.88 [0.25, 1.50] vs NPP, 0.63 [0.13, 1.25], incidence rate ratio [IRR] 1.12, 95% CI 0.76, 1.64) and 1 year (median [IQR] DAS28 [CRP]: PP, 2.98 [2.25, 3.75] vs

NPP, 3.00 [2.05, 4.05], coefficient 0.02, 95% CI -0.39, 0.43; HAQ: PP, 0.75 [0.13, 1.38] vs NPP, 0.63 [0.00, 1.25], IRR 1.12, 95% CI 0.76, 1.64). Similar results were seen when using longitudinal models to combine all the repeated measures (DAS28 [CRP]: coefficient -0.02, 95% CI -0.30, 0.26; HAQ: IRR 1.17, 95% CI 0.92, 1.48).

**Conclusion:** Treatment response is similar in pts with and without poor prognostic factors. These results suggest that, at this early stage of disease, baseline poor prognostic factors do not predict treatment response to conventional synthetic DMARDs, nor do they indicate that RA disease is reported as worse at 6 or 12 months in pts with vs without these poor prognostic factors.

## Relationship between Shift Work and the Onset of Rheumatoid Arthritis; Results from a Swedish Case-Control Study

Lars Alfredsson<sup>1</sup>, Anna Karin Hedström<sup>2</sup>, Torbjörn Åkerstedt<sup>3</sup> and Lars Klareskog<sup>4</sup>, <sup>1</sup>The Institute of Environmental Medicine, Karolinska

Institutet, Stockholm, Sweden, <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Stockholm University; Karolinska Institutet, Stockholm, Sweden, <sup>4</sup>Dept. of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Shift work has previously been associated with increased RA risk in females. The aim of this study was to investigate the potential association between permanent night shift work, rotating shift work, and day oriented shift work, and risk of developing anti-citrullinated peptide antibodies (ACPA) positive and ACPA negative RA.

**Methods:** The present report is based on a Swedish population-based, case-control study with incident cases of RA (1951 cases, 2225 matched controls). Using logistic regression, occurrence of RA among subjects who have been exposed to different kinds of shift work was compared with that among those who have never been exposed, by calculating the odds ratio (OR) with a 95% confidence interval (CI).

**Results:** Rotating shift work and day oriented shift work were associated with a 30% increased risk of developing ACPA positive RA, but not ACPA negative RA (table 1). There was an inverse association between permanent night shift work and risk of both ACPA positive RA (OR 0.7, 95% CI 0.6-0.9) and ACPA negative RA (OR 0.8, 95% CI 0.6-1.0) (table 1). For both subsets of RA, significant trends showed a lower risk of developing RA with increasing duration of permanent night shift work (table 2).

**Conclusion:** Sleep restriction as a consequence of shift work is associated with several biological effects among which changes in melatonin production may be involved. The present epidemiological findings of a complex relationship between sleep patterns and different forms of RA may be of importance for increasing the understanding of the pathophysiology of RA.

**Table 1.** Odds ratios with 95% confidence intervals of developing RA for subjects who have been exposed to permanent night shift work, rotating shift work, or day oriented shift work, compared with those who have never been exposed.

Type of shift work	ACPA positive RA			ACPA negative RA		
	case (n, %)	OR (95% CI) #	p value	case (n, %)	OR (95% CI) #	p value
Never	828/1537	1.0 (reference)		514/1537	1.0 (reference)	
Day oriented shift work	144/275	1.3 (1.0-1.7)	0.04	87/244	1.0 (0.7-1.4)	0.9
Rotating shift work	163/252	1.3 (1.0-1.6)	0.03	84/252	1.1 (0.9-1.5)	0.4

## Smoking and Rheumatoid Arthritis Susceptibility; Quantification of the Impact of Cumulative Dose, Frequency and Duration of Smoking, and Smoking Cessation

Lars Alfredsson<sup>1</sup>, Anna Karin Hedström<sup>2</sup>, Camilla Bengtsson<sup>3</sup> and Lars Klareskog<sup>4</sup>, <sup>1</sup>The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Inst of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>4</sup>Dept. of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smoking is one of the most established risk factors for rheumatoid arthritis (RA). The aim of this study was to estimate how age at smoking debut, smoking cessation, duration, intensity, and cumulative dose of smoking influence the risk of developing ACPA positive and ACPA negative RA.

**Methods:** The present report is based on a Swedish population-based, case-control study with incident cases of RA (3655 cases, 5883 matched controls). Using logistic regression models, subjects with different smoking habits were compared regarding risk of developing the two subsets of RA, by calculating odds ratios (OR) with 95% confidence intervals (CI).

**Results:** Smoking increased the risk of developing both ACPA positive (OR 1.9, 95% CI 1.7-2.1) and ACPA negative RA (OR 1.3, 95% CI 1.2-1.5). For both subsets of RA, a cumulative dose of smoking less than five pack years was not significantly associated with increased disease risk. A dose-response association was observed between cumulative dose of smoking (exceeding five pack years) and risk of developing both ACPA positive and ACPA negative RA (p values for trend <0.0001) (table 1). Duration of smoking had a higher influence on the association between smoking and RA than did intensity of smoking (table 2). Among both subsets of RA, the detrimental effect of smoking decreased after smoking cessation. Twenty years after smoking cessation, there was no longer an association between smoking and risk of ACPA negative RA, whereas the association between smoking and ACPA positive RA risk persisted and was dependent on the cumulative dose of smoking (table 3).

**Conclusion:** Smoking increases the risk of both subsets of RA with a more pronounced influence on the risk of ACPA positive RA. Preventive measures in order to reduce smoking are essential and may result in a decline in RA incidence.

**Table 1.** OR with 95% CI of developing ACPA positive RA and ACPA negative RA for ever smokers compared with never smokers, by cumulative dose of smoking.

## Exposure to Passive Smoking and RA Risk; Results from a Swedish Case-Control Study

Lars Alfredsson<sup>1</sup>, Anna Karin Hedström<sup>2</sup> and Lars Klareskog<sup>3</sup>, <sup>1</sup>The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Dept. of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smoking has consistently been associated with increased risk of developing rheumatoid arthritis (RA). We investigated the influence of passive smoking on the risk of developing ACPA positive and ACPA negative RA.

**Methods:** A population-based case-control study using incident cases of RA was performed in Sweden, and the study population in this report was restricted to include never smokers (589 cases, 1764 controls). Cases and controls answered an extensive questionnaire. The incidence of RA among never smokers who had been exposed to passive smoking was compared with that of never smokers who had never been exposed, by calculating the odds ratio (OR) with a 95% confidence interval (CI) employing logistic regression.

**Results:** No association was observed between exposure to passive smoking and risk of ACPA positive or ACPA negative RA, regardless if the exposure took place within 10 years prior to index, or earlier in life.

Compared with those who had never been exposed to passive smoking, the OR was 1.0 (95% CI 0.7-1.2) for ACPA positive RA, and 0.9 (95% CI 0.7-1.2) for ACPA negative RA among those ever exposed to passive smoking. There were no significant age or gender related differences.

There was no suggestion of a trend between duration of passive smoking and RA risk. Long term exposure to passive smoking for 20 years or longer was not significantly associated with increased disease susceptibility (table 1).

**Conclusion:** No association was observed between exposure to passive smoking and risk of ACPA positive or ACPA negative RA among never smokers. Our finding may be explained by a threshold below which no association between smoke exposure and RA occurs.

**Table 1.** OR with 95% CI of developing RA for subjects exposed to passive smoking compared with those who have never been exposed, by duration of exposure. All subjects were never-smokers.

Duration	ACPA positive RA		ACPA negative RA	
	ca/ca*	OR (95% CI)†	ca/ca*	OR (95% CI)†

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The association between smoking and risk of rheumatoid arthritis (RA) has been well documented; however, the relationship between smoking and RA disease activity is less clear. Previous studies have indicated a null association between smoking and pain, swollen joint count, physical function, and radiographic joint damage, while others have demonstrated an inverse association. Inconsistent findings may be ascribed to heterogeneous study designs or biases in statistical analyses. We examined the causal association between smoking and RA outcomes using methods that account for time-varying confounding and loss to follow-up.

**Methods:** We used electronic health record data from a safety-net health system between 2013-2017. We included individuals with a diagnosis of RA and at least 2 clinic visits within 12 months (n=291). Timepoints during the study period were defined in 3-month intervals. We assessed smoking status (yes/no) at each timepoint; additional covariates included sex, race/ethnicity, age, obesity (BMI > 30 kg/m<sup>2</sup>), and medications. We also controlled for depression among a subset of patients (n=165) who had completed the Patient Health Questionnaire (PHQ-9). We used longitudinal targeted maximum likelihood estimation to estimate the causal effect of smoking on disease activity as measured by the clinical disease activity index (CDAI) and patient global assessment (PGA) at 30 months (or 2.5 years). We also accounted for time-varying covariates and informative missingness of data.

**Results:** Patients were 82% female, with a mean age 59.2 ± 12.2 and 91% racial/ethnic minorities. Eleven percent of patients were smokers

and the mean BMI was 29.0 + 6.9 (Table 1). Smoking was associated with a CDAI score of 16.67 at 30 months compared to a score of 12.05 for non-smoking after adjusting for covariates. Conversely, smoking was associated with a lower PGA score compared to non-smoking over the same period (40.53 vs. 45.42, respectively;  $p<0.001$ ). However, additional control for depression based on the PHQ-9 did not change the association between smoking and disease activity based on CDAI ( $p<0.001$ ), but eliminated the significant inverse relationship between smoking and PGA ( $p=0.24$ ).

**Conclusion:** Smoking may be causally associated with higher levels of disease activity over time as measured by the CDAI. Differences in CDAI between smokers and non-smokers are likely clinically meaningful for individuals with low to moderate disease activity. Patient reported outcomes such as PGA may be influenced by other factors such as depression. These methods may be useful for investigations of additional exposures on longitudinal outcome measures in rheumatologic disease.

**Table 1. Baseline characteristics of rheumatoid arthritis patients included in the study (n=291)**

	N (%) or Mean (SD)

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Major dietary modification and omega-3 supplements are often promoted on patient counseling websites for those with RA. Given uncertainty regarding such approaches, we aim to study the frequency and characteristics of patients who undertake these complementary measures.

### Methods:

Included were 810 participants in the Epidemiological Investigation of Rheumatoid Arthritis (EIRA) in Sweden who answered questionnaires including diet (normal/Mediterranean/vegetarian/vegan/low glycemic index/other) and omega-3 supplement use at diagnosis, 1 year, and 3 years post-diagnosis. Prevalence of diet changes and supplement use were assessed. Logistic regression was used to analyze associations between changing diet post-diagnosis, omega-3 supplement use, and the lifestyle/demographic characteristics of education, sex, age, BMI, smoking, and pre-diagnosis diet.

### Results:

Between 1999 and 2016, 810 EIRA participants (women: 74%, median age at inclusion: 58 (min 17-max 85), median BMI at inclusion 25.1 (min 15.5-max 50.1), university degree holders: 30%). The proportion of participants with a non-normal diet increased from 23% in 2008 to 30% in 2013. 26% reported a major change in diet within 3 years post-diagnosis (Table). Those who made a change were more likely to be younger (OR 0.98 per year of age, 95% CI 0.96-0.99), have a university education (OR 1.89, 95% CI 1.28-2.80), be women (OR 1.77, 95% CI 1.28-2.80), be obese (OR 2.28, 95% CI 1.38-3.78), and have an non-normal diet at baseline (OR 2.81, 95% CI 1.36-5.79 for vegetarian; OR 10.12, 95% CI 5.79-17.71 for Mediterranean; OR 24.82, 95% CI 8.09-76.1 for others). Omega-3 supplement use increased from 20.4% at baseline to 30.9% at one year and decreased to 11.9% three years post-diagnosis. Participants were more likely to both change diets and use omega-3 supplements if they were younger (OR 0.98 per year increase, 95% CI 0.96-0.99), following an alternative diet at baseline (12.0, 95% CI 6.61-21.6), or obese (OR 2.05, 95% CI 1.09-3.88).

Table. Diet changes in first 3 years following a diagnosis with RA, n=806.

Description of diet change	n (%)
Maintained same diet for 3 years	600 (74.4)
Maintained normal diet	550 (68.2)
Maintained another diet	50 (6.20)
Changed diet between baseline and 1 year, then maintained new diet at 3 years	61 (7.57)
Changed to normal diet at 1 year	24 (2.98)
Changed to another diet at 1 year	37 (4.59)
Changed diet between 1 and 3 years	173 (21.5)
Changed to normal diet at 3 years	51 (6.33)
Changed to another diet at 3 years	122 (15.1)

### Conclusion:

Many RA patients change their diets or use supplements after diagnosis. To better target messaging about these complementary therapies, it may be beneficial to consider them by the sociodemographic and lifestyle characteristics that distinguish them.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Administrative claims and electronic health record (EHR) data are commonly used to assess outcomes in rheumatoid arthritis (RA). However, direct measures of functional status are typically not available in these data sources to control for confounding in comparative effectiveness research.

**Methods:** Corrona registry data linked to Medicare claims (2006-2014) were used to build a claims-based disability classifier, measured by HAQ. Eligible patients had RA per Corrona rheumatologist, and  $\geq 1$  yr prior coverage. Demographics, socioeconomic factors, comorbidities, healthcare utilization, and medications from claims data were included as predictors.

In separate analyses, HAQ was classified dichotomously ( $<1$ ,  $\geq 1$ ), as 3 categories ( $0 < 0.5$ ,  $\geq 0.5 < 1.5$ , and  $\geq 1.5-3$ ), and as a continuous variable, converted to corresponding HAQ category. Generalized logistic regression (GenLogit) with LASSO for variable selection and results were compared with machine learning methods including RandomForests, using a forest of 2000 trees. Separate models were run classifying each of the 8 HAQ subdomains separately, and then summing to form the composite HAQ score. Misclassification rates were compared and the area under the receiver operator curves (AUROC) was described.

**Results:** A total of 2,788 RA patients were eligible, classifying 52% of patients with low ( $n=1448$ ) and 48% with high ( $n=1340$ ) HAQ; and as 3 categories, low ( $n=887$ ), moderate ( $n=1109$ ), and high ( $n=792$ ). Univariable analysis showed higher HAQ was associated with older age, being disabled (per Medicare), rural residence, and greater comorbidity burden, and higher healthcare utilization.

Variables selected by various methods were similar (Table). In the 2 category HAQ models, overall misclassification was 29% (RandomForests), 28% , and 38% (LASSO), with an AUROC of 0.84. In the 3 category HAQ models, RandomForests yielded misclassification of ~48% that did not meaningfully differ across the 3 HAQ categories. Misclassification of the GenLogit model varied widely by HAQ category. When misclassification did occur in the 3 category analysis, patients were usually 1 category off; more extreme misclassification (categorizing low HAQ patients as high, or vice-versa) was uncommon ( $<8\%$ ). The median (IQR) difference in the (observed – predicted) HAQ was 0.00 (-0.45, 0.41) units. Ongoing work is refining these models, reducing the misclassification rate, and validating the approach.

**Conclusion:** Results from this preliminary analysis suggest that administrative claims and EHR data might be useful to classify RA-related disability as measured by the HAQ with reasonable accuracy. Larger datasets and richer information in EHR data likely will improve the accuracy of these methods.

Table: Key variables from administrative claims data selected by machine learning methods to classify HAQ category*

## Impact of the Multi-Biomarker Disease Activity Score Results on Whether Rheumatologists Changed Biologic Therapy for RA Patients

Jeffrey R. Curtis<sup>1</sup>, Kerri Ford<sup>2</sup>, Lang Chen<sup>3</sup>, Huifeng Yun<sup>3</sup> and Fenglong Xie<sup>4</sup>, <sup>1</sup>Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Crescendo Bioscience Inc., South San Francisco, CA, <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL, <sup>4</sup>Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The multi-biomarker disease activity (MBDA) score is a validated test used to assess disease activity for patients with rheumatoid arthritis (RA). How it is used in clinical practice in the U.S. is unclear. We evaluated the likelihood that rheumatologists would add or switch biologic therapies based on the MBDA test result.

**Methods:** Using previously published methods, we linked results of MBDA tests obtained as part of routine clinical care to 2012-2014 Medicare fee for service claims data for RA patients. We characterized patients as being on a biologic or targeted synthetic DMARD in the 90 days prior to the MBDA test and evaluated biologic/tofacitinib treatment changes in the 90 days following the MBDA test. MBDA test scores were classified as low (<30), moderate (30-44), and high (>44). The unit of analysis was the 90-day interval before and after each MBDA test score. Alternating logistic regression was used to compute odds ratios (OR) to quantify the likelihood that patients made any change (add or switch), accounting for the clustered nature of the data (intervals nested within patients, and patients nested within doctor

practices) and physician-level variability, controlling for patient age and sex. Sensitivity analyses used a 6-month interval for outcome ascertainment after the MBDA test.

**Results:** Using previously validated methods, a total of 27,621 unique RA patients were linked to 44,438 MBDA test scores. For the 27,256 intervals where RA patients were not on biologic therapy when the MBDA score was obtained, a total of 13.2% of patients added a biologic. Patients with high MBDA scores were significantly more likely to add a biologic (Table). For the 17,182 intervals where RA patients were already on a biologic, a total of 19.1% of patients switched or stopped the biologic that they were taking. Patients with lower MBDA scores were significantly more likely to stay on their therapy, whereas those with higher scores were more likely to stop and/or switch biologics.

After adjustment, results from the regression analyses showed that patients with moderate MBDA scores were 1.47 (95% 1.29-1.67)-fold more likely to add or switch biologics, and those with high MBDA scores were 2.54 (95% CI 2.19-2.94)-fold more likely to add or switch biologics. Men (OR=0.90, 95% 0.82-0.98) and older patients (OR=0.92 per 5 year increment, 95% CI 0.91-0.93) were less likely to add or switch therapy, even after controlling for variability between physicians (OR = 1.10, 95% CI 1.02-1.19). These results were robust and ORs were numerically larger when extending the interval to 6 months.

**Conclusion:** Results from the MBDA score were significantly associated with the likelihood that a physician added or switched biologic therapies, with either type of change being more frequent when the MBDA score was high. Further evaluation of outcomes after switching, conditional on the MBDA score, is warranted.

<b>Table: Proportion of patients who added or switching biologics after the MBDA test</b>		
<b>MBDA Score</b>	<b>Non-biologic users who added a biologic after the MBDA test</b>  N=27,256	<b>Biologic Users Who Switched or Stopped their Current Biologic after the MBDA test</b>  N=17,182
<b>Low (&lt;30)</b>	8.4%	14.0%
<b>Moderate (30-44)</b>	10.8%	16.2%
<b>High (&gt;44)</b>	16.3%	23.1%

## **Availability of Clinical Measures for Patients with Rheumatoid Arthritis in Integrated Delivery Networks Who Receive a Biologic or Targeted Synthetic Disease-Modifying Antirheumatic Drug: A Real-World Analysis of an Electronic Health Records Database**

**Benjamin Chastek**<sup>1</sup>, Chieh-I Chen<sup>2</sup>, Toshio Kimura<sup>2</sup>, Jonathan Fay<sup>2</sup>, Stephanie Korner<sup>3</sup> and Stefano Fiore<sup>4</sup>, <sup>1</sup>Optum, Eden Prairie, MN, <sup>2</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, NY, <sup>3</sup>Health Economics and Outcomes Research, Optum, Eden Prairie, MN, <sup>4</sup>Clinical Science, Sanofi Genzyme, Bridgewater, NJ

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In patients with rheumatoid arthritis (RA), ACR treatment guidelines recommend treating to targets based on quantitative endpoints, with modification of therapy as needed to achieve those targets. Integrated Healthcare Delivery Networks (IDNs) collect data in electronic health records (EHR), which can be used to assess quality of care, manage costs, and support treatment decisions. This study examined the availability of clinical measures across IDNs among patients with RA who received a biologic or a targeted

synthetic disease-modifying antirheumatic drug (tsDMARD).

**Methods:** In this retrospective analysis of the Optum One EHR database, patients were 18 years or older, had RA diagnoses  $\geq 7$  days apart between June 30, 2008 and July 31, 2015. For patients who switched from a tumor necrosis factor inhibitor (TNFi) to a different medication, the index date was the switch date. Among other patients with a prescription for a biologic or tsDMARD, the index date was the first prescription written. Analysis periods were “baseline” (1 year pre-index), or “follow-up” (1 year post-index). EHR reporting rates were determined for quantitative measures to guide treatment decisions: clinical measurements (height, weight, blood pressure, cholesterol, erythrocyte sedimentation rate [ESR], C-reactive protein [CRP], or tuberculosis [TB] test) and validated disease severity instruments (Routine Assessment of Patient Index Data [RAPID3], Disease Activity Score [DAS28], or Clinical Disease Activity Index [CDAI]). Mean ESR and CRP in follow-up were summarized.

**Results :** The 29,829 patients were 76.8% female, 80.1% age  $\geq 45$  years, and 83.8% Caucasian. Baseline TB reporting rate in EHRs was 18.8%. EHR reporting rates in follow-up (median, 6 office visits) were: 49.0% ESR or CRP; and 6.5%  $\geq 1$  disease severity measure (5.8% RAPID3, 0.2% DAS28, 0.6% CDAI). Data reporting in EHRs varied significantly across the 10 largest IDNs, including a range of 0.0% to 25.2% for disease severity measure reporting in follow-up. Mean $\pm$ SD values for ESR and CRP in follow-up were 13.9 $\pm$ 8.0 mm/hr and 5.7 $\pm$ 4.2 pcg/mL, respectively; variations in ESR and CRP values were less pronounced than variations in EHR reporting rates.

Table. EHR reporting rates and reported ESR/CRP values, by IDN							
	Baseline	Follow-up					
	$\geq 1$ TB Test in EHR, %	$\geq 1$ ESR or CRP Test in EHR, %	ESR, mm/hr		CRP, pcg/mL		$\geq 1$ RAPID3, DAS28, or CDAI Test in EHR, %

**Conclusion:** In this analysis of EHR reporting of clinical data among RA patients in IDNs who switched from a TNFi or received a biologic or tsDMARD, approximately 1 in 5 had a TB test reported pre-index and half had ESR and/or CRP reported post-index. Validated measures of disease severity (RAPID3, DAS28, or CDAI) were reported infrequently, and EHR reporting was highly variable across IDNs. With greater emphasis on a treat-to-target approach, more consistent and more complete EHR reporting is recommended to assist rheumatologists in tracking whether treatment targets for RA are being met with biologic or tsDMARD therapy appropriately.

## What Does It Mean to Have Rheumatoid Arthritis Now? a Current Burden of Disease Assessment in the United States

Rebecca Schumacher<sup>1</sup>, A Dominique<sup>2</sup>, Sofia Pedro<sup>1</sup>, TA Simon<sup>2</sup> and Kaleb Michaud<sup>1,3</sup>, <sup>1</sup>National Data Bank for Rheumatic Diseases, Wichita, KS, <sup>2</sup>Bristol-Myers Squibb, Princeton, NJ, <sup>3</sup>University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Known since 1859, RA is the most common inflammatory joint disease with 0.5-1% worldwide prevalence. Currently, there is a larger number of medications and strategies for treating RA earlier and more aggressively, which also necessitates a greater understanding of the current burden of RA. Our objective is to measure the impact of RA on the individual and society through patient reported outcomes using a large US registry.

### **Methods:**

We performed descriptive statistics of a random observation from RA patients enrolled in the National Data Bank for Rheumatic Diseases (NDB), a longitudinal US-wide study with comprehensive 6-month questionnaires from 1998-2017. We limited analysis to observations in the last decade (2007-2017) with a comparison to the previous 8 years (1998-2006). Health-related Quality of Life measures examined included HAQ, EQ5D, SF-36, activities of daily living, economic factors, and illness-related employment. With each of these individual testing measures, a total of 65 variables were considered for comparable analysis. **Results:**

Our study included 18,168 participants in the last decade with 82.2% female, mean (SD) age of 60.6 (13.5) and RA duration of 15.7 (12.1) years. The 1998-2006 cohort included 20,412 patients, with 77.1% female, age of 60.4 (13.5) and RA duration of 14.2 (11.0) years. Descriptive item responses are detailed in Table. Patient reported consequences of the burden within the 2007-2017 cohort show a slight improvement in HAQ, pain, fatigue, and SF-36 physical component score (PCS), but a worsening in global severity, sleep, SF-36 mental component score (MCS), quality of life (QOL) scale, health satisfaction, and functional limitations. When stratified by RA duration (Figure), patients with a duration of  $\geq 2$  years had the lowest HAQ, pain, PCS, comorbidities, functional limitations and a higher QOL while duration of  $>20$  years had the lowest fatigue, sleep and MCS score. Patients that took a DMARD or Biologic showed a definite improvement over patients that did not take any or prednisone. **Conclusion:**

Even in this era of effective new treatments, we found the burden of RA to still be severe and important. Current analyses show that HrQOL measures appear to be less related to type of treatment than decade of RA onset. Further analysis will be performed evaluating biologic vs. non-biologic treatments.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have previously observed an association between exposure to occupational physical workload (PW) and risk of

developing rheumatoid arthritis (RA)[1].We posit that PW could impose mechanical stress on the joints leading to neo-epitope formation and immune activation. The major solid component of the articular cartilage is collagen type II (CII). Elevated level of anti-CII antibodies do not predate RA development, but are transiently found in 6-9% early RA patients. These antibodies are associated with acute RA onset and HLA-DRB1\*01 and \*03, yet predict good long-term prognosis[2]. We hypothesized that exposure to PW especially in the period closely predating RA diagnosis would associate with anti-CII positive RA but not anti-CII negative RA.

**Methods:** Data involving 1396 incident RA cases and 5935 controls from the Swedish population-based case-control study, Epidemiological Investigation of Rheumatoid Arthritis (EIRA), were analyzed. Information on self-reported exposure to occupational PW was collected through questionnaire. Anti-CII was measured using ELISA. The odds ratio (OR) with 95% confidence interval (CI) of developing anti-CII positive RA or anti-CII negative RA associated with PW exposure was calculated using logistic regression. Adjustment for sex, age, residential area, educational level, alcohol consumption, body mass index, cigarette smoking, silica exposure and occupational class did not substantially change the estimates.

**Results:** The ORs observed for the association between anti-CII positive RA and different types of PW ranged from 1.0 (95% CI, 0.4-2.4) to 2.3 (95% CI, 1.3-4.0). There was no difference in the ORs for PW exposure at diagnosis or five years earlier (table1). The ORs for the association between anti-CII negative RA and PW ranged from 1.0(95% CI, 0.8-1.3) to 1.8(95% CI, 1.5-2.1). No statistically significant difference was observed between the ORs for anti-CII positive RA and the ORs for anti-CII negative RA (all p-values > 0.2).Stratification for HLA-DRB1\*01/\*03 or symptom duration did not change the results.

**Conclusion:** Since physical workload is associated with rheumatoid arthritis irrespective of anti-CII status or the presence of anti-CII associated HLA alleles, and regardless of whether the timing of PW exposure was close to the appearance of anti-CII. We found no evidence suggesting an association between PW and development of anti-CII in RA.

# Impact of the Five Components of the Euroqol 5-Dimensions Instrument on Healthcare and Work-Loss Costs in Rheumatoid Arthritis: Observational Data from Southern Sweden

Anders Gülfe<sup>1</sup>, Tor Olofsson<sup>1</sup>, Jonas K Söderling<sup>2</sup>, Martin Neovius<sup>2</sup> and **Johan K Wallman<sup>1</sup>**, <sup>1</sup>Department of Clinical Sciences Lund, Rheumatology, Lund University, Lund, Sweden, <sup>2</sup>Department of Medicine, Clinical Epidemiology Unit, Karolinska Institutet, Stockholm, Sweden

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Healthcare and work-loss costs are markedly higher in RA patients than in the general population. The EuroQol 5-Dimensions (EQ-5D) instrument, commonly applied to measure utility and quality-adjusted life-years (QALYs) in health-economic evaluations, is based on a questionnaire, asking respondents to value 5 health dimensions (mobility; self-care; usual activities; pain/discomfort; anxiety/depression) on a 3-leveled scale. In this study, we aimed to compare how these 5 EQ-5D components relate to healthcare, work-loss, and total societal costs in RA.

**Methods:** Clinical visits of anti-TNF treated RA patients, monitored in the observational South Swedish Arthritis Treatment Group register 2005-2011, were included (11674 visits in 2246 patients; >95% fulfillment of 1987 ACR criteria in a prior validation). EQ-5D questionnaire responses at visits were linked to register-derived costs of anti-rheumatic drugs, out- and inpatient care, and work-loss due to sick leave or disability pension from 30 days before to 30 days after each visit. Associations of the 5 EQ-5D components to healthcare (patient care and drugs), work-loss (in patients <65 years), and total societal costs (healthcare + work-loss costs; <65 years) were studied in separate, adjusted, generalized estimating equations regression models, comparing standardized  $\beta$  coefficients by nonparametric bootstrapping to assess which component best reflects costs.

**Results:** The strongest associations with both healthcare and work-loss (and thus also societal) costs were observed for the usual activities component ( $p < 0.05$  vs. all other components; Figure). Apart from that, the mobility and self-care components were more closely associated with healthcare costs than anxiety/depression, while stronger associations with work-loss costs were revealed for mobility and anxiety/depression than for pain/discomfort. For comparison, cost associations with the composite EQ-5D utility score (United Kingdom preference set) were (standardized  $\beta$  (95%CI)): -0.11 (-0.14 to -0.09) for healthcare, -0.07 (-0.08 to -0.05) for work-loss, and -0.12 (-0.15 to -0.09) for societal costs.

**Conclusion:** Of the 5 EQ-5D components, problems to perform one's usual daily activities was most strongly related to both healthcare and work-loss (as expected) costs. Moreover, the associations of the usual activities component to costs were on par with those observed for the composite EQ-5D utility score, making it an interesting simple marker of total societal costs in RA. Somewhat unexpectedly, relatively weak cost associations were observed regarding the pain/discomfort component.

## Baseline Characteristics and Rates of Hospitalized Infections in Patients with Rheumatoid Arthritis Treated with Non-TNF Inhibitors in Denmark and Sweden

**Kathrine Lederballe Grøn<sup>1</sup>**, Elizabeth V. Arkema<sup>2</sup>, Bente Glinthorg<sup>1</sup>, Johan Askling<sup>3</sup> and Merete Lund Hetland<sup>4</sup>, <sup>1</sup>The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark, <sup>2</sup>Clinical Epidemiology Unit, Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Unit of Clinical Epidemiology, Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, <sup>4</sup>The DANBIO registry and the Danish Departments of Rheumatology, Glostrup, Denmark

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hospitalized infections during treatment with biologic disease modifying drugs (bDMARDs) in rheumatoid arthritis (RA) are a concern. This have mainly been studied in patients (pts) treated with tumor necrosis factor inhibitors (TNFi), and only to a limited degree in pts treated with non-TNFi (abatacept (ABA), rituximab (RTX), tocilizumab (TCZ)). The aims of this interim report, which is part of an ongoing collaborative project between Denmark (DK) and Sweden (S), were to explore a) baseline characteristics and b) 12-month risks of hospitalized infections in RA pts treated with ABA, RTX and TCZ in routine care.

**Methods:** Observational, prospective cohort study conducted in parallel in DK and S. RA pts who started treatment with a non-TNFi between Jan 2010 and 2015 (DK: July 2015 and S: Dec 2015) were identified in the Danish DANBIO(1) and the Swedish ARTIS/SRQ registries(2). By use of unique identification codes, information on pts’ baseline clinical characteristics from the registers was enriched with information on previous malignancies, hospitalizations and hospitalized infections from the National Patient Registries (NPR). Information on hospitalized infections during follow-up was obtained from the NPRs. Follow-up was 12 months after treatment start or 90 days after withdrawal, whichever came first. Crude incidence rates (IR) of hospitalized infections were calculated for each drug in each country. For the current interim analysis, no formal comparisons of rates were conducted.

**Results:** 8931 treatment series were identified. The numbers of ABA/RTX/ TCZ treatment series were 830/718/1098 in DK and 1872/2630/1783 in S, respectively (Table). Age, gender, functional status and disease activity were typical for RA pts, but a pattern of higher age, more frequent previous cancer, hospitalizations or hospitalized infections in RTX treated patients was observed in both countries (Table). The crude 12-month hospitalized infection rates were 5.84-8.76 in DK and 4.28-6.81 in S (Table).

**Conclusion:** This collaborative project between DK and S included >8000 treatment series of RA pts treated with ABA, RTX and TCZ in routine care, and it demonstrated some channeling of patients to certain treatments, as reflected in differences in baseline characteristics. Variation in crude rates of hospitalized infections was observed across drugs and countries. Further analyses will explore underlying reasons that might explain differences in rates between the countries, as well as the impact of channeling, on the risk of hospitalized infections associated with each drug under study.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Comorbidity frequently complicates rheumatoid arthritis (RA) leading to poor long-term outcomes. However, whether comorbidity influences measures of RA activity over time is less well established. The purpose of this study was to examine the association of different comorbidity assessments with longitudinal disease activity and functional status.

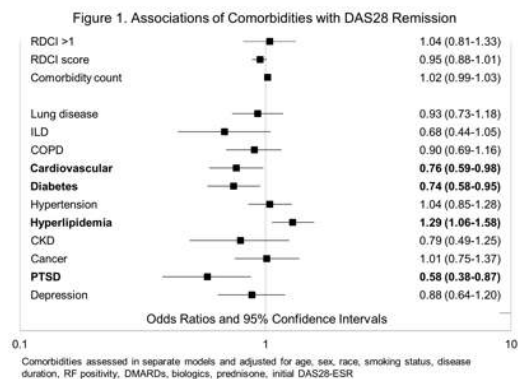

**Methods:** Participants were enrollees in a multicenter, longitudinal observational cohort of US veterans with RA. Comorbid conditions were collected at enrollment by treating rheumatologists and modeled using the Rheumatic Disease Comorbidity Index (RDCI) score, comorbidity count (range 0-53), or by the individual comorbid conditions. Disease activity (DAS28) and functional status (MD-HAQ) were assessed at routine clinic visits. Associations of comorbidity measures with disease activity and functional status over the initial 3 years of follow-up were examined using multivariable linear mixed effects models. Comorbidity measures were examined as main effects as well as by using interaction terms with time, the latter to examine whether a given measure was associated with diverging disease activity and functional status trajectories over follow-up. The odds of ever achieving DAS28 remission (<2.6) were examined using multivariable logistic regression.

**Results:** Among 2,516 participants with mean age of 64 (SD 11) years, RA duration 11 (11) years, 90% male, 79% RF positive, 78% anti-CCP positive, and 80% with smoking history, 75% had a RDCI <sup>3</sup>1. Hypertension (53%), hyperlipidemia (41%), lung (20%), and cardiovascular (CV) disease (19%) were the most prevalent comorbidities. Comorbidity, measured by RDCI <sup>3</sup>1, count, or RDCI score, was not associated with longitudinal disease activity or remission (**Table 1, Figure 1**) although comorbidity count and RDCI score were associated with reduced physical function (**Table 1**). Select individual comorbidities, including CV, lung, and psychiatric disease, were more closely associated with unfavorable longitudinal disease activity, remission achievement, and physical function (**Table 1, Figure 1**). CV and interstitial lung disease (ILD) were the only comorbidities with a significant time-interaction term (DAS28 models), suggesting a widening gap in disease activity over time for these conditions.

**Conclusion:** CV, lung, and psychiatric comorbidities, but not composite comorbidity scores, are associated with higher measures of disease activity and lower odds of achieving remission in RA. Specific comorbidities and composite measures are associated with longitudinal functional status.

**Table 1.** Associations of comorbidities with longitudinal disease activity and functional status.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a systemic inflammatory disease affecting about 1.5 million adults in the US (Helmick et al., 2008). Patients with RA have an increased burden of comorbidity such as cardiovascular disease (CVD), diabetes, cancer, and other inflammatory diseases. This study aimed to update prevalence estimates of RA and associated comorbidity in the US.

**Methods:** This was a retrospective descriptive study using the 2010-2015 20% Medicare sample data. Yearly prevalent RA cohorts (2011-2015) were defined based on ICD-9 diagnosis code 714.0 with the addition of ICD-10 codes for the 2015 cohort. For each cohort year, included patients were required to have Medicare Part A and Part B coverage with no Medicare Advantage, and to be alive for the entire year preceding a cohort year and through the first month of the cohort year. RA was defined if a diagnosis code was present in at least 1 inpatient claim or 2 or more outpatient claims, separated by at least 30 days. The baseline period was 1 year preceding the cohort year and was used to define comorbidity, including CVD, diabetes, hypertension, hyperlipidemia, cancer, anemia, and other inflammatory conditions such as psoriasis, psoriatic arthritis, non-alcoholic fatty liver disease (NAFLD), and cirrhosis. Prevalence of comorbidity was presented as a percentage of RA patients.

**Results:** This study included approximately 6 million Medicare beneficiaries in each year, 2011-2015; average RA prevalence was about 2.0% (Table 1). RA patient demographics were similar across years, with mean age 72.4 years; 77.0% were female, 83.4% white, and 10.7% black in the 2015 cohort. Common comorbid conditions in the 2015 RA cohort included hypertension (prevalence 67.3%), hyperlipidemia (48.5%), diabetes (26.6%), anemia (26.4%), arteriosclerotic heart disease (21.5%), peripheral artery disease (17.2%), congestive heart failure (13.2%), and cancer (8.8%) (Table 1). Prevalence of inflammatory conditions increased across years; for example, NAFLD was 0.96% in 2011 and 1.36% in 2015; corresponding values were 0.04% and 0.07% for cirrhosis, 1.14% and 1.45% for psoriasis, and 1.58% and 1.81% for psoriatic arthritis.

Table 1. Prevalence of RA and Associated Comorbid Conditions in 2011-2015 Medicare Patients

<b>Cohort Year</b>	<b>2011</b>	<b>2012</b>	<b>2013</b>	<b>2014</b>	<b>2015</b>

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial Lung Disease (ILD) is a rare but often severe consequence of several rheumatologic conditions including rheumatoid arthritis (RA). The comparative risk of incident ILD between RA therapies remains undetermined.

**Methods:** A retrospective cohort study using 2006-2014 Medicare and 2010-2015 Market Scan data was conducted to assess the risk of ILD among biologic and conventional DMARDs (cDMARDs) users. Adults with at least one ICD-9-CM RA diagnosis code from rheumatologist, initiated at least one biologic or cDMARDs were included. Patients had to have at least 1 year of full coverage (medical and pharmacy) prior to their RA treatment. Those with a diagnosis code for prevalent ILD, malignancy, HIV or organ transplantation (MHO), or prior oxygen use (suggesting treatment for pre-existing ILD) were excluded. Patients initiating cDMARDs with prior exposure to biologic or synthetic DMARDs (all available data) were also excluded. Follow up started at the initiation date of each therapy and ended at the earliest of: event, loss of full coverage, end of exposure (with 90 days extension), switch to other biologic or synthetic DMARDs, diagnosis of MHO (except for lung transplant), or end of study. ILD was defined as: one or more hospital discharge diagnosis code (any position) or 2 outpatient diagnosis codes from a physician visit with diagnostic tests for chest CT or lung biopsy. Incidence rates (IR) of ILD were calculated using Poisson regression; hazard ratios (HR) were calculated using COX regression, accounting for the clustering of RA treatments within patients. Among patients who developed ILD, initiation of home oxygen and death (Medicare only) were reported.

**Results:** A total of 150,225 RA patients with 208,641 initiations of biologics or DMARDs were eligible for analysis. A total of 958 patients developed ILD among 199,739 person years, resulting in an overall IR of 4.78 per 1,000 person years. The crude IRs for ILD ranged from a low of 3.05 (95%CI: 1.15-8.14) for tofacitinib to a high of 8.37 (7.29-9.61) for infliximab (INF) in Medicare (Table 1); and a low of 0.58 (0.08-4.13) for certolizumab (CER) to 3.87(2.08-7.19) for INF in Market Scan. Compared to abatacept (ABA), the adjusted HR ranged from 0.82 (0.30-2.22) for tofacitinib to 2.07 (1.62-2.64) for INF in Medicare; from 0.41 (0.05, 3.41) for CER to 2.85 (1.03-7.89) for INF in Market Scan.

Among 880 Medicare patients with ILD, 359 (41%) died after a mean (SD) 529 (640) days since diagnosis; 328 (37%) initiated home oxygen, at a mean (SD) of 177 (418) days. Among 78 Market Scan patients with ILD, 22 (28%) initiated oxygen at a mean (SD) of 114(262) days.

**Conclusion:** Compared to ABA, INF, rituximab, adalimumab, tocilizumab and etanercept were associated with increased risk of ILD, although the absolute IR differences between therapies were small. Initiation of home oxygen and mortality was high among RA patients with incident ILD.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The ACC/AHA recommends preventive strategies for patients with a high predicted risk of atherosclerotic cardiovascular disease (CVD). RA patients are at higher risk for CVD events, yet the role of systemic inflammation and the influence of traditional CVD risk factors is unclear with respect to risk prediction in RA. A simple and accurate algorithm for predicting CVD event risk that includes systemic inflammation might help risk assessment for RA patients and optimize preventive care.

**Methods:** We derived a U.S. cohort of RA patients with multi-biomarker disease activity (MBDA) test results linked to Medicare claims data. Patients had to have  $\geq 1$  year baseline with Medicare coverage prior to the first MBDA test. Exclusions were past MI, PCI/CABG, stroke, or cancer. Follow-up ended at the earliest of 1) CVD event; 2) other than CVD cause of death; 3) loss of coverage; or 4) 12/31/2014. The composite CVD event comprised of incident MI, stroke or fatal CVD event, using validated algorithms. MBDA scores were grouped as low ( $<30$ ), moderate (30-44), and high ( $\geq 44$ ). Other predictors included demographics, healthcare utilization, and comorbidities. Three separate models were developed using Cox regression. Model 1 included age, sex and race. Model 2 included age, sex, race, 9 comorbidities and CVD medication classes, plus interaction terms. Model 3 included age, sex, and race plus categorized MBDA score. We calculated the net reclassification index (NRI) for model 2 and 3 compared to model 1. We also plotted the observed vs. predicted probability of CVD event for each model, with risk categorized as low ( $<7.5$ ), moderate (7.5- $<15$ ) and high ( $\geq 15$ ) per 1000 person-years based upon annualized ACC/AHA cutpoints.

**Results:** A total of 15,757 RA patients were included; mean (SD) age 68.6(10.8) years, 80% female, 80% white. A total 209 CVD events occurred in 14,843 person years (1.41/100 py). The median (IQR) follow up time was 0.84 (0.41, 1.27) year. The maximum event time was at 2.7 year. All models had reasonable discrimination and calibration; model 3 was better than models 1 and 2 and observed vs predicted risk is shown (Figure). The sum of the absolute difference between observed and predicted probability was 0.56, 0.57 and 0.33 for models 1, 2 and 3 respectively. Compared to model 1, model 2 resulted in a positive overall NRI of 0.214 (non-event NRI=0.173, event NRI=0.041); model 3 resulted in positive overall NRI of 0.279 (non-event NRI=0.092, event NRI=0.187), consistent with more accurate CVD event classification.

**Conclusion:** Preliminary results from this analysis suggest that a simple algorithm consisting only of age, sex and race plus a multi-biomarker score can provide an accurate method to predict short term CVD risk in RA. Further validation with more extended time frames should improve the utility of this approach.

Figure: Observed vs. Predicted One-Year CVD Risk per 1000 person-years in RA Patients, using only Age, Sex, Race, and MBDA score (Model 3)

## No Effect of Tumor Necrosis Factor- $\alpha$ Inhibitors on Renal Function in Patients with Rheumatoid Arthritis from Kobio Registry from 2012 to 2016

Seong-Kyu Kim<sup>1</sup>, Jung-Yoon Choe<sup>2</sup>, Sung-Hoon Park<sup>3</sup> and Hwajeong Lee<sup>2</sup>, <sup>1</sup>Rheumatology, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of (South), <sup>2</sup>Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of (South), <sup>3</sup>Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Renal disease is prevalent in patients with rheumatoid arthritis (RA), although the precise prevalence of RA has not been determined. Increased mortality in patients with RA is associated with concurrent renal diseases. Impaired renal function in patients with RA is likely due to a chronic inflammatory response, antirheumatic drug toxicity, and renal involvement of RA itself. The effect of biological disease-modifying antirheumatic drugs (bDMARDs) on renal function in patients with RA has not been well established. We assessed whether tumor necrosis factor (TNF) inhibitors could affect renal function in RA.

**Methods:** A total of 2110 patients with RA enrolled in the Korean College of Rheumatology Biologics (KOBIO) registry were analyzed. All patients were taking bDMARDs or conventional synthetic DMARDs (csDMARDs). Renal function was evaluated by calculating the estimated glomerular filter rate (eGFR) using the Modification of Diet in Renal Disease (MDRD) equation. Renal insufficiency was defined as eGFR < 60 mL/min/1.73 m<sup>2</sup>. Differences in eGFR changes between different types of DMARDs were assessed at each follow-up time using the generalized linear model (GLM) method. Risk factors for renal insufficiency were identified using binary logistic regression analysis.

**Results:** The changes of eGFR values in patients treated with TNF inhibitors were not significantly different from those with csDMARDs alone or non-TNF inhibitors in all RA patients regardless of renal function. Among patients with renal insufficiency, GLM analysis revealed that the changes of eGFR values by TNF inhibitors were also compatible to those treated with csDMARDs alone or non-TNF inhibitors. Older age (> 55 years), longer disease duration (> 5 years), and use of methotrexate were identified as clinical determinants for renal insufficiency.

**Conclusion:** TNF inhibitors did not influence the change of renal function during RA treatment. TNF inhibitors may be a safe treatment option irrespective of renal function.

## **Estimating Prevalence and Cost of Depression Among Japanese RA Patients: A Retrospective Claims Data Base Analysis**

Rosarin Sruamsiri<sup>1</sup>, Jörg Mahlich<sup>2</sup> and Yuko Kaneko<sup>3</sup>, <sup>1</sup>Health Economics, Janssen Pharmaceutical KK., Tokyo, Japan, <sup>2</sup>Health Economics, Janssen Pharmaceutical KK, Tokyo, Japan, <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Significant evidence in the scholarly literature suggests that depression is a common comorbidity among patients with rheumatoid arthritis (RA) causing significant burden for the healthcare system. However, no studies are available for Japan and, hence, this is the first attempt to systematically assess the cost of depression in an RA patient cohort.

### **Methods:**

We used a large administrative claims data base (JMDC) to calculate prevalence and associated costs of depression within RA patients between March 2009 and September 2015. Descriptive statistics is used to describe baseline characteristics of included patients, healthcare utilization and total health care cost. Propensity score matching is applied to eliminate confounding effects (potential imbalances in baseline covariates) using 1:4 matching type.

### **Results:**

We identified 101,512 patients in the database with neither RA or depression diagnosis. 6,838 were diagnosed with RA but not with depression and 473 had a co-diagnosis of depression and RA indicating a prevalence of depression within RA patients of 6.5%. After matching, RA patients with depression had 55% more outpatient visits ( $p=0.010$ ) and caused 46% higher health care costs than those without depression ( $p=0.000$ ). Mean healthcare costs per patient per month was 102,101 JPY for the former and 70,079 JPY for the latter population.

### **Conclusion:**

A co-morbidity of RA patients with depression adds significant costs to the healthcare system and rheumatologists should be aware of this co-morbidity to ensure timely treatment initiation when necessary.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biologic therapy has revolutionised treatment pathways and improved outcomes for patients with Rheumatoid Arthritis (RA) who do not tolerate or respond to conventional synthetic therapies. However, for some patients on biologics, disease control remains elusive with so-called refractory disease. The aim was to quantify the frequency of biologic resistant disease and identify factors, measured at the start of first biologic, associated with resistant disease.

**Methods:** Patients with RA starting first-line TNFi (previously failed  $\geq 2$  DMARDs) in the BSRBR-RA were included if they had a full 10 years of study follow-up (N=5755). Patients were classified as “refractory” if they had used  $\geq 3$  classes of biologic, and were compared with “persistent” patients who remained on first TNFi for 10 years. Stop reasons were investigated. HAQ was assessed at 3 years (end of patient follow-up) and DAS28 at 10 years. Associations with age, gender, disease duration, baseline DAS28 and components, comorbidities, HAQ and refractory disease were analysed in a multivariable logistic analysis. Multiple imputation was used to account for missing data.

**Results:** Of the whole cohort, 2147 (37%) were classed as persistent TNFi patients, and 272 (5%) as refractory (Table 1). Refractory patients remained on their first TNFi for a mean of 2.9 years, and 51% stopped for inefficacy. Refractory patients had also used rituximab (94%), tocilizumab (77%), and other classes (48%), whilst 74% had also used  $>1$  TNFi. In the refractory cohort, 34% reported recurrent drug inefficacy only, 8% recurrent adverse events only and 50% a combination of reasons for repeated drug failures (with reasons missing in 8%). Disease activity was higher among patients with refractory disease (DAS28 5.0 vs 3.7; HAQ 2.0 vs 1.6). In multivariable analysis, older patients ( $>50$  years, OR 0.5 (95% CI 0.4, 0.7)) and those with longer disease duration ( $>10$  years, OR 0.7 (95% CI 0.6, 0.95)) had reduced odds of refractory disease. In addition, greater baseline HAQ (OR 1.8 (95% CI 1.4, 2.4)), and patient global assessment (OR 1.1 (95% CI 1.0, 1.2)) had increased odds of refractory disease (Table 2).

**Conclusion:** In this real-world cohort of patients with RA, followed for 10 years, approximately 5% had biologic resistant disease, with 2/3 reporting lack of response to any biologic. This may be an under-estimate as many patients in this study may have died before alternative non-TNFi biologics became available. Higher disability at the start of first TNFi predicted resistant disease but in general persistent and resistant patients were similar at the outset of therapy.

## Incidence of Hip Fracture in Rheumatoid Arthritis: British Columbia, Canada

C. Allyson Jones<sup>1</sup>, Pierre Guy<sup>2</sup>, Hui Xie<sup>3</sup>, Eric C. Sayre<sup>4</sup> and Diane Lacaille<sup>5,6</sup>, <sup>1</sup>Physical Therapy, University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Department of Orthopaedics, University of British Columbia / Centre for Hip Health and Mobility, Vancouver, BC, Canada, <sup>3</sup>Biostatistics, Faculty of Health Sciences, Simon Fraser University / Arthritis Research Canada, Burnaby, BC, Canada, <sup>4</sup>Arthritis Research Canada, Richmond, BC, Canada, <sup>5</sup>Arthritis Research Canada/ University of British Columbia, Vancouver, BC, Canada, <sup>6</sup>University of British Columbia, Arthritis Research Canada, Richmond, BC, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hip fractures have serious long-term effects, including a high 1-year mortality rate (usually 20-30%) and poor functional recovery, with approximately 50% not attaining pre-fracture functional status. Although risk of hip fractures is known to be increased in rheumatoid arthritis (RA), few studies specifically look at the incidence of hip fractures in patients with RA compared to general population controls. We estimated the incidence of hip fractures in a population-based cohort including all incident RA cases in a Canadian province, using administrative health data.

**Methods:** Using physician billing data and a previously published RA definition, we assembled an incident cohort of all cases with RA onset between 1997 and 2009. Controls (with no diagnosis of RA or other inflammatory arthritis) selected randomly from the general population were matched 2:1 to RA patients on birth year, gender and index year. RA and controls with prior hip fractures, pathological fractures or Paget's disease were excluded. Hip fractures (ICD9-CM codes 820.0, 820.2; ICD10-CA codes S72.0, S72.1, S72.2) were identified using hospitalization data (includes ≤25 codes defining reason for admission or complications during hospitalization). Crude incident rates were

calculated as number of new hip fractures per person-year (PY). Cox-regression models were used to compare age and sex adjusted risk of hip fracture in RA relative to controls.

**Results:** A total of 60,101 RA patients and 120,462 controls (mean age 57.2 yrs; 68% females for each cohort) were followed to December 2014, yielding 0.596 million PY and 1.23 million PY, resp. Incident hip fractures were observed in 2463 RA and 3566 controls. Mean (SD) age at time of fracture was 78.9 (10.9) yrs in RA and 82.1 (9.0) yrs in controls. Crude incidence rate was 4.1 and 2.9 per 1000 PY for RA and controls, resp., yielding an incidence rate ratio (IRR) of 1.42 [95% CI 1.35, 1.50]. Crude IRRs decreased with age and did not differ by sex (Figure 1). Adjusting for age and sex, persons with RA had 48% greater risk of hip fracture than persons without (HR 1.48, 95%CI 1.41, 1.56).

**Conclusion:** Risk of hip fractures in persons with RA is higher than age/sex matched controls particularly at younger ages. Given the impact of hip fractures, this has important implications for functional status and quality of life of people with RA. Further work on course of recovery, mortality and health services use post-fracture is needed.

**Disclosure:** C. A. Jones, None; P. Guy, None; H. Xie, None; E. C. Sayre, None; D. Lacaille, None.

## Patient Rheumatoid Arthritis Data from the Real World (PARADE) Study: Preliminary Results from an Apple ResearchKit™ Mobile App-Based Real World Study in the United States

Rachel Williams<sup>1</sup>, Emilia Quattrocchi<sup>2</sup>, Sarah Watts<sup>3</sup>, Sherry Wang<sup>4</sup>, Pam Berry<sup>4</sup> and Michelle Crouthamel<sup>4</sup>, <sup>1</sup>Real World Evidence and Epidemiology, GSK, Collegeville, PA, <sup>2</sup>R&D Immunoinflammation, GSK, Middlesex, United Kingdom, <sup>3</sup>GSK, Stevenage, United Kingdom, <sup>4</sup>GSK, Collegeville, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smartphone apps and sensors enable researchers to design novel endpoints and collect real world data directly from patients in a cost-effective, fast, and patient-focused approach. ResearchKit™, created by Apple in 2015, is an iOS-based, open-source platform for researchers to conduct App-based studies. We were the first pharmaceutical company to utilize the ResearchKit™ by conducting the Patient Rheumatoid Arthritis Data from the Real World (PARADE) Study. The objectives were to investigate the feasibility of utilizing a mobile app to recruit and enroll patients into a study and to gain insights about Rheumatoid Arthritis (RA) in a real world setting.

**Methods:** The PARADE study was conducted in the United States (US) using a customized Apple ResearchKit™ App. The PARADE App included study video, eligibility screen, electronic informed consent, and data collection. The enrolment period was July 12 through August 12, 2016. Recruitment was enhanced with advertisement on various targeted social media platforms. Participants could enroll if they were 21 years or older, spoke English, lived in the US, and had been diagnosed with RA by a doctor. Participants were asked to provide demographics, comorbidities, medications, and RA symptoms including pain, fatigue, mood and morning stiffness. Additionally, over the course of 12 weeks, participants were asked to complete validated questionnaires routinely used in RA clinical trials, namely HAQ, FACIT,

and EQ-5D. All data were self-reported and collected via their iPhone.

**Results:** There were 1170 downloads of the PARADE App with 428 consents to participate in the study. Of these, 399 participants provided analyzable data, defined as those completing all demographic questions. The study population was 80% female, 81% Caucasian, mean age 47.9 years, and 77% college graduates. The duration of diagnosed RA included 122 (30.6%) participants with RA for <2 years, 91 (22.8%) for 2-5 years, 91 (22.8%) for 5-10 years and 95 (23.8%) for >10 years. Most bothersome RA symptoms included joint pain (87.5%), fatigue (73.5%), morning stiffness (57.5%), poor sleep (52.4%), walk and balance (32.8%), and mood variations (23.7%). Mean pain score was 4.4 (SD 0.14) on a numerical rating scale of 0 (no pain) to 10 (worst pain imaginable). Mean scores for validated questionnaires were HAQ-DI, 1.1 (SD 0.04); Patient Global Assessment of Disease Activity, 5.4 (SD 0.14) (0=I don't feel arthritis to 10=Arthritis affects me severely); EQ-5D, 0.6983 (SD 0.00822), and FACIT, 25.5 (SD 0.66). RA medications are listed in the Table.

**Conclusion:** The PARADE study was the first Pharma-sponsored study in which real world patients could self-recruit, consent, enroll, and report data entirely via their iPhone using a ResearchKit™ App. This study successfully demonstrated the feasibility of this novel technology to gather insights into RA from a real world perspective.

Current RA medications among PARADE study participants	Proportion of population that answered this question (n=388)

## Are RA Patients at a Higher Risk for Car Accidents?

**Kaleb Michaud**<sup>1,2</sup>, Sofia Pedro<sup>1</sup> and Ted R. Mikuls<sup>3</sup>, <sup>1</sup>National Data Bank for Rheumatic Diseases, Wichita, KS, <sup>2</sup>University of Nebraska Medical Center, Omaha, NE, <sup>3</sup>Internal Medicine, Division of Rheumatology, University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Automobile driving is an important instrumental activity of daily living with heightened importance among arthritis sufferers who are disproportionately reliant on driving for the preservation of health, well-being, and quality of life. Despite its importance to patients, scant data exists regarding the impact of arthritis on driving performance. We investigated occurrences of motor vehicle accidents (MVA) in patients with RA and how clinical function measures may be associated with MVA.

## Methods:

Using a large US observational cohort, the National Data Bank for Rheumatic Diseases (NDB), we compare RA and adult non-RA rheumatic disease patients who had a validated MVA. Within each group, we also compare patients with and without a MVA measured at a random observation before the accident or at any time for those without an accident. Patients with <2 questionnaires were excluded. MVAs were identified by validated hospitalizations (code 162) and by death codes (ICD9, E81\*). We conducted a principal component analysis (PCA) using the 20 items from the HAQ. Scree plot and the Kaiser criterion were used to select the number of components.

## Results:

From a total of 37,743 patients, we found 142 MVA, 103 recorded as hospitalizations and 39 as deaths. From the 26,905 RA adults, 90 (0.33%) had a MVA while the 10,838 non-RA patients had somewhat higher number of 52 (0.48%) (P=0.037). There was no statistical difference in demographic or clinical outcomes between those with or without a MVA in patients with RA, though there was an association with the number of individuals living the patient's household with those in MVA having fewer (p=0.02). Non-RA patients with MVA were older than patients with no accidents or compared to RA patients (Table). Scree plot analysis and Kaiser criterion identified the first two components as being the most associated with MVA (Figure). Component 1 (overall disability score) accounted for 56% of the variance in MVA risk while Component 2 (individual HAQ items) accounted for an additional 8% of variance. Of note, Component 2 included HAQ response items focused on upper extremity function / mobility (i.e. opening a car door, eating, opening a jar) and did not include items focused on lower extremity function (Figure).

## Conclusion:

These findings provide evidence that reduced functional independence and hand mobility, outcomes associated with RA disease activity, may be linked to poor driving and/or future vehicle accidents.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

We previously observed that incident RA patients have an increased risk of cardiovascular (CV) mortality relative to the general population in Ontario. Our aim was to evaluate the incidence and factors associated with major CV events subsequent to RA diagnosis.

### Methods:

We studied incident RA patients within the population-based Ontario Rheumatoid Arthritis Database (ORAD). We analyzed all individuals who were diagnosed with RA after their 65th birthdate (ensuring comprehensive drug coverage) between 2000 and 2013. Our primary outcome was a composite measure which included acute myocardial infarction (AMI), stroke, congestive heart failure (CHF), revascularization with either percutaneous coronary intervention (PCI) or coronary artery bypass graft (CABG) surgery. All patients were followed from cohort entry until major CV event, censored on death, out-migration, or end of study period (Dec 2013), whichever occurred first. Factors associated with experiencing a major CV event during follow-up were analyzed using multivariable Cox regression to estimate hazard ratios (HRs), exploring the effects of baseline and time-varying medication exposures (including methotrexate, other DMARDs, anti-TNFs, COXIBS, NSAIDs, glucocorticosteroids, statins, antihypertensives), baseline comorbidities, time-varying development of extra-articular manifestations (as proxy for disease severity), healthcare use, and demographics (age, sex, rurality, socioeconomic status).

### Results:

Among 23,994 incident RA patients, 67% were female. Patients had a high CV risk burden at the time of diagnosis (70% had pre-existing hypertension, 23% diabetes, 16% coronary artery disease, 3% previous AMI and 1% cerebrovascular disease). During 115,453 person-years of follow-up, 3,294 (14%) patients experienced a CV event for a crude rate of 28.5 events (95% CI 27.6,29.5) per 1,000 person-years [24.6 events (95% CI 23.5,25.7) among females and 37.4 events (95% CI 35.5,39.5) among males]. In our multivariable analysis, we did not observe clear associations with use of anti-rheumatic treatment during follow-up. Greater use of statins was associated with a lower CV event risk [HR 0.96 (95% CI 0.94,0.98)], whereas greater cumulative exposure to glucocorticosteroids was associated with an increased risk [HR 1.08 (95% CI 1.05,1.11)]. The strongest independent risk factors for a major CV event were pre-existing comorbidities at time of RA diagnosis, including coronary artery disease [HR 1.72 (95% CI 1.57,1.87)], prior AMI [HR 1.53 (95% CI 1.32,1.76)], renal disease [HR 1.43 (95% CI 1.20,1.70)], diabetes [HR 1.41 (95% CI 1.30,1.52)], cerebrovascular disease [HR 1.36 (95% CI 1.03,1.80)], and hypertension [HR 1.16 (95% CI 1.05,1.28)].

### Conclusion:

Senior RA patients have a high CV risk burden at the time of RA diagnosis. Risk of experiencing a subsequent major CV event during follow-up was high. Pre-existing co-morbidities and glucocorticosteroids were positively associated with CV events, while statins were protective. This clearly highlights strategies to decrease CV events in RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Epidemiology and Public Health Poster I: Rheumatoid Arthritis

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) patients are at high risk of cardiovascular disease (CVD). Risk algorithms for the general population lack precision when applied to RA patients and validated RA-specific CVD prediction models are missing. Risk age estimations are recommended as adjuncts to assessment of absolute 10-year risk of fatal CVD events. Two risk age models based on the Systematic Coronary Risk Evaluation (SCORE) algorithm have been developed; the cardiovascular risk age and the vascular age. However, the performance of these models has not been compared. Using longitudinal data on CVD events in RA patients, we aimed to compare the discriminative ability of cardiovascular risk age and vascular age among RA patients and in subgroups of RA patients based on disease characteristics.

**Methods:** Patients with RA were included from an international consortium, aged 30-70 years at baseline. Those with prior CVD, diabetes and/or users of lipid-lowering and/or antihypertensive therapy at baseline were excluded. Cardiovascular risk age was estimated based on chronologic age, smoking status, total cholesterol and systolic blood pressure at baseline. Vascular age was derived from the 10-year risk of CVD according to the SCORE algorithm, with or without high density lipoprotein cholesterol, using the equations for low and high risk countries. Performance of each risk age model in predicting CVD events was assessed using the concordance index.

**Results:** Among the 1867 RA patients included, 74% were female, median (inter-quartile range) age and disease duration were 52.0 (44.0, 59.9) and 0.6 (0.1, 6.4) years, 72.5% were rheumatoid factor positive, 24.7% were using glucocorticoids and 10.3% were using biologics at baseline. Overall, 144 CVD events occurred and median follow-up time was 5.0 (2.6, 9.3) years. Median difference between estimated risk age and chronologic age was 4.0 to 6.7 years, depending on the specific risk age model applied. Overall, the C-index across risk models ranged from 0.71 to 0.73 with standard errors of 0.03. Across prediction models, the lowest observed concordance was found among women and in glucocorticoid users and in those with new-onset disease ( $\leq 1$  year). Additional analyses including RA patients on cardio preventive therapy yielded slightly lower c-indexes. Since SCORE was developed for use in Europe, we performed analyses on European RA patients, which yielded similar results. The trend of reduced concordance among women, glucocorticoid users and RA patients with short disease duration was preserved in these additional analyses.

**Conclusion:** The cardiovascular risk age and vascular age models have comparable performance in predicting CVD in RA patients. Sex, disease duration and/or glucocorticoid treatment may influence the performance of risk age estimations.

Scatter plot of age versus cardiovascular risk age and vascular age estimations according to the Systematic Coronary Risk Evaluation (SCORE) algorithms for high risk (Hrisk) and low risk (Lrisk countries), with or without high density lipoprotein cholesterol (HDLc). This figure depicts vascular age estimations according to the high risk country algorithms.

## Lack of Screening By Rheumatologists and Primary Care Physicians for Childhood Sexual Abuse in Patients with Fibromyalgia-Depression Overlap: An Unrecognized Crisis?

M. Anthony Albornoz<sup>1</sup>, Christian Albornoz<sup>2</sup> and Daniel J. Clauw<sup>3</sup>, <sup>1</sup>Rheumatology, Riddle Memorial Hospital/Mainline Health System, Media, PA, <sup>2</sup>Temple University School of Medicine, Philadelphia, PA, <sup>3</sup>Chronic Pain & Fatigue Research Center, University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Depression is reported in as many as 71% of patients with Fibromyalgia (FM). An association between Childhood Sexual Abuse (CSA) and FM has been well documented and is responsible for inducing disturbing levels of chronic physical and psycho-affective morbidity. Based on the 28-year experience of the lead author, the frequency of CSA in patients with Fibromyalgia-Depression Overlap (FDO) is thought to be highly underestimated, principally due to the underutilization of validated screening questions by Rheumatologists (RH), Internists and Family Medicine Physicians (PCP). We primarily sought to determine the frequency of CSA screening by RH and PCP in patients with FDO and the incidence of CSA in new patients with FDO. Additional clinical and psychosocial variables were secondarily assessed.

**Methods:** A retrospective analysis conducted over a 12 month period in an outpatient, community-based, solo private practice setting of 131 consecutive new adult patients diagnosed with FM by one RH. All patients were screened for depression, anxiety and CSA using validated tools (PHQ-9, GAD-7, Gen Hosp Psychiatry. 2007 Jan-Feb;29(1):8-13). CSA patients were asked whether past and/or present PCP and past RH inquired about CSA. All patients met the 2010 ACR criteria for FM.

**Results:** All data is summarized in Table. Noteworthy clinical findings included: Of the 131 FM patients, 100% were female, 82 (63%) were diagnosed with FDO and 18 (22%) of FDO patients revealed they were victims of CSA; CSA was not encountered in the non-FDO population; CSA mean age was 42 with an age range of 18-74; mean age at time of abuse 13; oldest age when CSA first divulged was 74; 16 (89%) of CSA patients were under age 65 and of these 13 (81%) were either on disability or unemployed; 6 (33%) family member(s) did not believe claim of CSA; 14 (78%) of CSA patients requested that abuse history not be included in the medical record; 11 (61%) of assailants were 1st degree relatives; CSA patients never queried by physicians about sexual abuse: active and/or past PCP 15 (83%) and past RH 9 (100%); Psychiatric/Psychological care given in 18 (100%) of CSA patients; 18 (100%) of CSA patients experienced past

suicidal ideations and 11 (61%) active suicidal ideations; 8 (44 %) attempted suicide; 18 (100%) had active depression and 16 (89%) had active anxiety; 15 (83%) active severe depression; 14 (78%) active severe anxiety; 16 (89%) active panic attacks.

**Conclusion:** The structure and small sample size of this investigation limits our ability to draw definitive conclusions. However, these data reveal that in an alarmingly high number of FDO patients previously evaluated by RH and PCP, CSA escaped detection. The results of this analysis highlights that patients with FDO-CSA likely represent a particularly at-risk population who are in need of greater physician awareness and a more focused assessment. A multi-state study addressing this topic is in progress.

## Effect of Vitamin D Supplementation in Chronic Widespread Pain: A Systematic Review and Meta-Analysis

**Wai Chung Yong,** Anawin Sanguankeo and Sikarin Upala, Bassett Medical Center, Cooperstown, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Abstract

**Background/Purpose:** Chronic non-specific widespread pain (CWP) including fibromyalgia (FM) is characterized by widespread pain, reduced pain threshold and multiple tender points on examination, causing disability and decreased quality of life. Vitamin D has been proposed as an associated factor in CWP. This meta-analysis aimed to explore the benefit of vitamin D supplementation in the management of CWP.

**Methods:** A comprehensive search of the CENTRAL, MEDLINE and EMBASE databases was performed from inception through January 2017. The inclusion criterion was the randomized clinical trials' evaluating the effects of vitamin D treatment in adult subjects with CWP or fibromyalgia. CWP was defined as chronic recurrent musculoskeletal pain without secondary causes; fibromyalgia patients met the American College of Rheumatology criteria for fibromyalgia. Study outcome was assessed using visual analog scale (VAS) of pain intensity. Pooled mean difference (MD) of VAS and 95% confidence interval (CI) were calculated using a random-effect meta-analysis. Meta-regression analysis using random-effects model was performed to explore the effects of change in vitamin D in the treatment group on difference in mean of VAS. Sensitivity analysis was performed to evaluate the robustness of results. The between-study heterogeneity of effect-size was

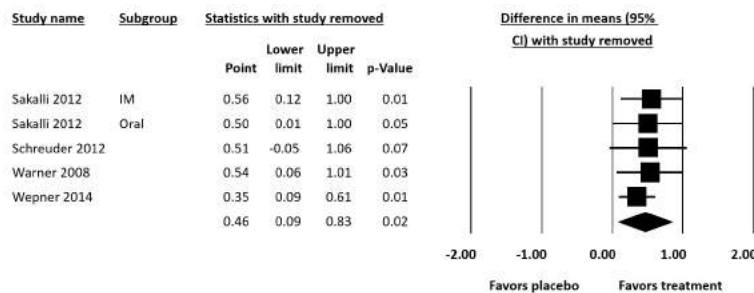

quantified using the  $Q$  statistic and  $I^2$ .

**Results:** Data were extracted from 4 randomized control trials involving 287 subjects. Pooled result demonstrated a significant lower VAS in CWP patients who received vitamin D treatment compared with those who received placebo (MD=0.46; 95% CI: 0.09 – 0.89,  $I^2 = 48\%$ ). Meta-regression analysis revealed no significant relationship between the changes of vitamin D and VAS with a coefficient = 0.04 (95% CI: -0.01 to 0.08),  $p=0.10$ .

**Conclusion:** In this meta-analysis, we conclude that vitamin D supplementation is able to decrease pain scores and improve pain despite no significant change in VAS after increasing serum vitamin D level. Further study needs to be conducted in order to explore the improvement of functional status, quality of life, and the pathophysiological change that improves chronic widespread pain.

## Effects of Taping Therapy in the Management of Fibromyalgia: A Randomized Controlled Study

Hae Joo Suh<sup>1</sup> and Sang Tae Choi<sup>2</sup>, <sup>1</sup>Seoul National University Hospital, Seoul, Korea, Republic of (South), <sup>2</sup>Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia is a medical condition characterized by chronic widespread musculoskeletal pain, accompanied by fatigue, insomnia, cognitive problems, psychiatric symptoms and various somatic symptoms. While a number of pharmacological and nonpharmacological therapies are attempting to treat the patients with fibromyalgia, fibromyalgia is still difficult to manage. Taping therapy has been reported to be effective in relieving pain in a variety of musculoskeletal diseases. However, there were no reports of the patients with fibromyalgia. Therefore, in this study, we aimed to evaluate the effectiveness of taping therapy in fibromyalgia management.

**Methods:** This is a randomized controlled trial, and total 60 patients with fibromyalgia were enrolled in this study. All patients were met the 2010 American College of Rheumatology (ACR) diagnostic criteria for fibromyalgia. Participants were randomized into the Kinesio taping group (n = 30) and the inelastic paper taping group (n = 30) as control. Kinesio taping therapy or inelastic paper taping was performed twice a week for three weeks in both groups. Three weeks later, Kinesio taping was applied to the control group for additional three weeks. To assess the effect, the widespread pain index (WPI), severity score (SS) and fibromyalgia impact questionnaire (FIQ) by ACR were used to measure pain, disease severity and dysfunctions in daily life. The Beck depression inventory (BDI) was used to assess depression, and quality of life was assessed by the EQ-5D INDEX and EQ-5D VAS by EurQol group.

### Results:

There were no significant differences between the two groups in mean ages, sex ratio and type of medications including anti-depressants and muscle relaxants. The Kinesio taping group showed significant improvement in pain (WPI,  $10.50 \pm 3.98$  vs.  $5.70 \pm 2.73$ ,  $p < 0.001$ ), symptom severity (SS,  $7.93 \pm 2.24$  vs.  $5.27 \pm 1.98$ ,  $p < 0.001$ ), dysfunction in daily life (FIQ,  $65.03 \pm 18.75$  vs.  $43.25 \pm 18.87$ ,  $p < 0.001$ ), depression (BDI,  $18.17 \pm 8.55$  vs.  $13.00 \pm 6.75$ ,  $p < 0.001$ ) and QoL (EQ-5D INDEX,  $9.10 \pm 1.54$  vs.  $7.67 \pm 1.40$ ,  $p < 0.001$ ; EQ-5D VAS,  $38.33 \pm 24.65$  vs.  $56.67 \pm 27.93$ ,  $p < 0.001$ ), respectively. In the control group, however, the significant difference was noted only in pain (WPI,  $10.53 \pm 3.87$  vs.  $9.27 \pm 3.57$ ,  $p = 0.014$ ). The changes in the Kinesio taping group before and after treatment showed significant differences compared to the control group; WPI ( $p < 0.001$ ), SS ( $p < 0.001$ ), FIQ ( $p < 0.001$ ), BDI ( $p = 0.001$ ), EQ-5D INDEX ( $p < 0.001$ ), and EQ-5D VAS ( $p < 0.001$ ), respectively. After changing from inelastic paper taping to Kinesio taping, all parameters have been significantly improved (WPI,  $p < 0.001$ ; SS,  $p < 0.001$ ; FIQ,  $p < 0.001$ ; BDI,  $p < 0.001$ ; EQ-5D INDEX,  $p < 0.001$ ; EQ-5D VAS,  $p < 0.001$ , respectively). There was no serious adverse event to all participants.

**Conclusion:** This randomized controlled study showed that Kinesio taping therapy is effective in pain, symptom severity, dysfunctions in daily life, depression, and quality of life in patient with fibromyalgia. Taping therapy could be a useful treatment modality in the management of fibromyalgia.

## Prevalence of Fibromyalgia in Nurses; A Cross Sectional Study

Sarah Alajmi<sup>1</sup>, Faisal Shahwan<sup>1</sup>, Yazeed Bajuaifer<sup>1</sup>, Rand Al Ohaly<sup>2</sup>, Maha Edrees<sup>2</sup>, Alanood Asiri<sup>2</sup> and Mohammed Omair<sup>3</sup>, <sup>1</sup>Internal Medicine, King Saud University Medical City, Riyadh, Saudi Arabia, <sup>2</sup>King Saud University Medical City, Riyadh, Saudi Arabia, <sup>3</sup>Division of Rheumatology, Department of Medicine, King Saud University, Riyadh, Saudi Arabia

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Nurses are at increased of developing pain sensitization syndromes due to stress and interrupted sleep. The prevalence of fibromyalgia (FM) in nurses is unknown. The aim of this study is to evaluate the prevalence of FM in nurses using different screening tools.

### Methods:

This was a cross-sectional study conducted in King Saud University Medical City (KSUMC). Nurses were invited to fill a questionnaire. The fibromyalgia Rapid Screening tool (FIRST), Fibromyalgia Survey Questionnaire (FSQ) and London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ) were used to identify patients with FM. Descriptive analysis was used for demographics. Non-parametric tests were to compare PIT with and without FM.

### Results:

A total of 335 nurses completed the questionnaire. They were mostly females (93.7%), married (64.5%) with a median (interquartile range) age and body mass index of 32 (10) years and 24.8 (4.7) respectively. Of those, 121 (36.1%) nurse admitted having body pain. The prevalence of FM using the FIRST, FSQ and LFESSQ were (1.8%), (0.6%) and (19.4%) respectively. None of them fulfilled the 3 criteria concurrently. Using the LFESSQ criteria, nurses with FM were more likely to complain from irritable bowel syndrome ( $p=0.018$ ), dry mouth ( $p=0.026$ ), chest pain ( $p=0.002$ ) and headache ( $p<0.001$ ). the underlying specialty had an impact on the prevalence of FM based on specialty was; emergency department (23.1%), clinics (17.2%), intensive care (10.6%), ward (5.3) and operation room (4.3%).

**Conclusion:** The prevalence of FM is variable among nurses based on the used screening tool. Educational programs and screening clinics are justified.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The 2010/2011 fibromyalgia (FMS) diagnostic criteria (1) were recently revised, with the addition of a generalized pain criterion in order to avoid misclassification of regional pain syndromes; furthermore, the diagnosis of fibromyalgia is now valid irrespective of other diagnoses. Aim of the present study was to evaluate whether patients classified as having (2016+) or not having (2016-) FMS by 2016 revised criteria truly represent different populations.

**Methods:** 334 patients (306 F and 28 M) with a diagnosis of FMS according to 2011 criteria were included in the study; mean age was

46.82 yrs (range 16 – 75), and mean disease duration 6.25 yrs (range 3 months -34 yrs). Widespread Pain Index (WPI) and Symptom Severity Scale (SSS) were assessed by a localized version of the Fibromyalgia Survey Questionnaire; furthermore, patients were asked to report the presence or absence -in the last 7 days- of each of the 41 somatic symptoms suggested by the original 2010 classification paper (2). An evaluation of overall pain level in the last 7 days (0-10 numeric rating scale, NRS), and of fatigue by the FACIT-Fatigue questionnaire were available in 101 and 137 patients respectively. Statistical analysis was performed by IBM SPSS v 22. Differences of mean values and of proportions were evaluated by parametric or non-parametric methods as appropriate.

**Results:** the diagnosis of FMS was confirmed by 2016 criteria in 290 (86.8%) patients, and not confirmed in 44 (13.2%) patients. Mean age ( $47.62 \pm 10.6$  yrs vs  $46.69 \pm 11.7$  yrs,  $p=0.625$ ), mean disease duration ( $6.27 \pm 6.37$  vs  $6.25 \pm 6.10$  yrs,  $p=0.982$ ), the percentage of females (93.2% vs 91.4%,  $p=0.688$ ), and the association with other clinically relevant diseases (27.3% vs 18.6%,  $p=0.179$ ) were not different in the 2016- group as compared to 2016+ group. 2016- patients had significantly lower values of polysymptomatic distress scale (PSD:  $16.59 \pm 2.4$  vs  $21.86 \pm 4.5$   $p < 0.001$ ), and of pain-related variables (WPI:  $7.57 \pm 2.1$  vs  $12.66 \pm 3.4$ ,  $p < 0.001$ ; TP:  $10.54 \pm 5.4$  vs  $13.28 \pm 4.3$ ,  $p=0.001$ ; NRS:  $5.64 \pm 2.9$  vs  $7.46 \pm 1.9$   $p=0.022$ ). SSS was similar in the 2 groups ( $9.03 \pm 1.9$  vs  $9.20 \pm 1.9$   $p=0.599$ ), but the number of somatic symptoms reported was significantly lower in 2016- patients ( $14.44 \pm 5.0$  vs  $17.49 \pm 6.6$   $p=0.005$ , Fig. 1), which reported higher levels of fatigue (FACIT-Fatigue  $28.3 \pm 10.8$  vs  $21.17 \pm 10.0$ ,  $p=0.010$ ).

**Conclusion:** The rate of disagreement between 2011 and 2016 criteria (13.2%) in our study is very close to the results (13.8%) reported in the only comparison study published to date (3). Patients failing to meet 2016 criteria seem to represent a truly different population, characterized by lower polysymptomatic distress, lower overall pain, and fewer somatic symptoms.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Physicians in training (PIT) are at increased of developing pain sensitization syndromes due to stress and interrupted sleep. The prevalence of fibromyalgia (FM) in PIT is unknown. The aim of this study is to evaluate the prevalence of FM in PIT using different screening tools.

**Methods:** This was a cross-sectional study conducted in King Saud University Medical City. PIT were invited to fill a questionnaire which included the fibromyalgia Rapid Screening tool (FIRST), Fibromyalgia Survey Questionnaire (FSQ) and London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ) to identify patients with FM. Non-parametric tests were used for the analysis.

**Results:** A total of 183 PIT completed the questionnaire. They were predominantly males (56.8%), single (56.3%) and at resident level (86.3%). The median (interquartile range) age and body mass index were 28 (4) years and 26.3 (7.86) respectively. Seventy-two (39.3%) PIT admitted having generalized body pain. The prevalence of FM using the FIRST, FSQ and LFESSQ were (8.2%), (11.5%) and (8.2%) respectively. Seven (3.8%) of them fulfilled the 3 criteria concurrently. Using the LFESSQ criteria, PIT with FM were more likely to have a family history of FM (37.5% vs 3.5%;  $p<0.001$ ), complain from irritable bowel syndrome ( $p<0.001$ ), non-specific headaches ( $p=0.001$ ), migraines ( $p<0.001$ ), interrupted sleep ( $p=0.003$ ), snoring ( $p=0.046$ ), and impaired concentration (0.045). Surgical residents had the highest prevalence (14.8%) followed by anesthesia (14.3%) and medical residents (13.4%).

**Conclusion:** The prevalence of FM is increased among PIT regardless of the used screening tool. Educational programs and screening clinics are justified.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The observation of several cases with coexistent antiphospholipid syndrome (APS) and fibromyalgia led us to this investigation. The objective was to define the frequency of fibromyalgia in a group of patients with antiphospholipid syndrome.

### Methods:

From March 24<sup>th</sup> to June 8<sup>th</sup> 2017 we studied all APS patients attending our outpatient rheumatology clinic. All of them fulfilled the Sapporo and/or Sydney APS classification criteria. The Institutional Ethics Committee approved the protocol. All patients underwent a history + physical examination with emphasis on musculoskeletal features. All filled-out the following questionnaires: the Revised Fibromyalgia Impact Questionnaire (FIQ-R), the 2016 revision of Wolfe's Fibromyalgia Diagnostic Criteria, and the quality of life EuroQol 5D-5L. The Damage Index in Thrombotic Antiphospholipid Syndrome (DIAPS) was also obtained. Spearman method was used to correlate APS clinical

features with fibromyalgia questionnaire scales. Chi square to compare categorical variables.

## Results:

Sixty one patients with APS were included. Their mean age:  $44 \pm 15$  years, 70% are female and 54% have primary APS. The prevalence of fibromyalgia was different when using the 1990 ACR diagnostic criteria (4.9%) compared to Wolfe's criteria (16.4%)  $p < 0.0001$ . The frequency of fibromyalgia was not different in patient with primary vs. secondary APS. In those patient who had concurrent APS and fibromyalgia according to Wolfe's criteria ( $n = 10$ ), there was a correlation between total number of thrombotic events with headache, depression, and abdominal pain ( $r = 0.636$ ,  $p = 0.048$ ), as well as with FIQ-R balance problems ( $r = 0.754$ ,  $p = 0.012$ ). Oddly, cumulative organ damage measured by DIAPS inversely correlated with FIQ-R quality of sleep ( $r = -0.820$ ,  $p = 0.004$ ). Quality of life measured by Euro Qol is poorer in APS + fibromyalgia patients ( $85 \pm 16$  vs  $64 \pm 12$ ,  $p < 0.001$ ).

## Conclusion:

In this cohort of patients with APS, more individuals can be classified as having concurrent fibromyalgia when the 2016 revised Wolfe's criteria is used. Recurrent thrombosis is associated to several fibromyalgia symptoms such as headache, depression and abdominal pain. Patients with APS and concurrent fibromyalgia have poorer quality life.

## Xerostomia in Patients with Fibromyalgia

Nicolas Lloves<sup>1</sup>, Anastasia Secco<sup>2</sup>, Virginia Durigan<sup>3</sup>, Santiago Scarafia<sup>2</sup>, Felix Romanini Sr.<sup>4</sup> and Marta Mamani<sup>4</sup>, <sup>1</sup>Rheumatology Department, Hospital Rivadavia, Buenos Aires, Argentina, <sup>2</sup>Hospital Bernardino Rivadavia, CABA, Argentina, <sup>3</sup>Reumatology, Hospital Bernardino Rivadavia, CABA, Argentina, <sup>4</sup>Hospital Rivadavia, Buenos Aires, Argentina

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Fibromyalgia (FM) is a rheumatic disease characterized by diffuse, chronic musculoskeletal pain, of non-articular origin, which is evidenced by the palpation of painful points in specific anatomical areas and is usually accompanied by non-repairing sleep, Tiredness, morning stiffness, cognitive alterations, among others.

FM affects approximately 0.5 -5% of the population, having a maximum prevalence between 40 and 50 years. No racial or socioeconomic predisposition has been determined to date.

Sicca syndrome whose term encompasses xerophthalmia, xerostomia, xeroderma and xerovagina, has been described in patients with FM. Xerostomia is the sensation of dry mouth due to lack or decrease of saliva. There are no clinical studies that determine the prevalence of xerostomia in patients with FM and on the other hand the reduction of salivary flow in these patients has not been studied with objective tests. The aim of this study was to determinate the frequency of xerostomia in patients with diagnosis of Fibromyalgia and describe their clinical and epidemiologic characteristics.

**Methods:** Patients were included according 1990 and 2010 ACR Classification criteria. Patients taking drugs that cause xerostomia were excluded as well as the ones presenting other rheumatologic diseases. Xerostomia was assessed by interrogation and physical examination, and a sialometry was performed in order to determinate the decrease of salival flow. A sialometry was positive if the saliva flow was under 1.5 ml in 15 minutes. In case of presenting positive sialometry patients were studied to rule out Sjogren Syndrome with laboratory and minor salivary gland biopsy.

**Results:** 50 patients were recruited during the study. The 100 % of them were women. The mean age was 47 years old ( $DS \pm 8.5$ ), while the mean time of evolution of FM was 6 years. 29 patients reported xerostomia of which 4 presented positive sialometry. No positive sialometry was found in the group that did not referred xerostomia. Smoking was more prevalent in patients with FM who did not report xerostomia with respect of those who reported xerostomia (31.8% vs 6.9%,  $p = 0.02$ ). There were not associations between xerostomia and hypothyroidism,

diabetes or menopause. The presence of Sjogren Syndrome was rule out in those 4 patients whose sialometry was positive.

**Conclusion:** The prevalence of xerostomia was 51%. No statistically significant associations were found in patients who reported xerostomia. A decrease in objective salivary flow was not demonstrated in patients with FM.

## Unexpectedly High Prevalence of Immunoglobulin Deficiency in Fibromyalgia – II

Xavier J. Caro<sup>1,2</sup> and Earl F. Winter<sup>2, 1</sup>Northridge Hospital Medical Center, Northridge, CA, <sup>2</sup>Southern California Fibromyalgia Research and Treatment Center, Northridge, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have recently reported that 70% of an unselected FM cohort (n = 107) had subtle laboratory findings of Primary Immune Deficiency (PID), usually consisting of one or more immunoglobulin subclass deficiencies (Arthritis Rheum 2014;55(11): S905). To better understand this finding we surveyed a second cohort of FM subjects for laboratory evidence of PID, and – additionally - any clinical evidence of recurrent infections. Our results are reported here.

**Methods:** We retrospectively reviewed serum Ig concentration values on all FM subjects seen between December 2013 and May 2017 in an outpatient, rheumatology office setting. No other diagnosis precluded inclusion in the study unless it was likely that it might predispose to Ig deficiency. A total of 81 consecutive FM subjects, meeting 2010 ACR criteria, were screened; 4 were excluded (i.e., alcohol abuse; prior cancer chemotherapy; age < 18 yrs.). Data on 77 remaining FM subjects were reviewed; 43 of these had coincident RA (26 % seropositive). Ig deficiency was defined as an Ig value below the lower limits of normal (LLN) suggested by Paul's *Fundamental Immunology* ( ); all deficient specimens were tested in duplicate. Ig abnormalities were confirmed by repeat analysis 6 - 9 weeks later. We also reviewed the prevalence of deficient or low mannose binding lectin in these subjects (deficient < 50 ng/ml; low < 500 ng/ml). In an attempt to further ascertain the role of Ig deficiency in FM we also studied the prevalence of any Ig level > LLN but within the lower most quartile of normal values (range / 4). We also collected data regarding a "Lifetime History of Infections" on all FM subjects and 26 "Apparently Healthy" aged-matched, community volunteers (± 5 years).

**Results:** Our findings are listed below:

### Serum Ig Deficiency in 77 FM Subjects Compared to Literature Based Controls

Immunoglobulin	Fibromyalgia Subjects			Estimated Normal Prevalence	P-value (2-tailed)
	No. with Ig deficiency	No. with- out Ig deficiency	Prevalence of FM Ig Deficiency		
IgG Subclass 1	27	50	35%	1/1200	<0.0001
IgG Subclass 2	12	65	16%	1/1200	<0.0001
IgG Subclass 3	37	40	48%	1/1200	<0.0001
IgG Subclass 4	34	43	44%	1/1200	<0.0001
IgA Subclass 1	20	57	26%	1/500	<0.0001
IgA Subclass 2	11	66	14%	3/100	0.002
IgM	1	76	1%	3/100	NS
IgE	11	66	14%	2.5/100	0.002
Any Ig	64	13	83%	1/1200	<0.0001

Schroeder HW, et al: Immunoglobulin Structure and Function. In *Fundamental Immunology*. 7<sup>th</sup> Ed.

Ed: Paul, WE. Lippincott, New York 2013. Analysis was by *Chi-square test*.

Of 71 FM subjects in whom Mannose Binding Lectin (MBL) was measured 18 (23 %) had levels <500 ng/ml, and 12 (16%) had levels <50 ng/ml. The prevalence any Ig in FM subjects being within our estimate of Paul's ( ) lowest quartile for normal Ig levels ranged from 40% to 74%. There was no significant difference in the prevalence of Ig deficiency in FM subjects with concomitant RA compared to those without RA. A history of recurrent sinus infections was not significantly more common in our FM subjects compared to controls, but a history of recurrent serious, non-sinus infections was more prevalent for FM ( $P(1) = 0.009$ ), and FM + RA ( $P(1) = < 0.0001$ ).

**Conclusion:** Our study shows that clinically significant Ig deficiency, particularly IgG subclass deficiency, is a common accompaniment to FM. It also strengthens the argument that FM may be a disorder associated with immune dysregulation. The precise mechanism of this interaction remains unclear, but deserves further investigation.

## A Systematic Review of the Upper Limb Soft Tissue Comorbidities in Patients with Type 2 Diabetes Mellitus

Michelle C Papandony<sup>1</sup>, Anita E Wluka<sup>2</sup>, Ar Kar Aung<sup>3</sup>, Yuanyuan Wang<sup>1</sup>, Sultana Monira Hussain<sup>4</sup> and Flavia M Cicuttini<sup>1</sup>, <sup>1</sup>Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, <sup>2</sup>Australia, Armadale, Australia, <sup>3</sup>Department of General Medicine, Alfred Health, Melbourne, Australia, <sup>4</sup>Monash University, Department of Epidemiology and Preventative Medicine, Melbourne, Australia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Soft tissue disorders affecting the upper limb are not commonly thought of as “classic” complications of type 2 diabetes mellitus. However, the majority of upper limb disorders including adhesive capsulitis, carpal tunnel syndrome, Dupuytren's disease, flexor tenosynovitis, limited hand mobility and rotator cuff tendinitis are more frequent in patients with type 2 diabetes mellitus compared to the general population. With population aging and increasing obesity, the epidemic of type 2 diabetes mellitus is expected to grow. As such, targeting upper limb soft tissue diseases, which contribute to difficulty performing activities of daily living, increased morbidity, poorer health outcomes and higher health service related costs will be important.

The aim of this systematic review is to determine the type and magnitude of upper limb soft tissue comorbidities in patients with type 2 diabetes mellitus compared to the general population.

### Methods:

A systematic literature review of the MEDLINE and EMBASE databases was performed. Any study describing upper limb soft tissue disease in patients with type 2 diabetes mellitus was included. A risk of bias assessment was performed. Where the prevalence of a condition was available, the median and range was presented.

### Results:

8035 manuscripts were identified by the search strategy. 31 articles were eligible for inclusion. Most studies were cross sectional in design. The risk of bias assessment was high. We found that upper limb soft tissue disease is common in type 2 diabetes mellitus (median 32.1%, range 19-57.7%).

Based on data from two studies, the prevalence of any hand abnormality was higher in T2DM compared to controls (median prevalence 45% (range 20.5-69.5%) and 4.9% respectively). Limited hand mobility in type 2 diabetes mellitus was common, with a median prevalence of 26.7% (range 0-80%) (data from 19 studies). Dupuytren's disease was more common in type 2 diabetes mellitus, with a median prevalence 18.8%, (range 0-43.4%), compared to 8% (range 0-39%) in controls (data from 18 studies). Carpal tunnel syndrome was also more common in type 2 diabetes mellitus compared to controls, with a median prevalence of 14% (range 0.32-83.3%) and 3.1% (range 0-17.5%) respectively. The median prevalence of flexor tenosynovitis in type 2 diabetes mellitus was 7.2% (range 2-16.7%) compared to 2% (range 0-

3.6%) in controls (data from 13 studies).

The prevalence of any shoulder abnormality in type 2 diabetes mellitus was 19.5% compared to 4.4% in controls (data from one study). Adhesive capsulitis in type 2 diabetes mellitus was more common (median prevalence was 14.6%, range 7-29%) compared to 2.5% (range 0.5-17%) in controls (data from 8 studies). The median prevalence of rotator cuff tendinitis in type 2 diabetes mellitus was also higher (23.3% (range 9.5-43.3%)) compared to 8.7% (range 0.8-50%) in controls (data from 3 studies).

#### **Conclusion:**

This systematic review has demonstrated that upper limb soft tissue disease is more prevalent in patients with type 2 diabetes mellitus compared to the general population. These associations need to be further investigated and targeted in patients with type 2 diabetes mellitus in order to optimize health outcomes.

#### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia is a chronic debilitating musculoskeletal pain syndrome that causes substantial physical and psychological impairments. With the release of the 2016 revised EULAR recommendations for the management of fibromyalgia, there is a growing interest in developing new exercise program aiming to improve patients' physical function and wellbeing. The Eight Brocades (EB) is an eight-section Qigong physical exercise, originated more than eight-hundred years ago in China, and it has been used by people to improving their general health or existing health issues. Lu Eight Brocades (LEB) is a modified EB, adapted by Chinese Medicine Master Zhi-zheng Lu, which is specifically tailored for patients with rheumatic diseases and is simple and easy to learn. The clinical study reported here was aimed to evaluate the effectiveness of LEB in the management of fibromyalgia in Chinese patients in China.

**Methods:** In this randomized blank-control study, 62 patients with fibromyalgia were assigned to LEB or control group by computer using the SAS system with a ratio of 1:1. Trained and guided by LEB certified physicians, patients practiced LEB one hour, twice a week for 12 weeks in GUAN AN MEN hospital. The primary outcome measure is Visual Analogue Scales for pain (pain VAS), and the secondary outcomes include the followings: Revised Fibromyalgia Impact Questionnaire (FIQR), Multidimensional Assessment of Fatigue (MAF), Pittsburgh Sleep Quality Index (PSQI), Beck Depression Inventory (BDI), Perceived Stress Scale (PSS), and Tender Points Count (TP). The outcome measures were assessed at baseline and at the end of week 4, 8, 12. As compensation, patients in blank-control group received LEB training for additional 12 weeks after the end of the study. Statistical analyses were conducted by a statistician using intention to treat analysis set.

**Results:** Sixty-two subjects were mostly women (55, 87.7%), mean age was 51.2 years (SD 10.6 years, range: 29-69 years), and mean duration was 32.1 months (SD 26.3 months, range: 4-128 months). At the baseline, there were no significant differences on demographics and disease characteristics between LEB and control groups. At the week 4, except for BDI and PSS, improvement of pain VAS, FIQR, MAF, PSQI, and TP were greater in LEB group compared to those in the control group ( $P \leq 0.046$ ). At week 8, all above the measures further improved in LEB group than those in control group ( $P \leq 0.033$ ). At the week 12, all the outcome measures were improved in LEB group compared with control ( $P \leq 0.004$ ). There were no complaints about side effects of LEB exercise during the study period using the side-effect report form.

**Conclusion:** This pilot study demonstrated the effectiveness of physician-guided LEB practice for 12 weeks in improving all spectrum of debilitation symptoms and the feeling of wellbeing in fibromyalgia participants. The study suggests LEB exercise could be a potential

valuable nonpharmacological treatment for patients with fibromyalgia, thus warrants for further larger scale investigations.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The coexistence of fibromyalgia (FM) and chronic arthritis is a challenge for an accurate identification of signs and symptoms associated with rheumatoid arthritis (RA), psoriatic arthritis (PsA), peripheral (PerSpA) and axial spondyloarthropathies (AxSpA). The Fibromyalgia Rapid Screening Tool (FiRST) is a validated questionnaire with high sensitivity and moderate specificity to identify 89% of FM cases, even when it is accompanied by anxiety, depression or functional disability. The use of full or tapered biological disease-modifying antirheumatic drugs (bDMARD) depends in many cases on the reliability of clinical indices which can be altered by the subjectivity of the patient and/or concomitant pathologies. Objective: To evaluate the prevalence of FM using the FiRST questionnaire in patients diagnosed with chronic arthritis and treated with bDMARD.

**Methods:** This cross-sectional study included 325 patients [178 (54,8%) females and 147 (45,2%) males] diagnosed of chronic arthritis and treated with bDMARDs. They were consecutively recruited in the Biological Therapy Unit from January to March 2015, all patients were in full or tapered bDMARD for at least 1 year. The dosage tapering had been made in patients with a maintained remission according to their rheumatologist attendant and the patient approval. All patients self-completed the FiRST questionnaire and a score > 5/6 was considered positive. The clinical assessment was always performed by the same investigator. Demographic, clinical and laboratory variables were collected and clinical indices related to each pathology were calculated (DAS28-ESR, DAS28-CRP, SDAI, CDAI, BASDAI, BASFI, ASDAS-CRP). Patients were classified as peripheral arthritis (PerAR: RA, PsA, PerSpA) and axial spondyloarthropathies (AxSpA).

### Results:

A total of 68/325 (21%) patients had a FiRST > 5/6. The time since diagnosis and the number of previous used bDMARD were not significant respect to FiRST < 5/6. In the PerRA vs. AxSpA group we observed that 19% (n=43) and 35% (n=25) had FiRST > 5/6, respectively (p=NS). Fifteen % of patients with tapered bDMARD had FiRST > 5/6 vs. 85% of patients in full bDMARD dosage (p=0.001). Patients in clinical remission were higher in the PerAR group with tapered bDMARD dosage according to DAS28-ESR, SDAI and CDAI [(96%, 94% and 94%) (p=0.01, p=0.04, p=0.032), respectively]. In the PerAR subgroups, we found an association between tapered bDMARD and remission only in patients with RA according to DAS28-VSG, SDAI and CDAI (p=0.026, p=0.04, p=0.043, respectively). In the AxSpA group with tapered bDMARD dosage 86% of patients were in clinical remission according to BASDAI (p=0.019).

**Conclusion:** There was no difference between PerAR and AxSpA groups regarding FiRST > 5/6. Patients with tapered bDMARD dosage had a lower proportion of FiRST > 5/6, therefore early detection of patients with FiRST > 5/6 might help us to better understand clinical activity in chronic arthritis and to improve diagnostic and therapeutic approaches of FM in these patients treated with bDMARD in terms of its efficacy and cost-effectiveness.

## **Fibromyalgia Screening Form in the Diagnosis of Concomitant Fibromyalgia**

**Robert S. Katz**<sup>1</sup> and Jessica L. Polyak<sup>2</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology Associates S.C., Chicago, IL  
**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have found that patients with a variety of rheumatic diseases who have concomitant fibromyalgia more frequently fail therapies for the underlying inflammatory rheumatic disease and osteoarthritis. Based on the 2010 ACR criteria for the diagnosis of fibromyalgia, a screening form was developed at the time of the study for accurate diagnosis. The screening assessment form is filled in by patients. It includes 19 pain areas as well as questions concerning sleep, energy, cognition, headache, abdominal pain, and depression. Adding this fibromyalgia screening questionnaire to the patient's initial visit can also help validate the diagnosis in the minds of patients and also clinicians. We had patients in a rheumatology office practice complete this diagnostic form.

**Methods:** There are 19 pain areas listed. Patients checked a box next to the areas of pain during the last 7 days and replied to questions for the other symptoms- sleep (0-3), energy (0-3), cognition (0-3), and abdominal pain (0-1), headaches (0-1) and depression (0-1). A score of 12 and above is consistent with fibromyalgia.

**Results:** 60 patients with various rheumatic diseases, but excluding primary fibromyalgia, filled out the assessment form developed for the 2010 ACR diagnostic criteria. In those patients with an underlying inflammatory rheumatic disease diagnosis, without known fibromyalgia, 14 (23.3%) had a finding of 12 or more points using the fibromyalgia diagnostic screening form.

**Conclusion:** The fibromyalgia screening form developed in conjunction with the ACR 2010 criteria for fibromyalgia diagnosis can be quite helpful in determining the presence of concomitant fibromyalgia. 23.3% of a group of patients with inflammatory arthritis, lupus, and osteoarthritis also had fibromyalgia, according to the screening form results.

This form can be used to suggest the possibility of concomitant fibromyalgia in patients with other rheumatic diseases. Concomitant fibromyalgia and an inflammatory rheumatic disease may be a reason for the failure of biologic modifier and other therapy aimed at reducing pain and improving global well-being.

## **The Effectiveness of Medications for Fibromyalgia Based on Patient Experiences**

**Robert S. Katz** and Frank Leavitt, Rush University Medical Center, Chicago, IL  
**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess patients' global assessment of frequently used treatments for the fibromyalgia syndrome (FMS), we asked patients with fibromyalgia to rank medications they have tried in the order of their effectiveness.

**Methods:** 95 patients (mean age of 50.5) diagnosed with fibromyalgia based on the 2011 ACR criteria, 88 females and 7 males, completed an in-office questionnaire regarding the effectiveness of various medications often used to treat fibromyalgia. The study ranked 9 medications, which include pregabalin, gabapentin, duloxetine, Muscle Relaxants, Sleep Aids, Stimulants, ADD Medications, Pain Medications, and NSAIDs. Patients rated the medications using this scale: 1=minimally helpful, 2=somewhat helpful, 3=moderately helpful, 4=very helpful.

**Results:** The three medications that were most positively rated by patients were opiate pain meds (mean=2.8), meds to improve sleep (mean=2.8), and ADD stimulants for fibro fog symptoms (mean=2.6).

Effectiveness ratings by fibromyalgia patients for other medications included: gabapentin (mean=0.73); duloxetine (mean=1.02); pregabalin (mean=1.26). 59.1% of FMS patients reported little or no help from pregabalin, and 83.3 % found gabapentin to be little help.

**Conclusion:** Fibromyalgia patients rated the effectiveness of various medications that had tried. Pain medication, sleep aids and stimulants given for the attention deficit component of fibro fog were judged by patients to be the most helpful.

## Depression Versus Frustration

Robert S. Katz<sup>1</sup> and Jessica L. Polyak<sup>2</sup>, <sup>1</sup>Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology Associates S.C., Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with fibromyalgia may feel depressed. But is it a clinical depression, suggesting the need for SSRI, SNRI, or other medication, or is it frustration related to the presence of the symptoms of the disease?

**Methods:** 115 fibromyalgia syndrome (FMS) patients, meeting the 2010 ACR criteria for the diagnosis, completed a questionnaire in a rheumatology office practice asking whether they were depressed and also whether they felt frustrated. The 62 FMS patients who responded yes to having depression also filled out a Patient Health Questionnaire-9 (PHQ-9) for depression. The PHQ-9 asked the following questions: little interest in doing things; feeling down/depressed; trouble with sleep; feeling tired/low energy; poor appetite; feeling bad about oneself; poor concentration; moving and speaking slowly or excessively fidgety; and thoughts of hurting oneself. Patients were asked to rate these questions based on how they felt over the last two weeks, as follows: 0 for not at all, 1 for several days, 2 for "more than half the days and 3

for nearly every day. A score of 5-9 minimal symptoms, 10-14 minor depression, 15-19 major depression, moderate; and >20 major depression, severe.

### The Patient Health Questionnaire (PHQ-9)

Patient Name \_\_\_\_\_ Date of Visit \_\_\_\_\_

Over the past 2 weeks, how often have you been bothered by any of the following problems?	Not At all	Several Days	More Than Half the Days	Nearly Every Day
1. Little interest or pleasure in doing things	0	1	2	3
2. Feeling down, depressed or hopeless	0	1	2	3
3. Trouble falling asleep, staying asleep, or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself - or that you're a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed. Or, the opposite - being so fidgety or restless that you have been moving around a lot more than usual	0	1	2	3
9. Thoughts that you would be better off dead or of hurting yourself in some way	0	1	2	3

Column Totals \_\_\_\_\_ + \_\_\_\_\_ + \_\_\_\_\_

Add Totals Together \_\_\_\_\_

PHQ-9 Score	Provisional Diagnosis	Treatment Recommendation <i>Patient Preferences should be considered</i>
5-9	Minimal Symptoms*	Support, educate to call if worse, return in one month
10-14	Minor depression ++ Dysthymia* Major Depression, mild	Support, watchful waiting Antidepressant or psychotherapy Antidepressant or psychotherapy
15-19	Major depression, moderately severe	Antidepressant or psychotherapy
>20	Major Depression, severe	Antidepressant and psychotherapy (especially if not improved on monotherapy)

**Results:** 96 FMS patients responded yes to the question “are you frustrated?” When asked, “Are you depressed?”, 62 FMS patients answered yes. Scores of the PHQ-9 in the 62 FMS patients feeling depressed were as follows: 12 (19.3%) that scored in the 5-9 range (“minimal symptoms”), 18 (29.2%) that scored in the 10-14 range (“minor depression”), 22 (35.4%) that scored in the 15-19 range (Major depression, moderate), and 10 (16.1%) that scored in the >20 range (Major depression, severe).

**Conclusion:** Of 115 patients with fibromyalgia, 62 reported depression. Using the PHQ-9 depression questionnaire 22 of these patients had a moderate major depression and 10 severe major depression. The great majority of patients with fibromyalgia express frustration but don't

meet the criteria for depression, based on the PHQ-9 questionnaire. Psychotherapy, including ventilation of the patient's symptoms in the rheumatologist's office, and continued in a psychologist's or psychiatrist's office, can be important. Separating depression, with the possibility of prescribing antidepressant medications, and frustration can be clinically and therapeutically important.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We compared patients with the Fibromyalgia Syndrome (FMS) and Rheumatoid Arthritis (RA) patients with respect to stresses that the patients believe may have caused their diseases to flare.

**Methods:** 201 office patients with FMS or RA (150 FMS:130 women and 20 men; mean age 51±12, 61 RA:45 women and 16 men; mean age 55±15) completed a questionnaire as to whether the following conditions caused their disease to flare: lack of sleep, fatigue, emotional stress, physical stress, depression, anxiety, traumatic events, overdoing it, being overworked, feeling overwhelmed, illness, personal changes, and confrontations with friends or family members. The chi-square test of association was done to compare FMS and RA patients with respect to their responses, using a 0.05 significance level.

**Results:** FMS patients were significantly more likely than RA patients to report that stress caused their disease to flare including, with regard to frequency, emotional stress (58% vs. 43%,  $p = 0.042$ ), physical stress (54% vs. 34%,  $p = 0.010$ ), and also lack of sleep (53% vs. 33%,  $p = 0.007$ ), concomitant illness (39% vs. 12%,  $p < 0.001$ ), anxiety (31% vs. 16%,  $p = 0.027$ ), depression (25% vs. 10%,  $p = 0.012$ ), and traumatic events (25% vs. 12%,  $p = 0.026$ ).

**Conclusion:** FMS patients were significantly more likely to be sensitive to a variety of factors compared with RA patients. Fibromyalgia patients recognize many things that tend to aggravate their symptoms. Stress reduction strategies might help fibromyalgia patients.

---

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Fetal exposure to maternal anti-SSA/Ro antibodies is necessary but insufficient for the development of congenital heart block (CHB), suggesting the potential of a fetal genetic predisposition. Prior studies identified an association of HLA and CHB risk providing a possible avenue into pathogenesis involving an interactive genetic effect between 6p21 and 19q13 wherein HLA-C acts as a ligand for the checkpoint receptor killer cell immunoglobulin-like receptors (KIR). A dimorphism at position 80 in HLA-C creates two epitope subgroups, defined by their KIR interactions: C1 (Asn80) and C2 (Lys80). We tested whether C2, which binds with high affinity to an inhibitory KIR rendering an NK cell incapable of restricting inflammation, contributes to CHB.

### Methods:

192 pedigrees from the US, Italy, and France (194 CHB, 91 unaffected siblings, 152 fathers, 167 mothers) and 1073 out-of-study controls were genotyped on the Immunochip single nucleotide polymorphism (SNP) microarray. There were 79 discordant CHB sibling pairs. HLA-C Asn80Lys and KIR imputation was completed. Tests for association used logistic regression, and matched analyses between affected and unaffected children employed McNemar's test.

### Results:

The C1 allele was enriched (and C2 allele reduced) in mothers compared to female controls ( $P=0.0014$ ;  $OR=0.63$ ). In contrast, C2 was increased in fathers compared to male controls ( $P=0.0123$ ;  $OR=1.40$ ). This gender-by-C2 interaction was statistically significant ( $P=0.0002$ ). CHB offspring had comparable C2 frequencies to the fathers (affected offspring frequency=0.42; fathers frequency=0.45) while unaffected C2 offspring frequencies were comparable to the mothers (unaffected frequency=0.31; mothers frequency=0.29). Formal assessment of C2 differences within a pedigree showed a significant increase in the C2 allele in affected vs. unaffecteds ( $P=0.0027$ ;  $OR=4.00$ ). Results were comparable in the CHB discordant sibling pairs in which mothers were homozygous for C1 ( $n=46$  pairs,  $P=0.07$ ;  $OR=2.75$ ). When the paired-sibling analysis was stratified by geographic region the results remained significant in each stratum (U.S.  $P=0.0325$ ;  $OR=3.67$ ; Europe  $P=0.0348$ ;  $OR=4.50$ ). There was no difference in the inhibitory KIR genotype (AA KIRs) between affected and unaffected children ( $P=0.55$ ).

### Conclusion:

The *HLA-C*-encoded supertypic epitope C2 was significantly enriched in CHB vs. unaffected offspring, establishing C2 as a novel genetic risk factor associated with disease. This observation supports a model in which anti-SSA/Ro exposed fetuses expressing C2 ligands may have impaired NK surveillance resulting in unchecked cardiac inflammation and scarring.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The rheumatoid arthritis (RA) risk locus *CCR6* rs3093024 SNP is associated with increased risk of RA in a sex-specific pattern in Asian populations. Specifically, the variant allele was associated with increased RA disease risk in ACPA-positive women. This SNP is in tight linkage disequilibrium with rs3093023, which has been associated with both RA risk and increased serum IL17 levels. We previously reported that these two SNPs altered estrogen receptor binding to estrogen response elements and resulted in the induction of *CCR6* by estradiol (E2) in a SNP-dependent fashion. Specifically, *CCR6* expression could be induced by E2 only in cells carrying the variant genotype. Strikingly, IL17A and IL17RA responded in a parallel fashion. The present study was designed to study mechanisms underlying the *CCR6* SNP effect on the estrogen-dependent regulation of immune mediators in relation to the pathogenesis of RA—a disease for which 2/3 of patients are women.

### **Methods:**

“Human Variation Panel” lymphoblastoid cell lines (LCLs) consisting of LCLs from 300 subjects were used to obtain genome-wide mRNA expression and genome-wide SNP data, and to perform functional genomic studies including site-directed mutagenesis, luciferase reporter assays, qPCR, NF- $\kappa$ B reporter assays and co-immunoprecipitation.

### **Results:**

A reporter construct with variant genotypes for the *CCR6* SNPs increased luciferase activity in response to E2 treatment as compared to wild-type ( $p < 0.001$ ), providing direct evidence for the functional role of these SNPs in the regulation of *CCR6* transcription. Use of the LCL model system allowed us to determine global mRNA expression profiling for functional study. We then performed pathway analysis using genes correlated with *CCR6* expression with  $p \leq 1E-08$  and found that those genes were enriched in immunological regulation pathways. Next, we validated genes significantly correlated with *CCR6* expression, with a focus on immunological genes, including cytokines, chemokines and toll-like receptors, all of which have been implicated in the pathogenesis of RA. *CCR6* knock down using LCLs with known *CCR6* SNP genotypes resulted in significant changes ( $p < 0.05$ ) in the expression of CCL20, IL7R, IL7, IL17RA, IL17A, IL6R, IL6, TLR2, TLR4 and NF- $\kappa$ B p65. Additionally, significant induction for IL17RA, TLR2, TLR4 and NF- $\kappa$ B p65 in response to E2 treatment was observed only in variant genotype cells ( $p < 0.05$ ). In parallel, NF- $\kappa$ B transcriptional activity responded in a *CCR6* SNP and E2-dependent fashion. Finally, *CCR6* could physically interact with NF- $\kappa$ B p65 as determined by co-immunoprecipitation. These results suggest that NF- $\kappa$ B signaling might be associated with *CCR6* SNP and estrogen-dependent effects.

### **Conclusion:**

*CCR6* SNPs are functionally relevant to the pathogenesis of RA. *CCR6* is estrogen inducible in a SNP-dependent fashion, resulting in downstream effects modulating the expression of proinflammatory cytokines and NF- $\kappa$ B transcriptional activity. Our results provide a mechanistic explanation for the results of previous genome-wide association studies that have linked these SNPs in the *CCR6* gene to RA risk and the differential effects of these SNPs on E2 treatment.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The search for novel targets in RA requires novel computational methods and *in silico* systems to identify non-obvious pathways that account for the diversity of responses to targeted agents. We developed and applied a novel integrative systems biology method that identifies transcription factors (TFs) central to regulatory patterns in RA fibroblast-like synoviocytes (FLS) and significant variations in gene networks between RA patients.

**Methods:** Our whole genome ATAC-seq and RNA-seq data (from 11 RA and 11 osteoarthritis [OA] FLS lines) were evaluated for overlaps between ATAC-seq peaks and known gene promoter regions (4kb upstream and 1kb downstream from the TSS). ATAC-seq peaks not assigned to promoters were considered as enhancer regions and linked with the nearest gene. TF binding motifs were curated from the CIS-BP database. 745 TFs had binding sites within 150-bp regions in ATAC-seq peak summits. 22 unique network topologies were constructed by forming directed edges between any parent node TF and child node gene or child node TF. Via the integration of RNA-seq expression data for each sample, the Personalized PageRank (PPR) algorithm was developed and run measure the global influence of each node and variance between RA patients.

**Results:** Initial analysis focused on differences between RA and OA. The mean PPR was calculated for TFs from RA and OA samples and were ranked based on the largest absolute difference between RA and OA (DPPR). Of these, 33 TFs were significantly different for RA vs. OA ( $p < 0.05$ ). For example, the glucocorticoid receptor NR3C1 was the highest rank DPPR ( $p$  value = 0.03). BACH1, which regulates osteoclastogenesis, was the second highest rank DPPR ( $p = 0.0005$ ). Other high DPPR genes included STAT1, YY1 (JAK-STAT signaling) and SPI1. We then looked within RA for inter-RA patient differences to understand individual network profiles. The intersection of the 33 significant RA vs OA TFs with TFs that have the highest variance of normalized PPR within the RA networks, yielded 15 hits. MGA (MAX gene-associated protein), which regulates the expression of MYC-MAX and T-box family target genes, had the highest intra-RA variance with a high rank DPPR ( $p = 0.024$ ) suggesting that this TF defines differences in RA pathogenesis between patients. Another high intra-RA variance gene within the intersection includes TBX2, which participates in mesenchymal cell differentiation. A smaller subset of RA patients (~30%) have high PPR values for ID1. ID family genes play a role in cell proliferation and angiogenesis in RA.

**Conclusion:** This systems biology approach not only defines disease specific TFs that contribute to the RA phenotype but also distinguishes patient-to-patient differences. The unique computational approach identifies novel targets and helps elucidate the mechanism of differential responses to highly targeted agents in RA. Key transcription factors, including well known genes such as NR3C1 and STAT1, along with novel patient-specific TFs targets like MGA emerge from this *in silico* method to individualize treatment.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Juvenile idiopathic arthritis (JIA) is a group of chronic arthropathies of unknown cause affecting children under 16yrs, and is the most common childhood inflammatory rheumatic diagnosis, affecting 1 in 1,000 UK children. In recent years great advances in dissecting the genetic basis of JIA have been made. In one landmark study, conducted on the two most common subtypes (oligoarthritis and RF-negative polyarthritis), 17 susceptibility loci were identified at genome-wide significance ( $p\text{-value} < 5 \times 10^{-8}$ ) with a further 11 reaching suggestive significance ( $p\text{-value} < 1 \times 10^{-6}$ ). These findings were the results of a large international collaboration using the ImmunoChip array, which targets 186 known loci in 12 autoimmune diseases. However, one limitation to the afore-mentioned study was that the analysis was limited to the selected loci; large genome-wide studies are now needed. The aim of this work is to identify novel genetic loci associated with disease susceptibility using a large cohort of UK JIA cases.

### Methods:

Whole-genome genotyping data was generated using four platforms (Illumina). Following stringent quality control common variants to all four platforms were extracted from the individual datasets before merging together. Imputation was performed using the Haplotype Reference Consortium panel on the Michigan Imputation Server using Minimac3 software. SNPs with imputation accuracy ( $r^2 > 0.5$ ), minor allele frequency  $> 1\%$  and Hardy-Weinberg  $p\text{-value} > 1 \times 10^{-3}$  were retained for analysis. Association was conducted using logistic regression; using the top three principal components as covariates. Bioinformatics analysis was performed using in-house Capture Hi-C data, to study long-range interactions, to elucidate the potential function of the associated SNPs.

### Results:

Post-QC, 2,585 cases and 5,181 controls were available for analysis with ~7.4 million SNPs. Analysis conducted within oligoarthritis and RF-negative polyarthritis cases, ( $n=1,617$ ) confirmed 13 previously identified JIA risk loci and identified more than 20 potentially novel regions above suggestive significance ( $2.25 \times 10^{-5}$ ). Of these, rs7874896, an intergenic SNP located between *TNFSF15* and *TNFSF8* on chromosome 9 was one of the most strongly associated ( $p\text{-value} 3.67 \times 10^{-7}$ ). *TNFSF15* in particular is interesting, as it has been found that *TNFSF15* drives expression of pro-inflammatory cytokines (IFN $\gamma$ ) and TNF $\alpha$  from CD4+CD161+ T-cells, yet these cells were found to be resistant treatment with an anti-TNF; suggesting that blockade of *TNFSF15* may possess therapeutic benefit in JIA. Further investigation of associated SNPs using Capture Hi-C data has yielded potentially interesting interactions within T- and B-cell lines.

### Conclusion:

This study represents the largest GWAS conducted in JIA to date and our preliminary results have identified novel associations with the most common subtypes of the disease and may have highlighted a potentially novel therapeutic target.

## New Autoinflammatory Phenotype Associated with Homozygous AGBL3 Variant

Ahmet Gül<sup>1</sup>, Neslihan Abaci<sup>2</sup> and Sema Sirma Ekmekci<sup>2</sup>, <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, <sup>2</sup>Department of Genetics, Istanbul University Institute for Experimental Medical Research, Istanbul, Turkey

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To identify new genes/pathways associated with autoinflammatory phenotype.

**Methods:** We screened genomic variations by whole exome sequencing in 3 families presented with autoinflammatory findings despite negative results for known autoinflammatory gene mutations. A systematic search was carried out specifically for identification of deleterious genetic variants in genes involved in novel inflammatory pathways.

**Results:** We identified a deleterious mutation in the AGBL3 (ATP/GTP binding protein-like 3) gene, in a consanguineous family of Assyrian origin. Index case, now 22-year-old male, presented to our outpatient clinic with recurrent attacks of fever, urticarial rash on the extremities and trunk, conjunctival injections and arthralgia. His attacks started when he was 13, and two to three day lasting attacks recurred more frequently during warm weather conditions or following hot baths. He had highly elevated CRP and ESR during attacks, but his acute phase response did not return to normal values in between the flares. Low C3 and C4 values were also observed during asymptomatic periods. He responded partially to corticosteroids as well as canakinumab and anakinra treatments, and he is currently on low dose steroids and 200 mg/day anakinra. Whole exome sequencing revealed homozygous c.769C>T mutation in AGBL3 gene, which results in early termination of the protein (p.Gln257Ter) and deletion of carboxypeptidase domain. This protein belongs to metalloproteinases that mediate both deglutamylation and deaspartylation of target proteins. AGBL3 is suggested to catalyze the deglutamylation of polyglutamate side chains, especially in proteins such as tubulins. Also, STRING search revealed interaction of AGBL3 with complement regulatory proteins, such as CD46, CD55, and CD59, which are potent inhibitors of the complement membrane attack complex.

We searched databases from Turkey and other sources, and we could not identify this variant in other individuals.

**Conclusion:** This study identifies the AGBL3 metalloproteinase gene as a potential autoinflammatory gene involved in a novel pathway, and its loss of function mutations may result in a potent innate inflammatory response associated with lower complement levels and a partial response to IL-1 blockade.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We performed a genome-wide association study (GWAS) of gout and its subtypes to identify novel gout loci including those that are subtype-specific.

**Methods:** Putative causal association signals from a GWAS of 945 cases and 1,213 controls were replicated with 1396 clinically-ascertained gout cases and 1,268 controls of Japanese males by using a custom chip of 1,961 single nucleotide polymorphisms (SNPs). We also first conducted GWASs of gout subtypes. Replication with Caucasian and New Zealand Polynesian samples was done to further validate the loci identified in this study.

**Results:** In addition to the five loci we reported previously, further susceptibility loci were identified at a genome-wide significance level ( $p < 5.0 \times 10^{-8}$ ): urate transporter genes (*SLC22A12* and *SLC17A1*) and *HIST1H2BF-HIST1H4E* for all gout cases, and *NIPAL1* and *FAM35A* for the renal underexcretion gout subtype. Although *NIPAL1* encodes a magnesium transporter, functional analysis did not detect urate transport via *NIPAL1*, suggesting its indirect association with urate handling. Localization analysis in the human kidney revealed expression of *NIPAL1* and *FAM35A* mainly in the distal tubules, which suggests the involvement of the distal nephron, as well as the proximal nephron, in urate handling in humans. Clinically-defined male gout cases and controls of Caucasian and Polynesian ancestries were also genotyped, and *FAM35A* was associated with gout in all cases. A meta-analysis of the three populations revealed *FAM35A* to be associated with gout at a genome-wide level of significance ( $P_{meta} = 3.58 \times 10^{-8}$ ). Further findings after this GWAS will be presented at the meeting. We also revealed by a fine mapping that rs671, a common functional SNP of *ALDH2*, is a genuine gout-associated SNP in the *CUX2* locus, which was detected by the previous gout GWAS. Further results of a replication study with Japanese for loci detected by a previous gout GWAS with Chinese population will be also discussed at the meeting.

**Conclusion:** Our findings including novel gout risk loci provide further understanding of the molecular pathogenesis of gout and lead to a novel concept for the therapeutic target of gout and hyperuricemia.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is characterized by immune cell infiltration into the synovial membrane of the joint, where they engage stromal cells such as synovial fibroblasts in a persistent proinflammatory feedback loop. Tumor necrosis factor alpha (TNF) and interleukin 17 (IL17) are elevated in RA and activate synovial fibroblasts. Chronically activated fibroblasts proliferate, degrade joint cartilage, and recruit additional immune cells. We found that stimulation of fibroblasts with IL17 alone produced little response compared to TNF, but the combination of IL17 and TNF synergistically increased chemokine and cytokine gene expression. The purpose of this study is to define the transcriptional network controlling the synergistic response to IL17 and TNF.

**Methods:** We assessed transcriptional changes over time and IL17 doses. We did 175 Smart-seq2<sup>TM</sup> RNA-seq experiments on synovial fibroblast cell lines from knee joint tissues obtained from 4 RA and 3 osteoarthritis (OA) donors. For each donor, we did a time series with 8 time points over 24 hours and 3 IL17 doses (0, 1, and 10 ng/mL) in combination with TNF (1 ng/mL). We repeated a subset of these RNA-seq experiments after siRNA silencing of specific transcription factors, this time with fewer time points and independent cell lines.

**Results:** We identified 813 genes at 5% false discovery rate (FDR) and >1.5 fold change between RA and OA, including two homeobox genes HOXC10 and HOXD11. Statistical analysis with linear models revealed 34 genes at 5% FDR and >1.5 fold change that respond to IL17 in a dose dependent manner, 10 of which are also differently expressed between RA and OA. We identified motifs enriched in these 34 genes' promoters representing binding sites for known transcription factors (TFs) such as NFKB p65 (Rel A) and CEBP. We also found a novel transcription factor, CUX1. Two CUX1 target genes, *CXCL2* and *CXCL3*, are highly dose-responsive to IL17 and these targets have CUX1 peaks in their promoters in ENCODE ChIP-seq data. Finally, exon level differential expression analysis revealed IL17 dose-dependent exon inclusion of 38 exons in 21 genes at 5% FDR, including an exon in NFKB inhibitor zeta (*NFKBIZ*) for an ankyrin repeat that likely binds to NFKB. Analysis of siRNA silencing experiments is ongoing.

**Conclusion:** IL17 and TNF costimulation activates a different transcriptional network than TNF or IL17 alone. A specific set of genes responds to dose of IL17, and putative transcription factors controlling these genes include NFKB p65 (Rel A), CEBP, and CUX1.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

As the cost of genome-wide genotyping plummets, and biobanking efforts integrating medical records and genetics are rapidly expanding, many patients will have genotyping available in medical records prior to patient visits. The question emerges: how informative this data is in a rheumatology clinic.

This study tests the potential for genetics to assign prior probabilities for six synovitis phenotypes; ACPA positive rheumatoid arthritis, ACPA negative rheumatoid arthritis, systemic lupus erythematosus, ankylosing spondylitis, psoriatic arthritis and gout.

### Methods:

Risk allele information was obtained from Immunobase and GWAS publications. The genetic probability (GP) for each phenotype was calculated using Bayesian theorem with the summation of the risk alleles times the risk effects of each genetic variant as the likelihood and the sex adjusted disease prevalence as the prior. The GPs were normalized so that the total of the six probabilities for each individual was one. If GPs are accurate we expect that the percent of individuals that have a disease tracks with GP.

#### I Benchmarking performance by simulation

We simulated a population of one million people with random genotypes using minor allele frequencies from the 1000 genome project. We randomly assigned phenotypic status based on the known genetic risk alleles, sex, and disease prevalence. We then scored all individuals with disease for posterior probabilities.

#### II Validation

We selected clinical cases on their ultimate diagnosis from Boston's Partners BIOBANK, using a rule-based algorithm based on clinical notes, lab tests and medication prescriptions.

### Results:

I In the simulation data set we observed that GPs were concordant with the phenotypic status, demonstrating that our model works in a

theoretical dataset.

**II** We identified 297 out of the 15,000 patients in the BIOBANK that had one of the six diseases of interest. We used these individuals and assessed the performance of the GP.

We observed that there was a high positive correlation between the GP and the clinical case risk for the phenotypes ( $r^2 = 0.95$ ). A high GP correctly corresponded with the clinical phenotypes: in all cases where the probability  $> 0.9$ , the patient indeed had that phenotype. More importantly, the GP could discard phenotypes: GPs  $< 0.1$  correctly corresponded with a clinical disease risk of  $< 10\%$ , whereby for all individuals 1-4 phenotypes could be effectively ruled out. We note however that the GP (mean 0.24) somewhat overestimated the clinical risk (mean 0.16).

### Conclusion:

In a cohort of synovitis patients, genetic information can facilitate decision making in early disease by ruling out and pointing towards the most likely phenotype. Seeing the importance of an early diagnosis in patients presenting with synovitis, genetics can be considered as part of a patient's medical history and as such it can inform us about the most likely diagnosis, without having to wait for more symptoms to arise.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Non-invasive biomarkers of lupus nephritis (LN) damage are needed to guide treatment decisions and determine risk for kidney failure. Urinary proteomics has advanced as a tool for novel biomarker discovery in recent years. Specifically, Isobaric Tags for Relative and Absolute Quantification (iTRAQ) is an advanced proteomics technique that quantifies and compares protein expression among samples by mass spectrometry in a single experiment. We aimed to use iTRAQ for discovery of candidate urine biomarkers (CUBMs) for LN

chronicity in a pediatric lupus cohort and then further pursued validation of CUBMs.

**Methods:** For the initial discovery cohort, urine was collected from children with LN (n=21) at the time of kidney biopsy. LN damage was characterized as per the NIH chronicity index (NIH CI, score range: 0-12) and categorized as none (0), low (1), moderate (2), or high ( $\geq 3$ ). iTRAQ experiments compared protein composition in four urine samples from different LN damage categories, respectively. The relative expression of differentially excreted proteins was tested for significant differences using a log-rank test. We then generated heat maps and performed network analysis to identify proteins associated with LN damage, also considering concurrent histological LN activity (NIH activity index scores). Upon identification of CUBMs from the discovery cohort, specific commercial ELISAs were performed on urine samples from children with varying levels of LN chronicity in a separate validation cohort (n=41). Analysis of Variance was performed to detect statistical differences between each of the CUBMs and LN chronicity, with adjustment for clinical LN activity.

**Results:** Overall, iTRAQ detected 112 proteins from the urine sample sets of the discovery cohort, and 51 proteins were quantifiable in all replicate sample runs. Initial log-rank test revealed 4 differentially expressed proteins with p-values  $<0.05$ . Further evaluation by heat map and network analysis led to identification of 7 CUBMs for LN chronicity: Afamin (AFM), Immunoglobulin Heavy Constant Alpha 1 (IGHA1), Alpha-1-Antichymotrypsin (SerpinA3), Transthyretin (TTR), Retinol Binding Protein 4 (RBP4), Alpha-1-Acid Glycoprotein, Type 2 (ORM2) and Transferrin (TF). In the validation cohort, only SerpinA3 was found to be different based on degree of LN chronicity after adjustment for concurrent LN activity. SerpinA3 levels were found to increase with higher degrees of LN chronicity.

**Conclusion:** Using advanced proteomic techniques followed by confirmation using specific ELISAs, we identified SerpinA3 as a potential urine biomarker to help quantify the degree of tissue damage from LN. Elevated levels of SerpinA3, a known inhibitor of neutrophil cathepsin G and angiotensin II production, could serve as both a danger signal and protective mechanism from further kidney damage. Further validation of SerpinA3 as an LN damage biomarker in an independent cohort is needed to determine its ability to guide treatment and predict prognosis.

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In a given patient with rheumatoid arthritis (RA), it is difficult to predict disease progression or identify to which treatments they will respond. Macrophages have been strongly implicated in the pathogenesis of RA and reduction in the number of macrophages in the synovial sublining of the joint is a key biomarker for better outcomes. However, without a deeper knowledge of the genes regulated *in vivo*, such as provided by unbiased high-throughput sequencing, it is difficult to discern the function of these macrophages in RA. Here, we describe our work to profile the genome-wide transcriptome of synovial macrophages in RA patients.

**Methods:** We used tissue obtained from synovial biopsies of the wrist joints in RA patients for histology and cell sorting via FACS. We gated for CD45<sup>+</sup>Lin<sup>-</sup>CD64<sup>+</sup>CD11b<sup>+</sup>CD14<sup>+</sup>HLA-DR<sup>+</sup> macrophages and distinguished 2 populations based on the expression of CD206. As a comparison, we also collected and sorted macrophages from OA patients via surgical discards. We processed all macrophage populations for RNA-seq and sequenced the libraries on an Illumina NextSeq 500 to an average depth of 5 million reads. The reads were aligned and mapped to genes using bowtie and HTseq, respectively, followed by bioinformatic analysis as described below.

**Results:** The quality of the RNA-seq data from RA macrophages was comparable to OA, confirming the feasibility of our approach. Next, we assessed the ability of our macrophage-specific RNA-seq to identify differentially expressed genes between RA and OA by fold-change, as compared with RNA-seq of the unprocessed whole synovial tissue. While the approaches generally agreed, we found many genes that were differentially expressed only in macrophages, supporting the value of cell-specific RNA-seq to uncover gene pathways that would be obscured in whole tissue RNA-seq. Next, we considered the heterogeneity of macrophages across RA patients by calculating the pairwise correlation between samples. We found that there were significant differences between RA transcriptional profiles that were best explained by classification of patients into lymphoid, myeloid, or pauci-immune phenotypes based on the dominant cell type. In order to overcome this difficulty in identifying genes associated with RA pathology, we focused on clustering genes into co-regulated modules based on their expression across samples. This allowed us to identify pathways with significant expression patterns, even if the relevant genes were up-regulated in only a portion of RA samples. For example, we found that a subset of RA patients demonstrated over-expression of certain cytokine-mediated pathways (including IL3, IL5, and IL13), while another subset was enriched for type I interferon signaling. Similarly, we found that Dock2, a gene involved in actin remodeling that was not significant at the whole-tissue level, was preferentially expressed in RA macrophages that also expressed Ccr1.

**Conclusion:** Together, these results help us to understand the role of different macrophage populations in RA heterogeneity. Our goal is to use these studies as the basis for predicting clinical outcomes and choosing between therapeutic options for treatment.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Genome-wide association studies and large-scale sequencing studies identify many non-coding genetic variants that

increase disease risk. At least 60% of these loci have been associated with genotype-dependent expression of nearby genes. It remains to be determined that 50-100% expression differences are biologically relevant in specific immune cell types. We focus on the expression quantitative trait loci (eQTL) at the ETS1 lupus-risk locus. Patients with lupus have 50% less peripheral blood mononuclear cell mRNA expression of ETS1 than people without SLE, and people with the risk haplotype at the ETS1 locus have 50% less mRNA expression than people with the non-risk haplotype. Since ETS1 is a transcription factor, differential ETS1 expression could have easily measurable consequences on transcription factor binding and downstream gene expression. There are nearly 800 genes that are known to be dysregulated in subjects with SLE.

**Methods:** We developed a system combining the Clustered regularly interspaced short palindromic repeats (CRISPR) Homology-directed Repair technique with Tet-inducible Controlled Gene Expression technique to precisely control gene expression. This system allows us to mimic the differential gene expressions caused by genetic variants.

**Results:** Our analyses of these genes using publically available ChIP-seq data sets from B cell line GM12878 and epithelial cell line K562 indicates that 191 and 151 of these genes, respectively, have ETS1 binding sites proximal to the transcription start site (enrichment of 3-4 fold compared to randomly chosen gene sets,  $p < 10^{-46}$ ). We hypothesize that these changes in ETS1 levels are important in 1) ETS1 binding throughout the genome, 2) expression of ETS1 downstream target genes (such as BLIMP1), and 3) immunological dysfunction and hyperactivity of B cells. We test these hypotheses by analyzing the binding of ETS1 (ChIP-seq) and the changes to the transcriptome of cells with 2-fold differences in *ETS1* expression (RNA-seq). Our CRISPR system successfully mimics the differential gene expressions.

**Conclusion:** The investigation of the ETS1 eQTL will allow us to make important progress in the field of human genetics and especially complex genetic disease etiology.

## SEC16A and Antigen Presentation Abnormalities in the Pathogenesis of Axial Spondyloarthritis

Fanxing Zeng<sup>1</sup>, Vidya Ranganathan<sup>2</sup>, Proton Rahman<sup>3</sup>, Darren O'Rielly<sup>4</sup> and Nigil Haroon<sup>5</sup>, <sup>1</sup>University Health Network, Toronto, ON, Canada, <sup>2</sup>University of Toronto, Toronto, ON, Canada, <sup>3</sup>Rheumatology, St Claire's Mercy Hospital, St Johns, NF, Canada, <sup>4</sup>Memorial University, St John's, NF, Canada, <sup>5</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Spondylitis Clinic, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Axial Spondyloarthritis (AxSpA) is a chronic inflammatory rheumatic disease of axial skeleton. Our group recently identified a novel rare mutation of the SEC16A gene that strongly tracked with AxSpA in a multiplex family. Remarkably, all individuals with HLA-B27 and the SEC16A mutation had or went on to develop AxSpA. Sec16a is an important player in the ER-Golgi transport pathway with potential effects on antigen presentation and the pathogenesis of AxSpA. We have previously shown that the SEC16A mutation hinders the assembly of COPII vesicles budding from the ER that leads to abnormal MHC I trafficking and ER stress. In this study we explore the functional impact of Sec16A abnormalities on CD8+ T cell immune response. In addition, protein-protein interaction assays followed by pathway analysis help us understand the impact of SEC16A mutation on different cellular processes.

### Methods:

AxSpA patients from the multiplex family (N=9) had both SEC16A mutation and HLA-B27. Controls (N=5) were family members with no disease and had HLA-B27 and wild-type (WT) SEC16A. B cell lines were generated from patients and controls by EBV transformation. For validation, SEC16A was silenced in B-lymphoblastoid cells with stable HLA-B27 expression (C1R-B27) and assays repeated. Total protein was extracted from B cells and the formation of HLA free heavy chain homodimer (FHC) was studied using HC-10 western blot under non-

reducing and reducing conditions. HLA-B27 mediated immune response was assessed by [cytotoxic T-lymphocyte assay](#). NP383-391 specific CTL clones were generated from HLA-B27 positive donor. The GFP-ubiquitin-NP383-391 construct was introduced by DNA transfection in B cells. Two days after transfection, B cells were incubated with NP383-391 specific CTL at a ratio of 1:10 for 4 hours. CTL activity was evaluated using caspase 3 cleavage in target cells. Pathway analysis assessed by protein-protein interaction was carried out to investigate the interactome of SEC16A variants.

## Results:

Both SEC16A mutation in patients' B cells and Sec16a deficiency (90% suppression) in C1R-B27 significantly ( $P<0.01$  and  $P<0.001$  respectively) increased the level of HLA-B27 FHC homodimers. This is likely due to a general disruption of MHC I trafficking by Sec16A abnormalities as we previously reported. GFP-ubiquitin-NP383-391 constructs were stably expressed in EBV-B cells at a similar level without having an effect on HLA-B27 surface expression. However, the cytotoxicity of NP 383-391 specific T cells were significantly lower against EBV-B cells with mutant SEC16A compared to EBV-B cells with WT SEC16A ( $p<0.01$ ). T cell cytotoxicity was almost completely abolished in SEC16A-suppressed C1R-B27 cells. Using protein-protein interaction and pathway analysis, we found that mutant Sec16a had lower affinity to interactors involved in ER-to-Golgi vesicle mediated transport, membrane budding, vesicle organization, and antigen processing/presentation.

## Conclusion:

Sec16a abnormalities can affect HLA-B27 intracellular transport, dimerization, antigen presentation and cytotoxic T cell responses. These changes can potentially play a role in AS pathogenesis.

## Intronic Variants of the B-Cell Proliferator RASGRP3 Affect Its Expression, and Might Contribute to Lupus Risk

Bhupinder Singh<sup>1</sup>, Philip Borden<sup>2</sup>, Julio Molineros<sup>3</sup>, Celi Sun<sup>3</sup>, Loren Looger<sup>2</sup> and Swapan Nath<sup>1</sup>, <sup>1</sup>Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>2</sup>Howard Hughes Medical Institute, Ashburn, VA, <sup>3</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is an inflammatory autoimmune disease with complex genetic underpinnings. Variants from RASGRP3 (RAS Guanyl Releasing Protein 3) is one of the most consistently replicated SLE susceptibility genes. We recently reported that two intronic variants (rs13385731 and rs12612030) explained RASGRP3-SLE association in Asians [Sun et al. 2016, Nat Genet]. However, the "causal" functional variants and the genetic mechanism(s) by which associated variants contribute to disease are largely unknown. We hypothesized that these intronic variants affect epigenetic regulation and modulate RASGRP3 expression.

**Methods:** First, we used in-silico bioinformatics and epigenetic analyses to define the potential regulatory effects of the candidate variants on gene expression using data on several histone marks, DNase-1 hypersensitivity, and eQTLs across multiple tissues from ENCODE, ROADMAP and GTEx data bases. Luciferase reporter assays in HEK293 cells were used to measure the effects of risk and non-risk variants/haplotypes on gene expression. Next, we used a combination of DNA pulldown, Electrophoretic Mobility Shift Assay (EMSA), Super-shift, Western blot and Mass Spectrometry to identify DNA-bound proteins followed by quantitative chromatin immunoprecipitation-PCR (ChIP-qPCR) to assess the allele-specific binding of interacting proteins. To assess the effect of risk alleles/haplotypes on cis-regulatory elements we also performed ChIP-qPCR with H3K27Ac and P300. Finally, using EBV-transformed cell lines, RASGRP3 mRNA and protein expressions were compared between risk and non-risk alleles/haplotypes.

**Results:** Bioinformatics predicted that these variants are located in active chromatin and have the potential to be dual enhancers/promoters.

We also predicted allele-specific binding to PARP1 and IRF1 at rs13385731. We observed significant ( $p < 0.005$ ) difference in RASGRP3 transcript and protein levels with increased expression in rs13385731 risk genotype (TT). Luciferase assays demonstrated significant ( $p < 0.005$ ) allele-specific enhancer and promoter activities. DNA pulldown and EMSA suggested allele-specific bound protein ~100 kD, which was identified as PARP1 protein by Mass Spectrometry and later confirmed by super shift and Western blot. We also verified differential allele-specific binding of PARP1 and IRF1 against rs13385731 using ChIP-qPCR. Interestingly, while PARP1 binding affinity is higher with risk (TT) genotype, IRF1 binding shows strong binding affinity with non-risk (CC) genotype of rs13385731.

**Conclusion:** Our results showed that rs13385731 is an eQTL, and the risk (TT) genotype is associated with increased RASGRP3 expression. Furthermore, this variant showed significant allele-specific binding to H3K27Ac, P300, PARP1 and IRF1 proteins, which might alter expression of RASGRP3, contributing to SLE risk. The activity of this variant provides insight into the molecular mechanisms underlying its association with SLE.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Our knowledge about the pivotal role DNA methylation plays in the pathogenesis of SLE has significantly increased in the last few years. However, we still have a relatively poor idea about the role of this epigenetic mark in the development of SLE in admixed populations. In addition, we do not yet understand the role of DNA methylation in explaining the higher prevalence and severity of SLE in these populations. To achieve these goals, we have conducted a genome-wide DNA methylation case-control study on individuals with different degrees of Amerindian ancestry.

**Methods:** Whole blood DNA from 60 females SLE patients and 59 female healthy individuals from Mexico were included in the study. The Native American ancestry was estimated using STRUCTURE and a set of ancestry informative markers (AIMs), and data from 1000 Genomes populations and a set of individuals of Nahua population were used as reference panel. In order to minimize the effect of other minor ancestries, all individuals were selected to have less than 10 % of Asian and African ancestries. DNA methylation data were generated using the Infinium MethylationEPIC BeadChip (Illumina). Differential methylation between groups was estimated by beta regression after adjusting for age, technical variables and estimated cell type composition. SLE patients were stratified according to clinical manifestations. Functional annotations were performed using DAVID/Panther.

**Results:** Differential DNA methylation pattern was observed among individuals with different degrees of native Amerindian ancestry. The probe cg03693186 located in *DAPK1* gene had the most significant signal detected ( $p$ -value =  $3.0 \times 10^{-19}$ ). In a case-control association analysis, an overall hypomethylation in lupus was observed, especially in genes involved in the type I interferon response and regulation such as *IFIH1*, *IF44*, *IF44L*, *MX1* and *NLRC5*, consistent with findings in other populations. When comparing DNA methylation changes associated with lupus nephritis, a significant enrichment in the canonical WNT/ $\beta$ -catenin signaling pathway ( $p$ -value adjusted =  $1.1 \times 10^{-7}$ ) was found among hypomethylated genes. Hypermethylated genes in lupus nephritis show a significant enrichment in Angiotensin II-stimulated signaling through G proteins and beta-arrestin ( $p$ -value adjusted = 0.0034).

**Conclusion:** Differential methylation of interferon-regulated genes is associated with SLE in an admixed Amerindian population from Mexico, consistent with the epigenetic interferon signature observed in other ethnicities. The Amerindian association found for *DAPK1* gene, a positive mediator of gamma-interferon induced programmed cell death, might provide clues to explain the higher SLE prevalence and severity observed in these populations. In addition, our results also identify other biological pathways associated with lupus nephritis that might help to clarify the high prevalence and severity of lupus nephritis in admixed populations.

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Psoriatic arthritis (PsA) and Rheumatoid arthritis (RA) are immune-mediated chronic inflammatory diseases. Synovial membrane is the initial site of inflammation in PsA and RA joints. This tissue can be used for diagnostic purposes since pathophysiological events occurring in the synovial are more likely than dispersed serum factors to reflect the clinical status and outcome in patients. Even though both tissues are morphologically similar, we hypothesize that there are differences in the molecular signature of the PsA and RA synovial membranes that can be employed for an accurate diagnosis of both pathologies. The purpose of this study is to create a new method for arthritic patient classification based on the spatially resolved molecular profiles detected by mass spectrometry imaging (MSI).

### Methods:

Synovial membrane slices obtained from 10 PsA and 10 RA patients were analyzed by matrix-assisted laser desorption/ionization fourier-transform ion cyclotron resonance mass spectrometry imaging (MALDI-FT-ICR-MSI) to characterize the specific profile and distribution of metabolites. Images of differentially expressed metabolites were generated with FlexImaging 4.1 software. Principal component analysis (PCA) and discriminant analysis (DA) were used to look for the metabolites with the highest differences between PsA and RA synovial membranes. Annotation of the detected metabolites was performed by matching accurate mass with METLIN and Human Metabolome Databases.

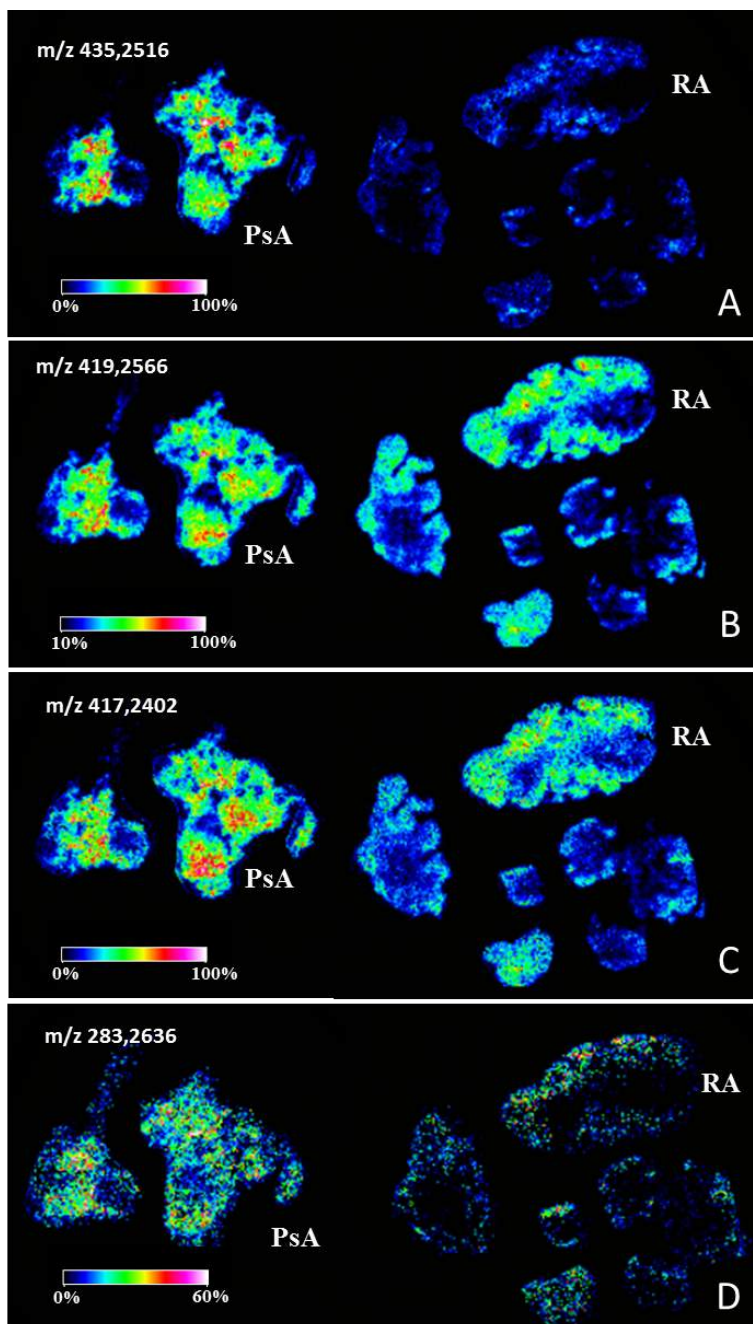

### Results:

PsA and RA synovial membranes were discriminated based on their metabolic signature using discriminant analysis. Sugars including *N*-acetylgalactosamine 6-sulfate (*m/z* 282,026), glucuronic acid 1-phosphate (*m/z* 273,0026), *N*-acetylneuraminic acid (*m/z* 290,0876) and different small lipids were identified and localized. Fatty acids and lysophosphatidic acids (LPAs) showed a higher expression in PsA compared to RA (Figure 1). On the contrary, all sugars displayed a stronger intensity in RA synovial tissues when compared to PsA. *N*-acetylneuraminic acid showed a higher abundance in the synovial sublining layer whereas glucuronic acid 1-phosphate was specifically localized in the lining layer (Figure 2).

### Conclusion:

We have localized and identified for the first time metabolites from human PSA and RA synovial membranes using MALDI-FT-ICR-MSI. Our results provide a fast and reliable classification of patients affected by PsA and RA.

**Figure 1. Spatial distribution of small lipids in synovial tissues after MALDI-FT-ICR-MSI measurements.** MALDI-MSI images of  $m/z$  435,2516,  $m/z$  419,2566,  $m/z$  417,2402 and  $m/z$  283,2636 identified as LPA(18:1) (A), LPA(18:0) (B), a different adduct of LPA(18:1) (C) and stearic acid (D), respectively.

**Figure 2.** Spatial distribution of *N*-acetylneuraminic acid and glucuronic acid 1-phosphate in synovial tissues. A. Hematoxylin and eosin section of PsA and RA synovial tissues. B. MALDI-MSI images of *m/z* 273,0026 corresponding to glucuronic acid 1-phosphate with a strong expression in the lining layer area (blue) in PsA and RA synovial tissue, and *m/z* 290,0876 identified as *N*-acetylneuraminic acid with a higher abundance in the sublining layer (red) in RA but not in PsA.

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The majority of trait-associated SNPs occur in noncoding regions and are enriched in enhancers. GWAS have identified numerous genetic variants associated with Systemic Lupus Erythematosus (SLE), but mechanistic insights remain limited, particularly for noncoding polymorphisms. miR-146a is a negative regulator of the interferon pathway. In SLE patients, the expression of miR-146a is low and contributes to the abnormal activation of interferon pathway. rs2431697 is associated with the miR-146a expression level and located approximately 15.3 kb upstream of miR-146a exon 1, but how this risk variant regulates miR-146a expression and functionally contributes to the underlying pathogenesis is still unclear. Now, the application of CRISPR-Cas9 for genome engineering provides a new approach to study the function of disease susceptibility variants. This study was undertaken to investigate the role of rs2431697-containing region in the regulation of miR-146a expression by CRISPR-Cas9 technology.

**Methods:** To confirm whether rs2431697-containing region is a distal enhancer, we carried out ATAC-seq and formaldehyde-assisted isolation of regulatory elements (FAIRE) to test chromatin accessibility of this region. Chromatin immunoprecipitation (ChIP) followed by qRT-PCR (ChIP-qRT-PCR) was adopted to probe the enrichment of active enhancer markers-H3K4me1 and H3K27ac. SAM system is a dCas9-based transcription activation system comprising of dCas9-VP64 and MS2-p65-HSF1 complex, which can transactivate target genes from distal enhancers. We also take this system to test the function of this region. To detect whether rs2431697-containing region is actually involved in the regulation of miR-146a expression, CRISPR-Cas9 technology was used to generate a 30 bp-deletion of the genomic region containing rs2431697 in U937 cells and miR-146a expression was analyzed by TaqMan microRNA assay. We also generated rs2431697 T allele and rs2431697 C allele containing cell clone in U937 cells by CRISPR-Cas9 induced homology-directed repair, and using bioinformatics to predict the SNP-specific binding transcription factor.

**Results:** ChIP-qRT-PCR analysis showed that rs2431697-containing region was enriched with H3K27ac and H3K4me1 modification. ATAC-Seq and FAIRE-qRT-PCR indicated that the region was open. Additionally, dCas9-vp64-SAM system could activate miR-146a expression based on the guide RNAs around this region. Importantly, the generation of 30 bp-deletions comprising rs2431697 dramatically reduced the miR-146a expression at transcriptional level of up to 10-fold, but had no effect on the expression of the neighbor gene PTTG1. rs2431697 T allele and C allele comprising cell clone had different miR-146a expression level at both native and TNF $\alpha$  stimulation. Bioinformatics analysis suggested that rs2431697 T and C allele may have differential RelA binding.

**Conclusion:** Using CRISPR-Cas9 technology, we first indicate that rs2431697-containing region participates in the regulation of miR-146a expression. We also demonstrate that rs2431697 is located in a distal enhancer and has differential transcription factor binding that modulates miR-146a expression involving in the pathogenesis of SLE.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Dysregulation or dysfunction of some key moleculars in signaling pathway is involved in disease pathogenesis. Long non-coding RNA (lncRNA), as a regulator of gene expression, plays great role in signaling pathway. The majority of susceptible single nucleotide polymorphisms (SNPs) of systemic lupus erythematosus (SLE) identified in GWAS studies are located in noncoding regions of the human genome. We hypothesized that disease-related functional SNP linked to lncRNA may affect expression or function of lncRNA and involve in key signaling pathway of SLE.

## Methods:

Deep sequencing of human renal samples to screen differential expression of lncRNAs between LN patients and healthy donors and mining GWAS data were applied to get candidate lncRNAs. RNA-FISH was used to identify subcellular location of lncRNA. Reporter gene assay was applied to ascertain effect of disease-related SNP on lncMKLN1 transcription. Stimulation in human renal mesangial cells (HRMC) by all kinds of TLR ligands, IFNs, and TNF $\alpha$ , and transfection in HRMC cells by antisense oligonucleotides (ASOs), and quantitative real-time polymerase chain reaction (RT-qPCR) were used to analyze the relative genes expression. lncMKLN1 transcription was activated or inhibited through CRISPR-dCas9 system in Hela cell line. RNA-seq was executed to examine the gene expression profile after changing lncMKLN1 expression, and western blot was applied to determine the key signaling molecules of IFN pathway.

## Results:

lncMKLN1, dominantly located in nucleus, was up-regulated in lupus patients compared to healthy donors, and could be induced by IFN $\alpha$  and TLR ligands in HRMC. GWAS data showed that there were two lupus-related SNPs located within proximal region of lncMKLN1 promoter. Promoter constructs containing susceptible allele have higher activity of transcription compared to another allele. Silencing lncMKLN1 significantly reduced the expression of a group of interferon-inducible genes, including IFIT3, OAS1, CXCL10, etc. We used lose-of-function and gain-of-function strategy through CRISPR system to confirm that lncMKLN1 positively regulated type I interferon pathway. Furthermore, it was identified the involvement of lncMKLN1 in interferon signaling pathway was through regulating the expression of STAT1, IRF9 and phosphorylation of IRF9 and STAT1 although its mechanism is also needed to investigate.

## Conclusion:

Functional susceptible SNP enhances lncMKLN1 expression, resulting in abnormal activation of interferon pathway of SLE.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Fatigue is common in primary Sjögren's syndrome (pSS), but the mechanisms that lead to fatigue are not fully understood. We hypothesized that there is a genetic basis for fatigue, and that specific gene-variants (single nucleotide polymorphisms – SNPs) influence the severity of

fatigue. To investigate this further we performed a genome wide association study (GWAS) of 367 Scandinavian pSS patients.

#### Methods:

PSS patients from 4 sites in Norway and Sweden were collected through the Scandinavian Sjögren's syndrome network. Genotyping was performed at the SNP&SEQ platform, Uppsala University, Sweden using the Illumina Human OmniExpressExome array. All included cases fulfilled the American-European Classification Criteria for pSS. Fatigue was assessed using the fatigue Visual Analogue Scale or the European Sjögren's Syndrome Patient Reported Index. Imputation was performed using SHAPEIT2 and IMPUTE2. After genotype and sample quality control and imputation a total of 365 samples and 4 966 159 SNPs remained for analysis. A linear regression analysis of fatigue scores versus minor alleles was performed.

#### Results:

The pSS patients were 92% females, mean age 57 years with a median fatigue score of 66 (range 0-100). Our analysis revealed five SNPs exceeding the genome wide significance (GWS) threshold of  $p=5E-8$  with a beta coefficient of 12.8. All five SNPs were in linkage disequilibrium and two of the SNPs, rs7626469 and rs73182503, were in the gene Receptor Transporter Protein 4 (*RTP4*), in which the minor allele was associated with less fatigue. RTP4 encodes a Golgi chaperone, involved in the cell surface expression of opioid receptors. In addition, 58 SNPs in 4 genes (Endoplasmic Reticulum to Nucleus Signaling 1 (*ERN1*), Long intergenic non-protein coding RNA 1553 (*LINC01553*), Long intergenic non-protein coding RNA 1184 (*LINC01184*) and (*RP11-15111.2*) reached a suggestive significance level ( $p<1E-5$ ).

#### Conclusion:

We identified genetic variants in *RTP4* exceeding the GWS level for association with fatigue. Notably, this gene encodes a protein involved in pain processing. Pain is known to influence fatigue, and this finding could point to a possible molecular explanation. The present study is the largest GWAS of fatigue in autoimmune disease, and adds further evidence to a genetic regulation of fatigue.

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Risk factors are known for many diseases, but the etiologies of most autoimmune diseases remain unknown and are idiopathic. Pathogenesis of disease likely involves complex interplay between genetic and environmental risk factors. Specifically, Epstein Barr virus (EBV) has suggestive associations with many autoimmune diseases, and EBV infection is nearly ubiquitous in adults. The molecular mechanisms underlying these associations, however, remain unclear.

**Methods:** We tested the hypothesis that some autoimmune variants might act by altering the binding of the EBV-encoded transcription factor Zta, consequently resulting in downstream changes in gene expression. To this end, we comprehensively characterized the DNA binding of Zta to both methylated and unmethylated DNA sequences using protein binding microarrays (PBMs). Based on these data, we identified plausible causal variants for multiple sclerosis (MS), systemic lupus erythematosus (SLE), and juvenile idiopathic arthritis (JIA) predicted to alter Zta binding. From among these, we identified variants located within likely regulatory regions in EBV-infected B cells using publically available functional genomic datasets. We screened these candidate variants using electrophoretic mobility shift assays (EMSAs) to identify general differential binding of nuclear factors, and validated differential Zta binding using EMSA-supershift and DNA Affinity Precipitation Assays coupled with Western blots (DAPA-Westerns).

**Results:** These experiments revealed three genetic variants, associated with MS, SLE, and JIA, respectively, exhibiting stronger Zta binding to the risk allele. We provide data showing that each of these variants is associated with genotype-dependent expression in EBV-transformed B cell lines. Using luciferase reporter assays, we further demonstrate that the MS risk allele in the RGS14 promoter results in greater promoter activity, and that this activity is significantly diminished in cell lines lacking EBV.

**Conclusion:** Collectively, these data demonstrate for the first time that differential binding of a viral protein to a disease-associated genetic variant can result in altered levels of host gene expression in ways that are predicted to influence autoimmune disease. Since Zta is a viral protein, and is expressed throughout human life subsequent to EBV infection, but only in virally infected cells, these results offer a potential therapeutic target for multiple autoimmune diseases.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Genetics, Genomics and Proteomics Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Genome-wide association studies have identified thousands of genetic associations with complex human diseases and traits. However, establishing the truly causal regions of risk haplotypes is complicated by the correlation of many non-causal variants to genetic associations through linkage disequilibrium (LD). This has made translating genetic findings into functional mechanisms an inefficient, resource-intensive task.

**Methods:** Here, we expedite causal variant discovery for autoimmune diseases by identifying genetic variants (epiQTLs) that leave an epigenomic footprint of allelic imbalance in sequencing reads recovered by chromatin immunoprecipitation of enhancer marks (H3K4me1 and H3K27ac ChIP-seq). We aligned sequencing reads using the WASP pipeline to control for reference genome bias. We used the combined haplotype test (CHT) to statistically test for robust footprints of allelic imbalance. We also characterized the three-dimensional chromatin interaction topography among H3K27ac-marked active enhancers of our cell lines by HiChIP.

**Results:** We discovered a total of 6261 epiQTLs across 25 patient-derived EBV-transformed B-cell lines. We overlaid these epiQTLs onto risk haplotypes from 21 autoimmune (AI) diseases and found that 145 reported AI risk haplotypes contained one or more of our epiQTLs. A total of 14 epiQTL SNPs matched AI risk SNPs reported in the NHGRI GWAS catalog, while 180 epiQTLs were proxies of these reported SNPs. We found that epiQTLs located on disease risk haplotypes disproportionately influence gene expression variance, beyond what can be expected by random chance, over non-epiQTL variants in tight linkage disequilibrium. A majority (78%) of epiQTLs were located in chromatin loop anchors. Using a generalized linear model, we identified 571 epiQTLs – not associated with autoimmune disease – that

modify gene expression from 68 previously established AI disease risk haplotypes through chromatin looping at FDR  $\leq 5\%$ . Expanding this analysis to include both risk haplotypes and independent eQTLs increased the number of epiQTLs with significant (FDR  $\leq 5\%$ ) modifier effects on gene expression to 1062. Of these gene expression modifying interactions, 717 (68%) increased eQTL-driven gene expression by the epiQTL, while 345 (32%) suppressed eQTL-driven gene expression.

**Conclusion:** Our data suggest that the epiQTL approach can facilitate the decomposition of risk haplotypes into specific regions that are highly likely to contain functional causal variants. Moreover, epiQTLs not associated with disease haplotypes function to modify gene expression from risk haplotypes and eQTLs through long-range allele-dependent epigenetic mechanisms.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Academic hospital leadership puts a priority on all patients (pts) having access to subspecialists. Often the demand for rheumatology consultation exceeds the ability to see pts promptly. This necessitates a consult triage system to ensure timely appointments for pts with inflammatory rheumatic diseases (IRD). The aim of this study was to evaluate the effectiveness of pre-appointment consult screening to identify pts with potential IRD who need timely access and the revenue implications of caring for these IRD pts compared to non-IRD pts.

**Methods:** During a 9 month period, all pts referred by a healthcare provider to our University rheumatology practice were screened and classified as either possible IRD or non-IRD based on a pre-appointment records request and review by a rheumatologist. Pts with possible IRD were scheduled for an appointment and diagnosis after clinical evaluation was recorded. Using the 2015 Medicare fee schedule, revenue generated through the care of pts accepted for evaluation was recorded for the subsequent 12 months after initial consultation (Table 1). Outpatient services necessary for initial diagnosis and subsequent patient monitoring were analyzed. Costs of medications, surgical procedures, and hospitalizations were not included. Revenues between IRD and non-IRD pts were compared using a Student's t-test. Pts categorized as non-IRD based on pre-appointment screening and denied evaluation received subsequent care through their referring provider and clinical outcome at one year was recorded if available.

**Results:** Of the 961 referrals, 673 pts (70%) were classified after consult review as possible IRD pts and scheduled for evaluation. Of the 597 pts who presented for initial evaluation (average time to first appointment 13 days, range 1-31), 357 pts (60%) were found to have an IRD (139 RA, 83 SLE/SSc/UCTD/ Sjogren's, 44 crystal dz, 38 spondylo, 34 vasculitis/myositis, 19 other) and 240 pts (40%) had a non-IRD. Of the 288 pts who were denied evaluation, 128 had follow-up data for at least one year with only six (0.5%) developing an IRD. The sensitivity of consult screening to identify IRD was 98% with a positive predictive value of 60%. Complete revenue data was available for 510 pts (318 pts with IRD, 192 pts with non-IRD); analysis demonstrated that care of pts with IRD generated 5.6 times more revenue compared to non-IRD pts ( $p < 0.05$ ).

**Conclusion:** Pre-appointment consult screening is an effective method to identify pts with IRD. This allows for timely access to care for pts in highest need of evaluation and for significantly more revenue generation.

Table 1: Total revenue (dollars) generated by patients with IRD versus non-IRD over 12 months

Care modality/Service	IRD (318 pts)	Non-IRD (192 pts)
Followup visits/Provider fees	68,580	1,620
Labs/radiology/rheumatology procedures	108,980	15,495
Specialty consults/PT/OT	38,500	6,300
Total	216,060; 679/pt	23,415; 122/pt

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

We are piloting a children and young people (CYP) community-based triage (called Rightpath) based on a validated adult MSK triage model developed by Pennine MSK Partnership Ltd (PMSKP), Greater Manchester. Rightpath aims to promptly identify CYP with MSK pathology and triage them to the appropriate service (rheumatology, orthopaedics, neurodisability or urgent care), and to manage those who do not need specialist referral appropriately within the community. Triage and referral guidance has been developed in partnership with MSK specialists and this study aims to test its safety, feasibility and acceptability in the community, and through application across two geographical areas in the UK to assess transferability.

### Methods:

Piloted first at PMSKP, with iteration of the triage guidance and process followed by roll out at a second site (South Tyneside NHS Trust). Using mixed methods, evaluation focused on key areas:

*Implementation* – workshops with service providers (triagers and clinicians) held at two time points to refine triage guidance and process.

*Training* – for triagers based on their weekly log of triage experiences and regular case based discussions and feedback.

*Evaluation* – (i) Parent/ patient questionnaire, incorporating the 'Friends and Family' test and 'Collaborate' (a patient reported measure of shared decision-making), completed immediately after consultation to explore expectations and satisfaction; (ii) Service providers weekly log documenting experiences and training needs; (iii) Routine patient data including demographic details, referral information, triage outcome, ultimate diagnosis/outcome and communication between triage teams and health care providers; (iv) Service providers signposted to key areas for self-directed learning (*paediatric musculoskeletal matters* [PMM] – [www.pmmonline.org](http://www.pmmonline.org)) and usage monitored.

This study had ethical approval.

## Results:

Total triaged 05/09/16 - 30/04/17 (101 to Rightpath, 264 to specialist paediatric services). The most common CYP MSK referrals from the community were knee pain, foot pain, flat feet and back pain; the most common conditions triaged to Rightpath were foot pain, knee pain, flat feet, and in-toeing. No significant pathology has been triaged inappropriately so far to Rightpath. Feedback from 66 Rightpath family participants was positive (no complaints or requests for onward specialist referral); 100% would recommend the service, with satisfaction (1-10) scores about community providers being high (1='no' and 9='every' effort made); '*helped understand your/your child's health issues*' (8.9), '*listened to things that matter most to you about your/your child's health*' (8.9), '*included what matters most to you in choosing what to do next*' (8.9). Community therapists and podiatry described the clinical workload to be appropriate for their existing skills. Triage staff deemed the triage process manageable (57% of decisions '*easy/very easy*') and triage guidance to be useful commenting that paediatric experience was important to support decision-making.

## Conclusion:

Initial data shows Rightpath to be feasible, safe and acceptable. Phase 2 of the pilot is in progress at the second site.

## Improved Identification of Pseudogout in Electronic Medical Records By Adding Text String Searching to a Billing Code Algorithm

Sara K. Tedeschi, Kazuki Yoshida and Daniel H. Solomon, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Calcium pyrophosphate deposition disease (CPPD) has a spectrum of manifestations, of which pseudogout is the most acute inflammatory phenotype. To facilitate clinical research on CPPD, an ICD-9 algorithm for "definite or probable CPPD" (per Ryan and McCarty's diagnostic criteria) was developed at a Veterans' Administration (VA) Medical Center.<sup>1</sup> The algorithm includes  $\geq 1$  ICD-9 code 275.49 ("other disorders of calcium metabolism") or 712.1-712.39 ("chondrocalcinosis" due to dicalcium phosphate crystals, pyrophosphate crystals, or cause unspecified). We hypothesized that the algorithm would be suboptimal for identifying pseudogout, and aimed to enhance its ability to identify pseudogout in electronic medical records (EMR).

**Methods:** Following the published methods, we applied the ICD-9 algorithm to patients with  $\geq 1$  encounter at our non-VA academic medical center over 2 years (1/1/15-12/31/16). 100 patients were randomly selected for EMR review from date of 1st qualifying ICD-9 code through 5/1/17. We evaluated whether patients fulfilled each of 3 clinical definitions: "definite or probable CPPD"—which the algorithm was designed to identify—and 2 pseudogout definitions (**Table**). We calculated the positive predictive value (PPV) and 95% confidence intervals (CI) of the ICD-9 algorithm for identifying each phenotype. We then modified the ICD-9 algorithm to include text string searching for "pseudogout" or "calcium pyrophosphate crystals" in narrative notes and re-assessed test performance characteristics.

**Results:** 55% of 100 patients were female; mean age was 68.6 ( $\pm 13.9$ ) years. Joint pain was present in 86% and synovitis in 34%. The published algorithm had 68% (59-77%) PPV for "definite or probable CPPD" in our sample (**Table**), compared to 91% (88-94%) PPV in the VA derivation study. The published algorithm identified only 18% (10-26%) of patients with crystal-proven pseudogout. In our sample of 100 patients, 50 had a positive text string search. Of these, 17 had crystal-proven pseudogout per EMR review, producing a PPV of 34% (25-43%) and NPV of 98% (95-100%). Text string searching was 94% sensitive (89-99%) and 60% specific (50-70%) for crystal-proven pseudogout in the sample.

**Conclusion:** Adding text string searching to a published ICD-9 CPPD algorithm improved PPV for identifying crystal-proven pseudogout from 18% to 34%, with excellent sensitivity and moderate specificity. The accuracy of identifying pseudogout in EMR data might be further improved using more advanced text searching methodology, such as natural language processing.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** High health care utilization and direct costs have been documented in multiple studies of SLE. The recently described lupus low disease activity state (LLDAS) has been associated with reduced flares and damage accrual. We hypothesized that LLDAS attainment would be associated with reduced healthcare cost.

**Methods:** This study utilized data from a single tertiary centre cohort of SLE patients (ACR criteria) between October 2013 and June 2016. Baseline demographics, and per visit disease activity (SLEDAI-2K, physician global and flare index) and medication use were matched to

healthcare utilization and cost data obtained from hospital information systems. LLDAS was defined as described (Franklyn K, et al. *Ann Rheum Dis* 2016;75:1615). Statistical analyses were performed using Stata version 14.

**Results:** 200 SLE patients (88% female, median age 42 years) were followed for 357.8 person-years. A history of lupus nephritis was present in 42%, anti-dsDNA antibodies in 70%, and SLICC damage index (SDI)>0 at study commencement in 57.3%. During the observation period, median (range) time adjusted mean SLEDAI was 4.0 (0–16.9), there were 571 hospitalizations (24.2% multi-day), and 31% of patients had at least one emergency room attendance. The mean (standard deviation) annual direct medical cost per patient was US\$7,413 (US\$13,133)/year. Patients in the highest quartile of annual cost were more likely to accrue new damage during the observation (34 vs 11%,  $p<0.001$ ) and had significantly more physician visits, hospitalizations, and emergency room visits (all  $p<0.001$ ). Mean annual costs were significantly greater in patients with baseline SLEDAI >6 or SDI>0, or who during observation had time-adjusted mean SLEDAI >6, renal disease activity, or used corticosteroids (all  $p<0.01$ ). In multivariable analysis, baseline organ damage, and moderate–high corticosteroid use (>7.5 mg/day) were significantly associated with increased cost (see table). In contrast, meeting LLDAS criteria for >50% of the observed time was associated with a 25% reduction in annual direct medical cost ( $p=0.041$ ).

#### Association of LLDAS with Annual Direct Medical Cost

Parameter	Ratio of Geometric Means	P Value for Association	Multivariable Association with Annual Direct Medical Cost <sup>#</sup>	
			Estimated Increment/Decrement in Annual Direct Cost (%)	Estimated Incremental/Decremental in Annual Direct Cost (US\$)
>50% time spent in LLDAS Treatment	0.74	0.041	-25.6	-895
Annual prednisolone dosage				
Low dosage ( $\leq 7.5$ mg/day)	1.0			
Moderate dosage (>7.5–15 mg/day)	1.56	0.018	56.5	1975
High dosage (>15 mg/day)	3.0	<0.001	203.7	7123
Damage				
Organ damage present at baseline	1.43	0.008	42.7	1493

<sup>#</sup>Adjusted for variables in table and geographic distance from the treating centre.

**Conclusion:** As in previous studies, baseline organ damage, high disease activity, and corticosteroid use were associated with increased cost. Our findings demonstrate that LLDAS attainment is associated with significantly reduced health care cost among patients with SLE.<sup>#</sup>Adjusted for variables in table and geographic distance from the treating centre.

## Challenges and Opportunities of Implementing a Patient-Reported Measure of Physical Function through an Online Electronic Health Record Patient Portal in Routine Rheumatology Practice

**Jing Li<sup>1</sup>**, Jinoos Yazdany<sup>2</sup>, Laura Trupin<sup>2</sup>, Zara Izadi<sup>3</sup>, Milena Gianfrancesco<sup>1</sup>, Sarah Goglin<sup>1</sup> and Gabriela Schmajuk<sup>4</sup>,

<sup>1</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, <sup>3</sup>Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, <sup>4</sup>San Francisco VA Medical Center, University of California San Francisco, San Francisco, CA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Despite significant interest in the collection of patient-reported outcomes (PROs) to make care more patient-centered, few studies have evaluated implementation efforts to collect PROs in real-world practice settings that serve diverse patient populations. In this study, we assessed the collection of PROs from rheumatoid arthritis (RA) patients in an academic rheumatology clinic, using a paper form and subsequently, an online form through the electronic health record (EHR) patient portal.

## **Methods:**

We identified patients seen at the clinic from June 2012-July 2016 with at least 2 face-to-face encounters with a rheumatology provider and ICD codes for RA,  $\geq 30$  days apart. In February 2013, the clinic implemented a paper version of the Patient Reported Outcome Measurement Information System (PROMIS) physical function (PF) form that was administered to patients upon their check-in at the clinic; in January 2015, an online version of the form became available via the EHR patient portal to patients with active portal accounts. We queried our EHR's SQL server to obtain demographic information, paper and online PROMIS scores, and their dates of completion. We compared the proportion of visits with documented PROMIS scores across age, race/ethnicity, and language, using chi-square and ANOVA tests and p-chart.

## **Results:**

We included 1,078 patients with RA with 7,049 in-person encounters at the rheumatology clinic over 4 years, with an average of 168 visits/month. 80% of patients were female; mean age was 55 (SD 16). Overall PROMIS PF score documentation increased from 60% of visits in 2013 to 74% in 2016. Online score documentation increased from 10% in 2015 to 19% in 2016 (Figure 1). Most users of the online form used it only once, reverting to the paper form in subsequent visits. African Americans were less likely to have any PROMIS PF recorded (63% vs. 81% for other racial groups,  $p < 0.001$ ). Compared with Whites, both African American and Hispanics were less likely to have active online EHR portal accounts (50% and 57% respectively, vs. 84% of Whites;  $p < 0.001$ ) and, once activated, less likely to use the online survey (14% and 18% respectively, vs. 31% of Whites;  $p = 0.02$ ). There was no significant difference in the proportion of any PROMIS PF recorded between Non-English vs. English speakers. However, Non-English speakers were less likely to use the online survey, likely because the online survey existed only in English (7% vs. 23% of English speakers;  $p < 0.001$ ). No significant differences were found across age or gender.

## **Conclusion:**

PROMIS PF form completion improved overall over 4 years, but lagged among racial/ethnic minorities and non-English speaking patients. Future studies should address issues of portal access, enrollment, satisfaction and persistence, and focus on developing PRO implementation strategies that accommodate the needs and preferences of diverse populations.

## Opioid Dispensation Among Systemic Lupus Erythematosus (SLE) Patients Who Persistently Frequent the Emergency Department (ED)

**Jiha Lee**<sup>1</sup>, Lisa Gale Suter<sup>2,3</sup> and Liana Fraenkel<sup>3,4</sup>, <sup>1</sup>Rheumatology, Yale University School of Medicine, New Haven, CT, New Haven, CT, <sup>2</sup>Medicine, Rheumatol., TAC S541, Rheumatology, VA Connecticut Healthcare System, West Haven, CT, New Haven, CT, <sup>3</sup>Rheumatology, Rheumatology, Yale University School of Medicine, New Haven, CT, New Haven, CT, <sup>4</sup>Medicine, Section of Rheumatology, Rheumatology, VA Connecticut Healthcare System, West Haven, CT, New Haven, CT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients who persistently frequent the ED are more likely to be prescribed opioids for pain, and opioid initiation in the ED has been found to increase the risk of long-term opioid therapy (LOT). Pain is frequently experienced by SLE patients, and a major cause of ED use. We sought to understand the prevalence of, and factors associated with opioid dispensation among SLE patients who persistently frequent the ED to identify opportunities to improve quality of care.

**Methods:** We identified SLE patients who persistently frequented the ED from 2013-2016 at a large urban academic medical center. Persistent use was defined as having three or more ED visits during the 12 months in a calendar year, for at least two out of the four years, consecutive or non-consecutive, during the study period. We collected patient-level variables including demographics and LOT use. Each encounter was categorized as either SLE-, infection-, pain-related or other. Additional encounter-level variables such as healthcare resource utilization and disposition were recorded. We used mixed effects logistic regression to analyze patient- and encounter-level factors associated with opioid administration in the ED and opioid prescription upon discharge from the ED. Variables with p-value <0.1 in univariate analysis were included in a multivariate model.

**Results:** Seventy-seven SLE patients had 1143 ED encounters. Opioids were administered in the ED for 38.4% of all encounters. In multivariate analysis, Medicaid, LOT use, MD as the ED provider (proxy measure for higher acuity), more imaging tests, and rheumatology evaluation were associated with increased odds of opioid administration in the ED (Table 1). Opioids were prescribed on discharge for 16.8% of encounters discharged from the ED. In multivariate analysis, African American patients, those on Medicaid, and patients utilizing the ED for SLE-related activity/complications were more likely to receive an opioid prescription upon discharge from the ED, than their respective counterparts (Table 2).

**Conclusion:** Opioids are commonly dispensed from the ED for SLE patients, even for those utilizing the ED for lupus-related activity/complications. Further study is warranted to inform how best to decrease opioid use in SLE patients both in the ED and upon discharge.

**Table 1:**  
Multivariate analysis of factors associated with opioid administration in the ED

Variables	OR (95% CI)	p-value

## Is the Nature of Rheumatology Practice Changing? Damage and Distress Contribute a Greater Proportion to Decision-Making Than Inflammation in Contemporary Care

**Theodore Pincus**<sup>1</sup>, Isabel Castrejón<sup>2</sup> and Joel A Block<sup>2</sup>, <sup>1</sup>Rheumatology, Rush University Medical Center, Chicago, IL, <sup>2</sup>Division of Rheumatology, Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inflammation generally is regarded as the primary concern of rheumatologists, and measures of inflammation, such as laboratory tests and pooled indices, usually are the only quantitative data recorded in routine care. Structural damage to joints and other organs, as well as patient distress seen as fibromyalgia, depression, etc., are recognized, but not quantitated routinely in clinical care. In recent years, advances in control of inflammation, along with increases of degenerative diseases in an aging population, and recognition of a high prevalence of fibromyalgia, may have shifted rheumatology patient mix and decision-making more toward damage and distress vs inflammation. We sought to analyze the importance of inflammation, damage, and distress in care of individual rheumatology patients, by quantifying levels on 0-10 visual analog scales (VAS) and estimating their relative contributions to management decisions.

**Methods:** As part of routine care, rheumatologists at one academic site complete a 0-10 physician global assessment (DOCGL) VAS, as well as 3 further 0-10 VAS to assess inflammation (reversible disease) (DOCINF), joint and other organ damage (irreversible disease) (DOCDAM), and patient distress (fibromyalgia, depression), etc. (DOCSTR). The proportion of clinical management decisions attributed to inflammation, damage, and distress (total=100%) also is estimated. Mean values were analyzed in a cross-sectional study of 570 patients, and compared in subgroups of 98 with rheumatoid arthritis (RA), 131 with osteoarthritis (OA) and 89 with fibromyalgia (FM), using t tests and analysis of variance (ANOVA).

**Results:** Mean 0-10 DOCGL scores were 4.4 in all patients, 4.4 in OA, 4.6 in RA, and 5.2 in FM (Table) (p=0.04). Highest mean scores were seen for DOCINF in RA, DOCDAM in OA, and DOCSTR in FM, and differing significantly in each diagnosis (Table), confirming face validity. Importantly, damage VAS scores (DOCDAM) were higher than inflammation (DOCINF) scores in all groups, including in RA, and mean estimates of the proportion of clinical management decisions attributed primarily to damage were greater than to inflammation in all conditions (Table). Scores for DOCSTR were higher than for DOCINF in all patients and subgroups, other than in RA.

Mean VAS Scores and % of clinical management decision attributed to inflammation, damage, and distress in patients with rheumatic diseases

	ALL	RA	OA	FM	P*
N	570	98	131	89	
Mean VAS Scores					
VAS DOCGL	4.4 (1.6)	4.6 (1.8)	4.4 (1.5)	5.2 (1.6)	0.04
VAS DOCINF	1.8 (2.0)	2.8 (2.4)	0.7 (1.1)	0.8 (1.3)	<0.001
VAS DOCDAM	3.1 (2.2)	3.8 (2.3)	4.4 (1.8)	1.7 (1.9)	<0.001
VAS DOCSTR	2.1 (2.9)	1.2 (2.2)	1.5 (2.5)	6.0 (2.5)	<0.001
P (DOCINF vs DOCDAM)	0.001	0.01	<0.001	<0.001	
P (DOCINF vs DOCSTR)	0.11	<0.001†	<0.001	<0.001	
Mean % of clinical management decision attributed to...					
%inflammation	29 (31)	39 (29)	12 (19)	6 (11)	<0.001
%damage	48 (35)	52 (30)	73 (31)	18 (23)	<0.001
%distress	22 (34)	9 (20)	15 (27)	76 (27)	<0.001

\*ANOVA - RA vs OA vs FM

† -only comparison in which DOCINF higher than DOCSTR

**Conclusion:** Physician VAS scores and attributions to clinical decisions in individual patients were higher for damage than for inflammation in all groups seen in a rheumatology setting, even in RA patients as a group. Control of inflammation remains the primary concern for rheumatologists, but has improved considerably in recent years, as damage and distress may have become more prominent in routine patient care, and systematic quantitation appears of value.

## **Patient Education Materials in Rheumatology: Only Adequate at Best**

**Aleksander Lenert**<sup>1</sup> and **Sujin Kim**<sup>2</sup>, <sup>1</sup>Internal Medicine, Div. of Rheumatology, University of Kentucky, Lexington, KY, <sup>2</sup>Division of Biomedical Informatics, College of Medicine, University of Kentucky, Lexington, KY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low health literacy and reading ability of rheumatologic patients is associated with poor outcomes [1]. In practice, patient education is commonly delivered via patient education materials (PEMs). However, readability of PEMs has been reported to be high and PEMs remain poorly understood [2]. We sought to determine the suitability of PEMs used in rheumatology practice.

**Methods:** Sixteen PEMs from 2 resources (ACR 2015 & UpToDate Basics 5-2017) were analyzed. PEMs on 4 diseases (OA, RA, SLE, vasculitis) and 4 treatments (abatacept, hydroxychloroquine, NSAIDs, rituximab) were scored for clinical complexity by 16 clinical rheumatologists. Suitability assessment of materials (SAM), a validated method to assess health-related educational resources, was used to score PEMs by 3 reviewers [3]. SAM scores were categorized and mean scores reported. Readability was measured by validated methods. PEMs were additionally assessed with 2 novel tools: information entropy and medical subject heading (MeSH) complexity. These methods provide further insight into information quantity and content complexity of PEMs. We compared means for ACR and UpToDate PEMs by Student t-test (1-sided alpha=0.05).

**Results:** Sixteen PEMs were rated by SAM: 3 were superior (with 2/3 on OA) and 13 were adequate (Figure 1). The mean SAM score for disease-PEM was highest for OA and lowest for vasculitis, and for therapy-PEM was highest for NSAIDs and lowest for abatacept. Mean SAM, information entropy and MeSH complexity scores did not significantly differ between ACR and UpToDate ( $p>0.05$ ) (Table 1). Readability was at 6<sup>th</sup> grade for only 4 PEMs (all UpToDate) while it was >8<sup>th</sup> grade level for 12 PEMs; 4 ACR PEMs had readability >12<sup>th</sup> grade. Mean readability grade was significantly higher for ACR compared to UpToDate ( $p=0.002$ ).

**Conclusion:** The suitability of PEMs in rheumatology is adequate at best for less complex topics but remains low for clinically complex topics. The majority of PEMs exceed the recommended 6<sup>th</sup>-grade reading level, especially PEMs by ACR. Development of personalized PEMs in rheumatology is needed to improve patient health literacy and impact outcomes.

## Evaluation of a Diversionary Back Pain Service

Lynden Roberts, Rheumatology, Monash Medical Centre, Clayton, Australia

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Surgical treatment of spinal pain is rarely indicated. Nevertheless, primary care clinician referrals to spinal surgeons for evaluation of spinal pain conditions are common. In the publicly funded hospital system in Australia, more than 90% of those referred to spinal surgeons with back pain do not receive surgery. It may be more appropriate for many people with spinal pain to be diagnosed and managed under a different model of health care.

**Methods:** A weekly spinal pain clinic was established at a publicly funded hospital. The clinic was staffed by a rheumatologist and 4 physiotherapists. All spinal pain referrals to the hospital's spinal surgeons were diverted to the new clinic, with the exception of referrals assessed as likely spinal cord compression or cauda equina syndrome. Patients with previously diagnosed chronic spinal pain were not seen in the new clinic. Clinical and administrative data was prospectively and routinely collected including clinical diagnosis, Short Form of the Örebro Musculoskeletal Pain Screening Questionnaire, and clinical outcomes including whether spinal surgery was done. An 11-point Likert scale (0-10) was used to collect the patient satisfaction with the clinic following the encounter.

**Results:** A total of 575 face-to-face patient encounters occurred in the first 12 months of the service including 363 new patients. Low back

pain with radiculopathy was the commonest diagnosis. Average Örebro score was 67%. The failure-to-attend rate was 7%. Nearly half of the patients were discharged to community physiotherapy management, 2% to a chronic pain service, and 9% to a spinal surgeon. For patients referred to a spinal surgeon, 80% underwent spinal surgery. Average patient satisfaction was 9.2.

**Conclusion:** A novel model of care involving the substitution of spinal surgeons with a rheumatologist and physiotherapists for the assessment of patients with spinal pain was established. The patients assessed had a high estimated risk for future work disability. Efficient clinical care and a high patient satisfaction was demonstrated.

## **Kinesiophobia Moderates the Association between Anxiety and Disability in Chronic Low Back Pain**

Jenna Goesling<sup>1</sup>, Stephanie Moser<sup>2</sup>, Jennifer Pierce<sup>1</sup> and Christian Bolton<sup>3</sup>, <sup>1</sup>Department of Anesthesiology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Anesthesiology, University of Michigan, Ann Arbor, MI, <sup>3</sup>University of Michigan, Ann Arbor, MI

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

- Low back pain is a debilitating and costly condition with complex biological, psychological, and social factors contributing to the development of chronic low back pain (CLBP).
- Kinesiophobia is defined as an “excessive, irrational, and debilitating fear of physical movement and activity resulting from a feeling of vulnerability to painful injury or re-injury” (1).
- According to cognitive behavioral models of fear and avoidance, maladaptive thoughts may lead to avoiding activity, which in turn may lead to illness behavior and increased disability.
- Previous research suggests that depression, anxiety and kinesiophobia contribute to pain perception and physical function.
- Yet, little is known about how kinesiophobia and anxiety and depression may interact to predict disability.
- The objective of the present study was to explore the moderating effect of kinesiophobia on the relationship between depression and anxiety and disability in a sample of adults with chronic low back pain (CLBP).

### **Methods:**

- The study included 283 new patients seeking treatment for chronic pain.
- New patients completed the Oswestry Disability Index, the Hospital Anxiety and Depression Scale, and the Tampa Scale of Kinesiophobia (TSK). High kinesiophobia was defined as a score greater than 37 on the TSK.

### **Results:**

- High kinesiophobia was reported in 64% (N=181) of participants.
- Kinesiophobia, depression and anxiety were associated with greater disability.
- The moderated effect of depression was nonsignificant.
- Kinesiophobia modified the association between anxiety and disability (Table 1). Namely, anxiety contributed to greater disability at high levels, but not low levels, of kinesiophobia (Figure 1).

## Conclusion:

- Kinesiophobia, anxiety, and depression were associated with greater disability. However, kinesiophobia moderated the relationship between anxiety and disability, such that having anxiety and high kinesiophobia was associated with a worse outcome.
- Kinesiophobia and anxiety are both modifiable psychological factors that can be addressed using cognitive restructuring and exposure based behavioral interventions.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** SLE is a chronic, debilitating, multisystem autoimmune disorder of connective tissue. In developing new treatment options, the economic burden of SLE should be quantified as a function of disease severity.

**Methods:** Anonymized data from the Betriebskrankenkassen (BKK) German Sickness Fund Database were used to perform analyses of real-world claims of patients (pts) with SLE. Health care utilization and resource use and costs were assessed annually for 2009–2014 for confirmed pts with SLE identified in 2009 (using repeated claims with SLE diagnosis, co-diagnosis codes, laboratory tests, or prescription treatment and specialty of diagnosing physician) and compared with those of matched controls. Pts were  $\geq 18$  years of age and had data available for 2009 and  $\geq 3$  years prior to index quarter in 2009. SLE cases were matched to controls by age, sex, and baseline Charlson Comorbidity Index (CCI). Continuous outcomes were compared with a nonparametric test (e.g., Wilcoxon–Mann–Whitney), because most outcome distributions were positively skewed.

**Results:** Of the 3,290,701 persons with evidence of 3 years of insurance prior to 2009, 1,228 were identified as SLE cases in 2009, representing a prevalence of 37.32 per 100,000 and an incidence of 5.96/100,000 per year. The prevalence increased during the next 5 years to 47.36 per 100,000 in 2014. The final sample included 1,160 confirmed pts with SLE who were  $\geq 18$  years of age and had data for 2009. Pts with SLE were 84% female, and had a mean age of 52 years and a baseline CCI range of 1–13. 85% who qualified for the cohort in 2009 had already been diagnosed with SLE before 2009. A combined approach of International Classification of Diseases-10 GM and medication/procedures codes classified SLE disease severity as mild for 148, moderate for 484, and severe for 528 pts. Pts with SLE had significantly greater mean annual total medical costs in 2009 than did matched controls (€6,895 vs. €3,692,  $p < 0.0001$ ), and in all subsequent years evaluated. Moreover, pts with moderate and severe SLE had significantly greater mean annual total medical costs in 2009 than did matched controls (moderate SLE: €4,867 vs. €3,380,  $p < 0.0001$ ; severe SLE: €10,001 vs. €4,239,  $p < 0.0001$ ), and in all subsequent years. Mean costs and numbers of outpatient visits, hospital stays, outpatient prescriptions and other benefits, and total number of hospital days, were significantly greater for the full SLE population and the moderate and severe SLE subpopulations than for matched controls. For example, mean costs for hospital stays, outpatient prescriptions, and other benefits in 2009 were €4335 vs. €1414, €2582 vs. €1087, and €1068 vs. €691, respectively, for pts with mild, moderate and severe SLE vs. controls.

**Conclusion:** In this analysis, the economic burden of moderate and severe SLE was greater than that of socio-demographically and morbidity-adjusted controls. Pts with SLE were greater users of the health care system and incurred greater total annual medical costs than did matched controls. Health care utilization by pts with SLE increased with disease severity, with the greatest burden for those with severe SLE. New treatments could reduce health care resource use and help alleviate economic burden.

## Patient Assistance Program Outcomes in a Community Clinic Setting

**Stephanie Cerritos**<sup>1</sup>, Yanira Ruiz-Perdomo<sup>1</sup>, Natalie Tobar<sup>1</sup>, Ann Biehl<sup>2</sup> and James D. Katz<sup>3</sup>, <sup>1</sup>National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, <sup>2</sup>Department of Pharmacy, National Institutes of Health Clinical Center, Bethesda, MD, <sup>3</sup>National Institute of Arthritis, Musculoskeletal and Skin Disease (NIAMS), Bethesda, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Uninsured rheumatic disease patients are at risk for inadequate treatment due to issues with access to care, such as medication costs that average at least \$1659/patient/10 weeks (Costs for medications obtained using government prime vendor pricing). Pharmaceutical companies created patient assistance programs (PAPs) as one way to address these barriers. However, the process of getting assistance is resource-intensive because eligibility requirements are not standardized across these foundations. This study aims to understand one aspect of direct care costs in a community health clinic population.

### Methods:

A clinical team was created to aid patients needing assistance for high-cost biologics. Patients were followed for about a year. We determined the rates of successful PAP approvals and stratified our analysis based on a diagnosis of Rheumatoid Arthritis (RA) or Other Autoimmune diseases (OTHER). We also catalogued reasons why some patients were unable to renew enrollment.

### Results:

Data collected from 6/2016-5/2017 revealed a 94% PAP success rate for our patients with identified need (Table 1). RA patients had a 93% success rate. Success rates were higher in OTHER patients. PAP denial was often due to inadequate income documentation. Delay was often due to eligibility for Medicaid/Medicare.

Table 1. Biological Therapy Access Rates

Category	Patients in need (#)	Successful Procurement Rate (#)	
All Patients	75	71	94.6%
RA	59	55	93.2%
Other Autoimmune	16	16	100%

Furthermore, analysis of patients enrolled in PAP from 6/2016-5/2017 revealed a 68% renewal success rate. Reasons for lack of renewal were: newly acquired health insurance, personal choice, insufficient income documentation, and enrollment in Medicare. Overall savings for our patient population, was estimated to be \$1.2 million per year. Our teams invest in counseling time with the patient, phone time with sponsoring foundations, computer resources for implementing a program renewal database, and pharmacy handling of infusion medications.

### Conclusion:

This study addresses the impact of a dedicated effort, within a community clinic setting, to expedite access to medications through a streamlined PAP. Outpatient drug costs for rheumatic diseases are important to target when containing overall direct health care costs. Our observations take this further to show a dedicated health care team can assist limited resource patients with accessing high cost biologics. Benefits from our program extend beyond immediate financial relief—there is educational value for rheumatology trainees and protected free time for clinical pharmacists which can be used for teaching, clinical oversight, and academic scholarship.

In conclusion, investing resources to support individuals with limited resources in securing of assistance is a successful endeavor. Further research is necessary to capture the downstream benefits of this effort.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Inflammatory arthritis (IA) commonly affects ability to work, yet few arthritis services exist addressing employment. We report on the process evaluation of the Making it Work program, an online self-management program to help people with IA deal with employment issues, performed in the context of a RCT testing its effectiveness at preventing work disability and improving at-work productivity.

**Methods:** Participants, recruited from rheumatology practices, a consumer organization (Arthritis Consumer Experts) and advertisements, were eligible if they had IA, were currently employed, aged 18-59, concerned about their ability to work. The program consists of five e-learning modules; five on-line group meetings using video conferencing led by a vocational rehabilitation counsellor (VRC); individual consults with an occupational therapist (OT) for an ergonomic work assessment and with a VRC.

### Results:

All program participants by 06/17 were included (N=236) [80% female, mean(SD) age: 45(10) years, RA:52%, AS:19%, PsA:15%, SLE:14%]. All participants Jan-Dec 2016 completed a feedback survey post program (n=69). Group meetings were successfully conducted online. Overall, participation was good. Median(25;75Q) no. group meetings attended: 4(3;5), with highest attendance in the first (86%) and lowest in the fourth (63%) meetings. Reasons for not attending included work obligations, health issues, family commitments, or other time constraints. 91% and 88% met with the OT and VRC. Completion of e-learning modules [Median(25;75Q) % of total slides viewed] ranged from 73(0-100)% for module 4, to 100(30;100)% for modules 1 & 2. Not all content is relevant to all, depending on disease and job characteristics.

Overall, participants were highly satisfied with the program. 94% would recommend it to others. Median [25Q;75Q] usefulness ratings (0-10, 0=not at all, 10=very useful) were: 8 [7;10] for online modules; 9[7.5;10] for group meetings; 8 [7;10] each for ergonomic & VRC assessments. Median time to complete each module was 60 min. Satisfaction with online group meetings was high: 93% were satisfied with facilitation; 87% with group dynamic; 84% were comfortable with the online format. Median [25Q;75Q] ratings (1-10) for ability to follow group discussion: 10 [9;10]; getting to know other participants: 7 [7;10]; feeling listened to and understood: 9 [8;10]; feeling that group was supportive: 9 [7;10].

### Conclusion:

Overall, online delivery of the Making it Work program was feasible and participants were highly satisfied. Our study demonstrates that self-management programs can be successfully delivered using an online format, which facilitates wider dissemination, greater convenience to patients, and lower costs.

## The Impact of Electronic Consults (E-Consults) on Positive ANA Referrals in a Veteran Population

**Veena Patel**<sup>1,2</sup>, Diana Stewart<sup>2,3</sup> and Molly Horstman<sup>1,2,4</sup>, <sup>1</sup>Internal Medicine, Baylor College of Medicine, Houston, TX, <sup>2</sup>Internal Medicine, Michael E. DeBakey VA Medical Center, Houston, TX, <sup>3</sup>Internal Medicine and Pediatrics, Baylor College of Medicine, Houston, TX, <sup>4</sup>Center for Innovations in Quality, Effectiveness and Safety (iQUEST), Houston, TX

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

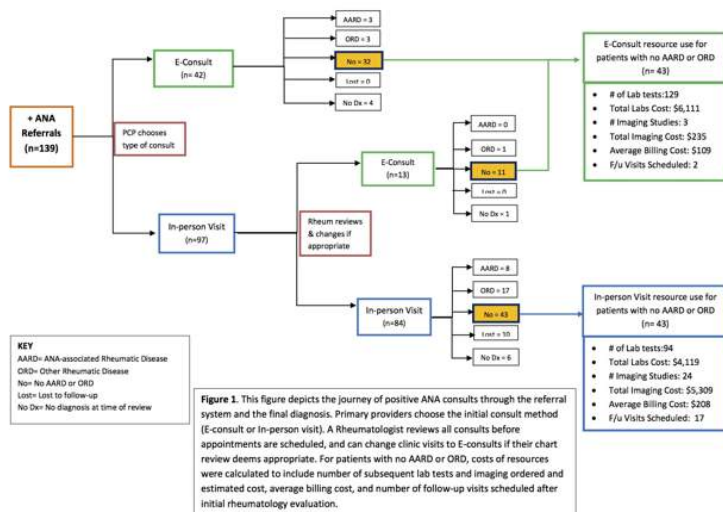

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Referrals to rheumatology for positive ANA in the absence of clinical signs and symptoms is a common practice, which may lead to unnecessary resource use and contribute to delays in patients seeing a rheumatologist. The electronic consult (E-consult) was developed for specialists to review a patient's medical record and make recommendations without an in-person visit in an effort to improve access to timely care. The aims of this project are to assess how E-consults for positive ANA are being used in clinical practice, examine their impact on resource use, and evaluate if the introduction of E-consults improved wait times for in-person rheumatology visits.

**Methods:** Charts were reviewed for Veterans referred to the Houston VA outpatient rheumatology clinic from 1/2015-3/2017 with "positive ANA" as the reason for consult. Demographic data, referral information, relevant rheumatologic labs and imaging were recorded. Veterans' final diagnoses were organized into the following categories: AARD (ANA-associated rheumatic disease), ORD (other rheumatic disease), no AARD or ORD, lost to follow-up or no definitive diagnosis at time of review. Lab costs for Veterans with no AARD or ORD were calculated using the cost to the Houston VA. The costs of consults were estimated using the 2017 Medicare National Fee Schedule. Imaging costs were estimated from the Healthcare Bluebook. An XmR control chart was created using average wait times for in-person clinic visits per month.

**Results:** A total of 139 Veterans had positive ANA outpatient consults. Figure 1 shows the number of patients with positive ANA consults and their final diagnosis category. 55/139 (40%) of Veterans received E-consults. 73% of patients with consults (86/139) did not have an AARD or ORD (n=43 E-consults, n=43 in-person visits). Of these, E-consults spent \$1,992 more on lab tests, while clinic visits spent \$5,074 more on imaging studies. Clinic visits were more likely to schedule follow-up visits and on average billed \$99 more per visit. Figure 2 is a control chart showing special cause variation with >7 points below the line of central tendency (circled graph points), indicating that E-consults have made an impact on decreasing in-person visit wait times.

**Conclusion:** E-consults are an effective way to address positive ANA consults, which has helped decrease wait times for in-person rheumatology visits. E-consults did spend more on lab tests, but had less follow-up appointments and imaging use. Future studies should address patient satisfaction and PCP satisfaction with the E-consult process.

Figure 2. Circled points show special cause variation of > 7 points below line of central tendency.

## Incremental Direct Medical Costs of Systemic Lupus Erythematosus Patients in the Years Preceding Diagnosis and the Impact of Sex: A General Population-Based Study

Natalie McCormick<sup>1,2</sup>, Carlo Marra<sup>3</sup> and J. Antonio Avina-Zubieta<sup>4</sup>, <sup>1</sup>Arthritis Research Canada, Richmond, BC, Canada, <sup>2</sup>Pharmaceutical Sciences, The University of British Columbia, Vancouver, BC, Canada, <sup>3</sup>School of Pharmacy, University of Otago, Dunedin, New Zealand, <sup>4</sup>Division of Rheumatology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Little is known about the healthcare costs of systemic lupus erythematosus (SLE) patients in the years leading up to SLE diagnosis. We estimated the incremental (extra) direct medical costs of a general population-based cohort of incident SLE for five years before diagnosis, and examined the impact of sex on these costs.

### Methods:

**Data Source:** Our administrative data captured all provincially-funded outpatient encounters and hospitalisations (1990-2013), and all dispensed medications, for ALL residents of the province of British Columbia, Canada.

**Sample:** We assembled a population-based cohort of incident SLE: those with a new diagnosis of SLE from at least one hospitalisation or rheumatologist visit, or two non-rheumatologist visits, between Jan 2001 and Dec 2010, and no prior SLE diagnosis between Jan 1990 and Dec 2000. For each SLE case, we matched up to 5 non-SLE from the general population on age ( $\pm 2$  years), sex and calendar year of diagnosis. All persons had  $\geq 5$  years' follow-up in the databases before index date (first SLE-coded encounter; random date for non-SLE).

**Cost Calculation:** Outpatient and prescription costs were summed directly from billing data. Case-mix methodology was used for hospitalisations.

### Analysis:

We estimated the unadjusted incremental costs of SLE (difference in per-person costs between SLE and non-SLE) for the five pre-diagnosis/pre-index years (Y-5 to Y-1) and index year (Y0).

Generalised linear models were used to further adjust for socioeconomic status (SES), urban/rural and comorbidities between SLE and non-SLE, and evaluate the impact of sex on costs.

### **Results:**

We included 3,632 incident SLE (86% female, mean age 49.6 years) and 18,152 non-SLE. Index-year (Y0) costs for SLE averaged \$12,019 per-person (2013 CDN): 59% from hospitalisations, 24% outpatient, and 18% medications. Costs increased by 35% per year, on average, with the biggest increases in the two years before diagnosis (see Table). Adjusted cost ratios between SLE and non-SLE rose from 1.7 in Year -3 (Y-3) to 1.9 (Y-2), 2.4 (Y-1), and 4.0 in Y0.

Among non-SLE, adjusted costs were higher for females than males, but among SLE, males had higher costs, controlling for age, SES and previous year's comorbidity score. SLE males had higher odds of hospitalisation than SLE females in Y-1 (OR=1.44, 95% CI=1.18-1.76), while non-SLE males had 15% lower odds. In Years -2 & -1, encounters with primary diagnosis of diabetes, or renal or cardiovascular disease accounted for 11% of costs for SLE males, vs. 5% for SLE females.

Adjusted M/F cost ratios in SLE were 1.15 (95% CI 1.03-1.29) in Y-2, 1.22 (1.11-1.35) in Y-1, and 1.44 (1.29-1.61) in Y0. When comparing costs of SLE and non-SLE, the Male\*SLE interaction term was significant in all years.

### **Conclusion:**

The incremental costs of SLE are considerable, even in the years prior to diagnosis. Unlike the general population, SLE males had higher costs than females, potentially from early comorbidities.

Table: Unadjusted Annual Mean Per-Person Costs for SLE and matched non-SLE, before and after SLE Diagnosis/Index Date (95% Confidence Interval)

	N	Mean (SD) Age	Mean (SD) Baseline Charlson-Romano Comorbidity Score	Year Before SLE Diagnosis					
				Year -5	Year -4	Year -3	Year -2	Year -1	Year 0 (index year)
All SLE	3,632	49.6 (15.9)	0.42 (0.49)	\$3,073 (\$2,872 - \$3,273)	\$3,416 (\$3,190- \$3,641)	\$3,682 (\$3,414- \$3,951)	\$4,409 (\$4,100- \$4,719)	\$6,111 (\$5,741- \$6,481)	\$12,019 (\$11,150- \$12,888)
All Non-SLE	18,152	49.8 (15.4)	0.14 (0.35)	\$1,709 (\$1,645- \$1,772)	\$1,872 (\$1,812- \$1,932)	\$1,932 (\$1,868- \$1,995)	\$2,113 (\$2,033- \$2,193)	\$2,274 (\$2,167- \$2,381)	\$2,447 (\$2,345- \$2,549)
<i>Cost difference</i>	-	-	-	\$1,364	\$1,544	\$1,750	\$2,296	\$3,837	\$9,572
SLE Females	3,111	49.1 (15.6)	0.40 (0.49)	\$3,042 (\$2,826- \$3,257)	\$3,310 (\$3,098- \$3,521)	\$3,555 (\$3,283- \$3,828)	\$4,257 (\$3,949- \$4,565)	\$5,869 (\$5,484- \$6,254)	\$10,945 (\$10,153- \$11,736)
Non-SLE Females	15,547	49.2 (15.1)	0.13 (0.34)	\$1,746 (\$1,677- \$1,815)	\$1,875 (\$1,812- \$1,939)	\$1,944 (\$1,880- \$2,009)	\$2,110 (\$2,024- \$2,196)	\$2,268 (\$2,148- \$2,388)	\$2,436 (\$2,326- \$2,546)
<i>Cost difference</i>	-	-	-	\$1,296	\$1,434	\$1,611	\$2,147	\$3,601	\$8,508
SLE Males	521	52.9 (17.1)	0.50 (0.50)	\$3,258 (\$2,710- \$3,806)	\$4,047 (\$3,109- \$4,986)	\$4,440 (\$3,513- \$5,367)	\$5,321 (\$4,193- \$6,449)	\$7,557 (\$6,393- \$8,720)	\$18,433 (\$14,682- \$22,185)
Non-SLE Males	2,605	53.0 (17.0)	0.17 (0.37)	\$1,485 (\$1,328- \$1,641)	\$1,852 (\$1,666- \$2,039)	\$1,857 (\$1,643- \$2,071)	\$2,133 (\$1,925- \$2,341)	\$2,312 (\$2,101- \$2,523)	\$2,512 (\$2,239- \$2,785)
<i>Cost difference</i>	-	-	-	\$1,773	\$2,195	\$2,583	\$3,188	\$5,245	\$15,921

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Urate-lowering therapy (ULT) is the mainstay of gout treatment. In our clinics, time to achieve target serum urate (SU) level during ULT titration was 37 weeks, during which 15% of patients developed gout attacks requiring hospitalization and the time from last outpatient visit to incident hospitalization was 16 weeks. The suboptimal management may be due to infrequent follow-up during ULT. We implemented and evaluated the efficacy and safety of a novel nurse-led telemedicine intervention for dose escalation (DE) of ULT for gout patients in a real-life clinical practice.

### **Methods:**

Consecutive gout patients fulfilling indications for ULT whose  $SU \geq 360 \mu\text{mol/L}$  were approached. Patients with estimated GFR  $< 30 \text{ mL/min}$ , cognitive impairment and immobility were excluded. A bundle of care was designed to support telemedicine as the main intervention led by a nurse. The bundle components included: nurse education; a safety program (SP) with 6 fortnightly phone calls for adverse drug reactions (ADRs); hotline service and virtual monitoring clinic (VMC) appointments. The VMC consisted of 6-weekly laboratory investigations at government clinics or hospital, protocolized DE of ULT and courier services for ULT. Patient satisfaction and adherence were assessed using a questionnaire survey of patient experience and Medication Adherence Report Scale (MARS-5), respectively. The primary outcome was the time to achieve target  $SU < 360 \mu\text{mol/L}$ , variables that trended towards a significant association ( $p < 0.1$ ) were examined in a multivariable Cox regression model.

### **Results:**

We recruited 100 gout patients from July 2016 to March 2017 with a median age of 52.5 years and 90% men; 53.0% were on pre-existing ULT. The median time to target SU was 19.0 weeks (IQR 17.5-20.5), with no hospitalizations for gout attacks. One patient had an ADR, 3 SP phone calls were made to the patient and allopurinol was stopped immediately after the rash developed. The average Likert summed scores were high and similar to the overall patient satisfaction. Cox regression model revealed that high levels of education (university versus primary), absence of gout attacks, lower baseline SU and number of VMC appointments in 6 months were associated with attainment of target SU.

### **Conclusion:**

Our study is the first to describe the utility of telemedicine in gout care. A nurse-led telemedicine intervention is effective, safe and well-accepted for the management of patients with gout. Telemedicine has the potential to improve access to care for gout patients, thereby decreasing burden of disability and overall healthcare utilization.

**Table 1. Results of a bundled telemedicine intervention for the management of gout.** Data are median (95% CI or IQR).

Time to achieve target SU (weeks)	
All gout patients	19.0 (17.5-20.5)
Gout patients naïve to ULT	20.0 (16.4-23.6)
Gout patients on ULT	14.0 (8.0-20.0)
Duration of follow-up (weeks)	14.0 (8.0-23.0)
No. of VMC appointments	2.0 (1.0-3.0)
No. of ULT dose escalations	2.0 (1.0-3.0)
Gout patients achieving target SU	64 (64.0)
No. of VMC appointments to achieve target SU in 6 months	
All gout patients	3.8 (2.7-4.8)
Gout patients naïve to ULT	3.8 (2.5-4.4)
Gout patients on ULT	4.0 (2.8-4.8)
No. of ULT DEs to achieve target SU in 6 months	
All gout patients	3.7 (2.1-4.4)
Gout patients naïve to ULT	3.9 (2.8-4.4)
Gout patients on ULT	3.1 (1.9-2.3)
Gout attacks	35 (35.0)
No. of gout attacks	
0	65 (65.0)
1	26 (26.0)
2	6 (2.0)
3	2 (2.0)
4	1 (1.0)
Hospitalizations for gout attacks	0 (0.0)
No. of SP phone calls	6 (4.0-6.0)
ADRs detected by SP	1 (1.0)
Patient satisfaction	
Average Likert summed score (1-5)	3.92 (3.67-4.46)
Overall satisfaction score (1-5)	4.00 (4.00-5.00)
MARS-5 (5-25)	24.0 (23.00-25.00)

**Table 2. Multivariable analysis of factors associated with achieving SU < 360 µmol/L.**

# Computer Learning (artificial intelligence) to Create a Computer-Based Triage Tool Classifying Referrals As Inflammatory or Non-Inflammatory Requiring Only Patient Reported Information

Cindy Kim<sup>1</sup>, Tanner Bohn<sup>2</sup>, Charles X. Ling<sup>3</sup>, Nikhil Chopra<sup>4</sup> and Janet E. Pope<sup>5</sup>, <sup>1</sup>Faculty of Medicine, University of Western Ontario, London, ON, Canada, <sup>2</sup>University of Western Ontario, London, ON, Canada, <sup>3</sup>Computer Sciences, University of Western Ontario, London, ON, Canada, <sup>4</sup>Rheumatology, Private Practice, London, ON, Canada, <sup>5</sup>Department of Medicine, Division of Rheumatology, University of Western Ontario, St Joseph's Health Care, London, ON, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To determine if a computer-based triage tool can accurately classify referrals as inflammatory or non-inflammatory using information obtained from the patient; not requiring assessment by healthcare workers.

**Methods:** Patient referrals to a single rheumatologist were studied. Patient lists for 11 commonly encountered diagnoses [rheumatoid arthritis (RA), psoriatic arthritis, lupus, osteoarthritis, gout, soft tissue rheumatism (i.e. arthralgia NYD, tendonitis, mechanical low back pain), ankylosing spondylitis (AS), polymyalgia rheumatica (PMR), and fibromyalgia] were created. The diagnoses of RA, lupus, AS, PMR, and other seronegative spondyloarthropathies were classified as inflammatory arthritis (non-crystalline) (IA). At least five patient charts for each diagnosis were reviewed and eligible for study if a self-reported patient pain diagram was also completed. The following patient-reported information was collected from each referral: age, sex, symptom duration, and pain diagram. Lab results for ESR, CRP, ANA, ENA, anti-DNA, anti-CCP antibodies, urate, and rheumatoid factor were also collected where available. Machine learning techniques were used to create a logistic regression model to classify referrals as inflammatory or non-inflammatory. Backward feature selection was used to enhance model performance by identifying features most predictive of referral state. Leave-one-out cross-validation was used to predict model performance. The models were subsequently evaluated on prospectively collected patient data from 20 new referrals seen after the creation of the triage tool, where data was coded blindly to patients' diagnosis.

**Results:** In creation of the triage tool, 168 patient charts were used; 73 were classified as IA after being seen by a rheumatologist. The triage tool correctly classified 65 of 73 referrals as inflammatory using patient-reported information (model 1) (sensitivity 89%, specificity 52%). When the referral tool was reevaluated using laboratory markers in addition to the information obtained from the patient (model 2), 67 referrals were correctly classified as inflammatory (sensitivity 92%, specificity 63%). When model 1 was tested on 20 prospective patients, all 6 patients with IA were correctly classified (sensitivity 100%, specificity 52%). Model 2 correctly classified 14 patients (who had lab values present) including 5 patients with IA (sensitivity 83%, specificity 64%). The results are shown in table. Further prospective multi-site testing is ongoing.

**Conclusion:** A referral tool that can be entered into a database for computer assessment has good sensitivity to detect high priority referrals from data that can be obtained directly from patients and ascertained by non-healthcare workers. This may be of benefit in areas of limited resources and long waiting lists to see a rheumatologist.

	Model 1		Model 2	
	Predicted (N=168)	Actual (N=20)	Predicted (N=168)	Actual (N=20)
Sensitivity	89.0%	100%	91.8%	83.3%
Specificity	51.6%	35.7%	63.2%	64.3%
NPV	86.0%	100%	90.9%	90.0%
PPV	58.6%	40.0%	65.7%	50.0%
IA Referrals Correctly Classified	65/73	6/6	67/73	5/6

## Analysis of Provider-to-Provider Variability in the Use of Biologics: Data from the Rheumatology Informatics System for Effectiveness Registry

**Douglas White**<sup>1</sup>, Michael Evans<sup>2</sup>, Gabriela Schmajuk<sup>3</sup>, Rachel Myslinski<sup>4</sup>, Salahuddin Kazi<sup>5</sup> and Jinoos Yazdany<sup>6</sup>, <sup>1</sup>Gundersen Health System, Onalaska, WI, <sup>2</sup>University of California San Francisco, San Francisco, CA, <sup>3</sup>San Francisco VA Medical Center, University of California San Francisco, San Francisco, CA, <sup>4</sup>Practice, Advocacy, & Quality, American College of Rheumatology, Atlanta, GA, <sup>5</sup>University of Texas Southwestern, Dallas, TX, <sup>6</sup>Medicine/Rheumatology, University of California San Francisco, San Francisco, CA  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Variations in biologic prescribing habits by rheumatology providers may account in part for variability in direct cost of care for patients with rheumatoid arthritis (RA). We used data from the Rheumatology Informatics System for Effectiveness (RISE) registry to estimate variability in biologic use among US rheumatologists.

**Methods:** RISE is a national, EHR-enabled registry that passively collects and houses data on all patients seen by participating practices and thereby avoids sampling bias. As of December 2016, RISE was connected to 632 providers (99.5% of which were physicians) representing an estimated 16% of the US workforce. We calculated, on a per-provider basis, the proportion of RA patients prescribed a biologic or tofacitinib at least once between January and December 2016 (inclusive). The population of patients in the denominator, numbering 58,055 across all participating practices, was defined as those assigned an ICD code for RA in at least two separate encounters in 2016. Consistent with other national performance analyses, providers who saw fewer than 30 RA patients (315 of the 632 RISE-connected providers) were excluded. Few patients saw >1 provider, but in those instances prescriptions were attributed only to the provider with the plurality of RA-coded visits; therefore, each patient was attributed to only one provider.

**Results:** Provider-to-provider variability in the proportion of RA patients who received a biologic prescription is shown in Figure 1. Across the US in 2016, an average of 38% of each provider's RA patients were prescribed a biologic but the fraction of patients prescribed a biologic ranged from 0 to 79%. A regional breakdown is shown in Table 1 and demonstrates statistically significant geographic variability as well.

**Conclusion:** These data estimate the degree to which biologic prescription patterns vary across the US. In light of existing data indicating that biologics account for the majority of the direct cost in providing care for US patients with RA, and ongoing initiatives such as the Merit Incentive Payment System to incorporate measures of resource utilization in payment reform, this study provides initial benchmarking information for rheumatology providers in the US. Our study does not address quality of care. Future studies adjusted for case mix and disease activity will be required to estimate variability in the value (quality divided by cost) of care.

Figure 1. Fraction of RA patients prescribed biologics, by provider. Red line indicates the mean.

Table 1. Fraction of RA patients prescribed biologics, on a per-provider basis, by region.

Region	Mean (%)	95% CI (%)
New England (CT, ME, MA, NH, RI, VT)	36.5	31.3 - 41.6
Mid Atlantic (DE, NJ, NY, PA)	32.4	27.1 - 37.7
East North Central (IL, IN, MI, OH, WI)	29.6	24.0 - 35.3
West North Central (IA, KS, MN, MO, NE, ND, SD)	40.3	36.6 - 44.0
South Atlantic (FL, GA, MD, NC, SC, VA, DC, WV)	41.2	38.4 - 44.0
East South Central (AL, KY, MS, TN)	37.6	33.0 - 42.2
West South Central (AR, LA, OK, TX)	45.8	42.5 - 49.1
Mountain (AZ, CO, ID, MT, NV, NM, UT, WY)	37.6	34.2 - 41.1
Pacific (AK, CA, HI, OR, WA)	41.9	31.4 - 52.3

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patients with autoimmune rheumatic diseases have higher risk of developing organ failure and may require admission to intensive care unit (ICU), however there are only few studies in the US addressing this topic. The aim of our study is to determine reasons of admission to the ICU, identify potential risk factors associated with mortality and assess outcomes of patients with rheumatic disease admitted to the ICU.

### Methods:

We conducted a retrospective chart review of patients admitted to the ICU from 2011 to 2016 using ICD-9/ICD-10 codes for morbidities. We identified patients with new or established diagnosis of a rheumatic disease. Patient's data included demographics, ICU admission diagnoses, co-morbidities, organ involvement, laboratory studies, length of stay in ICU/hospital, complications and immunosuppressive regimen. Short-term (ICU/30-day post-ICU) stay and long-term (1-year post) outcomes were assessed.

### Results:

A total of 80 rheumatic disease patients were identified with mean age of 48.8 (range 19-84), 67% were female, 56% were Hispanic. Most common disease associated with ICU admission was SLE in 34 patients (42%), followed by RA 21(26%). 10(12%) had Systemic Vasculitis

(5 with Granulomatosis with polyangiitis, 2 with PAN, 1 Eosinophilic granulomatosis with polyangiitis, 1 with Takayasu's, 1 with Microscopic polyangiitis). 5(6%) had SSc, 5(6%) had DM and 2(3%) had Sarcoidosis. Sjogren's, APS and AS were present in 1 patient each case.

Sepsis was the leading cause of ICU admission with 25 patients(31%), followed by acute hypoxemic respiratory failure due to pneumonia 8(10%) and congestive heart failure/CHF 8(10%). Others were respiratory failure due to underlying disease 6(8%) and cardiac tamponade 6(8%). Less common included cerebrovascular events(4), metabolic disturbances(3), Steven's Johnson (3), meningoenophalitis (3), encephalopathy(3), pulmonary hypertensions(2), diffuse alveolar hemorrhage (2), pancreatitis(2), cardiac arrest(2), anemia(1), hypertensive emergency(1) and pulmonary embolism(1).

45% of patients required mechanical ventilation and 31% vasopressor support. Mean ICU stay was 7 days and hospital stay 13.7 days. 16 of 80 patients (20%) died in ICU, 4(5%) died 30-days post-ICU and 6(7.5%) within 1-year of ICU stay, resulting into an overall mortality of 33% by the end of 1-year. Higher mortality found in patients with DM (40%) and SLE (24%). Predictors of increased mortality during ICU stay were cardiovascular involvement ( $p=0.01$ ), renal involvement ( $p=0.032$ ) and requirement for mechanical ventilation ( $p<0.01$ ). Worse outcome 30-days post ICU stay was influenced by development of venous thromboembolic disease (VTE) during hospitalization ( $p=0.03$ ). At 1-year post ICU-stay, survival for patients with CHF was 76.5% compared to 95.7% without CHF ( $p=0.041$ ).

#### Conclusion:

Our findings indicated that SLE is the most common rheumatic disease associated with ICU admission, followed by RA. Sepsis, respiratory failure due to pneumonia/ CHF were the most common causes leading to ICU admission. Factors associated with higher mortality were requirement for mechanical ventilation, renal and cardiovascular involvement on admission, development of VTE and history of CHF.

## Healthcare Utilization Among Young Adults Transitioning from Pediatric to Adult Care in a Safety Net Population

Nicole Bitencourt<sup>1</sup>, Una E. Makris<sup>1,2</sup>, Tracey Wright<sup>3,4</sup> and E. Blair Solow<sup>1</sup>, <sup>1</sup>UT Southwestern Medical Center, Dallas, TX, <sup>2</sup>Department of Medicine, VA North Texas Health Care System, Dallas, TX, <sup>3</sup>Pediatrics/Rheumatology, UT Southwestern Medical Center, Dallas, TX, <sup>4</sup>Texas Scottish Rite Hospital for Children, Dallas, TX

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

The transition from pediatric to adult care for young adults with chronic illness is a vulnerable period especially among socioeconomically disadvantaged populations. As part of a quality improvement project, we sought to characterize patterns of healthcare utilization, namely hospitalizations and emergency department (ED) visits during the transfer period between pediatric and adult rheumatologic care in a large public safety net healthcare system.

#### Methods:

Using an electronic medical record, 95 patients were identified as being between 17 and 21 years of age at the time of referral to adult rheumatology between 3/2014 and 4/2017. Following chart review, 65 of these patients were confirmed as transitioning between pediatric and adult care. Data on disease categories, demographics, medical coverage, and referring provider were extracted and comparisons made regarding hospitalizations and ED visits (excluding visits which were clearly unrelated to an underlying rheumatic disease) by using unpaired t-test and one-way analysis of variance.

#### Results:

Among the 65 patients transitioning to adult care, 72% were female, 74% were Hispanic, 49% had a connective tissue disease (CTD), 49% had juvenile idiopathic arthritis (JIA), 75% had Medicaid, and 74% were referred by a pediatric rheumatologist (Table 1). Hospitalizations and ED visits were common (20% and 28% of patients, respectively) during the transfer period, and were more common among those with a CTD (compared to JIA), and in blacks (compared with Hispanics and whites) (Figure 1). Those with a lapse in medical coverage during the transfer period and lack of coverage at the time of initial referral had significantly higher healthcare utilization than those with consistent medical coverage. Those referred to adult care by a pediatric rheumatologist had significantly fewer hospitalizations and ED visits than those referred by other clinicians (Figure 2).

### Conclusion:

Hospitalizations and ED visits are especially prevalent among patients transitioning from pediatric to adult rheumatologic care. Factors associated with high utilization included having a CTD, black race, lapse in medical coverage during the transfer period, lack of coverage at initial referral to adult care, and being referred by someone other than a pediatric rheumatologist.

## What Is the Value of the Prior Authorization Process in Specialty Drug Therapy?

Shally Alendry<sup>1</sup>, Melad Qodsi<sup>1</sup>, Travis Hunerdosse<sup>1</sup> and Eric M. Ruderman<sup>2,3</sup>, <sup>1</sup>Northwestern Medicine, Chicago, IL, <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>3</sup>Medicine/Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** As the use of specialty pharmacy drugs has grown, many insurers have instituted strict prior authorization requirements, ostensibly to ensure that the right patients get the right medications at the right point in their disease process. Rheumatologists, dermatologists, and patients, however, often question whether this process creates logistical barriers that delay treatment. Northwestern Medicine established a specialty pharmacy in 2014 to provide medication directly to patients at the institution. Rheumatology and dermatology clinics began working with this specialty pharmacy in 2015 and now utilize it for all new specialty drug prescriptions. When possible, medications are filled directly through the health system pharmacy. When insurers require use of an alternative specialty pharmacy, the prescription is transferred, but the NM specialty pharmacist continues to help guide the prior authorization steps. We analyzed the number of prescriptions approved or denied through this process, hypothesizing that few medications requiring prior authorization were ultimately denied.

**Methods:** We reviewed prior authorization requests from 6/1/2015 through 6/12/2017. We included primarily prescriptions for approved indications, at labeled doses. Indications included ankylosing spondylitis, juvenile idiopathic arthritis, psoriatic arthritis, rheumatoid arthritis, and psoriasis.

**Results:** Of the 3192 prescriptions handled by the specialty pharmacy, 840 did not require prior authorization. A total of 2,352 prior authorizations were submitted; 2113 of these were approved with the initial request, and 239 (10.1%) were denied. Appeals were submitted for 126 of these denials in rheumatology; the denial was overturned in 83 cases, upheld in 40, and 3 are pending. Dermatologists appealed fewer denials. As of the data cut, 2196 (93.4%) of the prescriptions submitted for prior authorization had been approved and filled. Results for individual diseases are shown in Table 1.

**Conclusion:** In our academic medical practice, rheumatology and dermatology specialty medications prescribed for approved indications are seldom denied, and most of the denials are reversed when appealed. These findings suggest that the time spent on prior authorizations, at

substantial cost to the practices involved, may be unnecessary, as appropriate treatments are rarely denied. Insurers may have other interests in the prior authorization process besides the stated reason of restricting inappropriate or unnecessary prescriptions. There appears to be little value in the prior authorization process for rheumatology- or dermatology-specific specialty drugs prescribed in an academic practice. A more streamlined approach could limit wasted time and effort, suggesting a need for exploration of alternative methods in partnership with payers.

**Table 1. Prior Authorization Status for Specialty Drugs in Rheumatology and Dermatology**

Disease	Approved	Denied	Not Needed	Appeal Granted	Appeal Denied	Appeal Pending
Ankylosing Spondylitis	133	11	45	2	2	-
Juvenile Idiopathic Arthritis	17	2	4	2	-	-

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Mycobacterium tuberculosis (MTb) screening is routine for clinical trial protocols, & authorization for immunomodulators use by health insurances. Real world data is needed to guide clinicians and researchers in appropriate test choice. The two interferon gamma release

assays (IGRAs) available to screen for MTb, QuantiFERON TB Fold In-Tube test (QFT-G) & SPOT TB (T-Spot), rely on an uncompromised immune system. Both, however, have a “+,” “-,” & “indeterminate (IND)” or in TSpot, “borderline” result. IND or borderline values have been theorized to result from an immunocompromised state, but the literature varies with regard to the effect of immunomodulation, particularly with corticosteroids, disease-modifying anti-rheumatic medications (DMARDs) and biologic response modifiers (BRMs)

**Methods:** The Center for Rheumatology and Bone Research (CRBR) obtained IRB review / waiver to conduct a retrospective chart review from 2014 to 2016. CRBR focused on care provided by Arthritis and Rheumatism Associates P.C. regarding medication use at the time of an IGRA. Data included IGRA type, test result (“+”, “-” & IND/borderline), & medication use. Medications were divided by corticosteroid (prednisone or methylprednisolone), DMARD use (including but not limited to hydroxychloroquine, sulfasalazine, MTX, azathioprine, leflunomide, cyclosporine) and exposure to a BRM (aka anti-TNF $\alpha$  therapy [such as etanercept, adalimumab, infliximab, certolizumab, golimumab], tocilizumab, abatacept rituximab and tofacitinib). A medication was considered active at the time of the laboratory if there were evidence of use within 1 month of testing. Statistical Analysis was performed using a student’s z-test as well as Chi-square analysis.

## Results:

A total of 796 IGRAs were reported. There were 722 QTF-G tests and 74 Tspot drawn. Negative QTF-G values occurred in 643/722 (89%), equally distributed between those on & off immunomodulators. Positive QTF-G values occurred in 41/722 (5.6%), equally distributed between those on & off immunomodulators. IND QTF-G occurred in 38/722 (5.9%); the distribution was imbalanced. IND QTF-G occurred in 24/38 (63 %) on immunomodulators while IND QTF-G occurred in 14/38 (37%) with  $p=0.0087$ . IND QTF-G were more likely to occur during corticosteroid + DMARD / BRM treatment, occurring in 19/38 (50%) vs. DMARD  $\pm$  BRM without corticosteroid, which occurred in 5/38 (13%) with  $p<0.025$ . This effect was not seen in non-steroid DMARD or non-steroid BRM treated cohort. This effect was not observed in the Tspot cohort, as IND / border line values occurred in 1/74 on immunomodulators while 2/72 subjects were not exposed to immunomodulators.

## Conclusion:

Our cohort demonstrated positive, negative and IND rate similar to other published studies. However, our large QTF-G cohort demonstrated a statistically significant difference in IND values while taking immunomodulators, largely related to steroid exposure. Our smaller Tspot cohort did not demonstrate this effect, but this may have related to the cohort size. Further study to guide IGRA choice is warranted, but clinicians should consider Tspot over QTF-G when the subject is exposed to corticosteroid within a month of testing.

## Direct Medical Costs of Systemic Lupus Erythematosus in South Korea

So-Yeon Park<sup>1</sup> and Sang-Cheol Bae<sup>2</sup>, <sup>1</sup>Department of Rheumatology, Myongji Hospital, Seonam university, Goyang, Korea, Republic of (South), <sup>2</sup>Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) has very high economic burdens on society and healthcare system. The aim of this study was to estimate the annual direct costs and predictors of cost in Korean patients with SLE

**Methods:** This study used a national insurance claims database during the period from 2006 to 2010. Information was taken from the Korea National Health Insurance (KNHI) Claims Database of the Health Insurance Review and Assessment Service (HIRA). Factors associated with the direct medical costs were analyzed by using multiple regression and multivariate logistic regression.

**Results:** A total of 13,047 SLE patients were mainly analyzed. The estimated total annual direct medical costs amounted to \$2,240 (2010 US dollars), of which 47.1% was accounted for by inpatient costs and 52.9% by outpatient costs. Among the cost domains for total direct medical costs, the biggest component was the costs of medication. The mean medication costs were \$983, which accounted for 43.9% of the

total healthcare costs, followed by costs for diagnostic procedures and tests, accounting for 32.8% of the total. For the type of insurance, national health insurance were 92%, and medical aid were 8%. Total reimbursement rates of patients with SLE were 86.4%, and copayment comprised 13.6%, respectively. Reimbursement rates have shown a tendency to increase, whereas, out-of-pocket was decreasing gradually each year between 2006 and 2010. In the multivariate regression analyses, the predictors of increased direct costs were male sex, medical aid -insurance type, more comorbidity disease, and the use of immunosuppressant including steroids

**Conclusion:** We have reported on the first population-based cost study of SLE patients in South Korea. The results of this study will contribute to a better understanding of the economic burden of SLE, and should provide information that is useful when allocating healthcare resources.

**Table 1. Annual direct medical costs\* in patients with SLE, 2006~2010 (US \$)**

	Annual direct medical cost per person, mean*

## Influence of Depression on Healthcare Expenditures Among Adults with Spondylosis, Intervertebral Disc Disorders and Other Back Problems in the United States

**Jawad Bilal**<sup>1</sup>, Adam Berlinberg<sup>1</sup>, Jaren Trost<sup>1</sup>, Sandipan Bhattacharjee<sup>2</sup> and Irbaz Bin Riaz<sup>1</sup>, <sup>1</sup>Banner University Medical Center, Tucson, AZ, <sup>2</sup>Department of Pharmacy, University of Arizona, Tucson, AZ

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Back pain is a very prevalent complaint affecting two-thirds of population, and accounts for 90.7 billion dollars annually in healthcare expenditure. The occurrence of depression is reported in existing literature among patients with back pain, but there is limited information regarding healthcare expenditures among patients with back pain and concurrent depression. To assess excess total and subtypes of healthcare expenditures among adults with spondylosis, intervertebral disc disorders and other back problems who reported having depression compared to those without depression in the United States (US).

**Methods:** We utilized a cross-sectional design pooling MEPS data from 2010-2012. The eligible study sample comprised of adults (age  $\geq$  18 years), who were alive during the calendar year and reported positive healthcare expenditure. Total and subtypes of healthcare expenditures constituted the dependent variable. Ordinary least square (OLS) regressions on logged expenditures were performed. Three models were developed to assess the influence of demographics, functional ability, and concurrent diagnoses on healthcare expenditures. All expenditure data are presented in terms of 2012 US dollars.

**Results:** A total of 6,559 adults with spondylosis, intervertebral disc disorders, and other back problems were assessed, 20.2% of which had concurrent depression. Adults with concurrent depression had significantly higher healthcare expenditures (\$13,153) compared to the non-depression group (\$7,477),  $p < 0.001$ . Inpatient, outpatient, prescription, and home health agency expenditures showed similar findings. There was no difference in emergency room and other expenditures between the two groups. The excess total expenditure was higher (119%) among depression group when adjusted for demographic characteristics. After adjusting for healthcare and functional disabilities, and comorbidities excess cost remained higher in depression group (53%).

**Conclusion:** This study demonstrates that presence of depression in the adults with spondylosis, intervertebral disc disorders, and other back problems significantly influence the economic burden. These findings remained consistent despite adjusting for all independent level variables (demographic characteristics, functional status, comorbidities). The study findings suggest that interventions resulting in better control of depression have the potential to significantly reduce the economic burden in this population.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To analyse whether epidemiologic factors (such as gender or age at diagnosis of the disease) are associated with particular disease expressions and define specific epidemiological subsets in patients with sarcoidosis.

**Methods:** In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed in agreement with the criteria proposed by the American Thoracic Society/European Respiratory Society/World Association of Sarcoidosis and Other Granulomatous Disorders (WASOG) 1999 statement on sarcoidosis. Organ involvement was retrospectively determined in each patient at the time of diagnosis using the 2014 WASOG organ assessment instrument. Ethnicity was defined according to the FDA classification.

**Results:** The cohort consisted of 1082 patients (82% biopsy-proven), including 618 (57%) women and 464 (43%) men, with a mean age at diagnosis of  $47.2 \pm 15.5$  years. One hundred forty (13%) patients were born outside Spain. With respect to the FDA ethnic classification, 965 (89%) patients were classified as White, 69 (6%) as Hispanic, 30 (3%) as Black/African American and 18 (2%) as Asian. Thoracic involvement was present at diagnosis in 979 (90%) patients, including 437 (40%) patients presenting with stage I, 374 (35%) with stage II, 123 (11%) with stage III and 26 (2%) presenting with stage IV. According to the WASOG classification, the most frequently reported extrathoracic involvements at diagnosis were cutaneous in 385 (36%) patients, extrathoracic lymph nodes in 218 (20%), liver involvement in 151 (14%) and ocular involvement in 118 (11%).

In the multivariate analysis models, women showed a lower frequency of thoracic involvement (87% vs 93% in men,  $p=0.019$ ) and a higher frequency of cutaneous (42% vs 26%,  $p<0.001$ ) and ocular (13% vs 9%,  $p=0.012$ ) WASOG involvements, patients with a younger disease onset ( $<35$  years) were more frequently born out of Spain (17% vs 11%,  $p=0.027$ ), had a higher frequency of thoracic disease (94% vs 88%,  $p=0.008$ ) and a lower frequency of kidney involvement (3% vs 6%,  $p=0.041$ ), and patients with an elderly onset (age  $>70$  years) were more frequently born in Spain (99% vs 86%,  $p=0.007$ ) and had a lower frequency of thoracic (81% vs 90%,  $p=0.006$ ) and cutaneous (23% vs 37%,  $p=0.001$ ) involvements and a higher frequency of bone marrow involvement (12% vs 4%,  $p=0.004$ ).

## Conclusion:

This is one of the largest series of sarcoidosis reported out of the US, predominantly composed by White patients in nearly 90% of cases. Thoracic and extrathoracic involvements at disease presentation were strongly influenced by specific epidemiologic features such as gender, age and ethnicity.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The increasing use of biological agents has been linked with the paradoxical development of autoimmune processes. The scenario has dramatically change in recent years due to the increased number and the emerging use of biologics in solid cancers.

**Methods:** In 2006, the Study Group on Autoimmune Diseases (GEAS) of the Spanish Society of Internal Medicine created the aeBIOGEAS Registry (autoimmune events) designed to collect data on autoimmune diseases secondary to the use of biologic agents through a systemic and yearly MEDLINE search. The baseline analysis identified in 2017 nearly 200 cases of autoimmune diseases triggered overwhelmingly anti-TNF. We present the updated results of the aeBIOGEAS Registry (cases included until May 31, 2017).

**Results:** The aeBIOGEAS Registry currently includes 12013 cases of autoimmune diseases related to the administration of biological agents, including more than 50 different systemic and organ-specific autoimmune processes; the most frequently reported were psoriasis (n=6377), inflammatory bowel disease -IBD- (n=783), demyelinating CNS diseases (n=453), lupus (n=369), interstitial lung diseases -ILD- (n=378), peripheral neuropathies (n=328), vasculitis (n=291) and hypophysitis (n=207). The main biological agents identified consisted of anti-TNF agents in 9220 cases (mainly adalimumab in 4051, infliximab in 3109 and etanercept in 1496), B-cell targeted therapies in 729 (mainly rituximab in 664), immune checkpoint inhibitors in 552 (mainly ipilimumab in 426 and nivolumab in 77) and vascular endothelial growth factor inhibitors in 504 cases (bevacizumab). With respect to the biologic, the main associations were reported for the development of lupus and hepatitis in patients treated with infliximab (44% and 45% of the reported cases of induced lupus and hepatitis, respectively), demyelinating CNS diseases, sarcoidosis, uveitis and IBD in patients treated with etanercept (47%, 41%, 67% and 83%, respectively), psoriasis in patients treated with adalimumab (56%), ILD in patients treated with rituximab (49%) and hypophysitis in patients treated with ipilimumab (96%). With respect to the underlying disease for which the patient received the biological agent, the main associations were reported for the development of lupus, vasculitis and sarcoidosis in patients with RA (68%, 84% and 47% of the reported cases of induced lupus, vasculitis and sarcoidosis, respectively), uveitis and IBD in patients with JIA (60% and 41%, respectively), psoriasis in patients with IBD (33%), hypophysitis in patients with melanoma (90%) and ILD in patients with hematological neoplasia (50%).

**Conclusion:** As the use of biological therapies expands, the number and diversity of induced autoimmune disorders is increasing exponentially (**Figure**). Management of these biologic-induced autoimmune diseases will be an increasing clinical challenge in the daily practice in the next years.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Not much attention has been paid to listening to the opinions of patients in most scientific studies on Spondyloarthritis, despite their opinions playing an increasingly important role in decision-making alongside clinical and public health criteria. To assess the opinions of patients with Axial Spondyloarthritis (ax-SpA) using qualitative information.

**Methods:** A sample of 680 patients diagnosed with ax-SpA was interviewed during 2016 as part of the Spanish Atlas, which aims to promote early referral and improve healthcare and the use of effective treatments in patients with ax-SpA. The Atlas is a CEADE initiative (Spanish Coordinator of Patients with ax-SpA in Spain) developed by the University of Seville and Max Weber Institute in collaboration with GRESSER (Spanish Rheumatology Society spondyloarthritis study group). Responses to qualitative items about patients' hopes and fears for their disease and their personal aims regarding their treatment were analysed.

**Results:** 53% were females, mean age 46 years and 77.1% were HLA-B27+. The five main hopes of patients are: stopping the disease, dream of a cure, elimination of pain, improve their quality of life and live without limitations. Additionally, patients have expectations on the medical research outcomes. Thus, 81% of patients hope that the research will make possible to find the cause and a cure for ax-SpA, developing more efficient biologic therapies (11%), and finding new techniques or medication (8%). The following stand out among drug treatment-related concerns: having more effective treatments (32%), sustaining the results of biologic therapies (29%), being able to start on biologics (8%), the public health system funding non-drug treatments for AS (8%), eliminating secondary effects (15%), reducing prices (4%), and correct use (4%). With respect to their fears, patients stated that their main concern was mobility loss (31%), followed by loss of independence (23%), disability (22%), stiffness (12%), structural damage (3%), organ damage (3%), other illnesses and diseases related (3%), physical decline (3%), and sight loss (1%). Patients who expressed fear regarding their disease listed their greatest concern was that they would not overcome or tolerate pain (56%), followed by the fear that the disease would develop (32%), along with

apprehension about flare-ups (7%), and tiredness (5%). With respect to patients' personal objectives in terms of their treatments, they highlighted the wish that their treatment would, first, help them to reduce and eliminate pain, increasing their in mobility, improved quality of life, the avoidance of structural damage and the disease eventually being cured.

**Conclusion:** Analysis of patient opinion using qualitative information has enabled the identification of important concerns for patients such as discovering the cause of the disease, reducing pain and structural damage, loss of self-sufficiency and disability.

## **Treatment Patterns in Large Vessel Arteritis (Giant Cell Arteritis and Temporal Arteritis): Findings from a Large Contemporaneous Real-World Cohort in the US**

Zhaohui Su<sup>1</sup>, Vandana Menon<sup>1</sup>, Richard Gliklich<sup>2</sup> and Tom Brecht<sup>1</sup>, <sup>1</sup>Research, OM1, Inc, Cambridge, MA, <sup>2</sup>OM1, Inc, Cambridge, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Health Services Research Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Giant cell arteritis (GCA) is the most common form of primary systemic vasculitis with annual incidence as high as 27 per 100,000 in persons over the age of 50 years. Key issues in management after a diagnosis of GCA include prompt initiation of therapy, prevention and treatment of adverse effects related to treatment, and close monitoring for disease flares. Glucocorticoids are the mainstay of therapy and are used for induction and maintenance of remission. However, there is little consensus on the optimal treatment strategies for GCA. We present treatment patterns in a large real-world population of patients with GCA managed by rheumatologists across the US.

### **Methods:**

The OM1 platform collects, links, and leverages, structured and unstructured data from electronic medical records (EMR) and other sources in an ongoing and continuously updating manner to create a next generation registry-a novel approach to real world evidence. The OM1 GCA Cohort includes data who met our definition of at least two GCA related diagnosis codes [ICD-10: M31.6, M31.5, M31.4; ICD-9:446.7, 446.5] within a 1 year period, treated by rheumatologists, between 2013 and 2016.

### **Results:**

The cohort included 1,567 patients with a mean age of 72 + 10 years, three quarters were Caucasian (78%) and female (76%). Median follow up time was 24 months with a mean of 12 rheumatology ambulatory encounters. Nearly a third of the cohort had a concomitant diagnosis of polymyalgia rheumatica (33%) and 17% had rheumatoid arthritis. A majority of the patients had at least one erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) measurement. Median ESR at baseline was 21mm/hr (IQR: 8, 48) and median CRP was 1mg/L (0.3, 4.0). Only 6% of patients had a documented temporal artery biopsy. Patient reported pain scores were available in 26% of the patients with a median duration of 6 months between first and last assessment. The majority of patients received glucocorticoids (85%), 22% were treated with methotrexate, 8% with hydroxychloroquine, 5% with aspirin, 5% with tocilizumab and 3.5% with azathioprine; 14% were treated with more than one drug concurrently.

### **Conclusion:**

We present findings from a large, representative, cohort of real-world patients seen in routine clinical practice. There are wide variations in patient profile and treatment practices which may reflect the lack of clarity around value of additional steroid-sparing agents to avoid the

common glucocorticoid adverse effects and to reduce time to remission.

## Perception of Access to Mental Health Services in Publicly Insured Vs Privately Insured Patients with Rheumatic Diseases

**Elizabeth Soto-Cardona**, Jackie Szymonifka and Robert F. Spiera, Rheumatology, Hospital for Special Surgery, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Health Services Research Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess perception of access to mental health services (MHS) and utilization of those services based on participant's insurance type. We compared responses of participants with public insurance (Medicare and Medicaid) and private insurance receiving rheumatologic care at an urban academic medical center.

**Methods:** Patients with rheumatic diseases seen in clinic and in private practices at a tertiary care academic medical center underwent a standardized interview by a single interviewer. Patient reported utilization of medical care and mental health services, as well as perceptions of access to those services was assessed using a standardized questionnaire. Socio-demographic variables were collected. Health characteristics included rheumatological diagnosis, physical functional status and mental health, measured by the SF36. High scores, reported on a scale from 0 to 100, define a more favorable health state. Responses from patients with public health insurance were compared to those with private commercial insurance.

**Results:** Participants with private insurance were more likely to be white ( $p=.037$ ), married ( $p=.001$ ) and home owners ( $p<.001$ ), whereas participants with public insurance were more likely to be disabled ( $p=.074$ ) and diagnosed with RA ( $p=.022$ ) or SLE ( $p=.022$ ). Those with private insurance scored higher on the SF-36 and were less likely to recognize role limitations due to emotional problems ( $p=.028$ ), score lower for pain ( $p=.019$ ) and to report worse physical function ( $p=.006$ ). [Table 1]

### Conclusion:

Of the 52 participants only 34 had received MHS in the past, 13/34 (38%) of public insurance patients, and 21/34 (61%) of private patients. Patients with public insurance were less likely to perceive barriers to access to mental health services than were those with private insurance, although that difference did not reach statistical significance (59% vs 24%,  $p=0.227$ ). In terms of relative ease of access to MHS vs physical health specifically, 38% of participants with public insurance felt they had less access to MHS than to medical services in general where as 61% of private practice patients reported perceiving less access to MHS ( $p=.041$ ) than to medical services in general. The majority of participants in both private (76%) and clinic settings (76%) felt access to MHS was important to their well-being. **Conclusion:** Patients with rheumatic diseases commonly value the importance of mental health services, but frequently perceive barriers to access those services. Perhaps surprisingly, patients with public insurance were less likely to perceive such barriers than those privately insured. Future investigations should focus on identifying those specific barriers to mental health access for private and publicly insured patients in order to facilitate provision of such services.

**Table 1. SF-36 component scores by insurance type**

	All patients (n=52)	Medicare or Medicaid (n=25)	Private insurance (n=27)	p- value
<b>SF-36 component</b>

## Ambulatory and Hospital Care for Arthritis and Related Conditions in Ontario, Canada

Y. Raja Rampersaud<sup>1</sup>, J. Denise Power<sup>2</sup>, Anthony V. Perruccio<sup>2</sup>, Michael Paterson<sup>3</sup>, Christian Veillette<sup>2</sup>, Elizabeth M. Badley<sup>4</sup> and Nizar Mahomed<sup>2</sup>, <sup>1</sup>Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada, <sup>2</sup>Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada, <sup>3</sup>Institute for Clinical Evaluative Sciences, Toronto, ON, Canada, <sup>4</sup>Health Care & Outcomes Research, Krembil Research Institute, University Health Network, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Health Services Research Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ontario, Canada's most populous province, has publicly funded, universal health insurance covering medically necessary hospital and physician services with no copayments. The purpose of this study was to quantify the burden of arthritis and related conditions (A&R) on the Ontario health care system, according to service type ( ambulatory vs. inpatient care) physician specialty (primary care, rheumatology, orthopedics), and hospital setting (emergency department (ED), day surgery, inpatient care).

**Methods:** Administrative health data were analyzed for fiscal 2013/14 for Ontarians aged 18+ years (N=10,841,302). Data sources included: the Ontario Health Insurance Plan (OHIP) Claims History Database, which captures data on in- and out-patient physician services; the Canadian Institute for Health Information (CIHI) Discharge Abstract Database, which records diagnoses and procedures associated with all inpatient hospitalizations; and the CIHI National Ambulatory Care Reporting System, which captures data on all ED and day surgery encounters. Services associated with A&R were identified using the International Classification of Diseases (ICD) diagnosis code identified on each physician service claim as the "main reason" for each outpatient physician visit and the "most responsible" ICD diagnosis code recorded on each hospitalization, ED visit and day surgery record. Patient visit rates and numbers of patients and visits were tabulated according to care setting, patient age and sex, and physician specialty for the grouping of all A&R, as well as for specific diagnoses, such as osteoarthritis (OA) and rheumatoid arthritis (RA).

**Results:** Overall, 1.3 million adult Ontarians (11.9%) made 2.7 million outpatient physician visits for A&R in 2013/14, with 62% of these visits occurring in primary care. Patient visit rates for A&R increased with age and were higher in women than men; women accounted for 60% of all A&R visits. Approximately 5% of adult Ontarians made an outpatient physician visit specifically for OA, with about 1% making at least 1 visit for RA. 63% of outpatient visits for OA, and 35% for RA, were in primary care. Just over 25% of adult Ontarians who saw a physician for OA consulted an orthopaedic surgeon at least once and 58% who made a visit for RA consulted a rheumatologist at least once. Just over 1% of adult Ontarians made an ED visit for which the most responsible diagnosis was A&R, for a total of 142,000 visits. Rates of hospitalization and day surgery for A&R were 410 and 190 per 100,000 population, respectively. The highest rate of inpatient hospitalization was associated with OA, at 340 per 100,000, which accounted for 82% of all A&R-related hospital admissions.

**Conclusion:** A&R place a significant burden on the health care system, particularly in primary care. As the population ages, it will be essential that health system planning takes into account the large demand for arthritis care, both in terms of health human resources planning and implementation of clinically and cost-effective models of care.

## **Clinical Pharmacist As Part of the Interprofessional Team Improves Quality of Care in Patients with Rheumatic Disease**

Jessica Farrell<sup>1</sup>, Lee S. Shapiro<sup>1</sup> and Mitchell Miller<sup>2</sup>, <sup>1</sup>The Center for Rheumatology, Albany, NY, <sup>2</sup>Albany College of Pharmacy and Health Sciences, Albany, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Health Services Research Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Successful multidisciplinary models exist for the management of chronic diseases such as diabetes, cardiovascular disease, infectious diseases, kidney disease and psychiatric illnesses. A multidisciplinary team including a pharmacist in the ambulatory care setting has shown to improve patient and population outcomes for various chronic disease states. Rheumatology healthcare providers recognize the burden of rheumatic disease requires an integrated, multidisciplinary team including a pharmacist. Recent data suggests pharmacists can improve adherence and health outcomes in the management of gout. This type of pharmacist-led intervention can easily be extrapolated to other rheumatic diseases. The addition of a pharmacist to the healthcare team can have many benefits, including improving patient compliance and education, serving as a drug information resource, and obtaining insurance coverage. This includes establishing patient relationships, gathering medication histories, preventing, identifying and resolving medication related problems, educating patients and other healthcare providers, monitoring patients and medication effects, and contributing to continuity of care for all patients. Clinical pharmacy services at The Center for Rheumatology (TCFR) have expanded over the past 8 years.

### **Methods:**

The aim of our project is to 1) provide billable pharmacy consult services which systematize practice-wide medication initiation and safety monitoring, 2) provide additional support to practice-wide procedures/protocols related to medication therapy and insurance authorizations, 3) provide evidence of improved patient and population outcomes when a pharmacist is part of the interdisciplinary team in a rheumatology practice, 4) serve as a business model of an innovative practice in pharmacy. Outcome measures include number of reimbursable visits, assessments of medication prior authorizations, denials and peer-to-peer calls, and provider, support staff and patient surveys.

### **Results:**

The pharmacist provides face-to-face problem/medication focused visits which are reimbursed through incident-to billing. Visits are focused on initiation and safety monitoring for high-risk DMARD and osteoporosis therapies. The drug information consult services and insurance authorization assistance have been shown to save providers and support staff time, ranging from 1-3+ hours per week per provider. Providers report the addition of a pharmacist allows them to provide a higher level of care focused on medication therapy and safety, and helps improves patient compliance and anxiety related to medications.

### **Conclusion:**

The addition of a pharmacist to the multidisciplinary team in a rheumatology practice can improve the quality of care delivered to patients, specifically related to medication safety and access by assisting in the prior authorization process and serving as patient advocates. The addition of clinical pharmacy services sets the practice apart from others by improving patient care and serving as an innovative business model for rheumatology practices to include a clinical pharmacist as part of their healthcare team.

## Creation of the First Massive Open Online Course for Patients with Rheumatoid Arthritis

Sonia Tropé<sup>1</sup>, Jean-David Cohen<sup>2</sup>, Catherine Beauvais<sup>3</sup>, Didier Poivret<sup>4</sup>, Alain Saraux<sup>5</sup>, Danielle VACHER<sup>6</sup>, Hervé Barkatz<sup>7</sup>, Pascal Lacoste<sup>7</sup>, Valérie Weill<sup>8</sup> and Gérard Thibaud<sup>9</sup>, <sup>1</sup>149 avenue du Maine, ANDAR, Paris, France, <sup>2</sup>IMMUNO-RHEUMATOLOGY, CHU LAPEYRONIE, MONTPELLIER, France, <sup>3</sup>Service de Rhumatologie, Hopital Saint Antoine, Paris, France, <sup>4</sup>Rheumatology, Metz, France, <sup>5</sup>Rheumatology, Brest University Medical School Hospital, Brest, France, <sup>6</sup>expert-patient, ANDAR patient organisation, Paris, France, <sup>7</sup>Hbmotion, Paris, France, <sup>8</sup>hbmotion, Paris, France, <sup>9</sup>ANDAR patient organisation, Paris, France

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Health Services Research Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** People with chronic conditions face the disease more effectively when they develop psychosocial skills and self-care. Health authorities thus recommend the organization of therapeutic patient education (TPE). Suffering from different limitations, a patient organisation had the idea to develop a digital training solution, accessible everywhere, complementary to TPE, for patients with rheumatoid arthritis.

**Methods:** The choice was made for an online training program such as Massive Open Online Courses (MOOC). A preliminary survey was carried out among the patients via an electronic questionnaire via social networks and an emailing to the organisation members.

A steering committee (COPIL) made up of representatives of the patients' association, expert patients and rheumatologists with the support of a specialized agency, determined the timetable, the educational objectives, the contents, the speakers and the evaluations.

**Results:** The initial investigation was stopped at 100 responses, obtained in 3 days.

The majority of respondents planned to follow the MOOC on their computer (85.9%), but to meet the needs of all, the device is responsive.

More than half of respondents (61%) had never participated in a TPE program and 94% were interested in joining MOOC to learn new information about the disease (78.8%), treatments (71.7%), have expert views (67.7%), share experience with other patients (56.6%), and better live with the disease (50.5%).

Respondents would like to have a weekly webconference lasting from 1 hour to 1h30.

About the MOOC :

- Using the Learning Management System platform drspoc.com
- Intervention of the experts via videos and live courses, evaluation of the achievements and, during two annual sessions, tutoring by patients trained specifically.

At the beginning and end of the session, learners are invited to answer different questionnaires (knowledge, skills, satisfaction).

The MOOC includes the following modules:

- Introduction and background on MOOC
- Understanding Rheumatoid Arthritis
- Explore the care pathway, current events and treatment prospects
- Everyday life with rheumatoid arthritis

- Manage pain and fatigue.

COPIL identified 15 experts (patient-experts, rheumatologists, occupational therapist, physiotherapist, nutritionist, social worker, psychologist, sexologist, nurse) who wrote the content of their speech. All texts have been validated by a pedagogical engineer and the director of the association.

215 people pre-registered during the month preceding the launch, 148 persons active during the first session.

41 responses recorded to the voluntary assessment questionnaire.

**Conclusion:** This is the first digital training strategy for people with rheumatoid arthritis.

This project proved to be useful to patients, offering an alternative or complement to TPE.

It will be necessary to evaluate the impact of this MOOC on the quality of life of the patients and their perception on its usefulness after several sessions. An update is planned according to patient feedback and possible changes in content.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Health Services Research Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Arthritis is associated with pain and disability. As a result there has been some interest in examining the receipt of care among those with arthritis. What has garnered less attention is care giving in this population. The purpose of this study was to describe both care giving and care receipt, and social engagement, in a nationally representative sample of later working age (age 45-64 years) people with arthritis.

### Methods:

Analysis was based on the first wave data from the Canadian Longitudinal Study on Aging (CLSA), a nationally representative sample of people aged 45-85. The questionnaire covers socio-demographic, health, functioning, social, and work variables. Analyses were limited to participants aged 45-64 (n=12,319).

### Results:

Overall, 30% reported arthritis: 4% reported RA, 17% OA, and 9% other arthritis. Arthritis was reported more frequently by women than men. Most people with arthritis were married (75%), and 70% had more than a high school education. A significant proportion (70%) of people with arthritis were overweight or obese. The majority of individuals with arthritis (68%) reported difficulty with at least one daily activity - most frequently were crouching, kneeling or stooping; standing up after sitting; and standing for a long period. More than 85% were currently in the labour force, and most were socially connected (e.g. 80% took part in community-based activities at least once a week).

Taking both informal and formal care together, around 20% of people arthritis in this age group received some form of care, with the majority of care being informal only. A small proportion received professional care - most often assistance around the house (3%) and medical care (2.5%). Overall, 18% received some kind of non-professional assistance: 14% around the house, 11% with transportation, and 10% with

meal preparation. Nearly 60% of the informal care received came from someone living in the same household, and a similar proportion was provided by men and women. Almost half of care had been received for 6 months or less, although 22% reported receiving care for 5 years or more. Over half of individuals with arthritis (53%) reported providing some kind of care to others: 39% gave assistance with transportation, 31% assistance around the house, 25% assistance with meal preparation. Care was most frequently provided to individuals living in another household. Care was provided for a median of 12 weeks in the past year and 5 hours per week. People reporting RA were slightly more likely to report receiving care than those with OA. There was no difference in the proportion with RA and OA giving care.

#### **Conclusion:**

Against a backdrop of substantial limitations in activities, the majority of people with arthritis in the later decades of working life were in the work force and engaged in the community. At the same time, more than half provided care to others, far more than the proportion that received care. The need to provide care and at the same time balance work and a social and family life for individuals with arthritis may impact their ability to care for themselves.

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Socioeconomic factors such as poverty may mediate racial disparities in health outcomes including those of total hip arthroplasty (THA), and confound analyses of differences between blacks and whites.

**Methods:** Using data from a large institutional THA registry, we compared pain and function 2 years after surgery between blacks and whites. The census tract variable “percent of the population with Medicaid insurance coverage” was used to measure community deprivation. We used geocoding to link patients to census tracts, built models that incorporated both individual patient and census tract data, and analyzed the interaction between race and percent of population with Medicaid coverage and its association with patient-reported outcomes 2 years after THA.

**Results:** Black patients, comprising 145/4170 (3%) of THA cases, had worse pain and function scores both at baseline and at 2 years after THA compared to whites (Table 1). There was a strong positive correlation between census tract Medicaid coverage and percent living below the poverty line ( $\rho = 0.69$ ;  $p < 0.001$ ). Racial disparities in 2-year WOMAC pain and function were magnified in communities with a high percentage of the population covered by Medicaid (Table 2). For blacks in these communities, 2-year WOMAC function scores were predicted to be 5.54 points lower (80.42 vs. 85.96) than in blacks from communities with a low prevalence of Medicaid coverage, while scores for whites did not differ between communities. Pain scores were also lower for blacks living in deprived areas, but the difference was not significant.

**Conclusion:** WOMAC pain and function 2 years after THA are similar among blacks and whites in communities with little deprivation (measured as percent of the population with Medicaid insurance coverage). WOMAC function at 2 years is worse among blacks in areas of higher deprivation, whereas this poverty gradient does not impact outcomes among whites.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

A previous study examining patients' expectations of elective foot and ankle surgery found that race is significantly associated with expectations. In this study, using a patient-derived institutional Foot & Ankle Surgery Expectations Survey, we aimed to examine the relationship between patients' preoperative expectations and census tract (CT) socioeconomic factors in addition to race.

### Methods:

All adult patients scheduled for elective foot or ankle surgery by one of six orthopedic surgeons were screened for inclusion between August 2015 and March 2016. Preoperatively, patients completed the Foot & Ankle Surgery Expectations Survey, which contains 23 expectations categories, each rated on a 5-point Likert scale ranging from "I do not have this expectation" to "complete improvement expected", with higher scores (range 1-23) indicating greater expectations. Using geocoding, individual-level registry data was linked to US census tracts data through patient addresses. Simple and multiple linear regression were used to model expectations scores as a function of individual race, and CT median income, Gini coefficient, and percentages of blacks, Hispanics, residents living below poverty, residents living alone, residents with insurance coverage, and residents with Medicaid coverage. The multiple linear regression model used backward selection methodology, requiring 0.05 significance to remain in the final model. An interaction between race and CT poverty was assessed.

### Results:

352 patients (mean age 55±14 years, 66% female) were included in this study. Factors that were significantly associated with higher expectations in univariate modeling were non-Caucasian race, female sex, and census tract percentage of blacks, census tract percentage of Hispanics, census tract percentage of residents with Medicaid insurance, census tract poverty level, and census tract Gini coefficient (all  $p < 0.05$ , Table 1). In multivariable modeling, females scored 5 points higher ( $5.00 \pm 1.93$ ,  $p = 0.01$ ) on the Expectations Survey than males. Caucasians scored nearly 11 points lower ( $-10.98 \pm 3.13$ ,  $p < 0.001$ ) than non-whites. There were no community CT variables that remained significant, and there was no interaction between race and CT poverty ( $p = 0.7$ ).

### Conclusion:

Among patients undergoing diverse procedures in foot and ankle surgery, we found that female sex and non-Caucasian race were independently associated with higher expectations, but community social factors were not significant. These findings may help inform surgeons' preoperative discussions as they address patients' expectations. Future studies are needed to explore whether preoperative expectations scores correlate with postoperative satisfaction, and whether the factors that affect expectations also affect satisfaction.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Healthcare disparities are recognized for surgical outcomes in patients with Limited English Proficiency (LEP) (1). The purpose of this study is to assess the association of LEP on Total Knee (TKR) and Total Hip Replacement (THR) outcomes.

## **Methods:**

Individual patient-level variables – namely, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores at baseline and 2 years after elective TKR and THR – were collected from a single institution registry between 5/07 and 2/11 and analyzed. We used census tract LEP – “Less than very well” as recommended for screening individuals. We obtained census level data using patients’ geocodable addresses (2). Only patients from closest states (NY, NJ and CT) were included (Figure 1). Data was analyzed using univariate and multivariable linear mixed effects models, with census tracts variables treated as random effects.

## **Results:**

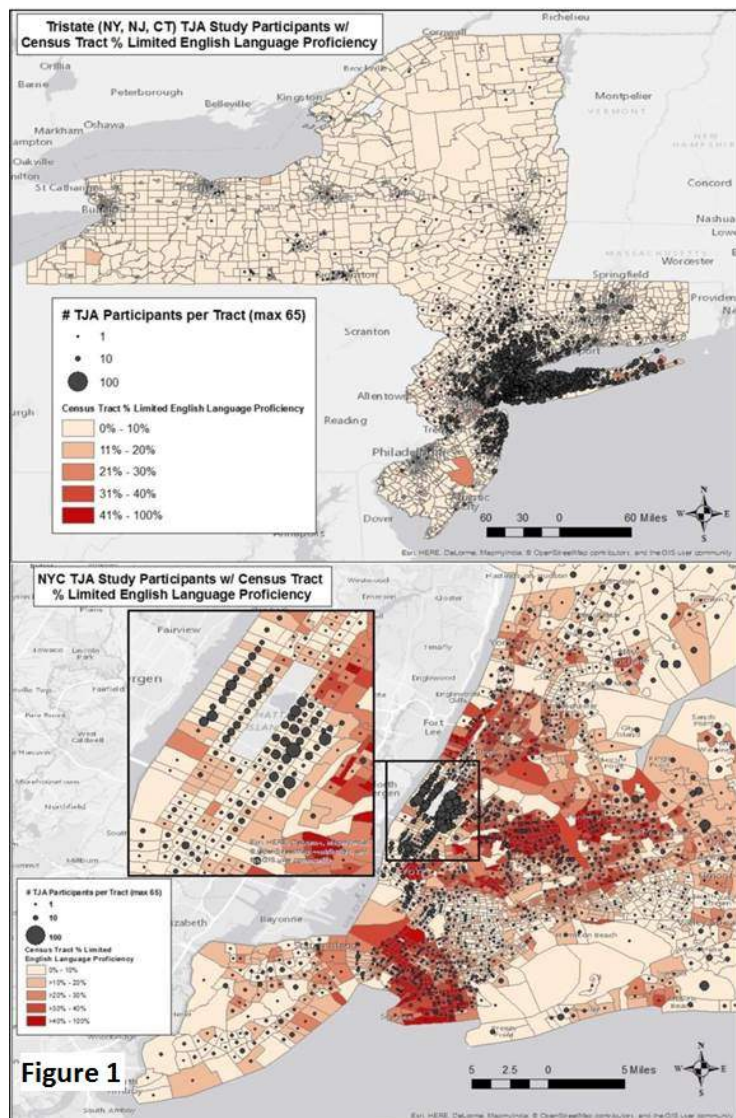

Table 1 describes the characteristics of the patients with THR and TKR. In univariable analyses, for every percent increase in LEP, the WOMAC scores at baseline and 2 year decreased significantly ( $p\text{-value} < 0.001$ ). However when adjusted for neighborhood poverty age, BMI, sex, comorbidities, and the Gini coefficient these changes were not statistically significant, suggesting potential confounders (Table 2). While women had worse baseline and 2-year WOMAC pain and function scores (all  $p \leq 0.04$ ), this difference was not significantly influenced by neighborhood LEP (all  $p_{\text{interaction}} = \text{NS}$ ).

## **Conclusion:**

Patients from LEP neighborhoods have worse pain and function scores in unadjusted models. However when adjusted for potential confounders, the difference is not significant. Community factors contributing to healthcare disparities are multidimensional; thus, further studies examining individual LEP data would be warranted.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

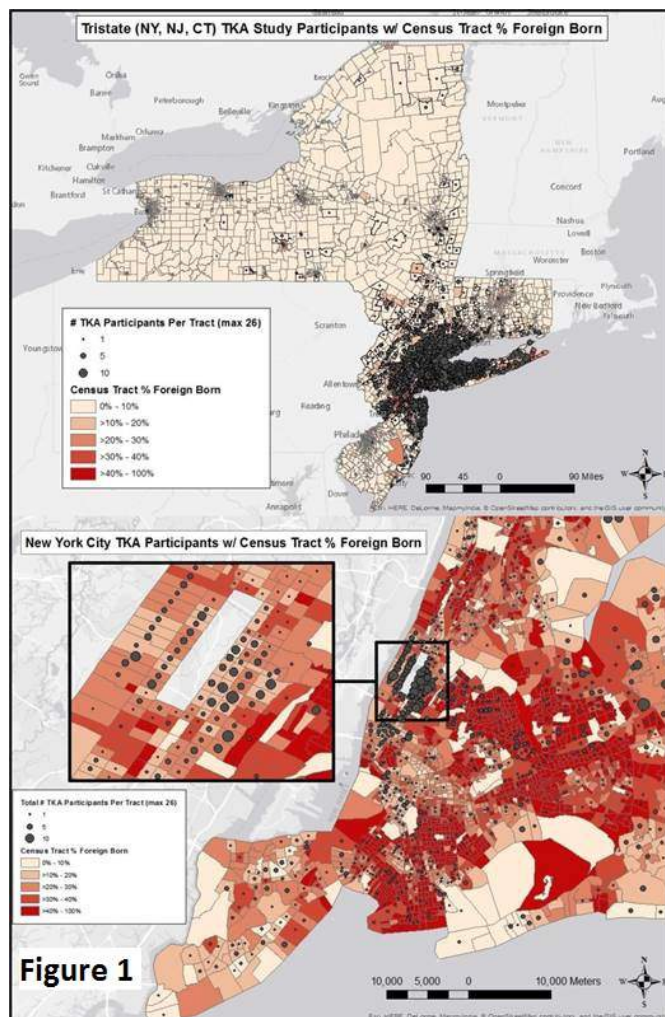

**Background/Purpose:** Social factors affect TKA (total knee arthroplasty) outcomes in osteoarthritis, both at the individual and neighborhood levels. However, prior studies have not evaluated the influence of the proportion of foreign-born individuals within a neighborhood, as reported for other high-cost procedures (1). Our objective was to determine the association of neighborhood foreign-born resident proportion (FBRP) on Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores at baseline and 2 years after elective TKA. We examined if this is different between sexes.

**Methods:** Individual patient-level variables were obtained from a single institution TKA registry from 5/07-1/11, including demographics, baseline and 2 year WOMAC pain and function, and geocodable US addresses. We only included patients living in the hospital's catchment area - i.e. New York, Connecticut and New Jersey (Figure 1). Individual patient-level variables were then linked to US Census Bureau data at the census tract level. Data was analyzed using univariate and multivariable linear mixed effects models, with census tracts variables treated as random effects. A separate linear mixed-effects model was used to assess the interaction between neighborhood FBRP and gender.

**Results:** Table 1 describes the 3,898 TKA cases analyzed. In multivariable analyses, patients from neighborhoods with low FBRP ( $< 10\%$ ) had slightly higher baseline and 2-year WOMAC pain and function scores than those with high FBRP ( $\geq 40\%$ ), but these differences were not statistically significant (Table 2). While women had worse baseline and 2-year WOMAC pain and function scores (all  $p \leq 0.04$ ), this difference was not significantly influenced by neighborhood FBRP (all  $p_{\text{interaction}} \text{ NS}$ ).

**Conclusion:** Patients coming from high ( $>40\%$ ) FBRP neighborhoods present with worse baseline pain and function. Two years later, worse pain and function persist; however, the difference is not significant. Although sex differences favoring males are notable, these differences are not associated with FBRP. Social factor contributions to healthcare disparities are multidimensional, and future studies examining immigration-related neighborhood characteristics may be warranted.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

System Lupus Erythematosus (SLE) is an autoimmune disease that is over-represented in the American Indian (AI) population and often manifests as a more severe disease. Although the clinical manifestations can be diverse, nearly all patients share the presence of autoantibodies, including anti-dsDNA and anti-Sm which have high specificity for the disease. American Indian SLE patients often lack reactivity to autoantigens commonly found in SLE patients of other ethnicities. We have observed that sera from 41% of AI SLE patients contain unidentified autoantigenic reactivity by precipitin testing compared to 24% for AA, 17% for EA, and 23% for HA. Therefore the goal

of this study is to identify non-traditional autoantibody specificities associated with disease in AI SLE patients.

#### Methods:

The sera from 100 AI SLE patients, 37 AI unaffected controls, 16 AI unaffected family members, and 17 AI patients with other systemic autoimmune diseases were screened using a 128 autoantigen protein array. Antigen reactivity based on a mean fluorescence intensity three standard deviations above the average of the unaffected negative controls for that antigen were considered positive. Hierarchical clustering of these data was used to identify shared autoantibody reactivities.

#### Results:

Twenty-two percent (n=22) of all of the positive SLE patients, 19% (n=3) of all positive unaffected family members, and 24% (n=4) of all positive other autoimmune disease samples had reactivity to the M2 mitochondrial antigen typically associated with primary biliary cirrhosis (PBC), an autoimmune liver disease. Furthermore, 91% (n=20) of the M2 positive SLE samples also contained 1 or more autoantibodies specific for or associated with myositis, whereas only 33% (n=1) of M2 positive unaffected family member samples, and 50% (n=2) of the M2 positive samples from individuals with other autoimmune disease contained myositis specific or associated autoantibodies.

#### Conclusion:

This study suggests that M2 and myositis autoantibodies are associated with disease in American Indian SLE patients. Although SLE patients are often diagnosed with more than one autoimmune disease, the coexistence of SLE and PBC or myositis is rare. The study was funded in part by Native American Research Centers for Health.

## Decreased Medication Adherence Is a Major Cause for Increased Risk of Hospitalizations Among High Risk Lupus Patients

Caroline Thirukumaran<sup>1</sup>, Katherine McCarthy<sup>2</sup>, Jessica Patel<sup>3</sup> and Allen P. Anandarajah<sup>4</sup>, <sup>1</sup>orthopedics, University of Rochester Medical Center, Rochester, NY, <sup>2</sup>Pharmacy, University of Rochester Medical Center, Rochester, NY, <sup>3</sup>Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester, NY, <sup>4</sup>Dept of Rheumatology, Univ of Rochester Medical Ctr, Rochester, NY

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low medication adherence in lupus has been associated with increased hospitalizations, more severe disease activity, and irreversible multi-organ damage. While lower socioeconomic levels, education, depression and polypharmacy have been identified as common determinants of non-adherence among patients with chronic diseases, few studies have investigated the rates of medication adherence with lupus.

**Purpose:** To compare medication adherence among patients with lupus at high risk for multiple admissions with all admissions for lupus.

**Methods:** We previously identified 171 lupus patients with a confirmed diagnosis that were admitted to Strong Memorial Hospital between July 1st of 2013 and June 30th of 2015. We then classified a high risk group of 28 lupus patients who had required  $\geq 3$  admissions/ year over the 2 years. For this study we linked the database of all lupus patients with pharmacy claims database for the same period to calculate the medication possession ratio (MPR), an indicator of whether a patient had adequate medication supply in a given time frame. For the bivariate analysis, we used t-tests and chi-square tests to check for the differences in distribution of patient demographics and MPR across the high-risk and non-high risk group. For the multivariate analyses, we estimated hierarchical linear regression models and controlled for the clustering of refills by patient and medication. We also controlled for patient demographics and medication details. We used two-tailed hypothesis tests and p-value<0.05 to indicate statistical significance.

**Results:** The high-risk group was significantly younger (mean age 39.64 years [SD: 19.09] as compared to mean age of 47.57 years in non-

high risk group, (p=0.03), 82% were females compared to 92% in the non-high risk group and the group had significantly higher proportion of African Americans 61% as compared to 41% in the non-high risk group (p=0.05) see Table 1. Complete pharmacy data was available for 102 patients. The mean MPR was lower among the high-risk group (73.40% as compared to 79.93% in the non-high risk group). Our multivariate analysis showed that after controlling for relevant confounders, on average high-risk patients had 10 percent point lower MPR as compared to non-high risk patients (Estimate: -10.41, 95% CI: [-21.36 to 0.54], p=0.06).

**Conclusion:** Medication non-adherence is a major cause of increased risk for admissions among patients with lupus. Targeting measures to improve medication adherence is an important component of the management of patients with lupus.

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is standard therapy for rheumatoid arthritis (RA) and also used to treat other rheumatic diseases. Existing guidelines for RA treatment/ MTX use did not contemplate the realities of resource limited countries. We aimed to understand MTX use patterns and barriers in African countries to inform the development of culturally appropriate guidelines.

**Methods:** We identified African physicians (MDs) from countries classified as low Human Development Index (LHDI) and medium/high HDI (MHDI) by the United Nations Development Programme and who self-identified as MTX prescribers. Each MD participated in a 45 minute semi-structured interview by phone in either English or French regarding their MTX practices.

**Results:** 29 MDs (23 rheumatologists; 6 internists) from 29 African countries were interviewed (17 LHDI; 12 MHDI) representing a population of 1,000.4 million; (LHDI 673.8 million; MHDI 326.6 million). The median (range) of rheumatologists/ million population in these countries was only 0.17 (0-9.4). LHDI countries had significantly fewer rheumatologists/ million population than MHDI (0.1 (0-0.66) vs 1.1(0-9.43)  $p=0.004$ ). MTX was prescribed by non-rheumatologists in 93% LHDI and 67% MHDI countries. Most MDs practised in capital cities and served adult patients. 88% LHDI and 67% MHDI MDs also provided pediatric care. The main indication for MTX use was RA with connective tissue diseases and psoriatic arthritis as secondary indications. Prior to prescribing MTX, most MDs (97%) evaluated patients for pulmonary, hepatic and renal dysfunction and excluded cytopenias. Screening was performed for TB (with CXR) by 62%, HIV by 55% and Hepatitis B/C by 52%. Pregnancy screening was usually by patient self-report (86%). Discussing alcohol consumption was considered pertinent to the local consumption by 42% of MDs. MTX dosing was similar between LHDI and MHDI countries, and usually given with folate (83%). Only 55% of countries had parenteral MTX. 55% of MDs reported barriers to MTX use due to drug availability or costs. Compared to MHDI countries, LHDI countries were more likely to have an inconsistent MTX supply throughout the year (82% LHDI vs 42% MHDI ( $p=0.05$ ) and less likely to have MTX available in the hospital pharmacy (35% LHDI vs 83% MHDI;  $p=0.02$ ). Major contributors to MTX non-adherence included drug cost or availability (85%), lack of prescribers (15%) and patients' beliefs/education/tolerance (37%).

**Conclusion:** The challenges of treating RA patients in African countries with low HDIs are unique. Costs of medical care and drugs, limited subspecialist availability, patient specific beliefs, and lack of MTX are significant challenges faced by MDs treating patients with rheumatic disease. Understanding the African LHDI reality is critical for the development of guidelines to improve care quality and outcomes. Table: Patterns of MTX prescription in Africa. ## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

African countries with a low Human Development Index (LHDI) based on life expectancy, education and income per capita, face competing social, economic, health and poverty related issues that distract from the treatment of chronic conditions such as Rheumatoid Arthritis (RA). Methotrexate (MTX) is standard of care for RA and used for other rheumatic diseases. We sought to determine MTX availability and MTX dispensing practices of pharmacy providers (PP) in Ethiopia, an LHDI country, in order to inform the development of culturally appropriate guidelines for using MTX to treat rheumatic diseases.

### Methods:

The Ecumenical Pharmaceutical Network and the Ethiopian Catholic – Social and Development commission (ECC-SDCO) is the second largest health institution in Ethiopia (next to the public health system) and oversees 83 health institutions of which 52 have a pharmacy department (includes 4 hospitals, 16 health centers and 32 clinics). In September 2016, PP attending the Essentials of Pharmacy Practice course provided by ECC-SDCO were invited to participate in an anonymous survey regarding their experience with dispensing MTX for the treatment of rheumatic conditions. We also conducted a 45 minute semi-structured interview for pharmacists serving the country's sole public rheumatology clinic in Ethiopia. Descriptive statistics are reported from the survey and interview notes.

### Results:

Twenty-three PP (18 pharmacy technicians; 5 pharmacists) from hospitals and health centers of 9 regional states and 2 chartered cities of Ethiopia completed the survey (18/23 were located outside Addis). Seven (32%) worked in a hospital based pharmacy, 12 (55%) in a health centre pharmacy and 3 (14%) in other areas (i.e. clinic pharmacy). The number of years of practice (median (range)) was less for pharmacy technicians compared to pharmacists (4 (1-8) vs 10(6-15)  $p<0.0001$ ). Methotrexate was available in only 3/23 pharmacies (2 were hospital pharmacies) and was only available as oral tablets. Five PP reported that MTX was available in the hospital pharmacy of their region. Only 2/23 PP had dispensed MTX and in both cases it was not for rheumatic conditions. Only 3(13%) PP reported feeling comfortable educating patients on how to take methotrexate, (2 had counseled on MTX, 1 had not, 1 counselled but without confidence). Counselling included need for blood work ( $n=3$ ), folic acid ( $n=3$ ) and alcohol intake ( $n=1$ ). No PP counselled on contraception. While interviewed pharmacists were confident regarding counselling patients on MTX, contraception was not consistently discussed. Additional barriers to prescribing MTX identified by interviewed PP included inconsistent supply and prioritizing use of MTX for non-rheumatologic conditions.

### Conclusion:

Bridging the gap of RA treatment between developed and emerging countries is both a need and a responsibility. The survey and interview identified two key aspects limiting the use of MTX in Ethiopia: a) availability of the drug in pharmacies, and b) confidence of designated pharmacists in supplying and counseling patients for methotrexate. Improved MTX access and recommendations for counselling are needed to increase the confidence of pharmacists in dispensing MTX.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Multiple epidemiological studies ascertained that GCA is one of the most common systemic vasculitis in western countries. But, there is only one study based on 2 patients in Tennessee to assess the low incidence of GCA in African descent (AD) populations. Moreover, very few series are devoted to these patients in the literature. Our objective was to describe the characteristics of GCA and study the incidence in the Afro-Caribbean (AC) population of Martinique, a French region of the West Indies where inhabitants are more than 90% of AD and have free access to health care including a regional competence center for systemic vasculitis.

**Methods:** Population based retrospective study in Martinique. Computed files of the 2 pathology units of the island (public and private) were analyzed to find all patients with a positive temporal arteritis biopsy. All medical files were reviewed to assess the incidence, but only AC patients (self-declared) were included to describe the disease in an African descent cohort.

**Results:** 40 patients had a biopsy proven GCA between 1991 and 2016. Mean age at GCA diagnosis was 75.7 years (SD±7.4; range: 63-91). Main manifestations at diagnosis of the 38 patients of AC origin (30 women, 8 men) were: fever 9.1% (3/33), asthenia 64.5% (20/31), weight loss 75.7% (25/33), headache 69.4% (25/36), jaw claudication 36.3% (12/33), scalp tenderness 35.2% (12/34), anterior ischemic optic neuropathy 31.4% (11/35), stroke 2.9% (1/34), and polymyalgia rheumatica 35.2% (12/34). C-reactive protein was over normal value for 96.8% (n=31; mean value 106.5, range: 7-283). ESR was positive in 86.3% (19/22). Available for 15 patients, CT scan of the aorta and its branches revealed one aortitis and one arteriopathy of lower limbs. All patients were treated by steroids. Twenty three patients (60.5%) were followed >18 months and mean follow up duration was 43.7 months. Eleven patients relapsed. Six patients died (15.8%). Kaplan Meier analysis found 93.9%, 84.6%, 75% survival rates at respectively 6, 12 and 24 months. Crude mean annual incidence of GCA in Martinique was 3.12 cases for 10<sup>6</sup> inhabitants from 1991 to 2016. Mean number of GCA gradually increased from 0.5 patient/year between 1991 and 2000, 1.6 between 2001 and 2010 to 3.8 between 2011 and 2016, parallel to the increasing proportion of elderly in the martinican population (13% was over 60 years old in 1990, 23% in 2016 and official estimation is 39.6% in 2032).

**Conclusion:** This is the first population based description of GCA in an AD population. The features in Martinique are similar to the literature, except for the ischemic complications that seem less frequent in our population. Our data confirm the low frequency of GCA in AD populations compared to Caucasians. The retrospective nature of the study and the absence of negative biopsy GCA could weaken conclusion. We note a progressive increase of annual number of cases during the 25 years of survey, parallel to the accelerated ageing of the martinican population. We could hypothesize that low incidence of GCA in AD populations is at least partially related to the low rate of elderly in most of these populations around the world, and could also increase in the future.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chinese-Americans are a fast growing US immigrant group, and many use Traditional Chinese Medicine (TCM). Ethnic Chinese patients also have worse outcomes in SLE and RA compared to Caucasians. In order to optimally care for this growing population with rheumatic diseases, rheumatologists must have some understanding of patients' traditional cultural beliefs and practices, which may influence medication taking behaviors, and thus ultimately outcomes. TCM use by Chinese-American rheumatology patients has not previously been studied, and whether patient-reported outcomes differ between TCM users and nonusers is unknown.

**Methods:** Subjects were recruited from two rheumatology clinics that serve a predominantly Chinese-American immigrant population. Inclusion criteria were English or Mandarin Chinese fluency and being actively treated for a systemic rheumatic disease. Questionnaires were used to assess TCM use, acculturation, and demographics. Self-reported health status was assessed using Patient-Reported Outcome Measurement Information System (PROMIS®) short forms. Chart review was performed to gather clinical data. Parametric and nonparametric statistics were performed as appropriate. Multivariable logistic regression using step-wise selection was used to examine factors independently associated with TCM use.

**Results:** 230 enrolled, median age 55 years (range 20-97), 65% female, 71%  $\leq$  high school education, 70% Medicaid, and 22% reported English fluency. 50% reported TCM use in the past year, most frequently *tuina* massage (47%), acupuncture (45%), and herbs (37%). 60% of TCM users used TCM to treat rheumatic disease, but only 34% discussed TCM use with the rheumatologist. TCM users had worse scores in PROMIS® anxiety, depression, pain interference, fatigue, physical function, and social health. There was no difference in PROMIS® scores between herb users and nonusers; however more frequent TCM users and those using TCM to treat rheumatic disease had worse pain and function. In multivariable analysis, older age (Odds Ratio [OR] 1.03,  $p=0.04$ ), female sex (OR 2.3,  $p=0.02$ ),  $\geq$  some college education (OR 2.1,  $p=0.04$ ), US residence for  $\geq 20$  years (OR 2.2,  $p=0.03$ ), more anxiety (OR 1.05,  $p=0.004$ ), fewer years since rheumatic disease diagnosis (OR 1.1,  $p=0.01$ ), reporting western medicine to be ineffective (OR 5.3,  $p=0.003$ ), and belief in TCM (OR 2.8,  $p=0.01$ ) were independently associated with TCM use.

**Conclusion:** In this group of Chinese-American rheumatology patients with low education, low socioeconomic status, and poor acculturation, TCM use is common (50%) and is independently associated with older age, female sex, better education, longer US residence, higher levels of anxiety, more recent rheumatic disease diagnosis, perceived ineffectiveness of western medicine, and stronger belief in TCM. Providers should ask Chinese-American patients about TCM use because it may be a proxy for unmet therapeutic needs in this population, as TCM users have worse patient-reported outcomes across many important domains.

## Characterizing Indigenous Community Engagement Patterns in Published Arthritis Studies: A Systematic Review of the Literature

Chu-Yang Lin<sup>1</sup>, Kelle Hurd<sup>1</sup>, Cheryl Barnabe<sup>2</sup> and Adalberto Loyola-Sánchez<sup>3</sup>, <sup>1</sup>University of Calgary, Calgary, AB, Canada, <sup>2</sup>Division of Rheumatology, University of Calgary, Calgary, AB, Canada, <sup>3</sup>Rheumatology, University of Calgary, Calgary, AB, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Indigenous populations in Canada, Australia, New Zealand and the United States of America have a higher prevalence of arthritis conditions and experience worse outcomes. Research can play a pivotal role in identifying and addressing care gaps, and community engagement (CE) approaches are the most promising ways for achieving positive and sustainable impacts. This systematic review characterizes CE patterns in arthritis studies involving Indigenous populations from four countries.

**Methods:** We performed a secondary systematic review (MEDLINE, EMBASE, CINAHL and Indigenous-specific online indexes up to May 2016) that characterized the epidemiology, clinical outcomes, mortality and health services utilization for arthritis in Indigenous populations of the four countries ( $n=5,269$  titles and abstracts). 159 studies met inclusion criteria for the relevant outcomes. Included studies were evaluated for their descriptions of CE at inception of research, data collection, and data usage (i.e. results interpretation and dissemination). Extraction was performed in duplicate using standardized criteria. Descriptions were subsequently mapped onto a CE spectrum adapted from the Beacon for Public Engagement, ranging from the lowest to highest level of engagement: inform, consult, involve, collaborate or empower.

Any studies that reported CE above consultation were assigned with meaningful community engagement (MCE) at the respective stage of research.

**Results:** Of the 159 included studies, 127 were CAN/USA publications and 32 were AUS/NZ publications. Only 32% (n=51) of the 159 included studies reported any description of CE (n=43 CAN/USA, n=8 AUS/NZ). Few studies report CE activities at the inception of research (n=6, 12%), with consultation described in 3 studies and collaboration discussed in 3 studies. In comparison, 98% (n=50) of studies described CE at the data collection stage, which also had the highest frequency of MCE compared to other research stages (n=11 studies). Here, the majority of studies (n=30) reported community consultation, while 11 studies reported involvement or collaboration. Nine studies recruited community members to aid data collection. During data usage, ten studies (20%) described CE, including 4 studies where Indigenous communities were informed or consulted with, and 6 where Indigenous communities were involved or collaborated with. Regionally, the reporting of MCE was concentrated in CAN/USA, with MCE described in all stages of research, whereas publications from AUS/NZ only reported MCE at data collection.

**Conclusion:** The reporting of CE in Indigenous arthritis studies in the specified countries is limited in frequency, with few studies reaching the higher end of the CE spectrum (i.e. collaboration and empowerment). CE was most frequently reported during the data collection stage and is mostly described at the consultation level, which can be reached merely by obtaining informed consent. This reflects researchers' adherence to ethical guidelines rather than a CE effort. Regional differences in CE reporting are likely explained by differences in research policies for Indigenous research. We call for CE guidelines specific to Indigenous rheumatology research.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is not well characterized among Asian Americans, particularly among subgroups of Asians. We aim to compare measures of disease status, including severity, damage, activity, and physical functioning, by race/ethnicity in a diverse SLE cohort.

**Methods:** Data were derived from the California Lupus Epidemiology Study (CLUES), a population based, multi-ethnic cohort of SLE patients in the San Francisco area begun in 2015. SLE was defined according to the 1997 ACR criteria. At baseline, participants had a physician exam that included the SELENA- SLE Disease Activity Index (SLEDAI) and SLICC/ACR Damage Index (SDI). The Lupus Severity Index (LSI) was computed based on the ACR criteria confirmed at the study visit. The LSI assigns a weighted value to each criterion and is scaled 0-10; it has been shown to correlate with disease activity and mortality. Patients completed the SF-36 Physical Functioning (PF) subscale; this scale has a potential range of 0-100, with higher values indicating better function. They also provided self-identified race/ethnicity and details of Asian origin. We compared SLE status measures by race/ethnicity and within subgroups of Asian origin, in regression models controlling for age, disease duration, income < 125% of the federal poverty limit, and gender. Tukey post hoc tests were used to compare the outcomes among Asian subgroups.

**Results:** Among 283 patients, 30% were white, 20% Latino, 11% African American, and 39% Asians. The 102 Asian Americans included 62 Chinese, 23 Filipino and 17 from all other subgroups. Nearly 90% of the cohort were women, with mean age 45±14 and mean disease duration of 16±10 years. Just over half the cohort had some damage (SDI> 0) at baseline. Overall means and distributions of the status measures are shown in the table, along with results from the regression models. Asian Americans in all subgroups had significantly higher LSI scores than whites, as did Latinos and African Americans. However, Asians did not differ from whites in SLICC, SLEDAI or SF-36 PF. Comparing outcomes among the Asian subgroups, the only significant differences were in the SF-36 PF scores, for which Chinese patients had less impairment (mean 48.0) compared to Filipinos (mean 42.1, p=0.02) or other Asians (mean 42.3, p=0.04).

**Conclusion:** In this multi-ethnic cohort, Asians had high disease severity, similar to African Americans and Latinos, but accumulated significantly less damage than these other racial/ethnic groups over time. The social, environmental, biological or health factors leading to this paradox among Asians requires further investigation. With the exception of physical functioning, there were few differences between the Asian subgroups, but this analysis was limited by small sample size and should be further explored as the cohort expands.

**Table. SLE Disease Status Measures by Race/Ethnicity**

	Lupus Severity Index	SLICC Damage Index	SELENA-SLEDAI <i>unadjusted mean±sd (range)</i>	SF36 Physical Functioning
Total (n=238)	6.8 ± 1.6 (3.4-9.5)	1.2 ± 1.6 (0-7)	2.8 ± 2.9 (0-16)	44.1± 11.9 (15-57)
Race/ethnicity		<i>adjusted mean (95% confidence interval) *</i>		
Asian	7.1 (6.8-7.4)**	1.2 (0.9-1.5)	2.8 (2.2-3.3)	46.3 (44.1-48.4)
African American	7.1 (6.6-7.6)**	1.8 (1.2-2.3)**	2.5 (1.5-3.5)	38.2 (34.3-42.1)**
Hispanic	7.2 (6.9-7.6)**	1.3 (1.0-1.7)	3.2 (2.5-3.9)	42.0 (39.4-44.7)
White	6.2 (5.9-6.5)	0.8 (0.5-1.2)	2.7 (2.1-3.3)	45.4 (43.0-47.8)
p-value				
(diff by race/ethnicity)	<0.001	0.02	0.67	0.001
* Adjusted for age, gender, disease duration, poverty level income (<125% federal poverty limit).				

\*\* Results significantly different from Whites for indicated measure.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** PROs play a prominent role in evaluating patient status in rheumatic diseases. PROs often reveal disparities in individuals with low education or income or among racial/ethnic minorities. Limited health literacy (LHL) may also be more prevalent in these groups. While some have acknowledged that LHL may create challenges in disease management, the impact of LHL on PROs has received little attention. We examined the impact of LHL on PROs in a diverse SLE cohort.

**Methods:** Data were from the California Lupus Epidemiology Study (CLUES), a population-based, multi-ethnic SLE cohort (n=281). Subjects participated in an in-person research clinic, in which study physicians completed the SLEDAI and SLICC Damage Index (SDI), and completed a structured interview administered by a trained interviewer, in which the following PROs were administered: SF-36, short forms of ten PROMIS domains, and self-reported measures of disease damage and activity (Table). Health literacy was assessed using a 3-item validated scale<sup>1</sup>. Individual education and household income were self-reported. Bivariate analyses examined differences in all PROs by education level (≤12 yrs vs. >12 yrs), income (≤125% of federal poverty level for household size vs. >125%), and LHL using t-tests. Multivariate linear regression analyses examined differences in PROs by LHL controlling for age, sex, race/ethnicity, disease duration,

SLEDAI, SDI, education, and income.

**Results:** The sample was 29% white (W), 23% Hispanic (H), 11% African American (AA), and 37% Asian (AS); 89% female; mean age 45 ( $\pm 14$ ) years; 22% with education  $\leq$  high school; 12% with poverty-level income; mean disease duration 16 ( $\pm 10$ ) years. 85% of interviews were completed in English. 35% had LHL, with significant differences by race/ethnicity (W 21%, AS 36%, AA 42%, H 46%,  $p < .01$ ). Physician assessments of SLE activity and damage were not significantly different by health literacy ( $p > 0.50$ ). Bivariate analyses showed significant differences in all PROs by LHL and income, but few differences by education. In multivariate analyses, significant differences by LHL remained in all PROs except self-reported disease damage, even after controlling for all covariates including income and education (Table).

**Conclusion:** Individuals with SLE and LHL had worse status as measured by a wide range of PROs, even after accounting for physician-assessed disease, income, education, and race/ethnicity. Whether differences are due to unmeasured effects of LHL or to differential interpretation of PRO measures by individuals with LHL is unknown. However, findings suggest that attention to health literacy is crucial in the development and validation of PROs to ensure that variations in scores reflect actual differences in the underlying construct and not differential understanding or interpretation of the questions.

## **Long Term Survival of Biological Agents in Patients with Axial Spondyloarthritis. the Impact of Sociodemographic Factors in Latin-America**

**Magdalena Cavalieri**<sup>1</sup>, Emilce E Schneeberger<sup>2</sup>, Fernando Dal Pra<sup>1</sup>, Rodrigo Garcia Salinas<sup>3</sup>, Hernán Maldonado Ficco<sup>4</sup> and Gustavo Citera<sup>1</sup>, <sup>1</sup>Section of Rheumatology, Instituto de Rehabilitación Psicosfísica, Buenos Aires, Argentina, Buenos Aires, Argentina, <sup>2</sup>Instituto de Rehabilitación Psicosfísica, Buenos Aires, Argentina, Buenos Aires, Argentina, <sup>3</sup>Section of Rheumatology, Hospital Italiano de La Plata, Buenos Aires, Argentina, La Plata, Argentina, <sup>4</sup>Section of Rheumatology, Hospital San Antonio de Padua, Córdoba, Argentina, Córdoba, Argentina

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The introduction of biological agents improved the prognosis of axial Spondyloarthritis (axSpA). The Lund Efficacy Index (LUNDEX) allows evaluation of both survival and efficacy of drugs. Our aims were to evaluate the long-term efficacy of biological disease modifying drugs (b-DMARD) in axSpA using the LUNDEX, compare them and to determine the variables associated to the discontinuation of these treatments. **Methods:** Patients  $\geq 18$  years old who met ASAS 2009 criteria for axSpA and who started b-DMARD for the first time between 01/2002 and 12/2016 were included. Sociodemographic variables, comorbidities, type of axSpA, disease duration and previous treatments were registered. Duration of therapy, causes of its suspension, efficacy and safety were evaluated. BASDAI was assessed at baseline and during the treatment and LUNDEX was calculated at 6 months and at 1 year of treatment using BASDAI cut-off  $<4$  as efficacy endpoint. Cumulative drug survival was assessed by Kaplan Meier curves and comparisons using log Rank. **Results:** We included 101 patients. 80.2% were male, with a median age of 42 years (IQR 35-54.5), and median disease duration of 19.3 years (IQR 9.4-28.8). 26.7% of patients didn't have health insurance. 63.4% had pure axSpA, 13.8% Psoriatic Arthritis, 3% Reactive Arthritis, 3% Inflammatory Bowel Disease and 16.8% Juvenile axSpA. The frequency of first b-DMARD was: 44.6% Etanercept (ETA), 41.6% Adalimumab (ADA), 7.9% Infliximab and 5.9% Certolizumab. 67.3% received b-DMARD monotherapy. BASDAI significantly improved over time. The mean (X) cumulative survival time was 66.2 months (95%CI: 51.8-80.5). ADA survival was longer than ETA one [ADA X 74.8 months (95%CI: 57.2-92.4) versus ETA X 53.2 (95%CI: 35.8-70.6)  $p = 0.02$ ]. The causes of suspension were: lack of provision of the medication 41.1%, inefficacy 26.8%, adverse events 12.5% and other reasons 19.6%. Mean cumulative survival time was lower for ETA vs ADA ( $53,18 \pm 8,8$  vs  $74,8 \pm 8,9$ , Log Rank=0.02), being the main cause the lack of provision of the medication. In multivariate Cox regression analysis, after adjusting for other factors, having private health insurance was the only factor that influenced on the survival of the b-DMARD (HR 2.54, 95%CI 1.18-5.75). The global LUNDEX was 52.7% at 6 months and 46.9% at 12 months. The ADA LUNDEX was 50% at 6 months and 39.3% at 12 months, while ETA LUNDEX was 60,2% at 6 months and 52% at 12 months. **Conclusion:** In our cohort of patients with axSpA, survival time of b-DMARD was clearly affected by socio-economic factors. Patients who can afford a private health insurance are more likely to persist with medication.

## **The Charla De Lupus (Lupus Chat)® Program: Assessing the Needs of Teens and Young Adults with Lupus and Their Caregivers to Develop a Family Model Nutrition and Fitness Intervention**

**Melissa T. Flores**<sup>1</sup>, Jillian Rose<sup>2</sup>, Priscilla Toral<sup>1</sup>, Lillian Mendez<sup>1</sup>, Dariana M. Pichardo<sup>1</sup>, Roberta Horton<sup>1</sup> and Lisa F. Imundo<sup>3</sup>, <sup>1</sup>Social Work Programs, Hospital for Special Surgery, New York, NY, <sup>2</sup>Hospital for Special Surgery, New York, NY, <sup>3</sup>Pediatrics, Columbia University Medical Center, New York, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Studies show Hispanics/Latinos are significantly impacted by health disparities, with higher rates of obesity & diabetes than Whites. Combined with SLE & higher risk for related health conditions, culturally tailored nutrition & fitness education efforts are warranted. A nutrition & fitness needs assessment was conducted for teens & young adults with SLE & their loved ones who participate in a bilingual hospital-based SLE support & education group. The program reported on a SLE specific nutrition intervention at ACR/ARHP in the past, & for the last 3 years, program evaluation data showed that nutrition was rated one of the top 5 topics.

### **Methods:**

Two 72-item surveys with Likert scale, multiple choice & open-ended questions were conducted for teens/young adults (T/YAs) & parents/caregivers (Ps). Questions covered demographics, food intake, MyPlate food guide & food labels, exercise, & interest in a nutrition/fitness program. Separate analyses were conducted for T/YAs & Ps.

## Results:

There were 147 surveys distributed electronically, 31% completed (55% T/YAs & 45% Ps). Over half (59%) were Hispanic, 30% White, 28% some other race, 25% Black/African American, 10% American Indian & 6% Asian. T/YAs mean age was 24 & 85% female. Most T/YAs (65%) were diagnosed < 10 years ago. Top reported lupus symptoms were joint pain (72%), fatigue (64%) & muscle weakness (56%). Top reported lupus medications were plaquenil (84%) & steroids (48%). Most T/YAs (54%) & Ps (90%) reported that their diet was “good,” but shared they would like to eat healthier (88% & 100%). T/YAs (30%) reported drinking ≤ 3 glasses of water a day & 22% reported consuming a sugary beverage daily.

While most T/YAs & Ps heard about MyPlate (87% & 72%), only 25% T/YAs & 46% Ps knew that it had 5 food groups. Ps (94%) reported ↑ desire to learn how to use food labels, while T/YAs (87%) had ↑ confidence in their ability to use food labels.

When asked about exercise, 74% T/YAs & 67% Ps reported that they exercised & 63% indicated that a MD suggested they do physical activity. However, 83% Ps & 61% T/YAs did not feel they were at ideal weight. Most respondents (94% Ps & 80% T/YAs) were interested in learning more about nutrition/exercise, & 88% Ps & 70% T/YAs expressed specific interest in a team nutrition/exercise program.

When asked about nutrition goals, Ps responses included “eating less fast foods” & “learn new ways to cook healthy.” T/YAs focused on “build bone mass due to osteoporosis” & “maintain a good weight.” When asked about fitness goals, Ps desired to exercise regularly & T/YAs indicated a desire to lose weight. When asked about motivation, the top 2 answers for both T/YAs & Ps were group activities (93% & 80%) & a coach/trainer (87% & 86%). Similarly, both groups reported that they would prefer to track their progress by cell phones (100% & 71%) & 52% preferred texting.

## Conclusion:

Despite a small sample size, results show that nutrition & fitness are areas of concern for both T/YAs with SLE & Ps, with opportunities to increase nutrition/fitness knowledge & activity. Results reveal that participants were interested in a group-based nutrition/fitness program that is culturally tailored. Next steps are to organize focus groups with participants to discuss specific interventions.

## Engaging Community Stakeholders through a National Lupus Education Workshop

**Karen Mancera Cuevas**<sup>1</sup>, Rosalind Ramsey-Goldman<sup>2</sup>, Sheryl McCalla<sup>3</sup>, Patricia Canessa<sup>4</sup> and Zineb Aouhab<sup>1</sup>, <sup>1</sup>Rheumatology, Northwestern University, Chicago, IL, <sup>2</sup>FSM, Northwestern University, Chicago, IL, <sup>3</sup>American College of Rheumatology, Atlanta, GA, <sup>4</sup>Illinois Public Health Association, Springfield, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The Popular Opinion Leader (POL) model based on health education theoretical foundations associated with Social Network Theory and Diffusion of Innovation was successfully piloted in several local Hispanic communities. The initial aim of the pilot problem was to develop and teach a core curriculum to address lupus health disparities and a second aim in conjunction, with the American College of Rheumatology and an Office of Minority Health funded grant, 1-CPIMP-151087-01-00 was to disseminate the program as a workshop in May 2016 to engage stakeholders in other targeted communities in the United States that served African American and Native American constituents. The target audience for the curriculum were POLs or Community Health Worker (CHW) equivalents.

### Methods:

The multidisciplinary project team who provided training in the POL model included the Project Director who is a rheumatologist, a community Field Director who is a psychologist with cultural competency expertise, a rheumatology trainee, and the POL project manager.

The 14 stakeholders who are involved in ongoing lupus health disparities projects participated in the workshop training and they represented a wide range of institutions including community based organizations, academic centers and the ACR. The day long workshop included training of fundamental concepts, curriculum design, application exercises incorporating theory, community practice, and project dissemination adapting culturally-competent practices. Training was done in lecture format and interactive roundtable discussions. Participants completed a qualitative assessment of the workshop at the end of the training sessions.

### Results:

Thirteen of fourteen participants responded questions covering workshop purpose and objectives, clarity and appropriateness of the workshop presentation, roundtable interactivity, participant involvement, use of workshop time, and overall satisfaction. Additionally, open-ended questions were provided on expanding on the workshop strengths and weaknesses, and suggestions/additional comments on this workshop.

All respondents agreed that objectives were clearly stated and that all meeting participants were actively involved and satisfied with the workshop. The majority of respondents reported that the workshop was clear and relevant, that the round table discussions were interactive, and that there was shared decision-making in the workshop. The main shortcoming reported was that there were concerns about effective use of meeting time as some presentations during the workshop were longer than originally programmed.

### Conclusion:

The major finding from the workshop is that participants were overall satisfied with their participation, programming of the event, particularly the roundtable discussion activities. Future directions include building on the initial workshop and based on future funding expand the learning experience to lupus-specific stakeholders. In future iterations of the workshop, it will be important to follow-up with program participants to assess program impact.

## Impact of Arthritis Among Populations with Chronic Health Conditions in Rural Counties of the United States – 2015

Michael Boring<sup>1</sup>, Louise Murphy<sup>2</sup>, Jennifer M. Hootman<sup>3</sup> and Yong Liu<sup>2</sup>, <sup>1</sup>Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, <sup>2</sup>Division of Population Health, Centers for Disease Control and Prevention, Atlanta, GA, <sup>3</sup>Centers for Disease Control and Prevention, Kennesaw, GA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Healthcare Disparities in Rheumatology Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** US rural populations have well documented health disparities, including higher prevalence of chronic health conditions; however, arthritis prevalence among those with other chronic conditions is unknown. We estimated prevalence of arthritis and arthritis-attributable activity limitations (AAAL), among those with chronic health conditions in rural areas using 2015 Behavioral Risk Factor Surveillance System (BRFSS) data.

**Methods:** BRFSS is an ongoing, state-based, random-digit-dialed landline and cellphone survey of the noninstitutionalized adult population aged ≥18 years of the 50 states, the District of Columbia (DC), and the U.S. territories. Respondents had arthritis if they answered “yes” to “Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?” Among adults with arthritis, AAAL was identified by a “yes” to “Are you now limited in any way in any of your usual activities because of arthritis or joint symptoms?” Rural categories were created using the National Center for Health Statistics 2013 Urban-Rural Classification Scheme for Counties; we used 2 rural county classification categories: micropolitan (large rural [LR]) and noncore (small rural [SR]). Age-standardized prevalence of arthritis and AAAL were estimated by rural categories among those with each of 9 common chronic health conditions (hypertension, coronary artery disease [CAD], obesity, diabetes, chronic obstructive pulmonary disease [COPD], depression, asthma, cancer, and chronic kidney disease [CKD]). All analyses accounted for BRFSS’ complex sampling design.

**Results:** Overall, arthritis prevalence was high in rural populations with chronic health conditions (range = 36.0-56.0%). In SR areas,

arthritis prevalence was particularly high among those with CKD (53.6%), COPD (51.6%), stroke (49.5%), and CAD (49.5%). In LR areas, arthritis prevalence was highest among those with CAD (56.0%), COPD (54.8%), and CKD (50.7%). Overall, AAAL prevalence among those with arthritis and  $\geq 1$  chronic condition ranged from 58.4 to 76.5%. In SR areas, age-standardized AAAL prevalence was highest among those with arthritis and depression (71.2%), COPD (68.8%), CAD (65.8%), and stroke (65.5%). In LR areas, AAAL prevalence was highest among those with depression (66.1%), COPD (71.9%), CAD (69.9%), and stroke (76.3%).

**Conclusion:** In rural areas, arthritis commonly occurs with other chronic conditions; for some more than half had arthritis. Individuals with arthritis and chronic conditions in rural areas are significantly impacted by arthritis with roughly 2 in 3 reporting AAAL. Strategies that reduce arthritis impact include weight loss, routine physical activity and participation in self-management education courses (e.g., Chronic Disease Self-Management Program); these approaches also reduce adverse effects of co-occurring chronic conditions. By recommending these strategies to their patients, health care providers can simultaneously manage the impact of arthritis and other chronic conditions. Our results indicates the high need for these self-management strategies among rural adults.

## **MRI in Rheumatoid Arthritis: Does Quantifying the Number of Erosive Lesions Improve Detection of Subtle Erosive Progression Compared to the Omeract RA MRI Scoring System?**

Ulf Sundin<sup>1</sup>, Anna-Birgitte Aga<sup>2</sup>, Tore K Kvien<sup>3</sup>, Siri Lillegraven<sup>4</sup> and Espen A. Haavardsholm<sup>4</sup>, <sup>1</sup>\*Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, <sup>2</sup>Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, <sup>3</sup>Diakonhjemmet Hospital, Oslo, Norway, <sup>4</sup>Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early detection of erosive progression is an important application of MRI in RA. For research purposes the OMERACT Rheumatoid Arthritis MRI Scoring system (RAMRIS) is commonly applied, with semi-quantitative assessment of erosive volume. However, over time new erosive lesions can occur without sufficient increase in volume to result in a higher score. This could allow for subtle erosive progression to go undetected. We aimed to examine if quantifying the number of erosions in addition to erosive volume could provide improved sensitivity to change.

**Methods:** In a cohort consisting of 84 patients, all fulfilling the 1987 ACR criteria for RA, with disease duration of  $< 1$  year, MRI of the dominant wrist was acquired at 0, 3, 6, and 12 months. A trained reader, blinded for patient data, scored the MRI images in known chronological order according to the RAMRIS method. In addition, we registered the number of erosive lesions at each site. The 78 patients who had completed at least the baseline and 6- or 12-month exams were by each method identified as either progressors or non-progressors, using an increase of 1 unit as cut-off value. The results were compared using cross tables and Spearman correlation.

**Results:** The median baseline age (25th, 75th percentile) was 58.1 (47.3, 66.4) years, disease duration was 107 (70, 186) days, 77% were female, and 55% were anti-CCP positive. Median baseline RAMRIS erosion score was 8 (5, 11) and the median number of MRI erosions was 10 (6, 14). Median 1 year change in RAMRIS erosion score was 1 (0, 2), and median change in number of erosions was 1 (0, 2). Both methods identified an equal number of patients as progressors, and agreement was observed in 82% of cases. Seven patients were progressors by the RAMRIS method only and 7 by the counting erosive lesions method only (table). The Spearman correlation coefficient of the two scores was 0.75,  $p < 0.001$  (figure).

Table				
Cross-table showing progressors and non-progressors as identified by the two scoring methods				
Progression in RAMRIS erosion score	Progression in number of erosions			
		Yes	No	Total
	Yes	38	7	33
	No	7	26	45
Total		33	45	78

**Conclusion:** The RAMRIS erosion score was generally low, both with respect to baseline level as well as progression rate. By supplementing the assessment with quantification of the number of erosive lesions, we could in this material identify a limited number of additional patients as progressors. Further longitudinal studies could show to what extent patients with this type of early minimal erosive lesions on MRI progress on conventional radiographs, and if this is clinically important.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess whether magnetic resonance imaging (MRI) inflammation and damage in the wrist and hand of rheumatoid arthritis (RA) patients are associated with patient-reported outcomes (PROs) at clinical remission and relapse.

**Methods:** MRIs of the right wrist and hand were obtained in 114 patients with established RA in sustained clinical remission (>1 year), before tapering their biologic disease-modifying antirheumatic drug. MRIs were assessed according to the Outcome Measures in Rheumatology (OMERACT) RA MRI score (RAMRIS) for inflammation (synovitis/tenosynovitis/osteitis) and damage (bone erosions/joint space narrowing (JSN)) at baseline (i.e. remission, n=114) and in case of a relapse (n=70). Status and change MRI-scores were assessed for associations with patient-reported physical function (health assessment questionnaires (HAQ)), visual analogue scales for global disease activity and pain, EuroQol 5 dimensions and Short Form 36 physical and mental component summary (SF-36 PCS/MCS) using Spearman correlations, and in univariate/multivariable linear regression analyses including generalized estimating equations. C-reactive protein and swollen joint counts were forced into the models. MRI features were also assessed for trends against specific hand-related HAQ-items using Jonckheere trend tests.

**Results:** MRI-assessed bone erosion, JSN and combined damage score were associated with impaired PROs, mainly HAQ and SF-36 PCS at clinical remission and relapse ( $p<0.01$ ), independent of clinical measures. The levels of bone erosions and JSN were associated with the level of the HAQ score in 4 of 5 hand-related HAQ-items ( $p<0.05$ ). MRI-assessed inflammation was generally not associated with PROs at remission or relapse.

**Conclusion:** In patients with established RA MRI-assessed wrist and hand damage, but not inflammation is associated with patient-reported physical impairment at clinical remission and relapse, and the amount of damage in the wrist and hand is associated with reduced function of the hand.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although the European League Against Rheumatism (EULAR) response criteria based on the Disease Activity Score (DAS) 28 has been widely used for assessment of treatment response in clinical trials for rheumatoid arthritis (RA), it is still unclear whether it is indeed reflected by the change of synovitis severity. Musculoskeletal ultrasonography (US) is now one of the standard tools for the diagnosis and monitoring of active synovitis. Here, we investigated the association between the EULAR response criteria and the US assessment in monitoring RA activity.

**Methods:** Power Doppler (PD) US was performed in 24 joints, including all PIP, MCP, bilateral wrist and knee joints, as comprehensive evaluation in 23 RA patients treated with certolizumab pegol (CZP;  $n = 15$ ) or tofacitinib (TOF;  $n = 8$ ). Before and after treatment with CZP or TOF, PD signals and gray-scale (GS) images were scored semiquantitatively from 0 to 3 in each joint. Total PD score-24 and total PD score-8 were calculated by summing up PD scores of the 24 joints and the selected 8 joints (bilateral second and third MCP, wrist, and knee joints), respectively. Total GS score-24 and total GS score-8 were also calculated by summing up GS scores of the 24 joints and the selected 8 joints, respectively.

**Results:** Among the 23 patients, no response was shown in 5, moderate response was in 12, and good response was in 6 patients by EULAR response criteria. The change of total PD score-24 by treatment with CZP or TOF was significantly different between the patients with no response and moderate response ( $1[\text{interquartile range } (-2)-(-2)]$  vs  $-5[(-11)-(-1.75)]$ ,  $p = 0.012$ ) or good response ( $1[(-2)-(-2)]$  vs  $-8[(-9.75)-$

(-7)],  $p = 0.0043$ ). The change of total PD score-8 was also significantly different between the patients with no response and moderate response (1[(-2)-(-2)] vs -3.5[(-7.25)-(-1.75)],  $p = 0.012$ ) or good response (1[(-2)-(-2)] vs -6.5[(-7.75)-(-5.25)],  $p = 0.0022$ ). The change of total GS score-24 and total GS score-8 were significantly different between the patients with no response and good response (-2[(-2)-(-1)] vs -9[(-16.5)-(-4.5)],  $p = 0.011$ , and -1[(-1)-(-1)] vs -6[(-8)-(-4)], 0.0022, respectively). Among the patients with no response, 2 (40%) showed decrease in total PD score-24 and total PD score-8, and 3 (60%) and 4 (80%) showed decrease in total GS score-24 and total GS score-8, respectively. Among the patients with moderate response, 2 (17%) showed no improvement in total PD score-24 and total PD score-8, and 3 (25%) and 5 (42%) showed no improvement or even increase in total GS score-24 and total GS score-8, respectively. Thus total 4 (17%) and 6 (26%) showed discrepancy between EULAR response criteria and 24-joint US assessment.

**Conclusion:** Although this study indicates the relationship between EULAR response criteria and US assessment as a whole, there are some cases showing discrepancy between these two assessment methods in monitoring RA activity. Thus the US assessment can be an essential method for monitoring response to treatment in RA patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Efficacy of cycling of TNF inhibitors, judged by composite measures, is inferior to non-TNF biologics in patients with RA inadequate response to previous TNF inhibitors (TNF-IR patients). Ultrasonography (US) is a non-invasive imaging method to evaluate activity of synovitis more accurately than physical examinations, however, no previous reports have examined comparative efficacy of alternate TNF inhibitors or non-TNF biologics in RA patients inadequate response to previous TNF inhibitors by US. The aim of this study is to determine whether US find the difference of efficacy in switching to cycling TNF inhibitors compared to non-TNF biologics in TNF-IR patients.

**Methods:** We have investigated the above-mentioned comparison by the administrated RA patients in Kyushu multicenter rheumatoid arthritis ultrasound prospective observational cohort in which bilateral 22 wrists and finger joints were semi-quantitatively examined every 3 months by grey-scale (GS) and power Doppler (PD) from 0 to 3. US disease activity was determined as sum of GS or PD score (total GS score or PD score; 0-66, respectively). Among the 223 patients who registered and completed the first 12 months observation, thirty-nine subjects were classified as switched to alternate TNF inhibitors (N = 11) or non-TNF biologics (N = 28) as second bDMARDs. We compared the efficacy of alternate TNF inhibitors group with non-TNF biologics group by US for 12 months using LOCF analysis.

**Results:** The characteristic of both groups at study entry was comparable including DAS28-ESR, duration of diseases, positivity of ACPA or RF and sum of GS and PD score. Drug retention rate at 12 months was superior in non-TNF biologics group compared to alternate TNF inhibitors group. Accordingly, sum of US score, especially PD score, clearly decreased in non-TNF biologics group whereas did poorly change in alternate TNF inhibitors group (Fig. 1). Change of DAS28-ESR was also more prominent in non-TNF biologics group compared to alternate TNF inhibitors group.

**Conclusion:** Our data confirm the previous clinical finding by US, especially PDUS, that switching to non-TNF biologics is more effective than cycling TNF inhibitors as a second choice of bDMARDs in TNF-IR patients.

Figure 1. PD score decrement is clear in non-TNF biologics group compared to alternate TNF inhibitors group

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Early diagnosis of rheumatoid arthritis (RA) is important for controlling disease activity and preventing joint damage. Individuals positive for anticitrullinated protein antibodies (ACPA) and/or rheumatoid factor (RF) are at risk of developing RA. In this study we investigated whether ultrasound (US) can predict development of arthritis in seropositive arthralgia patients.

### Methods:

We included ACPA and/or RF positive patients with arthralgia, but without clinical arthritis. US was performed at baseline in 12 joints: bilateral MCP2-3, PIP2-3, wrist and MTP5. Images were scored semiquantitatively for synovitis and Power Doppler (PD) on a scale of 0-3. Grades 2 to 3 for synovitis and grades 1 to 3 for PD were regarded as abnormal. The association of ultrasound abnormalities with the development of arthritis was analyzed using Fisher's exact test, expressed as odds ratios (OR) with 95% confidence interval (CI). Kaplan

Meier survival analysis with log-rank test and Cox regression analysis were used to assess the timing of arthritis development, expressed as median time to arthritis and hazard ratios (HR) with 95% CI.

## Results:

In total, 169 seropositive arthralgia patients underwent US examination. Mean age was 51 (standard deviation (SD) 11) and 73% was female. Of these patients, 44 (22%) developed arthritis during a mean follow-up time of 27 (SD 19) months. Thirty seven (84%) patients developing arthritis satisfied the 2010 ACR/EULAR classification criteria for RA. Synovitis and PD signal in at least one joint was observed in 14 (8%) and 7 (4%) patients, respectively. The presence of synovitis was associated with arthritis development (OR 8.9, CI 2.6-30.2,  $p<0.01$ , Table 1), whereas the presence of PD signal was not (OR 1.1, CI 0.2-6.1,  $p=1.0$ ). Corresponding positive predictive values were 71% and 29%, respectively. Patients with synovitis or PD in at least one joint developed arthritis earlier than patients without US abnormalities (synovitis: median time to arthritis 11 versus 14 months,  $p<0.01$ ; PD: median time to arthritis 5 versus 12 months,  $p<0.01$ ; Fig 1) with corresponding HRs of 3.5 (CI 1.5-7.9,  $p<0.01$ ) and 6.9 (CI 1.5-32.2,  $p<0.02$ ) respectively.

## Conclusion:

Synovitis on US predicted arthritis development in seropositive arthralgia patients. This association was not found for PD, however PD frequency was low and therefore the power to predict arthritis was low. However, when taking into account the time to arthritis development, both synovitis and PD were associated with an increased hazard on developing arthritis.

Table 1. Association of ultrasound abnormalities with arthritis development

US abnormalities	Arthritis – n=125	Arthritis + n=44	OR (95% CI)	p-value	PPV
Synovitis*	4 (3%)	10 (23%)	8.9 (2.6-30.2)	$p<0.01$	71%
Power Doppler*	5 (4%)	2 (5%)	1.1 (0.2-6.1)	$p=1.0$	29%

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Joint destruction in rheumatoid arthritis (RA) includes both bone and cartilage lesions. By X-ray examination, cartilage destruction is evaluated as the joint space narrowing (JSN). However, JSN is not a direct evaluation of cartilage. Previously we have confirmed the usefulness of the direct imaging of finger joint cartilage thickness (FJCT) by ultrasound (US). Then we aimed to evaluate the FJCT by semiquantitative US score and clarify its clinical significance in patients with RA.

**Methods:** We enrolled 53 RA patients in low disease activity or clinical remission (DAS28-CRP < 2.7) in this study. The FJCT of metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints of 2nd to 5th fingers was bilaterally visualized and measured at the middle portion of MCP and PIP joints from a longitudinal dorsal view, with approximately 90 degrees flexion. Furthermore, one US examiner performed the semiquantitative scoring of the recorded cartilage images in a blinded manner on a scale of 0–2 (0 = normal, 1 = minimal, and 2 = severe)<sup>1</sup>. In addition, the JSN of fingers was scored by van der Heijde-modified Sharp method with a hand X-ray obtained within 2 months of US examination. The relationship among the total FJCT, the semiquantitative FJCT score and the JSN score were assessed by Spearman's rank correlation coefficient.

**Results:** The total FJCT from 8 fingers ranged from 4.0 to 8.8 mm (median 6.7 mm), which was significantly correlated with the semiquantitative score ( $\rho = -0.681$ ,  $p < 0.001$ ). And both total FJCT and semiquantitative score were significantly correlated with the total JSN score ( $\rho = -0.684$ ,  $p < 0.001$ , and  $\rho = 0.639$ ,  $p < 0.001$ , respectively). The semiquantitative score was associated with disease duration ( $\rho = 0.347$ ,  $p = 0.011$ ), especially for MCP joints ( $\rho = 0.453$ ,  $p < 0.001$ ), but not for PIP joints ( $\rho = 0.071$ ,  $p = 0.614$ ). Age, height and seropositivity were not associated with semiquantitative FJCT score and JSN score.

**Conclusion:** A simplified and direct evaluation of cartilage damage by semiquantitative US score is valid and useful in patients with RA.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

The AMP-RA network applies cutting edge technologies to the study of tissue obtained by ultrasound guided synovial biopsy from patients with rheumatoid arthritis (RA). Ultrasound provides objective joint level measures of synovial inflammation, including hypertrophy (greyscale ultrasound, GSUS) and hyperaemia (Power Doppler ultrasound, PDUS). Furthermore, ultrasound joint count assessments enable higher sensitivity for measurement of systemic disease activity compared to clinical joint assessments alone. We examined the relationship between joint level ultrasound variables and synovial histology in Phase I patients with active RA. we also validated ultrasound measures against conventional measures of disease activity.

## Methods:

During Phase I of AMP-RA we recruited patients fulfilling clinician RA diagnosis, 1987 or 2010 ACR/EULAR RA criteria with at least one joint amenable to biopsy. Patients were required to have a CDAI $\geq$ 10; patients receiving i.a. steroids in the previous 4 weeks, i.m. in the last 8 weeks or oral steroids >10mg were excluded. 12 joint extended ultrasound assessments of 10 MCPs and 2 wrist joints using four point semiquantitative GSUS and PDUS scales were performed alongside collection of standard RA disease activity measures including DAS28CRP domains. 12 joint ultrasound indices were calculated by summing 0-3 grades for all joints. GSUS and PDUS measures were also assessed in the biopsied joint prior to the procedure. Retrieved tissue was fixed, stained and paraffin embedded prior to sectioning and staining by H&E. Tissues were assessed for quality: Where 50% or more tissue fragments out of a minimum of 4 contained lining layer histology, tissues were Krenn scored for lining layer and inflammatory infiltrate, and qualitative assessment of tissue pathology by three histologists. In parallel, tissues were enzymatically disaggregated and cell yield determined using trypan dye exclusion.

## Results:

In 15 tissue samples meeting QC taken from wrist (5), knee (9) and MCP (1) joints, Greyscale ultrasound (GSUS) grade correlated with the Krenn index of cellular inflammation ( $p<0.01$ ,  $r=0.65$ ) and the Krenn lining layer score ( $p<0.05$ ,  $r=0.52$ ). Power Doppler Ultrasound (PDUS) grade failed to correlate with either histological measure ( $p=0.34$ ,  $p=0.48$  respectively). Tissues with higher USGS, but not USPD scores, were more likely to show a lymphocyte predominant histological pathology than other patterns ( $p<0.05$ ). There was no consistent relationship between GSUS or PDUS measures of synovitis and cell yield at tissue disaggregation. GSUS extended joint indices correlated with DAS28CRP, 28 swollen joint and tender joint counts ( $p<0.05$ ,  $r=0.70$ ;  $p<0.01$ ,  $r=0.78$ ;  $p<0.05$ ,  $r=0.65$ ), while PDUS extended joint indices correlated with DAS28CRP and 28 swollen joint counts ( $p<0.05$ ,  $r=0.66$ ;  $p<0.05$ ,  $r=0.76$ ).

## Conclusion:

Ultrasound measures of synovial hypertrophy correlate with the complexity of joint infiltrates and lining layer thickness. There was an association between synovial hypertrophy and a lymphocyte predominant pathology. Extended joint indices demonstrate validity when compared to existing clinical domains.

Bingham III<sup>5</sup>, <sup>1</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Johns Hopkins University, Baltimore, MD, <sup>3</sup>Biomedical Imaging Science, Johns Hopkins University, Baltimore, MD, <sup>4</sup>Radiology, Johns Hopkins University, Baltimore, MD, <sup>5</sup>Rheumatology, Johns Hopkins University, Baltimore, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** This preliminary study was designed to determine the agreement and reproducibility of a novel cone beam CT (CBCT) extremity scanner, MRI and ultrasound (US) for detection of erosions in rheumatoid arthritis (RA). For this purpose, we compared the bone erosion scores for CBCT, MRI, and US in RA patients along with test-retest reproducibility of the CBCT data.

**Methods:** Ten patients (5 males, 5 females; mean age 58 years, age range 34 – 81 years) with a clinically confirmed diagnosis of RA were recruited for this institutional review board-approved study. All patients underwent an MRI, CBCT and US scan of the wrist and hand followed by a second CBCT scan one week later. The MRI was done using a 3T clinical MR scanner with dedicated hand coil; US using a state-of-the-art machine with an 18 Mhz hockey stick probe; while the CBCT was done using a prototype CBCT extremity scanner. US scans were performed and read by a rheumatologist with 5 years of experience in musculoskeletal ultrasound, scoring for the presence or absence of erosion in each joint. A radiologist with 7 years of musculoskeletal imaging evaluated MRI and CBCT images for erosions using RAMRIS like scoring between 1 to 10 (1 is 0-10% erosion, 2 is 11-20% erosion etc). The 2<sup>nd</sup> to 5<sup>th</sup> metacarpophalangeal joints, carpal bones and distal radius and ulna were assessed. Repeatability and agreement between methods were evaluated with Intraclass Correlation Coefficients (ICC) and Bland-Altman plots.

**Results:** Bland-Altman analysis showed agreement of  $0.02 \pm 3.5$ ,  $3.5$  to  $-3.5$  (bias  $\pm$  repeatability coefficient, 95% limits of agreement interval) with ICC score of 0.77 showing good correlation between MRI, US, and CBCT bone erosion scores. Correlation was higher for bone erosion scores of MCPs than for wrist joints. Test-retest reproducibility for the CBCT scans showed an excellent ICC score of 0.95.

**Conclusion:** Good correlation was seen for bone erosions as detected by CBCT, MRI and US, while the prototype extremity CBCT images showed high test-retest reproducibility. This study provides a good first approximation for evaluation of bone erosions across the three modalities.

Figure 1. Images of erosions on CBCT, MRI and US in an RA patient

Figure- 53 year old male with rheumatoid arthritis of the right hand. Figures (A and C) show the bone erosions on 2<sup>nd</sup> metacarpo-phalangeal (MCP) joint on CBCT images; same erosions are visualized on ultrasound (B) along with correlating bone marrow edema on the T2 fat suppressed image on 3T MRI (D). 3D volume rendered image (E) shows classic Boutonniere deformity along with 2<sup>nd</sup> MCP bone erosions (arrow).

### Tracer Uptake from High Resolution Bone SPECT/CT is Linked to Response in Rheumatoid Arthritis Patients.

#### Background/Purpose:

To evaluate the association between response to TNF- $\alpha$  blockers and tracer uptake from dual-phase technetium-99m methylene diphosphonate (<sup>99m</sup>Tc-MDP) bone scanning of the hands via a SPECT/CT system in patients with rheumatoid arthritis.

#### Methods:

Four patients with established rheumatoid arthritis (RA) were enrolled in this IRB-approved prospective pilot study. They were referred for performing bone scan prior to receiving TNF- $\alpha$  blockers. Early blood pool (15 minutes after tracer injection, marker of hypervascularity) and delayed osseous phase (3 hours after the same injection, marker of osteoblastic activity) scans of the hands using <sup>99m</sup>Tc-MDP were performed using high-resolution SPECT/CT scanner. A special hand positioning device was designed and used during the scans. Second- to 5<sup>th</sup> metacarpophalangeal joints (MCP) were assessed qualitatively (normal vs. abnormal uptake) and quantitatively (by measuring the maximum counts). All counts were corrected to the background (defined as the median count from all normal joints). Qualitative and quantitative data were assessed against response.

#### Results:

After a median follow-up of 7.8 months (range: 6.9-21.7), two patients were considered responders and two were non-responders. A total of 32 joints were assessed. Early and delayed uptake in the 2<sup>nd</sup> to 5<sup>th</sup> MCP joints were abnormal in 7 joints, all belong to non-responders; while it was normal in 25 joints, 16 of them were in responders & 9 in non-responders;  $P = 0.007$ .

The median corrected counts from delayed scans were 0.92 (range: 0.49-1.49) in responders vs. 1.14 (range: 0.81-2.93) in non-responders;  $P = 0.002$ .

The median corrected counts from blood pool scans were 0.95 (range: 0.6-1.67) in responders vs. 1.1 (range: 0.55-2.29) in non-responders;  $P = 0.2$ .

#### Conclusion:

Delayed osseous uptake in metacarpophalangeal joints of rheumatoid arthritis patients, measured from <sup>99m</sup>Tc-MDP SPECT/CT, performed prior to treatment with TNF- $\alpha$  blockers, was significantly higher in non-responders compared to responders, which might reflect higher baseline osteoblastic activity in non-responders.

**Table 1: Ratio of the counts measured on 2nd to 4th metacarpophalangeal joints in responders and non-responders**

<b>Baseline SPECT/CT</b>		<b>Responders</b>	<b>Non-Responders</b>	<b>P</b>
<b>Blood Pool</b>	<i>Median (Range)</i>	0.95 (0.6-1.67)	1.1 (0.55-2.29)	0.184
	<i>Mean<math>\pm</math>SD</i>	0.98 $\pm$ 0.32	1.29 $\pm$ 0.57	
<b>Delayed Phase</b>	<i>Median (Range)</i>	0.92 (0.49-1.49)	1.38 $\pm$ 0.61	<b>0.002</b>
	<i>Mean<math>\pm</math>SD</i>	0.88 $\pm$ 0.25	1.14 (0.81-2.93)

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

PET imaging with macrophage tracers has been shown promising for detection of (sub)clinical synovitis, making it useful for both early diagnostics and therapy monitoring in rheumatoid arthritis (RA) patients (1,2). For detection of more subtle arthritis, a previously investigated macrophage tracer, (R)-[<sup>11</sup>C]PK11195, was limited in use due to high background uptake in bone and bone marrow. [<sup>18</sup>F]fluoro-PEG-folate binds to the folate receptor  $\beta$ , which is expressed on synovial macrophages (3). Preclinical research in arthritic rats has shown excellent targeting, making it a promising tracer for clinical testing in RA patients (4). In this study, we investigated the value of [<sup>18</sup>F]fluoro-PEG-folate PET-CT for imaging of inflamed joints in patients with clinically active RA.

### Methods:

Nine RA patients with a minimal of two clinically inflamed hand joints were included. PET-CT scans were performed of the hands, after intravenous administration of either 185 MBq of [<sup>18</sup>F]fluoro-PEG-folate (n = 6) or 425 MBq of (R)-[<sup>11</sup>C]PK11195 (n = 3) for comparison. Joints with visually marked uptake were further analyzed by calculation of Standardized Uptake Values (SUVs) in Volumes of Interest (VOI), drawn on top of the PET positive joints. We drew background VOIs on metacarpal bone in order to calculate Target-to-Background (T/B)

ratios.

## Results:

None of the patients showed adverse effects, establishing the safety of [ $^{18}\text{F}$ ]fluoro-PEG-folate for use in humans. Arthritic joints were clearly visualized (Fig 1).. In the patients injected with [ $^{18}\text{F}$ ]fluoro-PEG-folate, 25 positive joints were observed, with a minimum of two joints per patient. In 10 of these 25 joints, clinical arthritis was confirmed. In the remaining 15 positive joints clinical inflammation was absent, suggesting the presence of subclinical inflammation. Whilst both [ $^{18}\text{F}$ ]fluoro-PEG-folate and (*R*)-[ $^{11}\text{C}$ ]PK11195 showed clear uptake in arthritic joints, [ $^{18}\text{F}$ ]fluoro-PEG-folate demonstrated a significantly lower background uptake than (*R*)-[ $^{11}\text{C}$ ]PK11195 (SUV of 0.18 vs 0.75;  $p < 0.001$ ) respectively. T/B-ratios were significantly higher for [ $^{18}\text{F}$ ]fluoro-PEG-folate (3.60vs 1.72,  $p = 0.009$ ).

Figure 1: [ $^{18}\text{F}$ ]fluoro-PEG-folate uptake on PET-CT in inflamed hand/wrist joints of a RA patient.

## Conclusion:

[ $^{18}\text{F}$ ]fluoro-PEG-folate shows great potential as a macrophage tracer to image both clinical and presumably also subclinical arthritis in RA patients. The tracer shows improved characteristics compared to the established macrophage tracer (*R*)-[ $^{11}\text{C}$ ]PK11195 for imaging arthritis, because of lower background signal.

## Abstract

**Background/Purpose:** To evaluate splenic glucose metabolism in macrophage activation syndrome (MAS), characterised by overwhelming systemic inflammation. Splenic  $^{18}\text{F}$ -fluorodeoxyglucose (FDG) uptake was compared in patients with MAS and sepsis using positron emission tomography/computed tomography (PET/CT).

**Methods:** Clinical and FDG-PET/CT findings from patients with MAS and those with culture-proven sepsis were evaluated. Standardised uptake value (SUV) for the spleen and liver were measured. The maximum of the spleen to liver SUV ratio ( $\text{SLR}_{\text{max}}$ ) was calculated as  $\text{spleen SUV}_{\text{max}}/\text{liver SUV}_{\text{mean}}$ . Radiological splenic volume was also measured, and splenic metabolic volume (MV) was defined as total splenic volume with an  $\text{SLR}_{\text{mean}} > 1.14$ . The association between clinical features, laboratory variables, and  $\text{SLR}_{\text{max}}$  was analysed.

**Results:** The median  $\text{SLR}_{\text{max}}$  and splenic MV were significantly higher in patients with MAS ( $n = 38$ ) than they were in those with sepsis ( $n = 15$ ) ( $\text{SLR}_{\text{max}}$ : 1.51 vs. 1.09,  $p = 0.001$ ; MV: 346.0 vs. 154.0,  $p = 0.015$ ) (Figure 1). Multivariate analyses revealed that  $\text{SLR}_{\text{max}} > 1.31$  was useful for discriminating between MAS and sepsis (Table 1).  $\text{SLR}_{\text{max}}$  positively correlated with ferritin and lactate dehydrogenase level in MAS. Furthermore, MAS patients with high splenic FDG uptake ( $\text{SLR}_{\text{max}} > 1.72$ ) had higher in-hospital mortality compared to those with moderate to low splenic FDG uptake ( $p = 0.013$ ).

**Conclusion:** This study was the first to demonstrate that splenic FDG uptake is significantly elevated in patients with MAS compared to those with sepsis. This may be useful to differentiate between MAS and sepsis, and to predict poor prognosis in patients with MAS.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** To assess the intra- and inter-reader agreement and responsiveness of a novel scoring system for FOI-assessed synovitis.

**Methods:** FOI of were obtained of both wrists and hands of 46 RA patients inducing or escalating anti-rheumatic therapy and who had ≥1

clinically swollen joint in the hand at baseline, after 3 and 6 months' follow-up. The hands were placed in the FOI-unit and the patient received a bolus of i.v. ICG-Pulsion (1mg/kg body weight) 10 seconds after starting the examination, which obtained 1 image/second over 6 minutes. The image-sets were anonymized and randomized and were assessed for synovial pathology at the wrist, 1<sup>st</sup>-5<sup>th</sup> metacarpophalangeal (MCP), 1<sup>st</sup> interphalangeal (IP) and 2<sup>nd</sup>-4<sup>th</sup> proximal interphalangeal (PIP) joint levels in both hands by two readers blinded to patient data but not chronology. The readers performed a calibration session before the exercise. The images of 23 patients were re-anonymized and were assessed as an intra-reader analysis. The scoring system for synovitis was based on the theory that inflamed tissue would demonstrate a more rapid enhancement than surrounding tissues. For each joint, the images were assessed sequentially from start of injection of ICG-Pulsion to peak enhancement. Synovial pathology was defined as a sharply margined enhancement with clear integrity from surrounding tissues and correct anatomical location lasting  $\geq 3$  seconds. The thickness of the pathology fulfilling these criteria were measured in the transverse plane of the hand at the 3<sup>rd</sup> second of enhancement and were scored as follows: 0: no enhancement, 1:  $<1/3$ , 2:  $\geq 1/3$  but  $<2/3$ , 3:  $\geq 2/3$  of joint thickness. Descriptive statistics and the Wilcoxon signed-rank test were used to assess change in score over time. Intra-/inter-reader for status and change scores were assessed using single measure intra-class correlation coefficients (ICC) and smallest detectable change (SDC, change scores only). Responsiveness was assessed using standardized response mean (SRM).

**Results:** The median (IQR) change in total synovitis score between baseline and 3/6 months' follow-up were -5.0 (-10.0;-1.0)/-8.0 (-13.5;-3.0) ( $p<0.01$ ). Intra- and inter-reader ICC were good to very good for status and change scores at all joint levels and for total scores (Table 1). The SDC were generally low and for the inter-reader SDC, 56%/60% of the patients had a change larger than the SDC between baseline and 3/6 months respectively. The mean SRM for total change scores between baseline and 3/6 months' follow-up were moderate to good (0.7/0.8).

**Conclusion:** The novel FOI RA synovitis scoring system showed high reliability and moderate to good responsiveness in the hands. Future studies should focus on comparing the sensitivity and specificity of FOI with ultrasound and magnetic resonance imaging.

**Table 1**

	Baseline	3 months' follow-up	6 months' follow-up	$\Delta$ Baseline – 3 months	$\Delta$ Baseline – 6 months
<b>Intra-reader ICC (SDC), reader 1</b>					
<b>Total scores</b>	0.90	0.86	0.83	0.87 (6.2)	0.92 (4.9)
<b>Wrist</b>	0.82	0.92	0.62	0.88 (1.4)	0.91 (1.4)
<b>MCP joints</b>	0.86	0.72	0.93	0.76 (4.8)	0.85 (3.6)
<b>PIP joints</b>	0.95	0.96	0.86	0.90 (2.9)	0.90 (3.3)

## Near Infrared Indocyanine Green Imaging Reveals Diminished Flow in Basilic Associated Lymphatic Vessels in the Hands of Rheumatoid Arthritis Patients during Flare

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Near infrared (NIR) imaging studies of subdermal indocyanine green (ICG) in murine models of inflammatory arthritis established the important contribution of lymphatic vessel (LV) function in joint homeostasis and flare. However, the role of lymphatic vessel function and altered joint drainage in rheumatoid arthritis (RA) flare is unknown.

**Methods:** The web spaces in both hands of 7 healthy controls (Ctl) and 2 subjects in RA flare were injected with 0.1ml of 100 $\mu$ M ICG on 2-4 separate occasions and the NIR fluorescence of the dorsal aspect imaged. Two independent graders counted the total number of fluorescent LVs crossing the mid-dorsal aspect of the hand, and the number of LVs associated with the basilic and cephalic veins and their tributaries. Differences between Ctl vs RA were evaluated using Fisher's Exact Test, pooling left and right hand observations across all visits (n=32 Ctl, n=10 RA). The frequency of lymphatic contractions of these LVs were determined from graphs of region of interest intensity across time to calculate contractions per minute; differences evaluated using a Wilcoxon Rank Test.

**Results:** Representative raw images of Ctl and RA hands are presented in **Fig 1A-B** demonstrating the Mid-Dorsal region (Blue Box), Basilic (Dark Green Arrows) and Cephalic (Dark Red) associated clusters and their tributaries (Basilic = Light Green, Cephalic = Light Red). The number of basilic associated LVs crossing the mid dorsal region and the feeding tributaries were decreased in RA subjects compared to controls (**Fig 1C and F**,  $p<0.05$ ). Contour plots generated by stabilizing and averaging all images during the 10min session show clear anatomic and bulk flow differences (**Fig 1D-E**). Note the lack of Basilic LV filled with ICG in RA (circled region in **E**). Representative 3D plots of the ROI analysis are shown in **Fig 2A and B** with scored contractions (Black Arrows) revealing a significant increase in contraction frequency in the cephalic associated LVs in RA subjects (**Fig 2C**,  $p<0.05$ ).

**Conclusion:** For the first time, we have characterized the lymphatic vessel anatomy of the hands of healthy subjects and RA subject using NIR ICG imaging. Furthermore, RA patients in flare show a reduced number of fluorescent LVs in the hands compared to Ctl. A decline in the number of LVs removing inflammatory cells and molecules from the joints and compensatory redirection of flow is likely to play a significant role in RA flare. Further studies to confirm these initial findings are underway.

## Validation of Objective Quantification System for Disease Progression in Patients with Juvenile Idiopathic Arthritis

Olga Kubassova<sup>1</sup>, N Tzaribachev<sup>2</sup>, Romiesa Hagoug<sup>3</sup> and Mikael Boesen<sup>4</sup>, <sup>1</sup>R&D, Image Analysis Group, London, England, <sup>2</sup>University Medical Center Schleswig-Holstein, Bad Bramstedt, Germany, <sup>3</sup>Imaging, Image Analysis Group, London, United Kingdom, <sup>4</sup>Radiology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Frederiksberg, Denmark

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Imaging as outcome measure has been studied and extensively used in the assessment of treatment for adult patients with rheumatoid arthritis (RA)<sup>1</sup>. In children with juvenile idiopathic arthritis (JIA) similar knowledge is very limited. This abstract presents a novel imaging based system for the assessment of treatment efficacy in JIA patients and its initial validation against clinical outcome measures.

### Methods:

Patients with polyarticular JIA with insufficient ( $\geq 3$  affected joints) response or intolerance to  $\geq 3$  months of Methotrexate, Etanercept were assessed by imaging. The MCP joints in clinically most affected hand were imaged with Dynamic Contrast Enhanced (DCE)-MRI at baseline (BL), month 3 and 6 of treatment using a 0.2T scanner. Clinical scores included active joint (AJ) counts. Clinical response was considered a state of  $\leq 3$  AJ. A region of interests (ROIs) were placed in DCE-MRI to quantify the synovium in MCPs 2-5. Output parameters included Dynamic Enhanced MRI Quantification scores (DEMRIQ-Vol) corresponding to the volume of enhancing voxels within the synovial ROIs alone or multiplied with the mean of the maximum enhancement (ME) or the initial rate of enhancement (IRE), DEMRIQ-ME and DEMRIQ-IRE. Differences in DEMRIQ-Vol scores between visits were analyzed using t-test ( $p < 0.05$  \* = statistically significant,  $p < 0.25$  \*\* = clinically meaningful). Correlation between clinical and DEMRIQ scores were described.

### Results:

18 Caucasian patients (12 girls, median age 12.6 years, median disease duration 1.2 years) were included in the study. Two patients discontinued imaging after BL but continued treatment. In all but 3 of the remaining patients statistically significant and/or clinically meaningful changes were documented for DEMRIQ ME between visits.

In 4 patients, clinical and DEMRIQ scores showed corresponding changes. In all other patients, clinical and DEMRIQ scores were non-concordant. Based on DEMRIQ change (irrespective of the clinical scores) the outcome of the patient could be predicted:

- in 5 patients, improvement of DEMRIQ scores predicted response to treatment (within 2-6 months after last MRI examination)

- in 4 patients, an increase or persistence of a high DEMRIQ predicted non-response to treatment
- in 7 patients, increase in DEMRIQ (after initial decrease) or persistence of a high DEMRIQ predicted flare (in 3 of the patients flare occurred after treatment discontinuation)

In all patients, subclinical disease could be detected on MRI in clinically unaffected joints.

#### Conclusion:

DEMRIQ scores supported clinical examination by detecting subclinical inflammation. In most patients, the imaging scores were predictive of the patient outcomes such as response and non-response to treatment and flare, making it a useful outcome measure in clinical practice and research.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Ultrasound (US) has received an increasing attention in detecting uric monosodium urate (MSU) deposits, and is included in the ACR/EULAR classification criteria for gout. The OMERACT US group has developed definitions for US elementary lesions in gout including double contour (DC) sign (deposits of crystals on the surface of cartilage), tophus (larger hypo-echoic aggregation of crystals, usually well delineated), aggregates (small hyper-echoic deposits) and erosions. MSU deposits may be found in many different regions in an individual with gout but with some predilection sites. The present objective was to assess by US the presence of MSU deposits in a high number of locations known to be involved, and to identify areas to include when screening for gout by US.

#### Methods:

This includes baseline data from a prospective observational study where patients with crystal-proven gout who presented after a recent gout flare were included (117 patients (mean (SD) 56.9 (14.1) years old, 8.5 (7.3) years disease duration, 93.2% men), all with insufficiently treated serum uric acid level (>360 µmol/L/>6 mg/dl). We performed a systematic extensive assessment with US (GE E9 machine, grey scale 15MHz) to detect MSU deposits, using the OMERACT definitions for DC, tophi and aggregates. The following locations were assessed bilaterally; radiocarpal joint, MCP 2, insertion of triceps and quadriceps, the patellar tendon (divided into proximal and distal), cartilage of distal femur (maximal flexed knee) and the talar cartilage of the tibiotalar joint, the MTP 1 joint as well as the Achilles tendon. Sum of sites with deposits was calculated and correlations were performed by use of Spearman, and frequencies of deposits were calculated as percentages at each site.

#### Results:

The mean (SD) serum uric acid level was 488 (88) µmol/L. There was no significant correlation between number of sites with deposits and uric acid level ( $r=0.11$ ), but with disease duration ( $r=0.25$ ,  $p=0.007$ ). The table shows that DC was primarily found in MTP1, followed by talar and femoral cartilage. Tophi and aggregates were primarily found in MTP1, followed by distal patellar and triceps tendons. There were no major differences between right and left side. In 21 patients (17.9%) DC was seen on femoral or talar cartilage, but not in the MTP1 joints.

## Conclusion:

There is limited knowledge on the primary locations of MSU deposits, and the present study suggests US examinations of MTP1, distal patellar and triceps tendons as well as talar and femoral cartilage to be the most important sites to explore for presence of MSU deposits in patients examined for possible gout.

	Double contour		Tophus		Aggregates	
	Right	Left	Right	Left	Right	Left
Wrist	1.7	0	7.7	9.5	7.7	8.6

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Joint ultrasonography (US) is a noninvasive examination that can evaluate arthritis and uric acid deposition at gout attacks.

The purpose of this study was to investigate the progression of gouty arthritis using cross sectional data from the aspect of the joint sonographic features such as double contour sign (DCS), hyperechoic aggregate (HA), and bone erosion (BE). DCS and HA are signs showing uric acid deposition.

### Methods:

The subjects were 644 consecutive male patients (Age: 45.7±10.7 y.o.) with hyperuricemia and/or gout attack. Seventy one patients (11%) had experienced neither any attacks nor diagnosis of gout (N group). One hundred eighty seven patients (29%) were diagnosed as the first

attack of gout (1st group), while 386 patients (60%) had their past history of the attacks (His group). They underwent joint US. Observed rates of DCS, HA, and BE (D: only DCS; H: only HA; B: both DCS and HA; A: DCS or HA; E: BE) in the first metatarsophalangeal (1st MTP) were compared.

## Results:

In the N group, the observed rates of D, H, B, A, and E were 45%, 1%, 0%, 46%, and 1%, respectively. In the 1st group, arthritis on US was observed in the joints of the first metatarsophalangeal (1st MTP) (72%), ankle (18%), and knee (5%). In the 1st group, the patients of which attack was at 1st MTP represented that observe rates were D 29%, H 20%, B 38%, A 87%, and E 29%, while the patients of which attack was at other than 1st MTP were D 20%, H 4%, B 0%, A 24%, and E 0%. In His group, the observed rates were D 16%, H 18%, B 66%, A 100%, and E 57%. Observed frequency of DCS was highest in N group and was decreased along with articular destruction, respectively. In His group, 100% and more than 50% patients showed sonographic features of uric acid deposition and bone erosion. Fisher's exact tests demonstrated a significant relationship in HA and BE, but not in DCS and BE ( $p < 0.05$ ).

## Conclusion:

The results suggested that DCS was the earliest sign of uric acid deposition that was observed in the asymptomatic stage in gout. Even at the first attack HA was frequently observed that was leading to BE.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The prevalence of hyperuricemia ranges from 2.6% to 47.2% in various populations [1,2]. Ultrasound evidence of urate crystal deposition in the form of double contour sign (DCS) and hyperechoic aggregates (HAGs) in asymptomatic hyperuricemic (AH) individuals has been documented in studies [3]. It has been reported that assessment of one joint (ie, radiocarpal) and two tendons (ie, patellar and triceps) for HAGs, and three articular cartilages (ie, first metatarsal (1<sup>st</sup> MTP), talar and second metacarpal/femoral) for DCS showed the best balance between sensitivity and specificity (84.6% and 83.3%, respectively) in diagnosing intercritical gout[4]. So we aimed to find the preferred sites of urate crystal deposition among these six sites in AH individuals.

**Methods:** 24 AH (serum uric acid (SUA)  $\geq 7$ mg/dl) and fifty controls (SUA  $< 7$ mg/dl) with age more than 18 years were included in this study. DCS was looked for at three articular cartilage sites (1<sup>st</sup> MTP, tibiotalar and femoral condyle) whereas HAGs were looked for at one joint site (radiocarpal joint) and two tendon sites (patellar tendon and triceps tendon). Ultrasound was done using multifrequency linear array transducer (8–13 MHz) of Logiq E; GE Medical Systems Ultrasound, on B mode gray scale (GS). Settings of machine were as follows: dynamic range of 40–50 dB, GS frequency of 11–13 MHz and GS gain of 60 dB.

**Results:** 8 out of 24 AH patients had ultrasound evidence of urate crystal deposition in 1<sup>st</sup> MTP joint area followed by knee joint area which was detected in 6 patients. The detection rate of ultrasound abnormalities in AH was 45.8% with two joint area (knee and 1<sup>st</sup> MTP) and 50% with six sites assessment. Amongst controls, 16% were found to have these abnormal ultrasound findings by both two joint area and six sites exams. (Figure: DCS at knee and 1<sup>st</sup> MTP joint)

**Conclusion:** The highest predilection of urate crystal deposition in AH patients is the articular cartilage of Knee and 1<sup>st</sup> MTP joints.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To look correlations between clinical and ultrasound (US) scores of peripheral enthesitis (PE) and disease activity scores of SpA

**Methods:** A prospective study of 208 SpAs meeting SpA ASAS criteria. In the same consultation, 30 enthesitic sites per patient were examined clinically and 34 sites per patient were examined with US according to the US OMERACT 2014 definition of enthesitis. PE was assessed by the following clinical scores: Enthesitis Peripheral Score (PES= Sum of symptomatic peripheral entheses sites on clinical examination), Visual Analog Scale of peripheral enthesitis (VAS), Spondyloarthritis Research Consortium of Canada score (SPARCC) as well as the following US enthesitis scores: Acute Enthesitis score. Correlations between clinical scores and ultrasound scores and disease activity scores were calculated using SPSS software.

**Results:** A total of 208 patients were included, mainly men (63.5%). The mean age was  $40.2 \pm 11.7$  years. The mean duration of the SpA was  $11.8 \pm 8.7$  years. Axial radiographic SpA was the most frequent phenotype (69.2%). On examination 64.4% of SpA were NSAIDs and 88.9% had active disease (ASDAS-vs and / or ASDAS-crp > 1.3). Tables (1, 2) summarize the results of correlations between clinical

scores and US scores and disease activity scores. A weak correlation was found between: the acute enthesitis score and two clinical scores (peripheral enthesitis score, mean score of enthesitic VAS); the global enthesitis score and all clinical enthesitis scores and finally between the SES score and two clinical enthesitic scores (peripheral enthesitis score, mean score of enthesitic VAS).

A moderate correlation was observed between disease activity scores and all US scores of peripheral enthesitis except for the chronic enthesitis score for which the correlation was weak.

Table 1

Scores	PES	VASm Enthetis	SPARCC
Acute Enthesitis	<b>r: 0,15</b> <b>p: 0,03</b>	<b>r: 0,15</b> <b>p: 0,03</b>	r: 0,13 p: 0,06

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

While MRI of the sacroiliac is a sensitive method for detection of bone marrow edema (BME) and structural lesions in axial spondyloarthritis (axSpA), there is only limited data regarding the specificity in a non-SpA population. Mechanical stress is considered to be an important factor in the pathogenesis of SpA. However, currently there are no data on the effect of intensive physical activity on the sacroiliac joints and how this could impact MRI findings of the sacroiliac joints (MRI-SIJ).

### **Methods:**

Twenty-two military recruits underwent an MRI-SIJ before and after 6 weeks of intense and uniform physical training. Bone marrow edema (BME) and structural lesions were scored by 3 trained readers, blinded for time sequence and clinical findings. The Spondyloarthritis Research Consortium of Canada (SPARCC) score was used to assess BME and an adjusted method derived from the SPARCC scoring method was used to assess structural lesions: sclerosis, erosions, fatty lesions and ankylosis were scored per quadrant on 6 consecutive slices representing the cartilaginous part of the joint. Additionally, the agreement with the definition of a positive MRI defined by ASAS was evaluated.

### **Results:**

At baseline, 40.9% (9/22) of recruits already presented with at least one BME lesion, whereas this number increased to 50.0% (11/22) at week 6 ( $p=0.625$ ). In subjects displaying BME, the mean number of BME lesions was 2.4 ( $\pm 0.4$ ) at baseline, compared to 3.7 ( $\pm 1.3$ ) at week 6. Overall, the mean change in BME lesions over time in all 22 individuals was 0.9 ( $\pm 0.6$ ) ( $p=0.109$ ). A positive MRI according to ASAS was present in 22.7% (5/22) of recruits at baseline, which increased to 36.4% at follow up ( $p=0.375$ ). Structural lesions were present in 36.4% (8/22) of subjects at baseline, which increased to 50% subjects (11/22) after 6 weeks of intense physical training ( $p=0.453$ ). There was a significant increase of MRI lesions over time when combining both structural and inflammatory lesions ( $p=0.038$ ).

### **Conclusion:**

We found a markedly high prevalence of BME and structural lesions in young, active, healthy volunteers, with almost 23% of them fulfilling the ASAS definition of a positive MRI. Overall, MRI lesions seem to increase after 6 weeks of intense physical training. Thus, our study underscores the necessity to interpret MRI findings of the sacroiliac joints in the appropriate clinical context, even in a young active population.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Enthesitis is a prominent feature of spondyloarthropathy (SpA), including psoriatic arthritis (PsA). The evaluation of enthesitis has conventionally been conducted by clinical exam, a method with significant limitations mainly its low sensitivity. Ultrasound can image entheses in high fidelity and may assist in the diagnosis and management of SpA patients. As part of the GRAPPA US sub-committee "Enthesitis Project" we performed a systematic review of the literature in order to assess the evidence and knowledge gaps in scoring systems of enthesitis in PsA.

### **Methods:**

A systematic search of Pubmed, Embase and Cochrane was done. The search strategy was constructed to find original publications in English containing terms related to US, enthesitis, SpA or PsA. Two reviewers screened all abstracts for eligibility. Studies that reported used global sonographic scoring systems for assessment of enthesitis in patients with spondyloarthritis or their modifications were included. Data was extracted independently by 2 reviewers. Data extraction focused on the properties of the enthesitis scoring system used in each study. Specifically, we assessed the following component of the OMERACT filter: reliability of acquisition, feasibility, and construct validity as related to clinical assessment of enthesitis, biomarkers and imaging of enthesitis by other modalities, discriminative validity and responsiveness to treatment.

### **Results:**

Fifty-one of 310 identified manuscripts were included. 13 studies used Glasgow Ultrasound Enthesitis Scoring System (GUESS) or its modifications, 9 used Madrid Sonographic Enthesitis Index Scoring System (MASEI), 6 used D'Agostino scoring system, 5 used Belgrade Ultrasound Enthesitis Score (BUSES), 3 used Sonographic Enthesitis Index (SEI), 1 used PsASon-Score, and 14 did not use a formal score. Only one of these scoring systems (PsASon) was developed and validated in patients with PsA. Only 18 (35%) of the studies involved patients with PsA, while the rest focused on SpA. Concerning the OMERACT filter, construct validity was assessed using biomarkers in 10 (19.6%) studies, only one study (2%) in PsA. Construct validity using clinical examination was assessed by 26 (51%), 11 (21.5%) were in PsA, only 6 (11.7%) compared US finding to imaging - none of them was performed on PsA. Responsiveness to treatment was assessed in 7 studies, none of them included PsA patients. Six (11.7%) studies evaluated discriminative validity two (4%) of them in PsA.

### **Conclusion:**

Although sonographic indices have been developed for Spondyloarthropathy, only a few have been validated for PsA. None of them fulfilled all the OMERACT filter criteria in patients with PsA. Additional research is needed to assess the validity or modification of existing scoring systems in patients with PsA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Digital ulcers (DUs) are a major burden in patients with systemic sclerosis (SSc). Laser speckle contrast analysis (LASCA) is a novel technique that can analyse blood perfusion (BP) in the fingers and in DU areas. The objective of the present study was to evaluate BP in patients with SSc and DUs and correlate these values with the treatments and healing time.

### Methods:

From February 2016 to March 2017, 23 consecutive Ssc patients presenting with DU at fingertips were enrolled: M:F=2:21; 15 lcSSc and 8 dcSSc; mean age 56±15.8 years. BP was assessed by LASCA in fingers affected by DUs, unaffected fingers, DU area, peri-ulcer area and the same area of unaffected fingers. DUs were defined infected if local signs of infection were present (swelling, severe pain, erythema, discharge). The treatment with major vasoactive drugs (iloprost, bosentan, sildenafil), the latency between the appearance of DU and first evaluation, and the time to DU healing under standard local treatment were collected.

### Results:

BP was higher in peri-ulcer area with respect to the DUs area (84.1±21.0 vs 60.3±15.1 p<0.001), and no differences were observed between DUs area and similar area of unaffected fingers.

In patients without infection (n=17), healing time was negatively associated both to DUs BP (r=-0.618 p=0.011) and peri-ulcer BP (r=-0.488 p=0.011). The latency between appearance of DUs and first evaluation in our centre was also negatively correlated to mean healing time (r=0.36 p=0.036).

Patients with infection (n=6) presented a higher ulcer BP compared to non-infected pts (198.0±112.2 vs 103.3±66 p=0.023) and DUs needed a longer healing time (mean 130 vs 100 days).

The treatment with bosentan and iloprost was associated with higher BP in the unaffected fingers (respectively p=0.002 and p=0.001) but no BP changes at DU area or at fingers with DUs were observed. Sildenafil was not associated with significant differences in blood perfusion.

### Conclusion:

Our study suggests a potential usefulness of LASCA analysis of BP in the assessment of DUs in SSc patients. Although all DUs are ischaemic in nature (blood flow is lower than in unaffected area and per ulcer area), BP values could help in identifying difficult to heal lesions, either due to a markedly reduced perfusion (low BP) or to the presence of an infection (higher than expected BP).

Additional data are needed to better define the role of BP as a guide to treatment, ulcer management and prevention in routine clinical practice.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Approximately 50% of patients with systemic sclerosis (SSc) will develop painful digital (finger) ulcers (DUs) at some point during their disease course. These lesions can be extremely disabling and are often refractory to treatment, requiring close monitoring of healing progression. Also, DUs are often the primary outcome measure in clinical trials of SSc-related digital vasculopathy. Our aims were to: (1) demonstrate the feasibility of patients with SSc taking smartphone photographs of their DUs, and (2) use software image analysis on collected images to track lesion area as a marker of wound status.

**Methods:** Patients with SSc and incident DUs were asked to photograph their lesion(s), using their own smartphone, once per day for a maximum period of 35 days. Patients received normal clinical wound care for the duration of the study, which in most cases was patient self-management. Image length scales were initially calibrated using a fixed (non-varying) object in each image sequence, allowing relative

length/area tracking throughout a sequence. Using digital planimetry software (developed and successfully tested in previous work on digital ulcer photographs [1]), lesion area was measured by fitting an elliptical shape to the wound image by a single observer. Areas from each image were then normalised to the area measured first in the time sequence.

**Results:** Image sequences describing 7 lesions were collected in-person at the end of the study period from 4 patients. The 7 image sequences cover median [range] duration of 29 [13-35] days. The relative area time course for each lesion is shown in Figure 1. At sequence end, relative lesion areas had, on average, reduced to 56% of the area measured on day 1, with 6 out of 7 lesions reducing in size over the time course.

**Conclusion:** We have demonstrated the feasibility of patients with SSc collecting images of digital ulcers using smartphone cameras. Images collected are of sufficient quality to allow software monitoring of wound progression (healing or worsening). Further work to build a smartphone app for lesion monitoring (for use in both clinical practice and as an outcome measure in clinical trials) is now required.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung disease (ILD) in systemic sclerosis is treated by immunosuppressive drugs (e.g. cyclophosphamide), aimed at reduction of inflammatory response. Differentiation between inflamed and non-inflamed fibrotic tissue might help to develop treatment stratification, with the aim of improving the prognosis of (subgroups of) SSc-ILD patients. <sup>18</sup>F-Fluoro-Dexoxyglucose Positron

Emission Tomography ( $^{18}\text{F}$ -FDG PET) scan might be a promising tool to detect inflamed lung areas, as formerly shown in a semi-quantitative setting [1, 2]. This study aims to investigate the potential role of  $^{18}\text{F}$ -FDG PET –scan for the quantitative assessment of metabolically active SSc related ILD.

**Methods:**  $^{18}\text{F}$ -FDG PET -scans of 22 patients with systemic auto-immune disease, including 9 with SSc, 9 with systemic lupus erythematosus (SLE) and 4 with primary Sjögren's syndrome (pSS), were retrospectively analyzed. FDG-uptake was quantitatively measured within 2cm-sized Regions of Interest (ROIs) at apical, medial and basal lung levels. A total of 22 ROI's were drawn in each patient. SUVmean values of all ROI's were corrected by the medial SUVmean bloodpool value. Subsequently, the average of 6 posterior basal SUVmean values was divided by the average of 6 posterior apical SUVmean values (basal/apical ratio). High Resolution Computed tomography (HRCT)-scans and Pulmonary Function Tests (PFT) were examined to confirm the diagnosis of ILD and to specify the pattern of fibrosis.

**Results:** Mean age of patients was 69.4 (SSc-ILD), 62.5 (SSc without ILD), 38.9 (SLE) and, 49.3 (pSS). In SSc patients, the mean disease duration was 5.0 (SSc-ILD) and 4.4 (SSc without ILD) years. Diffuse cutaneous sclerosis was present in 2 SSc-ILD and 1 SSc without ILD patients, while other SSc patients were diagnosed with limited cutaneous SSc. ILD was present in 5 out of 9 SSc patients as confirmed by HRCT and PFT. ILD was active in 3 out of 5 SSc-ILD patients. Posterior basal/apical SUVmean ratios of SSc-ILD patients were significantly increased compared to SSc patients without ILD ( $p=0.016$ ), and compared to SLE and pSS patients without ILD ( $p=0.001$  and  $p=0.016$ , respectively), which is shown in Figure 1.

**Conclusion:** Our findings demonstrate that  $^{18}\text{F}$ -FDG PET is potentially useful for the quantitative assessment of active ILD lesions in SSc patients. The technique may therefore provide opportunities to select the patients with inflammatory regions in ILD that are most likely to respond to immunosuppression.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Echocardiography is frequently performed in patients with connective tissue diseases (CTD), mostly to evaluate cardiac involvement or development of pulmonary arterial hypertension (paH). Despite the application as part of routine clinical follow-up, there is incomplete data for the range and frequency of findings in different CTD.

**Methods:** We included all consecutive patients from a tertiary rheumatological referral center with CTD diagnosis and echocardiographic examination between January 1<sup>st</sup> 2006 and December 31<sup>st</sup> 2015 by retrospective chart review. For each echocardiographic finding, the proportion of patients per diagnosis with a pathological result in at least one examination was calculated. Further, each finding's frequency in patients with and without previously documented inflammatory cardiac involvement was compared. For patients with more than one visit, we recorded how often findings developed or resolved over time.

**Results:** 1004 patients with different CTD and a total of 1660 performed echocardiographies were identified. Table 1 displays the frequency of findings in the whole cohort and for each CTD, respectively. The most common findings were mitral, aortic and tricuspid regurgitation, aortic valve sclerosis, left ventricular dysfunction, and left atrial dilatation. Table 2 shows which findings were significantly more common in patients with a history of inflammatory cardiac involvement (n=109). 314 patients had consecutive examinations; medium interval between first and last examination was 40 months (SD: 28, range: 0.9-115). Development and regression of findings during follow-up are given in table 3. Mitral (24%) or tricuspid regurgitation (21%), aortic valve sclerosis (18%) and left ventricular dysfunction (20%) most commonly developed.

**Conclusion:** This study is the first to report echocardiographic findings in a large cohort of different CTD. Abnormal findings are common in all disease entities. Some pathological findings are more common in patients having suffered from cardiac involvement, these seem to be disease-related. In follow-up, a change of findings was frequently observed. These results support the role of echocardiography for routine examination and in follow-up in patients with CTD.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Modern imaging techniques including ultrasound (US), magnetic resonance imaging (MRI), computed tomography (CT) and  $^{18}\text{F}$ -FDG positron emission tomography (PET) are increasingly studied in large vessel vasculitis (LVV); however, their role in daily clinical practice remains elusive so far. The aim of this study was to perform a systematic literature review (SLR) to inform the EULAR recommendations for imaging in LVV on the role of imaging methods on (1) diagnosis, (2) disease monitoring, (3) outcome prediction and (4) technical aspects in LVV

**Methods:** A systematic literature search was conducted in the MEDLINE, EMBASE and Cochrane Library databases (until 10<sup>th</sup> March 2017) without language restriction. Full research articles of prospective studies enrolling >20 patients and investigating the index test (US, MRI, CT, PET) in patients with suspicion of (diagnostic studies) and/or established (studies on monitoring or prediction) primary LVV were selected. The risk of bias for diagnostic accuracy and prognostic studies were evaluated by the QUADAS2 and QUIPS tools, respectively. Meta-analysis was conducted, whenever possible, to obtain pooled estimates for sensitivity, specificity, positive and negative likelihood ratios, by fitting random effects models.

**Results:** Forty-four studies were included [27 diagnosis giant cell arteritis (GCA), 6 outcome prediction GCA, 15 monitoring disease activity GCA, 5 technical aspects GCA, 2 diagnosis Takayasu arteritis (TAK), 2 monitoring disease activity TAK with some studies addressing more than one index test/key objective]. The “halo” sign at temporal arteries, as identified by US (8 studies, 605 patients), yielded a pooled sensitivity of 77% (95% CI: 62-87%) and a pooled specificity of 96% (95% CI: 85-99%) as compared to clinical diagnosis of GCA. MRI of extra-cranial arteries was found to have a pooled sensitivity of 73% (95% CI: 57-85) and a pooled specificity of 88% (95% CI: 81-92), when clinical diagnosis (6 studies, 509 patients) was used as gold standard. For both, US and MRI, similar diagnostic performances were observed when temporal artery biopsy was used as reference standard instead of clinical diagnosis. Only 2 studies (93 patients) addressed the diagnostic accuracy of PET in GCA reporting sensitivities of 67-77% and specificities of 66-100%. Studies addressing the role of imaging for outcome prediction, monitoring disease activity and technical aspects were very heterogeneous. For TAK, 1 MRI (30 patients) and CT angiography study (25 patients) was identified revealing both a sensitivity of 98% and a specificity of 100% in comparison to conventional angiography. No study on isolated aortitis was identified.

**Conclusion:** The SLR confirms the good performance of US and MRI for the diagnosis of cranial GCA. Data on outcome prediction, monitoring and technical aspects of GCA, as well as imaging studies in TAK are limited.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Aortitis is the inflammation of the aortic wall. This entity is often under-recognised because most of its manifestations are non-specific. PET/CT scan plays an important role in the diagnosis and management of aortitis; however this technique is expensive.

Our aim was to compare the baseline characteristics of patients with a suspicion of aortitis and positive results on PET/CT scan and those with a negative result in order to search for predictive factors that improve the clinical probability of diagnosis aortitis by this imaging technique.

## Methods:

Retrospective study on 170 patients and PET/CT scans ordered by suspicion of aortitis from a referral center from January 2010 to December 2016. According to a pre-specified protocol, the baseline epidemiological and clinical variables of patients with positive and negative PET/CT scans results for aortitis were reviewed. Distributions of *categorical variables* were compared by the Pearson Chi<sup>2</sup> or Fisher exact test. Quantitative variables were analyzing using the Student t test or Mann-Whitney U test as appropriate.

## Results:

In 170 patients, PET/CT scans were performed due to clinical suspicion of aortitis, being positive in 93 (54.7%) cases. Patients (113W/57M) had a mean age of  $67.7 \pm 13.1$  years (range, 20-90 years). One patient was excluded because missing clinical or laboratory data.

The underlying conditions at the momento of orderinf the PET/CT scan were: giant cell arteritis (GCA) (n=28), spondiloarthropaties (n=7), conectivopaties (n=6), Takayasu arteritis (n=3), ulcerative colitis (n=3), other condition (n=11) The remaining 111 patiens dud not hace any underlying condition suggestive of aortitis.

Characteristics of patients with positive and negative PET/CT sacan were shown in the Table. Patients with GCA had a higher percentage of positive PET/CT scans, whereas the were negative more frequently in patients who did not have any conidition suggestive of underlying aortitis. Only inflammatory low back pain and polymyalgic syndrome were significantly more frequent in patients with positives PET/CT scans.

## Conclusion:

In this study, we have found the presence of inflammatory low back pain and polymyalgic syndrome, especially in GCA patients, may have clinical relevance in ordering a PET/CT scan when aortitis was suspected.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** At the age of Giant Cell Arteritis (GCA) atherosclerosis is common. The ultrasonographic (US) appearance of athermanous plaque is usually easily differentiated from the hypoechoic halo of GCA. However, the US increase of the intima-media-thickness (IMT) in an atherosclerotic arteries may have a similar appearance as the halo sign (homogenous, hypoechoic wall thickening, well delineated towards the luminal side, visible in longitudinal and transverse planes). The new US high frequencies probes make possible not only to see the halo sign but also measure the increase of the intima-media-thickness (IMT), in this sense the aim of this study was to explore the better cut-off in the IMT of temporal arteries (TA) to minimise the number of false-positive GCA diagnosis caused by atherosclerosis.

**Methods:** Consecutive non selected patients,  $\geq 50$  years-old with high vascular risk according to European Guidelines on cardiovascular disease prevention, and without signs or symptoms of GCA, were included.

*Ultrasonography of carotid artery:* Carotid US examinations were performed on a Mylab Seven (Esaote Medical Systems, Italy) with a 4–13 MHz linear-array. The system employed dedicated software radiofrequency-tracking technology to obtain IMT (QIMT®).

*Ultrasonography of temporal superficial artery:* A color Doppler ultrasound (CDU) and grey scale measure of the IMT/halo sign in both TA and its branches was performed by a second experienced sonographer. A Mylab Twice equipment (Esaote, Geneve, Italy) was used, with a 22 MHz frequency for grey scale and a 12.5 MHz for CDU (color gain of 51, PRF of 2 kHz). The sonographer was blind to the clinical and carotid ultrasound IMT data.

**Results:** Forty patients were studied, 28 men (70%), with a mean age of  $70.6 \pm 6.9$  years. Three patients were active smokers and 27 ex-smokers. Arterial hypertension was present in 39 (97.5%), dyslipidaemia in 34 (85%) and diabetes in 19 (47.5%). The mean erythrocyte sedimentation rate was  $13.6 \pm 11.0$ . Eighty carotids were studied, 50 had plaques and 30 did not with a IMT ranged from 0.528 to 1.480 mm. A increase in the carotid IMT is associated with an increase in the IMT of the TA with a weak Spearman correlation (parietal branches 0.282  $p = 0.012$  and frontal branches 0.228  $p = 0.048$ ). The table shows that an IMT  $> 0.30$  mm (halo sign) was seen in at least 1 TA branch of 18 patients (45%) with 33 TA branches affected (20.6%). An IMT cut-off  $> 0.34$  mm, was present in 4 patients (10 %). When at least two affected branches with this measure were required to make the US diagnosis (criteria recommended to improve specificity) only one patient (2.5%) produced a false-positive halo sign.

	Carotid IMT, mm	Right		Left		Number of Branches with Halo	
		TA Frontal	TA Parietal	TA Frontal	TA Parietal	Cut-off IMT > 0.3 mm	Cut-off IMT > 0.34 mm

**Conclusion:** Carotid atherosclerosis increase the IMT in TA and is a potential cause of false-positive halo sign. We propose a cut-off of AT IMT > 0.34 mm in at least two branches to minimise the number of false positives in GCA diagnosis.

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Fluorine-18-fluorodeoxyglucose (FDG) PET/CT is increasingly used to diagnose large vessel GCA (LV-GCA), but has previously been considered unable to reveal inflammation in temporal arteries due to limited spatial resolution. However, the arteritic pattern in GCA is heterogeneous and additionally may not always uniformly involve the entire vessel, rendering interpretation of the PET images difficult. An increased FDG uptake in branches of the external carotid artery, i.e. the temporal (TA) and maxillary arteries (MA), may therefore add to diagnostic specificity.

**Methods:**

21 patients fulfilling the ACR criteria of GCA were identified from a LV-GCA cohort (table 1). Laboratory tests, temporal artery ultrasound (US) and FDG PET/CT (Siemens Biograph 64) were performed prior to treatment.

An experienced nuclear medicine physician performed blinded assessment of FDG uptake in TA and MA. FDG uptake was visually scored on a 4-point scale (a.m. Meller<sup>1</sup>: 1; ≤ blood pool, 2; > blood pool, ≤ liver, 3; ≥ liver, 4; ≥ 2xliver), where score ≥2 was considered indicative of inflammation. In addition, mean and max standardized uptake values (SUV<sub>mean</sub>, SUV<sub>max</sub>; 20 hottest interconnected pixels) and target to background ratio (TBR=SUV<sub>max</sub>(artery)/SUV<sub>mean</sub>(venousblood)) were recorded for each vessel based on volumes of interest drawn on the PET images.

Correlations were calculated using Spearman’s test. Mann–Whitney U test or Student t test, when applicable, were used for quantitative data. Associations between two categorical variables were evaluated using *Fisher’s exact test*.

**Results:**

FDG uptake in cranial arteries was detectable in 20/21 patients; 12/21 TA and 20/21 MA. In 11 patients, at least one of the arteries was categorized with a Meller score ≥2 indicating significant inflammation. SUVs and TBRs are shown in table 1. SUVs and TBR correlated with Meller scores.

In the 3 patients with negative TA US (n=2 biopsy positive) and in the 2 patients with negative TA biopsies (n=1 US positive), FDG uptake in TA and MA was either not detectable or with a Meller score of 1. Meller score in the TA correlated with the degree of inflammation (none, <transmural, transmural) in the TA biopsy (rho=0.64, p<0.01). Patients with a TA or MA Meller score ≥2 were more likely to have severe cranial symptoms (p=0.02), jaw claudication (p<0.02), had a shorter disease duration prior to diagnosis (median 8 vs 17 weeks, p<0.02) and were younger (median 65 vs 69 years, p<0.01) than patients with Meller score <2. However, they did not differ in gender or CRP at time of diagnosis.

**Conclusion:**

Increased FDG uptake in the cranial arteries of GCA patients is frequent, correlated to histological inflammation and subjective symptoms and detectable by normal PET/CT systems. It may add to the diagnostic accuracy of 18F-FDG PET/CT in GCA and should not be overlooked by reading physicians.

Table 1

### Baseline characteristics of patients fulfilling ACR criteria for GCA

No. patients	21
Age, median (range)	68 (60-84)
Gender, females no.	13
CRP, mean (95% CI)	82 (65; 104)
Temporal artery biopsy positive, no	16/18
Temporal artery ultrasound positive	18/21
Temporal artery PET characteristics	
SUV <sub>mean</sub>	2.18 (1.69; 2.68)
SUV <sub>max</sub>	3.10 (2.27; 3.94)
TBR	1.95 (1.47; 2.48)
Maxillary artery PET characteristics	
SUV <sub>mean</sub>	2.21 (1.77; 2.64)
SUV <sub>max</sub>	2.86 (2.21; 3.71)
TBR	2.04 (1.49; 2.58)

Patients fulfilling ACR criteria for GCA were identified in a prospective cohort of 24 large-vessel GCA patients. Inclusion criteria in the cohort were: Age>50 years, CRP>15 or ESR>40, either cranial symptoms of GCA, abrupt new-onset of extremity claudication or weightloss>5kg or fever>38 for more than 3 weeks and PET proven large vessel involvement (FDG uptake higher than liver FDG uptake in aorta and/or supraaortic branches).

### Background/Purpose:

Calcification of the coronary arteries, aorta, and branch vessels can occur in both large vessel vasculitis (LVV) and atherosclerosis. The

study objective was to determine 1) the location and amount of vascular calcification in LVV versus hyperlipidemia (HLD) and 2) risk factors associated with vascular calcification in LVV.

**Methods:**

Patients with giant cell arteritis (GCA), Takayasu’s arteritis (TAK), and HLD were recruited into an observational cohort. All subjects underwent computed tomography of the aorta and branch vessels. We developed a novel semi-automated software to compute vascular calcification in 14 specific arterial territories (ascending aorta, aortic arch, descending thoracic aorta, abdominal aorta, carotids, subclavians, innominate, iliacs, femorals and coronary arteries). Total amount of calcification throughout the large arteries was quantified by calculating a cumulative Agatston score. Multivariate linear regression analyses were performed in LVV to determine associations between total Agatston score and traditional or disease-specific risk factors. Traditional risk factors were age, gender, body mass index, smoking, statin use and hypertension. Disease-specific risk factors were disease duration, clinical activity status, glucocorticoid dose, inflammatory markers (ESR, CRP, fibrinogen) and vascular inflammation as measured by positron emission tomography (FDG-PET). Only variables with  $p<0.10$  in univariate analyses were included in the multivariate models. Frequencies were compared by the chi-squared test. Agatston scores were compared by Kruskal-Wallis test with post-hoc Dunn’s test.

**Results:**

A total of 88 subjects, including GCA (n=29, median age=72, %female=79); TAK (n=22, median age=37, %female=73); and HLD (n=37, median age= 66, %female=43), participated in the study. There were no differences in the location of vascular calcification in the aorta and branch vessels between LVV and HLD, except coronary artery calcification was more prevalent in HLD compared to both TAK and GCA ( $p<0.01$ ). Total Agatston scores were higher in GCA (median 3260, range 25-18138) versus HLD (460.5, 19-17215) ( $p<0.01$ ) but did not significantly differ between GCA and TAK (1944, 52-47520) ( $p=0.53$ ). An Agatston score  $>1000$ , consistent with severe calcification burden, was observed in many patients with GCA (74%), TAK (56%), and HLD (42%). Factors associated with calcification in LVV are shown in the table.

**Conclusion:**

We have developed a novel software to quantify calcification in vascular territories. This software could be repurposed to calculate calcification burden in other regions of interest. Location of vascular calcification was found to be similar between LVV and HLD; however, the amount of calcification was higher in patients with LVV. Both traditional and disease-specific risk factors are associated with vascular calcification in LVV.

## A Novel Method to Assess Subchondral Bone Formation Using Naf-PET in the Evaluation of Knee Osteoarthritis

Taratuta<sup>1</sup>, Abass Alavi<sup>2</sup> and Joshua Baker<sup>3</sup>, <sup>1</sup>Radiology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Department of Radiology/Division of Nuclear Medicine, University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Rheumatology, University of Pennsylvania, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies using  $^{18}\text{F}$ -sodium fluoride positron emission tomography (NaF-PET) have quantified the increase in bone formation associated with osteoarthritic (OA) abnormalities with the maximum standardized uptake value ( $\text{SUV}_{\text{max}}$ ) in user-defined regions of interest (ROIs). A limitation of this method of quantification is that it assumes that the voxel with the highest SUV within the ROI represents the overall activity of the affected tissue. To address this limitation, we developed a novel method of global joint analysis to assess regions of expected bone turnover in articulating joints using NaF-PET in a group of patients at high risk for OA.

**Methods:** The study population consisted of 18 patients with Rheumatoid Arthritis who underwent static NaF-PET 90 minutes after the intravenous administration of NaF tracer. The global knee activity was defined as the area-weighted average of the mean NaF tracer uptake within the ROI. These global assessments at the knee were subsequently adjusted for overall bone formation at a non-articular location by determining the ratio of tracer uptake at the knee over the uptake at the femoral neck. For comparison, the  $\text{SUV}_{\text{max}}$  for each ROI was calculated methods. Standard radiographs of the knee were also obtained from the medical record in 9 patients and scored by a radiologist using the Kellgren-Lawrence (K/L) grading system.

**Results:** The average  $\text{SUV}_{\text{mean}}$  score for the knees was 1.48 (SD = 0.68) with a range of 0.54 to 2.96. Patients with greater NaF uptake demonstrated greater deterioration of the medial and lateral intercondylar tubercles, as evidenced by the larger lesions in the corresponding NaF-PET/CT scans (Fig. 1). Greater NaF global joint activity was observed among individuals with higher K/L grading scores ( $\rho = 0.69$ ,  $p = 0.04$ ). K/L grading was also associated with  $\text{SUV}_{\text{max}}$  values ( $\rho = 0.93$ ,  $p = 0.0003$ ).

**Conclusion:** Both methods were strongly associated with K/L grading of knee OA. The potential advantage of the novel  $\text{SUV}_{\text{mean}}$  method is that it may be more sensitive at detecting changes in intra-ROI OA progression since new spatially distinct lesions with a lower SUV that develop within an ROI would not be detected by the  $\text{SUV}_{\text{max}}$  methodology. Furthermore, the adjustment for fluoride uptake in non-articular sites is likely important in order to adjust for age-related declines in overall bone turnover. Further study is needed to determine the utility of this methodology in longitudinal studies.

Figure: Anatomical definition and cross-sectional analysis of the knee. The X-ray, CT, PET, PET/CT, and PET/CT with ROI show how degenerative changes were visualized and quantified. Patients with low and high NaF tracer uptake were observed.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Osteoarthritis (OA) is characterized by gradual loss of articular cartilage. Evaluation of cartilage in the small joints of the hands has shown that ultrasound may differentiate between normal and pathological joint cartilage, whereas semiquantitative scoring is not reliable. These studies have however assessed the dorsal aspects of the joint, in which osteophytes often limits the acoustic window.

The aim of the present study was to test the reliability of a semiquantitative scoring system for the assessment of palmar finger joint cartilage by ultrasound in a patient-based exercise of patients with hand OA.

### Methods:

Six experienced sonographers participated in a patient-based reliability exercise. Bilateral proximal interphalangeal (PIP) joints of 12 patients with hand OA were assessed twice on the same day by all experts using ultrasound machines (GE Logiq E9) equipped with high-frequency transducers (18MHz) with presets calibrated for the appropriate assessment of cartilage. The palmar aspects of the joints were assessed in a transverse view with the fingers fully extended, and the participants had an imaging atlas available during the exercise (figure).

Intraclass correlation coefficient (ICC) values with 95% confidence intervals (CI) were calculated with average-measure for inter-reader and single-measure for intra-reader reliability. Reliability was defined as poor (<0.5), moderate (0.5–0.75), good (0.75–0.9) and excellent (>0.90).

### Results:

A three-grade semiquantitative was applied: grade 0, normal cartilage (anechoic structure with visible margins of cartilage); grade 1, focal thinning of cartilage or loss of sharpness of at least one cartilage margin; grade 2, focal or complete loss of cartilage. In total 96 joints were assessed twice by every sonographer. The inter-reader reliability was excellent (ICC=0.90, 95% CI 0.77–0.97). Intra-reader reproducibility was excellent (0.95, 0.83–0.98) to moderate (0.56, 0.02–0.85), with a mean ICC value of 0.74.

### Conclusion:

A semiquantitative scoring system for the assessment of joint cartilage in palmar aspects of PIP joints by ultrasound showed excellent inter- and moderate to excellent intra-reader reliability in a patient-based reliability study. Our study demonstrates that ultrasound with a high-frequency probe is a reliable tool for evaluating cartilage and supports the use of a new semiquantitative scoring system for assessment of finger cartilage in hand OA patients.

### SESSION INFORMATION

Session Date: Sunday, November 5, 2017

Session Title: Imaging of Rheumatic Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

**Background/Purpose:** The estimated prevalence of hand osteoarthritis (HOA) varies severely according to the selection of different diagnostic modalities, items of interest and subject samples. In most studies conventional radiography (CR) was used in this matter. Recently ultrasound (US) was considered reliable and reproducible, and even more sensitive in detecting HOA signs such as osteophytes. We assumed that the prevalence of HOA detected by US was higher as described in previous studies. The objectives of this study were to investigate the prevalence and precise pattern of HOA in a working population by US.

**Methods:** The study included 427 participants (15.7% women, 84.3% men, mean age 53.5 years). A total of 11,840 images were scored for synovitis 0-3, synovitis mm, erosions 0-3, osteophytes 0-3, joint space mm and cartilage thickness mm. US assessment was provided for both hands, scanning 26 finger joints of each participant (CMC 1, MCP 2-5, PIP 2-5 and DIP 2-5) using an Esaote Mylab 25Gold unit with an 18 MHz linear transducer. Gray-scale US was performed on the palmar side with all joints in neutral position. Static images were stored and evaluated afterwards using Esaote Mylab-Desk software. HOA was defined as present if one or more joints of the participant showed osteophytes.

**Results:** The overall prevalence for HOA was nearly 100%. Only one participant had no osteophytes. There is strong evidence to suggest that the number of osteophytes increase with age ( $p < 0.001$ ). With every additional year, a mean increase of 0.18 (standard error 0.03) osteophytes has been observed. We found no evidence for an association of the number of osteophytes with sex ( $p = 0.4$ , after adjustment of age  $p = 0.9$ ). The prevalence rates of osteophytes in the following joints of the right hand were: 8.5% MCP 5, 38.2% PIP 5, 56.8% DIP 5, 18.1% MCP 4, 51.4% PIP 4, 65.6% DIP 4, 28.3% MCP 3, 58.7% PIP 3, 67.4% DIP 3, 19.8% MCP 2, 48.5% PIP 2, 66.7% DIP 2 and 37.5% CMC 1. The prevalence rates of osteophytes in the following joints of the left hand were: 7.3% MCP 5, 34% PIP 5, 47.5% DIP 5, 12.3% MCP 4, 51.5% PIP 4, 56.2% DIP 4, 19.7% MCP 3, 53.2% PIP 3, 67.3% DIP 3, 14.6% MCP 2, 45.8% PIP 2, 59.6% DIP 2 and 40.1% CMC 1. Overall, DIP 3 on the right-hand side was the most frequently affected joint, followed by DIP 3 on the left-hand side, then right-hand DIP 2 and DIP 4, then left-hand DIP 2.

**Conclusion:** US detected HOA shows a higher prevalence when compared to studies using CR. This supports prior studies emphasizing that US is more sensitive than CR in detecting HOA signs such as osteophytes. Nearly all participants showed HOA signs and on average more than 15% of the MCP joints were affected which could possibly be misinterpreted in the context of accompanying inflammatory joint diseases. Regarding that, HOA is an underestimated problem in sonographic assessments and has to be more carefully respected when interpreting US images of hand and finger joints.

## Musculoskeletal Ultrasound As a Diagnostic Tool for Eosinophilic Fasciitis and Correlation with MRI Findings

Florentina Berianu<sup>1</sup>, Neha Narula<sup>2</sup> and Andy Abril<sup>1</sup>, <sup>1</sup>Rheumatology, Mayo Clinic Florida, Jacksonville, FL, <sup>2</sup>Division of Rheumatology, Mayo Clinic, Jacksonville, FL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Eosinophilic fasciitis (EF) presents with pain and induration of the skin. Currently the clinical diagnosis is based on typical physical findings along with MRI enhancement of the fascia, and the diagnosis is confirmed by documenting fascial thickening and inflammation on tissue histology, including eosinophilic infiltrates. A recent case report has suggested fascia thickness can be measured with use of MSK ultrasound. Changes in compressibility of subcutaneous tissue using a high-frequency probe have been shown to help distinguish it from scleroderma patients. **Objective:** To describe a cohort of 7 patients with MSK US finding supporting the diagnosis of eosinophilic fasciitis with corresponding MRIs findings compared with normal controls.

**Methods:** 7 patients with suspected EF seen in our rheumatology clinic underwent MSK US of upper or lower extremities that exhibited findings of induration suggestive of EF. An ultrasound was performed using a 12-18 MHZ linear array transducer to visualize muscle and fascia in the area of pain and induration. A measurement of fascial thickness was recorded in all patients. MSK US was also performed in 7 healthy controls. Patients subsequently underwent MRI of the same region. Full thickness skin to muscle biopsy to confirm the diagnosis was performed in 6 out of 7 cases (one patient refused biopsy). Initial labs with serum eosinophils were recorded. None of the patients had Raynaud's or showed clinical or laboratory findings of scleroderma.

**Results:** 4 females and 3 males were included. Mean age: 43.5. Absolute eosinophil values ranged from 1051-4780/microL. The mean thickness of the fascia was 0.43 cm (ranges 0.21-0.7 cm) versus 0.14 cm in normal controls (ranges: 0.11-0.19 cm). All patients had MRI with contrast with evidence of thickened and enhanced fascia of the same region. Diagnosis of EF was confirmed with tissue histology in all cases in which biopsy was performed.

**Conclusion:** MSK US may represent a quick, safe, inexpensive and reliable diagnostic method for patient with suspected EF. It can also help locate the best site for biopsy.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Sjögren's syndrome is an autoimmune disease that involves salivary and lacrimal gland, which influences life quality of patients. In the recent classification criteria declared by ACR/EULAR in 2016, salivary gland biopsy remained one of the main diagnostic factors. Salivary gland ultrasonography (SGUS) has been evaluated recently for diagnosis Sjögren's syndrome or detection the morphological change of the gland. SGUS offered a non-invasive, time-consuming way in elucidating the condition of salivary gland. Although SGUS had been used in detection autoimmune diseases, such as IgG4 disease or sarcoidosis, the usefulness and effectiveness in Sjögren syndrome remained controversial.

**Methods:**

Total 74 patients were enrolled. SGUS was conducted by a 10MHz-13MHz linear probe at both parotid and submandibular glands. Each gland was scored from 0 to 4 according to the scoring scale proposed previously. The total maximum score was 16. Minor salivary gland biopsy results were examined by pathologist with Chisholm-Mason grade. Blood samplings and ESSPRI questionnaires were conducted after SGUS.

**Results:**

Total 47 patients with primary Sjögren's Syndrome, 9 patients with secondary Sjögren's Syndrome, and 18 patients with sicca symptoms were examined. SGUS score correlated with serum anti-Ro/SSA ( $p=0.012$ ), anti-La/SSB ( $p=0.004$ ), ESSPRI score ( $p<0.001$ ), and Chisholm-Mason score of salivary gland biopsy ( $N=24$ ,  $p=0.012$ ). Furthermore, dryness scale and fatigue scale correlated with SGUS score ( $p=0.001$  and  $0.002$ , respectively), but not with pain scale ( $p=0.199$ ). In patient with primary Sjögren syndrome, the correlations between ESSPRI and SGUS remained ( $p=0.024$ ), but it did not exist in patient with secondary Sjögren syndrome ( $p=0.073$ ) or sicca symptoms ( $p=0.074$ ).

**Conclusion:**

In our study, SGUS score correlated with patients' self-reporting ESSPRI score and the microscopic biopsy result. It also correlated with serology markers such as anti-Ro/SSA and anti-La/SSB. SGUS may provide a direct evaluation tool for evaluation the severity of gland architecture as well as an alternative representative for histological change.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Biobadasar is a registry that monitors adverse events in patients who use biological treatments in rheumatologic diseases conducted by the Argentine Society of Rheumatology. As in others international registries the community acquired pneumonia (CAP) has been detected as one of the most frequent infectological adverse events. Although all immunosuppressed patients should be vaccinated against streptococcus pneumoniae, there is a proportion of patients who are not.

Evaluate the prevalence of pneumococcal vaccination in patients with CAP within the Biobadasar database. Assess factors associated with severe CAP in these patients.

## Methods:

A cross-sectional, multicenter study was made in Biobadasar database from 2010 to 2016. In patients who reported CAP data of demographics, comorbidities and state of pneumococcal immunization was collected.

Microbiological data, treatment and outcome of the event was considered. The severity of CAP was assessed according to the opinion of the attending physician, hospitalization, risk of life and / or death.

Values are expressed as mean  $\pm$  standard deviation, median (ranges) and frequencies (percentages), as appropriate. We performed bivariate and multivariate logistic regression analysis to identify variables associated with the event.

## Results:

Of the 4029 patients enrolled in the registry, the cumulative incidence of CAP was 4.2% (n 170), 72.4% (n 123) were women. The mean age was 57 (SD  $\pm$  14.5). Biological treatment was found in 81.8% (n 139). Patients that have received the pneumococcal vaccine were 40.6% (n = 69). Severe CAP was detected in 7.1% with ICU admission requirement in and 31.8% were in general admission. Streptococcus pneumoniae was the main pathogen isolated in 13% of the cases. Overall mortality was 4.1%. Among the comorbidities of patients with CAP, the following were found: AHT 31.8%, Osteoporosis 16.5%, Smoking 12.9%, DBT 4.7%, interstitial lung disease 2.9%, CKD 1.8%. The most frequent rheumatic disease was RA in 74.5%, followed by PAs 6.5% and SLE in 6.5%. The median time to progression of the underlying disease was 9 years (R: 1-45). A logistic regression was performed to evaluate risk factors in severe CAP. In the univariate analysis for severe CAP we found statistical significance for Smoking OR 3.88, CI95 1.063-14.22,  $p = 0.029$  and chronic kidney disease (CKD) OR 31, CI95 2.6-376,  $p = 0.007$ . When performing a multiple logistic regression model, only renal failure OR 7.39 CI95 0.003-0.38  $p = 0.007$  was a predictor of severe CAP. Not significant association with immunosuppressive treatment ( $p = 0.09$ ), age ( $p = 0.464$ ), or vaccination ( $p = 0.937$ ).

## Conclusion:

The annual incidence of CAP in Argentina varies between 0.5 -1.1% while in our cohort it was four times higher. The prevalence of pneumococcal vaccination was less than 50%, showing that, although the literature and guidelines establish the need for vaccination, this is not so in the real world. In the multivariate analysis, only CRD was related to severe CAP. Although in the univariate analysis the CKD and the smoking habit represented factors associated with severity. We must emphasize the medical education in following the international vaccination guidelines.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Infection with the HIV has been associated with an increased risk of developing avascular necrosis (AVN), however there are only few studies in the US that analyzed the frequency and risk factors of the AVN in HIV patients on antiretroviral therapy (ART). The aim of this study was to determine the prevalence of AVN in well-controlled HIV-infected patients who were receiving antiretroviral treatment and evaluate potential risks factors including HIV medications.

### **Methods:**

: A retrospective review of our medical record database over a 6 year period was conducted using ICD-9 and ICD-10 codes. Three thousand patients with chronic HIV infection on ART that had more than 2 visits in the HIV clinic were identified. Individual electronic patient charts were reviewed and we identified patients diagnosed with AVN that was confirmed by magnetic resonance imaging studies. We collected data regarding patient's demographic characteristics, co-morbidities, T-helper lymphocytes with CD4 cell surface marker count, HIV RNA viral load and antiretroviral regimen. Two hundred randomly selected HIV-infected patients on ART without a diagnosis of AVN were used as a control group. Group differences were statistically compared and presented using Mann-Whitney U and Fisher's exact test.

### **Results:**

Forty two out of 3000 HIV patients (1.4 %) with AVN were identified (mean age of 49.5 years, 87% male). The most commonly involved joint was the hip (80%, n=34), followed by the glenohumeral (7.5%, n=4), femoral condyle (4.7%, n=2) and ankle (4.7%, n=2). Associated co-morbidities in patients with AVN included hyperlipidemia (21%, n=9), hypertension (19%, n=8), COPD/asthma (12%, n=5), hepatitis C (12%, n=5). All the patients with COPD/asthma have been treated with corticosteroids. Ten patients underwent joint replacement (23%), 4 core decompression surgery (9%) and the rest non-operative management.

Compared with the 200 HIV control patients, the patients with AVN were older (mean age of 49.5 vs. 42.7 years; p<0.01), had a history of COPD treated with corticosteroids (p= 0.02) and had a longer duration of HIV infection (mean duration of 16.8 vs.10.3 years; p<0.01). Patients who developed AVN were more likely to be receiving integrase strand transfer inhibitors (66%) compare to those who never received integrase inhibitors (20%; p<0.01). No differences were found between ANV patients and controls with respect to CD4 cell counts or viral load

### **Conclusion:**

AVN remains one of the most frequent musculoskeletal complication in HIV patients. Potential risk factors associated with the development of AVN in HIV patients were older age, longer duration of HIV infection, history of COPD/asthma, corticosteroid use and the use of ART regimens containing integrase strand transfer inhibitors.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Intravesical instillation of Bacillus Calmette-Guerin (iBCG) is used as an effective immunotherapy of bladder cancer. However it may have, as adverse event, a reactive arthritis (ReA) and the frequencies are known as about 0.5 to 1 % in Western countries. Objective is to evaluate the trend of incidence rate, frequency and HLA phenotype of reactive arthritis (ReA), uveitis and other adverse events in Japanese patients with bladder cancer following iBCG therapy.

**Methods:** The clinical findings of Japanese patients who received iBCG ( $n = 555$  [250 and 305 in Kochi Medical School Hospital and Kurashiki Medical Center, respectively]) for bladder cancer from March 1997 to February 2017 were retrospectively assessed, with specific attention to patients with ReA and uveitis. HLA phenotypes of patients with ReA were also looked. Moreover, iBCG-induced ReA diagnosed from 1997 to 2007 were compared with that from 2007 to 2017.

**Results:** Patients' mean age was  $72 \pm 10$  years and male/female ratio was 438/117. Fever, haematuria, and dysuria were presented in 91/555 (16.4%), 121/555 (21.8%), and 196/555 (35.3%), respectively of all enrolled patients. Of the 555 cases, ReA and uveitis were revealed in 11/555 (2.0%) and 4/555 (0.7%). The protocol of iBCG therapy was stable over the 20 years. Notably, HLA-B27, -B35, -B39 and -B51 positivity was more frequent in ReA patients (9.1%, 36.3%, 36.3% and 63.6%, respectively) ( $p < 0.05$ ) than in healthy subjects without ReA (0.3%, 8.3%, 4.0% and 9.1%, respectively). All 4 cases with uveitis had ReA, and showed positive HLA-B27 (25%), -B39 (50%) and -B51 (25%). Finally, the overall incidence of iBCG-ReA was not different between from 1997 to 2007 and 2007 to 2017.

### Conclusion:

The 2.0% iBCG-induced ReA frequency in Japanese patients exceeds that in Western countries, and its incidence has been stable over the last 20 years. HLA phenotype, especially HLA-B51 and -B39 alleles in addition to -B27, may be a risk factor in iBCG-induced ReA in Japanese patients.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Cytomegalovirus (CMV) infection is one of the most common opportunistic infections in rheumatic diseases. A definite diagnosis of CMV infection usually requires histopathological confirmation, but performing biopsy is usually difficult in patients with poor general condition. The CMV antigenemia test, which detects the virus-specific protein PP65 antigen in polymorphonuclear leukocyte, is widely used to examine immunocompromised patients with rheumatic diseases and becomes positive (CMV reactivation) regardless of the symptoms. Anti-CMV agents should not be exclusively and needlessly used for asymptomatic patients with CMV reactivation to avoid side effects and social burden due to high medication cost. The aim of this study was to determine the difference in the clinical characteristics between patients with symptomatic and asymptomatic reactivation in rheumatic diseases.

### Methods:

We retrospectively examined patients with CMV infection at our department, from January 2008 to December 2016. Patients positive for CMV reactivation were divided into two groups based on the symptoms they experienced, namely, CMV disease (with any symptoms) and asymptomatic CMV reactivation (without symptoms). The CMV antigenemia assay was used to assess the difference in the clinical characteristics between the two groups and their transitions 4 weeks prior to, and during, the first positive diagnosis.

### Results:

In 80 patients with CMV reactivation, 31.2% were men and the mean age was 61.0±15.7 years. In the univariate analysis, patients with CMV disease were mostly men, with oral candidiasis, hypoalbuminemia, low lymphocyte count, and high titer CMV antigenemia count. In the multivariate analysis, the odds ratios (ORs) are 8.82 (95% confidence interval (CI) 1.64–47.30, P value=0.01), 0.81 (95% CI 0.69–0.95, P value<0.01), and 1.26 (95% CI 1.05–1.50, P value=0.01) for oral candidiasis, serum albumin, and CMV antigenemia count, respectively (Table 1). Moreover, the transitionfs ORs 4 weeks prior to the first positive diagnosis using the CMV antigenemia are 1.96 (95% CI 1.09–3.54, P=0.025) and 2.02 (95% CI 1.07–3.8 P=0.03) for lymphocyte count and serum albumin, respectively (Table 2).

### Conclusion:

Patients with CMV reactivation, who have a gradually decreasing serum albumin and lymphocyte count 4 weeks prior to the first positive diagnosis and who presented with hypoalbuminemia, oral candidiasis, and high CMV antigenemia count during the first positive diagnosis, are highly at risk for CMV disease in rheumatic diseases.

**Table 1**

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Human T cell leukemia virus type 1 (HTLV-1) is the causative agent of adult T-cell leukemia (ATL). ATL is an aggressive T-cell malignancy caused by HTLV-1 infection and often occurs in HTLV-1-endemic areas, such as southwestern Japan, the Caribbean islands, Central and South America, Intertropical Africa, and Middle East. Recent study indicated that the estimated annual number of new HTLV-1 infection was 4,190 in nationwide blood donor surveillance in Japan. However, it is still not clear that the prevalence of HTLV-1 infection in patients with RA. Additionally, there are questions as to whether comorbidity of RA and its treatment in HTLV-1 carriers could increase the risk of developing ATL. The aim of this study is to clarify the prevalence of HTLV-1 infection in RA patients in HTLV-1 endemic area Miyazaki, Japan. In addition, we investigated the risk factors of developing ATL in HTLV-1 positive RA patients.

**Methods:** We established HTLV-1 positive RA cohort study in Miyazaki from 2012. Eight hundred sixty-one patients with RA were registered in this cohort until 2015. We evaluated blood levels in HTLV-1 proviral load (PVL) samples by real-time PCR, HTLV-1 antibody titer by particle agglutination assay, and the level of soluble IL-2 receptor (sIL-2R) by ELISA.

**Results:** The prevalence of HTLV-1 infection in RA patients was 6.0 % in this cohort. The age of HTLV-1 positive RA patients was higher than in HTLV-1 negative RA patients (p= 0.003). In the distribution of PVL, 20% of HTLV-1 positive RA patients showed highly PVL (> 4%), which was the known risk factor for ATL. The levels of sIL-2R in sera correlated to the levels of PVL, significantly (p=0.01).

Treatment of disease modifying anti-rheumatic drugs (DMARDs) including biologics were administered in the all patients. No effect to the levels of PVL and sIL-2R by the treatment with DMARDs was observed. A patient developed chronic type ATL, who were treated with MTX and anti-TNF inhibitor during 3-years observation periods (121 person-years) in this cohort.

**Conclusion:** The prevalence of HTLV-1 infection in RA patients in this cohort tended to be higher than that in nationwide surveillance in Japan. The incidence of ATL in HTLV-1 carriers was estimated to one per 1000 person-years. The incidence of ATL in HTLV-1 positive RA patients was higher than that in their study, although the sample size was small. A long-term follow-up of HTLV-1 positive RA patients is required to resolve whether the comorbidity of RA and its treatment increase the risk of developing ATL.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To estimate the frequency of chronic joint pain after infection with chikungunya virus in a Latin American cohort.

**Methods:** A cross sectional follow-up of a prospective cohort of 500 Chikungunya patients from Atlántico Department, Colombia clinically diagnosed with chikungunya during the 2014-2015 Colombian epidemic. Baseline and follow-up (20-months) symptoms were evaluated in serologically confirmed cases.

**Results:** Among 500 patients enrolled, 485 cases were serologically confirmed with chikungunya. Patients were predominantly adults (age  $49 \pm 16$  years), female, had a high school or less level of education and were of mestizo ethnicity. The most commonly affected joints were the small joints including the wrists, ankles and fingers. The initial joint pain lasted a median of 4 days (IQR 3-8). Sixteen percent of participants reported missing a median of 4 days (IQR 2-7) of school or work. After 20-months, one fourth of the participants had persistent joint pain. A multivariate analysis indicated that significant predictors of persistent joint pain included college graduate status, initial symptoms of headache or knee pain, missed work, normal activities affected, 4 or more days of initial symptoms, and 4 or more weeks of initial pain.

**Conclusion:** This is the first report to describe the frequency of chikungunya-related arthritis in the Americas after a 20-month follow-up. The high frequency of chronic disease highlights the importance of development of prevention and treatment interventions.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cytomegalovirus (CMV) infections occur frequently in immunocompromised patients. This disease will be fatal if proper treatment is not done. Therefore, in the treatment of connective tissue disease (CTDs), care should be taken while paying attention to the onset of cytomegalovirus infection. The purpose of this study is to clarify the predictors of CMV infection that developed in patients undergoing immunosuppressive treatment.

**Methods:** All CTD patients who were diagnosed as a CMV infection from January 2009 to March 2017 at our hospital were retrospectively reviewed. The diagnosis of CMV was made by clinical symptoms, radiological findings, the presence of CMV pp65 antigen in polymorphonuclear leukocyte (C7-HRP) and pathological findings of organ specimen. We compared the sequential changes in laboratory data between one month before diagnosis and at diagnosis. The differences in laboratory data between the survivors and non-survivors were also compared. Statistical analyses were performed using XLSTAT.

**Results:** A total of 20 patients were diagnosed with CMV infection (12 bone marrow suppression; 4 pneumonia; 2 enteritis; 1 genital ulcer; and 1 retinitis) and enrolled in this study. The mean age was 67.9 years old and 60% of patients was female. The CTDs of patients as follows: dermatomyositis (25%), adult-onset Still's disease (15%), and microscopic polyangiitis (15%). All patients were positive for CMV pp65 (mean C7-HRP:  $287.6 \pm 510.0/50,000$  WBC), who were treated with a moderate to high dose of glucocorticoids (mean prednisolone dose:  $33.4 \pm 15.9$  mg/day). When compared laboratory data between one month before diagnosis and at diagnosis, reduction of leukocyte cells, lymphocytes, platelet counts and IgG levels were predictive for occurring CMV infection. Among them, lymphopenia was critical for distinguishing between survivors and non-survivors.

**Conclusion:** The decreased in the leukocyte, lymphocyte, platelet, and IgG levels are important predictive factors for CMV infection in CTDs. Among them, decreased lymphocytes counts is a critical predictive factor for life threatening condition.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

## Background/Purpose:

Chikungunya fever (CHIK) has joint involvement as a striking characteristic, which may persist for months. This study aimed to better understand the clinical impact of this new disease, evaluating the patients of a reference center for infectious disease (Evandro Chagas National Institute of Infectious Diseases, Oswaldo Cruz Foundation – FIOCRUZ) in Brazil during the 2016 CHIK outbreak.

## Methods:

From April 2016 to October 2016, patients who sought care at the FIOCRUZ's Acute Febrile Disease Outpatient Clinic, with symptoms suggestive of CHIK (fever, musculoskeletal pain) were evaluated by a team of infectologists and rheumatologists through medical history, physical exam, clinical questionnaires and diagnostic lab tests. Patients were stratified by symptoms duration at first evaluation, classified as acute if symptoms present for  $\leq 14$  days and subacute/chronic if symptoms present for  $> 14$  days. After about 1 year from the initial visit, we contacted the patients by phone to obtain information about the current clinical status regarding joint pain, swelling and morning stiffness.

## Results:

We evaluated 61 patients with suspected CHIK. Diagnosis was confirmed in 41 patients by serology or PCR; in 20 patients, lab results were not available. Demographic and clinical characteristics of patients with diagnostic confirmation were similar compared to those without lab results; thus, both groups were analyzed together. There were 36 women and 25 men; none had autoimmune disease. In 18 patients, extra-articular manifestations (bursitis, tenosynovitis and carpal tunnel syndrome) were described. Baseline characteristics are shown in Table.

At 1 year, we managed to contact 30 patients; 9 of them referred symptoms resolution and 11 presented partial improvement, while 10 patients reported pain level similar to the initial presentation. Most patients had peripheral involvement, mainly hands and feet. Pain was considered mild in 9 patients, moderate in 9 patients, and intense in 3 patients. Subjects who chronically persisted with similar symptoms had significantly higher mean HAQ-DI at baseline (HAQ-DI = 2.4, 95% confidence interval (CI) 2.0–2.8) than those who achieved partial improvement or symptoms resolution (HAQ-DI = 1.5, 95% CI 1.1–2.0,  $p=0.01$ ).

## Conclusion:

Our study showed that CHIK results in dramatic, and often chronic joint involvement, with severe pain, fatigue and functional disability. Furthermore, the baseline HAQ-DI may predict chronicity of symptoms, although our conclusions are limited by our sample size.

**Table: Characteristics of patients with Chikungunya fever at first evaluation.**

	Symptoms duration		Total n = 61
	$\leq 14$ days n = 35	$> 14$ days n = 26

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It is well known that viral infections can trigger autoimmune rheumatic diseases. In 2014 there was an outbreak of Chikungunya (CHIK) virus infection in Venezuela. A majority of infected patients develop a flare of self-limited acute polyarthritis followed by complete remission. Some patients continue to experience subacute and chronic joint inflammatory symptoms. However, it is not well known how many of those patients evolve into a well-defined chronic rheumatic condition. The aim of this study was to examine how many patients with post-CHIK chronic inflammatory rheumatism (CHIK-CIR) evolve into a definite chronic rheumatic disease.

**Methods:** One hundred and sixty-eight patients seen during the period between 2014 and 2016 were included in this study. Post-CHIK CIR criteria were: 1. A triad of arthritis, fever and rash in presence of musculoskeletal manifestations (N=50, 29.76%) or 2. Musculoskeletal manifestations with or without the whole triad plus a positive IgM or IgG CHIK serology ELISA test (N=118, 70.23%). In both cases persistence of the symptoms for more than three months was required. The diagnosis for a definite rheumatic disease was done following the corresponding American College of Rheumatology (ACR) criteria. Statistical analysis was done by Chi-square and the Exact Fisher's test. P-values of < 0.001 were considered statistically significant. All patients signed an informed consent.

**Results:** A positive CHIK serology test was tested and resulted positive in 70.23% of patients (IgM and IgG in 44 and 117 patients, respectively). Rheumatoid factor (RF) was positive in 24.13% and anti-citrullinated peptide antibodies (ACPA) in 25.66% of the patients. Of the total population (168 patients) with post-CHIK-CIR, 89.29% were female, mean age was 55.33 ± 12.72 years, and mean disease follow-up was 73.9 ± 15.6 months. Forty patients (23.80%) had family history for autoimmunity. Thirty patients (17.85%) evolved into the following definite rheumatic diseases: rheumatoid arthritis (12.50%), psoriatic arthritis (2.38%), spondyloarthritis (1.79%) and systemic lupus erythematosus (0.60%). There was a statistically significant association between positivity of RF, ACPA or both with development of the *de novo* rheumatic diseases ( $P < 0.0001$  in each case). Other variables studied no related with development of *de novo* rheumatic disease were: IgM and IgG serology titers, presence of tenosynovitis and elevation of acute phase reactants.

**Conclusion:** CHIK virus infection can trigger a chronic autoimmune rheumatic disease, predominantly rheumatoid arthritis. Risk factors are the appearance of either RF or ACPA, or both.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Infections are the most frequent and concerning serious adverse events related to rheumatoid arthritis (RA) treatment with biologic drugs (bDMARDs). Their safety profile might have substantial regional differences. In January 2009 started BiobadaAmerica, a common platform registry project open to all Latin American countries, focused on safety monitoring of bDMARDs. Purpose of this study is to present data on factors associated with serious infections (SI) in patients with RA exposed to bDMARDs in two Latin-American not mandatory registries.

**Methods:** Data from Argentinian Registry (BiobadaSar) and Brazilian Registry (BiobadaBrazil), both initiated in 2010, were downloaded on December 31, 2016, merged and analyzed. The same constant monitoring process guaranteed data quality. Patients with rheumatic diseases were included prospectively when started the first bDMARD. Time of exposure was set from start of the drug to the date of last administration or censorship. SI incidence rate was calculated per 1000 patient/years with 95%CI

**Results:** Data from 2591 RA patients were analyzed, for a total of 9300 p/y. Treatments were 3784, 64% aTNF (Adalimumab, Certolizumab, Etanercept, Golimumab, Infliximab), 36% non-aTNF (Abatacept, Rituximab, Tocilizumab) including Tofacitinib. Females 85%, at baseline mean age 53 (SD 12.8)yrs, mean disease duration 10(8.5)yrs, mean follow-up 2.7 (2) yrs. The overall incidence rate of SI was 30.54 (CI 27.18-34.30). Comparing patients with (191) and without (2400) SI, age, sex, disease duration, use of concomitants DMARD, presence of diabetes mellitus or pulmonary chronic disease and a positive history of previous cancer did not differ statistically. Exposition to more than one bDMARD ( $p<0.01$ ), corticosteroid use ( $p<0.01$ ), smoking ( $p=0.01$ ) and presence of renal failure ( $p=0.03$ ) were statistically associated with SI. Unexpectedly, basal DAS28 was higher in patients without SI ( $p=0.03$ ).

**Conclusion:** Corticosteroid use, exposition to more than one biologic, smoking and renal failure are associated with serious infections in RA patients on bDMARDs.

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

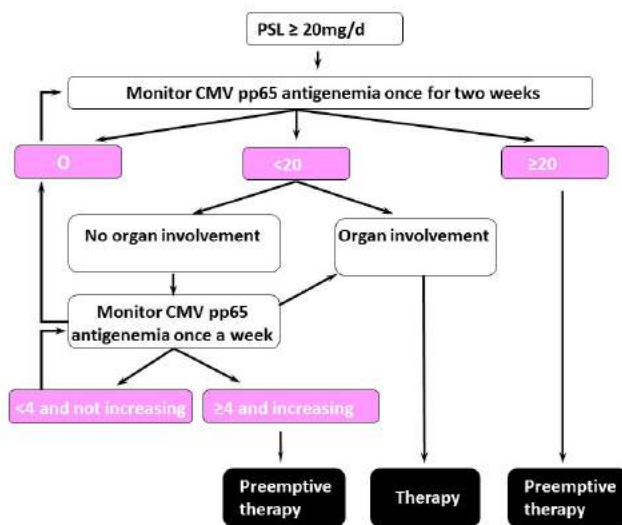

**Background/Purpose:** Cytomegalovirus (CMV) infection is a life-threatening complication in immunocompromized hosts. There are no official guidelines for CMV infection management in patients with connective-tissue diseases (CTD) under immunosuppressive therapy. CMV infection management according to the guidelines of the Japan Society for Hematopoietic Cell Transplantation (JSHCT) 2011 was performed in CTD patients and its usefulness and safety were evaluated.

**Methods:** We retrospectively examined 98 CTD patients who were admitted to the National Defense Medical College Hospital from October 2012 to March 2017, and were receiving  $\geq 20$  mg/day of prednisolone. CMV infection was defined by the detection of CMV pp65 antigenemia. CMV disease was diagnosed by both detection of CMV pp65 antigenemia and the involvement of organs due to CMV reactivation. We managed the CMV infection according to the guidelines. The primary endpoint was mortality and major organ involvement due to CMV infection. We also evaluated the risk factors for CMV reactivation and intervention after scoring positive for CMV antigenemia.

**Results:** Sixty-six cases of positive CMV pp65 antigenemia occurred in the 98 patients. An antiviral drug was administered in accordance with the JSHCT guidelines in 36 cases (treatment group). The patients in the remaining 30 cases did not receive treatment (observation group). No patients died due to CMV disease. Four patients in the treatment group died due to renal failure, Pneumocystis pneumonia or deterioration of adult-onset Still's Disease, in observation group none died. Persistent major organ involvement due to CMV infection did not occur in either groups. The risk factors for CMV reactivation were older age and steroid pulse therapy. The risk factor for CMV disease was CMV test positivity in the early period ( $<4$  weeks) of steroid therapy. Thrombocytopenia is the most common manifestation of CMV disease.

**Conclusion:** This study demonstrates the usefulness of CMV infection management according to the JSHCT guidelines for CTD patients under immunosuppressive therapy.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** immunosuppressive therapies and bDAMRDs especially, increase the risk of infections. According to the EULAR guidelines, all patients affected by autoimmune/inflammatory diseases should receive vaccinations against influenza and pneumococcus. The primary aim of this work is to evaluate the prevalence of flu and pneumococcal vaccinations in a cohort of patients affected by inflammatory arthritides and SLE treated with biological drugs. The secondary aim was to explore the reason why patients do not receive vaccination.

**Methods:** we administered a self-reporting questionnaire about both flu and pneumococcal vaccination, to 274 consecutive patients from February to April 2017 treated with bDMARDs.

**Results:** the 65.3% of patients declared to have been informed from rheumatologist about the possibility to received vaccinations during biological treatments but the 19.5% declared to have never been informed about them. The 46% of patients vaccination for influenza was performed after rheumatology suggestion and the 21% after their general practitioner suggestion, while the 30.1% has declared to have not performed it for several reasons: because concerned about adverse events (5.1%), because they don't see it as useful (17.4%) or for other reasons. The injection has been administered for free in the majority of patients (GPs 36.8%, local healthcare 33.5%). The 60.9% would have undergone vaccination even for a fee. The anti pneumococcal vaccination was administered to the 25.3%, while to the 50.3% has never been suggested to do it. The 4.4% has declared to have not performed it because concerned about adverse events and the 6.6% because they don't see it as useful. The injection has been administered for free at local healthcare facilities in the 84% of the patients. The 97.3% would have undergone vaccination even for a fee. At last the patients have declared to have always been well informed about vaccinations (48,9%), to have been well informed only about certain vaccinations (9,5%) or to have been informed only after asking (9,1%); The 19.1% was unsatisfied.

**Conclusion:** the acquired vaccine rate has been low for the influenza vaccination (<60%) and extremely low for the pneumococcal vaccination (26%). Even if the reasons of this results are partially attributable to a low patients' compliance (47.5% for the influenza vaccination, 11% for the anti pneumococcal vaccination), almost 20% has declared not to have ever been informed about vaccinations. So an additional effort to improve these results is mandatory.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The economic impact of the extrahepatic manifestations (EHM) of hepatitis C virus (HCV) infection remains unknown for France. To estimate the prevalence of HCV-EHM and the direct medical costs associated with HCV-EHM in France.

**Methods:** Estimates of thirteen EHM prevalence were obtained (i) from a retrospective data analysis of HCV-infected patients in specialized center in France, and the baseline prevalence in the general French population and (ii) from an international systematic review and meta-analysis. Per-patient-per-year (PPPY) inpatient, outpatient and medication costs to treat EHM in France were obtained from the literature, national databases, or expert opinion. The impact of achieving SVR after antiviral therapy was applied to the French healthcare costs.

**Results:** Using approach (i), increased EHM prevalence rates in HCV patients compared to the general population were observed for most

EHM, including cryoglobulinemia vasculitis (51.5% vs. 1.5%), rheumatoid-like arthritis (47.8% vs. 0.1%) and lymphoma (14.2% vs. 0.24%). The mean PPPY cost of EHM in the French tertiary center was 3,296 € [95% CI 1,829; 5,540]. In France, HCV-EHM amounted to a total cost of 215 million (M) € per year [144; 299]. Using approach (ii), the mean PPPY cost of EHM in France was estimated to be 1,117 €. The estimated total cost reduction in France associated with SVR was 13.9 M€ for diabetes, 8.6 M€ for cryoglobulinemia vasculitis, 6.7 M€ for myocardial infarction, 2.4 M€ for end-stage renal disease, and 1.4 M€ for stroke.

**Conclusion:** Extrahepatic manifestations of HCV infection substantially add to the overall economic burden of HCV infection in France. Sustained virological response after antiviral therapy is expected to significantly reduce the total costs of managing HCV-EHM in France.

## The Value of Imaging As an Early Noninvasive Test for Prosthetic Joint Septic Arthritis

Kevin Byrne<sup>1</sup>, Mary Louise Fowler<sup>2</sup>, Sarah Lieber<sup>3</sup>, Robert Shmerling<sup>4</sup> and Ziv Paz<sup>3</sup>, <sup>1</sup>Boston University School of Medicine, Boston, MA, <sup>2</sup>Boston University School of Medicine, Boston, MA, <sup>3</sup>Beth Israel Deaconess Medical Center, Boston, MA, <sup>4</sup>Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Infection-related Rheumatic Disease Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Medical imaging is commonly obtained in evaluating patients with suspected prosthetic joint septic arthritis (PJSA); it may be helpful to detect other pathology in the joint (e.g., chondrocalcinosis), to establish a baseline, or to detect the presence of synovial fluid. Imaging may even help diagnose PJSA, but there is little data available to evaluate the value of various imaging modalities for the diagnosis of PJSA.

**Objectives:** To examine how the use of medical imaging for PJSA has changed over the 17 years of this study and to assess the value of different imaging modalities in differentiating patients with culture-positive PJSA from patients with culture-negative PJSA.

**Methods:** We conducted a retrospective study that included all patients ages 18 years and older who were diagnosed with monoarticular PJSA and underwent surgical intervention at a single, tertiary-care hospital between 1997 and 2014.

**Results:** Of the 280 patients with diagnosed PJSA, 214 (76.4%) had at least one imaging study during the index admission. Radiographs were performed in 167 patients (59.6%). The second most common imaging modality was CT scan (17 patients; 6.1%). The most common imaging findings were joint effusion in 91 (32.5%) patients and soft tissue swelling in 41 (14.6%) patients. Of the 280 patients assigned a diagnosis of PJSA, 190 (69.3%) were culture-positive. Patients with culture-positive PJSA were less likely to have normal findings in their plain radiographs (3.7 vs. 13.1%,  $p=0.007$ ), more likely to have gas/free air (7.4 vs. 1.2%,  $p=0.043$ ), but no more likely to have joint effusions (28.9 vs. 25.0%,  $p=0.56$ ) or soft tissue swelling (13.2 vs. 8.3%,  $p=0.31$ ). The percentage of patients receiving each imaging modality remained relatively constant over the course of the study (Figure 1).

**Conclusion:** Imaging studies—especially radiographs—are commonly ordered to evaluate patients with suspected PJSA. Our study demonstrates that patients with culture negative PJSA are more likely to have normal findings on imaging, including radiographs. Patients with culture-positive PJSA were significantly more likely to have radiographic findings of gas or free air. Imaging studies in general and radiographs in particular demonstrated joint effusions in patients at similar rates among PJSA patients with and without positive cultures. This study demonstrates that in most cases imaging studies have limited utility among patients with suspected PJSA and cannot be relied upon to demonstrate specific findings to suggest the diagnosis.

**Figure 1:** Trend over time for the percentage of patients receiving different modalities of imaging studies. The line labeled “Overall” indicates the percentage of patients receiving any form of imaging study.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Accelerated atherosclerosis has become increasingly recognized as a complication of chronic inflammatory disease, such as in patients with rheumatoid arthritis (RA). RA patients have a 2-fold increased risk of developing coronary artery disease (CAD) regardless of traditional risk factors and cardiovascular complications substantially contribute to their increased mortality. The inflammatory lesions in RA and CAD share the chronicity of tissue-destructive immune responses, with macrophages representing abundant effector cells.

**Methods:** Patients with RA who fulfilled 2010 ACR/EULAR RA Classification Criteria and patients with CAD (history of at least one myocardial infarction) were enrolled together with healthy age-matched controls. Monocytes were isolated from peripheral blood and differentiated into macrophages with macrophage colony-stimulating factor. Macrophages were polarized into M1 cells with IFN- $\gamma$  and lipopolysaccharide. Mitochondrial reactive oxygen species (ROS) were quantified by MitoSOX staining and their production was inhibited with the ROS scavenger mitoTEMPO. Cellular ATP concentrations were quantified by fluorometric assay. Glycolytic rates and oxygen consumption were measured by Seahorse Flux Analyzer experiments. Relative gene expression was analyzed by quantitative RT-PCR and adjusted for  $\beta$ -actin transcripts.

**Results:** Seahorse experiments demonstrated increased glycolytic rates (ECAR) in RA and CAD macrophages compared to age-matched healthy controls. Key enzymes of glycolysis, HK-1 and PKM-2, were upregulated as well as GLUT-1, the main glucose uptake receptor in macrophages. The breakdown of glucose resulted in high mitochondrial activity characterized by an increase in mitochondrial membrane potential and by greater oxygen consumption, with mitochondria from CAD macrophages respiring even more than those from RA macrophages. Pharmaceutical uncoupling of the electron transport chain was used to measure maximal mitochondrial respiration. Notably, CAD mitochondria had explicitly more reserve capacity to work against imminent energy deficits and RA mitochondria still showed higher capacity than healthy ones. A byproduct of enhanced mitochondrial respiration is the generation of mitochondrial ROS, which was confirmed

by MitoSOX staining to be substantially higher in patient-derived macrophages. Production of pro-inflammatory key cytokines of the synovial joint and the atherosclerotic plaque was directly related to mitochondrial activity, as indicated by the effective inhibition of IL-6, IL-1b, IL-18, and IL-23 when cells were pretreated with mitoTempo, a ROS-scavenger that specifically targets mitochondria-derived superoxide.

**Conclusion:** Macrophages from RA and CAD patients share a distinct metabolic profile characterized by upregulated glycolysis and high mitochondrial activity; fueling excess production of ROS and cytokines. Metabolic activity directly regulates the macrophages' inflammatory potential and might contribute to accelerated atherosclerosis in RA patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** LXR $\alpha$  is an oxysterol-regulated transcription factor that plays a key role in reverse cholesterol transport by inducing the expression of ATP binding cassette A1 (*ABCA1*) and other genes. LXR $\alpha$  also promotes macrophage (M $\phi$ ) polarization away from proinflammatory (classically activated, M1) toward alternatively activated (M2) M $\phi$ . M1 M $\phi$  are metabolically dependent on glycolysis, whereas M2 M $\phi$  require oxidative metabolism. Hypoxia-inducible factor 1- $\alpha$  (HIF1 $\alpha$ ), a key regulator of glycolysis, promotes M1 M $\phi$  polarization. We have shown that M $\phi$  depletion prevents diffuse alveolar hemorrhage (DAH) in mice with pristane-induced lupus. The present study explored the mechanisms involved.

**Methods:** Murine M $\phi$  subsets were phenotyped by flow cytometry and the cell subsets were flow-sorted. Gene expression in SLE patients and mice with pristane-lupus was determined using RNA-Seq and real-time PCR. Cell metabolism was evaluated by extracellular flux analysis (Seahorse assay). Pristane-treated C57BL/6 mice received daily injections of the synthetic LXR agonist T0901317 (or vehicle) for 14-d after which we assessed DAH.

**Results:** Peritoneal M $\phi$  from pristane-treated mice had an M1 phenotype with high CD274, Ly6C, CD86, and TNF $\alpha$  expression and low CD273, Ym1, and IL-10 vs. mice treated with mineral oil (MO), a control inflammatory oil that does not cause lupus. MO treatment induced the opposite pattern from pristane, consistent with an M2 phenotype. Glycolytic metabolism (extracellular acidification rate, ECAR) was higher in pristane-treated mice (M1-like) whereas oxidative metabolism (oxygen consumption rate, OCR) was higher in MO-treated mice (M2-like). HIF1 $\alpha$  and the HIF-regulated gene phosphofructokinase (*PFKL*) were higher in pristane-treated mice whereas LXR $\alpha$  and the LXR-regulated gene *ABCA1* were higher in MO-treated mice. Similarly, SLE patients' monocytes exhibited low LXR $\alpha$ /ABCA1 and high HIF1 $\alpha$ /PFKL expression vs. healthy controls consistent with M1 polarization. T0901317 inhibited type I interferon and increased *ABCA1* *in vitro* in both SLE patients' monocytes and in mice. In pristane-lupus, T0901317 re-polarized M $\phi$  to M2, increased M $\phi$  OCR, and decreased TNF $\alpha$ . It also completely abolished autoimmune lung disease (DAH).

**Conclusion:** M $\phi$  may play a more important role in SLE than previously recognized. Murine and human SLE both are associated with low LXR activity in M $\phi$  and monocytes. Our data suggest that high LXR $\alpha$  activity is a marker for the generation of M2 M $\phi$ , which mediate the resolution of chronic inflammation, while protecting from end-organ disease in lupus. LXR agonist therapy prevents DAH in mice and raises ABCA1 expression on patients' monocytes *in vitro*, suggesting a possible therapeutic role in SLE.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Serum amyloid A (SAA) is an acute phase protein and its serum levels may increase up to 1000-fold over normal levels during inflammation, triggering perpetual inflammatory responses. The level of SAA has been reported to have a correlation with rheumatoid arthritis (RA) symptoms. However, the direct role of SAA in the RA pathogenesis remains unclear. In this study, we have identified that SAA contributes to the activation of macrophages through induction of nuclear factor of activated T cells 5 (NFAT5), resulting in the aggravation of arthritic symptoms.

**Methods:** Expression of NFAT5 was examined in the SAA-treated macrophages using Western blot analysis and immunofluorescence. The transcriptional activation of NFAT5 was measured by luciferase reporter assay and Matrigel assay. To find the receptor and signaling pathway involved in the SAA-induced NFAT5 expression, chemical inhibitors and genetically deficient macrophages were used. The cell migrations were compared between wild type and NFAT5 knock-down or knock-out macrophages by using transwell migration assay, wound-healing assay and air-pouch mouse model. To confirm the importance of SAA-NFAT5 axis *in vivo*, we injected SAA into the arthritis mouse model induced by injection of methylated-bovine serum albumin/interleukin-1 $\beta$  (mBSA/IL-1 $\beta$ ).

**Results:** SAA induced the expression and activation of NFAT5 in macrophages, which is mediated by TLR2 and TLR4 on their surface. MAPKs and PI3K signaling pathways, especially JNK1/2, were involved in the NFAT5 expression induced by SAA treatment. The induced NFAT5 contributed to the cytoskeletal rearrangement in macrophages, thereby leading to the cell migration *in vitro* and *in vivo*. Moreover, SAA injection aggravated disease severity, including increased macrophages, in the joints of mBSA/IL-1 $\beta$ -induced arthritis.

**Conclusion:** Our data show novel findings that SAA could induce the activation and migration of macrophages by stimulating the expression and activity of NFAT5 through TLR2/4 and MAPKs signaling pathways. Moreover, increased SAA could contribute to the aggravation of arthritis symptoms in the mouse model. Thus, targeting SAA-NFAT5 axis may potentially be of therapeutic value in chronic inflammatory diseases accompanied by elevated SAA levels, such as rheumatoid arthritis.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Macrophages contribute to the pathogenesis of rheumatoid arthritis (RA). They can display various states of activation or « polarization », characterized by distinct functions and plasticity. M1 polarization corresponds to the “classical”, pro-inflammatory activation as identified in RA. M2 “alternative” polarizations display immunoregulatory and wound-healing properties. Data concerning the effects of RA anti-cytokine biological drugs (bDMARDs) on macrophage polarization are scarce.

We aimed to assess in vitro modulation of macrophage polarization by RA bDMARDs.

**Methods:**

Blood monocytes from 15 healthy controls and 10 RA patients were positively sorted by CD14<sup>+</sup> magnetic selection. Macrophages were Derived from Monocytes (MDM) by 5 days of culture in the presence of MCSF, and activated or not for 24h as M1 pro-inflammatory MDM (by LPS + IFN $\gamma$ ) or as M2 alternative MDM by IL10 or IL4, respectively M2(IL10) and M2(IL4). M1 MDM were cultured with or without bDMARDs.

We evaluated 2 anti-TNF agents (etanercept (ETA), adalimumab (ADA)), 1 anti-IL6R agent (tocilizumab (TCZ)), and 1 anti-CD20 agent (rituximab (RTX)) used as control monoclonal antibody. bDMARDs effects were assessed on M1 activation phase by flow cytometric analysis of membrane markers. Functional aspects of polarization were assessed by analysis of cytokine production in cell culture supernatants (cytometric bead array and ELISA) and phagocytosis (flow cytometry).

M1 MDM cultured in the presence of bDMARDs were compared to untreated M1 MDM by a Wilcoxon matched pairs test.

**Results:**

We validated *membrane polarization markers* in our culture model: CD40 and CD80 as M1 (LPS + IFN $\gamma$ ) markers; CD16, CD163, MerTK and CD64 as M2(IL10) markers, CD206 and CD200R as M2(IL4) markers.

When compared to MDM from healthy controls, MDM from RA patients displayed a biased *plasticity*: they significantly expressed higher levels of M1 markers after M1 activation and expressed lower levels of CD16 after differentiation or M1 and M2 activations.

Concerning the effect of bDMARDs on *surface markers after M1 activation* (M1 MDM): in RA patients and healthy controls, anti-TNF agents induced a significant decrease in M1 markers and a significant modulation in M2(IL10) markers. We observed (i) a decrease in CD40 and CD80, (ii) an increase in CD16, CD163, and MerTK, (iii) a decrease in CD64 with ETA and an increase with ADA. TCZ induced a slight but significant decrease in CD40 and an increase in CD64. RTX only increased CD64.

Anti-TNF agents led to a significant *modulation of cytokines produced by M1 MDM* from healthy controls: we observed a decrease in TNF $\alpha$ , IL6, IL12 and IL10 levels, and an increase in TGF $\beta$ . TCZ mainly affected IL6 and TNF $\alpha$  productions with a significant decrease. No significant effect was observed with RTX.

In healthy controls, *phagocytosis* was superior in M2(IL10) and M2(IL4) activated MDM than in M1 MDM. Anti-TNF agents, but neither TCZ nor RTX, induced an increase of phagocytosis in M1 MDM.

**Conclusion:**

Anti-TNF agents modulate the phenotype of MDM from healthy donors as well as from RA patients. They up-regulate M2 alternative properties and downregulate M1 inflammatory properties in macrophages.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** rs26232 in the first intron of *C5orf30* has been associated with risk of developing rheumatoid arthritis (RA) and severity of tissue damage. *C5orf30* is highly expressed by RA synovial fibroblasts (RASf) and macrophages. Inhibition of *C5orf30* in RASf results in increased cellular invasiveness and migration *in vitro* and inhibition in the collagen-induced arthritis model accentuated joint inflammation and damage. There is no published data on the biological activities of *C5orf30* in macrophages.

**Methods:** Monocyte cell line (THP1) and primary monocyte-derived macrophages (MDM) were used. *C5orf30* mRNA was assessed by qPCR and protein via Western blot. Transcript and protein half-lives were assessed using actinomycin D and cyclohexamide. Polarization to M1 and M2a phenotypes and stimulation with TNF and LPS on *C5orf30* expression were compared. *C5orf30* levels were manipulated using siRNA and functional effects on macrophage biology was assessed using ELISAs, invasion assays, pathogen phagocytosis assays, reactive oxygen species assays, gene expression and intracellular signalling assays. *In vivo*, antisense morpholino oligonucleotides were used to knockdown *C5orf30* in zebrafish. Confocal imaging was used to assess the number of invading macrophages.

**Results:** *C5orf30* has a half-life of 3.13 hours, which does not significantly change with the addition of inflammatory (LPS + IFN $\gamma$ ) or anti-inflammatory (IL-4) stimuli. Protein half-life is 19.54 hours, rising to 22.05 hours when pretreated with LPS + IFN $\gamma$  (M1-like) and decreasing to 15.07 hours when pretreated with IL-4 (M2a-like). Polarization to M2a increased *C5orf30* protein expression whereas polarization to M1 resulted in phosphorylation of *C5orf30* protein and decreased expression of *C5orf30* ( $p=0.01$ ). Treatment with TNF or LPS reduced *C5orf30* expression (TNF  $p=0.001$ , LPS  $p=0.02$ ). LPS phosphorylates *C5orf30*. Pretreatment of cells with the JNK inhibitor SP600125 retarded the phosphorylation of *C5orf30* in response to LPS in a dose-dependent manner and prevented downregulation of *C5orf30* gene expression. Knockdown of *C5orf30* reduced the invasive capacity of macrophages ( $p=0.003$ ) with an associated decrease in *MMP1* ( $p=0.01$ ), *MMP3* ( $p=0.01$ ) and *MMP9* ( $p=0.03$ ). Decrease in invasion was intensified upon incubation with either TNF ( $p=0.02$ ) or LPS ( $p=0.01$ ). *C5orf30* knockdown increased phagocytosis when co-stimulated with LPS ( $p=0.01$ ). *C5orf30* knockdown also increased activation of the JNK pathway. *In vivo*, tail amputations in zebrafish with *C5orf30* deficient embryos showed an increased macrophage infiltration at the wound site ( $p=0.01$ ).

**Conclusion:** Stimulation with inflammatory mediators induces phosphorylation of *C5orf30* and downregulates *C5orf30* gene expression, whereas treatment with anti-inflammatory signals increases *C5orf30* protein expression. *C5orf30* knockdown enhanced the proinflammatory macrophage phenotypes of phagocytosis and JNK activation whilst diminishing the tissue-clearing (M2-like) phenotype of macrophage invasion. This data indicates an important role for *C5orf30* in the immunomodulatory regulation of macrophages and is consistent with our previous findings in RASf.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

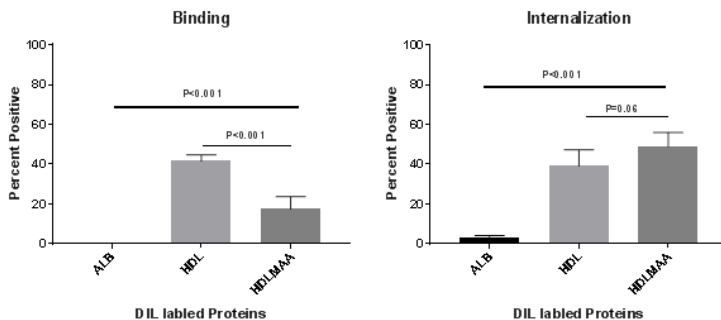

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is associated with an increased cardiovascular disease (CVD) burden, one that appears to be mitigated by increased concentrations of circulating HDL resulting from effective disease-modifying treatment. Our group has demonstrated that proteins modified with malondialdehyde-acetaldehyde (MAA), are present in the synovial tissues of RA patients and atherosclerotic lesions from non-RA patients with CVD. Previous data has also shown that MAA-modified proteins are bound and internalized by scavenger receptors (SRs) (SRA, SRBI, LOX-1, and CD36) present on immune cells. Therefore, in this study we evaluated whether HDL is modified by MAA and bound or internalized by monocytes.

**Methods:** Human HDL was labeled with 1,1'-dioctadecyl-3,3,3',3'-tetramethylindocarbocyanine perchlorate (DIL-HDL). For MAA modification DIL-HDL (1 mg/ml) was incubated with 2mM malondialdehyde and 1mM acetaldehyde for 3 days and fluorescence of the dihydropyridine structure determined. To evaluate receptor mediated binding and internalization, PMA activated THP-1 cells (human monocytic) were incubated on ice at either 4°C or 37°C (respectively) for 90 minutes with 25 µg/ml of DIL-Albumin, DIL-HDL and DIL-HDL-MAA. Cells were washed, fixed in paraformaldehyde, and subjected to flow cytometry at 594 nm wavelength. Analysis was performed using FlowJo V10. Data are expressed as percent positive compared to the DIL-labeled human albumin.

**Results:** Human HDL was modified at 30,000 fluorescent units (FU), which was greater than the MAA modification observed for human serum albumin (22,000 FU). As shown in the Figure, THP-1 cells bound HDL (41.73%) at the cell surface significantly better than HDL-MAA (17.55%;  $P<0.001$ ). Internalization studies revealed that HDL-MAA (48.9%) was taken up more by the cells than HDL (39.14%) alone, although this difference did not achieve statistical significance.

**Conclusion:** These data show that HDL can be modified with the MAA adduct and HDL-MAA is subsequently bound and internalized by human monocytes. THP-1 cells contain multiple scavenger receptors capable of binding and internalizing altered self-ligands as a normal clearance mechanism. These results demonstrate that HDL modified with MAA is bound at lower levels than HDL alone, but is internalized more efficiently by human monocytes. Taken together, these results suggest that MAA modification could impact cellular trafficking of HDL, thus influencing CVD pathogenesis in conditions characterized by oxidative stress and increased MAA adduct formation.

## Characterization of Neutrophil Subsets and Neutrophil Extracellular Traps in Pyogenic Arthritis, Pyoderma Gangrenosum and Acne (PAPA) Syndrome

**Pragnesh Mistry**<sup>1</sup>, Carmelo Carmona-Rivera<sup>1</sup>, Nickie Seto<sup>1</sup>, Monica Purmalek<sup>1</sup>, Amanda Ombrello<sup>2</sup>, Ivona Aksentijevich<sup>2</sup>, Daniel L. Kastner<sup>2</sup> and Mariana J. Kaplan<sup>1</sup>, <sup>1</sup>Systemic Autoimmunity Branch, NIAMS/NIH, Bethesda, MD, <sup>2</sup>Inflammatory Disease Section, NHGRI/NIH, Bethesda, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pyogenic arthritis, pyoderma gangrenosum and acne (PAPA) syndrome is an autosomal dominant autoinflammatory disorder caused by mutations in the *PSTPIP1/CD2BP1* gene. PAPA syndrome is characterized by recurrent flares of sterile arthritis and severe skin inflammation in the absence of adaptive immune responses. Mutations in *PSTPIP1* likely dysregulate the pyrin inflammasome leading to exuberant IL-1 $\beta$  production. PAPA patients respond to treatment with cytokine inhibitors, including IL-1 inhibitors. Neutrophils can undergo a form of cell death called NETosis where dying cells release a meshwork of decondensed DNA decorated with granule proteins called neutrophil extracellular traps (NETs). NETs have been shown to induce tissue damage in other systemic diseases. While previous studies have suggested that neutrophils may play critical roles in driving inflammation in PAPA syndrome, the mechanism by which it happens is still unclear. A subset of proinflammatory neutrophils called low-density granulocytes (LDGs) has been identified in other autoimmune/autoinflammatory conditions and these cells display an enhanced capacity to form NETs. Here, we aimed to elucidate the role of neutrophil subsets and NETs in the pathogenesis of PAPA syndrome.

**Methods:** Normal density neutrophils were isolated by dextran sedimentation from control and PAPA patients. LDGs were isolated by negative selection from the PBMC fraction. Immunofluorescence (IF) was used to assess the presence of NETs. To assess the effect of serum in NET formation, control neutrophils were incubated with 10% serum from control or PAPA patients in the presence or absence of the IL-1 receptor antagonist anakinra for 2 h. Circulating NET remnants were quantified by ELISA against citrullinated histone H3 (citH3)-DNA complexes. A skin biopsy from a PAPA patient was analyzed by IF, quantitative PCR, and western blot analysis for the presence of NETs and proinflammatory cytokines.

**Results:** LDGs were detected in PAPA patients. Neutrophils and LDGs from PAPA patients displayed an enhanced capacity to spontaneously form NETs when compared to control neutrophils. Serum from PAPA patients induced NET formation in control neutrophils and this process was inhibited in the presence of IL-1 inhibitor, anakinra. NET products, as measured by cit-H3-DNA complexes in plasma from PAPA patients, were significantly higher when compared to control plasma. We detected NETs in a skin biopsy from a PAPA patient, in association with upregulation of tissue IL-1 $\beta$  and IL-8 when compared to healthy skin biopsies. Furthermore, an immature granulocyte signature was detected in the skin biopsy tissue suggesting the presence of LDGs.

**Conclusion:** Taken together, neutrophils and LDGs in PAPA patients display dysregulated NET formation as assessed by *in vitro* spontaneous NET formation and the presence of circulating NET remnants. Proinflammatory cytokines in serum and affected tissues of PAPA patients trigger the NET formation. Anakinra ameliorates serum-induced NETosis, suggesting a role of IL-1 signaling in NETosis. The identification of LDGs in skin tissue from PAPA patients point out a strong myeloid signature in this condition.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neutrophils play a key role in host defenses and have recently been implicated in the pathogenesis of autoimmune diseases by several mechanisms including formation of neutrophil extracellular traps (NETs) through a distinct form of programmed cell death called NETosis. Techniques to assess and quantitate NETosis *in vitro* in an unbiased, reproducible and efficient way are lacking, considerably limiting the advancement of this field. We optimized and validated a new method to automatically quantify the percentage of neutrophils undergoing NETosis in real time using IncuCyte ZOOM™, a two-color, live-content imaging platform, and the membrane permeability properties of two different DNA dyes. We also evaluated whether this technology would allow for the differentiation of various forms of neutrophil cell death.

**Methods:** Neutrophils were isolated from healthy controls and their nuclei were stained with the membrane permeable DNA binding NUCLEAR-ID red dye to count all cells. They were then seeded on a 96-well plate and incubated with various stimuli or inhibitors and a membrane-impermeable DNA dye, Sytox Green, that helped to assess cell death. Images were taken every 10 minutes and a processing definition was devised to automatically count all neutrophils at baseline and neutrophils undergoing cell death based on fluorescence intensity and stained nuclear area size.

**Results:** This imaging platform enabled efficient, real-time imaging and quantification of cells undergoing NETosis. Findings were confirmed with established method of immunofluorescence microscopy and the percentage counts of cells undergoing NETosis correlated well. The platform's ability to rapidly measure NETosis and effects of drugs to modulate it was used to test various concentrations of an inhibitor of NETosis (Akt-inhibitor XI) which showed a dose dependent effect. This method was also able to distinguish between distinct neutrophil cell deaths. Neutrophils undergoing NETosis induced by phorbol-myristate acetate, bacterial toxin nigericin, calcium ionophore A23187 or platelet activating factor, exhibited a loss of multi-lobulated nuclei, nuclear decondensation and eventual membrane compromise. Necrosis induced by freeze-thaw resulted in instantaneous damage to membrane integrity with minimal change to nuclear morphology. In contrast, apoptotic cells induced by staurosporine showed nuclear condensation and cytoplasmic blebbing.

**Conclusion:** The IncuCyte ZOOM platform is a novel assay that quantifies NETosis in a rapid, automated and reproducible way, while retaining the ability to distinguish between different types of neutrophil cell death, and offers a significant advancement in the study of neutrophils. It is a powerful tool to assess neutrophil physiology and to swiftly develop novel neutrophil targets in autoimmune diseases.

## Neutrophil Extracellular Traps Are Induced By Adenosine and Stimulate Release of TNF Alpha from Macrophages in Deficiency of Adenosine Deaminase 2 (DADA2)

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Reduction of adenosine deaminase 2 (ADA2) activity due to autosomal recessive loss of function mutations in the CECR1 gene results in a systemic illness known as DADA2 characterized in part by early-onset stroke, vasculitis, and clinical response to TNF-inhibitors. Adenosine, which is extracellularly degraded by ADA2, modulates inflammation via four different adenosine receptors (ARs). Neutrophils and a subset of neutrophils known as low-density granulocytes (LDGs) have been implicated in the pathogenesis of small-vessel vasculitis through the formation of neutrophil extracellular traps (NETs). The study objective was to determine whether neutrophils and NETs play a pathogenic role in DADA2.

**Methods:** Neutrophils and LDGs were isolated from healthy volunteers, patients with DADA2, and their family members. NETs were quantified and visualized by fluorescence microscopy. Immunofluorescence was performed against citrullinated-histone H4 and macrophage

markers to detect NETs and macrophages in affected tissue from a patient with DADA2. Neutrophils were incubated with adenosine +/- ADA2 enzyme and resultant NET formation was quantified. Pharmacologic approaches were utilized to determine the specific receptor(s) and pathways that mediate NET formation by adenosine. ELISA quantified TNF-alpha release in supernatants from macrophages incubated with NETs.

**Results:** An abundance of circulating LDGs prone to spontaneous NET formation were observed during active disease in DADA2 and were significantly reduced after remission induction by anti-TNF therapies. Increased circulating LDGs were identified in unaffected heterozygous carriers of *CECR1* mutations. *In vivo* evidence demonstrated NETs and macrophages in affected gastrointestinal tissue in a patient with DADA2. Adenosine triggered NET formation by engaging A1 and A3 adenosine receptors and through ROS- and PAD4- dependent pathways. Adenosine-induced NETosis was inhibited in the presence of recombinant ADA2, A1/A3 AR antagonists, or an A2A agonist. M1 macrophages incubated with NETs from patients with DADA2 released significantly increased amounts of TNF-alpha. Treatment with IL-1Ra (anakinra) or an A2A AR agonist decreased nuclear translocation of NFkB and pro-inflammatory cytokines-induced by NETs in macrophages.

**Conclusion:** Neutrophils may play a pathogenic role in DADA2. LDGs and NETs are observed during active disease. Adenosine can trigger NET formation, and deficiency of ADA2 may enhance adenosine-mediated NETosis. M1 macrophages produce TNF-alpha when exposed to NETs from patients with DADA2, potentially explaining the efficacy of anti-TNF therapies in this disease. Modulation of adenosine-mediated NET formation may constitute a novel and directed therapeutic approach in the treatment of DADA2.

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Aberrant Neutrophil Extracellular Trap (NET) formation contributes to the induction and propagation of inflammation and plays a key role in causing tissue damage in conditions like sepsis, SLE, RA and vasculitis. Citrullination of proteins is involved in the formation of NETs, autoimmunity, and the breaking of tolerance in NET-driven autoimmune diseases. In SLE and RA, neutrophils undergo enhanced NETosis, and NET components are observed in blood, inflamed tissues and joints.

Therapeutic ACPA (tACPA) are first in class NETosis-inhibiting antibodies targeting citrullinated histones 2A and 4, which are being developed for the treatment of human diseases in which aberrant NET formation adds to the severity of the pathology with an initial focus on autoimmune diseases.

Here, we demonstrate the utility of tACPA as a NETosis-inhibiting therapy for different NET-based diseases beyond RA, including SLE and Idiopathic pulmonary fibrosis (IPF).

### Methods:

Previously, using two RA animal models, the therapeutic properties of tACPA have been demonstrated (Chirivi *et al.*, 2013). In the current studies, neutrophils from RA and SLE donors, as well as biological NET-inducing stimuli, such as RA synovial fluid (SF), gout SF and

activated platelets, have been used to demonstrate the NETosis-inhibiting properties of tACPA in different human disease contexts. We have further expanded tACPA's therapeutic utility by testing it in a surrogate model for NET-mediated organ damage (sepsis) and idiopathic pulmonary fibrosis (IPF).

#### **Results:**

NETosis in human RA and SLE neutrophils have been induced with a calcium ionophore and could be inhibited by tACPA treatment (40-100% reduction). Similar results were obtained using RA and gout SF or activated platelets as NETosis inducers in combination with neutrophils from healthy donors. These observations have been confirmed with multiple NET readouts such as MPO activity, MPO/DNA ELISA, DNA quantification as well as imaging readouts. In addition, we demonstrated that in an LPS-induced sepsis model 30% of tACPA-treated mice survived (compared to 0 % in placebo controls), showing protection against organ failure. In a bleomycin-induced IPF mouse model, tACPA protected mice from the development of lung fibrosis (compared to placebo controls). When determining neutrophil counts in bronchoalveolar lavage samples, we found that in tACPA-treated mice, neutrophil levels were normal, while levels in placebo-treated mice were elevated.

#### **Conclusion:**

In a sepsis and IPF mouse model, tACPA prevented NET-mediated organ damage, providing evidence that tACPA could be a promising therapeutic strategy for diseases where NET-mediated endothelial toxicity causes organ damage like SLE, vasculitis and IPF. Central to our strategy for generating a preclinical data package supporting clinical testing, is to demonstrate that patient NETosis can be significantly inhibited *ex vivo*. We will present data that confirm that tACPA can block human SLE NETosis as well as human NETosis induced by activated platelets or gout SF.

#### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neutrophil extracellular traps (NETs), extracellular structures composed of decondensed chromatin, are released in a process called NETosis. NETs, which are part of normal host defense, have also been implicated in multiple rheumatologic diseases including rheumatoid arthritis, lupus, and vasculitis. Unfortunately, methods for quantifying NETs have limitations involving cost, speed, bias, and/or ease of use, which constrain the study of NETs in disease. The purpose of this project is to advance the methodology for NET quantification in order to maximize the ability of investigators to further elucidate the role of NETs in health and disease.

**Methods:** We created DNA Area and NETosis Analysis (DANA), a novel ImageJ/Java based program which provides a simple, semi-automated approach to quantify NET-like structures and DNA area for many fluorescent microscope images at once providing data on a per cell, per image, and per sample basis. To test DANA, 2 different individuals determined the frequency of NET-like structures for fluorescent microscope images of Sytox-stained human neutrophils by eye followed by running DANA on those images. DANA was then used to analyze images of neutrophils from rheumatoid arthritis subjects and control subjects. To test the ease of implementing DANA and applicability to other species and DNA stains, two individuals with no programming background installed DANA and repeated the above experiments using images of DAPI-stained unstimulated and stimulated murine bone marrow derived neutrophils.

**Results:** DANA quantified a similar frequency of NET-like structures to the frequency determined by eye, and in a fraction of the time, for

both human Sytox-stained neutrophil images and murine DAPI-stained neutrophil images. Also, as expected, DANA detected increased DNA area and frequency of NET-like structures in rheumatoid arthritis subjects compared to controls and in stimulated murine neutrophils compared to unstimulated.

**Conclusion:** DANA provides a means to quantify DNA decondensation and the frequency of NET-like structures in a reliable, simple, high-throughput, and cost-effective manner making it ideal to assess NETosis in a variety of conditions.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

- **Background/Purpose:** Neutrophil extracellular traps (NETs) are immunogenic, extracellular DNA structures that harness important autoantigens to be recognized by the adaptive immune system. NETs are thought to play a pivotal role in the pathogenesis of ANCA-associated vasculitis (AAV) and SLE. However it is still unclear how and if NETs can act as a common pathway in the pathophysiology of these clinically divergent autoimmune diseases. The aim of the present study is to characterize AAV- and SLE-induced NETs.

- **Methods:** The present study involved 88 AAV patients according to the Chapel Hill consensus definitions of 2012, 59 SLE patients according to the ACR criteria 1997 and 10 healthy controls. Healthy neutrophils were stimulated with 10% serum of AAV or SLE patients to induce NETs. Ex vivo NET induction by serum and IgG-depleted serum was measured by a novel, highly-sensitive NET quantification assay using 3D-confocal microscopy<sup>1</sup>. Qualitative characteristics of NETs were studied by immunofluorescence to detect NET-related auto-antigens. Additionally, the morphology and kinetics of AAV- and SLE-induced NETosis were visualized by live cell imaging and electron microscopy.

- **Results:** Ex vivo NET induction by AAV sera was 19.36 [9.161 – 73.08], (median [Q1 – Q3]) fold higher than sera of healthy controls (n=10) and also significantly higher than NET induction by SLE sera 5.56 [2.34 – 14.33] (Figure 1). Depletion of IgG from serum did not reduce NET induction in AAV, but it decreased NET induction significantly in SLE, indicating that different triggers mediate the induction of neutrophil extracellular traps in these autoimmune diseases. Additionally, the colocalisation of NET-related auto-antigens was different: citrullinated histon-3 (CitH3) was predominantly found on AAV-induced NETs, whereas high mobility group box protein-1 (HMGB-1) was exclusively found on SLE-induced NETs. Moreover, live cell imaging demonstrated that the kinetics of SLE-induced NETs peaked at 60 minutes, while AAV-induced NETs peaked at 4 hours (Figure 2). Intriguingly, SLE sera induced immediate clustering of neutrophils surrounding NETs whereas AAV sera induced NETs composed of long, thin DNA-fibres through lytic expulsion.

- **Conclusion:** We demonstrate intrinsically distinct features of AAV- and SLE-induced NETs, indicating that NET formation in AAV and SLE is based on different mechanisms. Future studies should be directed at unravelling how different NETs are involved in causing SLE- or AAV-associated glomerulonephritis.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Lupus is an autoimmune disease characterized by a type I interferon signature thought to be initiated by granulocyte NETosis. The granulocyte population in the periphery of lupus patients contains abnormal LDGs (low-density granulocytes) that are correlated with SLEDAI and anti-

dsDNA antibodies. The current experiments were carried out to identify LDGs quantitatively by their genomic signature in peripheral and tissue datasets from lupus patients.

## Methods:

Publicly available microarray or RNASeq gene expression profiles from lupus patients were identified in GEO, including those obtained from neutrophils, whole blood (WB), PBMC and skin, synovium, and kidney. The raw data were downloaded, normalized, curated and assessed for differentially expressed (DE) genes. Correlation with clinical or histologic features was carried out by WGCNA and variation in pathway activity was determined in individual samples and groups of samples by Gene Set Variation Analysis (GSVA). Curated STRING-based protein-protein interaction analysis was carried out using MCODE in Cytoscape. Functional categories were defined using the BIG-C clustering algorithm.

## Results:

Analysis of control or lupus neutrophil RNA expression datasets as well as lupus LDGs resulted in three WGCNA modules that are consistent across patient samples. Specifically, modules were identified that were positively correlated with LDGs but negatively correlated with lupus and normal neutrophils (or vice-versa). Two WGCNA modules were identified in the LDG to neutrophil comparison that were positively correlated (A, 334 genes; B, 92 genes). "A" contains genes related to platelet activation and adhesion. "B" contains genes classic for neutrophils and granulocytes. One module was negatively correlated (C, 82 genes) and contains genes related to nuclear transport and translational machinery. The most informative module was "B". 41/92 of "B" genes have been described to characterize neutrophils/granulocytes (M2.2)<sup>1</sup>. 30/92 genes fall under the Neutrophil Granulation GO term and 13 of the 30 genes described by the Neutrophil Granulation GO term are contained in M2.2. An end goal of this analysis was to identify a group of genes that could be used to query whole blood, PBMC and tissue datasets for the presence of neutrophils and LDGs. WGCNA modules for whole blood and PBMC were compared to the LDG modules described above and GSVA was utilized to examine the consistency across patients. Module B containing LDG genes was found in 3/3 PBMC and 3/3 WB datasets by three measurements (gene overlap LDG module to PBMC or WB module, eigengene correlation with module "B" and eigengene correlation with clinical traits).

Assessing correlation of the log<sub>2</sub> fold change of DE genes in the WGCNA "B" module with the test sets (PBMCs or WB) gives an r range of 0.6-0.8 (p value < 0.05) regardless of disease activity. Genes within modules "A" and "C" were not significantly correlated. This observation was not found for lupus-affected tissues.

## Conclusion:

These results indicate that a discrete LDG module can be identified in the periphery of lupus patients. However, the contribution of these cells to tissue pathology is uncertain.

## Multiplexed Characterization of Circulating and Joint-Derived Human Neutrophils in Inflammatory Arthritis

**Ricardo Grieshaber Bouyer**<sup>1</sup>, Olha Halyabar<sup>2</sup>, Anais Levescot<sup>1</sup>, Kacie Hoyt<sup>2</sup>, Lauren Henderson<sup>2</sup> and Peter Nigrovic<sup>1,2</sup>, <sup>1</sup>Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, <sup>2</sup>Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Neutrophils are innate immune cells that play a central role in the initiation of inflammatory arthritis as well as mediating tissue damage. We

sought to improve our understanding of the role of neutrophils in joint inflammation using two multiplex discovery modalities. We characterized simultaneous circulating and transmigrated, joint-derived neutrophils from patients with inflammatory arthritis and blood from healthy controls via mass cytometry (CyTOF) and RNA-Seq with the goal of gaining new insights into the biology of neutrophils in inflamed environments.

#### Methods:

We established a biospecimen pipeline that allowed for both immediate processing as well as cryopreservation of fresh samples. Synovial fluid and simultaneous peripheral blood samples were obtained from seven consented patients with inflammatory joint disease. Purified neutrophils were cryopreserved and stained with metal-conjugated antibodies directed against 30 surface proteins including lineage markers, adhesion molecules, chemokine receptors, Fc- and complement receptors and immune checkpoints. Gene expression of freshly isolated neutrophils from inflammatory arthritis patients and healthy controls was examined via Smart-seq2. Each gene was modeled as a linear-mixed combination of donor- and group-specific effects using DESeq2.

#### Results:

Circulating and transmigrated neutrophils demonstrated fundamentally distinct gene- and surface protein expression. Joint-derived neutrophils exhibited an activated phenotype reflected by increased surface expression of integrins, adhesion molecules and chemokine receptors and increased transcription of complement receptor, TNF and CD69 among many others. Intriguingly, joint neutrophils overexpressed the adaptive immunity regulatory gene PD-L1 – confirmed by CyTOF – suggesting that they might also act to restrain pathological inflammation by negatively regulating T-cell function. We further identified 11 significantly enriched Gene Sets in joint neutrophils compared to blood, including TNF- $\alpha$  signaling, IFN- $\alpha$  response, IL-2 and IL-6 signaling. Confirmation studies are ongoing.

#### Conclusion:

Using multiplex discovery modalities, this study examined both circulating and joint-derived neutrophils in the context of joint inflammation. The dysregulated pathways identified suggest that neutrophils not only serve as effectors of immunity but also provide feedback that could potentially regulate adaptive immune responses.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Certain rheumatic diseases including systemic sclerosis (SSc) are characterized by chronic activation of innate immune responses, leading to excessive fibrosis. A normal innate immune response is comprised of an onset phase characterised by generation of pro-inflammatory lipid mediators, chemokines, adhesion molecules, and tissue infiltration of inflammatory cells. This is followed by a resolution phase where the balance of lipid mediators shifts from pro-inflammatory mediators to novel Specialized Pro-resolving Lipid Mediators (SPMs), pro-inflammatory cytokines and chemokines are inhibited, pathogens and inflammatory cells are cleared from involved tissues, and active wound healing processes are completed. Persistent inflammation and progressive fibrosis can reflect an imbalance that favors onset phase over resolution phase. Anabasum (JBT-101) is a cannabinoid receptor type 2 agonist that showed evidence of clinical benefit on Phase 2 testing in systemic sclerosis. Anabasum activates resolution of skin and lung inflammation in animal models of SSc. Using a novel *in vivo* human skin challenge model of an innate immune response, we tested the effect of anabasum on inflammatory onset and resolution and compared it to prednisolone.

**Methods:** In this placebo-controlled study, subjects (N = 20) received placebo (n = 5), oral anabasum 5 mg BID (n = 5), anabasum 20 mg

BID (n = 5), or prednisolone 15 mg OD (n = 5) for 4 days. On the 4th day, acute inflammation was triggered by intradermal injection of ultraviolet light-killed *E coli* on both the forearms of healthy subjects. Local inflammatory exudate was acquired into a suction blister raised at 4 hr on one forearm (onset time point) and at 10 hr on the contralateral forearm (resolution time point). Inflammatory exudate was analyzed for soluble mediators and immune cells. Blood flow to the site of inflammation was monitored by laser doppler.

**Results:** Anabasum exerted a profound anti-inflammatory effect in this model by accelerating the resolution phase of the innate immune response. Anabasum: increased blood flow during the resolution phase at 10 hours; reduced IL-8 and neutrophils in blister exudate 10 hours post-challenge, as did prednisolone; reduced the proinflammatory lipid mediators LTB<sub>4</sub>, PGF<sub>2a</sub>, TxB<sub>2</sub> and PGE<sub>2</sub>; increased the SPMs lipoxins (LXA<sub>4</sub>, LXB<sub>4</sub>) and resolvins (RvD1, RvD3, RvD5); and hastened bacterial clearance, whereas prednisolone slowed bacterial clearance during the resolution phase (resolution toxic).

Exudate content	Hours	Mean (SE)			
		Placebo	Anabasum 5 mg BID	Anabasum 20 mg BID	Prednisolone 15 mg QD
IL-8, pg/ml	4	5931 (923)	3299 (773)	3024 (1235)	4289 (1375)
	10	3241 (784)	1679 (602)	2007 (515)	2267 (543)
Neutrophils/ml x 10 <sup>3</sup>	4	262 (71)	55 (17)	66 (16)	72 (25)
	10	244 (101)	120 (52)	72 (21)	69 (16)
Macrophage CD163 intensity	4	705 (244)	1420 (460)	711 (277)	5233 (2145)
	10	2383 (478)	3610 (968)	3338 (744)	5427 (1381)
Endotoxin, relative units	4	14.6 (4.2)	5.3 (2.0)	6.8 (4.3)	17.2 (5.3)
	10	5.0 (3.3)	6.9 (4.5)	5.9 (2.7)	11.5 (3.2)

**Conclusion:** Anabasum has novel biologic effects on infection-induced innate immune responses as it exerts a striking anti-inflammatory effect greater than that of prednisone and leading to timely resolution of inflammation. This activity offers promise for anabasum in the treatment of SSc.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nitric oxide (NO), a proinflammatory mediator responsible for various physiological processes, plays a central role in the pathogenesis of rheumatoid arthritis (RA). As a heme-based sensor for NO, a transcription factor neuronal PAS domain protein 2 (NPAS2) forms a heterodimer with clock gene BMAL1. Using RA fibroblast-like synoviocytes (-FLS), we previously reported the interaction of clock genes and Bcl-2-interacting killer (BIK) which was known to be an inducer of mitochondrial apoptosis, and the promoter site of BIK has the NPAS2/BMAL1 heterodimer binding enhanced box sites (E-box sites). In this study, we evaluated the role of NPAS2 in RA synovium in views of relationship between NO and BIK.

**Methods:** The synovium were obtained during total knee replacement surgery from patients. Immunohistochemistry was performed to determine NPAS2 expression in synovial tissue. Cell proliferation was assessed with WST-8 assay in RA-FLS, using varying concentrations of the NO donor, S-Nitroso-N-acetyl-DL-penicillamine (SNAP) (0-20 nM). To evaluate the relationship between NPAS2 and BIK, NPAS2-siRNA was used to measure BIK mRNA expression in the absence and presence (5, 20 nM) of SNAP in RA-FLS. Moreover, we cloned the three BIK promoters (see Figure1), made luciferase assay model, and measured the luciferase activity in the absence and presence of SNAP in RA-FLS.

**Results:** NPAS2 expression was observed in RA synovium. Cell proliferation was significantly increased by SNAP. In the presence of SNAP, BIK mRNA expression was significantly reduced in the control-siRNA group, but not in the NPAS2-siRNA group (Figure 2, \*,  $P < 0.05$ ). In the presence of SNAP, the luciferase activity was significantly reduced in the Bik-E2-promoter group, but not in the Bik-E0-promoter group (Figure 3, \*,  $P < 0.05$ ).

**Conclusion:** NPAS2 enhance Bik expression, and NO inhibited Bik expression by NPAS2. These results suggests that NO may inhibit NPAS2 to bind E-box of Bik promoter. We propose a novel action of NO that inhibits mitochondrial apoptosis of RA-FLS by preventing the binding between NPAS2 and BIK. Therefore, we suggested that the inhibition of NO and NPAS2 may clinically be potential of anti-hyperproliferation and anti-bone destruction in RA synovium.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We previously demonstrated over-expression of the DNA-binding protein ARID3a in peripheral blood B lymphocytes from patients with systemic lupus erythematosus (SLE) compared to healthy controls. In addition, we found that ARID3a is induced in healthy control blood cells in response to toll receptor signaling, and specifically to CpG stimuli. Furthermore, ARID3a expression was associated with interferon alpha production in a subset of B lymphocytes from both CpG-stimulated healthy controls and SLE patients. Therefore we hypothesized that ARID3a might also be associated with interferon alpha production in other cell types that secrete interferons.

**Methods:** De-identified peripheral blood samples were obtained via our IRB approved protocol from SLE patients (classified via ACR criteria) and healthy age-matched control participants of the Oklahoma Rheumatic Diseases Core Center. Peripheral blood mononuclear cells were isolated over ficoll gradients and either subjected directly to immunofluorescence staining and flow cytometry analyses, or they were first subjected to magnetic bead enrichment for neutrophils or plasmacytoid dendritic cells (pDCs). Purified pDCs and neutrophils were subjected to RNA-seq and were evaluated for gene expression patterns in relation to ARID3a levels.

**Results:** Linear regression analyses demonstrated strong associations between ARID3a expression and interferon production in pDCs and neutrophils in SLE patients. In addition, ARID3a expression in those cell types was associated with increased SLE disease activity indices. Surprisingly, interferon subtypes were heterogeneously transcribed in neutrophils and pDCs. Gene expression data show increased interferon-associated transcripts in patients with increased ARID3a protein expression.

**Conclusion:** Our data indicate co-expression of ARID3a and interferon in SLE patient blood cells may be linked to interferon signatures observed in SLE.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** MicroRNAs (miRNAs) have been shown to contribute to the inflammatory response in rheumatoid arthritis (RA) and several of these miRNAs have been found to be dysregulated in synovial tissue, synovial fluid or plasma of RA patients. In addition, also inflammatory cells such as macrophages, which are infiltrating the synovium and promoting the pannus generation, exhibit an aberrant miRNA expression. As toll-like receptors (TLRs) play a pivotal role in RA, we conducted a study to explore the role of TLRs in regulating the expression of miRNAs in macrophages under conditions prone to RA. Based on a miRNA-screen in TLR-stimulated M1- and M2-macrophages we selected several potential candidates for further studies, among them miR-221-3p. We then compared the release of inflammatory versus anti-inflammatory cytokines upon miR-221-3p overexpression or inhibition in stimulated M1- and M2-macrophages.

**Methods:** Monocytes were isolated from buffy coats of 8 healthy donors by CD14 microbead separation and differentiated into M1 and M2 by culturing them in the presence of 50ng/ml GM-CSF and M-CSF, respectively, for 6 to 8 days. Subsequently, cells were stimulated for 8.5 or 24 hours with TLR2/3/4 ligands Pam3, PolyIC or LPS. Cytokine release was measured by ELISA and miRNA expression by qRT-PCR. For miRNA mimic and inhibition studies, cells were transfected with corresponding pre-miR or antagomir using lipofectamine for 72 hours prior to the stimulation of M1- and M2-macrophages with TLR ligands.

**Results:** The general outcome of the miRNA-screen showed that a higher proportion of the tested miRNAs were downregulated in M2 macrophages upon stimulation with TLR ligands Pam3 and LPS. The basal expression level of miR-221-3p was similar in M1- and M2-macrophages, however, stimulation with LPS and PolyIC resulted in a prominent downregulation of miR-221-3p only in M2-macrophages. In M1-macrophages LPS caused only a slight decrease of miR-221-3p expression. Since several recent studies detected higher miR-221-3p levels in serum of RA patients and also in synovium of an induced RA-mouse model, we checked how macrophages respond to aberrant miR-221-3p levels under inflammatory conditions. Overexpression or inhibition of miR-221-3p showed no effect in unchallenged M1- or M2-macrophages on the secretion of IL-6, IL-8 or IL-10. However, miR-221-3p overexpression in combination with LPS stimulation, but not Pam3 or PolyIC, significantly increased IL-6 and IL-8 cytokine secretion in M2 macrophages. In contrast, the same combinatorial treatment (LPS + miR-221-3p overexpression) significantly decreased the IL-10 secretion in M2 macrophages.

**Conclusion:** We herein demonstrate that aberrant miR-221-3p expression is significantly downregulating the anti-inflammatory activity of TLR4-stimulated M2-macrophages by decreasing the ratio of secreted IL-10/IL-6 and IL-10/IL-8. Thus, abundant miR-221-3p might contribute to promote and sustain the chronically inflammatory conditions apparent in disease settings such as RA synovial tissue by deregulating the pro-/anti-inflammatory cytokine profile of synovial macrophage subpopulations.

## From Monocytes to Macrophages: the Pathogenesises of Spontaneous Inflammatory Arthritis in CD11c-Flip-KO (HUPO) Mice

Qi Quan Huang<sup>1</sup>, Renee E. Doyle<sup>2</sup>, Philip J. Homan<sup>1</sup>, Harris Perlman<sup>3</sup>, Deborah R. Winter<sup>3</sup> and Richard M. Pope<sup>2</sup>, <sup>1</sup>Division of Rheumatology, Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>2</sup>Medicine/Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>3</sup>Department of Medicine Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Innate Immunity and Rheumatic Disease Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

We have generated a CD11c-Flip-KO mouse line (HUPO) that spontaneously develops erosive arthritis with incidence 70-80% at age  $\geq$  20 weeks. This study aimed at understanding the role of monocytes in HUPO arthritis and to define the molecular changes during differentiation to macrophages in the inflamed joint compared with controls.

### Methods:

Arthritis was evaluated by clinical score. Cell types from blood and ankle joints are determined by flow cytometry. Cell proliferation are determined by BrdU incorporation and populations of cells were isolated for RNAseq.

### Results:

Circulating monocytes, defined as CD45<sup>+</sup>CD11b<sup>+</sup>CD115<sup>+</sup>F4/80<sup>lo</sup>, were further characterized as classical (CM), Ly6C<sup>+</sup>CD62L<sup>+</sup>, or non-classical (NCM), Ly6C<sup>+</sup>CD62L<sup>-</sup>. CM were markedly increased in HUPO mice with arthritis and positively correlated with arthritis severity. 70 -90% of CM are also CCR2<sup>+</sup> in HUPO mice with arthritis, similar to that in control mice. In contrast, in the HUPO mice without arthritis, only 0-7% of these cells are CCR2<sup>+</sup>, and the CM numbers were normal. Monocytes recently recruited into synovium are defined as CD45<sup>+</sup>Ly6C<sup>+</sup>CD64<sup>+</sup>CD11b<sup>+</sup>F4/80<sup>int</sup>Ly6C<sup>+</sup>MHCII<sup>-</sup>. This population demonstrated reduced CD115 and increase F4/80 compared with CMs. Within 24 hours after BrdU injection, in both HUPO and control mice, >60% of these Ly6C<sup>+</sup>MHCII<sup>-</sup> macrophages incorporated BrdU, comparable to CM and bone marrow monocytes. In contrast, < 1% in NCM incorporated BrdU. In HUPO mice during further differentiation the macrophages became Ly6C<sup>+</sup>MHCII<sup>+</sup> and then Ly6C<sup>-</sup>MHCII<sup>+</sup>, with less BrdU incorporation in the more differentiated cells. A similar transition was observed in the control mice except the Ly6C<sup>+</sup>MHCII<sup>+</sup> population was not identified. CMs and F4/80<sup>int</sup> macrophages were isolated for RNAseq. In the controls, clusters of differentially expressed genes were identified in CMs, and Ly6C<sup>+</sup>MHCII<sup>-</sup> and Ly6C<sup>-</sup>MHCII<sup>+</sup> joint macrophages. For example Immune response and leukocyte activation were increase in CMs while cell cycle and cell division were increased in Ly6C<sup>+</sup>MHCII<sup>-</sup> macrophages. There were differences in these transcriptional profiles of the macrophages subset between HUPO and control mice, including those regulating cell cycle and differentiation as well as for monocyte differentiation and antigen processing.

### Conclusion:

These observations demonstrate that during chronic inflammation, CMs enter the joints and undergo macrophage differentiation during homeostasis and chronic inflammation. The differences in transcriptional profiles between the control and HUPO mice will provide important insights into the mechanisms contributing to chronic inflammation.

## Outcomes after Hip Fracture in the Elderly: Does Social Isolation Matter?

**Lisa A. Mandl**<sup>1</sup>, Omar Halawa<sup>2</sup>, Jackie Szymonifka<sup>3</sup>, Kirsten Grueter<sup>4</sup> and Joseph Lane<sup>5</sup>, <sup>1</sup>Rheumatology, Hospital for Special Surgery Weill Cornell Medical College, New York, NY, <sup>2</sup>Hospital for Special Surgery, New York, NY, <sup>3</sup>Rheumatology, Hospital for Special Surgery, New York, NY, <sup>4</sup>Orthopaedic Surgery, Hospital for Special Surgery, New York, NY, <sup>5</sup>Orthopaedic Surgery, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hip fractures are a serious public health issue with a significant population burden, especially among those over 65 years old. Social isolation—how integrated a patient is into his/her community—is a novel and potentially modifiable risk factor for poor health outcomes after low trauma hip fracture. This study evaluates the association of pre-operative social isolation with death, short-term complications and patient-reported functional recovery in elderly patients 3 months following surgical repair of low-trauma hip fracture.

**Methods:** The Lubben Social Networks Scale-18 (LSNS-18), a validated instrument specifically designed to measure social isolation in the elderly, PROMIS-29, which measures patient-reported outcomes, and the Lower Extremity Activity Scale (LEAS), which measures physical function, were administered to cognitively intact patients  $\geq 65$  years old with no active cancer, 2-4 days after surgical repair of hip fracture. Patients were specifically asked about their pre-fracture status. Patients were contacted 1 and 3 months after surgery and asked about adverse events and hospitalizations. The LSNS-18, PROMIS-29 and the LEAS were administered again at 3 months.

**Results:** 109 patients were enrolled, 72.5% female, 92.7% white, 78% college educated with a mean age of  $80.7 \pm 8.5$  years. 45% of patients enrolled were socially isolated. Of the 109 patients enrolled, 19 had adverse events including pulmonary emboli, hypotension, hypoxia, urinary tract infection, peri-prosthetic fracture, CHF exacerbation, cholecystitis, lower extremity cellulitis, falls, wound dehiscence and duodenal ulcers. 5 patients died within the first 3 months. Of the 76 patients eligible for 3 month follow-up, 63 (83%) completed 3-month questionnaires. A higher proportion of socially isolated patients died by 3 months (8.2% vs. 1.7%), although this was not statistically significant ( $p=0.172$ ). There was no statistically significant difference between socially isolated and non-socially isolated patients in short-term complications, or PROMIS-29 and LEAS scores 3 months after surgery.

**Conclusion:** There is a positive trend suggesting social isolation is associated with 3-month mortality in elderly patients undergoing surgical repair of low trauma hip fracture. There was no association between social isolation and short-term complications or self-reported short-term functional recovery. Whether social isolation is associated with longer term functional outcomes or mortality is unknown. Recruitment for this study is ongoing and all subjects will be studied for up to 1 year following surgery.

## Usefulness of Consecutive Doppler Ultrasound Examinations for Detecting Deep Venous Thrombosis during the Perioperative Period in Patients with Osteoporotic Fractures of the Proximal Femur

**Ken Nakaseko** and Norihiro Mayumi, Department of Orthopaedic Surgery and Rheumatology, Kuwana City Medical Center, Kuwana Mie, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Deep venous thrombosis (DVT) can lead to a venous thromboembolism and increase the risk of a pulmonary thromboembolism (PE). PE is one of the most common causes of death in hospitalized surgical patients. Although there have been some prospective studies regarding the prevalence of DVT on Doppler ultrasound examinations of the lower extremities, there have not been any prospective studies in which three consecutive Doppler ultrasound examinations were performed to detect DVT during the perioperative period. The purpose of the present study was to prospectively evaluate the occurrence of DVT in patients with osteoporotic fractures of the proximal femur, based on the results of examinations involving three consecutive ultrasound scans. In addition, the usefulness of the D-dimer level as a predictor of DVT was investigated.

**Methods:** This study was a single-center prospective study. Eighty-seven patients (14 males and 73 females) between the ages of 46 and 95 years with osteoporotic fractures of the proximal femur were enrolled. All patients were asymptomatic in terms of their clinical DVT findings. Three Doppler ultrasound examinations of the lower extremities were conducted in each case: on admission, one day before surgery, and one week after surgery. The period from admission to surgery ranged from 2 to 7 days (mean: 5.3 days). The D-dimer level was measured at one week after surgery and its relationship with the presence/absence of DVT was evaluated by calculating sensitivity, specificity, positive predictive, and negative predictive values.

**Results:** DVT was detected in 16 patients (2 patients on admission, 8 patients one day before surgery, and 6 patients one week after surgery). The overall prevalence of DVT in the perioperative period was 18.4% (16/87). As for the characteristics of the patients that did and did not develop DVT, there were no significant differences between the two groups. When the D-dimer cut-off level was set at 4.3 µg/ml, the sensitivity and negative predictive value reached 100%, while the specificity was 15.5%, and the positive predictive value was 21.1%. A receiver operating characteristic (ROC) curve was drawn, and the optimal D-dimer cut-off level was examined. The ROC curve was closest to the upper left corner when the D-dimer cut-off level was 12.2 µg/ml. At that point, the sensitivity, specificity, positive predictive value, and negative predictive value were 62.5%, 70.4%, 32.3%, and 89.3%, respectively.

**Conclusion:** In this prospective study, DVT was detected in 2 patients on admission, 8 patients one day before surgery, and 6 patients one week after surgery. As DVT can occur at any moment, performing repeated Doppler ultrasound examinations in the perioperative period is useful for quickly detecting DVT, which can cause PE. As for the D-dimer level, its sensitivity and negative predictive value reached 100% at a cut-off level of 4.3 µg/ml. Therefore, D-dimer assays could be a useful screening tool for DVT and might be a suitable substitute for Doppler ultrasound examinations.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Wearing high-heeled shoes (HHS) may include structural and functional abnormalities due to repetitive stress particularly in the knee and forefoot. The aim of this study was to investigate whether the distal femoral cartilage, Achilles tendon and plantar fascia were different between healthy young women wearing HHS and flat shoes.

**Methods:** A total of 91 healthy women (aged 20-45 years) participated in this cross-sectional study. Women wearing shoes with a heel height of >5cm were enrolled in the HHS group, and those wearing shoes with a heel height of <1.4 cm were included in the flat shoes group. Femoral cartilage from the lateral femoral condyle (LFC), intercondylar area and medial femoral condyle (MFC), and Achilles tendon and plantar fascia thicknesses were measured by using ultrasound.

**Results:** There were 34 women (mean age; 31.1±6.4 years, BMI; 21.6±2.3 kg/m<sup>2</sup>) in the HHS group and 57 women (mean age; 29.5±7.3 years, BMI; 22.5±3.4 kg/m<sup>2</sup>) in the control group (both p>0.05). In group comparisons, thicker right MFC and left Achilles tendon were obtained in the HHS group (both p<0.05). Between group comparisons yielded thicker left Achilles tendon in the HHS group than the flat shoes group (p<0.05). Plantar fascia thicknesses were similar both within and between group comparisons (both p>0.05). Right Achilles tendon thickness was positively correlated with right (r=0.469, p=0.005) and left (r=0.402, p=0.018) plantar fascia thicknesses only within the HHS group.

**Conclusion:** Wearing HHS resulted in thickening of the right MFC and left Achilles tendon in women wearing HHS which might definitely be interpreted as secondary to chronic overload. Our results may provide an understanding of the morphological changes with wearing HHS and recommend that this "social" issue that exists in women's lives be investigated further to reveal the musculoskeletal consequences.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To compare demographic characteristics, characteristics of pain and functional status according to the presence of inflammatory anterior or posterior arch MRI abnormalities in low back pain (LBP) patients.

**Methods:** Design: Monocentric cross-sectional study. Patients: Chronic LBP patients with a lumbar spine MRI planned in the Toulouse Hospital Radiology Center were prospectively selected and filled a standardized questionnaire to get clinical data. MRI: STIR and T1 sagittal images from 3 and 1.5 Tesla MRI going up to T8-T9 stages were reviewed by two experienced rheumatologists, blinded from the diagnosis and clinical data. Inflammatory anterior arch abnormalities (IAAA: i.e.: MODIC I or II, inflammatory corner lesions) and inflammatory posterior arch abnormalities (IPAA: i.e.: pedicle edema, transverse and spinous process edema, interspinous process edema, costo-transverse or zygapophyseal joint arthritis) were collected. Analyses: Clinical data (age, sex, disease duration, ODI, pain VAS, inflammatory pain, NSAIDs efficacy) were compared according to the presence/absence of IAAA or IPAA by Chi2 or Wilcoxon tests.

**Results:** Ninety-five patients were included in this study, 66 have IPAA. Inter and intra-observer agreement was excellent (κ=0.938). The most prevalent IPAA was zygapophyseal joint arthritis (62.5%), then 31.9% patients have interspinous process edema, 9.7% pedicle edema and 4.2% spinous process edema. Patients with IPAA had more frequently Modic I and/or II lesions than patients without

IPAA (39.2% versus 9.5%,  $p=0.01$ ). There was no statistically significant association between IPAA presence and clinical data, including pain characteristics. IPAA seemed to be more prevalent in women (62.1% versus 41.4%,  $p=0.06$ ), in patients with longer pain duration (6 years versus 4.75 years,  $p=0.22$ ), with morning stiffness more than 30 minutes (42.4% versus 24.1%,  $p=0.2$ ), and with better NSAID response (65.9% versus 55%,  $p=0.35$ ). Furthermore, patients with Modic I had a better response to NSAIDs (90% versus 52%,  $p=0.04$ ). Patients with Modic II seemed to be older than patients without Modic (66 years versus 43 years,  $p=0.0004$ ). Modic I was often associated with IPAA at the same vertebral stage.

**Conclusion:** The most prevalent IPAA in patients with LBP was zygapophyseal joint arthritis. Modic I and/or II were more prevalent when patients have IPAA. There was no significant association between IPAA presence and clinical data. However, NSAIDs had a better efficacy in patients with Modic I, and Modic I was often associated with IPAA at the same vertebral stage.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To assess the glycosaminoglycan (GAG) content of lumbar intervertebral discs (IVD) in patients with low back pain (LBP) and radiculopathy using glycosaminoglycan chemical exchange saturation transfer imaging (gagCEST).

**Methods:** 258 lumbar IVDs of 53 participants, 21 healthy volunteers, 19 patients with LBP and 13 patients with radiculopathy (28 female; 25 male; mean age:  $45.5 \pm 16.7$  years; range: 23 - 83 years), were examined with a 3T MRI scanner. Biochemical gagCEST imaging was used to determine the GAG content of each nucleus pulposus (NP) and annulus fibrosus (AF).

**Results:** Significantly reduced gagCEST values of NP were found in patients with LBP and/or radiculopathy ( $p < 0.0001$ ) compared to healthy control group. NP gagCEST values were significantly lower in patients with LBP ( $p < 0.0001$ ) and radiculopathy ( $p = 0.0005$ ) compared to healthy volunteers, respectively. We saw an association between pain and GAG loss with significantly lower gagCEST values in participants with dorsal pain at examination day ( $p = 0.0004$ ) and higher pain scores ( $p < 0.0001$ ) compared to participants without LBP. Participants with body mass index  $\geq 25$  revealed lower gagCEST values compared to participants with BMI  $< 25$  ( $p = 0.02$ ).

**Conclusion:** GagCEST analysis indicated significantly lower GAG values of NP in patients with LBP or radiculopathy, in participants with elevated BMI, current pain at examination day and elevated pain scores.

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

DISH is a non-inflammatory condition affecting the spine, and characterized by ossification of paravertebral ligaments. DISH is traditionally considered asymptomatic, detected incidentally on spine radiographs. We investigated the frequency of DISH diagnosis, the associated morbidity and healthcare utilization by patients attending our university hospital.

### Methods:

Our University's radiology database was searched from years 2005 to 2015 for the words "DISH" or "diffuse idiopathic skeletal hyperostosis" in the recorded results of spinal radiographs. Patients from the year 2015 whose spinal radiographs mentioned these words were selected for further analysis. Their spinal radiographs were re-read by two authors. Patients were divided into those who fulfilled the Resnick Criteria for DISH (Group A), and those who did not fully meet the criteria but had radiographic features suggestive of DISH (Group B). Means and proportions were used to describe variables, for group comparisons, T-test and  $\chi^2$  were used. A p-value less than 0.05 was considered statistically significant. All computations were done in the R statistical program.

### Results:

Between 2005-2015, 3439 radiology records had DISH mentioned as a diagnosis. Out of 196 patients diagnosed with DISH In 2015, 153 fulfilled the Resnick criteria (Group A), 41 didn't fulfill the criteria but were diagnosed as DISH by the radiologists (Group B), and 2 had erroneous diagnoses. The Table shows the comparison between the two groups. Thoracic radiographs where DISH was mentioned were more likely to fulfill the Resnick criteria than not (35% vs 15%) compared to other radiographs ( $p < 0.03$ ). Chronic back pain was very common in both groups, and more often reported in Group B than Group A (81% vs. 63%,  $p = 0.04$ ). Back pain was the reason for performing the initial diagnostic radiograph in 45% of Group A and 61% of Group B. A substantial portion of patients required opioid medications for pain control (51%), spinal surgery (31%), and consultations with various specialists for regional pain (57%). Health care interventions were similar in both groups.

### Conclusion:

DISH is a common diagnosis with significant morbidity, despite being commonly considered to be an asymptomatic condition. Majority of DISH patients had chronic back pain, required opioid medication, and a large proportion required spinal surgery. Future research is needed to systematically assess the healthcare utilization by DISH patients.

**Table: Comparison of DISH patients: those fulfilling Resnick criteria vs. not fulfilling Resnick criteria but diagnosed by radiologists (ns = not significant)**

Variable	Group A: Resnick Criteria fulfilled (n = 153)	Group B: Resnick Criteria not fulfilled (n = 41)	p

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

We hypothesized that compression assisted arthrocentesis of the knee would improve arthrocentesis fluid yields and intraarticular injection outcomes.

### **Methods:**

We performed conventional arthrocentesis on 215 painful knees, both with and without effusions prior to injection. Subsequently a constant compression device (a commercially available elastomeric brace positioned or modified so classic arthrocentesis portals could be utilized) was placed and arthrocentesis was performed on 215 painful knees. In all cases, post arthrocentesis, 1mg/kg of triamcinolone acetonide (60-80 mg total, 80 mg maximum) was injected into each knee. Arthrocentesis fluid yield and time to the next flare were measured. The data were compared using Student's T-test.

### **Results:**

The demographics of the study groups were similar. Fluid yield for complete arthrocentesis with constant compression was greater (by 230%) than the conventional technique: constant compression 5.3±11.2 ml, conventional 1.6±6.4 ml (difference 3.7 ml, CI of difference 1.9757 <3.7 < 5.4243, p<0.00001). Fluid yield was also increased in the effusive knee subgroup (by 166%): constant compression (n = 38) 26.6±113.4 ml, conventional (n=37) 10.0±13.3 ml (p<0.00001)(Figure 1). Time to flare was 35% longer in the subjects treated with constant compression 6.9±3.5 months as opposed to conventional treatment 5.1±2.7 months (p<0.00001)(Figure 2). The prolonged effect of constant compression was present in both the effusive knee (30% longer, p<0.02) and the non-effusive knee (38% longer, p<0.01).

Figure 1:

Figure 2:

## Conclusion:

Constant compression of the knee results in greater arthrocentesis fluid yield and improved injection outcomes in both the effusive and non-effusive knee. We hypothesize that more accurate needle placement, forced extrusion of interstitial fluid and cytokines from compressed tissues, and more complete removal of fluid decrease inflammatory cells and cytokines and increase intraarticular drug concentrations, resulting in improved outcomes. Constant compression of the knee is a straightforward and effective quality improvement intervention for knee arthrocentesis and intraarticular injection.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The objective of this study was to determine whether extended versus flexed knee position is superior for arthrocentesis.

**Methods:** 55 clinically effusive knees with osteoarthritis underwent arthrocentesis: 20 knees in the extended knee position using the lateral superior approach, and 35 knees in the flexed knee position using the inferiolateral approach. Conventional arthrocentesis maneuvers including manual compression were used and fluid yield in milliliters measured. After fluid return ceased in the flexed knee, constant compression was applied using an elastomeric knee brace on the superior knee and additional fluid yield recorded. The measurement data were compared using the Student test.

**Results:** Fluid yield for arthrocentesis with the extended knee was greater (191% greater) than the flexed knee: extended knee:  $16.9 \pm 15.7$  ml, flexed knee  $5.8 \pm 6.3$  ml (difference 11.1 ml, CI 0.91 < 8.8 < 16.7,  $p < 0.02$ ). After constant compression to the flexed knee fluid yields were identical (1% different): extended knee:  $16.9 \pm 15.7$  ml, flexed knee  $16.7 \pm 11.3$  ml (difference -0.2 ml, 95% CI 11.09 < -2.7 < 5.6,  $p = 0.73$ ).

**Conclusion:** The extended knee lateral approach is superior to the flexed knee approach for conventional arthrocentesis. However, when constant compression is applied, the two approaches have identical fluid yields. This new flexed knee constant compression technique is particularly useful for patients who cannot get onto the examining table, who are in wheelchairs, have flexion contractures, or who cannot otherwise extend their knee.

## **Total Ankle Arthroplasty for Rheumatoid Arthritis Cases in This Biologics Era: Mid to Long-Term Follow-up**

**Makoto Hirao**<sup>1</sup>, Jun Hashimoto<sup>2</sup>, Hideki Tsuboi<sup>3</sup>, Kosuke Ebina<sup>4</sup> and Hideki Yoshikawa<sup>5</sup>, <sup>1</sup>Orthopaedic Surgery, Osaka University, Graduate School of Medicine, Suita, Japan, <sup>2</sup>Rheumatology/Orthopaedics, Osaka-Minami Medical Ctr, Kawachinagano, Japan, <sup>3</sup>Orthopaedics/Rheumatology, Osaka Rosai Hospital, Sakai, Japan, <sup>4</sup>Orthopaedics, Osaka University Graduate School of Medicine, Suita, Japan, <sup>5</sup>Department of Orthopedics, Osaka University Graduate School of Medicine, Suita Osaka, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Outcomes after total ankle arthroplasty (TAA) combined with additive techniques (augmentation of bone strength, control of soft tissue balance, adjustment of the loading axis) for destructive rheumatoid arthritis (RA) cases were evaluated after mid to long-term follow-up. The influences of biologic treatment on the outcomes after TAA were also evaluated.

**Methods:** A retrospective observational study was completed involving 50 RA cases [mean follow-up period: 7.1 years] who underwent TAA. RA foot ankle scales were administered using the Japanese Society for Surgery of the Foot (JSSF) standard rating system, and a postoperative self-administered foot evaluation questionnaire (SAFE-Q) was also checked at final follow-up. Radiographic findings were also checked.

**Results:** This procedure significantly improved the clinical scores of the JSSF RA foot and ankle scales. Of 50 ankles, 48 had no revision TAA surgery. Prosthesis sinking at the talus side was seen in 8 ankles (6 ankles in biologics group, 2 ankles in non-biologics group); 2 required revision TAA. The social functioning score of the SAFE-Q scale at final follow-up was significantly higher in the biologic treatment group than in the non-biologic group. The biologic treatment group showed a significantly lower rate of prednisolone usage (12%) than the non-biologic treatment group (71%), and disease activity was significantly improved in the biologic treatment group at final follow-up.

**Conclusion:** TAA is recommended for RA cases, if disease control, augmentation of bone strength, control of soft tissue balance, and adjustment of loading axis are taken into account. Withdrawal of the steroid in biologics treatment might have a good effect on the durability of prostheses in long-term observation in the perspective of bone-mineral structure. Biologics treatment contributed to increase social activity after TAA in RA cases. So, prevention of talar component sinking for RA cases with such higher social activity should be further discussed and resolved in this biologics era.

**Background/Purpose:** To project the future utilization of total hip and knee joint arthroplasty (THA, TKA).

**Methods:** We used the 2000-2010 U.S. National Inpatient Sample combined with Census Bureau data to develop projections for primary and revision THA and TKA from 2020 to 2040 using negative binomial regression.

**Results:** Predicted total annual counts for THA and TKA utilization in the U.S. by 2020, 2025, 2030 and 2040 are (in thousands): primary THA, 527 (95% CI, 495, 561), 765 (95% CI, 712, 823), 1087 (95% CI, 999, 1184) and 2040 (95% CI, 1828, 2081); primary TKA, 1611 (95% CI, 1531, 1699), 2675 (95% CI, 2516, 2847); 4306 (95% CI, 4008, 4632) and 10314 (95% CI, 9391, 11343); revision THA 56 (95% CI, 51, 61), 68 (95% CI, 61, 76), 82 (95% CI, 72, 93) and 204 (95% CI, 183, 228); and revision TKA, 153 (95% CI, 140, 168), 250 (95% CI, 226, 279), 399 (95% CI, 353, 452) and 1031 ((95% CI, 939, 1134) (Figures 1 and 2). The utilization is projected to increase for both females and males (Figure 3), all age groups and all race/ethnicities (data not shown).

**Conclusion:** Significant increases in THA and TKA utilization are expected in the future. A policy change may be needed to meet increased demand.

### SESSION INFORMATION

Session Date: Sunday, November 5, 2017

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Obesity is a risk factor for development of knee osteoarthritis due to altered gait biomechanics. Gait analysis was performed mostly on older obese adults with knee osteoarthritis. Biomechanics of young obese individuals is unclear. The aim of this study was to investigate the effect of obesity on gait biomechanics in young women; and the relationship between obesity and occurrence of knee osteoarthritis.

**Methods:** 31 healthy normal-weighted and 31 obese women aged between 30-45 years and body mass indexes (BMI) between 30-40 kg/m<sup>2</sup> were included in this study. Anthropometric measurements like body weight (BW), height, waist/hip ratios were measured. Skinfold thickness (SFT) was measured from right side of the body. Isokinetic quadriceps and hamstring muscle strengths were measured at 60°/s angular velocity and 0-90° joint range of motion. Body composition analyses were determined before breakfast. Gait analyses were performed by Vicon 612 gait analyses system with the subjects' comfortable walking speed.

**Results:** Mean age of obese group was 39.4 years and control group was 35.8 years ( $p>0.05$ ). Circumferences and SFT, body fat ratio, fat free mass (FFM) found higher in obese group ( $p<0.001$ ) and there was a strong relation between fat ratio and circumferences ( $r=0.89$ ), BMI ( $r=0.85$ ) and SFT ( $r=0.83$ ). When peak torque were normalized to BW, Isokinetic quadriceps and hamstring muscle strengths were significantly lower in obese individuals ( $p<0.001$ ). Walking speed, single support time, step length and stride length were lower and stance phase, double support time and step width was higher in obese individuals ( $p<0.001$ ). In obese group we found that total excursion of pelvic obliquity, hip rotation and knee flexion-extension angle was lower ( $p<0.001$ ), knee varus moment ( $p<0.05$ ) and second peak of vertical ground reaction force was higher in obese group ( $p<0.001$ ).

**Conclusion:** In obese subjects, isokinetic quadriceps and hamstring muscles strengths were lower, knee and hip joint range of motion was diminished. Knee peak varus moment and vertical ground reaction force at the end of stance phase were significantly higher in obese group. These results suggest that obesity may contribute to knee osteoarthritis. Thus, prospective studies are needed to identify the influence of higher loading rates on knee osteoarthritis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous randomized controlled trials have led to conflicting findings regarding the effects of exercise on anxiety in adults with arthritis and other rheumatic diseases (AORD). The purpose of this study was to use the meta-analytic approach to try and resolve these discrepancies.

**Methods:** The *a priori* inclusion criteria were: (1) randomized controlled trials, (2) exercise (aerobic, strength training, or both)  $\geq 4$  weeks, (3) comparative control group, (4) adults  $\geq 18$  years of age with osteoarthritis, rheumatoid arthritis or fibromyalgia, (5) published and unpublished studies in any language since January 1, 1981, (6) anxiety as an outcome assessed. Studies were located by searching 8 electronic databases, cross-referencing and expert review. Dual selection of studies and data abstraction were performed. Hedge's standardized effect size ( $g$ ) was calculated for each result and pooled using the recently developed inverse-heterogeneity (IVhet) model. Non-overlapping 95% confidence intervals were considered statistically significant. Heterogeneity was estimated using  $Q$  and  $I^2$  with alpha values  $< 0.10$  for  $Q$  considered statistically significant. Small-study effects were examined using funnel plots and Egger's regression test. In addition, the number-needed-to-treat (NNT), percentile improvement, and subgroup analyses were conducted. Risk of bias was assessed using the Cochrane Risk of Bias Assessment Instrument. Training program characteristics were reported as mean  $\pm$  standard deviation.

**Results:** Of the 639 citations screened, 14 studies representing 926 initially enrolled participants (539 exercise, 387 control) met the criteria for inclusion. Length of training averaged  $15.8 \pm 6.7$  weeks, frequency  $3.3 \pm 1.3$  times per week and duration  $28.8 \pm 14.3$  minutes per session. Overall, statistically significant exercise minus control reductions in anxiety were found ( $g = -0.40$ , 95% CI,  $-0.65$ ,  $-0.15$ ,  $\tau^2 = 0.14$ ;  $Q = 40.3$ ,  $p = 0.0004$ ;  $I^2 = 62.8\%$ ). The NNT was 6 with a percentile improvement of 15.5% and an estimated 5.3 million inactive US adults with AORD improving their anxiety if they started exercising regularly. Statistically significant small-study effects were observed ( $p < 0.0001$ ). No between-group differences in anxiety were observed between type of arthritis and type of exercise. All studies were considered to be at high risk of bias with respect to blinding of participants to group assignment. Given the lack of information provided, greater than 50% of studies were at an unclear or high risk of bias with respect to (1) incomplete outcome reporting (78.6%), (2) allocation concealment (78.6%), and (3) blinding of outcome assessors (57.1%).

**Conclusion:** Exercise is associated with reductions in anxiety among adults with AORD. However, a need exists for additional, well-designed, randomized controlled trials on this topic.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Current guidelines emphasize an active lifestyle in the management of knee osteoarthritis (OA), but up to 90% of OA patients are inactive. Several modifiable risk factors are associated with low physical activity participation, including lack of motivation, doubts about effectiveness of exercise, and lack of health professional advice regarding ways to adjust their activities based on symptoms. Our study aimed to assess the efficacy of a wearable-enabled physical activity counselling program for improving activity participation and disease status in people with knee OA.

**Methods:** Eligible participants had a self-reported knee OA diagnosis, or symptoms of knee OA based on a validated questionnaire. After baseline assessment and randomization, the *Immediate Intervention Group (II)* received group education, a Fitbit, and 4 biweekly phone calls by a physiotherapist to counsel activity goals over a 2-month period. The *Delayed Intervention (DI) Group* received the program 2 months later. Participants were assessed at baseline (T0) and the end of 2, 4 and 6 months (T1, 2, and 3). Outcome measures included: 1) mean moderate/vigorous physical activity (MVPA) time measured with a SenseWear® monitor; 2) mean daily step count; 3) mean sedentary behaviour time; 4) Knee Injury & OA Outcome Score (KOOS). Analysis of covariance (ANCOVA) was used to evaluate the effect of the group type on the outcome measures at T1, 2, and 3, after adjusting for T0. We assessed three planned contrasts of changes: 1) compared T0–T1 between the two groups to determine if *II* was superior to *DI* (the control); 2) compared T0–T2 in *II* against T0–T3 in *DI*; 3) compared T0–T2 in *II* against T1–T3 in the *DI*. The last 2 models assessed whether the two-month delay had an impact on the effect of the intervention.

**Results:** In 2015–2016, we recruited 61 participants (*II*: n=30, 73% women; *DI*: n=31, 90% women). Both groups were similar in age (*II*: 61.3 (9.4) years; *DI*: 62.1 (SD 8.5)] and body mass index [*II*: 29.2 (5.5); *DI*: 29.2 (4.8)]. Figure 1 summarizes the results. Pre-specified contrast analyses revealed a significant effect whereby the *II* group improved in the MVPA time at T0–T1 compared to the *DI* (contrast coefficient: 25.2; 95% CI 5.5, 44.9;  $p = 0.01$ ). A significant effect was also found in the mean daily steps at T0–T1 (contrast coefficient: 1,519; 95% CI 256.2, 2,782.3;  $p = 0.02$ ). We found no significant effect in any outcome measures in the other contrast analyses.

**Table 1: Results of outcome measures**

	Immediate Intervention Group				Delayed Intervention Group			
	(n = 30)				(n = 31)			
	T0	T1	T2	T3	T0	T1	T2	T3
<b>Mean MVPA time [mins]</b>	62.1 (54.6)	75.5 (54.3)	62.6 (56.3)	65.6 (48.5)	65.3 (77.4)	49.6 (46.8)	60.1 (76.8)	70.7 (71.9)
<b>Mean daily steps</b>	7,069.2 (3,375.3)	8,217.4 (3,095.5)	8,132.5 (3,420.7)	8,215.1 (3,725.6)	7,556.6 (5,054.1)	6,713.6 (3,354.3)	7,631.9 (4,054.3)	7,573.6 (4,477.1)
<b>Mean sedentary time [mins]</b>	464.1 (137.7)	437.6 (133.9)	505.9 (167.2)	435.8 (138.8)	497.4 (200.7)	503.0 (160.7)	508.9 (189.0)	496.9 (179.5)
<b>KOOS (0-100; higher = better)</b>								
<b>Symptoms</b>	59.8 (16.1)	62.6 (15.6)	62.4 (14.7)	62.1 (15.3)	62.9 (17.2)	61.7 (14.5)	63.4 (16.7)	61.4 (19.8)
<b>Pain</b>	66.2 (17.5)	70.9 (17.0)	67.5 (15.5)	68.6 (17.5)	65.1 (17.9)	64.8 (14.6)	66.3 (15.2)	66.2 (16.4)
<b>ADL</b>	71.8 (17.5)	76.0 (16.1)	76.6 (17.5)	75.1 (15.9)	74.1 (17.6)	71.0 (16.5)	75.2 (17.2)	73.9 (15.8)
<b>Sports &amp; recreation</b>	47.3 (26.6)	49.3 (24.9)	50.0 (25.6)	50.4 (26.3)	52.7 (27.7)	47.0 (23.3)	48.9 (27.7)	49.8 (29.2)
<b>Qol</b>	41.0 (19.8)	47.2 (18.9)	45.4 (17.6)	44.9 (17.9)	44.6 (16.3)	42.4 (16.8)	47.5 (13.6)	48.1 (19.1)

**Conclusion:** Our wearable-enabled counselling program improved MVPA time and step counts in people with a diagnosis or symptoms of knee OA. The finding is important since an active lifestyle is recognized as an important component of successful self-management.

## Pain, Fatigue and Function in Patients with Ehlers-Danlos Syndrome and Hypermobility Spectrum Disorder – Relationship with Perceived Benefits and Barriers to Exercise

Leslie Soever<sup>1</sup>, Laura Passalent<sup>2</sup>, Ahmed Omar<sup>3</sup> and Medha Soowamber<sup>4</sup>, <sup>1</sup>Toronto General Hospital, Toronto, ON, Canada, <sup>2</sup>Allied Health, Toronto Western Hospital, Toronto, ON, Canada, <sup>3</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>4</sup>University Health Network, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Orthopedics, Low Back Pain and Rehabilitation Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Ehlers-Danlos Syndromes (EDS) are a heritable group of connective tissue disorders with predominant features including joint hypermobility, skin hyperextensibility and tissue fragility. Hypermobility Spectrum Disorders (HSD) include all phenotypes presenting with joint hypermobility plus one or more of its secondary manifestations but not satisfying the criteria for EDS (Castori, 2017). Common symptoms reported by patients with EDS and HSD include pain and fatigue, resulting in decreased function, including lack of exercise. It has been shown that patients with EDS and HSD overall improve with exercise interventions (Palmer, 2014). The purpose of this study was explore relationships between self-reported pain, fatigue, and function; with perceived benefits and barriers to exercise.

**Methods:** A retrospective chart review was completed on 38 consecutive patients with either EDS or HSD to determine if there were any relationships between the scores for pain (high scores indicate greater pain), fatigue (high scores indicate greater fatigue), and function (low scores indicate greater function), as per the Multi-Dimensional Health Assessment Questionnaire (MD- HAQ); and the total score (high scores indicate more positive perception of exercise), benefits score (high scores indicate more positive perception of exercise), and barriers score (high scores indicate greater perception of barriers to exercise) on the Exercise Benefits and Barriers Scale (EBBS). These instruments were administered to patients as part of routine care to assist with treatment planning and recommendations. Descriptive statistics and univariate analysis (Pearson correlation coefficients) were used to determine if relationships existed between self-reported pain, fatigue and function; and perceived benefits scores, barriers scores, and total EBBS scores reported by patients.

**Results:** The majority of the sample was female (96 %); and the average age was 33.5 years. According to the 2017 International Classification for EDS, 23 patients had EDS (hypermobility type n=20; classical type n=1; vascular type n=1; kyphoscoliotic type n=1) and 15 patients had HSD. Overall, EBBS scores indicated high perceived value of exercise. There was no relationship between fatigue ( $r = -0.143$ ;  $p = 0.39$ ) nor pain ( $r = -0.192$ ;  $p = 0.25$ ) with total EBBS scores. However, the higher patients reported their level of function, the higher were their total EBBS scores ( $r = 0.392$ ;  $p = 0.015$ ). Similarly, higher function scores, correlated with higher total benefits scores ( $r = 0.383$ ;  $p = 0.018$ ); and patients who reported higher function reported fewer perceived barriers to exercise ( $r = -0.44$ ;  $p = 0.006$ ).

**Conclusion:** These results support previously reported importance of exercise in the management of patients with EDS and HSD; and further highlight the critical role of programs to educate patients, with EDS and HSD regarding the importance of exercise, who are experiencing difficulty with function.

### **Risk Factors for Blood Transfusions Following Total Joint Arthroplasty in Patients with Rheumatoid Arthritis**

#### **Abstract**

**Background/Purpose:** Despite effective therapies, rheumatoid arthritis (RA) can result in joint destruction requiring total joint arthroplasty to maintain patient function. An estimated 16% to 70% of those undergoing total joint arthroplasty of the hip or knee will receive a blood transfusion. Few studies have described risk factors for blood transfusion following total joint arthroplasty in patients with RA. The purpose of this study is to identify demographic and clinical risk factors associated with receiving a blood transfusion following total joint arthroplasty among patients with RA.

**Methods:** A retrospective study ( $N = 3,270$ ) was conducted using de-identified patient health claims information from a commercially-insured, U.S. dataset (2007-2009). Data analysis included descriptive statistics and multivariate logistic regression.

**Results:** Females were more likely to receive a blood transfusion (Odds ratio [OR]=1.48; 95% Confidence Interval [CI]: 1.16-1.87;  $p=.001$ ). When compared to those in the South, patients residing the Midwest were less likely to receive a blood transfusion following total joint arthroplasty (OR=0.56, 95% CI: 0.44-0.71). Relative to those receiving total knee arthroplasty, patients who underwent total hip arthroplasty were more likely to receive a blood transfusion (OR=1.39, 95% CI: 1.14-1.70), and patients who underwent a total shoulder arthroplasty were less likely to receive a blood transfusion (OR=0.14 and 95% CI: 0.05-0.38;  $p<.001$ ). Patients with a history of anemia were more likely to receive a blood transfusion compared to those who did not have this diagnosis (OR=3.30, 95% CI: 2.62-4.14;  $p<.001$ ).

**Conclusion:** Risk factors for the receipt of blood transfusions among RA patients who have undergone total joint arthroplasty were identified.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Background/Purpose:** The bone forming agent romosozumab (Romo) was previously shown to reduce vertebral and clinical fractures in postmenopausal women with osteoporosis. Here we report the efficacy and safety results of the ARCH study (NCT01631214).

**Methods:** This multicenter double-blind study enrolled postmenopausal women age 55–90 years with osteoporosis and high fracture risk, defined as a BMD T-score  $\leq -2.5$  at total hip [TH] or femoral neck [FN] and either  $\geq 1$  moderate/severe or  $\geq 2$  mild vertebral fractures, or a BMD T-score  $\leq -2.0$  at TH or FN and either  $\geq 2$  moderate/severe vertebral fractures or a history of a recent hip fracture. Subjects were randomized 1:1 to 210mg Romo SC QM or 70mg alendronate (ALN) PO QW for 12 months, followed by open label 70mg ALN PO QW in both groups. Primary endpoints were subject incidence of new vertebral fracture through 24 months and clinical fracture through the primary analysis (PA). PA was performed when  $\geq 330$  clinical fractures had occurred and all subjects had completed the month 24 visit. Nonvertebral fracture at the PA was a secondary endpoint, as was BMD at the lumbar spine, TH, and FN at months 12 and 24. Hip fracture was evaluated as an additional secondary endpoint.

**Results:** 4093 women (mean age 74, mean TH T-score  $-2.8$ ) were randomized to Romo or ALN. 12 months of Romo prior to ALN vs ALN alone significantly reduced new vertebral, clinical, nonvertebral, and hip fractures (Table). Treatment with Romo also significantly increased BMD at all sites measured, at months 12 and 24 vs ALN alone (Table). Overall adverse events were balanced between groups. During the open label ALN period, 6 subjects (2 Romo; 4 ALN) were positively adjudicated for AFF and 2 subjects (1 Romo; 1 ALN) for ONJ. Cardiovascular (CV) serious adverse events (SAEs) were independently adjudicated; at 12 months the subject incidence was 2.5% in the Romo group vs 1.9% in the ALN group with cardiac ischemic events at 0.8% vs 0.3% and cerebrovascular events at 0.8% vs 0.3%, respectively.

**Conclusion:** In postmenopausal women with osteoporosis, Romo 210mg QM followed by ALN significantly reduced new vertebral, clinical, nonvertebral, and hip fracture risk vs ALN alone, suggesting that in osteoporotic patients at high risk for fracture, a treatment regimen starting with Romo followed by ALN leads to superior fracture risk reduction over ALN alone. An observed imbalance in CV SAEs compared with ALN was not seen in the previous placebo-controlled 7180-patient FRAME study and is currently being evaluated.

Efficacy Table

	Subject Incidence of Fracture (%)		Relative Risk Reduction	Nominal P value	Adjusted P value <sup>a</sup>
	ALN 70mg QW / ALN 70 mg QW N=2047 <sup>b</sup>	Romo 210mg QM / ALN 70 mg QW N=2046 <sup>b</sup>			
New vertebral Fx <sup>c</sup>	8.0	4.1	50%	P<0.001	P<0.001
Clinical Fx <sup>d</sup>	13.0	9.7	27%	P<0.001	P<0.001

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Romosozumab (Romo), a sclerostin antibody, has a dual effect of increasing bone formation and decreasing bone resorption. In the FRAME study, one year of Romo treatment resulted in large BMD increases at the lumbar spine and total hip versus placebo (PBO); the differences between groups remained after all subjects transitioned to denosumab (DMAb) during the second year of the study (Cosman *NEJM* 2016). Here, we further characterize the BMD gains during the FRAME study and the effect of building bone with Romo on fracture risk reduction upon transition to DMAb.

**Methods:** Subjects in FRAME (NCT01575834) were randomized to receive Romo 210 mg QM or PBO for 12 months, after which all subjects received DMAb 60 mg Q6M for an additional 12 months. Endpoints for the current analysis were mean change from baseline in BMD T-score, percent of subjects with a BMD gain, and subject incidence of fractures in the second year of the study, including new vertebral, clinical (nonvertebral plus symptomatic vertebral), and other fracture categories.

**Results:** There were 7180 subjects in the study (N=3589 Romo, N=3591 PBO). At month 12, mean change from baseline in lumbar spine BMD T-score was 0.88 for Romo and 0.03 for PBO; at month 24, after both treatment groups received DMAb in the second year, the mean change from baseline was 1.11 for Romo/DMAb and 0.38 for PBO/DMAb. At the total hip, the mean changes were 0.32 for Romo and 0.01 for PBO at month 12, with month-24 changes of 0.45 for Romo/DMAb and 0.17 for PBO/DMAb. 99% of subjects in the Romo group showed some increase in BMD at month 12, with 89% achieving  $\geq 6\%$  gains in lumbar spine BMD (Figure). Administration of Romo during the first year led to relative risk reductions in fractures between groups during the second year, despite both groups receiving DMAb in year two, with reductions of 81% for vertebral fractures ( $p < 0.001$ ), 32% for clinical fractures ( $p = 0.052$ ), and 39% for major osteoporotic fractures ( $p = 0.034$ ).

**Conclusion:** Romo resulted in substantial T-score increases after one year; upon transition to DMAb, gains in both groups were similar, resulting in unprecedented BMD gains after treatment with Romo followed by DMAb. As a result of one year of Romo before transition to DMAb, fracture rates were substantially reduced during year two, when subjects in both groups received DMAb. The data support the clinical benefit of rebuilding the skeletal foundation with Romo treatment before transition to DMAb.

Figure. Percent Change in Lumbar Spine BMD From Baseline to Month 12 by Individual Subject

N = Number of subjects with values at baseline and at least one post-baseline visit at or before month 12. Data are percent change in lumbar spine BMD from baseline to month 12 by individual subject. N's included subjects with baseline and ≥ 1 postbaseline measurement; missing data were imputed by last observation carried forward. X-axis represents each individual subject. Dotted horizontal lines reflect 3%, 6%, and 10% BMD gain from baseline to month 12. Lines with arrowheads below the X-axis represent the percent of subjects with the indicated BMD gains (> 0%, ≥ 3%, ≥ 6%, and ≥ 10%). BMD, bone mineral density.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Background/Purpose:** The VERO trial was an active-controlled fracture endpoint clinical trial that recruited postmenopausal women with low bone mass and prevalent vertebral fractures (VFX). We have reported that the risk of new VFX and clinical fractures [a composite of clinical VFX and non-vertebral fragility fractures (NVFFx)] in patients treated with teriparatide (TPTD) compared with those treated with risedronate (RIS) was reduced by 56% and 52% respectively ( $p<.001$  for each), with a non-significant reduction in NVFFx (34%,  $p=0.099$ ). Here we present the pre-specified exploratory analysis of clinical vertebral fracture (ClinVFX) incidence over 24 months.

**Methods:** 1,360 postmenopausal women (680/arm; mean age: 72.1 years) with at least 2 moderate or 1 severe VFX and low bone mass (BMD T-score  $\leq -1.5$ ) were randomized to TPTD 20  $\mu\text{g}$  sc/day or RIS (35 mg po/week) in a 2-year, double-blind, double-dummy trial. A ClinVFX was defined as an clinical episode associated with signs and symptoms suggestive of a VFX, such as acute onset of severe back pain, pain with little or no exertion or pain localised to a specific vertebra and associated with limited back mobility, confirmed with a new or worsened radiographic VFX (centrally adjudicated). A new vertebral fracture was radiologically defined as a loss of vertebral body height of at least 20% and 4 mm from the baseline radiograph by quantitative morphometry measurements, confirmed with a semiquantitative assessment (i.e.; the vertebral body also has an increase of 1 or more severity grade according to the Genant scale). Cumulative incidences of the first ClinVFX were obtained by Kaplan-Meier, and comparison was based on a stratified long-rank test. The stratified HR was computed from the log-rank test. Incidence rates, depicted as number of events per 100 patient-years, were also assessed.

**Results:** The mean (SD) number of prevalent VFX was 2.7 (2.1), 55.4% of the women had a BMD T-score  $<-2.5$  (lowest value measured at the lumbar spine or hip), 36.5% a history of ClinVFX within the year before randomization, 27.9% were naïve to osteoporosis medications, and 57.9% were previously treated with bisphosphonates. A total of 31 women were diagnosed with an incident ClinVFX over the 24-month study duration: 7 women in the TPTD group (1.1%) compared to 24 women (3.9%) in the RIS group (hazard ratio: 0.29; 95% CI: 0.14-0.58;  $p=0.002$ ) (Figure). The incidence rates (95% CI) were 0.58 (0.23-1.18) and 1.97 (1.27-2.91) events/patient-years in the TPTD and RIS treated subjects, respectively ( $p=0.004$ ).

**Conclusion:** In postmenopausal women with severe osteoporosis, TPTD treatment for 24 months significantly reduced by 71% the risk of new clinical vertebral fractures compared with RIS.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Four clinical trials have separately shown greater BMD gains with transitioning to denosumab (DMAb) compared with continuing on bisphosphonates (BP) in subjects previously treated with oral BPs (Kendler *JBMR* 2010; Recknor *Obstet Gynecol* 2013; Roux *Bone* 2014; Miller *JCEM* 2016). The aim of this meta-analysis was to improve estimates of effect size and provide an integrated assessment of safety/efficacy of DMAb vs BPs with different dosing regimens (weekly, monthly, yearly) and administration routes (oral, intravenous), over 12 months in postmenopausal women pretreated with oral BPs.

**Methods:** Data were pooled from 4 randomized studies in postmenopausal women with low bone mass or osteoporosis, aged  $\geq 55$  years, and pretreated with oral BPs, who were randomized 1:1 to DMAb (60mg every 6 months) or an oral (alendronate 70mg weekly, ibandronate 150mg monthly, risedronate 150mg monthly) or intravenous (zoledronic acid 5mg yearly) BP for 12 months. Percentage (%) change from baseline (BL) in BMD at the lumbar spine, total hip, femoral neck, and 1/3 radius (assessed in 2 studies) at month 12; % change from BL in serum C-terminal telopeptide of type I collagen (sCTX, in a subset of 1058 subjects) at 1, 6, and 12 months (in 2 of the studies); and safety were assessed. Fractures were collected as adverse events (AEs) and not adjudicated.

**Results:** A total of 2850 subjects were included (1426 DMAb; 1424 BP). Mean (SD) age was 68 (8) years, mean (SD) lumbar spine BMD T-score was -2.5 (1.0), and mean (SD) duration of prior oral BP use was 3.8 (3.6) years. BMD % change from BL at month 12 was significantly greater with DMAb vs BPs at all measured skeletal sites (Figure) and independent of length of prior BP use ( $<2$  or  $\geq 2$  years) at all sites measured (except for 1/3 radius for those with  $<2$  years of prior BP use). Median sCTX % decrease from BL was greater with DMAb than BPs at months 1 (-58% vs -12%), 6 (-36% vs -14%), and 12 (-26% vs 8%; all  $p < 0.0001$ ). Overall AEs/serious AEs were similar between groups. There were no cases of osteonecrosis of the jaw. Three events consistent with the definition of atypical femoral fracture were observed (2 DMAb; 1 BP). Osteoporosis-related fractures were reported in 47 (3.3%) DMAb and 43 (3.1%) BP subjects.

**Conclusion:** This integrated assessment shows greater clinical benefit with increases in BMD and reductions in bone turnover and similar safety profile in transitioning from oral BPs to DMAb, compared with continuing on or cycling through the same therapeutic class (from one BP to another).

**Figure. Percentage Change in BMD From Baseline at Month 12**

\* $p < 0.0001$  and † $p = 0.001$  denosumab vs bisphosphonate.

Data are least-squares means and 95% confidence intervals based on an ANCOVA model adjusting for treatment, duration of prior bisphosphonate use, baseline BMD, study, DXA machine type, and baseline-BMD-value-by-machine-type interaction.

1/3 radius was assessed in 2 of the 4 studies.

## **Safety of Denosumab in a Monocentric Cohort of Kidney Transplant Recipients**

Sonia Doddoli, Pierre Lafforgue and **Thao Pham**, Rheumatology, APHM, Aix Marseille Univ, Marseille, France

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Safety of denosumab, a fully human monoclonal antibody against RANKL developed for osteoporosis and prevention of fracture remains unclear in kidney transplanted patients.

A recent placebo-controlled trial has demonstrated its efficacy on bone mineral density (BMD) and bone turnover biomarkers (Bonani et al. Am J Transplant. 2016). Patients in the denosumab group experienced more episodes of cystitis and asymptomatic hypocalcemia than patients in the placebo group.

Our aim was to assess the clinical and biological tolerance of denosumab in this specific population.

## Methods:

Prospective observational monocentric cohort.

*Inclusion criteria:* kidney transplant recipient who received at least one subcutaneous injections of 60 mg denosumab; age  $\geq 18$  years.

*Safety outcomes:* The following variables were collected every 6 months: infection, reaction at the injection site, plasmatic parameters of renal function and mineral metabolism (estimated glomerular filtration rate, serum creatinine, calcium, 1–25 [OH], vitamin D, PTH).

## Results:

Patients were recruited from April 2014 to September 2015. All patients received immunosuppression therapy including prednisolone  $\geq 5$  mg/d.

The main baseline characteristics of the 37 kidney transplant recipients were the following [mean]: male: 41%, age: 60.5 years, BMI: 24.1, transplantation duration: 7.1 years, osteopenia: 36%, osteoporosis: 64%, total lumbar spine T-score: -2.04 SD, total hip T-score: -2.7 SD, T-score femoral neck: 0.676 g/cm<sup>2</sup>, serum creatinine: 132.8 mmol/L, calcium: 2.33 mmol/L, 1–25 [OH] vitamin D: 93.5 nmol/L, PTH 95: ng/l. All patients were prescribed vitamin D and calcium supplementation.

During the mean 12-month follow-up period, there were no unexpected adverse event [AE] or severe adverse event, no graft failure and no deaths. No patient experienced fracture. Only one patient presented an infectious AE with recurrent cutaneous abscess. Renal function remained stable with no difference in serum creatinine between baseline and 12 months for the majority of the kidney transplant recipients. However, 9 recipients experienced a decrease in renal function with a mean increased in serum creatinine of 32.5 micromol/L between baseline and 12 months. Serum calcium was stable, no hypocalcaemia was observed. Among patients with normal baseline PTH, two presented hyperparathyroidism during the follow-up period. Among the 11 patients with baseline hyperparathyroidism, 7 had an increased PTH level between baseline and 12 months. None were initiated on cinacalcet. None of them experienced severe hypercalcemia, nor hypocalcemia.

## Conclusion:

Our results suggest that denosumab is safe in kidney transplant recipients. We did not observe an increase in the infection rates, nor hypocalcemia. However, several patients experienced a decrease in their renal function or an increased hyperparathyroidism.

## Evaluation of Invasive Oral Procedures and Events in Women with Postmenopausal Osteoporosis Treated for up to 10 Years with Denosumab: Results from a Phase 3 Open-Label Extension Study

Nelson B. Watts<sup>1</sup>, John T. Grbic<sup>2</sup>, Neil Binkley<sup>3</sup>, Peter W. Butler<sup>4</sup>, Xiang Yin<sup>4</sup>, Antoniette Tierney<sup>4</sup>, Rachel B. Wagman<sup>4</sup> and Michael McClung<sup>5</sup>, <sup>1</sup>Mercy Health, Cincinnati, OH, <sup>2</sup>Columbia University, New York, NY, <sup>3</sup>University of Wisconsin School of Medicine and Public Health, Madison, WI, <sup>4</sup>Amgen Inc., Thousand Oaks, CA, <sup>5</sup>Oregon Osteoporosis Center, Portland, OR

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antiresorptive therapy use is associated with osteonecrosis of the jaw (ONJ), an infrequent but serious adverse event. Positively adjudicated ONJ in the denosumab (DMAB) clinical trial program is rare (between  $\geq 1$  and  $<10$  per 10,000).

Completion of the 7-year FREEDOM Extension study (EXT) permitted an in-depth assessment of the risk factors and observed invasive oral procedures and events (OPEs; eg, dental implants, tooth extraction, natural tooth loss, scaling/root planing [extensive subgingival cleaning]) in the clinical trial setting.

**Methods:** In the randomized, placebo-controlled FREEDOM study, women received DMAB 60mg or placebo SC every 6 months for 3 years. Patients who missed  $\leq 1$  dose of investigational product and completed the Year-3 visit were eligible to participate in the 7-year open-label EXT to receive DMAB, regardless of original treatment assignment in FREEDOM. Women who reached the EXT Year-3 visit were asked to chronicle their history of invasive OPEs since the start of the EXT through Year 2.5, as well as oral events (including jaw surgery) in the prior 6 months. The oral event questionnaire was then administered every 6 months through the end of the EXT.

**Results:** During the EXT, the overall ONJ rate was 5.2 per 10,000 patient-years. The majority of women (79%; 3591/4550 patients) participated in the survey. Over the EXT, 1621 (45.1%) reported at least one invasive OPE; the incidence of five individual OPEs were similar between groups (Table). There were 12 confirmed cases of ONJ among women who participated in the survey (11 had OPE and one did not) and one additional case in a woman who did not complete the survey. ONJ incidence was 0.7% (11/1621 patients) in women reporting invasive OPEs and 0.05% (1/1970 patients) in women reporting no invasive OPEs. Of the 12 ONJ cases with survey results, one outcome was unknown due to consent withdrawn, one was ongoing at the end of study, and 10 resolved with treatment.

**Conclusion:** Nearly all cases of ONJ observed in this study occurred after a reported invasive OPE, yet while invasive OPEs were common in this group of DMAB-treated women with postmenopausal osteoporosis, ONJ incidence was low. The actual number of invasive OPEs may be underestimated due to limited capture of OPEs in medical charts and possible recall bias in patients with events that occurred in the first 2.5 years of the EXT. ONJ is an adverse event of interest that continues to be monitored in DMAB pharmacovigilance activities.

Table: Invasive OPEs during the EXT for patients who completed at least one oral event questionnaire

	7-year FREEDOM Extension		
	Cross-over (N = 1731)	Long-term (N = 1860)	All (N = 3591)
Age at EXT baseline in years, mean (SD)	74.3 (4.9)	74.4 (4.8)	74.3 (4.8)
Any invasive oral procedure or event, n (%)	795 (45.9)	826 (44.4)	1621 (45.1)
Scaling / root planing	503 (29.1)	531 (28.5)	1034 (28.8)
Tooth extraction	434 (25.1)	458 (24.6)	892 (24.8)
Dental implant	100 (5.8)	112 (6.0)	212 (5.9)
Natural tooth loss	72 (4.2)	75 (4.0)	147 (4.1)
Jaw surgery*	16 (0.9)	17 (0.9)	33 (0.9)
N = Number of patients who received $\geq 1$ dose of investigational product in the EXT and responded to $\geq 1$ oral event questionnaire related to the EXT			
n = Number of patients with an OPE			
*Collected in the oral event questionnaire every 6 months; therefore, jaw surgery in the first 2.5 years of the EXT was not captured

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although early intensive treatment has improved medication of rheumatoid arthritis (RA), treatment for osteoporosis (OP) in RA patient will be more important. Here, we report 2-year outcome of denosumab (DMB) on OP of RA patients. This was a multiple center, prospective study (TBCR-BONE) to investigate the efficacy of DMB for 2 years on OP of RA patients and the predictors for the efficacy in DMB treatment.

**Methods:** 74 females completed 24-month (m) DMB treatment and were used for the analysis. Bone mineral density (BMD) of lumbar spine (LS) and total hip (TH) by DEXA, and P1NP and TRACP-5b were measured every 6m.

**Results:** Mean age was 70.2 years old. Mean RA duration was 17.1 years. Oral PSL was used in 26 cases. Biological agents (BIO) were used in 17 cases. 33 cases had the past history of fractures. The rate of change in LS-BMD (%LS-BMD) significantly increased as 4.4% at 6m, 5.8% at 12m, 7.2% at 18m and 7.6% at 24m. %TH-BMD significantly increased as 2.7% at 6m, 3.3% at 12m, 4.6% at 18m and 4.6% at 24m. %P1NP at 24m was -28.1%. %TRACP-5b at 24m was -20.6%. To confirm the predictors for large increase of %LS-BMD at 24m and %TH-BMD at 24m, all cases were divided into two groups, good outcome group (LS-GO group: n=47, mean %BMD at 24m=11.4% and TH-GO group: n=47, mean %BMD at 24m=6.8%) and no good outcome group (LS-NGO group: n=24, mean %BMD at 24m=0.18% and TH-NGO group: n=24, mean %BMD at 24m=0.21%) with the cutline of %LS-BMD at 24m (4.0%) and %TH-BMD at 24m (3.1%) made of each superior two thirds of all cases. We performed multivariate logistic regression analyses and confirmed large decrease of %TRACP-5b at 12m was associated with large increase of %LS-BMD at 24m [OR (%) 0.97, 95% CI 0.95-0.99], and concomitant use of BIO was associated with large increase of TH-BMD at 24m (OR 5.8, 95% CI 1.10-30.64). The cutoff value of %TRACP-5b at 12m for larger increase of %LS-BMD at 24m was -38.7% (AUC of ROC=0.766). We divided all cases into two groups, large decrease of %TRACP-5b at 12m group (L group: n=36) and small decrease of %TRACP-5b at 12m group (S group: n=37) with this cutoff value. %LS-BMD at 24m was 8.9% vs. 5.9% (p<0.01), %TH-BMD at 24m was 5.0% vs. 4.2% (n.s.), %P1NP at 24m was -59.6% vs. 0.6% and %TRACP-5b at 24m was -48.8% vs. 5.6% (L group vs. S group). At last, to evaluate the efficacy of combination of BIO and DMB, all cases were divided into two groups, BIO used group (B group: n=17) and no BIO used group (NB group: n=57). %LS-BMD at 24m was 9.7% vs. 7.0% (n.s.), %TH-BMD at 24m was 6.5% vs. 4.0% (p<0.01), %P1NP at 24m was -33.8% vs. -26.5% and %TRACP-5b at 24m was -26.7% vs. -18.7% (B group vs. NB group).

**Conclusion:** DMB was effective in OP of RA patients. Large decrease of %TRACP-5b at 12m was a predictor for large increase of %LS-BMD at 24m. Combination of BIO and DMB was a predictor for large increase of %TH-BMD at 24m. They might suggest that there are different mechanisms associated with increase of LS-BMD and TH-BMD in DMB treatment for OP of RA patients.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Bisphosphonates are recommended for patients with osteoporosis, however concerns have been raised with regards to their effect on kidney function. The aim of this study was to investigate the safety of bisphosphonates on renal function in patients with magnetic resonance imaging-proven acute osteoporotic vertebral fractures after vertebroplasty.

### **Methods:**

This retrospective study enrolled patients with osteoporosis and acute vertebral fractures who underwent vertebroplasty between January 2001 and December 2015. Their gender, age, body mass index, co-morbidities, and use of zoledronic acid were recorded. The patients with increased creatinine were defined as having worse renal function. Logistic regression was used to adjust for variables.

### **Results:**

Of the 224 included patients (184 females; mean age,  $72.91 \pm 9.26$  years), 82 took zoledronic acid and the others received other anti-osteoporotic agents. Fifty-four (65.9%) of the patients who took zoledronic acid had an increased creatinine level, compared to 92 (64.8%) of those who received other anti-osteoporotic agents ( $p=0.885$ ). After adjusting for confounding variables, zoledronic acid was not significantly associated with an increase in creatinine ( $p=0.815$ ; OR: 0.926; 95% CI: 0.487-1.761).

### **Conclusion:**

The use of zoledronic acid did not lead to an increase in creatinine compared to those who used did not use zoledronic acid. However, further studies are needed to confirm our findings.

**Table . Risk of zoledronic acid treatment increasing creatinine after adjustments for covariates**

	Regression coefficient	SE	P value	OR(95CI)

## **Osteoporosis and Vertebral Fractures Are Associated with Disease Activity, Low Vitamin D Levels and Spinal Radiographic Damage in Patients with Axial Spondyloarthritis**

Cintia Romera-López<sup>1</sup>, Cristina Fernández-Carballido<sup>2</sup>, Miguel Ángel García-Moreno<sup>3</sup> and Teresa Pedraz<sup>4</sup>, <sup>1</sup>Rheumatology, Hospital Universitario del Vinalopó, Elche, Spain, <sup>2</sup>Hospital General Universitario de Elda, Elda, Spain, <sup>3</sup>Hospital Universitario de Elda, Elda, Spain, <sup>4</sup>Hospital Universitario de Elda, Elda, Spain

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporosis and vertebral fractures are comorbidities of Axial Spondyloarthritis (axSpA). We evaluated the relationship between disease activity and radiographic damage and bone mineral density (BMD) and vertebral fractures (VF) in patients with axSpA.

**Methods:** Cross-sectional study of patients with axSpA (ASAS Criteria). Disease activity variables: Bath AS Disease Activity Index (BASDAI), ESR, CRP, ASAS-endorsed disease activity scores (ASDAS). Lumbar spine and hip BMD by dual x-ray absorptiometry (DXA) (187(91%) patients). VF assessed by a semiquantitative method (Genant) in lateral thoracic and lumbar spine X-rays. Risk of fracture was assessed with FRAX tool. Bivariate analysis performed to investigate the associations with the presence of osteoporosis and/or VF. Then, binary and multiple logistic regression models applied. SPSS (v23); p-values significant if < 0.05.

**Results:** We included 206 patients (62 female and 144 male). Mean values: age 51,7±14,1; BASDAI 3,6±2,2; ASDAS-CRP 2,2±0,95; ASDAS-ESR 2,5±0,99; BASFI 3,3±2,78; mSASSS 20,46±19,14; CRP 4,97±8,97mg/L; ESR 18,2±14,8 mm; 25OHvitD 19,83±9,25 ng/mL. Vitamin D deficiency detected in 85.7% of the patients. Low lumbar BMD was detected in 25,7% (z score) and 28,9% (t score) of the patients and low femoral neck BMD in 45,2% (z score) and 59,7% (t score). Lumbar osteoporosis was present in 3,2%/6.9% and hip osteoporosis in 9,1%/13,4% (applying z/t scores respectively). VF were detected in 34% of the patients. Bivariate analysis: ESR, ASDAS-ESR, age, male sex, low 25OHvitD and radiographic damage(mSASSS) were associated to low BMD. Multivariate models confirmed an association between disease activity (ASDAS-ESR) [OR 3.32 (IC 2.35–4.55) p=0.016] and 25OHvitD [OR 0.95 (IC95 0.86–0.98) p=0.029] and low hip BMD(z score). Differences between patients with and without fractures shown in table 1. Multivariate models confirmed the association between CRP [OR2.34 (IC95 1.10-4.98) p=0.027], radiographic damage [mSASSS lumbar OR 1.06 (IC95 1.03-1.10) p=0.001], high lumbar BMD [OR 296 (IC95 5.07-12258)p=0.006] and low hip BMD (femoral neck t score) [OR 0.11 (IC95 0.03-0.12)p=0.000] and VF.

**Conclusion:** In patients with axSpA, low BMD is associated with disease activity and low 25OHvitD. The presence of vertebral fractures is associated with CRP and low hip BMD (p=0.001). Radiographic damage “falsely” increases lumbar BMD results but is associated with the presence of fractures.

Table 1. Significant differences between patients without fractures versus patients with vertebral fractures

Variable	No fractures	Fractures	p value	t Student
CRP (mg/L)	5.10	9.51	p = 0.003	t = -3.503
ESR (mm/h)	15.87	23.12	p = 0.002	t = -3.302
25OHvitD (ng/mL)	20.80	18.043	p = 0.049	t = 1.979
mSASSS cervical	8.02	13.11	p = 0.002	t = -2.146
mSASSS lumbar	8.93	12.36	p = 0.000	t = -5.271
mSASSS total	17.66	27.13	p = 0.000	t = -3.873
BMD lumbar	1.090	1.191	p = 0.002	t = -3.068
BMD femoral neck	0.912	0.773	p = 0.000	t = 6.589

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporotic fractures are associated with high morbidity and mortality. Persons with rheumatoid arthritis (RA) have twice the risk of osteoporosis-related fracture than age-matched controls. It is not known, however, which characteristics of RA or its treatments have the greatest impact on bone mineral density (BMD). We investigated associations of RA characteristics, medication use, and body composition to low BMD in patients with RA.

**Methods:** We performed a cross-sectional analysis of an existing longitudinal RA cohort study from years 2007-2009. All patients met ACR classification criteria for RA. Demographic, clinical, laboratory and functional variables were collected at study visits. Body composition (fat, lean muscle and BMD) was measured by dual x-ray absorptiometry. We used linear regression to evaluate the association between predictors and femoral neck BMD. To identify independent predictors of BMD, we performed multivariable linear regression analyses that included variables significant in the univariable analyses at  $p < 0.10$ . To determine if there was a linear trend between anti-cyclic citrullinated peptide (CCP) level and BMD, we repeated the linear regression analysis restricted to anti-CCP positive participants.

**Results:** Of the 138 participants (82 women, 56 men), 70% were rheumatoid factor positive, and 55% were anti-CCP positive to a level 3 times the upper limit of normal. Mean disease duration was  $19 \pm 10.9$  years. 44% of participants reported taking prednisone and of those taking prednisone, the mean dose was  $7.1 \pm 6.1$  mg/day. The mean body mass index (BMI) was  $27.2 \pm 6.0$  kg/m<sup>2</sup>, and mean appendicular lean mass index (ALMI) was  $6.4 \pm 1.2$  kg/m<sup>2</sup>; 59% of the participants were obese based on percent total body fat. 52% had low BMD based on a T or Z score  $\leq -1$  and 27% reported taking osteoporosis medications. Age and anti-CCP positivity were negatively associated with BMD, even after controlling for other variables ( $\beta = -0.003$  and  $-0.055$ , respectively,  $p < 0.05$ ) (Table). ALMI had an independent positive association with BMD ( $\beta = 0.053$ ,  $p < 0.0001$ ). Among anti-CCP positive participants ( $n = 61$ ), higher anti-CCP level was associated with lower BMD ( $\beta$  for each 20-unit increase in anti-CCP =  $-0.011$ ,  $p = 0.026$ ) when controlling for age, sex, disease duration, ALMI and knee flexion strength.

**Conclusion:** Anti-CCP positivity, ALMI and age were independently associated with BMD in patients with RA. The linear relationship of anti-CCP levels with lower BMD supports the hypothesis that processes specific to RA negatively impact BMD. In contrast, ALMI was positively associated with BMD, emphasizing the role of muscle mass as a potentially modifiable risk factor. Our findings highlight the complicated interplay of RA disease-specific and functional factors and their impact on bone mass.

**Table 1.** Multivariable linear regression of the entire cohort on the outcome of femoral neck bone mineral density (g/cm<sup>3</sup>) (N=117,  $r^2 = 0.353$ ).

Variables	$\beta$	95% CI	p-value
Age	-0.003	-0.005 to -0.001	0.009
Male sex	0.014	-0.034 to 0.062	0.567
Anti-CCP Positive	-0.054	-0.097 to -0.010	0.016
Disease Duration (years)	-0.001	-0.003 to 0.001	0.305
Fat Mass Index	0.001	-0.005 to 0.007	0.723
Appendicular LMI	0.053	0.028 to 0.077	<0.0001

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The risk of osteoporotic (OP) fracture among patients with rheumatoid arthritis (RA) is higher than that of the general population. The worldwide incidence of OP fractures in high-risk individuals is expected to double over the next 40 years. It is unknown if improvements in the management of RA and OP has decreased the OP fracture risk in patients with RA. To address this knowledge gap, we compared the risk and incidence of OP fracture among patients with RA to the general population over two chronologic periods.

**Methods:** Using an electronic medical record database representative of the United Kingdom general population (The Health Improvement Network), we identified patients with incident RA and up to five individuals without RA matched for age, sex, and calendar year of diagnosis between 1999 and 2014. The RA cohort was divided in two sub-cohorts based on the year of RA diagnosis: the early cohort (1999-2006) and the late cohort (2007-2014). We identified incident OP fracture using physician diagnosis (READ) codes. Subjects with previously-diagnosed prevalent fractures were excluded from this analysis. We calculated the period-specific incidence rates of total OP fracture and hip fragility fracture for each cohort separately. We calculated the hazard ratio (HR) of incident fracture using a Cox proportional hazard model. In the multivariable model, we adjusted for age, body mass index, smoking status (non-smokers, ex-smokers, current smokers), alcohol use (non-drinkers, ex-drinkers, current drinkers), comorbidities, medication use, and the number of PCP visits.

**Results:** Both the early and late cohorts (N=54,291 and 59,915, respectively) had a similar mean age (60 and 59 years) and sex proportion (~70 and 69% female), and RA patients showed an increased risk of OP fracture compared with their corresponding comparison cohort (**Table**). In both cohorts, the incidence rate of total OP fracture slightly increased, and the corresponding relative risk (RR) was not significantly different between the two periods (corresponding multivariable HRs=1.23 [95% CI: 1.04 to 1.47] vs. 1.45 [95% CI: 1.26 to 1.68]; p for interaction = 0.21) (**Table**). Meanwhile, in both cohorts, the incidence rate of hip fragility fracture slightly declined and the corresponding RR was not significantly different between the two periods (corresponding multivariable HRs=1.68 [95% CI: 1.28 to 2.21] and 1.53 [95% CI: 1.16 to 2.03]; p for interaction = 0.24) (**Table**).

**Conclusion:** This general population-based cohort study indicates that RA patients still experience a higher risk of all OP and hip fragility fractures compared to non-RA patients, and that this difference has not improved over the past several decades despite advances in RA and OP therapy. This unclosing gap in increased fracture risk among RA patients calls for improved management of osteoporosis in RA.

Period	1999-2006		2007-2014		P for Interaction

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In 2011, we evaluated serum vitamin D levels in Japanese patients with rheumatoid arthritis (RA) and reported the prevalence of, and factors associated with, vitamin D deficiency [1]. Limited data exist in the literature concerning factors that predispose patients with RA to a worsening vitamin D deficiency. The aim of this study was to investigate predictive factors for a worsening vitamin D deficiency using our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort.

**Methods:** Established in the year 2000, the IORRA cohort is a single institute-based large cohort of Japanese RA patients. Over 120 publications have described various characteristics of Japanese patients with RA using this large cohort. In 2013, fresh serum from those patients who participated in our first vitamin D study in 2011 was evaluated for 25-hydroxyvitamin D [25(OH)D] levels via radioimmunoassay. A vitamin D deficiency was defined as serum 25(OH)D levels <20 ng/mL. To determine the predictive factors of a worsening vitamin D deficiency over a 2-year period, multivariate logistic regression analyses were used.

**Results:** Among the 2534 patients with RA who participated in our vitamin D studies in 2011 and 2013 (2179 women and 355 men; mean age 59.6 years), the mean ( $\pm$  standard deviation) serum 25(OH)D level was 18.0 ( $\pm$ 5.8) ng/mL, and the prevalence of vitamin D deficiency was 68.2% in 2013. Via multivariate analysis, younger age, female gender, and a high score for the Japanese version of the Health Assessment Questionnaire disability index (J-HAQ-DI) were significantly associated with vitamin D deficiency ( $P<0.05$ ). Serum vitamin D levels decreased by >5 ng/mL over the 2 years from 2011 to 2013 in 224 (8.8%) patients. For that subset of patients, a multivariate analysis revealed, younger age, female gender, bisphosphonate disuse, and higher baseline serum 25(OH)D levels were significantly associated with the decrease in vitamin D levels over the two years ( $P<0.05$ ) (Table).

**Conclusion:** In Japanese patients with RA, younger age, female gender, bisphosphonate disuse, and a high baseline serum 25(OH)D level appear to be associated with serum vitamin D levels that worsen over time.

Table: Factors associated with a further decrease in serum 25(OH)D levels in Japanese patients with RA from 2011 to 2013.

Variables	Odds ratio (95% CI)	<i>P</i>
Age	0.981 (0.964-0.999)	0.0338
Female gender	2.190 (1.100-4.360)	0.0254
Bisphosphonate use	0.431 (0.201-0.925)	0.0308
Baseline serum vitamin D levels	1.310 (1.27-1.35)	<0.0001

## **Change in Bone Mineral Density in Patients with Rheumatoid Arthritis: Minimal 10-Year Follow-up**

**Hiraku Motomura**, Isao Matsushita, Toshihito Hiraiwa and Tomoatsu Kimura, Department of Orthopaedic Surgery, Faculty of Medicine, University of Toyama, Toyama, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

To investigate the long-term change in bone mineral density (BMD) in patients with rheumatoid arthritis (RA).

### **Methods:**

In a longitudinal study of 40 patients with RA, we collected clinical data and measured hip BMD by dual-energy X-ray absorptiometry at baseline and after at least 10 years. BMD of the total hip was measured as the percentage of young adult mean (YAM). We compared clinical characteristics between patients with osteopenia (BMD < 80% of YAM) and those without (normal group; BMD ≥ 80% of YAM) at baseline. We also analyzed factors associated with a decrease in YAM of >5% during the follow-up period using multivariate logistic regression analysis.

### **Results:**

The mean patient age was 59.8 years, the mean disease duration was 11.5 years, and the mean follow-up period was 10.4 years. Most of the patients (90%) were women. At baseline, 22 patients (55%) were being treated with methotrexate (MTX, mean dose 5.4 mg/week), 26 patients (65%) with prednisolone (PSL, mean dose 6.7 mg/day), and one patient (2.5%) with a biologic disease-modifying antirheumatic drug (DMARD). The antiresorptive drug intervention rate at baseline was 20%. The mean serum C-reactive protein (CRP) and matrix metalloproteinase-3 (MMP-3) values at baseline were 2.21 mg/dL and 258.6 ng/mL, respectively. At follow-up, the mean dose of MTX had increased to 7.0 mg/week and the mean PSL dose had decreased to 2.9 mg/day. The antiresorptive drug intervention rate had increased to 77.5%, and treatment with biologic DMARDs had also increased to 55%. The mean CRP and MMP-3 values had decreased to 0.33 mg/dL and 105.4 ng/mL, respectively. Total hip BMD had decreased from 80.0% YAM at baseline to 76.8% YAM at follow-up. At baseline, 19 patients (47.5%) were classified as osteopenia (BMD < 80% of YAM). The total hip BMD in this group increased slightly from 67.2% YAM at baseline to 69.7% YAM at follow-up. By contrast, the normal group showed a significant decrease in BMD from 91.6% YAM at baseline to 83.1% YAM at follow-up. At both baseline and follow-up, the antiresorptive drug intervention rate was significantly higher in the osteopenia group than in the normal group. No significant differences were found in age, disease activity, use of MTX, PSL, or biological DMARDs between the osteopenia and normal groups. Multivariate logistic regression analysis was used to determine individual factors associated with a reduction in BMD (>5% decrease of YAM). Current use of antiresorptive drugs was strongly associated with a decreased risk for total hip bone loss (odds ratio: 0.04, 95% confidence intervals: 0.003–0.436, P = 0.009).

### **Conclusion:**

Our findings suggest that osteoporosis treatment and tight control of RA disease activity are important for maintaining total hip BMD over a 10-year period. Even RA patients without osteopenia should be started on osteoporosis treatment to inhibit the progression of bone loss.

## **Case Series: Comparison of Repository Corticotropin Injection (H.P. Acthar Gel) Versus Glucocorticoids on Bone Density in SLE Patients**

**Anny T. Wu**<sup>1</sup> and Joshua June<sup>2</sup>, <sup>1</sup>Rheumatology, Franciscan Alliance, Munster, IN, <sup>2</sup>3394 E Jolly Rd Ste C, Great Lakes Center of Rheumatology, Lansing, MI

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Repository Corticotropin Injection (RCI) is an adrenocorticotropin hormone in 16% gelatin with a prolonged release after intramuscular (IM) or subcutaneous injection. Adverse effects of RCI are primarily related to its steroidogenic effects including decrease in BMD. However, there is recent renewed interest in RCI's role as an alternative to high dose glucocorticoids and as last resort therapy for SLE.

**Methods:** This retrospective case series looks at the bone density changes of 5 adult female patients with mean age of 59 years on RCI vs. glucocorticoids at a Rheumatology practice. A list of 73 patients on RCI was populated using the EMR. Chart review was performed and patients were selected with the following criteria: on RCI for at least 6 months, history of SLE, verifiable DXA scan results from before and after starting RCI. Patients were then excluded if they had been on bone sparing agents during this time interval. The bone with the lowest density on the DXA report post-RCI is selected for comparison to the pre-RCI BMD. The lowest significant change of each BMD value is operator dependent and is within 95% confidence interval based on the certified technologist's past DXAs. The same technologist performed all of the above DXAs. An example is as follows: for this particular technologist, her range of lowest significant change (at 95% confidence interval) in measurement of the femoral neck is plus or minus 0.010 gm/cm<sup>2</sup>. If the difference in BMD of the femoral neck falls outside of this range on a latter DXA, then there is indeed a significant change.

**Results:** Two of the 5 patients had nonsignificant changes to their BMD before and after starting RCI. Two patients had a decrease in BMD that were significant but were noted to have been on higher doses of Prednisone (10mg and/or 20mg a day) and received more IM glucocorticoid injections. One patient had an increased BMD, although for her, RCI was started just 3 months prior to her latter DXA. Her third DXA scan 2 years later did show a significant decrease in BMD but she, too, had received more glucocorticoid IM injections.

**Conclusion:** These cases illustrate the possibility that RCI by itself does not contribute to significant BMD decrease. Rather, significant decrease in BMD is seen in those patients who have concurrently received more oral, IM or intra-articular glucocorticoids while on RCI. Although RCI may be understood to have similar side effects as glucocorticoids, we see a possible difference in side effects such as BMD decrease as compared to glucocorticoids.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous evidence indicates an association between vitamin D deficiency and autoimmune diseases. The aim of this study was to evaluate serum 25-hydroxyvitamin D (25OHD), acute phase reactants and disease activity in patients with rheumatologic diseases (RD).

**Methods:** This retrospective study evaluated 173 patients with RD (94 rheumatoid arthritis (RA), 18 spondyloarthropathies (SA), 61 collagenopathies (COL) (systemic lupus erythematosus, vasculitis, scleroderma, undifferentiated disease, superposition syndrome) and compared them with a control group (CG, n=121) matched by age (CG= 55.0±14.7 years; RD= 53.4±13.6, sex and body mass index (BMI). All patients were from Rosario (32°52'18''S) and Buenos Aires (34°36'14''S) cities. Exclusion criteria: supplementation with vitamin D, pregnancy, intestinal malabsorption, chronic liver or kidney disease, and cancer. Data are expressed as mean±SEM. Differences between groups were analyzed using the Mann-Whitney or Kruskal-Wallis tests. Correlations were performed with Spearman's correlation test. Univariate linear regression and logistic regression analysis were performed. Contingency tables were evaluated with  $\chi^2$  test. The difference was considered significant if  $p<0.05$ .

**Results:** RD patients had significant lower 25OHD levels as a control group (CG= 26.8±1.1 ng/ml; RD= 19.8±0.6 ng/ml;  $p<0.0001$ ). Furthermore, all subgroups had lower 25OHD (RA=20.7±0.7 ng/ml, SA= 15.4±1.3 ng/ml, COL= 19.7±1.1 ng/ml). The OR of patients with RD being vitamin D deficient (25OHD <20 ng/ml) was 2.7 (95%CI 1.6 to 4.4) with a probability of 73%. Consistent with 25OHD differences, significant lower serum calcium (CG= 9.33±0.04; RD= 9.14±0.08 mg/dl) and higher PTH (CG= 39.72±2.37; RD= 49.93±3.34 pg/ml) levels were found. No differences in serum phosphate, urinary calcium and urinary deoxypyridinoline were observed. 25OHD significantly correlated with erythrocyte sedimentation rate (ERS) [ $r= -0.28$ ;  $p=0.0017$ ] as acute phase reactants. No differences was found in reactive C-protein (RCP). Lower values of 25OHD were found at higher DAS-28 (<3.2= 22.9 ng/ml; 3.2-5.1= 19.8 ng/ml; >5.1= 19.9 ng/ml;  $p=0.23$ ) and HAQ-DI (0-1= 22.9 ng/ml; 2= 19.8 ng/ml; 3= 19.9 ng/ml;  $p=0.001$ ). Activity scores in other RD couldn't be analyzed because of the small number of patients. Age, BMI, presence of RD, RCP and HAQ-DI were significantly and inversely associated with 25OHD levels. BMI, presence of RD, ERS and RCP were significantly associated with vitamin D deficiency.

**Conclusion:** Patients with RD have a high probability of being deficient in 25OHD. Low 25OHD levels are associated with high acute phase reactants in the whole group, and with high disease activity scores in RA patients.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Atypical femoral fractures (AFF) are low energy femoral fractures with a specific radiographic pattern and subtrochanteric / diaphyseal localization that have been related to long-term bisphosphonate therapy. Glucocorticoid and rheumatic diseases, mainly rheumatoid arthritis has also been implicated in this comorbidity. Therefore, the aim of this study was to evaluate a cohort of patients with AFF from a Tertiary Rheumatology Center, including clinical presentation, radiographic data and findings of bone histomorphometry.

**Methods:** From January 2007 to May 2017, all patients from the Outpatient Clinic (Osteometabolic Disease) of a Tertiary Rheumatology Service, Clinics Hospital- School of Medicine who fulfilled the American Society of Bone Mineral Research (ASBMR, 2010) criteria for atypical fracture were included in this study. Clinical-epidemiological data were obtained from electronic chart review. Anteroposterior radiographs of bilateral hip were analyzed, according to ASBMR. Confirmation of bilateral AFF was performed by magnetic resonance imaging or scintigraphy. Serum markers of bone remodeling, C-terminal telopeptide of type 1 collagen (CTX) and alkaline phosphatase (AP) were also evaluated. Iliac crest bone biopsy and static and dynamic bone parameters (compared to reference values of healthy controls matched by sex and age) were performed by histomorphometric analysis (Osteomeasure® software).

**Results:** Eighteen patients presented AFF, mostly women (94.4%), Caucasian (72.2%), mean age of  $64.9 \pm 13.3$  years and all had prodromal pain in the anterolateral region of the thigh before the clinical fracture. Seventeen used bisphosphonate ( $5.83 \pm 2.74$  years), mostly alendronate (83.3%) at the time of fracture. One patient was taking denosumab, but had previously received bisphosphonate for 6 years. Presence of any inflammatory rheumatic disease was observed in 9 (50%) patients: rheumatoid arthritis (n=4), systemic lupus erythematosus (n=1), Sjögren's syndrome (n=1), Behçet's disease (n=1), inclusion body myositis (n=1) and adult-onset Still's disease (n=1). Eight patients (44.4%) were using oral glucocorticoid at a median dose of 5 mg/day (ranged 5-15mg/day). All fractures presented diaphyseal localization, 16 (88.8%) were complete fracture and 4 (22.2%) bilateral. Bone markers were in the normal range (CTX:  $0.28 \pm 0.18$  ng/mL and AP:  $76.11 \pm 30.22$  U/L). Bone biopsy performed in 6 patients revealed suppression of bone turnover (100%), with reduction of osteoid tissue, as well as decreasing of resorption, osteoclastic and osteoblastic surfaces and impairment of bone mineralization. Sixteen patients underwent surgical treatment and 2 only clinical treatment (teriparatide). In total, 14 patients received teriparatide, 1 strontium ranelate and 3 remained without medication.

**Conclusion:** Our study alerts the rheumatologist about the possibility of AFF in those patients with bisphosphonate above 5 years, mainly with inflammatory rheumatic diseases and glucocorticoid use. Bone biopsy revealed a bone turnover suppression. Attention should be aware of the prodromal thigh or groin pain and subclinical imaging changes in the lateral femur, both associated with AFF.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** ARHP Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Denosumab (Dmab) is an antiresorptive agent with an approximate half-life of 26 days and according to the prescribing information the recommended dose is 60 mg subcutaneous every 6 months. Although in real world clinical practice, strict adherence to this dosing regimen is frequently hampered due to delays in prior authorizations, follow up appointment scheduling and missed visits. We hypothesized that patients who did not adhere to the standard dosing regimen would have impaired efficacy of Dmab. The objective of this study is to determine whether there is difference in bone mineral density (BMD) after 2 years of therapy in patients who received Dmab at recommended 6 month intervals as compared with patients who did not.

**Methods:** All patients between 2009 and 2015 with a primary diagnosis of post-menopausal osteoporosis that had received 4 doses of Dmab in 2 consecutive years were identified from the electronic data base. Furthermore patients were required to have a baseline DXA within 2 years prior to Dmab initiation and a follow up DXA within 2-3 years thereafter done on the same GE Lunar machine (least significant change for hip 0.036 g/cm<sup>2</sup>). Patient records were reviewed to obtain information on demographics, weight, smoking history, baseline vitamin D level, Dmab administration and DXA results. Change in BMD at lowest T-score of hip or femoral neck for each patient was used as the outcome measure. Adherence to therapy was defined as receiving subsequent injections at 6 month  $\pm$  4 week intervals. Patients were divided into 3 groups with Group 1 being adherent with all injections. Patients in Group 2 were adherent with 2 of 3 subsequent injections whereas Group 3 patients received subsequent injections at 8-12 month intervals and were considered to be non-adherent. Descriptive analysis included continuous variables (means  $\pm$  SD) and categorical variables (%). Data were compared by using ANOVA.

**Results:** 50 patients, all females, with mean age of 75 yrs ( $\pm$  9.4), 74% were Caucasian, 12% African American, 6% Hispanic and 8% were of other ethnicities. 60% smokers and 56% had history of fragility fractures. Mean Vitamin D level was 39.3 ng/ml ( $\pm$  21.5). The mean lowest BMD at the hip or femoral neck at baseline and follow up were 0.705 g/cm<sup>2</sup> ( $\pm$  0.130) and 0.726 g/cm<sup>2</sup> ( $\pm$  0.130), respectively. 14% of patients were adherent with all 3 injections whereas 40% were categorized as Group 2. 46% were non adherent. The mean change in BMD stratified by groups was 0.035 g/cm<sup>2</sup> ( $\pm$  0.061) for Group 1, 0.006 g/cm<sup>2</sup> ( $\pm$  0.035) for Group 2 and 0.031 g/cm<sup>2</sup> ( $\pm$  0.057) for Group 3. There was no significant difference in mean lowest BMD change at the hip or femoral neck between the 3 groups through ANOVA analysis ( $p=0.2073$ ).

**Conclusion:** Despite low adherence to the standard dosing regimen for Dmab there was no significant difference in change of BMD in patients who were not adherent to the current prescribing information.

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The target of treatment in psoriatic arthritis (PsA) should be remission or inactive disease. A potential definition that would fit with the Treat-to-Target Recommendations would be minimal disease activity (MDA) meeting all 7 criteria<sup>1</sup>, proposed as a definition of very low disease activity (VLDA) in PsA. Patient reported outcomes (PROs), such as those provided by the novel PsAID questionnaire<sup>2</sup>, are also important to evaluate healthcare interventions and to reflect the impact of PsA on patients' lives. The aims of this study were to evaluate the prevalence of VLDA in patients with PsA and how much residual active disease is still present, so as to determine whether PsAID could be an additional useful tool to assess PsA interventions in clinical practice.

### **Methods:**

This was a sub-analysis of the MAAPs study<sup>3</sup>. Patients were considered in VLDA when they met all the MDA criteria: tender joint count  $\leq 1$ , swollen joint count  $\leq 1$ , Psoriasis Area Severity index (PASI) score  $\leq 1$  or body surface area  $\leq 3\%$ , patient pain visual analog scale (VAS) score  $\leq 15$ , patient global disease activity VAS score  $\leq 20$ , Health Assessment Questionnaire (HAQ) score  $\leq 0.5$ , and tender entheseal points  $\leq 1$ . Patient acceptable symptoms state (PASS) is considered a PsAID value  $< 4$ . Comparisons of qualitative variables have been made with the chi-square test or Fisher's exact test. Comparisons of quantitative variables were made with the Student's T test or with non-parametric tests if necessary.

**Results:** 227 patients from 25 Spanish rheumatology departments were included, and among them, 26 (11.5%) were in VLDA. The majority (96.2%) of VLDA patients had a PASS situation while 49.2% of non VLDA patients had a PASS,  $p < 0.001$ .

BASDAI	3.0 (2.3)	0.6 (0.6)	<0.001
Pain VAS (0-10)	3.4 (2.7)	0.6 (1.2)	<0.001
Pt. disease activity	3.5 (2.5)	0.5 (0.6)	<0.001

CHD: coronary heart disease. ETA: etanercept. ADA: adalimumab. PsAID: psoriatic arthritis impact of disease. Pt: patient. Values are expressed as percentages and mean (SD).

#### Conclusion:

11.5% of Spanish PsA patients achieved VLDA state in routine clinical practice. PsA patients who reached this state also had a minimal impact of disease according to PsAID. VLDA state could represent a situation of clinical remission in PsA.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many patients with RA do not achieve guideline-recommended treat-to-target (T2T) goals in clinical practice. There is a paucity of data regarding the challenges that patients face when attempting to achieve better control of their RA disease activity. In this study we sought to identify and prioritize patient-perceived barriers to achieving RA disease activity control.

**Methods:** Participants were recruited from the within the Consortium of Rheumatology Researchers of North America (Corrona) registry by email and invited to participate in 4 nominal groups. Each group generated a list of barriers that made it challenging for patients to control their RA disease activity. All generated items were combined in a single dataset and subjected to a card sort procedure to create common themes. A random sample of patients with RA enrolled in Corrona were invited by email to complete a compensated online survey and asked to rank their top 3 barriers. A weighted score was assigned for each barrier by considering the number of respondents who ranked it and the priority rank they assigned. The barriers were sorted into domains. The survey also included knowledge items about T2T strategy and attitudes about RA treatment.

**Results:** Four nominal groups with 37 RA patients identified 17 themes to achieving control of RA activity. We sent 1567 email invitations to complete the survey and 463 patients with RA responded within 3 weeks. Demographic and clinical data was available for 1331 persons, 383 of whom responded to the survey. There were no differences in age, sex, or disease duration between survey-respondents and non-respondents. A higher proportion of respondents were college-educated. A total of 289 (76%) respondents considered RA to be a high priority for their health, 193 (51%) reported being familiar with T2T as a treatment strategy, and 233 (75%) agreed that it is important to accept the risk of side effects now in order to improve the chance of being healthy in the future. Among the challenges to controlling RA disease activity, the domain that received the highest score was unpredictability of RA and its treatment, which comprised the following barriers: unpredictability of how RA may progress, medication risk aversion, effectiveness, and safety/tolerability concerns (Figure). Symptoms and illness burden domain received the second highest score, followed by the health system domain (Figure).

**Conclusion:** Important patient-perceived barriers to achieving RA disease control include unpredictability of how RA may progress, medication risk aversion, cost of RA care and RA physical limitations. Addressing these barriers, when possible, may improve goal-directed RA care.

## Patient-Reported Flares Were Correctly Predicted By an Algorithm Using Machine-Learning Statistics on Activity Tracker Data on Steps, in a Longitudinal 3-Month Study of 170 Patients with Rheumatoid Arthritis (RA) or Axial Spondyloarthritis (axSpA)

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The natural history of RA and axSpA comprises periods of low disease activity and flares. However, there are few data linking patient-reported flares to quantifiable outcomes. We previously indicated in the ActConnect study that flares were related to a moderate decrease in physical activity (1). Objective: to predict patient-reported flares based on activity-tracker-provided continuous flows of steps per minute.

**Methods:** This prospective multi-center observational study (ActConnect) included patients with definite RA (ACR/EULAR criteria) or axSpA (ASAS criteria), owning a smartphone. Over 3 months, physical activity was sampled continuously (each minute) using an activity tracker, and flares were self-assessed weekly using a specific flare question. In this reanalysis of the dataset, Machine Learning

statistical methods were used. Physical activity data were first normalized at patient level using each patient's mean and standard deviation of steps for a similar timeframe without flares. Then the data were analysed by multiclass Bayesian methods with a Machine Learning software belonging to Orange (2). The software was instructed to find the best predictive model of patient-reported flares. Sensitivities and specificities were calculated. Several sensitivity analyses were performed using different physical activity timeframes, different definitions of flares.

**Results:** In all, 170/178 patients (91 RA and 79 axSpA patients; 1228 weekly flare assessments and 24,972 1-hour physical activity assessment timeframes) were analyzed: mean age 45.5±12.4 years, mean disease duration 10.3±8.7 years; 60 (35.3%) were males and 90 (52.9%) received biologics. Disease was well-controlled (mean DAS28: 2.3±1.2; mean BASDAI: 3.3±2.1) but flares were frequent: reported in 24% of all the questionnaires. The Khiops generated model detected correctly both flares and absence of flare (Table) with a sensitivity of 96% and a specificity of 97%. The corresponding positive and negative predictive values were respectively 89% and 99%. Sensitivity analyses were confirmatory.

**Conclusion:** Machine Learning methods are useful to deal with repeated data in big datasets. The results confirm objectively the functional impact of patient-reported flares. Furthermore, the correct detection of flares by the activity tracker and adapted statistics opens the way for future studies of flares using connected devices with great precision and minimal patient burden.

1 - Jacquemin C et al. Physical activity decreased significantly but moderately during weeks where patients reported flares: A 3-month study of 170 rheumatoid arthritis (RA) or axial spondyloarthritis (AXSPA) patients wearing an activity tracker, Ann Rheum Dis 2017 (suppl): EULAR congress, poster FRI0700.

## Measurement Properties of Paindetect, a Neuropathic Pain Screening Tool, for Evaluating Pain Phenotype in Patients with Rheumatoid Arthritis: Developing Neuropathic Pain Scale As a Measure of Treatment Outcome By Applying Rasch Analysis

Yong Gil Hwang<sup>1</sup>, Lei Zhu<sup>2</sup>, Ajay Wasan<sup>3</sup> and Larry W. Moreland<sup>1</sup>, <sup>1</sup>Rheumatology & Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Departments of Anesthesiology and Psychiatry, University of Pittsburgh, Pittsburgh, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ongoing pain state in rheumatoid arthritis (RA) often persists after the resolution of inflammation, indicating the transition between the acute inflammatory pain and post-inflammatory persistent pain phenotypes. PainDETECT (PDQ) was developed as a self-reported neuropathic pain screening tool. We conducted a Rasch analysis to investigate whether measurement properties of PDQ can be used as an outcome measure.

**Methods:** For RA subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER), Rasch analysis was conducted for all RACER patients who completed PDQ and PROMIS29 short form. Unidimensionality, reliability, item difficulty, category functioning, and differential item function were examined using the partial credit model for polytomous items (WINSTEPS ver. 3.93.2). Differential item function (DIF) analyses for gender and age groups (<60,60-70,>70) were performed to examine item invariance for different groups.

**Results:** For the 302 subjects analyzed, age was 63.8  $\pm$  12.4 (mean  $\pm$  SD) years with disease duration of 18.4  $\pm$  11.9 years. Given misfit and high fit residuals, time course and radiating pain items were removed. Remaining 7-item PDQ fit the Rasch model (Table 1). Item residuals showed high correlation between the burning and slight pressure items and these items were treated as a testlet. Cold-or-heat item exhibited marginally disordered threshold but the rescoring did not substantially affect fit (Table 2). DIF analyses for gender and age groups showed uniform DIF. Person-item distribution showed that PDQ was reasonably targeted (Figure).

**Conclusion:** Rasch analysis of 7-item PDQ suggests that PDQ may function as an outcome measure and may provide a useful tool to predict RA treatment outcome for neuropathic pain.

Table 1. Summary statistics for all analyses (\*Log-likelihood chi-squared: The chi-square value is approximately = -2 \* log-likelihood of the active data points, \*\*probability: the probability that these data fit the Rasch model globally, df: degree of freedom, SE: Standard Error, RMSR: Root-Mean-Square Residual, MNSQ: Mean Square)

## Patients’ Attitudes and Experiences of Transitional Care in Paediatric Rheumatology: A Systematic Review of Qualitative Studies

Ayano Kelly<sup>1,2,3,4</sup>, Fiona Niddrie<sup>5</sup>, David Tunnicliffe<sup>4,6</sup>, Camilla Hanson<sup>4,7</sup>, Gabor Major<sup>8,9</sup>, Davinder Singh-Grewal<sup>10,11,12</sup> and Allison Tong<sup>4</sup>, <sup>1</sup>Rheumatology, The Canberra Hospital, Canberra, Australia, <sup>2</sup>School of Medicine, Australian National University, Canberra, Australia, <sup>3</sup>Canberra Rheumatology, Canberra, Australia, <sup>4</sup>Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, Australia, <sup>5</sup>Rheumatology, Bone and Joint Institute, John Hunter Hospital, Newcastle, Australia, <sup>6</sup>Sydney School of Public Health, University of Sydney, Sydney, Australia, <sup>7</sup>Sydney School of Pubic Health, University of Sydney, Sydney, Australia, <sup>8</sup>Medicine, University of Newcastle, Newcastle, Australia, <sup>9</sup>Rheumatology, Bone and Joint Institute, John Hunter Hospital NSW Australia, Newcastle, Australia, <sup>10</sup>Faculty of Medicine, University of New South Wales, Sydney, Australia, <sup>11</sup>Department of Rheumatology, The Sydney Children's Hospital Network, Sydney, Australia, <sup>12</sup>Sydney Medical School, University of Sydney, Sydney, Australia

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite the increasing number of transition programs available for rheumatology patients moving from paediatric to adult care, transition continues to pose challenges for patients and leads to poorer health outcomes. We aimed to describe patients' attitudes and experiences of transitional care in paediatric rheumatology to capture a deeper understanding of patients' perspectives and inform the development of patient-centred transitional care programs.

**Methods:** MEDLINE, Embase, PsycINFO, CINAHL, dissertation databases and reference lists were searched to February 2017 and thematic synthesis was used to analyse the findings.

**Results:** We included 18 studies involving 267 patients with paediatric rheumatic conditions (juvenile idiopathic arthritis [n=162], systemic lupus erythematosus [n=79], mixed connective tissue disease [n=5]). We identified six themes (with subthemes): a sense of belonging (familial care and community, yearning for friends with shared experiences, comfort and reassurance in age appropriate care, communication to gain understanding and acceptance); trust in familiarity (emotionally preparing for a new environment, building connection with continuity, valuing privacy, a supportive point of contact); abandonment and fear of the unknown (abrupt and forced independence, ill-equipped to transfer medical information, shocking view of future self); depersonalised and discredited (like an object on a conveyer belt, unmet needs and disjointed priorities, sterile and uninviting environment, sudden loss of validation); quest for autonomy (refreshingly liberated, ready to leave the nest, freedom to disclose); and needing control of parental involvement (unintentionally undermined, the guilt of independence, reluctant solitude).

**Conclusion:** There are limited qualitative studies on transitional care in paediatric rheumatology which focus largely on patients with juvenile idiopathic arthritis. Available qualitative studies show that successful transition can be nurtured by building trust in familiarity, creating a sense of belonging and facilitating an adolescent's quest for autonomy. However, some patients feel de-personalised, abandoned, ill prepared and out of control of the transition process. The findings of this review highlight important elements to include into transitional care programs and the need for further research into patients' needs in transitional care.

## Accessing Positive (but Not Negative) Online Reviews Is Associated with Increased Willingness to Take Medication

Changchuan Jiang<sup>1</sup>, Ellen Peters<sup>2</sup> and Liana Fraenkel<sup>3</sup>, <sup>1</sup>Yale University, New Haven, CT, <sup>2</sup>Decision Research, Eugene, OR, <sup>3</sup>Rheumatology, Rheumatology, Yale University School of Medicine, New Haven, CT, New Haven, CT

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Testimonials have been shown to have a strong influence on patient decision-making. Patients are increasingly accessing the Internet as a source of medical information. In this study, we sought to examine whether the number of positive or negative reviews accessed influence willingness to take a medication.

**Methods:** We administered a survey to Mechanical Turk workers ( $\geq 50$  years old) who were not currently taking any medications for osteoporosis or osteopenia. Participants' received information describing outcomes using one of three randomly distributed formats: icon array, icon array followed by narrative reviews, or narrative reviews followed by icon arrays. Subjects in the latter two groups were

included for these analyses. The outcomes in the reviews were purposely composed to match the actual distribution of outcomes associated with a commonly used osteoporosis treatment. Each review was rated by actual patients on a 5-point scale (illustrated by stars). Willingness to take medication was measured on a 10-point scale before and after reading the description of the medication and reviews (in the two groups including testimonials). Reviews could be read by clicking on links. We examined whether ratings and number of online testimonials accessed influenced change in willingness to take the medication using linear mixed models adjusting for baseline willingness, age, sex, race, education, numeracy, osteoporosis/osteopenia and previous history of osteoporosis/fracture. Reviews rated above ‘3’ were defined as positive; the rest were defined negative. The influence of positive and negative reviews was examined in separate models due to their strong collinearity.

**Results:** 276 participants were randomized to one of the two groups including testimonials. The mean (SD) age was 59 (7), and the majority were female (61%), white (73%) and college graduates (67%). We found significantly positive associations between the number of accessed positive testimonials and willingness to take the medication ( $p=0.015$ ). However, no significant association was found between the number of accessed negative testimonials and willingness. Education level and numeracy did not modify the association between reviews accessed and willingness to take the medication (data not shown).

**Conclusion:** In this study, we found that willingness to take a medication for osteoporosis was positively associated with the number of positive online testimonials accessed. These results support the need to examine the impact of evidenced-based narratives as decision support tools.

**Table. Association between Positive (Model 1) and Negative (Model2) reviews with willingness to take a medication for osteoporosis.**

	Model1		Model2	
	$\beta$ coefficient	p-value	$\beta$ coefficient	p-value

## Understanding Perceptions and Experience of Gout through Linguistic Analysis of Online Search Activities

Kayla Jordan<sup>1</sup>, James Pennebaker<sup>1</sup>, Keith Petrie<sup>2</sup> and Nicola Dalbeth<sup>2</sup>, <sup>1</sup>University of Texas at Austin, Austin, TX, <sup>2</sup>University of Auckland, Auckland, New Zealand

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Online search engines are widely used to seek information about disease and management strategies. The aim of this study was to understand what terms people seeking information about gout use most frequently in their online searches and to explore the psychological and emotional tone of these searches using a linguistic analysis of their search histories.

**Methods:** In cooperation with Microsoft Research, a large de-identified dataset of search histories from 200,000 consenting individuals was obtained from ComScore, a web analytics company, covering a two year period (2011 to 2013). Time-stamped search terms were logged from all major search engines (e.g., Google, Bing). From the larger dataset, three groups were identified: participants who searched for gout at least once (n = 1,388), participants who had searched for arthritis (arthritis control group, n = 2,289, matched to the gout group on age and sex), and a random set of participants matched on age and sex (general control group, n = 2,150). Meaning Extraction Helper (Boyd, 2016), a word frequency software, was used to calculate search term frequencies from the search history of each participant. Group membership was correlated with individual word frequencies. Search terms were further analyzed using Linguistic Inquiry and Word Count (LIWC; Pennebaker, Boyd, Jordan, & Blackburn, 2015), a text analysis software from which psychological processes can be inferred from the words people use.

**Results:** The most frequent unique searches in the gout group included gout-related and food-related terms (including uric, kidney, meats, purine, and atkins). Those who searched for gout were more likely to search for words related to eating or avoidance. In contrast, those who searched for arthritis were more likely to search for disease or health-related words. In the LIWC analysis, compared with the general control group, total word count was higher for the gout and arthritis groups, indicating higher information seeking by both groups. Both the gout and arthritis groups searched more for health (e.g., clinic, flu, pill) and ingest (e.g., dish, eat, pizza) words, and fewer social (e.g. family, talk, they), leisure (e.g., cook, chat, movie), and sexual (e.g. love, sex) words. Compared with the general control group, the searches of both the gout and arthritis groups were lower in positive emotion tone and higher in sadness words. There were very few differences between the gout and arthritis groups in the LIWC analysis, with the exception of higher use of health words by the arthritis group and higher use of insight words (e.g., know, learn, and means) by the gout group.

**Conclusion:** People searching about gout or arthritis have high levels of information seeking. The perception of gout as a condition managed by dietary strategies aligns with online information-seeking about the disease and its management. In contrast, people searching about arthritis are more focused on searching about medical strategies. Linguistic analysis reflects greater disability in social and leisure activities and lower positive emotion for those searching for medical conditions such as gout or arthritis.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

It is well established that RA patients have lower health related quality of life (HRQoL) across several domains compared with the general population, whereas less is known about PsA patients.

The aim of this study was to compare the Medical Outcomes Survey Short Form-36 (SF-36) Physical and Mental Component Summaries (PCS, MCS) as well as domain scores between RA and PsA patients from a large prospective observational registry.

## Methods:

We included first-time enrolled RA and PsA patients from the prospective observational multicenter NORwegian-Disease Modifying Anti-Rheumatic Drug (NOR-DMARD) study, starting synthetic and biologic DMARDs between year 2000 and 2012. Continuous variables were compared using independent t-test or Mann-Whitney U-test, as appropriate. Prespecified ANCOVA analyses adjusted for age, gender and disease duration were performed to compare the SF-36 domains between RA and PsA patients at baseline and after 3 months follow-up. Spider diagram was made to visualize the differences in health domains (0 worst, 100 best) between the RA and PsA patients.

## Results:

A total of 3903 RA and 1518 PsA patients were included (mean (SD) age 56.8 (31.6)/ 47.9 (12.6) years, median (25th-75th percentile) disease duration 1.9 (0.07-11.0)/ 2.0 (0.12-9.6) years, 71.2%/ 50.2% women). Mean (SD) 28-joint Disease Activity Score was higher in RA vs. PsA patients at baseline (4.9 (1.4)/ 4.2 (1.3)) and at 3 months (3.8 (1.5)/ (3.3 (1.4)) follow-up ( $p \leq 0.001$ ). Unadjusted means and adjusted estimated marginal means of PCS, MCS and domain scores all improved during follow-up (table, figure). In adjusted analyses PCS and MCS were similar between the RA and PsA patients. However, RA patients had slightly worse physical function and role emotional domains and PsA patients had slightly worse general health and vitality domains both at baseline and at 3 months. Bodily pain was similar between RA and PsA patients at baseline, but slightly worse in the PsA patients at 3 months follow-up.

## Conclusion:

Levels of HRQoL were comparable across all SF-36 domains and component summary scores between patients with RA and PsA, in spite of higher levels of joint inflammation in the RA patients.

**Table** Unadjusted and adjusted analyses of SF-36 component summary and domain scores

	Summary score/ domain	Unadjusted analyses, mean (SD)		p-value <sup>1</sup>	Estimated marginal means (95%CI)		p-value <sup>2</sup>
		RA	PsA		RA	PsA	
Baseline	Physical Component Summary	31.0 (9.9)	31.8 (9.5)	0.01	31.7 (31.3-32.0)	31.6 (31.1-32.1)	0.88

## What Is the Impact of Functional Medicine on Patient Reported Outcomes in Inflammatory Arthritis?

Nicole Droz<sup>1</sup>, William Messner<sup>2</sup> and M. Elaine Husni<sup>3</sup>, <sup>1</sup>Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, <sup>2</sup>Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, <sup>3</sup>Rheumatology, Cleveland Clinic, Cleveland, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Both RA and PsA patients carry significant morbidity despite advances in treatment. Patients often do not achieve clinical remission which can be limited by patient's global assessment of disease (PtGA). Currently utilized disease activity and functional status assessments do not address all treatment outcomes that are important to patients (such as fatigue, psychological distress and quality of life). These outcomes drive PtGA and represent important areas of focus to achieve remission in RA and PsA patients. The Patient Reported Outcome Measurement Information System (PROMIS®) developed by the National Institute of Health, is a set of patient centric measures evaluating physical, mental and social health and is a precise and reliable way to measure domains critical to PtGA.

Functional medicine utilizes a patient-centered approach, addressing sleep, exercise, nutrition, stress and other lifestyle factors. The desire for this approach has led more patients to turn to functional medicine for adjunctive care.

**Methods:** In this 12 week retrospective study, RA and PsA patients were identified by ICD 10 code. They were included if they were diagnosed by a board certified rheumatologist and participated in a 12 week functional medicine program adjunctive to their usual care. PROMIS global physical and mental health and pain scores were collected at baseline and after 12 weeks of enrollment and compared to patients with similar baseline characteristics who received usual care alone. Changes in PROMIS T score domains in global physical, global mental health and pain were compared between treatment groups using two-sample *t*-tests.

**Results:** 38 patients were identified for inclusion. Both functional medicine + usual care (n=19) and usual care alone (n=19) had similar baseline characteristics including age, gender, smoking status and seropositivity. Baseline global physical and mental health scores were similar, however, pain was significantly lower at baseline in the functional medicine group as compared to the usual care group. At 12 weeks, there was no statistically significant difference between groups in any primary outcome, however there was a trend towards improved physical health scores and pain in the functional medicine group at 12 weeks (Table 1).

Table 1: Change in primary outcome scores from baseline to week 12

Factor	Total (N=38)	Usual Care (N=19)	Usual Care + Functional Medicine	p- value
			(N=19)	
Physical Health T-Score Change*	1.7±4.9	0.58±5.5	2.9±4.0	0.16
Mental Health T-Score Change*	1.2±3.8	0.99±4.0	1.5±3.7	0.70
Pain Change*	0.05±2.0	0.42±2.0	-0.33±1.9	0.25

\*Data not available for all subjects.

Statistics presented as Mean ± SD

p-values computed via two-sample *t*-tests

**Conclusion:** Enrollment in an adjunctive functional medicine program did not demonstrate a statistically significant improvement in pain, functional or mental health scores after 12 weeks but did show trends toward improvement in pain and physical function. Larger, prospective studies of longer duration are needed to identify the subset of patients who would benefit from a functional medicine intervention.

## Real World Clinical Trial Comparing the Patient Reported Outcomes Measurement Information System Short Forms and Profiles to CDAI Disease Classification in Rheumatoid Arthritis Patients

Jeffrey R. Curtis<sup>1</sup>, Sergio Schwartzman<sup>2</sup>, Shelly Kafka<sup>3</sup>, Dennis Parenti<sup>3</sup>, Shawn Black<sup>3</sup>, Stephen Xu<sup>4</sup>, Wayne Langholf<sup>4</sup> and Clifton O. Bingham III<sup>5</sup>, <sup>1</sup>Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Weill Cornell Medical College, New York, NY, <sup>3</sup>Janssen Scientific Affairs, LLC, Horsham, PA, <sup>4</sup>Janssen Research & Development, LLC, Spring House, PA, <sup>5</sup>Rheumatology, Johns Hopkins University, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient (Pt) reported outcomes (PROs) play a role in overall disease evaluation, therapeutic response assessment and care of rheumatoid arthritis (RA) patients (Pts). The Pt Reported Outcomes Measurement Information System (PROMIS [P])

questionnaires developed by the NIH have been used in clinical practice and observational studies in RA (Bartlett 2015). AWARE (Comparative and Pragmatic Study of Golimumab Intravenous [IV] Versus Infliximab in RA) is a large, pragmatic multi-center United States-based, real-world evidence study of golimumab IV (GLM) vs. infliximab (IFX) in RA and will assess infusion reactions, disease activity, and multiple PROs as outcomes.

**Methods:** AWARE is a prospective, noninterventional, ongoing study in which 1200 adult Pts will be enrolled on initiation of treatment with GLM or IFX. Objectives include PRO assessments of Pt response to treatment using the PROMIS-29 Profile v2.0 (P29v2), P Pain Interference Short Form-6b (PISF) and P Fatigue Short Form-7a (FSF), 36-Item Short Form Health Survey (SF-36v2) and Clinical Disease Activity Index (CDAI). We report here an interim analysis of 747 pts' baseline PROMIS questionnaire and CDAI scores, and their inter-relationships. PROMIS questionnaire results are normalized to the US population and reported as a "T-score" (mean of 50 and standard deviation (SD) of 10) with higher scores indicating more of the trait being measured. PROMIS T-scores were compared between HDA with MDA, LDA and remission, respectively. Data shown are mean  $\pm$  SD. Statistical testing compared T-scores across CDAI categories using ANOVA for this IA of baseline data (before drug administration). Data from GLM and IFX pts are combined.

**Results:** Overall baseline CDAI score was  $32.5 \pm 15.4$ , with 71.7% of pts in high DA (HDA), 22.5% in moderate disease activity (MDA), 5.2% in low disease activity (LDA) and 0.7% in remission. All P29v2 domains, PISF and FSF scores were significantly worse in pts with CDAI $>22$  vs. CDAI $\leq 22$  ( $p < 0.05$ ), as was true for the 8 SF-36 domains (data not shown). PROMIS T-scores (P29v2 domains, PISF and FSF) were compared to the 4 CDAI disease activity categories. As shown below, PROMIS T-scores correlated with CDAI disease category, with HDA Pt T-scores significantly (\*,  $p < 0.05$ ) different from those of MDA, LDA and Remission pts (except between HDA and remission for Anxiety, Depression and Sleep Disturbance domains).

Mean $\pm$ Standard Deviation of PROMIS T-Score of All Patients in Interim Analysis Dataset and a Comparison of T-Scores of PROMIS-29 Domains, Fatigue Short Form and Pain Interference Short Form to CDAI Disease Activity Category					
	All Patients (n=672-682)	Remission CDAI $\leq 2.8$ (n=5)	LDA 2.8<CDAI $\leq 10$ (n=38)	MDA 10<CDAI $\leq 22$ (n=165)	HDA CDAI $>22$ (n=526)
P29-Physical Function	37.9 $\pm$ 6.6	47.5 $\pm$ 5.7	45.0 $\pm$ 7.6	40.0 $\pm$ 6.7	36.6 $\pm$ 5.9*
P29-Anxiety	53.8 $\pm$ 10.4	45.2 $\pm$ 6.7 <sup>#</sup>	47.7 $\pm$ 8.6	51.3 $\pm$ 10.0	55.2 $\pm$ 10.3*
P29-Depression	52.5 $\pm$ 10.3	42.6 $\pm$ 3.6 <sup>#</sup>	45.9 $\pm$ 6.5	49.4 $\pm$ 9.8	54.0 $\pm$ 10.3*
P29-Fatigue	58.8 $\pm$ 9.9	42.3 $\pm$ 5.4	49.7 $\pm$ 9.7	55.6 $\pm$ 9.2	60.8 $\pm$ 9.4*
P29-Sleep Disturbance	55.5 $\pm$ 8.7	48.2 $\pm$ 13.6 <sup>#</sup>	51.5 $\pm$ 7.9	53.2 $\pm$ 8.4	56.7 $\pm$ 8.6*
P-29 Ability to participate in Social Roles and Activities	43.2 $\pm$ 8.6	57.3 $\pm$ 7.6	50.8 $\pm$ 8.5	45.9 $\pm$ 8.5	41.6 $\pm$ 8.0*
P29-Pain Interference	63.5 $\pm$ 7.7	46.9 $\pm$ 7.2	53.9 $\pm$ 8.4	60.1 $\pm$ 7.7	65.4 $\pm$ 6.5*
Fatigue Short Form 7a	59.3 $\pm$ 8.5	46.7 $\pm$ 8.8	51.6 $\pm$ 9.0	56.2 $\pm$ 7.5	61.0 $\pm$ 8.1*
Pain Interference Short Form 6b	62.5 $\pm$ 7.6	45.9 $\pm$ 7.5	53.9 $\pm$ 9.3	59.3 $\pm$ 5.6	64.3 $\pm$ 6.4*
P29 Pain Intensity (scored 0-10 scale)	6.0 $\pm$ 2.2	1.6 $\pm$ 2.6	3.5 $\pm$ 2.3	5.1 $\pm$ 2.2	6.6 $\pm$ 1.9*
T-scores $> 50$ indicate worsening of the domain relative to the general population, except "Physical Function" and "Ability to participate in Social Roles and Activities", where T-scores $< 50$ indicate worsening of these domains relative to the general population. * = $p < 0.05$ vs respective scores in MDA, LDA and remission DA categories. <sup>#</sup> = not statistically different from HDA					

**Conclusion:** Our interim findings demonstrate the feasibility of using PROMIS short forms and profiles to evaluate RA pts in clinical trials. These results confirm the domain validity of PROMIS measures according to CDAI disease category. PROMIS measures show the range of impact across multiple domains of physical, emotional, and social health experienced by RA pts. With a fully enrolled AWARE trial, evaluation of PROs, their responsiveness over time, and comparison with SF36 will provide important additional validation for their use in clinical trials.

## **The Patient Experience of Musculoskeletal Imaging Tests for Investigation of Inflammatory Arthritis: A Mixed Methods Study**

**Sandra Bourke**<sup>1,2</sup>, **Nicola Dalbeth**<sup>1</sup>, **William J. Taylor**<sup>3</sup>, **Anthony Doyle**<sup>1</sup> and **Merryn Gott**<sup>1</sup>, <sup>1</sup>University of Auckland, Auckland, New Zealand, <sup>2</sup>Auckland district health board, Auckland, New Zealand, <sup>3</sup>University of Otago, Wellington, New Zealand

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Musculoskeletal (MSK) imaging is widely used in rheumatology for diagnosis and management of arthritis. Although the technical and performance properties of MSK imaging tests are well recognised, few studies have examined the patient experience of undergoing these tests. The aim of this study was to understand the patient experience of MSK imaging tests for investigation of inflammatory arthritis, and factors that contribute to this experience.

**Methods:** In this mixed methods study, we conducted a thematic analysis of semi-structured interviews with 33 patients who had undergone a recent peripheral joint conventional radiograph, ultrasound, computed tomography or magnetic resonance imaging scan for investigation of inflammatory arthritis. Data from these interviews were used to generate an 18-item questionnaire about the experience of MSK imaging which was posted to rheumatology clinic patients within six weeks of peripheral joint imaging. Variables associated with the overall patient experience of the test were analysed using stepwise linear regression models.

**Results:** Analysis of the interviews identified six themes; knowledge about the test, the role of imaging in clinical care, awareness of potential harm, discomfort, experience of waiting, and 'seeing is believing'. Patient understanding was informed by the information they received and previous experience of the test. Patients perceived imaging as part of clinical care and believed the benefits of having the test outweighed the potential risks. Discomfort was experienced by some patients, both emotional due to negative experiences of interactions with staff and claustrophobia, and physical due to positioning for the test. Some patients felt anxious about waiting times for the test and for receiving results. Viewing of the images (particularly during ultrasound) improved understanding of disease and gave a sense of personal involvement in their arthritis treatment. Completed questionnaires were available from 132 patients. In regression analysis (Table), a strong negative association was observed between the 'Discomfort during the test' item and the overall experience of the test (standardised beta 0.35,  $p < 0.001$ ). 'Staff made the experience better' (0.26,  $p < 0.001$ ) and 'Information provided' (0.28,  $p < 0.001$ ) were positively associated with the overall experience of the test. For those who viewed their images, 'looking at the images with my doctor made me feel more involved in my care' (0.24,  $p < 0.019$ ) was also associated positively with overall experience.

**Conclusion:** Factors before, during and after a musculoskeletal imaging test contribute to the patient experience. The overall experience is most influenced by patient discomfort, interactions with staff during the test, information provided, and viewing images to improve patient involvement in clinical care.

Table 1. Stepwise linear regression analysis of question items (excluding non-applicable questions) independently associated with overall experience of the test (all participants)					
Dependent variable	Predictors	Standardized $\beta$	R <sup>2</sup> change	p	Model
Overall experience	Discomfort during the test	-0.35	0.16	<0.001	Adjusted R <sup>2</sup> = 0.32  F = 20.0  P < 0.001
	Information provided	0.28	0.11	<0.001	
	Staff made the experience better	0.26	0.06	<0.001	
Items included in this analysis: imaging modality and all questionnaire items that did not include a not applicable response.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient reported outcomes (PRO) provide valuable insights into patients' perceptions of their disease and overall health and function, and these perceptions influence management of their disease. The objective of this study was to examine patient factors (also termed contextual factors) that may be associated with the Routine Index of Patient Data (RAPID3) score among patients with psoriatic arthritis (PsA).

**Methods:** Patients with PsA were enrolled in the Psoriatic Arthritis Research Consortium (PARC) between 2015-2016. PARC is a longitudinal observational cohort study conducted at four institutions in the United States: University of Pennsylvania, Cleveland Clinic, New York University, and University of Utah. Only baseline data are included in this cross-sectional analysis. Potential contextual factors were defined prior to statistical testing. A contextual factor is defined by OMERACT as a "variable that is not an outcome of the study but needs to be recognized and measured in order to understand the study results." We examined the association between potential contextual factors and RAPID3 scores using univariable linear regression models. Variables significant at the univariable stage (defined as  $p < 0.05$ ) were included in multivariable linear regression models. A final model to identify factors with an independent relationship with RAPID3 score after accounting for disease activity (e.g., swollen and tender joint counts, skin global assessment, enthesitis) was formed using backwards selection.

**Results:** Among the four centers, 401 patients were enrolled; 55% were female, mean age was 51.3, and 76% identified as Caucasian. Using RAPID3 cut-offs designed for RA, the mean disease activity (9.0, SD 6.7) would be categorized as "moderate." Contextual factors significantly associated with RAPID3 score were female sex, current alcohol use, body mass index (BMI), depression, education level, and insurance status. In a multi-variable model insurance status, depression and BMI were most strongly associated with RAPID3 score, after accounting for PsA disease activity. These factors were similarly associated with the individual components of the RAPID3 (physical function, global assessment, and pain).

**Conclusion:** In PsA, the RAPID3 score is influenced by depression, insurance status, and obesity. These factors must be taken into account when using RAPID3 in clinical practice. Additionally, treating depression and improving obesity may be potential targets for improving the overall perception of disease in patients with PsA.

Table. Univariable and Multivariable Associations with RAPID3 scores

The  $\beta$ -coefficients can be interpreted as the difference in the mean PRO score between the two groups. The 95% confidence intervals do not include 0 (no

difference). CIs that do not cross 0 indicate statistical difference.

Prevalence of obesity was 42%, depression 19%, diabetes 10% and cardiovascular disease 18%.

Sex was specifically included in the previous model given others studies reporting an association between sex and patient reported outcome scores.

\*All other items that were not significant in the multivariable models were removed.

## **Disease Burden at One Academic Rheumatology Routine Care Setting Is Similar in Osteoarthritis (OA) and Rheumatoid Arthritis (RA) at First Visit but Significantly Greater in OA at a 6-Month Follow-up Visit**

Block<sup>2</sup> and Theodore Pincus<sup>2</sup>, <sup>1</sup>Division of Rheumatology, Rush University Medical Center, Chicago, IL, <sup>2</sup>Rheumatology, Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis commonly is regarded as less severe and less debilitating than RA. However, limited data are available for direct comparison of OA versus RA, in large part because different measures traditionally have been used to assess patients, primarily a HAQ (Health Assessment Questionnaire) in RA and WOMAC (Western Ontario and McMaster Universities Osteoarthritis Index) in OA. RAPID3 (Routine Assessment of Patient Index Data) on an MDHAQ (Multi-Dimensional HAQ) is a composite of 3 patient self-report measures that was developed for RA, but is informative in many other rheumatic diseases, including OA<sup>1</sup>. Recent observations from 4 settings indicate that RAPID3 and other MDHAQ scores were similar or higher in OA versus RA patients<sup>2</sup>. Those findings were from a cross-sectional convenience sample, and likely were affected by treatment in most patients. We analyzed MDHAQ/RAPID3 scores in patients with a primary diagnosis of either OA or RA at their first visit to a rheumatology center and at 6 month follow-up.

**Methods:** At one academic center, all patients complete an MDHAQ/RAPID3 prior to seeing the rheumatologist. The 2-page MDHAQ/RAPID3 includes scores for physical function (FN) (0-3 converted to 0-10) and 0-10 visual analog scale (VAS) scores for pain (PN) and patient global assessment (PATGL), compiled into a 0-30 composite RAPID3. Patients with physician-diagnosed primary OA or RA were included in the study. Mean FN, PN, PATGL and RAPID3 scores in RA and OA at baseline and 6-month follow-up (range 3-9 months) were compared for differences between first and second visits using t-tests, as well as between OA and RA adjusted using MANOVA.

**Results:** At first visit, RAPID3 was 15.9 in OA vs 15.3 in RA - no meaningful differences in individual measures or index (Table). At 6-month follow-up, in OA, RAPID3 fell from 15.9 to 14.9 (-1.0, p=0.06) vs 15.3 to 11.1 (-4.2, p<0.001) in RA, indicating greater improvement in RA, resulting in significantly higher disease burden in OA vs RA. These differences remained significant after adjusting for age, sex, body mass index, and education level.

Mean and standard deviation (SD) at first visit and 6-month follow up visit MDHAQ/RAPID3 of patients with OA and RA seen in routine care

Measures	OA (n=109)	RA (n=102)	OA vs RA p value	OA vs RA p adjusted*
First visit				
Function (0-10)	3.15 (1.9)	2.89 (2.2)	0.34	0.60
Pain (0-10)	7.01 (2.3)	6.36 (2.9)	0.07	0.49
PATGL (0-10)	5.69 (2.8)	5.85 (3.0)	0.69	0.30
RAPID3 (0-30)	15.9 (5.9)	15.3 (7.0)	0.52	0.47
Follow-up visit				
Function(0-10)	2.93 (1.9)	2.24 (2.2)	<b>0.02</b>	<b>0.006</b>
Pain (0-10)	6.36 (2.5)	4.60 (3.0)	<b>&lt;0.001</b>	<b>0.03</b>
PATGL (0-10)	5.62 (2.7)	4.10 (3.2)	<b>&lt;0.001</b>	<b>0.001</b>
RAPID3 (0-30)	14.9 (6)	11.1 (7.6)	<b>&lt;0.001</b>	<b>0.001</b>

\*adjusted for age, sex, BMI and education

**Conclusion:** Patients with OA or RA have similar disease burdens at first visit, but OA patients have a considerably higher burden 6 months later, reflecting more effective treatments for RA than for OA. Nonetheless, OA is a severe disease at first visit, suggesting a need for further research in OA toward improved treatment and outcomes. MDHAQ/RAPID3 is feasible and useful to assess and monitor clinical status in routine care of patients with different rheumatic diseases.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sustained remission (SR) is the most desirable status in patients with rheumatoid arthritis (RA). For adoption by patients, SR should reflect symptom's resolution and impact patient-report-outcomes (PRO). The study was performed in an inception cohort of recent-onset RA, initiated in 2004. Objectives of the study were to describe PRO from patients who achieved SR for the first time, as well as the proportion of those patients who achieved PRO norms, and to describe the pattern of PRO's normalization.

**Methods:** In November 2016, the cohort had 145 patients with  $\geq 30$  months of follow-up, with complete and regular rheumatic evaluations that additionally included a patient-pain visual analogue scale (PVAS), a patient-overall disease-VAS (OVAS), the health assessment questionnaire (HAQ), the Short-Form 36v2 Survey (SF-36) and fatigue assessment. First SR was defined according to DAS28 cut-offs (DAS28-SR) and to the ACR/EULAR 2011 Boolean definition (B-SR), if maintained for at least 12 months. The dependent t test and Mc Nemar's tests were used. The study was approved by IRB and written informed consent was obtained from all the patients.

**Results:** At cohort inclusion, patients were primarily middle-aged female with a high frequency of auto-antibodies. Up to SR, 98% of the patients were on traditional DMARDs and 37-42% were receiving combined low doses of corticosteroids.

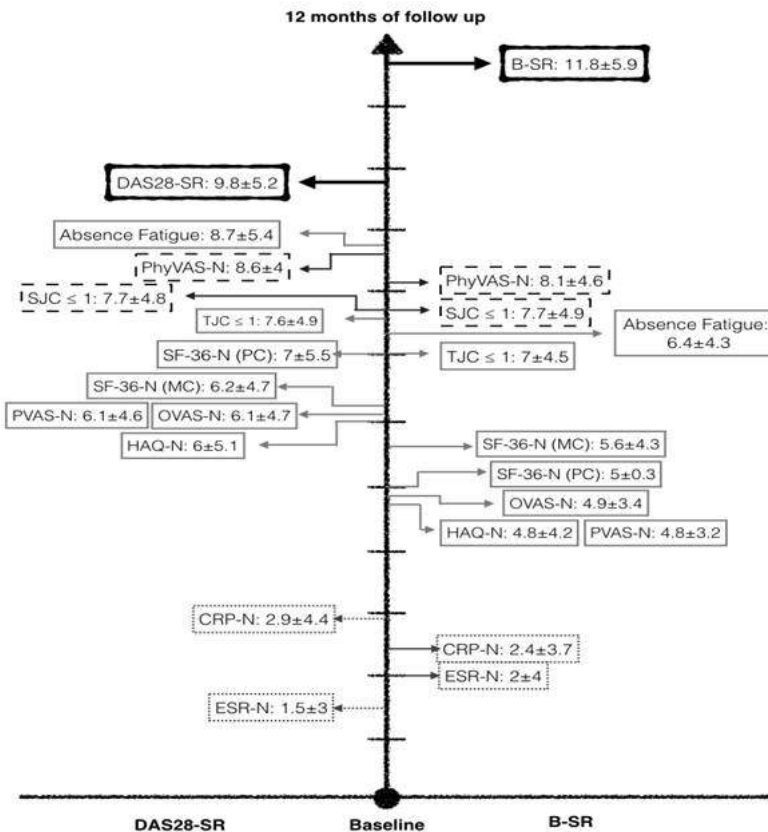

An increased number of patients achieved DAS28-SR compared to B-SR (78 vs. 63 patients, respectively). In addition, follow-up to DAS28-SR was shorter than to B-SR, and the duration of DAS28-SR was longer than the duration of B-SR ( $p \leq 0.03$  for both).

In general, at SR (either DAS28-SR or B-SR) patients had PRO proxy to normal values (PRO-N); the percentage of patients with PRO-N varied from 97% for HAQ, but decreased to 50% for absence of fatigue.

In SR patients, we calculated (mean $\pm$ SD) months of follow-up to achieve each particular PRO-N, and to achieve values within the normal range of erythrocyte sedimentation rate (ESR) and C reactive protein (CRP) and of overall-disease-physician-VAS. In DAS28-SR patients, normalization of ESR and CRP was detected at 1.5 and 2.9 months from baseline, respectively, followed by HAQ-N, PVAS-N, OVAS-N, SF-36-N (achieved between 6 and 7 months of follow-up); absence of fatigue was detected late, at 8.7 months of follow-up, similar to DAS28-SR, which was achieved at 9.8 months. A similar pattern was observed in B-SR patients (**Figure. Pattern of outcome normalization**).

**Conclusion:** At SR, RA patients achieved PRO proxy to normal values although the percentage of patients with PRO-N varied depending on each particular outcome. We identified a particular temporal pattern of outcome normalization. PRO provide unique information that cannot be collected from a physician and aid to complete the clinical picture of RA patients in SR.

## **Preferences and Satisfaction in a Pediatric Multidisciplinary Infusion Center**

**Catherine McDermott** &<sup>1</sup>, Brian Sohl<sup>1</sup>, Lisa M. McGregor<sup>2</sup> and Lisabeth V. Scalzi<sup>3</sup>, <sup>1</sup>Penn State Hershey Medical Center, Hershey, PA, <sup>2</sup>Penn State Hershey Children's Hospital, Hershey, PA, <sup>3</sup>Department of Rheumatology, Penn State Hershey Children's Hospital, Hershey, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Many pediatric rheumatology patients receive infusions in multi-specialty infusion centers (MSICs). There is little data about pediatric patient satisfaction and preferences within MSICs and no data about their physicians' perceptions of these preferences. In order to better understand and improve the patient experience, we studied these concepts.

### **Methods:**

We created and administered a survey containing free response and 5-point Likert scale questions to parents of children receiving infusion therapy and their respective physicians at our center. We compared means and sums of the scores using t-tests and ANOVA analyses.

### **Results:**

We surveyed 21 physicians (8 oncologists, 13 non-oncologists) and 174 parents of patients with oncologic (n=66) and non-oncologic (n=108) diagnoses who were receiving infusions in our MSIC. Our results showed significant differences between family satisfaction/preference and physician perception (Fig 1).

For all 3 questions, families responded positively towards the multi-specialty nature of the infusion center, though oncology families to a lesser degree than non-oncology families (respectively, mean=4.5 ±0.07 vs. 4.8 ±0.05; p<0.009).

Rheumatologists had a greater discrepancy than oncologists did in their perceptions of their patients' preferences, predicting their patients would be less satisfied receiving care in an MSIC than patients reported (Fig 2). In addition, rheumatologists believed their patients would prefer to receive infusions in a center specific for children without cancer, despite families not having this preference (mean = 1.3 ± 0.58 vs. 2.7±0.90; p<0.027, respectively).

Lastly, the majority of families surveyed reported they had increased awareness and empathy from exposure to children with other diagnoses, reflected in their comments (Table 1).

### **Conclusion:**

Pediatric rheumatology patients are satisfied with their experiences in an MSIC. Patients are significantly more satisfied than their physicians perceive. As infusion therapy for rheumatologic conditions increases, it is important to understand patient preferences as a crucial aspect of patient-centered care. Patients are content to receive infusions in an MSIC and find value in their experiences with families of children with other diagnoses.

**Figure 1: Satisfaction and Preferences of Parents/Patients vs. Physicians' Perceptions**

**Question 1:** My patients/I am content to have my child receive infusions in the same clinic as patients with/without cancer.

**Question 2:** My patients/I am content that the Penn State Children's Hospital Infusion Center treats children with a variety of diseases, both cancer and non-cancer related.

**Question 3:** My patients/I would not prefer my child to receive infusions in a center specifically for kids who have/do not have cancer.

**Figure 2: Three Question Mean Score of Oncologists & Oncology Patients vs. Rheumatologists & Rheumatology Patients**

**Table 1: Families find value in exposure received and connections made in a multi-specialty infusion center**

"No one [illness] is 'harder' than another, I think being exposed to other 'issues' children are dealing with makes you a more educated person and also makes you appreciate what you have... [there] is always someone who is dealing with something that is harder..."
"I like the fact that this shows my daughter that there are many kiddos with differences, yet they're similar in that they like to play in the play area just like she does."
"Because some of these other diseases are some that we may have never heard of if we weren't in a situation like the clinic. And when you meet someone in this type of environment it makes you want to learn more..."
"[It] makes us more aware of how blessed we are to be where we are at"
"...to see other children with other diseases helps him understand that it's not only kids like him must endure treatment."
"Being around others with different diagnoses is almost like going to school. Awareness and learning of other diseases/treatments may one day link a cure."
"It was good to be able to show my son that there are children who have conditions/ diseases that have affected their lives far worse than his... he could have had it much worse."

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treatment targets for gout generally focus on serum urate, but patient-centred targets may be equally important. We seek to determine the relationship between gout flare rates and patient self-classification into 3 disease activity states: remission (no symptoms of disease), low disease activity (LDA, no symptoms of disease that require additional therapy), and patient acceptable symptom state (PASS, level of symptoms acceptable to the patient).

**Methods:** Patients with 2015 ACR/EULAR gout criteria attending rheumatology clinics in 17 countries were asked to recall the number of flares over the preceding 6 and 12 months. For each time horizon they were asked to consider whether they thought their gout had gone away (remission), didn't require any additional or stronger therapy (LDA) or was controlled to their satisfaction (PASS). Multinomial logistic regression was used to determine the association between being in each disease state, flare count and self-reported current flare. A distribution-based approach and 3-state analysis of the volume under a ROC surface (VUS) with extended Youden index identified possible flare count thresholds for each state.

**Results:** 512 patients were recruited with mean (SD) age 58 (14) years, 89% were male, and disease duration of 12 (10) years. The states of LDA/PASS were combined since the distribution of recalled flares was very similar for these states. Each recalled flare reduced the likelihood of self-classified remission by 52% for 6 months and 23% for 12 months, and the likelihood of LDA/PASS by 15% and 5% for 6 and 12 months, respectively (Table). Not currently self-reporting a flare was strongly associated with self-classification into remission (OR 15.20 for 6 months and 15.13 for 12 months) or LDA/PASS (OR 5.74 for 6 months and 5.13 for 12 months) (Table). The VUS for 6-month flare count was 0.41 (95%CI 0.36 to 0.46) and the thresholds identified from the extended Youden index were 0 and 3.5; for 12-month flare count, the VUS was 0.38 (95%CI 0.33 to 0.43) and thresholds were 0 and 4.5. A threshold of 0 flares in preceding 6 and 12 months was associated with accurate classification of remission in 58% and 56% of cases, respectively.

**Conclusion:** Recalled flares are significantly associated with patient perceptions of disease activity in gout, supporting flare as an important target of therapy. Zero flares over prior 6 or 12 months were necessary for most patients to self-categorise as remission. Current flare is strongly associated with perception of disease activity, independently of the number of prior flares. However, recalled flare counts alone do not fully predict self-categorised states, suggesting that other factors may also contribute to perception of gout disease activity.

Table. Association between self-categorized disease state and recalled flares and current flare.				
	Disease activity category*		OR (95% CI) <sup>‡</sup>	p-value
Considering the previous 6 months	Remission	No. of flares	0.48 (0.38 to 0.60)	<0.001
		Current flare absent <sup>†</sup>	15.20 (5.58 to 41.37)	<0.001
	LDA/Pass	No. of flares	0.85 (0.79 to 0.90)	<0.001
		Current flare absent	5.74 (3.51 to 9.37)	<0.001
Considering the previous 12 months	Remission	No. of flares	0.77 (0.70 to 0.85)	<0.001
		Current flare absent <sup>†</sup>	15.13 (5.68 to 40.34)	<0.001
	LDA/Pass	No. of flares	0.95 (0.92 to 0.97)	<0.001
		Current flare absent	5.35 (3.33 to 8.60)	<0.001

\* The reference category is: Not in any of the 3 low disease activity states.

† The reference category is: Current flare present

‡ The OR are derived from a multinomial logistic regression model (separate models for 6 and 12 months), where the dependent variable was disease activity category and the independent variables were flare count and presence/absence of current flare

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Increasing emphasis has been placed on the use of patient reported outcomes (PROs) in both research and clinical practice. Capturing this data in clinical practice, however, is often challenging for providers and clinical staff: paper forms are easily lost and verbal questions may be rushed or skipped in busy clinics. Many electronic medical record systems (EMRs) have developed patient portal systems with the capacity to electronically administer questionnaires. This study aims to evaluate the use of a patient portal system for collecting PROs in a pediatric rheumatology clinic.

**Methods:** Response rates to patient reported outcome questionnaires were compared one month pre- and four months post-implementation of an electronic data capture system. Pre-implementation, verbal responses were manually entered into the chart by the physician. Post-implementation, data were captured electronically through our medical record patient portal. Questionnaires were completed on clinic computers or tablets in the waiting or exam room. Questions examined current physical symptoms, performed psychiatric screening, reported both patient pain and fatigue on 0-10 ordinal scales, and allowed entry of any concerns. English and Spanish versions were available. Patients and clinical staff were surveyed about their experiences.

**Results:**

There were 106 and 307 questionnaires completed pre- and post-implementation, respectively. Post-implementation, the majority of patients/parent-proxies entered their own data. Patient-portal activation increased from 53% to 88% ( $p<0.01$ ). Higher response rates were seen in psychiatric symptoms after electronic questionnaire implementation. Identification of positive responses pre- and post-electronic questionnaire implementation respectively, are reported: depression increased from 3 to 14% ( $p<0.01$ ), anxiety increased from 2 to 27% ( $p<0.01$ ), and difficulty sleeping increased from 16 to 30% ( $p<0.01$ ). Questionnaires also revealed themes in parental concerns, including “When can we reduce medication?” and “What can we do about her pain?” Physician satisfaction surveys estimated a time savings of 2-5 minutes per visit. Patients reported positive feedback to having portal access and state it allows more time to think about the questions. Furthermore, it introduces patients and their families to other functions within the portal, such as viewing labs and communicating with providers. There were 29 patient-portal correspondence messages prior to implementation and mean of 22 messages/month thereafter. Staff reported there was difficulty with activation of proxy accounts and password recovery workflow.

**Conclusion:** Integration of novel patient electronic data capture systems within pediatric clinics improve recognition and identification of psychiatric symptoms. It can also save valuable physician time. Improved discrete data capture is necessary to further improve clinical systems and patient care.

## **Psychometric Features of a New Methotrexate (MTX)-Specific Adherence Tool for Use in the Management of Patients with Rheumatoid Arthritis (RA): Preliminary Results from an Online Patient Community**

Elodie de Bock<sup>1</sup>, Corrado Bernasconi<sup>2</sup>, Tan P. Pham<sup>1</sup>, Ana Maria Rodriguez<sup>3</sup>, Khaled Sarsour<sup>4</sup>, J. Michael Nebesky<sup>2</sup> and Christine de la Loge<sup>1</sup>, <sup>1</sup>Mapi, Lyon, France, <sup>2</sup>F. Hoffmann-La Roche, Basel, Switzerland, <sup>3</sup>Patients Like Me (PLM), Cambridge, MA, <sup>4</sup>Genentech, South San Francisco, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** F. Hoffmann-La Roche Ltd. and Mapi collaborated to develop a medication adherence measure among RA patients taking MTX—the Methotrexate Experience Questionnaire (MEQ). The MEQ aims to facilitate communication between patients and clinicians during consultation to help clinicians identify patients having difficulty with MTX adherence and specific issues

leading to nonadherence. The MEQ was developed in accordance with best psychometric practices, including patient interviews, and contains several domains providing a comprehensive picture of drivers and descriptors of adherence issues encountered by RA patients treated with MTX. An observational study was conducted with patients from the PatientsLikeMe (PLM) online community. The aims of the present analysis were to provide preliminary results regarding the MEQ psychometric features and identify drivers of poor adherence in a population of PLM online users treated with MTX for RA.

**Methods:** This was a cross-sectional study where PLM RA subjects treated with MTX (currently or within the past 6 months) were asked to complete the 4-item Morisky Medication Adherence Scale (MMAS-4) and the MEQ online. The MEQ includes 29 items with 4- or 6-point Likert scale answers. Key psychometric MEQ features were described: acceptability and appropriateness of items (quality of completion, distribution, floor and ceiling effects), construct validity (multi-trait correlation-based analyses), concurrent validity (description and comparison of MEQ scores across MMAS-defined adherence and clinical groups). Linear, logistic, and partial least squares regressions were used to identify drivers of poor adherence.

**Results:** The population included 217 patients (80.2% aged 40-65 years; 90.8% women) whose mean duration of RA was 9 years (SD  $\pm 10.5$ ). The MEQ was well accepted (only 3.2% of completed questionnaires were missing  $\geq 1$  MEQ items). Some revisions to the theoretical structure were proposed in the process toward the development of the MEQ scoring algorithm (5 dimension scores were proposed: Perceived benefits of MTX, Convenience aspects of MTX, Drivers of nonadherence to MTX, Negative sides of MTX, Patient information). As expected, convenience and noncompliance scores were highly correlated to MMAS-4 ( $r=0.661$  and  $0.661$ , respectively), while Patient information and Perceived benefits did not show a significant association. Moreover, MEQ convenience, noncompliance, and Negative sides scores discriminated between low, moderate, and high adherence groups as defined by the MMAS-4 ( $p<0.0001$ ). Multiple drivers of poor adherence were identified, including aspects related to convenience, symptom improvement, how sick the patient felt, patient activities, and patient travel plans.

**Conclusion:** These preliminary results related to psychometric features of MEQ look promising as the instrument appears to discriminate between low, moderate, and high adherence as defined from the generic MMAS-4 in an online community of patients with RA. Future research includes psychometric validation of the MEQ in patients with clinically diagnosed RA against an objective measure of adherence (prescription claims data).

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite the global prevalence of rheumatoid arthritis (RA), there is no single model of care (MoC) and little is known about the RA patient journey at the population level. 18 RA patient organizations launched a global survey to understand patient experiences of RA MoCs and identify common challenges, gaps, and opportunities for improvement.

**Methods:** A short online questionnaire of RA patients recruited by patient organizations from 25 countries in Europe, the Middle East, and North and South America was conducted by Kantar Health (March 15–June 9, 2017) in 16 languages. The survey include questions on the patient's disease journey through 5 key elements of an RA MoC: 1) recognize symptoms/seek care, 2) access to specialist care, 3) medical management, 4) shared care, and 5) self-care. Countries with  $>30$  respondents were included in this analysis. Data were

analyzed at the global and country levels; descriptive (means, medians, percentages) analyses were conducted using STAR ODEC version 2.9.13. Global results are presented.

**Results:** 2690 respondents from 14 countries were included in this analysis (Table 1): 90% women, 71.5% between 35-65 years of age, and 69.7% from urban communities. Most respondents first heard they had RA from a rheumatologist (66%) (Table 2) and classified their current RA severity as moderate (59%) or severe (24%). Respondents reported an average of 22 mo (median, 5 mo) to receive an RA diagnosis and 20 mo (median, 3 mo) for an initial rheumatologist visit after first experiencing RA symptoms. Although 47% waited <1 mo for their first rheumatologist appointment, 33% had to wait >3 mo. Half (49%) see a rheumatologist once every 3 mo for management, 32% less frequently, and 9% as needed or do not see a rheumatologist. The majority (92%) have been treated with methotrexate, hydroxychloroquine, or sulfasalazine; however, most have not taken or did not know whether they have received biologics (72%) or small molecule treatment (82%). One-third (30%) reported it took from 4 mo to “never” for a first medication effectiveness assessment. Many respondents (39%) are not completely confident when describing RA to other people (Table 2). Access to additional information about living with RA and self-care was noted as a need by half (49%).

**Conclusion:** This large international patient survey highlights self-reported gaps and delays in all 5 key elements of a standardized RA MoC, including significant delays to diagnosis and specialist access globally, delayed therapy effectiveness assessment, and additional education/information to increase the level of confidence to describe RA and improve effective self-care practice.

# Multidomain Functional Assessment in a Cohort of Patients with Systemic Lupus Erythematosus: A Pilot Study

Laura Plantinga<sup>1</sup>, Benjamin Tift<sup>2</sup>, C. Barrett Bowling<sup>3</sup>, Charmayne M. Dunlop-Thomas<sup>4</sup>, S. Sam Lim<sup>5</sup> and Cristina Drenkard<sup>5</sup>,

<sup>1</sup>Department of Medicine, Emory University School of Medicine, Atlanta, GA, <sup>2</sup>Edward Via College of Osteopathic Medicine, Spartanburg, SC, <sup>3</sup>Durham Veterans Affairs Medical Center, Durham, NC, <sup>4</sup>Emory University School of Medicine, Atlanta, GA,

<sup>5</sup>Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a chronic, complex disease with multiple comorbid conditions and non-disease-specific manifestations. Consequently, the impact of SLE on both physical and cognitive function may be analogous to what is seen in the general geriatric population. We used a multidomain functional assessment, commonly performed in geriatric patients but novel among SLE patients, to better understand the magnitude of the functional impairment in this population.

**Methods:** We recruited 60 adult ( $\geq 20$  years old) SLE patients from an ongoing cohort study of Atlanta-area SLE patients for an in-person visit (10/16-4/17), in which we evaluated physical and cognitive function in several domains shown to be associated with poor outcomes in geriatric populations: physical performance (by the Short Physical Performance Battery; range on balance, gait speed, and lower body strength scores, 0-4; higher scores = better performance); cognitive performance (by NIH Toolbox measures of five fluid cognition domains; reported as adjusted t-scores); and self-reported measures including physical functioning (reported as t-scores), activities of daily living (ADLs), falls, and life-space mobility, which measures how far, how often, and how much help is needed as respondents move through their community (scale 0-120; higher scores = greater community mobility).

**Results:** Balance and gait speed scores were high, while mean lower body strength scores were low (Table). Cognitive performance was close to average (score=50) in the domains of episodic and working memory, but mean scores for cognitive flexibility, processing speed, and attention/inhibitory control were  $\sim 1$  SD below average for healthy individuals of the same age, sex, race, ethnicity, and education level. Patients reported independence in most basic ADLs but dependence in several instrumental ADLs. Nearly half (45.0%) of patients reported falling in the prior year, and only 40.0% reported unlimited ability to travel without the help of another person. Overall, scores did not differ substantially by age, although older patients had slightly lower self-reported physical functioning and higher cognitive performance scores than younger patients in general.

Functioning Measure	Value
<b>Mean (SD) physical performance (scale 0-4, higher=better)</b>	
Balance	3.65 (0.84)
Gait speed	3.37 (1.04)
Lower body strength	1.78 (1.34)
<b>Mean (SD) cognitive performance (scale 0-100; higher=better)</b>	
Episodic memory	47.72 (9.24)
Working memory	48.58 (11.22)
Cognitive flexibility	43.72 (14.22)
Processing speed	42.55 (14.83)
Attention/inhibitory control	38.80 (8.58)
<b>Mean (SD) self-reported physical functioning (scale 0-100, higher=better)</b>	38.82 (10.92)
<b>No. (%) reporting difficulty with ADLs (most common):</b>	
Shopping	25 (41.7%)
Food preparation	21 (35.0%)
Housework	8 (13.3%)
Bathing	8 (13.3%)
Dressing	9 (15.0%)
Incontinence	12 (20.0%)
<b>No. (%) with falls in prior year</b>	27 (45.0%)
<b>Mean (SD) life-space mobility (scale 0-120, higher=better)</b>	54.44 (34.35)

**Conclusion:** SLE patients of all ages report a substantial burden of functional impairment across multiple domains, similar to that among geriatric patients. Because impairment seems to be relatively independent of age in SLE and because greater levels of function may lead to better clinical and patient-centered outcomes, such as the ability to live independently, the value of functional assessment in the setting of SLE should be further explored. Further research could help inform potential interventions to improve or prevent further declines in functioning in this population.

## Perceptions and Outcomes of Pregnancy and Lactation in Patients with Rheumatic Diseases

**Brooke Mills**<sup>1</sup>, Kathryn H. Dao<sup>2</sup>, Kristen Tecson<sup>2</sup>, Emily Fishman<sup>3</sup>, Rachel Tate<sup>2</sup> and John J. Cush<sup>2</sup>, <sup>1</sup>Internal Medicine, Baylor University Medical Center, Dallas, TX, <sup>2</sup>Baylor Research Institute, Dallas, TX, <sup>3</sup>Texas A&M HSC College of Medicine, Dallas, TX  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Once diagnosed with a rheumatic disease, women often defer or avoid pregnancy or lactation, fearing adverse outcomes for their offspring or for themselves. Scant data exist regarding the attitudes of women with these diseases toward pregnancy and lactation. Furthermore, there is an unclear relationship between breastfeeding and disease activity. Our study evaluates the perceptions of women with rheumatic diseases on pregnancy and lactation while analyzing their outcomes during this period.

**Methods:** We conducted a single center cohort study of women of childbearing age regarding their attitudes, concerns, and outcomes of pregnancy and lactation. Information was gathered from chart review, telephone interviews and surveys. Those who completed a pregnancy and breastfed were queried further regarding their use of disease modifying anti-rheumatic drugs (DMARD) or biologics while breastfeeding and if their infants had any adverse outcomes.

**Results:** 154 subjects were included. 51.6% of respondents indicated their diagnosis changed their views on pregnancy. Opinions differed significantly across the diagnoses of JIA (28.6%), AKS (45.5%), RA (43.1%), and SLE (69.4%) ( $P=0.04$ ). 65.6% of women were concerned about medications affecting the baby. 33.6% indicated that their views on breastfeeding changed as a result of their disease diagnosis. Views on breastfeeding did not differ significantly between diagnoses. 29.7% of respondents said their diagnosis changed their minds about having children, a sentiment that differed significantly by diagnosis (AKS: 11.1%, JIA: 0.0%, Other: 30.0%, PSA: 33.3%, RA: 20.4%, SLE: 53.1%;  $P=0.01$ ). The rates of breastfeeding did not differ significantly for babies born before or after the mothers' diagnosis (before: 86.6%, after: 82.2%;  $P=0.50$ ). Breastfeeding duration did not differ by diagnosis status ( $P=0.21$ ). After diagnosis, more women stopped breastfeeding early to start a medication they believed to be contraindicated (before diagnosis: 2, 3.5%; after diagnosis: 12, 20%;  $P=0.005$ ). Of the 46 who responded, breastfeeding positively, negatively, or did not affect the mother's disease state in 21.7%, 43.5%, and 34.8%, respectively. There were 35.3% (12/34) instances of having to change medical therapy due to disease worsening while breastfeeding. 18 women breastfed 21 babies on a DMARD or biologic. None of these women reported a delay in their children's developmental milestones.

**Conclusion:** After disease diagnosis, nearly half of women negatively changed their views on pregnancy, and a third of women negatively changed their views on lactation. Women were concerned that the use of a DMARD or biologic may affect their own health or their baby's health. There was no difference in the rates or duration of breastfeeding between women before and after diagnosis, however after diagnosis, some respondents refrained from or curtailed breastfeeding due to concerns for medications or lack of information. Disease activity during lactation is variable based on our data; further studies are needed to fully evaluate this issue. This study highlights an unmet need in patients of childbearing potential for data and education regarding pregnancy and lactation.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The increasing availability of biologic treatments over the past 10 years has revolutionized the management of rheumatic diseases. In April 2016, the first etanercept biosimilar (EtnBS) was launched in Sweden, representing a cheaper option to its innovator counterpart and other anti-TNF agents. The objective of this study was to describe the position of etanercept innovator (EtnI) within the Swedish biologic market for rheumatic diseases, before and after the launch of its biosimilar. The study also provides early real-world data on the market penetration of EtnBS by evaluating switching dynamics to and from this drug since the date of launch.

**Methods:** The overall biologic market share across all type of rheumatic diseases was monthly tracked over the last year of available data in the Swedish Prescription Registry (100% coverage). The proportion of patients receiving a rheumatologists' prescription for any biologic in each month, from November 2015 to March 2017, was recorded. In addition, switching dynamics of patients initiating EtnBS treatment between April 2016 and March 2017 were studied. The proportion of patients receiving no biologic treatment (naïve) and of those on treatment with EtnI, adalimumab and other biologic agents in the 12 months prior to initiate EtnBS was reported. Further, the proportion of patients who switched from EtnBS back to EtnI or adalimumab and the median time to this second switch were also evaluated.

**Results:** EtnI and adalimumab dominate the biologic market for rheumatic diseases in Sweden, holding the 40% and 28% of market share, respectively, up to April 2016. However, in the 11 months after EtnBS was launched, the share of EtnI decreased constantly, dropping to 22% in March 2017. Since April 2016, we identified in total 5,387 patients receiving first prescription of EtnBS by a rheumatologist. Of these, 1,845 (34%) were naïve to treatment, 2,938 (55%) had prior treatment with EtnI, 235 (4%) with adalimumab, 369 (7%) with other biologics. Among the patients who changed to EtnBS from prior EtnI, 11% switched back to EtnI after a median time of 55 days. Similarly, of those who were on previous adalimumab treatment, 5% switched back to adalimumab after, median time, 67 days.

**Conclusion:** Many patients changed from EtnI to its biosimilar treatment since its launch in Sweden. However, this study showed that 11% of these patients switch back to their original treatment after short time. Despite the change from a brand biologic to the biosimilar is very likely made for economic reasons, the reasons for switching back to the innovator are not clear and may imply patients' preference or clinical reasons. Interestingly, the same pattern is observed for patients changing from adalimumab to EtnBS. Longer-term studies are required to confirm these early observations and investigate the reasons for switching back.

These results were presented at EULAR, Madrid 14-17 June 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Flare is a central feature of gout and patient self-report of flare was found to be an important element in a gout flare definition for research. However, patients may disagree with the clinicians on presence of a flare. In this study, we investigated factors impacting the concordance and discordance between investigators with expertise in gout and their patients, on presence of a gout flare.

## Methods:

We used gout patient data collected at 21 international sites from a gout flare definition study published in 2012 and its ongoing validation study. Information on demographics, gout flares, and anatomical location of swelling and warmth during a flare were collected during routine clinic visits. We performed Chi-square and t-test comparisons of these variables in patients who agreed with the investigator on the presence of a flare (concordant) versus those who disagreed with the investigator on the presence of a flare (discordant). We also made comparisons within the discordant group (when investigator diagnosed a flare but patient disagreed versus when patient self-reported a flare and the investigator disagreed).

## Results:

Concordant and discordant flares were noted in 187 and 81 cases, respectively. There were no differences between groups in age, sex, or disease duration. Compared to the discordant group, the concordant group had higher pain scores, increased patient global assessment of disease severity, greater proportions of patients with lower extremity joint (knee, ankle, or foot joints) involvement, and lower proportion of patients with tophi (Table). Fewer patients in the discordant group had either swollen or warm joint (patient reported) compared to the patients with concordant flares (76.5% vs 97.9%,  $p < 0.0001$ ). Within the discordant group, 70.4% of flares were patient determined and not endorsed by the investigators. All patients with an investigator-determined flare where patients disagreed had at least one swollen joint (100%) compared to only 57.9% in flares that were patient-determined but the investigator disagreed with ( $p < 0.0001$ ).

## Conclusion:

We identified factors associated with agreement and disagreement among patients and investigators on the presence of a gout flare. Lower extremity involvement, higher patient global assessment of disease, less tophaceous disease, higher pain scores, and presence of at least one swollen or warm joint is associated with concordance. Having a swollen joint was a determinant in all the investigator-defined flares when patients disagreed, however it was much less important in patient-determined gout flares.

Table: comparison between patients in discordant flare group to concordant group

Variable	Discordant flare N=81	Concordant flare N=187	P value
Age in years; Mean (SD)	54.7 (13.8)	53.8 (14.0)	0.65
Male sex; n (%)	75 (93.8)	165 (88.7)	0.20
Disease duration in years; Mean (SD)	11.8 (8.1)	11.8 (10.3)	0.98
Presence of tophi; n (%)	50 (61.7)	87 (46.8)	0.0246
Lower extremity involvement in a flare; n (%)	48 (59.3)	157 (84.0)	<0.0001
PGA (0-10); Mean (SD)	4.3 (3.3)	6.6 (2.5)	<0.0001
Pain at rest (0-10); Mean (SD)	4.1 (3.3)	6.9 (2.5)	<0.0001
Patient- reported	62 (76.5)	183 (97.9)	<0.0001
Any swollen or warm joint (%)			
Any Swollen (%)	57 (70.4)	178 (95.2)	<0.0001
Any warm (%)	38 (46.9)	153 (81.8)	<0.0001

SD= standard deviation, PGA = patient global assessment of disease severity

## Patients and Physicians Have Different Perceptions of the Relative Bother of the Symptoms and Impacts on Daily Activities in Psoriasis and Psoriatic Arthritis

**M. Elaine Husni**<sup>1,2</sup>, Anthony Fernandez<sup>1</sup>, Rakesh Singh<sup>3</sup>, Brett Hauber<sup>4</sup>, Jessie Sutphin<sup>4</sup>, Joshua Posner<sup>4</sup> and Arijit Ganguli<sup>3</sup>,  
<sup>1</sup>Cleveland Clinic, Cleveland, OH, <sup>2</sup>Rheumatology Dept A50, Cleveland Clinic Foundation, Cleveland, OH, <sup>3</sup>AbbVie Inc., North Chicago, IL, <sup>4</sup>RTI Health Solutions, Research Triangle Park, NC

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriasis and psoriatic arthritis arise from the same immune system response but result in different symptoms and impacts on daily activities. A patient with both conditions may be treated by a dermatologist, rheumatologist, or both. Our objective was to assess patient, dermatologist, and rheumatologist perceptions of the bother of individual psoriatic outcomes in 3 separate areas: skin and joint symptoms and impacts on daily activities.

**Methods:** We developed a set of 7 skin symptoms, 7 joint symptoms, and 6 impacts on daily activities of psoriatic disease from existing validated measures. To measure perceived relative bother, we created an online best-worst scaling survey in which patients, dermatologists, and rheumatologists in the US, recruited through internet panels, indicated which of 5 items from the full set of 20 was most and least bothersome in each of 16 questions determined by an experimental design. We used these data to rank perceived relative bother in skin symptoms, joint symptoms, and daily activities for each respondent group.

**Results:** We surveyed 200 patients with self-reported physician diagnosis of both psoriasis and psoriatic arthritis with mean (SD) age of 42 (14) years. On a scale from 0 (none) to 10 (severe), patients had mean self-reported skin symptoms of 6.8 (2.5) and joint symptoms of 6.4 (2.6). Patients, dermatologists (n=150), and rheumatologists (n=150) differed on the most bothersome skin symptom (Table 1).

All respondent groups ranked joint pain, soreness, or tenderness as the most bothersome joint symptom and discomfort while doing everyday tasks as the most bothersome impact on daily activities. Among skin symptoms, embarrassment was ranked highest (most bothersome) by dermatologists, while painful skin was ranked higher than embarrassment by patients and rheumatologists. Among joint symptoms, patients and physicians ranked the relative burden of eye problems differently. Among daily activities, patients and physicians ranked the relative bother of difficulty sleeping differently.

**Conclusion:** The perception of the bother of psoriatic disease outcomes differs among patients, dermatologists, and rheumatologists. Greater communication among these groups is warranted and may help patients and physicians better address patient needs.

Table 1. Item Rankings for Dermatologists, Rheumatologists, and Patients

Ranking	Dermatologists	Rheumatologists	Patients
<b>Skin Symptoms</b>			
1	Embarrassment	Itching skin	Painful skin
2	Itching skin	Painful skin	Itching skin
3	Flaking skin	Flaking skin	Flaking skin
4	Painful skin	Embarrassment	Redness of skin
5	Redness of skin	Redness of skin	Embarrassment
6	Nail problems	Nail problems	Nail problems
7	Difficulty choosing clothing	Difficulty choosing clothing	Difficulty choosing clothing
<b>Joint Symptoms</b>			
1	Joint pain, soreness, or tenderness	Joint pain, soreness, or tenderness	Joint pain, soreness, or tenderness
2	Swelling of fingers or toes	Swelling of fingers or toes	Difficulty walking
3	Difficulty walking	Difficulty walking	Eye problems
4	Morning stiffness	Morning stiffness	Swelling of fingers or toes
5	Fatigue	Fatigue	Morning stiffness
6	Difficulty dressing	Difficulty dressing	Fatigue
7	Eye problems	Eye problems	Difficulty dressing
<b>Impact on Daily Activities</b>			
1	Discomfort while doing everyday tasks	Discomfort while doing everyday tasks	Discomfort while doing everyday tasks
2	Difficulty with work or school activities	Difficulty with work or school activities	Difficulty sleeping
3	Difficulty with social or leisure activities	Difficulty going shopping or doing housework or yard work	Difficulty going shopping or doing housework or yard work
4	Difficulty going shopping or doing housework or yard work	Difficulty with social or leisure activities	Difficulty with work or school activities
5	Problems with relationships	Problems with relationships	Difficulty with social or leisure activities
6	Difficulty sleeping	Difficulty sleeping	Problems with relationships

## Nurse Telephone Education for Promoting a Treat-to-Target Approach in Recently Diagnosed Rheumatoid Arthritis Patients – a Preliminary Review

Bonita Libman<sup>1</sup>, Siobhan Farley<sup>1</sup>, Melinda Edwards<sup>1</sup>, Carl Possidente<sup>2</sup> and Amanda Kennedy<sup>3</sup>, <sup>1</sup>Medicine/Rheumatology, University of Vermont Medical Center, Burlington, VT, <sup>2</sup>Medical Affairs, Pfizer, Inc., Jericho Center, VT, <sup>3</sup>Internal Medicine, University of Vermont, Burlington, VT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A successful Treat-to-Target approach to managing Rheumatoid Arthritis (RA) requires shared decision making with patients and healthcare providers. However patients may not have the education they need around the time of a new diagnosis to effectively partner with their providers in their RA care. Educational efforts must focus on interventions that are feasible, sustainable, and available to all RA patients as part of their rheumatology care. The purpose of this project was to implement a pragmatic nurse telephone education program for patients with recently diagnosed RA that promotes shared decision making and a treat-to-target approach.

**Methods:** This was a pilot project of newly diagnosed adult RA patients between November 2015 and December 2016. Rheumatology clinic nurses telephoned patients to offer disease education, targeting no more than 20 minutes per call. A shared decision making toolkit was mailed to the patient. Demographic data included patient age, sex, and zip code. RA-specific data included date of RA diagnosis, prescribed RA medications, routine assessment of patient index data 3 (RAPID3) scores if recorded, and date of next visit with the rheumatologist. Process measures included median call attempts, median call time, and a qualitative description of the free text notes. Outcome measures included the results from the satisfaction survey and proportion of patients who adhered to their next rheumatology visit. Data were analyzed descriptively and qualitatively.

**Results:** Twenty-six patients participated in the nurse calls. Most patients were female (65%), with a median age of 54 years (range 22-78). Median call length was 14.5 minutes with a range of 8-23 minutes. Qualitative notes indicate patients overwhelmingly support the nurse calls. Five patients returned the survey. All five patients indicated they would like calls from a nurse more than once per year. Twenty-three patients had follow-up visits at the time of this report. Sixteen patients (69.5%) were adherent to their follow-up visit.

**Conclusion:** This preliminary review successfully implemented an educational program that included a nurse-facilitated, RA-specific, telephone call and toolkit. The strength of our approach was designing our educational program with the goal of long-term sustainability and generalizability. This educational program could be a model for similar educational efforts by other rheumatology clinics.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The SpENAT, a Spanish version of the Educational Needs Assessment Tool, is a self-completed questionnaire that assesses educational needs (ENs) with the purpose of providing tailored and patient-centered information. It consists of 39 questions grouped into the 7 following domains: Pain management, Movement, Feelings, Arthritis process, Treatments, Self-help measures and Support system. The objective of the study was to describe the educational needs of RA patients using the SpENAT and to determine the main sources of information that these patients consult.

**Methods:** Multicenter, observational, cross-sectional study. We included consecutive patients  $\geq 18$  years with diagnosis of RA (ACR-EULAR 2010). Socio-demographic data, disease characteristics and clinimetric measurements were recorded. All patients completed the SpENAT and were asked about the sources employed to obtain information about their disease. Statistical analysis: Population characteristics were described. ENs were determined as percentages of the highest possible score for each domain. Needs for each domain according to sex, years of education, duration of disease, use of biologicals and functional capacity were analyzed by means of Anova test, and bivariate comparisons were made with Student's T test and Bonferroni correction. Correlation between domains was determined with Spearman's test. ENs were described by geographic region. We compared patients' age by source of information with Student's t-test.

**Results:** We included 496 patients from 20 centers across the country. More ENs were observed in Movement, Feelings and Arthritis process domains (Table). Patients with higher educational level ( $> 7$  years) reported more ENs in Arthritis process and Self-help measures domains. A higher functional impairment (HAQ-A  $\geq 0.87$ ) was associated with more ENs in every domains. Patients with high activity showed more ENs than those in remission in Managing Pain, Movement, Feelings, Treatments and Support system domains; and also than those with low activity in Self-help measures and Support system domains. Patients with moderate activity showed more ENs in Managing pain domain compared to patients in remission. All SpENAT domains showed positive correlations with each other ( $p < 0.0001$ ), being the most important Managing pain/ Movement and Treatments/ Arthritis process ( $r \geq 0.7$ ). The most consulted source of information was the rheumatologist (93.95%); those who made use of internet were on average younger ( $p = 0.0004$ ).

**Conclusion:** RA Patients were very interested in knowing more about their disease. ENs were higher in Movement, Arthritis process and Feelings domains. High functional impairment was associated with more ENs. Patients with high disease activity had higher EN levels in almost every domain. The rheumatologist was the main source of information of the patient with RA.

EN in RA patients according to the domain (N=496)

	Pain management	Movement	Feelings	Arthritis process	Treatments	Self-help	Support system
Median	79.17	90	81.25	89.29	78.57	75	75
(IQR)	(70.83-91.67)	(75-95)	(75-100)	(75-100)	(71.43-100)	(70.83-93.75)	(62.5-93.75)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Periodic fever syndromes (PFS) are a group of autoinflammatory disorders characterized by recurrent bouts of fever and severe localized inflammation which, if not treated, can result in severe complications such as amyloidosis. Flares can last for several days to weeks and are typically associated with high symptom burden. Due to the rarity of these conditions detailed analysis of the patient experience with PFS is lacking. HEROES (Hereditary Periodic Fevers Burden of Illness Observational Patient Diary Study) is the first international study to document the nature and extent of the humanistic and economic burden experienced by patients (pts) and their families during and between flares.

### **Methods:**

Eligible pts had diagnosis of TRAPS (TNF-receptor associated periodic syndrome), MKD/HIDS (mevalonate kinase deficiency/hyperimmunoglobulinemia D syndrome) or crFMF (colchicine-resistant FMF), were expected to flare at least once every 6 months despite current treatment and be of sufficient severity to be eligible for (or currently receiving) biologic therapy. Investigators provided background information including treatment history and response to colchicine for crFMF pts. Disease burden was captured through participant completion of an electronic diary. Diaries were completed by adult pts ( $\geq 18$  years old) or caregivers for younger pts; adolescent pts (13-17 years old) provided input into the daily questionnaire. Baseline questionnaire collected background information including demographics, disease history, treatment satisfaction and long-term impact of PFS. Daily and weekly on and off flare forms focused on patient function, emotional/social wellbeing and pain. Quality of life measures by SF-12v2, SF-10v2 and Sheehan Disability Scale version 3 (SDSv3) were quantified. Disease activity was assessed using patient/parent's global assessment of disease activity (PPGA).

**Results:** The study enrolled 67 pts across 10 sites in France, Germany, Israel, the UK and the US, including 49 crFMF, 11 MKD/HIDS, and 7 TRAPS pts. Of these, 24 were children (2-12 years old), 11 were adolescents, and 32 were adults. All pts received drug therapy for their PFS. At least one flare was recorded in 58 (87%) pts. Fourteen (40%) children/adolescents reported that PFS impacted their education. Twenty-five (78%) adult pts reported that condition impacted their work achievements. Of the 35 caregivers participating in the study, 71% reported that their child's PFS impacted their employment. All caregivers not working full-time reported that their child's PFS was at least one, if not the main reason for reduced working hours. A large proportion (64% and 43%) of pts had at least one hospital or ER visit related to their PFS in the last year, respectively. The vast majority (86% and 88%) of pts and caregivers, respectively, report that PFS interfered with their social activities.

### **Conclusion:**

Severe PFS have a very broad impact on the lives of pts and their families, including work productivity and educational attainment. Therapeutic interventions that reduce the flare burden and long term complications of severe PFS, as well as psychosocial support for pts and caregivers, are needed.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Health insurance plan designs often have benefits that result in highly prescriptive patient (pt) treatment options that can result in switching of patient's medications for non-medical (economic) reasons.

**Methods:** An online pt survey was conducted in pts recruited from advocacy organizations (Global Healthy Living Foundation, National Psoriasis Foundation) and a research panel (Research Now). Pts were eligible if they were ≥18 years of age, resided in United States; had a diagnosis for one of the following: rheumatoid arthritis, Crohn's disease, ulcerative colitis, psoriasis or psoriatic arthritis; were currently taking a biologic; and consented to participate. Pts who met these criteria answered follow up questions about their experiences related to a possible non-medical switch (NMS) of their biologic medication. Descriptive statistics (n%, mean, SD) were used to summarize responses.

**Results:** A total of 1,696 pts completed the 20-minute survey; 993 were from advocacy groups and 703 from a research panel. Of the 1,696 patients that were asked about their perceptions to a possible biologic NMS, 90% expressed that they wouldn't want to switch biologics if their current medication was helping my disease. 71% indicated they would not risk switching to another biologic. Only 29% would switch if the new biologic was cheaper. 86% of patients expressed concern that switching may cause more side effects, and 81% worried that switching would increase their stress. 74% were concerned that switching would cause them to lose their copay support. 20% (n=337) of patients had received notification their biologic insurance coverage was changing and they should consider switching biologics to avoid paying a higher cost. Of these, 79% took at least one action to avoid a NMS, most often asking their doctors' offices to appeal the switch; 56% did not make the switch. Of pts that agreed to a NMS (n= 150), 67% did so to avoid paying a higher cost for their current biologic medication; most often pts switched to a biologic with the same mode of administration. Additionally, of patients that reported a NMS, 67% indicated that the biologic they were previously taking worked well for them, and 70% didn't want to switch to another biologic. More than half (56%) went without therapy for administrative reasons during the period of transition from the old biologic to the NMS treatment.

**Conclusion:** Pts reported multiple concerns about NMS that would impact treatment outcomes, and many of the pts who non-medically switched in this survey missed treatments. Future studies should be conducted on real world pt experience with NMS to understand the impact on treatment persistency and pt outcomes.

## Work Productivity Benefit in Patients with Rheumatoid Arthritis Initiating Etanercept in the United States

Mahdi Gharaibeh<sup>1</sup>, Bradley S. Stolshek<sup>2</sup>, Alex Mutebi<sup>3</sup>, Amy M. Sainski-Nguyen<sup>4</sup>, David Collier<sup>5</sup> and Emily Durden<sup>4</sup>, <sup>1</sup>Amgen Inc., Thousand Oaks, CA, <sup>2</sup>Amgen, Inc., Thousand Oaks, CA, <sup>3</sup>Amgen, Thousand Oaks, CA, <sup>4</sup>Truven Health Analytics, Ann Arbor, MI, <sup>5</sup>Amgen, Inc, Terni, Italy

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Rheumatoid arthritis (RA) is a chronic inflammatory disease that can progress to joint destruction, functional impairment and disability that can lead to work productivity losses. Biologics are generally prescribed when conventional disease modifying agents are no longer effective or following disease progression. Treatment with etanercept (ETN), either as monotherapy or in combination with methotrexate (MTX), has been shown to improve functioning and work productivity in clinical and observational studies. The aim of this study was to assess the productivity benefit of treating RA patients with ETN compared to MTX.

### Methods:

In this retrospective administrative claims analysis using the MarketScan Health and Productivity Management and the Commercial Claims and Encounters databases, adults diagnosed with RA who were treated with ETN, ETN+MTX, or MTX between January 1, 2007 and December 31, 2013 were identified. The index date was the date of the earliest qualifying ETN or MTX pharmacy or medical claim. Patients were continuously enrolled with medical and pharmacy benefits 12 months prior to and 12 months following the index date. Patients who switched to or added another biologic during the post-index period were excluded. Patients diagnosed with other autoimmune diseases or had evidence of pregnancy or childbirth at any time during the study period were excluded. The proportions of patients with any workplace absence (ABS) or short-term disability (STD) in the 12 months prior to and following the index date were evaluated. Multivariable logistic regression was used to compare the odds of work loss during follow-up for the ETN and ETN+MTX groups relative to the MTX group, adjusting for demographic and baseline clinical characteristics including but not limited to age, gender, additional RA-related medications, and baseline RA-related costs.

### Results:

For the work loss due to ABS analysis, 34 patients on ETN monotherapy, 49 patients on ETN+MTX, and 308 patients on MTX monotherapy were identified. For the STD analysis, 207 patients on ETN, 274 patients on ETN+MTX, and 1,620 patients on MTX were identified. The proportions of patients with at least one event of ABS during the pre-index period for the ETN, ETN+MTX, and MTX cohorts were 82.4%, 73.5%, and 85.4%, respectively. In the post-index period, the proportions of patients with at least one event of ABS for the ETN, ETN+MTX and MTX cohorts were 85.3%, 75.5%, and 87.0%, respectively.

The proportion of patients with at least one event of STD during the pre-index period for the ETN, ETN+MTX and MTX cohorts were 8.7%, 13.9%, and 11.5%, respectively. In the post-index period, the proportion of patients with at least one event of STD for the ETN, ETN+MTX and MTX cohorts were 7.7%, 8.4%, and 11.7%, respectively. After adjusting for potential confounders, the odds (95%CI)

of losing a day due to ABS in the ETN and ETN+MTX groups relative to the MTX group were 0.61(0.19-1.98) and 0.33(0.13-0.85), respectively. The odds (95%CI) of having STD in the ETN and ETN+MTX groups relative to the MTX group were 0.61(0.35-1.07) and 0.50(0.30-0.84), respectively.

#### **Conclusion:**

Adding ETN to MTX reduces the probability of ABS from work by 67% and the probability of STD by 50% compared to those on MTX alone.

#### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Canakinumab (CAN) has demonstrated its efficacy and safety in systemic juvenile idiopathic arthritis in clinical trials. We report on the experience with CAN in the clinical practice.

**Methods:** Surveillance of patients exposed to biologics is performed by the BIKER registry. Data on patients' and disease characteristics, disease activity and safety reports until Dec. 2016 were analysed.

**Results:** Until June 2017, 39 JIA patients were registered in the German BIKER registry in whom CAN was started, representing 59.2 PY of exposure. In 14 patients CAN was used as first biologic agent. 25 patients were pretreated with other biologics, 14 received 1, 7 two, 3 three and 1 four biologics. 15 had been treated with Tocilizumab, 11 with Anakinra, 9 with Etanercept and 9 with Adalimumab. Of interest, 3 patients in the pre-exposed cohort had experienced a macrophage activation syndrome. Patient's and disease characteristics comparison of biologics naïve and preexposed patients are given below.

Patients pretreated were older, had a longer disease duration and more comorbidities (Macrophage activation syndrome, pericarditis, pleuritic organomegaly and Cushing's) than naïve patients. The proportion of patients with active arthritis, active systemic features and both were comparable.

Disease activity at baseline (number of active joints, Patient's and physicians' global, ESR, CRP and the JADAS) was higher in the biologic naïve cohort suggesting some clinical benefit from pretreatment in the exposed cohort. Dosing of CAN was comparable (3.9+/-0.4 vs. 3.5+/-0.7 mg/kg) as well as the median treatment duration.

Treatment efficacy at 6 month of treatment was stronger in the naïve cohort with more patients reaching a PedACR50/90 response, CRP normalisation, normal CHAQ, physician global indicating no activity (p=0.05) JADAS remission (p=0.02). Treatment with CAN was discontinued by 42% in the naïve cohort and 48% in the exposed cohort. Reasons for withdrawals were inefficacy (n=7; 19%), intolerance (n=2; 5%) and remission (n=7; 19%) of the disease and other (n=2;5%).

**Conclusion:** First experience with CAN for treatment of systemic JIA in clinical practice is presented. A high proportion of patients gained significant response to treatment. JADAS remission was reached in significantly more biologics naïve patients while few

patients discontinued treatment in remission so far. Intolerance was rare. The further long term surveillance of patients exposed to biologics is intended by the registry.

**Table 1:** Baseline characteristics in the comparison groups

	Biologics naïve	Biologics pre-exposed
N ( female gender)	14 (28%)	25 (52%)
Age at JIA onset (years); Median (IQR)	3.3 (2.7-5.2)	3.7 (2.6-7.1)
Disease duration (years); Median (IQR)	0.7 (0.2-5.6)	1.9 (0.6-8.7)
Concomitant treatment at baseline: NSAIDS	7 (50%)	10 (40%)
Steroids	6 (43%)	11 (44%)
MTX	3 (21%)	6 (24%)
Patients with active joints	8 (57%)	10 (40%)
Patients with active systemic features	9 (64%)	10 (40%)
Active joint count; Median (IQR)	2.5 (0-3)	0 (0-3)
Physician global VAS (0-10); Median (IQR)	5.2+/-2.8; 6.2 (3.2-7.2)	3.8+/-3m.4 ; 3.7 (0.7-6.3)
Patient Global VAS (0-10); Median (IQR)	4.8+/-2.9; 4.6 (2.7-7)	3.3+/-2.9; 2.6 (0.6-5.1)
CHAQ-DI (0-3); Median (IQR)	0.5 (0.38-1.24)	0.65+/-0.84; 0.25 (0-1.22)
ESR (mm/h); Median (IQR)	28 (10-55)	9 (4-18.5)
CRP (mg/l); Median (IQR)	43 (25-109)	3 (1-11)
JADAS10; Median (IQR)	15.2 (14-20.9)	9.5(5.5-11.8)

# Canakinumab Treatment in Patients with Still’s Disease: A Pooled Analysis of Systemic Juvenile Idiopathic Arthritis Data By Age Groups

**Eugen Feist**<sup>1</sup>, Pierre Quartier<sup>2</sup>, Bruno Fautrel<sup>3</sup>, Rayfel Schneider<sup>4</sup>, Paolo Sfriso<sup>5</sup>, Petros Efthimiou<sup>6</sup>, Luca Cantarini<sup>7</sup>, Karine Lheritier<sup>8</sup>, Karolynn Leon<sup>9</sup> and Antonio Speziale<sup>8</sup>, <sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin, Germany, <sup>2</sup>Necker-Enfants Malades Hospital, Paris, France, <sup>3</sup>UPMC University Paris 06, Pitié-Salpêtrière Hospital, Paris, France, <sup>4</sup>University of Toronto and The Hospital for Sick Children, Toronto, ON, Canada, <sup>5</sup>University of Padova, Padova, Italy, <sup>6</sup>Medicine/Rheumatology, New York University School of Medicine/NYU Langone Health, New York, NY, <sup>7</sup>University of Siena, Siena, Italy, <sup>8</sup>Novartis Pharma AG, Basel, Switzerland, <sup>9</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017  
**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous  
**Session Type:** ACR Poster Session A  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Still’s disease presents in pediatric and adult patients as a disease continuum with similar symptoms and pathophysiology.<sup>1,2</sup> The objective of this analysis was to evaluate the efficacy and safety of canakinumab, a selective human anti-IL1  $\beta$  monoclonal antibody, in systemic juvenile idiopathic arthritis (SJIA) patients from pooled data across three age groups: children, adolescents and adults (the latter representing adult-onset Still’s disease [AOSD] population).

**Methods:** Data of canakinumab treated patients were pooled from 4 SJIA studies (NCT00426218, NCT00886769, NCT00889863, NCT00891046). Canakinumab was administered at 4 mg/kg every 4 weeks in majority of the patients. Efficacy parameters (adapted American College of Rheumatology [aACR] pediatric responses, juvenile idiopathic arthritis [JIA] ACR responses, patients with inactive disease), C-reactive protein (CRP) levels over 12 weeks and safety were assessed by age groups. One study (NCT00426218) was excluded for efficacy outcomes.

**Results:** 216 children (2–<12 years), 56 adolescents (12–<16 years) and 29 adults ( $\geq$ 16 years) were analyzed for efficacy outcomes. The efficacy parameters across the three age groups were comparable (Table 1). The safety profile of canakinumab was similar across age groups (Table 2). One patient from the adolescents group died because of pulmonary hypertension that was associated with macrophage activation syndrome. Clinical, laboratory and immunogenicity data showed no notable differences between the age groups.

**Table 1.** Efficacy: responses by age group and time point

Age group	%	aACR pediatric; n/N (%)		JIA ACR; n/N (%)	
		Day 15	Day 85	Day 15	Day 85
Children	≥30	158/216 (73.1)	90/133 (67.7)	169/216 (78.2)	93/133 (69.9)
	≥70	109/216 (50.5)	77/133 (57.9)	111/216 (51.4)	77/133 (57.9)
	≥100	46/216 (21.3)	42/133 (31.6)	47/216 (21.8)	42/133 (31.6)
Adolescents	≥30	47/56 (83.9)	20/27 (74.1)	47/56 (83.9)	20/27 (74.1)
	≥70	33/56 (58.9)	18/27 (66.7)	33/56 (58.9)	18/27 (66.7)
	≥100	15/56 (26.8)	8/27 (29.6)	15/56 (26.8)	8/27 (29.6)
Adults	≥30	25/29 (86.2)	15/18 (83.3)	25/29 (86.2)	15/18 (83.3)
	≥70	19/29 (65.5)	13/18 (72.2)	19/29 (65.5)	12/18 (66.7)
	≥100	4/29 (13.8)	4/29 (13.8)	4/18 (22.2)	4/18 (22.2)
		Inactive disease; n/N (%)		CRP, median; mg/L (n/N)	
Age group		Day 15	Day 85	Day 15	Day 85
Children		40/216 (18.5)	32/133 (24.1)	12.00 (211/216)	9.75 (168/216)
Adolescents		18/56 (32.1)	10/27 (37.0)	10.00 (55/56)	8.40 (45/56)
Adults		6/29 (20.7)	8/18 (44.4)	4.50 (26/29)	7.80 (23/29)

aACR, adapted American College of Rheumatology; CRP, C-reactive protein; JIA, juvenile idiopathic arthritis

**Table 2.** Safety: adverse events

	Children, n (%) N = 233	Adolescents, n (%) N = 60	Adults, n (%) N = 31
<b>AEs (at least one)</b>	202 (86.7)	53 (88.3)	27 (87.1)
<b>AEs leading to study drug discontinuation</b>	26 (11.2)	10 (16.7)	6 (19.4)
<b>AEs most common/special interest</b>			
Infections and infestations	176 (75.5)	42 (70.0)	23 (74.2)
Gastrointestinal disorders	122 (52.4)	32 (53.3)	18 (58.1)
Musculoskeletal and connective tissue disorders	119 (51.1)	33 (55.0)	16 (51.6)
Opportunistic infections	3 (1.3)	4 (6.7)	1 (3.3)
Neutropenia	11 (4.7)	2 (3.3)	0
<b>SAEs (at least one)</b>	81 (34.8)	25 (41.7)	9 (29.0)

AEs, adverse events; SAEs, serious adverse events

**Conclusion:** Pooled analyses indicate similar efficacy of canakinumab across all the age groups of children, adolescents and adult SJIA patients. There were no meaningful differences in safety profiles across the different age groups. These analyses suggest similar efficacy of canakinumab in AOSD patients as observed in the SJIA patients.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) comprises 7 ILAR categories, but systemic-onset JIA (sJIA) appears to be distinct in genetic background and pathogenesis from the other categories of JIA. The aim of this study is to investigate real-world therapeutic short-term responses in patients with sJIA starting tocilizumab (TCZ) or anakinra (ANK), the 2 most common biologics used currently for this ILAR category.

**Methods:** This analysis included patients with sJIA enrolled in the UK Biologics for Children with Rheumatic Diseases (BCRD) study starting TCZ or ANK from 01/01/2010 (study start date), with data available at baseline, 6 months and 1 year by 31/12/2016. Disease activity was assessed at baseline, 6 months and 1 year, including outcomes; minimal disease activity (MDA), clinically inactive disease (CID) and ACRPedi90. Univariable logistic regression was used to identify baseline characteristics associated with the outcomes. Multiple imputation was used to account for missing data.

**Results:** A total of 78 sJIA patients were included (54 TCZ; 24 ANK) (Table); 55% were female and 70% received this drug as their first biologic. Patients starting ANK had a shorter disease duration (0 vs 2 years;  $p=0.003$ ), and more had a history of macrophage activation syndrome (MAS) (38% vs 8%;  $p=0.002$ ). Response rates between the 2 drugs were similar. In the whole group, at 1 year, 54% achieved ACRPedi90, 47% MDA and 33% CID (Table). Mean JADAS-71 change was -14 ( $p<0.001$ ). No baseline characteristics were associated with achieving response. Nineteen (24%) patients stopped their biologic treatment by 1 year (Figure), for reasons including remission ( $N=1$ ), inefficacy ( $N=6$ ), adverse events ( $N=10$ , including one case of MAS in patient receiving TCZ) and unknown ( $N=2$ ). Treatment survival was better with TCZ (87% at 1 year vs 50% ANK), with 4 children stopping for injection-related problems.

**Conclusion:** In this real-world cohort of children with sJIA receiving TCZ or ANK, approximately half the patients achieved a significant clinical short-term response, and one-third achieved inactive disease within 1 year. Although numbers in this analysis are low, reflecting the rarity of sJIA, it is important to report these reassuring real-world outcomes and similarities in response with other JIA categories. As this UK JIA study continues to develop, future analyses investigating longer term tolerability and safety will be possible.

**Table:** Baseline characteristics and one year outcomes of 78 systemic JIA patients; 54 tocilizumab and 24 anakinra.

## Interleukin-1 Receptor Antagonist Is a Potential Treatment for Undifferentiated Autoinflammatory Syndromes

Ananta Subedi<sup>1</sup>, Daniella Schwartz<sup>2</sup>, Karyl Barron<sup>3</sup>, Daniel L. Kastner<sup>4</sup> and Amanda Ombrello<sup>5</sup>, <sup>1</sup>National Institute of Arthritis, Musculoskeletal and Skin Disease (NIAMS), Bethesda, MD, <sup>2</sup>NIAMS - Rheumatology, National Institutes of Health, Bethesda, MD, <sup>3</sup>National Institutes of Health, Inflammatory Disease Section, National Human Genome Research Institute, Bethesda, MD, <sup>4</sup>Inflammatory Disease Section, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, <sup>5</sup>Inflammatory Disease Section, NHGRI/NIH, Bethesda, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The autoinflammatory diseases (AIDs) are a group of disorders of the innate immune system characterized by seemingly unprovoked inflammation<sup>1</sup>. A variety of genetic alterations are attributed to the clinical and pathological manifestations of these conditions; however, many of the patients presenting with clinical features of AIDs do not have a pathogenic mutation to be

classified under one of the monogenic AIDs<sup>2</sup>. These patients are referred to as having an undifferentiated autoinflammatory syndrome. Blocking of the interleukin 1 (IL-1) pathway is defined as a treatment modality in some of the AIDs (FMF, CAPS, TRAPS and MVK); but, there is limited data on their use in undifferentiated autoinflammatory syndromes.

**Aim:** We aim to review the treatment effects of the IL-1 receptor antagonist, anakinra, in pediatric undifferentiated autoinflammatory syndrome patients.

**Methods:** We identified the pediatric patients enrolled in the protocol 94-HG-0105 "Genetics and Pathophysiology of Familial Mediterranean Fever and Related Disorders" who were prescribed Anakinra between October 2010 and October 2016. Patients who tested positive for known genetic mutation to cause periodic fever syndromes (FMF, CAPS, TRAPS, MKD, PAPA, DIRA, HA20 and DADA2) by commercially available methods were excluded. Medical records were reviewed to identify the response to treatment with Anakinra. Clinical response was determined based on the patient reported outcome. Laboratory data ((White Blood Cell Count (WBC), ESR and CRP)) were compared before and after the treatment. Statistical tests were done using RStudio (<http://www.R-project.org>). Clinical response to treatment were presented as frequency diagram. Laboratory data before and after the use of Anakinra was compared using the Wilcoxon signed rank test.

**Results:** We identified 75 patients who met the pre-specified criteria. Among the 75 patients, the majority of the patients were male (65%). The disease was predominantly seen among Caucasians (84%). Anakinra was prescribed as needed (PRN) for 56% of the patients, 44% required a daily dose. 59% of the patients were responders, 9% were partial responders and 17% did not have clinical response to the treatment. 13% of the patients were non-compliers, 1% could not tolerate and 1% of the patient did not have a follow up. Among the patients who had clinical response to treatment, we found a statistically significant decrease in ESR after treatment with anakinra (p-value = 0.01416, 95 percent confidence interval: 1.000085 8.999991).

**Conclusion:** The management of pediatric undifferentiated autoinflammatory syndromes is challenging. We found anakinra a very effective treatment option for use on both an intermittent and continuous basis. Anakinra has the potential to significantly improve the quality of life of such patients.

## **Evaluation of Efficacy and Safety of Opocalcium Colchicine, and Anti-IL1 Treatment in Childhood Colchicine-Resistant Familial Mediterranean Fever**

Kenan Barut, Amra Adrovic, Sezgin Sahin, Asli Kaplan and **Ozgur Kasapcopur**, Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The colchicine-resistant FMF (crFMF) is defined as 6 or more polyserositis attacks in the last year despite the regular usage of colchicine in the highest tolerable dose. IL-1 receptor antagonists have been shown to be efficient in crFMF. We tried to define the efficacy of opocalcium colchicine (OC), anakinra and canakinumab by FMF50 scores, complete and partial clinical responses.

### **Methods:**

Patients who were under OC, anakinra and canakinumab are considered to be resistant to standard colchicine treatment. The FMF50 score is used to define the response to treatment. Complete clinical and laboratory response is characterized by an absence of clinical features and normal laboratory findings. The partial clinical and laboratory response include 30 % improvement in clinical and laboratory features.

### Results:

A total of 839 FMF patients has been assessed and 49/839(5,8%) of them has been considered colchicine resistant. FMF50 response has been obtained in 4/49(8.2%) patients under standard colchicine treatment; in 14/30 (46.7%) patients treated with OC, in 5/6 (83.3%) with anakinra and in 12/13(92.3%) patients with canakinumab. The FMF50 response significantly differed according to treatment modality ( $p<0.005$ ). Clinical remission has been achieved in 10/30(33.3%), 5/6(83.3%) and in 11/13(84.6%) patients treated with OC, anakinra and canakinumab, respectively. Patients treated with OC significantly differed from those treated with anti IL-1 according to complete clinical remission ( $p<0.002$ ). Laboratory remission has been obtained in 7/30(23.3%), 4/6(66.7%) and 11/13(84.6%) patients treated with OC, anakinra and canakinumab, respectively. The laboratory remission was significantly different between patients treated with OC and with anti IL-1 ( $p<0.0001$ ).

The most common adverse effect was diarrhea in 17/49(34.6%), transaminases elevation in 3/49(6%) patients and leukopenia in 1 patient. Diarrhea was seen in 3/30(10%) patients under OC treatment. Local allergic reactions were seen in 3/6(50%) anakinra patients. One patient developed pneumonia while on canakinumab treatment; upper respiratory tract infection has been registered in 3/13(23%) patients and acute gastroenteritis in one patient. None of the patients developed severe adverse effect.

### Conclusion:

The FMF50 response has not been achieved in majority of patients under OC treatment, although their drug compliance was better comparing to standard colchicine compound in our country. Complete clinical remission has been obtained in minority of patients treated with OC. In contrary, FMF50 response, complete clinical and laboratory response have been detected in most of patients treated with anakinra and canakinumab. Both of anti IL-1 agents were safe and effective in crFMF patients.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Various infections play significant roles in flares of systemic lupus erythematosus (SLE). Hepatitis A virus is one of these infectious agents that has high endemicity particularly in developing countries. Hence, immunization via vaccination against this infectious agent would provide a better management of the disease. However, both immunosuppressive drugs and the disease itself are believed to impair the normal functioning of immune system. Little is known regarding the safety and immunogenicity of vaccinations in SLE patients. Moreover, to the best of our knowledge safety and efficacy of hepatitis A vaccination were not studied in children with SLE.

In the present study, we aimed to compare the antibody titers and seropositivity rates in juvenile SLE and healthy subjects after hepatitis A vaccination. Besides, we examined the effect of immunosuppressive drugs and disease activity on antibody responses.

### Methods:

Sixty-nine juvenile SLE patients were enrolled in the study. Initially, we evaluated anti-HAV IgM and anti-HAV IgG titers in juvenile SLE patients. Of the 69 subjects, 37 patients were seronegative and eligible for hepatitis A vaccination. Among them, 7 juvenile SLE patients refused to participate to the study. Finally, anti-HAV Ig G negative 30 patients and 39 healthy subjects were vaccinated with two doses of hepatitis A vaccine (at 0 months and at sixth months). After vaccinations, anti-HAV Ig G titers were measured and compared between two groups.

### Results:

Anti-HAV Ig G concentrations were measured after vaccination in 30 patients with juvenile SLE and 39 control subjects. Anti-HAV Ig G titer of the juvenile SLE patients was significantly lower than that of the healthy controls (median 4.6 *versus* 11.9 IU/L,  $p=0.02$ ). Although the rate of seropositivity was lower in juvenile SLE patients ( $n=24/30$ , 80%) compared to healthy controls ( $n=33/39$ , 84.6%); this was not statistically significant ( $p=0.6$ ). No adverse reaction was reported after vaccination.

### Conclusion:

Although anti-HAV Ig G antibody titers after vaccination have found to be somewhat lower than that of the healthy subjects, significant portion of juvenile SLE patients were seropositive. According to these results, we conclude that hepatitis A vaccine is adequately immunogenic and quite safe in juvenile SLE patients.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To validate the 2016 ACR/EULAR classification criteria of macrophage activation syndrome (MAS) complicating systemic juvenile idiopathic arthritis (s-JIA) in Japanese patients.

**Methods:** A combination of expert consensus and analysis of real patient data was conducted by a panel of 15 paediatric rheumatologists. Eighty-three profiles comprised 25 patients with s-JIA-associated MAS and 58 patients with active s-JIA without evidence of MAS. From these profiles, 19 points for full-blown MAS, 16 points for MAS onset and 58 points for acute s-JIA without MAS were evaluated.

**Results:** Evaluation of the classification criteria to discriminate full-blown MAS from acute s-JIA without MAS showed a sensitivity of 0.947 and specificity of 1.000 at the time of full-blown MAS. Sensitivity was 0.438 and specificity 1.000 at the time of MAS onset. The number of measurement items that fulfilled the criteria increased in full-blown MAS compared to that at MAS onset. At MAS onset, the positive rates of patients who met the criteria for platelet counts and triglycerides were low, whereas those for aspartate aminotransferase and fibrinogen were relatively high. At full-blown MAS, the number of patients who met the criteria for each measurement item increased.

**Conclusion:** The classification criteria for MAS complicating s-JIA had a very high diagnostic performance. However, the diagnostic sensitivity for MAS onset was relatively low. For the early diagnosis of MAS in s-JIA, the dynamics of laboratory values during the course of MAS should be further investigated.

## Longer Term Outcomes of Chronic Relapsing Multifocal Osteomyelitis in a UK Tertiary Adolescent and Young Adult Rheumatology Centre

Kristina E.N. Clark<sup>1</sup>, Francesca Josephs<sup>2</sup>, Nicola Daly<sup>3</sup>, Claire Louise Murphy<sup>3</sup> and Debajit Sen<sup>4</sup>, <sup>1</sup>Rheumatology, University college London Hospitals, London, United Kingdom, <sup>2</sup>rheumatology, UCL, London, United Kingdom, <sup>3</sup>Rheumatology, University College London Hospital, London, United Kingdom, <sup>4</sup>Adolescent Rheumatology Department, University College London Hospital NHS Trust, London, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Chronic relapsing multifocal osteomyelitis (CRMO) is a rare autoinflammatory bone condition presenting primarily in children & adolescents. It characteristically affects the epiphysis & metaphysis of long bones & presents with bony pain, local swelling & warmth.

The aim of this study was to collate our centre's experience of managing patients with CRMO & establish their longer term outcomes.

## Methods:

Our Centre provides a tertiary service for adolescents & young adults >13 years. We performed a retrospective case note review of all patients known to our service with a diagnosis of CRMO.

## Results:

We identified 17 (10 female) patients with CRMO presenting between 1999 & 2015. The median age of initial symptoms & age of presentation was 12 years. Median follow up duration 4.75 years (range 1-16.5 years).

On review of long term outcomes, several patients evolved into a different disease phenotype: 3 SAPHO (synovitis, acne, pustolosis, hyperostosis, osteitis), 3 ERA (enthesitis related arthritis) & 2 oligoarticular juvenile idiopathic arthritis (OJIA). The clinical phenotype of patients with SAPHO was predominantly multifocal (involving wrists, jaw, ankle & ribs), with one patient having disease of only the sternoclavicular joints. Of the ERA patients, 2 had sacro-iliac & clavicle involvement, 1 had initial femur involvement which has progressed to ERA around the hips. All patients with OJIA had ankle involvement, with 1 developing knee synovitis as well & 1 wrist & shoulder inflammatory arthritis.

Unifocal osteomyelitis was seen in 35% of patients & 65% multifocal as confirmed by whole body MRI. 70.5% patients had recurrent episodes of inflammation, while 29.5% had only one flare & then remitted (either clinical or confirmed with MRI). 15 patients had their diagnosis confirmed with biopsy, 2 did not due to site of disease being close to the growth line (diagnosis based on clinic impression & typical radiographic findings).

Multiple sites of disease have been confirmed in our patients & include lower limbs (70%), upper limbs (35%), clavicle (29.4%), mandible (17.6%) & spine/pelvis (23.5%).

All patients were treated with NSAIDs. During the course of the disease at any point 76% have been on methotrexate; 47% had one pamidronate infusion & 23% more than 1. Other medications include sulfasalazine, azathioprine, risedronate & anti-TNFs.

On last clinic review, 35% of patients have evidence of ongoing active disease

## Conclusion:

The perceived wisdom is that CRMO is a self-limiting disease which eventually goes into remission. However our Centre's experience is that nearly 50% of our patients have a disease which evolves into another systemic autoimmune disease (SAPHO, OJIA or ERA). This is more frequent in those with multifocal CRMO. Previous case series have suggested only 0-30% of patients' disease evolves. Our findings may be a reflection of our older cohort of patients.

The majority of patients have a recurrent and multifocal disease. The most common site of disease was in the lower limbs. All patients were treated with NSAIDs, a combination of DMARDs, bisphosphonates & biologic agents have been used, which has resulted in remission of disease in the majority of patients.

## Phenotype of Chronic Recurrent Multifocal Osteomyelitis in a Tertiary Referral Centre: The Great Ormond Street Hospital Experience

**Kulsoom Riaz**<sup>1</sup> and Sandrine Lacassagne<sup>2</sup>, <sup>1</sup>Paediatric Rheumatology/Gastroenterology, Great Ormond Street Hospital, London, United Kingdom, <sup>2</sup>Paediatric Rheumatology, Great Ormond Street Hospital, London, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Recurrent Multifocal Osteomyelitis (CRMO) is an aseptic inflammatory bone disease that typically affects the metaphases of the long bones. It affects children, adolescents and young adults. The main presenting feature is local bone pain and/or swelling. It has a protracted course for years with exacerbations and improvement with treatment. The diagnosis of CRMO can be made on clinical presentation and confirmed by magnetic resonance imaging (MRI) and bone biopsy. On MRI examination there are mostly multifocal, and symmetrical lesions (especially in the metaphysics of tubular long bones, flat bones and spine). CRMO can be associated with skin, gut involvement and other rheumatological conditions.

### Methods:

We reviewed reports of whole body MRI scans of 300 children, done in last 5 years between January 2012 and December 2016. Patients with MRI scan results consistent with CRMO were included in the study. Retrospective analysis of electronic clinical records of these patients was done and we recorded their clinical symptoms at presentation, any associated illnesses and Family history. Histopathological/ microbiological findings of bone biopsies were reviewed to rule out haematological, infectious or malignant causes.

### Results:

Twenty three patients were included in the study. Five were male and eighteen female. These children were 8-18 years old with median age of 15 years. The clinical features of CRMO at first presentation are as under. All patients presented with musculoskeletal symptoms like backache, clavicular involvement, or joint pain. Five patients (21%) presented with abdominal pain and blood in stool. These patients were diagnosed as Inflammatory bowel disease (IBD) on the endoscopic and histopathological findings. Three patients presented with gut symptoms first and later on they developed joint pain and swelling. However one patient presented with joint pain to start with and diagnosed as CRMO. This patient later on developed gut symptoms. One patient presented with simultaneous onset of diarrhoea, blood in stool, abdominal pain and joint pain with swelling. There is significantly more raised inflammatory markers in the IBD/CRMO group than in the CRMO alone group. History of trauma was present in 13% of patients who presented with musculoskeletal symptoms. Hyper mobility was present in four patients. Juvenile idiopathic arthritis was an associated diagnosis in three patients. One patient was diagnosed as Enthesitis related arthritis (ERA) and CRMO overlap. Psoriasis, palmoplantar pustulosis, acne, atopic dermatitis, dermatitis artefacta were the skin conditions associated with CRMO but not in IBD/CRMO overlap group. There was family history of connective tissue disorders in six (26%) out of 23 patients, including systemic lupus erythematosus, ankylosing spondylitis, Crohn's disease, rheumatoid arthritis, antiphospholipid syndrome and psoriasis. Only one patient (4%) out of 23 was HLAB27 positive.

### Conclusion:

CRMO has a varied presentation. We identified that CRMO is associated with IBD in 21% of the patients. Further studies are needed to identify whether the CRMO/IBD overlap group has a separate phenotype.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Some studies have suggested that chronic recurrent multifocal osteomyelitis (CRMO) and spondyloarthropathies (SpA) fall on a spectrum of disease, as they have been noted to share overlapping radiographic and clinical features. Most studies examining the link between inflammatory bone lesions and SpA have involved adult patients with SAPHO syndrome, with limited pediatric data. This study was done to test whether gender, HLA-B27 positivity, or age at onset of disease, influence whether and when pediatric CRMO and SpA patients develop overlapping features. Understanding of the clinical factors influencing overlap may have implications for earlier diagnosis, risk stratification, and treatment options.

### **Methods:**

This was a retrospective inception cohort study of SickKids hospital charts. Eligible pediatric patients diagnosed with either CRMO or SpA between January 2000 and December 2016 were collected using the SickKids Rheumatology patient database. Using a secure web application (REDCap), we collected and compared the clinical, laboratory, and radiographic data of 40 randomly sampled patients from each of the CRMO and SpA groups. The MRIs were re-read by a radiologist. A patient was considered to have an overlap diagnosis if they had radiologic and clinical features of both CRMO and SpA.

### **Results:**

7 patients (17.5%) and 8 patients (20.0%) from the CRMO and SpA groups, respectively, developed overlap. The median time to overlap was 36.0 months and 31.5 months, respectively. A survival (time-to-event) analysis, using the Kaplan-Meier approach, was used to show the proportion of patients without overlap features, since time of symptom onset. 28% of the entire sample population was HLA-B27 positive. Multivariable regression models using the Cox Proportional Hazards regression technique showed that the overall likelihood ratio test was not statistically significant ( $p=0.59$ ), with hazard ratios of 1.11, 0.91, and 1.17 for each of male gender, HLA-B27 positivity, and age at symptom onset, respectively.

### **Conclusion:**

Patient gender, HLA-B27 positivity, and age of symptom onset did not appear to increase the risk of developing overlap features of CRMO and SpA in our sample population. Nonetheless, overlap of clinical and radiologic features was found in approximately 20% of our patients. CRMO and SpA may represent two diseases on the same spectrum, though prospective studies with longer follow up are needed. Our study was limited by the small sample size and retrospective design, as it is unknown whether overlap may occur in the time exceeding clinical follow-up. Study of their clinical overlap is important to allow a better understanding of how to recognize and treat these rare diseases.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chronic nonbacterial osteomyelitis (CNO) is an autoinflammatory bone disease. For detection of active bone lesions, bone scintigraphy and magnetic resonance imaging (MRI) are much more sensitive than radiographs, but are more expensive and often require sedation for young children. A rapid and noninvasive imaging tool, infrared thermal imaging, was evaluated for its utility to detect active CNO lesions in extremities of children with CNO.

**Methods:** Children with suspected or established diagnosis of CNO in their lower extremities were enrolled. All subjects underwent infrared thermal imaging of both entire legs with four views each (anterior, posterior, medial, and lateral) and MRI examinations of their lower extremities. Relevant demographic, laboratory and clinical data were collected. Infrared thermal data were analyzed using custom software. Lower legs were divided equally into three segments longitudinally, and distal thigh was defined as the same length of proximal lower leg (**Figure 1**). Median and 95<sup>th</sup> percentile temperatures were recorded for each leg segment. MRI examinations were graded by a blinded pediatric musculoskeletal radiologist to determine the presence of bone edema as confirmation of inflammation within each segment. Temperature differences between inflamed and uninflamed extremities were evaluated using mixed-effects regression models.

**Results:** Nineteen children with MRI-confirmed CNO in their lower extremities were enrolled, **Table 1**. Overall, 26 distal, 2 mid (excluded from analysis), 18 proximal lower leg and 12 distal thigh lesions were detected on MRI. Inflamed distal lower leg segments had significantly higher median and 95<sup>th</sup> percentile temperatures than uninflamed counterparts ( $p < 0.01$  in all views). The mean difference between two groups ranged from 0.7<sup>0</sup>C to 1.7<sup>0</sup>C, with the greatest difference from medial view (**Figure 2**). Distal thigh and proximal lower leg temperatures did not differ between inflamed and uninflamed legs from any view.

**Conclusion:** Children with active CNO lesions in the distal lower leg exhibited higher regional temperatures versus healthy limbs. Further research is needed to evaluate infrared thermal imaging as a convenient and cost-effective tool to identify patients needing additional evaluation by MRI.

**Table 1.** Demographic information of children with MRI-confirmed active CNO lesions

Population	Children with CNO (n=19)
	N (%) or Median (range)
Age (y)	10.2 (5.8-14.1)
Gender, F	9 (47%)
Race, Caucasian	17 (89%)
Height (cm)	138.6 (118.6-159.5)
Weight (kg)	35.1 (21.3-46.5)
Number of CNO lesions	3 (1-6)
Current medications	10 NSAIDs, 2 CS, 4 MTX, 4 Biologic, 1 PAM
Patient pain score	3 (0-7)
CHAQ score	0.4 (0-1.8)
Physician global assessment	2 (1-5)
ESR (mm/hr)	12 (5-34)
CRP (mg/dL)	0.8 (0.8-3.3)

NSAID: non-steroidal anti inflammatory drug; CS: corticosteroid; MTX: methotrexate; PAM: pamidronate

Figure 1. Illustration of thermal analysis

- Mark the edge of knees and ankles, divide lower leg into 3 equal segments
- Then add the same segment length above the knee as distal thigh
- R1: proximal lower leg
- R2: mid lower leg
- R3: distal lower leg
- R4: distal thigh

Figure 2. Box plots of median temperatures from each leg segment in medial view, grouped by the status of inflammation.

## Controlled Discontinuation of Colchicine Therapy in Familial Mediterranean Fever Patients with Single MEFV Mutation

Yonatan Butbul Aviel<sup>1</sup>, Shafe Fahoum<sup>2</sup> and Riva Brik<sup>3</sup>, <sup>1</sup>Department of Pediatrics B Pediatric Rheumatology Service, Ruth Rappaport Children's Hospital, Rambam Medical Center, Haifa, Israel, Haifa, Israel, <sup>2</sup>Department of Pediatrics B,, Ruth Children's Hospital, Rambam Medical Center, Haifa, Israel, Pediatric Rheumatology Service, .Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel, <sup>3</sup>Pediatrics, Rambam Medical Center, Haifa, Israel

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Familial Mediterranean fever (FMF) traditionally has been considered an autosomal recessive disease; however, the diagnosis remains predominantly clinical, since mutations cannot always be identified on both alleles.

The aim of our study was to evaluate cessation of colchicine therapy in selected group of patients with FMF who possess only 1 or none demonstrable MEFV mutation.

### **Methods:**

We performed a prospective controlled study evaluated cessation of colchicines therapy in patients that were previously diagnosed and treated for FMF based on clinical features and did not carry any common MEFV mutation or were heterozygote for one of the mutations .

Patients were included in the study if they were between the age of 2-18 years and were treated with colchicine, had a normal level of serum amyloid A (SAA )and had at least 6 months free of FMF attacks.

SAA levels were evaluated before colchicine cessation and at 3 and 6 months following cessation. Colchicine therapy was resumed in case of FMF attacks reappeared during this period.

### **Results:**

thirteen patients ages 10.6±4 years enrolled in the study. Prior to entering the study patients were treated with colchicine for an average of 36.3 month ( 7-141 months median 31 months ). The average time with no FMF attacks before enrolment into the study was 12.8±8.6 months and the average follow up after stopping colchicine therapy was 16.3±6 months . Five patients were heterozygote for the M694Vmutation four patients were heterozygote for E148Q two patients had other mutations and two patients had no mutations .

Five patients (41.6%) had an FMF attack during follow up and needed to renew colchicine therapy, the average time to renew colchicine therapy was 5.3 months (range 1.5-11.4 months) 3 of them (60%) carried the M694V mutation.

There were no differences between the groups of patients that did not relapse and the groups that needed to renew therapy regarding age (10.7±1.6 vs 10.6±6.3 p= 0.97) or levels of SAA at time of enrolment (4±3.6 vs 3.3±2.4 p=0.7). Length of colchicine therapy prior to enrolment showed tendency that didn't reach significance towards longer time in the patients needed to resume therapy (22.3±12.6 vs 53±51 months p=0.18) .

### **Conclusion:**

Cessation of colchicine therapy in selected group of patients who are not homozygous for the common MEFV mutation should be considered. Monitoring SAA levels every 3 months could not predict FMF attacks following cessation of colchicine therapy.

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** AIDAI is a novel, validated tool for the assessment of disease activity across a wide spectrum of autoinflammatory diseases including recurrent fever syndromes such as familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and TNF receptor-associated periodic syndrome (TRAPS).<sup>1</sup> Canakinumab (CAN), a fully human anti-interleukin-1 $\beta$  monoclonal antibody, has demonstrated efficacy in resolving flares and preventing new flares in RFS patients (pts) through CLUSTER study (NCT02059291).<sup>2</sup> Here we evaluate AIDAI scores over 16 weeks (wks) of CAN treatment in pts from CLUSTER study and assess correlation between AIDAI and disease/response characteristics.

**Methods:** CLUSTER study consisted of 3 cohorts (crFMF, HIDS/MKD and TRAPS).<sup>2</sup> AIDAI was calculated as the sum of 12 items (Yes=1 or No=0)<sup>1</sup> for 30 consecutive days. AIDAI score was calculated if the first score was recorded before  $\geq 29$  days. Missing AIDAI scores between first and last assessments were imputed with 'No'. Missing items beyond last evaluable measurement were imputed by last observation carried forward (LOCF). Proportion of pts with inactive disease (ID; AIDAI score  $< 9$ ) was calculated at Wk 16. Correlation analysis of AIDAI with C-reactive protein (CRP), serum amyloid A (SAA), physician global assessment (PGA), Sheehan disability score (SDS), child health questionnaire–psychological/physical (CHQ–PsCS/PCS) and short form 12–physical/mental component summaries (SF12–PCS/MCS) were performed at baseline and Wk 16, with significance set at  $p < 0.05$ .

**Results:** Overall, 181 (crFMF, N=63; HIDS/MKD, N=72; TRAPS, N=46) pts were randomized to CAN 150 mg or placebo every 4 wks. Median AIDAI scores in all 3 cohorts decreased from baseline to Wk 16 (Figure 1). The proportion of pts with ID at Wk 16 was 52% in crFMF, 40% in HIDS/MKD and 46% in TRAPS cohort. AIDAI at Wk 16 correlated significantly with: SDS in all 3 cohorts; PGA in HIDS/MKD and TRAPS; SF12–MCS in crFMF and HIDS/MKD (Table 1). CRP and SAA did not correlate with AIDAI.

**Conclusion:** Decrease in AIDAI scores over 16 weeks in crFMF, HIDS/MKD and TRAPS patients treated with canakinumab corroborates rapid and sustained disease control with canakinumab in CLUSTER study. At Week 16, approximately half of the crFMF and TRAPS patients, and 40% of the HIDS/MKD patients had inactive disease. AIDAI improvements at Week 16 correlated with patient and physician driven evaluations (PGA, SF12–MCS and SDS). CRP and SAA are indicators of response to treatment rather than a disease activity parameter.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Periodic Fever Syndromes (PFS) are a rapidly expanding group of disorders primarily of the innate immune system that often affect the inflammasome. In our previous report (ACR 2014 Annual Meeting), we detailed 30 patients with about 1/3 with Periodic Fever, Aphthous Stomatitis, Pharyngitis and Adenopathy (PFAPA), 1/3 with a genetically defined PFS, and 1/3 unclassifiable. We now report with improved genetic testing (Medical Neurogenetics NextGen PFS Panel – 37 genes) novel phenotypic expressions of genetically determined PFS in 15 patients.

**Methods:** Case acquisition was performed by three methods: 1) review of ICD 9/10 coded records for Familial Mediterranean Fever (ICD 9 277.31); 2) laboratory test records for PFS genetic screening; and 3) clinic records between 1/1/2011 and 12/31/2017 after receiving approval from the Institutional Review Board for a de-identified retrospective case analysis.

**Results:** Twenty seven cases (12 female and 15 male) were obtained that underwent extensive clinical evaluation including PFS genetic screening. Clinical diagnoses included FMF (10), Muckle Wells (2), TRAPS (4), and HIDS (1). Other diagnoses included Crohn's (1), SoJIA (1), FUO (1), PFAPA (6), and cold induced urticaria (1). Of these 27 cases, 15 were subsequently associated with a genetic cause. Seven of the 10 FMF cases were confirmed genetically, all of whom were either heterozygous or compound heterozygotes. Both cases of Muckle Wells had non classical genetics – one was a compound heterozygote for CIAS 1, and the other had a mutation in the NOD gene. Both TRAPS cases were atypical – one was asymptomatic, and the other developed SLE. Two patients had novel syndromes. One TRAPS patient had a mutation in the TNFRSF-1A gene who eventually remitted with IVIG after failing multiple drugs. The other had SoJIA with a mutation in the LPIN 2 gene but responded to colchicine. Only 1 of the 15 genetically proven cases had a classical presentation and classical genetics (HIDS secondary to a mutation in the MVK gene).

**Conclusion:** Most patients presented atypically both from a clinical and genetic standpoint, making treatment challenging and difficult. Genetic testing with PFS screen was helpful in over ½ of the cases to develop therapeutic treatment plans. Given the atypical clinical presentations seen with genetically determined PFS, extensive genetic testing is indicated for all patients presenting with a PFS except those with a classical PFAPA syndrome.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

COPA syndrome is a newly discovered primary immunodeficiency resulting in immune dysregulation showing autosomal dominant inheritance with incomplete penetrance. Its name is derived from the mutation of the gene encoding for the alpha subunit of the coatomer complex-I that is responsible for transportation of molecular cargo from the Golgi to the Endoplasmic Reticulum. Previously, studies have elucidated the molecular mechanisms responsible for the disease phenotype. Clinical features of COPA syndrome primarily included pulmonary disease (interstitial lung disease, pulmonary hemorrhage), musculoskeletal (MSK) manifestations, autoantibody formation and renal disease. Here we aim to review and describe the MSK features of this newly defined disorder.

### Methods:

After IRB approval, we reviewed the MSK manifestations of patients with COPA mutation, as to characteristic nature, physical findings and diagnostic features. The clinical course of a family from this cohort, that was followed at our institution, was described.

## Results:

The previously reported cohort included 21 patients with 62% female. The mean age at presentation was 3.5 years with a range of 6 months to 22 years. Joint pain was present in 24% of patients at initial presentation and joint complaints were mostly intermittent in nature. Findings of arthritis were described in 95% of patients involving both small and large joints along the clinical course, often with polyarticular disease. Most commonly affected joints included the knees, and the interphalangeal joints of the hands. Two patients had osteonecrosis along the femur, patella and tibiofibula. Fatty necrosis was noted in one patient. Notably, presence of autoantibodies was a prominent feature of this disorder: rheumatoid factor (43%), ANA (67%), and ANCA/MPO/PR-3 (71%).

The most common diagnosis included Rheumatoid Arthritis, Juvenile Idiopathic Arthritis and undifferentiated arthritis. Arthralgia exacerbation was found to mirror pulmonary disease flare. Joint manifestation had varying response to NSAID, steroids, methotrexate and anti-TNF therapy. Multimodal anti-inflammatory, immunolytic and immunomodulatory therapy indicated for the severe pulmonary and renal features did not provide prolonged remission of arthritis.

**Table 1: COPA patients from single family carrying the R235H mutation**

Patient	Sex	Age at disease onset (y)	Age at arthritis onset (y)	Ethnicity	MSK features at presentation	Type of arthritis
1	M	2	4	Caucasian	Knee arthritis	Polyarticular
2	F	1.25	Unknown	Caucasian	Ankle, wrist arthritis	Polyarticular
3	M	12	12	Caucasian	Shoulder arthritis	Polyarticular
4	F	4	9	Caucasian	Wrist, ankle arthritis	Polyarticular

## Conclusion:

Musculoskeletal manifestations are a prominent and important feature of COPA syndrome. Due to similarities in clinical features it is difficult to differentiate COPA arthritis from other inflammatory arthropathies of systemic immune mediated disorders.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** H Syndrome is an autosomal recessive disorder characterized by cutaneous hyperpigmentation, hypertrichosis, and induration with numerous systemic manifestations. The syndrome is caused by mutations in *SLC29A3*, a gene located on chromosome 10q23, which encodes the human equilibrative transporter 3 (hENT3). Less than 100 patients with H syndrome have been described in the literature, with the majority being of Arab descent, and only a few from North America. Here we report five pediatric patients from three medical centers in the United States who were identified to have H syndrome by whole exome sequencing as well as their response to treatment.

**Methods:** All five patients presented to pediatric rheumatologists prior to diagnosis and include two of Northern European descent, bringing the total number of Caucasian patients described to three. Cases were discussed and compared in order to gather more data on H Syndrome and optimize treatment regimens.

**Results:** The patients were found to share many of the characteristics previously reported with H syndrome, including hyperpigmentation, hypertrichosis, short stature, insulin-dependent diabetes mellitus, arthritis and systemic inflammation, as well as some novel features, including selective IgG subclass deficiency and autoimmune hepatitis. They share genetic mutations previously described in patients of the same ethnic background, as well as a novel mutation. In two patients, treatment with prednisone improved inflammation, however both patients flared once prednisone was tapered. In one of these patients, treatment with tocilizumab alone resulted in marked improvement in systemic inflammation and growth. The other had partial response to prednisone, azathioprine, and TNF inhibition; thus, his anti-TNF biologic was recently switched to tocilizumab due to persistent polyarthritis. Another patient improved on Methotrexate, with further improvement after the addition of tocilizumab.

**Conclusion:** H syndrome is a rare autoinflammatory syndrome with pleiotropic manifestations that affect multiple organ systems and is often mistaken for other conditions. Rheumatologists should be aware of this syndrome and its association with arthritis. Some patients respond to treatment with biologics alone or in combination with other immune suppressants; in particular, treatment of systemic inflammation with IL-6 blockade appears to be promising. Overall, better identification and understanding of the pathophysiology may help devise earlier diagnosis and better treatment strategies.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Background/Purpose:** Crude prevalence estimates indicate Down syndrome arthropathy (DA) is 3-8 times more common than juvenile idiopathic arthritis (JIA), however, DA is still largely under recognized, and has a 2 year average delay from onset of symptoms to diagnosis. The majority of patients with DA present with greater than 5 affected joints, with small joints affected more predominantly. Additionally, treatment can be challenged by lack of efficacy and intolerance. Further, gaps in literature exist around optimal treatment approach and outcomes. The objective of this study was to investigate treatment approach and outcomes of DA at our institution.

**Methods:** In a retrospective chart review, potential DA patients were identified through electronic medical record system (EMR) from January 1, 1995 to December 31, 2015. ICD-9-CM codes were used to identify patients (less than 18 years of age) with both Down Syndrome (DS; 758.0) and JIA (714.3, 714.31, 714.32, 714.33). Individual charts were then manually reviewed to confirm diagnosis of DS and JIA. Chart review included analysis of all documents found in the EMR, including clinical visits and treatment data.

**Results:** Of 26 identified patients, (3 did not have DS and 2 had incomplete records) 21 met inclusion criteria and were analyzed. Patients were 62% female with polyarticular, RF negative presentation at diagnosis and had a mean (SD) follow-up of 4 ( $\pm$ 4) years. There was a 19 month ( $\pm$ 16) mean delay in diagnosis of arthritis from symptom onset, and at diagnosis of arthritis, 71% had morning stiffness with an average of 14 ( $\pm$ 10) active joints, 12 ( $\pm$ 10) limited joints, and mean physician global of disease activity (MD PGA) of 4.9 ( $\pm$ 2). All patients were started on nonsteroidal anti-inflammatory drugs (NSAIDs) at diagnosis with 33% simultaneously starting a disease modifying antirheumatic drug (DMARD), and 5 % a Biologic. Over the course of disease, 62% used a DMARD (57% MTX) and 48% used a biologic (90% etanercept). Six patients (29%) had at least one change in DMARD and another six patients had at least one change in biologic therapy (Table 1). Compared to diagnosis, at the last recorded visit there was a significant decrease in mean (SD) active joints: 3 ( $\pm$  4), limited joints: 5 ( $\pm$  6) and MD PGA: 1.7 ( $\pm$  1.6) ( $p$ <0.01 respectively). Of those on DMARD therapy 54% had drug discontinuation due to side effects and 56% had an inadequate response to first-line biologic therapy.

**Conclusion:** Down syndrome arthropathy remains under recognized despite reports of higher prevalence compared with JIA. Although treatment approach is unclear, DA patients have significant improvement in the number of active and limited joints with NSAID, DMARD, and biologic therapies. Other barriers that inhibit optimal treatment and outcomes are DMARD toxicity and lack of anti-TNF effectiveness. More research is needed to determine the timing and choice of optimal therapy in patients with Down syndrome.

## Down's Arthritis (DA) – Clinical and Radiological Features of Arthritis in Children with Trisomy 21

**Charlene Foley,** Emma Jane Mac Dermott and Orla Killeen, National Centre for Paediatric Rheumatology, Our Lady's Children's Hospital Crumlin, Dublin, Ireland

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Down's Arthritis (DA) was first reported in the literature in 1984. Crude estimates suggest higher incidence and prevalence rates of DA compared with Juvenile Idiopathic Arthritis (JIA), (JIA prevalence 1/1000, estimated DA prevalence 8.7/1000). Despite this fact, there remains a paucity of data on this condition. DA is rarely recognised at onset, & remains under-diagnosed. As a direct consequence children with DA are presenting with significant joint damage and disability at diagnosis. Our aim was to perform a musculoskeletal examination on children with Trisomy 21 (T21) aged 0-20 years, looking specifically for features of undiagnosed arthritis. We also wanted to better define the disease in terms of its clinical and radiological features.

**Methods:** Children with T21 were invited to attend a screening clinic. Screening involved completion of a health questionnaire and a comprehensive musculoskeletal examination. DA cases detected were investigated & managed as per normal clinical practice. Data on a convenience sample of 33 newly diagnosed children with JIA was collected to create a comparison group.

**Results:** 503 children with T21 were screened for DA and 22 new cases identified. All of these children had poor language skills or were non-verbal. Only 11% of the parents suspected that their child may have arthritis prior to attending our screening clinics, and this was only after reading our recruitment literature. In total, we now have 33 children attending our centre with DA (combining cases attending pre-dating the start date of the study). This suggests the prevalence of DA in Ireland is 18-21/1000.

The majority of children presented with a polyarticular RF negative pattern of disease. No cases of uveitis have been observed to date. Small joint involvement of the hands was observed in 88% of the DA cohort, significantly higher than in the JIA comparison group (43%,  $p < 0.01$ ). Erosive changes were reported on X-Ray in 29.2% of the DA cohort (9.5% in the JIA Cohort). Methotrexate-associated nausea was a significant barrier to treatment with this DMARD in DA. There was a significant delay in diagnosis of DA, 1.7 years (0.2-4.9yrs) versus 0.7 years (0.2-2.4yrs) in the JIA cohort.

**Conclusion:** Children with T21 are at increased risk of developing arthritis. There is a lack of awareness of this risk among health care professionals & the general public at large. This almost certainly contributes to poor recognition of the disease and a delay in diagnosis. The predominant pattern of disease is polyarticular small joint arthritis. Treatment with standard protocols used in JIA is complicated by drug-associated side effects in children with T21. However, a good response to treatment with steroid intra-articular joint injections and anti-TNF therapy has been observed. Our study has raised a number of questions. Our on-going research aims to accurately define this disease in terms of its immunological, histopathological and genetic basis, & identify best practice with regards to treatment. We advocate that all children with T21 should have an annual musculoskeletal examination as part of their health surveillance programme.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Down's Arthritis (DA) is an inflammatory joint condition affecting children with Down syndrome (DS). It is 18-21 times more common than JIA in the general paediatric population (JIA prevalence 1/1000). Children with DA usually present with a poly-articular, RF negative pattern of disease, with predominance in the small joints of the hands & wrists. Despite it's higher prevalence, a significant delay in diagnosis is frequently observed. Joint laxity & hypotonia are almost universal in children with DS, contributing to an increased risk of a number of musculoskeletal disorders & degenerative joint disease. Clinical signs & symptoms may not always help differentiate between inflammatory joint disease & joint hypermobility. We aim to report the radiological features described by a Paediatric Musculoskeletal Radiologist (PMR) when reviewing hand & wrist radiographs in a cohort of children with DA.

**Methods:** A retrospective review of all hand & wrist radiographs in a convenience sample of 19 children with DA was undertaken by a PMR. Bone age, carpal & metacarpal bone abnormalities were documented, as were corresponding clinical findings following musculoskeletal examination by a Paediatric Rheumatologist. Wrist MRIs were performed on 4 of the 19 children. The results of these studies were also included in our report.

**Results:** 18/19 children (10/19 (53%) Female; Average Age 13yrs (0.8-19yrs); 100% Full Trisomy 21 genetics) had radiographs of their hands & wrists. Bone age was below chronological age in 5 (28%) of the cohort imaged. Time to DA diagnosis from symptom onset was known in 8/19 children & on average was 1.8 years (0.14-4.9 years). Over half (63%) of the cohort were detected through a musculoskeletal screening programme offered to children with DS & not from direct referral to the Tertiary Rheumatology Centre. On musculoskeletal examination the most commonly affected joints, 95% of cases, were the PIP joints, followed by the wrists (68%), knees (58%), toes (37%) & MCP joints (32%). The average joint hypermobility score using the Beighton system was 2 (0-6).

Radiograph & MRI review highlighted a range of carpal & metacarpal bone abnormalities. The most common abnormality was crowding of the carpal bones with associated degenerative disease (63%). The earliest sign of degenerative disease was observed in a child aged 10 months whose MRI with gadolinium contrast demonstrated synovial enhancement of the proximal carpal row. The second most common finding (42%) was scalloping of the base of the first metacarpal. Other less frequent features identified (5% of cohort) included carpal pits, tuft irregularity & dactylitis. Bone erosions were evident on plain film in 50% of the cohort.

**Conclusion:** Radiographic carpal & metacarpal bone changes appear to be prevalent in DA & do not always correspond to clinical signs & symptoms. Undetected, these features can have a significant functional impact. If detected & managed in a timely & appropriate manner, irreversible joint damage & long-term sequelae could be avoided. These results support the importance of access to a specialist PMR & MRI. Our plan now is to compare these results with two separate cohorts; children with JIA & children with DS with no evidence of inflammatory arthritis.

## **Immunogenicity of 13 Valent Pneumococcal Vaccine in Children with Lupus: Single Center Experience in South Texas**

Elissa Gonzalez, Joe Cole and **Mark Gorelik**, Pediatrics, Baylor College of Medicine/Children's Hospital of San Antonio, San Antonio, TX

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pneumococcal vaccination is an important part of the care of pediatric and adult patients with systemic lupus erythematosus, and is recommended as a quality indicator for management of children with SLE. Literature on the immunogenicity of pneumococcal vaccines in children is scant. As part of a quality improvement project to increase the rates of pneumococcal vaccination in our center, we sought to evaluate immunogenicity to the 13-valent pneumococcal vaccine in our patients with lupus, and also to identify patients that may be at higher risk of infection due to non response.

**Methods:** Patients undergoing vaccination with 13-valent pneumococcal vaccine had pre-vaccination antibody levels to serotypes obtained when possible, and then post-vaccination antibody levels were obtained 4 weeks after vaccination. The percentage and number of patients with pre and post vaccination protective levels (defined as >70% serotypes  $\geq$  1.3 mcg/dl) were evaluated. Medication status, disease activity and demographic information was obtained from these patients as well.

**Results:** 15 patients had pre and post pneumococcal antibody levels available for evaluation, and a further 5 had post pneumococcal antibody levels only. 5 of 15 patients had pre-vaccination protective levels of pneumococcal antibody despite no known previous vaccination. 8 of 10 patients with both pre and post pneumococcal antibody levels available demonstrated conversion to protective status, while 2 did not; a further 3 of the 5 patients who had post pneumococcal levels only available did not demonstrate achievement of protective levels. Thus in total, 15 of 20 patients achieved protected status. Patients not achieving protected status had a higher rate of recent rituximab or higher dose mycophenolate treatment, while patients with previous cytotoxin exposure generally achieved protected status.

**Conclusion:** While the 13-valent pneumococcal vaccine achieves protective status for a majority of pediatric lupus patients, a significant number of these patients do not achieve this status after this vaccine. Further evaluation for responses after 23-valent vaccination is ongoing, but these results suggest that patient responses to vaccination may be important to evaluate in order to identify patients that are at higher risk of future infection.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Hepatitis B infection remains a significant public health challenge, particularly for patients on chronic immunosuppressive therapy, due to a considerable mortality risk associated with hepatitis B reactivation. Serologic screening for immunocompromised patients should include hepatitis B surface antibodies (anti-HBsAb) to assess for immunity, hepatitis B core antibodies (anti-HBcAb) and hepatitis B surface antigen (HBsAg) to evaluate for acute or chronic infection. Our primary aim was to determine the burden of non-immunity against hepatitis B, provide insight into factors leading to lack of immunity against hepatitis B and establish the basis for the need for universal screening of these patients. Secondly, we determined serologic response to a single hepatitis B vaccination booster.

### Methods:

Subjects are patients seen at the rheumatology and inflammatory bowel disease (IBD) clinics who are immunocompromised. We use a clinical algorithm as part of standard practice to check hepatitis B serology in immunocompromised patients, offer a booster vaccination if needed, and then repeat serology to determine the response. The results of anti-HBsAb are reported as positive, negative or indeterminate. Immunity is defined as a positive result for anti-HBsAb. An indeterminate or negative result for anti-HBsAb is non-immune. A retrospective chart review was performed to collect demographic and clinical factors as well as serology results. Descriptive statistics were calculated for all variables. R software was used to perform all analyses. For continuous variables, mean and standard

deviation are reported, and comparisons were calculated using two-sample t-tests. For categorical variables, frequency and percentage are reported, and comparisons were calculated using chi-square tests.

Results:

A total of 502 patient charts of immunocompromised patients were reviewed, 280 rheumatology and 222 IBD. Out of the 502 patients, 70% were non-immune (anti-HBsAb negative/indeterminate) (see Table). The highest portion of non-immune patients were those between the ages of 16-20 years (p=0.005) There was no clinically significant difference between immune and non-immune patients with regards to diagnosis (p=0.69), age at the start of treatment (p=0.72) or type of medications. A total of 196 non-immune patients received a booster dose of hepatitis B vaccine and 61 (72%) of those re-screened developed a positive anti-HBsAB. Of note, one patient was identified with a previously unknown chronic hepatitis B infection (anti-HBcAb positive).

Conclusion:

A majority of patients had non-immune hepatitis B serology. Lack of serologic immunity is highest at 16-20 years. A majority of patients developed positive anti-HBsAb following booster vaccination. Results support serologic screening for hepatitis B in immunocompromised patients.

Table. Clinical characteristics by immune status

	Non-immune (anti-HBsAb -) (n=349)	Immune (anti- HBsAb +) (n=153)	P-value

## **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Vaccine-preventable infections, including reactivation of hepatitis B virus, are a leading cause of morbidity and mortality in immunocompromised patients. Guidelines recommend that all immunosuppressed patients should be screened with hepatitis B serologies for active or chronic infection as well as need for repeat vaccination. Previously at our center, we have implemented hepatitis B serology screenings for patients on intravenous biologics and pneumococcal vaccines for all immunocompromised patients. The aim of this intervention was to adapt these processes to hepatitis B serology screenings and vaccinations for all immunocompromised pediatric rheumatology patients.

**Methods:** The Model for Improvement was used to form a team, map the process, construct a key driver diagram, and develop an algorithm (Figure 1). Eligible patients included those over 7 years identified as immunocompromised using a validated algorithm in the electronic health record (EHR). A series of Plan-Do-Study-Act (PDSA) cycles were performed to test and implement the multi-step process. After building an electronic order-set in the EHR, we adopted the process of clinic staff pending needed orders during pre-visit planning. We also provided education and developed “talking points” for clinic staff and providers. **Results** were tracked on a statistical process control chart weekly, and failures were identified through Pareto analysis.

**Results:** The intervention began in December 2016 at a tertiary care pediatric rheumatology clinic. Prior to start, a subset of patients had previously received screenings and vaccines due to an initial process for patients on intravenous biologics. However, by systematically adopting interventions, we were able to rapidly and reliably achieve our goal performance (Figure 2). There were few failures for the serology screenings from orders not signed. Failures for vaccine administration included deferred, primary care preference, refusal, leaving before vaccine, and vaccine orders not signed. To date, we have screened 862 patients and administered 302 booster vaccines.

**Conclusion:** By adapting processes that were previously successful in our clinic setting, we were able to reliably implement a hepatitis B serology screening and vaccination program over a short time-frame. Next steps include sustainability planning and spread to other clinics with immunocompromised patients. The results of this project support the importance of adoption and spread of successful processes in order to expedite improvement in quality of care.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Autoinflammatory Disorders and Miscellaneous

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) is one of the most frequent and most disabling rheumatic diseases in childhood. Children suffering from JIA receiving immunosuppressive and genetically engineered biological agents belong to the high risk group for the development of bacterial and viral infections, including those managed by vaccine preventive means.

**Objectives:** To evaluate the effectiveness of vaccination of 13-valent pneumococcal polysaccharide vaccine (PPV) in children with JIA for the level of specific anti-pneumococcal antibodies (anti-SPP) IgG for *Streptococcus pneumoniae* in the blood serum in patients with JIA before and after vaccination, as well as by recording the number of infections of the upper respiratory tract and pneumonia.

**Methods:** In a prospective, open comparative study, the effectiveness of vaccination was determined by the level of specific anti-pneumococcal antibodies (anti-SPP) IgG to *Streptococcus pneumoniae* in serum in patients with JIA, as well as by the number of adverse events, the number of infections of the upper respiratory tract and pneumonia. An open prospective comparative study was conducted, which included 42 children with JIA: 21 children with JIA in the active stage of the disease, 21 - in remission of the disease. Vaccination with 13-valent conjugated PPV vaccine was carried out once in a dose (0.5 ml) subcutaneously, against the background of therapy of the underlying disease with methotrexate or etanercept, or 3 weeks before the appointment of methotrexate or etanercept.

### Results:

The study included 42 children with JIA: 21 with JIA in the active stage of the disease, 21 - in remission of the disease. As a result of vaccination of all patients, an increase in the level of anti-pneumococcal antibodies (anti-SPP) IgG in children with JIA in the active stage was observed from 23.9 to 51.6 mg /l, with JIA in the remission phase from 26.1 to 73.0 mg /l ( $p = 0.005$ ). Episodes flare of JIA were not detected in any subject patient. Analysis of the frequency of ENT organs infections (otitis, rhinitis, sinusitis, tonsillitis, adenoiditis) and lower respiratory tract before and 12 months after vaccination showed a statistically significant decrease in the incidence rate. In the JIA group at the stage of remission of the disease, this index was 4 (3, 7) cases per year, after vaccination, it was reduced to 2 (1, 2) ( $p = 0.001$ ). A similar situation was observed in the group of children with exacerbation of the disease: before the vaccination, the median number of cases of infection with ENT organs was 4 (3, 4); within 12 months after the vaccination, the index decreased to 1 (1, 2) cases ( $p = 0.001$ ). Pneumonia and / or bronchitis for 1 year after vaccination are not registered in any patient. Serious adverse events were not recorded during the study.

**Conclusion:** Thus, vaccination of 13-valent PPV of 13 PPV of children with JIA in the remission phase receiving MT or etanercept and children in the acute stage prior to the initiation of immunosuppressant or GIBP is highly effective, and is not accompanied by exacerbation / increase in the activity of the disease and the development of serious undesirable phenomena.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Synovial tissue macrophages (STMs) are critical in the pathogenesis of rheumatoid arthritis (RA). During homeostasis, the majority of murine synovial tissue resident macrophages (TRMs) are MHCII<sup>-</sup>Ly6C<sup>-</sup> and TRMs in other tissues are F4/80<sup>hi</sup>. In our novel CD11c-Flip-KO (HUPO) mouse model of RA, erosive, progressive arthritis develops spontaneously. This study examined the F4/80<sup>hi</sup> subsets of ankle macrophages from HUPO mice with arthritis and littermate controls.

### Methods:

Arthritis was evaluated by clinical score. Cell types within the ankle joints were determined by flow cytometry. STMs were defined as CD45<sup>+</sup>CD11b<sup>+</sup>CD64<sup>+</sup>F4/80<sup>+</sup>, which were further grouped into subsets according to the expression of F4/80, MHCII and Ly6C. Subsets of F4/80<sup>hi</sup> STMs were isolated for RNAseq.

### Results:

All STMs that are F4/80<sup>hi</sup> were also Ly6C<sup>-</sup> in both HUPO and control mice. In the controls mice, under homeostatic conditions, ~80% of the Ly6C<sup>-</sup>F4/80<sup>hi</sup> STMs were MHCII<sup>-</sup> and 20% MHCII<sup>+</sup>, and those that are MHCII<sup>-</sup> were considered TRMs. In contrast, in HUPO mice with arthritis the F4/80<sup>hi</sup>MHCII<sup>+</sup> macrophages are greatly increased representing >90%, while the F4/80<sup>hi</sup> MHCII<sup>-</sup> macrophages were markedly reduced (<10%), and this reduction was inversely correlated with arthritis severity and duration. In HUPO mice, by flow cytometry, IL-6 expressing cells are increased in both MHCII<sup>+</sup> and <sup>-</sup> subsets, while IL-10 expressing cells were reduced, compared with controls. The F4/80<sup>hi</sup> STM populations were further analyzed by RNAseq. From over 5,000 differentially expressed genes, a similarity analysis demonstrated limited correlation between HUPO and control F4/80<sup>hi</sup> STMs. Further, functionally distinct clusters were identified between HUPO and controls. For both MHCII<sup>+</sup> and <sup>-</sup> subsets, cell differentiation and cell morphogenesis pathways were reduced, while pathways for innate immunity and inflammation were increased in the HUPO mice. In contrast, differences between the MHCII<sup>+</sup> and the MHCII<sup>-</sup> subsets were observed for antigen processing and presentation and the regulation of hematopoiesis in the control mice, while metabolic processes and for tRNA and ntRNA regulation were differentially expressed in the HUPO mice.

### Conclusion:

These observations demonstrate that F4/80<sup>hi</sup> STMs are markedly different under homeostatic and inflammatory conditions. The reduction of TRMs and an increase of inflammatory F4/80<sup>hi</sup>MHCII<sup>+</sup> macrophages contribute to the pathogenesis of HUPO arthritis. Further studies on the regulation of macrophage biology under homeostatic and chronic inflammatory conditions will help inform the pathogenesis of RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The most important immunological event in rheumatoid arthritis (RA) is the development of anti-citrullinated protein autoantibodies (ACPAs). ACPAs are present in 2/3 of patients. The mechanisms leading to the production of ACPAs are unknown. ACPAs are produced in the absence of identified T cell responses specific for each citrullinated protein. Peptidyl arginine deiminase 4 (PAD4), which binds numerous proteins and citrullinates them is the target of autoantibodies in early RA. This suggests a model for the emergence of ACPAs in the absence T cells specific for each citrullinated antigen: anti-citrullinated protein autoantibodies could arise because PADs are recognized by T cells which help the production of autoantibodies to proteins being citrullinated by PADs, according to a “hapten/carrier” model. Here, we tested this model in mice.

### Methods:

We used C3H mice which express a particular IEB<sup>k</sup> whose third hypervariable region is highly homologous to that of RA-associated HLA-DRB1\*04:01 allele and DBA/2 mice whose IEB<sup>d</sup> is similar to that of non RA-associated HLA-DRB1\*04:02. Mice were immunized subcutaneously with PADs or phosphate buffered saline (PBS) in Freund’s complete adjuvant (CFA). Three booster injections of PAD or PBS in Freund’ incomplete adjuvant (IFA) were given subcutaneously 15, 35 and 55 days later. Sera from primed mice were: 1) tested for anti-PAD antibodies by ELISA. 2) tested for T cell responses to native or citrullinated fibrinogen 65 days after PAD immunization. 3) tested for anti-citrullinated fibrinogen antibodies by ELISA using fibrinogen peptides under citrullinated and native form.

### Results:

C3H mice immunized with human PAD2 or PAD4 developed antibodies and T cells to PADs and IgG antibodies to citrullinated peptides from fibrinogen, in the absence of T cell response to fibrinogen. To test whether the observed hapten carrier effect applies to immunization with self-proteins, we immunized C3H mice with murine PAD2 or PAD4 and looked for antibodies to peptides from fibrinogen under native or citrullinated form. The hapten carrier effect also occurred in the self-situation. Finally, to analyze the effect of the MHC background on hapten carrier immunization, we immunized DBA/2 mice whose IEB<sup>d</sup> is similar to that of non RA-associated HLA-DRB1\*04:02. DBA/2 mice failed to develop antibodies to citrullinated fibrinogen peptides.

### Conclusion:

T cell immunization to PAD proteins triggers ACPAs through a hapten carrier mechanism in which the carrier is PAD which performs citrullination and the hapten any protein being citrullinated by PAD.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prostaglandin (PG) E<sub>2</sub> is known to enhance the expansion of T helper 17 (Th17) cell population via EP4 receptor (EP4) in the early phase of rheumatoid arthritis (RA). Furthermore, EP4 signals are involved in inflammatory hyperalgesia. Therefore, EP4 antagonists would be useful disease modified anti-rheumatic drugs (DMARDs) with analgesic effect. On the basis of this concept, pharmacological characteristics of S-110483, our novel potent and selective EP4 antagonist, were compared with existing EP4 antagonists; in addition, evidence regarding the immunomodulatory/analgesic potential of S-110483 is provided using an RA model.

**Methods:** The antagonistic activities of S-110483 and existing EP4 antagonists were evaluated in mammalian cells overexpressing rat, mouse, or human EP4. The effects of S-110483 on the production of PGE<sub>2</sub> and PGI<sub>2</sub> were evaluated using human umbilical vein endothelial cells (HUVEC) stimulated with IL-1 $\beta$ . For estimating the effects on the Th17 expansion, inhibition of IL-23 release from mouse dendritic cells was measured. The anti-edema and analgesic effects of S-110483 were evaluated by using rat adjuvant-induced arthritis (AIA) models as follows. Rats received intradermal injections of adjuvant suspension on their left hind paw (day 0). S-110483 (0.003–3 mg/kg) or celecoxib (0.003–3 mg/kg) were orally administered once a day on days 9–20. On day 18, anti-hyperalgesia effects were evaluated by measuring the vocalization threshold. Anti-edema effects were evaluated by paw volume of day 8, day 14, and day 18.

**Results:** S-110483 showed potent antagonistic activities for the rat/mouse/human EP4 with IC<sub>50</sub> of 10.9/9.0/5.4 nmol/L, respectively. S-110483 (10–1000 nmol/L) did not inhibit PGE<sub>2</sub> and PGI<sub>2</sub> production from HUVEC. S-110483 dose-dependently inhibited IL-23 release from activated mouse dendritic cells. The *in vitro* evaluation including the EP4 antagonistic activity revealed that S-110483 is the most potent and effective antagonist among existing EP4 antagonists. In the AIA models, S-110483 (0.3 mg/kg) had considerable analgesic and anti-inflammatory effects. Compared to celecoxib, S-110483 showed the maximum anti-hyperalgesic effects starting at dose that was 10 times lower.

**Conclusion:** Our studies demonstrated that S-110483 is the best in class among EP4 receptor antagonists, and it shows not only immunomodulatory effects but also anti-inflammatory and analgesic effects without inhibiting PGE<sub>2</sub> and PGI<sub>2</sub> production. These findings suggested that S-110483 could become a superior therapeutic option in RA patients.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** S-110483 is our novel potent and selective EP4 receptor (EP4) antagonist. In addition to the well-known fact that EP4 antagonists have anti-inflammatory effects, it has recently been shown that the prostaglandin E<sub>2</sub>-EP4 signal is involved in osteoclastogenesis through RANKL expression in osteoblasts. Therefore, EP4 antagonists are expected to become useful DMARDs with anti-inflammatory and anti-bone destruction effects. The objective of this study is to clarify the usefulness of S-110483 as a novel DMARD, and it consists of the following experiments. (1) To evaluate the effects of S-110483 on the osteoclastogenesis and RANKL expression as well as (2) to evaluate the therapeutic potentials of S-110483 as a novel DMARD using rat arthritis models.

**Methods:** 1. Osteoclastogenesis: Mice bone-marrow cells were stimulated with M-CSF/RANKL and the numbers of differentiated osteoclasts were counted. 2. RANKL expression on osteoblasts: Mice preosteoblast cell line (MC3T3-E1) was stimulated with IL-1 $\beta$  and RANKL expression was evaluated. 3. The therapeutic effects of S-110483 and DMARDs on an adjuvant-induced arthritis (AIA) model: Rats were orally administered S-110483 or DMARDs for 25 days starting immediately after the adjuvant injection. Paw volumes were measured regularly. Twenty-five days after the adjuvant injection, rats were sacrificed and the wet weight of the thymus was measured. Furthermore, bone condition was evaluated by using X-ray and micro CT analysis. 4. Therapeutic effects of S-110483 and celecoxib on collagen-induced arthritis (CIA) model: DA rats were immunized with type-II collagen in CFA, and arthritis score and the paw volume were measured regularly. S-110483 or celecoxib was administered orally once a day from arthritis onset. Sixteen days after arthritis onset, bone condition was evaluated.

**Results:** 1. S-110483 (1–10  $\mu$ mol/L) inhibited the osteoclastogenesis and its effect was more potent than tofacitinib and MTX. 2. S-110483 (1–10  $\mu$ mol/L) also inhibited RANKL expression of osteoblast as well as DMARDs. 3. In the AIA model, anti-edema and anti-bone destruction effects of S-110483 were comparable with those of MTX (1 mg/kg), and were more potent than those of tofacitinib (10 mg/kg) and iguratimod (10 mg/kg). Furthermore, S-110483 showed the inhibitory effect on inflammation-related bone formation, unlike DMARDs, suggesting that S-110483 possessed excellent inhibitory effects on joint deformity. Interestingly, S-110483 improved thymus atrophy, an index of immunosuppression, unlike MTX and tofacitinib. 4. In the CIA model, while anti-edema effect of S-110483 was comparable to that of celecoxib (10 mg/kg), the anti-bone destruction effect of S-110483 was significantly more potent than that of celecoxib (10 mg/kg).

**Conclusion:** Our novel EP4 antagonist, S-110483, has not only anti-inflammatory effects but also has direct effects on osteoclasts and osteoblasts, similar to DMARDs. Furthermore, the anti-edema and anti-bone destruction effects of S-110483, without strong immunosuppressive effect, are comparable to those of DMARDs. These findings would support the excellent potential of S-110483 as a clinically useful DMARD.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) patients are at higher risk for insulin resistance (IR). The association between RA and IR, and its role on the different characteristics of the disease, such as duration and activity have not been well defined. In addition, there is a gap of knowledge regarding the link between systemic/local inflammation and insulin sensitivity and lipid metabolism in RA patients. **Objective:** To explore the effects of the inflammation on the glucose and lipid metabolism in the RA context, following three strategies: RA patients, collagen induced arthritis (CIA) mouse model and in vitro treatment of 3T3L1 adipocytes.

**Methods: Human study:** 150 RA patients and 40 healthy donors were included. IR was quantified using the homeostatic model assessment of IR (HOMA-IR). **Mouse model:** 20 CB57J/BL mice were used; 5 mice were used as non-diseased group, and 15 were used in CIA modelling: sorted in low and high activity of the disease based on the number of inflamed digits depending on the duration of the disease. Plasma, leukocytes, skeletal muscle, liver and adipose tissue were collected. **Treatment of adipocytes with serum from RA patients:** 3T3L1 adipocytes were treated with serum 10% of RA patients and healthy donors for 24h. The expression of genes and proteins involved in inflammation, lipid metabolism and insulin signalling was analysed in all the tissues and cells.

**Results:** Percentages of obesity, hypertension, atherogenic risk, metabolic syndrome and IR were significantly increased in the RA group. Although mean time of evolution was 7 years, no association between IR and the duration of the disease was found. Levels of HOMA-IR significantly correlated with DAS28 and C-reactive protein levels, suggesting a link between the degree of systemic inflammation and the development of IR in these patients. These results were strengthened by observing that the induction of arthritis in mice resulted in a global inflammatory state characterized by defective carbohydrate and lipid metabolism in leukocytes, liver, muscle and adipose tissue, consistent with defects in insulin signaling. Adipose tissue was the organ most susceptible to the RA-induced metabolic alterations, which were observed from early stages of the disease. These metabolic effects were recapitulated in 3T3-L1 adipocytes treated with serum from RA patients.

**Conclusion:** 1) IR was closely associated with an increase in disease activity and systemic inflammation in RA patients. 2) Induction of arthritis in mice promoted an increase in inflammation in skeletal muscle, adipose tissue and leukocytes, accompanied by alterations in metabolic pathways favouring the development of insulin resistance on these tissues. 3) The inflammatory mediators in RA are the direct responsible for the metabolic alterations observed in adipose tissue. Altogether, our results show the direct effect of RA-associated chronic inflammation mediating the alterations occurred in glucose and lipid metabolism associated with this disorder. Thus, therapeutic strategies aimed to inhibit inflammation targeting proinflammatory cytokines might be an excellent option to normalize the metabolic alterations associated with RA. ### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Numerous studies have demonstrated the closely association between rheumatoid arthritis (RA) and metabolic complications such as obesity and insulin resistance (IR). Thus, there is an urgent need for the use of therapies targeting both the activity of the disease and such metabolic disorders. Yet, the beneficial/negative effect of conventional synthetic DMARDs (disease-modifying antirheumatic drugs) on the metabolic complications associated with cardiovascular disease prominent in RA patients is unknown yet. Objective: To analyze and compare the effects of methotrexate (MTX), leflunomide (LFN) and hydroxychloroquine (HDQ) on the obesity and IR in an obese collagen-induced arthritis (CIA) mouse model.

**Methods:** CIA was developed in obese-induced by high fat diet (HFD) and lean mice. 55 C57Bl/6 mice (4-5 weeks) were used. Groups of study: 5 non-diseased lean mice, 9 CIA lean mice, 5 non-diseased OB mice, 9 OB-CIA mice, 9 OB-CIA mice treated with LFN, 9 OB-CIA mice treated with MTx and 9 OB-CIA mice treated with HDQ for 15 days. Mice were weighted and the number of total swollen digits was recorded daily. After treatment, glucose tolerance test (GTT) was performed. HOMA-IR was calculated in all groups. Serum, plasma and adipose tissue were collected. Gene and protein expression of molecules involved in inflammation, insulin signaling and lipid metabolism.

**Results:** HFD promoted an early development of arthritis onset, however fat overloading did not affect the CIA effector phase. In contrast, the development of arthritis had not effect on body weight. Although the disease overcome was unaffected, obese CIA mice were more insulin resistant and display an elevated inflammatory state and an alteration of adipokines (at serum/plasma and adipose tissue levels) compared to lean CIA mice and non-arthritic obese mice. After 15 days of treatment, the therapies more effective on the disease progression were HDQ and MTX. Only the treatment with HDQ significantly reduced the body weight and improved insulin sensitivity at systemic level (HOMA-IR and area under the curve-GTT). Although systemic and adipose tissue high inflammatory status was reverted by the three DMARDs, MTX and HDQ, these were able to restore the metabolic alterations observed on adipose tissue. Thus, these DMARDs increased the expression of genes involved in insulin signaling (IRS-1 and 2, GLUT4 and AKT), lipid accumulation (DGAT, PLIN), and adipogenesis (PPAR $\gamma$ , SREBP1 and INSIG1) and modulate the expression of leptin and adiponectin.

**Conclusion:** 1) Lipid overloading accelerates the disease onset in CIA mice. Although disease overcome was unaffected, the induction of arthritis in an obese state aggravates the metabolic alterations, suggesting that inflammation associated with RA strongly contributes to the development of metabolic complications. 2) MTX and HDQ can reduce the metabolic abnormalities induced by arthritis, modulating glucose and lipid metabolism and favoring the improvement of insulin sensitivity. Thus, they can be used as an excellent therapeutic strategy in patients with metabolic complications related to RA. Funded by ISCIII-FIS (CP15/00158) and Roche Pharma S.A

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Follicular helper T (T<sub>fh</sub>) cell is a novel T cell subset which promotes follicular B cell activation, differentiation to plasma cell and antibody production. Recently, circulating T<sub>fh</sub> has been reported to be increased in RA and other autoimmune diseases. Some reports have showed the existence of T<sub>fh</sub> subsets which share same characteristics as conventional Th subsets, but their function in RA has been still unclear. The aim of this study was to explore the role of T<sub>fh</sub> subsets in glucose-6-phosphate isomerase (GPI) induced arthritis (GIA), which mouse model was dependent on CD4<sup>+</sup> T cells, B cells and IL-17.

### Methods:

- 1) The fluctuation in numbers of T<sub>fh</sub>, the subsets and germinal center (GC) B cell in draining lymph nodes from GIA were analyzed by FACS during the course of arthritis.
- 2) The localization of T<sub>fh</sub> and the subsets were analyzed by IF staining of the draining lymph nodes.

3) Anti-GPI antibody titers of sera from GIA were measured by ELISA. To assess Tfh function, Tfh and plasmablasts from GIA were co-cultured and the antibody titers of the culture supernatant were also measured.

### Results:

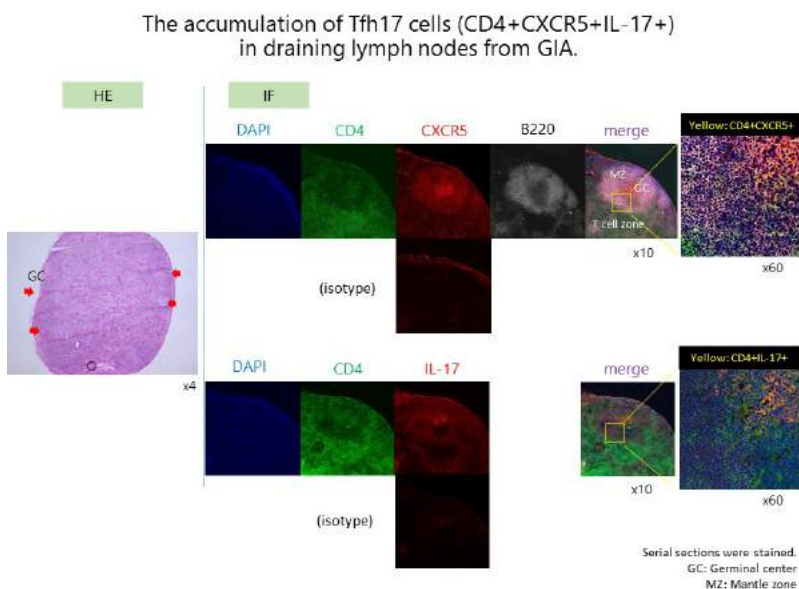

1) Tfh cell population was increased after the immunization of GPI. The increase was peaked on day 7, just at the onset of the arthritis, then gradually subsided. The subset analysis revealed the specific increase of IL-17 producing Tfh (Tfh17) at the same phase. The increased population of GC B cells was also observed through the course of arthritis. Its increase started on day 7 in response to Tfh, and peaked on day 14.

2) The IF staining showed that Tfh17 cells were accumulated in the T cell zone of GC and physically contacted with GC B cells in the draining lymph nodes of GIA (Figure).

3) Anti-GPI antibody was detected from day 7 in the sera from GIA, and the titers were gradually elevated over time. The titers of anti-GPI antibody in the culture supernatant were significantly increased compared with those from non-Tfh CD4<sup>+</sup> cells and plasmablasts co-culture.

### Conclusion:

Tfh, particularly Tfh17, might have a crucial role in the development of arthritis via B cell activation and anti-GPI antibody production in GIA. We are now elucidating the function of Tfh17 in the generation of GIA.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) has an increased prevalence and severity in women compared to men, yet the underlying etiology of this sexual dimorphism is unknown. Similar sex differences in the tumor necrosis factor-transgenic (TNF-Tg) mouse model of RA have been reported. Most notably, female TNF-Tg mice die earlier than males, with the majority dying between 6-7 months of age, while male mice die sporadically between 5-12 months of age. Recent studies have suggested that the gut microbiota significantly contribute to the pathogenesis of RA. This has been supported by the K/BxN mouse model of arthritis, which only develops arthritis when colonized with commensal bacteria. Based on this influence of microbiome on arthritis, we hypothesize that a sexually dimorphic microbiome exists in TNF-Tg mice, which is associated with disease severity.

**Methods:** An initial pilot study was performed to assess beta-diversity in male vs. female TNF-Tg mice (n=10), by 16S rRNA sequencing of fecal pellets. We also performed a principal coordinate analysis (PCoA) on these data. Based on significant findings, we collected samples from 4 separately housed cohorts of mice at 5.5 months of age, when TNF-Tg females have advanced disease and males have moderate disease. Cohorts were formed for the purpose of comparing TNF-Tg vs. WT and female vs male gut microbiome profiles (n=6 per cohort). 16S rRNA sequencing was performed on all samples.

**Results:** We found that female TNF-Tg mice had a significantly decreased beta-diversity ( $p<0.05$ ) compared to their male counterparts. PCoA demonstrated a clear spatial separation between male and female samples, suggesting distinct gut microbiome profiles. Follow up studies demonstrated that female TNF-Tg mice had enriched levels of several Bacteroidetes and Firmicutes species, as well as suppressed levels of Bifidobacterium pseudolongum, a known commensal bacterium with noted immunosuppressive properties.

**Conclusion:** Here, we have shown for the first time that the TNF-Tg model of RA demonstrates both a disease-associated dysbiosis, as well as a sexually dimorphic microbiome profile within the TNF-Tg population. We have also shown that the female TNF-Tg microbiome was enriched in certain Bacteroidetes and Firmicutes species compared to the male cohort. The greatest disparity was with the bacterium Bifidobacterium pseudolongum, which multiple studies have suggested has an immunosuppressive phenotype and was greatly suppressed in female TNF-Tg mice. Further research is needed to investigate its role in inflammatory environments and whether active manipulation of the gut microbiome with probiotics may alter the disease state.

#### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The pathogenesis of rheumatoid arthritis (RA) is characterized by the infiltration of immune cells into the synovial tissues and the excessive proliferation of synovial fibroblasts, resulting in synovial hyperplasia (pannus formation) and subsequent destruction of the bones and joints. Therapeutic strategies to inhibit pro-inflammatory cytokines or immune cells with methotrexate and biologics are the mainstay in the current treatment of RA. However, they cannot induce complete clinical remission in all of the patients. Cyclin-dependent kinase (CDK) 4/6 are key regulators in cell cycle, and its inhibitors have been reported to attenuate the proliferation of synovial fibroblasts and the progression of arthritis without inhibiting acquired immune responses in mouse RA models. To provide novel therapeutic option to inhibit the synovial hyperplasia, we performed the screening for CDK4/6 inhibitors and found out Compound X with high potency and selectivity for CDK4/6. Here we show the pharmacological and safety profiles of Compound X.

**Methods:** *In vitro* activities of Compound X were examined in kinase assays to determine the inhibitory activity against CDK4/6 and the selectivity to other kinases. *In vivo* efficacies of Compound X were examined in collagen-induced arthritis (CIA) of mice. Combination efficacy of Compound X and etanercept was examined in anti-collagen antibody-induced arthritis (CAIA) of mice. Adjuvant-induced arthritis (AIA) in rats was performed to determine the safety margin of Compound X. Compound X was orally administered twice daily for 19 days in mice and once daily for 3 weeks in rats, respectively. A toxicological profiling of Compound X was conducted with 4-week repeat dose studies in rats and monkeys. Telemetry study in monkeys and proarrhythmia study in human iPS cell-derived cardiomyocytes were conducted to evaluate the risk of the cardiovascular system.

**Results:** Compound X showed dose-dependent inhibition of the progression of arthritis and bone destruction in the CIA mice. The serum MMP-3 level was decreased by Compound X, which is consistent with the finding that inhibition of MMP-3 secretion by Compound X in synovial fibroblasts from RA patients. Furthermore, combination of Compound X with etanercept suppressed arthritic score and MMP-3 level more than monotherapy with Compound X or etanercept at the most effective dose. Whereas myelosuppression was observed at 120 mg/kg of Compound X in the AIA rats, the best efficacy in arthritic score was observed at 15 mg/kg. Four-week general toxicity studies in rats and monkeys demonstrated that Compound X is well-tolerated and has no critical concerns. In addition, telemetry study in monkeys and proarrhythmia study using human iPS-derived cardiomyocytes revealed a low risk of the cardiovascular system.

**Conclusion:** Compound X is an orally available CDK4/6 inhibitor and a promising candidate for development for RA treatment.

## Phospho-STAT1 Inhibition Is the Initial Step after Tofacitinib Treatment in Rabbits with Severe Chronic Synovitis

Sandra Pérez-Baos, Paula Gratal, Juan Ignacio Barrasa, Ana Lamuedra, Gabriel Herrero-Beaumont and Raquel Largo, Bone and Joint Research Unit, IIS-Fundación Jiménez Díaz UAM, Madrid, Spain

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib (TOFA) is a Janus Kinase (Jak) inhibitor approved for the treatment of rheumatoid arthritis (RA) <sup>1</sup>. It has recently been shown to selectively inhibit the expression of several chemokines in the synovium of RA patients that were treated over 28 days, without modifying the expression of various pro-inflammatory cytokines, nor the histopathological synovial inflammation, including macrophage infiltration <sup>2</sup>. Despite being the synovium the main articular tissue affected by RA, to date there are very limited data regarding the early modulation of synovial cytokines by this Jak inhibitor. In this sense, animal models may allow

a better understanding of the consequences of Jak inhibition in chronic arthritis (CA). Our aim was to develop a rabbit model of CA which mimicked severe human RA in early phases of treatment, in order to evaluate early tissue changes rather than the final therapeutic effect.

**Methods:** Twenty-four male, New Zealand white rabbits were randomly assigned to two groups: control (n=8) and CA (n=16). CA was induced over six weeks via intra-dermal ovalbumin sensitization and four subsequent intra-articular injections on a weekly basis. After the second intra-articular injection, eight CA rabbits were treated with TOFA (10mg/kg/day).

**Results:** CA animals showed reduced weight gain compared to controls, which TOFA tended to increase (weight gain, kg; Control:  $0.8 \pm 0.05$ ; CA:  $-0.09 \pm 0.06^*$ ; CA+TOFA:  $0.18 \pm 0.1^{* \#}$ ;  $*p < 0.05$  vs Control;  $\#p = 0.07$  vs CA). A substantial increase in serum C-reactive protein (CRP) was found both in CA and CA+TOFA animals. CA animals showed a severe synovitis that was partially prevented by TOFA (Krenn Score; Control:  $0.9 \pm 0.3$ ; CA:  $7.6 \pm 0.2^*$ ; CA+TOFA:  $6.6 \pm 0.2^{* \#}$ ;  $p < 0.05$  \*vs. control;  $\#$  vs. CA), and exhibited an augmented macrophage infiltration which was not modified by this inhibitor. TOFA effectively reduced the synovial expression of matrix metalloproteinases MMP-1 (93% inhibition,  $p < 0.05$ ) and MMP-3 (83% inhibition  $p < 0.05$ ), the C-C Motif Chemokine Ligand 2 (CCL2, 74% inhibition,  $p < 0.05$ ) as well as the pro-inflammatory cytokines Interleukin-6 (IL-6, 42% inhibition,  $p < 0.05$ ) and Tumor Necrosis Factor- $\alpha$  (TNF $\alpha$ , 55% inhibition,  $p < 0.05$ ). However, IL-1 $\beta$  was not modified with this Jak inhibitor. Signal Transducer and Activator of Transcription (STAT) -1 and -3, and Nuclear Factor- $\kappa$ B (NF- $\kappa$ B) were activated during CA, but TOFA was only able to diminish STAT-1 phosphorylation.

**Conclusion:** In a synovial tissue with an intense inflammatory activity, TOFA treatment initially blocked STAT-1 phosphorylation, whereas phospho-STAT-3 levels remained unchanged. This Jak inhibitor induced a partial decrease in the synovitis score along with a marked reduction of the expression of MMPs and, to a lesser extent, other pro-inflammatory mediators. These data suggest a key role of STAT-1 in the initial changes occurring in the synovium after TOFA treatment.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) mAb demonstrated a promising efficacy in active RA patients who were inadequately controlled by MTX and/or TNF- $\alpha$  inhibitors. In RA joint tissue, increased expression of FKN and abundant infiltration of CX3CR1-positive cells were observed. However, the precise mechanism(s) of FKN-CX3CR1 axis in RA, especially on joint destruction remains to be elucidated. FKN is expressed on endothelial cells and fibroblast-like synoviocytes in synovium and also expressed on osteoblasts. CX3CR1 is expressed on monocytes/macrophages and osteoclast precursor cells (OPCs). Therefore, FKN-CX3CR1 interaction could play pivotal roles in migration, differentiation and activation of those cells. Thus, we examined the roles of FKN-CX3CR1 axis in joint destruction, particularly focused on osteoclast precursor cells in *in vitro* and *in vivo* by using anti-mouse FKN mAb (anti-mFKN mAb).

**Methods:** DBA/1J mice were immunized with intradermal injections of bovine type II collagen to induce arthritis. Anti-mFKN mAb or control IgG were intraperitoneally injected twice a week. The clinical arthritis score was monitored, and joint destruction was evaluated by soft X-ray and histopathology. Blood parameters were measured using ELISA. In *in vitro*, effect of immobilized FKN on RANK ligand (RANKL)-induced osteoclast differentiation was examined. Cell survival of bone marrow-derived OPCs without or with immobilized FKN was also assessed by FACS. In *in vivo*, OPCs were labeled by fluorescein and transferred to CIA mice to evaluate migration of OPCs into inflamed synovium. Anti-mFKN mAb or control IgG were injected before the cell transfer. The number of fluorescein-labeled OPCs that migrated into the CIA joint tissue were counted.

**Results:** In both prophylactic and therapeutic treatments, anti-mFKN mAb clearly reduced the clinical arthritis score, soft x-ray score and histopathological changes (synovitis, bone erosion and cartilage destruction). The number of TRAP-positive cells in the joint was clearly decreased with anti-mFKN mAb treatment. Interestingly, anti-mFKN mAb suppressed plasma levels of COMP and MMP-3 without affecting those of IL-6, TNF- $\alpha$  and SAA. In *in vitro*, RANKL-induced osteoclast differentiation was enhanced by immobilized FKN, and anti-mFKN mAb suppressed FKN-dependent enhancement of osteoclast formation. FKN enhanced cell survival of OPCs and eventually increased the number of OPCs. In *in vivo*, fluorescein-labeled OPCs migrated into inflamed joint tissues, and anti-mFKN mAb clearly abrogated their migration into synovium.

**Conclusion:** Anti-mFKN mAb remarkably ameliorated the joint destruction with the marked reduction of osteoclasts by the inhibition of both OPC survival and OPC migration in inflamed joint tissues without affecting systemic inflammatory parameters. These results strongly indicate that inhibition of FKN-CX3CR1 axis by a humanized anti-FKN mAb, E6011, is an attractive and affected joints-selective therapeutic strategy for the treatment of both inflammatory synovitis and joint destruction in RA patients.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many types of inflammatory arthritis (IA) are treated with systemic therapy. In situations where only one or a few joints are active, intra-articular drug administration may offer distinct advantages over starting or escalating systemic therapy by increasing drug bioavailability locally and reducing the potential for drug-induced systemic toxicity. However, local delivery of therapeutics is limited by short intra-articular half-lives. A drug delivery method that generates a local drug depot and titrates drug release to arthritis activity would represent an attractive solution to this problem. We investigated the utility of hydrogels generated from a generally recognized as safe (GRAS) compound for inflammation-responsive local drug delivery in a mouse model of IA.

**Methods:** Hydrogels were generated from triglycerol monostearate (TG-18) and loaded with triamcinolone acetonide (TA) or a fluorescent dye (DiR). TA-loaded hydrogels were incubated *in vitro* with defined enzymatic activities or human synovial fluid. TA release was measured using high performance liquid chromatography. IA was induced in C57BL/6 mice by two i.p. injections of K/BxN serum. DiR-loaded hydrogels were injected into the right hindpaw prior to disease induction and fluorescence signal decay was measured by IVIS imaging. To test therapeutic efficacy, TA-loaded hydrogel, blank hydrogel or free TA were injected into the right hindpaw immediately after disease induction, and disease severity was assessed by measuring paw thickness with calipers and clinical scoring.

**Results:** TG-18 hydrogels efficiently and stably encapsulate TA. In vitro, TA-loaded hydrogels released drug on-demand upon exposure to enzymes including matrix metalloproteases or synovial fluid from patients with rheumatoid arthritis. In mice with K/BxN serum transfer arthritis, locally injected DiR-hydrogels demonstrated loss of fluorescence over time due to hydrogel disassembly that correlated with arthritis severity. Moreover, a single dose of TA-loaded hydrogel but not the equivalent dose of locally injected free TA reduced arthritis activity in the injected paw.

**Conclusion:** Our results suggest that an inflammation-responsive hydrogel as self-titrating on-demand drug delivery system can offer improved therapeutic benefit in IA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Rosiglitazone is a selective ligand for peroxisome proliferator-activated receptor-gamma (PPAR- $\gamma$ ), which is expressed by antigen presenting cells (APCs) and plays a fundamental role in immune responses. Tolerogenic dendritic cells (tDCs) are professional APCs with antigen-specific immune regulation to induce autoimmune tolerance, suggesting the potential as antigen-specific immunotherapy for autoimmune diseases. The aim of this study was to investigate therapeutic effects of rosiglitazone-mediated DC (Rosi-DC) in a collagen-induced arthritis (CIA) mouse model.

### Methods:

Rosi-DCs were generated by treating immature DCs with TNF- $\alpha$ , type II collagen, and rosiglitazone. CIA mice then received subcutaneously two injections of Rosi-DCs. The severity of arthritis was then assessed three times until Day 50 post-primary immunization. The phenotypes of the DC and regulatory T (Treg) cell populations in CIA mice were determined by flow cytometry and the effect of Rosi-DCs on the secretion of autoimmunity-inducing cytokines was examined by ELISA.

### Results:

Rosi-DCs expressed lower levels of DC-related surface markers (CD80, CD86, CD40 and CD54) than mature DCs. Rosi-DCs produced lower levels of pro-inflammatory cytokines (IL-1 $\beta$ , IL-6, and IL-12p70) than mDCs. Upon the co-culture of DCs and T lymphocytes, Rosi-DCs markedly increased FoxP3+CD4+CD25+ Treg cell population and reduced the Th1/Th17 cell population.

Histopathological examination revealed that the degree of inflammation in the paws of Rosi-DC-treated mice was much lower than that in the paws of PBS-treated CIA mice. *In vivo*, the percentage of Treg cells in the spleens and inguinal lymph nodes of mice vaccinated with type II collagen-pulsed Rosi-DCs was markedly higher than that in mice injected with Ag-mismatched (myosin pulsed) or Ag-

unpulsed Rosi-DCs and PBS-treated CIA mice. Treatment with type II collagen-pulsed Rosi-DCs resulted in a reduction in the percentage of Th1 and Th17 cells within the splenocyte population.

## Conclusion:

In this study, these results clearly show that rosiglitazone-mediated DCs ameliorate CIA, most likely via the induction of antigen-specific Treg cells.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid Arthritis (RA) is characterized by extra-articular involvement including interstitial/inflammatory lung disease (ILD). Whereas the coexistence of RA and ILD is known, mechanisms linking the two conditions are poorly understood. The objective of this study was to combine an established organic dust extract (ODE) inhalation injury model with the collagen-induced arthritis (CIA) murine model to assess lung and bone/joint inflammatory outcomes.

**Methods:** Using an established intranasal inhalation protocol, DBA/1J mice were treated with saline or organic dust extract (ODE) daily for 5 weeks. CIA arthritis was induced with collagen emulsified in Freund's complete adjuvant and injected on Days 1 and 21. Mice (9-10/group; 2 independent experiments) were assigned to 1 of 4 groups: 1-Sham (saline injection/saline inhalation); 2-CIA (CIA/saline inhalation); 3-ODE (saline injection/ODE inhalation); 4-CIA+ODE (CIA/ODE inhalation). Arthritis inflammatory scores were calculated weekly (0-4 range) based on swelling and redness of the hind paw. Five hours following final ODE, mice were euthanized. Bones, bronchoalveolar lavage fluid (BALF), and lung tissues were collected.

**Results:** Table depicts experimental outcome results. Arthritis and histologic inflammatory scores and were increased in CIA+ODE>CIA alone>ODE alone as compared to Sham. Trabecular bone micro-CT analysis showed loss of bone mineral density, volume and deterioration of bone micro-architecture and mechanical strength to be most pronounced in CIA+ODE. Evidence of bone deterioration was also found in the CIA, but not ODE or Sham animals. In contrast, ODE-induced airway neutrophil influx and cytokine/chemokine (TNF- $\alpha$ , IL-6, CXCL1, CXCL2) in BALF were greater in ODE as compared to ODE+CIA. Similarly, lung pathology showed ODE-induced lymphoid aggregates and alveolar inflammation were increased in ODE>ODE+CIA. By flow cytometry, ODE increased lung tissue neutrophils and activated CD11c<sup>+</sup>CD11b<sup>hi</sup> macrophages to Sham. Comparable trends, but to a lesser degree, were demonstrated in CIA+ODE. CIA increased lung activated CD11c<sup>+</sup>CD11b<sup>hi</sup> airway macrophages as compared to Sham.

**Conclusion:** This is the first study to explore the interaction between a repetitive inhalant injury and arthritis induction with findings supporting a compartmentalized immune response. The combined exposures (CIA+ODE) resulted in the greatest degree of arthritis and

diffuse bone loss. However, data support a suppression of the lung inflammatory response in the setting of arthritis. Activation of the lung macrophage during arthritis induction may be responsible for this paradoxical finding. Finally, this co-exposure model could be exploited further and in other murine strains to better understand the pathogenesis and response to potential treatments for RA-ILD.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smoking is an important epidemiological factor for development of rheumatoid arthritis (RA). However, the mechanism of proarthritic role of smoking is not well understood. The purpose of this study is to precisely explore the arthritic role of smoking in two experimental arthritis models including collagen induced arthritis (CIA) and IL-1 receptor antagonist (Ra) knockout (KO) mice. Cigarette smoking was challenged by two routes of inhalation and drinking.

**Methods:** To deliver elaborate dosage of smoking, we utilized good laboratory product (GLP)-grade closed inhalation chamber system which is equipped in Korea Institute of Toxicology. Smoke was generated by routine analytic cigarette-smoking machine (ISO standard 3308). Tobacco produce-3R4F cigarette (9.4mg tar/0.7mg nicotine) was chosen by ISO standard 3402 for atmosphere conditioning and testing. This study was strictly followed by OECD guidelines for the testing of chemicals section 4 health effects test No.412 Subacute inhalation toxicity. CIA was induced in a total of 60 mice (negative control (n=10), CIA control (n=10), smoke control (n=10), and cigarette smoke (n=30)). After 1<sup>st</sup> collagen immunization, three different doses (T1~T3) of smoke were delivered to collagen induced mice (T1 dose 150 ug/L (n=10), T2 dose 300 ug/L (n=10), T3 dose 600 ug/L (n=10)). It is known that concentration of smoke exposure possibly ranges from 50 to 800 ug/L in real world. Cigarette smoke delivery was done 1 hour once a day, 5 days/week, for 4 weeks in close ventilation system. As a second smoking study, cigarette smoke extract (CSE) was delivered per oral to IL-1RaKO mice arthritis model.

**Results:** Cigarette smoking facilitated the onset arthritis. Twenty percent of mice in cigarette smoke group developed arthritis less than a week after 1<sup>st</sup> immunization, while control CIA mice showed 20% incidence of arthritis on four weeks after immunization. Time points of 60% arthritis incidence was on 3 weeks after 1<sup>st</sup> immunization, 4 weeks, and 6 weeks in high dose (T3), low dose (T1) and control CIA group, respectively ( $p<0.05$ ). Higher dose of smoke challenge induced more lymphocyte infiltration in subpleural area of lung. Citrullination was dose dependently increased in smoking inhaled groups. Splenic Th17 population increased dose dependently in smoking groups. In contrary to smoking experiment, CSE drinking did not affect the arthritis development in experimental arthritis model. However, interestingly CSE aggravated arthritis score in female group as a subgroup analysis.

**Conclusion:** In this study, we revealed cigarette smoking facilitated the onset of arthritis and aggravated arthritis score in a dose-dependent manner. Smoking may play a role in advancing the onset of arthritis in those who are at risk of cigarette smoke exposure and contribute to developing RA. Female also can be more vulnerable to cigarette challenge. More precise, large scale epidemiological study may help to verify these observations.

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The composition of intestinal microbiota is perturbed in patients with new-onset and chronic rheumatoid arthritis (RA). However, it is not known whether the changes in the intestinal microbiome precede the development of arthritis or are rather a consequence of the inflammatory processes. Furthermore, while both germ-free condition and administration of oral antibiotics prevent arthritis in mice, it is unclear whether modulation of the intestinal microbiota after the onset of arthritis may still suppress the disease. We aimed to identify alterations of the intestinal microbiome in the preclinical phase of inflammatory arthritis, and evaluate the efficacy of microbiota modulations in the treatment of established arthritis in mice.

## Methods:

We sequenced fecal bacterial 16S rRNA genes of mice immunized for the induction of collagen-induced arthritis (CIA) prior to the onset of arthritis compared with naïve condition. To assess the efficacy of microbiota modulation during arthritis, mice with ongoing CIA were treated with oral antibiotics to partially eliminate the intestinal microbiota. T cell differentiation and production of cytokines in intestinal lamina propria and joint-draining lymph nodes were assessed by flow cytometry and Luminex. Arthritis was assessed macroscopically and by histology. K/BxN serum-transfer arthritis was used to assess the role of microbiota in T cell-independent arthritis.

## Results:

The preclinical phase of arthritis in mice was characterized by marked changes in the intestinal microbiome, represented by a significant increase of the phylum *Bacteroidetes* and a decrease of *Firmicutes* and *Proteobacteria*. Among the most abundant bacterial families, *S24-7* and *Staphylococcaceae* were expanded, whereas *Lachnospiraceae* were reduced during the early immune-priming phase of CIA. Several operational taxonomic units associated with *S24-7* family increased, while those assigned to *Lachnospiraceae* and *Ruminococcaceae* decreased in the intestinal microbiota before the clinical onset of arthritis. The abundance of intestinal lamina propria Th17 cells significantly correlated with the severity of CIA; however, lamina propria Th1 cells were not correlated with arthritis. Elimination of intestinal microbiota during established arthritis specifically suppressed intestinal Th17 cell differentiation without affecting Th1 and regulatory T cells. Importantly, elimination of intestinal microbiota suppressed Th17 cell differentiation and IL-17 production in joint-draining lymph nodes, and reduced the severity of established CIA. In contrast, the T cell-independent serum-transfer arthritis was not affected by this strategy.

## Conclusion:

These observations suggest that perturbations of the intestinal microbiome precede the development of inflammatory arthritis. Similar studies are warranted in human pre-RA or at-risk individuals to shed light on the potential relevance of the microbiome in the preclinical phase of RA. Our studies also suggest that modulation of the intestinal microbiota after the onset of arthritis may still provide opportunities to treat inflammatory arthritis.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Cardiovascular disease is a major cause of morbidity and mortality in patients with rheumatoid arthritis (RA). RA patients have an increased incidence of both myocardial infarction (MI) and congestive heart failure. Cardiac immune cells have been demonstrated to influence cardiac remodeling post infarction and our study examined the effect of inflammatory arthritis on cardiac immune cells using a mouse model of myocardial infarction in SKG mice, a model of inflammatory arthritis.

## Methods:

Arthritis was induced in female SKG mice (BALB/c ZAP-70<sup>W163C</sup>-mutants) with a single injection of zymosan at 12 weeks age and were examined after development of arthritis at 4 weeks. Wild type Balb/c mice, SKG mice, and SKG mice with arthritis (4 weeks post-zymosan) with MI underwent permanent left anterior descending coronary artery ligation. Cardiac leukocytes were evaluated at day 1 and 6 post-infarction, following harvest with cardiac perfusion, disaggregation of the heart, collagenase digestion, cellular isolation and antibody staining for multicolor flow cytometry. Cells were analyzed using a FACS Aria and FlowJo software (hearts were analyzed individually, 5 mice per group) using lineage markers (CD90/CD19/NK1.1/Ly-6G) to evaluate T cells, B cells, NK cells, granulocytes and myeloid markers CD11b, F4/80, Ly-6C.

## Results:

Hearts isolated from SKG mice without arthritis showed a slight increase in the number of cardiac neutrophils compared with wild type Balb/c, that was increased by 3-4 fold in SKG mice with arthritis. At baseline SKG mice with arthritis also had a 2-3 fold increase in inflammatory macrophages (Ly6C+) compared with either SKG or Balb/c mice. Hearts isolated from SKG mice with arthritis 1 day post MI, showed a 5-6 fold increase in Ly6G+ cells (neutrophils) and Ly6C+/CD11b (monocyte/macrophages) cells compared to the basal numbers seen in hearts isolated from wild-type Balb/c mice. At day 6, SKG mice and SKG mice with arthritis both showed a persistent increase in Ly-6C+ macrophages compared with the decrease in these cells observed in Balb/c mice at the same time point. Functional outcomes post-MI correlated with these changes are currently being evaluated.

## Conclusion:

We found that inflammatory arthritis induces changes in the number and phenotype of cardiac immune cells in mice both before and after myocardial infarction which likely influences cardiac repair and ventricular remodeling post-MI contributing to detrimental cardiac outcomes with inflammatory arthritis.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The pathogenesis of rheumatoid arthritis (RA) is thought to be influenced by a combination of genetic and environmental factors. Observations of microbial dysbiosis in patients with RA have raised interest in studying microbial-mucosal interactions as a potential trigger of RA. Using the murine collagen-induced arthritis (CIA) model, which is dependent upon generation of T and B cell reactivity

to CII as well as complement activation, we hypothesized that microbiota are required for the development of robust autoimmune arthritis.

#### **Methods:**

Male 6-week old DBA/1j mice were immunized with bovine type II collagen (CII) in Complete Freund's Adjuvant (CFA) on days 0 and 21. Microbiota depletion was performed by continuous administration of broad spectrum antibiotics in drinking water early (7 days preceding and throughout the study) or late (starting after day 21 throughout the study) in the disease process. Microbial depletion was confirmed by quantifying bacterial 16S rRNA by qPCR in feces. Sera were collected every 7 days during the study for autoantibody and cytokine testing. Mice were euthanized on day 35 and intestinal tissues were harvested for cytokine analyses by ELISA. Disease severity starting at day 21 was assessed by assigning a score for the degree of paw swelling.

#### **Results:**

Depletion of the microbiota prior to the induction of CIA resulted in ~50% reduction in disease severity associated with significantly reduced serum inflammatory cytokines and anti-CII antibodies. In intestinal tissue, we observed delayed IL-17A and IL-22 responses. Unexpectedly, microbial depletion during the late, effector phase of CIA resulted in >90% decrease in disease severity and 50% reduction in prevalence. In these mice, anti-CII antibodies were mildly reduced, but were significantly impaired in their ability to activate complement. In addition to reduced systemic inflammatory cytokines and intestinal IL-17A and IL-22, IL-23 was significantly reduced, suggesting it may link mucosal immune responses with systemic autoantibody effectivity. Studies are now aimed at understanding this mechanism.

#### **Conclusion:**

While future studies are needed to solidify the role of the microbiota in driving CIA, our data supports a model in which intestinal dysbiosis triggers mucosal immune responses that stimulate systemic B cell activities that are key for the development of inflammatory arthritis. Understanding the pathway by which microbiota and mucosal immune responses modulate systemic autoantibody production is pivotal, as targeting the microbiota during the preclinical, seropositive phase of RA may have potential for disease prevention.

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) manifests in persistent synovial inflammation, cellular infiltration and pro-inflammatory cytokine production, resulting in progressive joint destruction. Macrophages have been implicated in RA progression and persistence through production of degradative enzymes, cytokines, and chemokines. However, the mechanisms underlying these activities are not fully elucidated. We previously demonstrated that naïve mouse joints contain both MHC II<sup>+</sup> (monocyte-derived) and MHC II<sup>-</sup> (tissue-resident) macrophages. Interestingly, we have shown that the monocyte-derived macrophages drive inflammation, while the tissue-resident macrophages are involved in resolution based on an acute model of inflammatory arthritis. Thus, we have optimized a multi-parameter flow cytometry protocol to isolate synovial macrophage subsets to perform subset-specific transcriptomic analysis.

**Methods:** We used 3 mouse model of arthritis: the acute inducible K/BxN serum transfer-induced arthritis (STIA) model, and chronic inducible collagen induced arthritis (CIA) model, and the spontaneous KRN/Ag7 mice. STIA and CIA was induced in 10-12 week old female C57BL/6 mice. Flow cytometric analysis was employed to delineate macrophage subsets via expression of MHC II and CX3CR1 to obtain 4 distinct macrophage populations. These populations were sorted throughout the course of arthritis by FACS. RNA was extracted from sorted macrophage populations and processed for RNA-seq using Quantseq 3' mRNA library preparation. The RNA-seq libraries were sequenced on an Illumina NextSeq 500 to an average depth of 5 million reads. The reads were aligned and mapped to genes using STAR and HTseq respectively.

**Results:** We observe by flow cytometry that the predominance of individual synovial macrophage subsets shift throughout the initiation, progression and resolution phases of arthritis and eventually return to their steady-state phenotype. PCA analysis of macrophage subsets in a naïve mouse show distinct transcriptional profiles. Analysis of the transcriptional profiles over the course of arthritis reveals that each macrophage subset responds differently at each phase of inflammation. K-means clustering of specific synovial macrophage subsets have identified distinct gene clusters and cellular processes that are differentially regulated to dictate their function during arthritis. Synovial macrophage populations from each arthritic model display a similar response to inflammation, suggesting that the transcriptional signatures and function of macrophages are consistent in inflammatory arthritis.

**Conclusion:** We conclude that fluctuations in the synovial macrophage populations over the course of arthritis coincide with the different phases of joint inflammation. These dynamics indicate that the specific macrophage subsets have different function during the course of disease as evidenced by their distinct transcriptional profiles. These high-throughput genomic approaches applied to macrophage subsets from models of both acute and chronic inflammatory arthritis allows us to comprehensively map their role in disease, thereby providing insight into potentially useful targets for therapy.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is an autoimmune disease of the joints associated with accelerated aging and increased mortality. Further, RA is linked with a number of co-morbidities including cardiovascular disease, which accounts for 40% of RA mortality. Synovial macrophages are a key effector cell in joint inflammation, and a reduction in sublining synovial macrophages is the only current reproducible biomarker for successful response to therapy. Thus, characterization of synovial macrophages during disease could provide insight into progression of RA and increased mortality upon aging. To that end, the aim of this study was to use KRN Ag7 mice that develop spontaneous arthritis and atherosclerosis to monitor changes in the cellular composition of arthritic synovium in parallel with non-diseased C57Bl/6 controls.

**Methods:** KRN Ag7 and C57Bl/6 mice were bred in house and euthanized at desired timepoints (1, 3, 6, 9, 12, and 18 months) when ankles were collected for extraction of synovium. Single cell suspensions were prepared from synovial tissue and stained with an antibody cocktail designed to identify monocyte and macrophage populations, which were sorted from single cell suspensions using BD FACSAria 4-Laser. Statistical analysis was carried out in Flowjo v9 and Prism7. Statistical significance was defined  $P \leq 0.05$ .

**Results:** KRN Ag<sup>7</sup> mice displayed arthropathy from birth, and 20% increased mortality compared to C57Bl/6 at 12 months. Flow cytometry analysis of synovial tissue showed a trend towards an overall reduction in CD11b<sup>+</sup> leukocytes in KRN Ag<sup>7</sup> mice, which became statistically significant from 6 months. Further analysis of KRN Ag<sup>7</sup> synovium identified two phases of disease, an inflammatory phase from months 1-3 and an attempted resolution phase from 6 months. The inflammatory phase was characterized by significant increases in eosinophils and neutrophils and a decrease in dendritic cells compared to C57Bl/6. During resolution phase levels of these three populations trended towards C57Bl/6 levels, but remained significantly different. Levels of neutrophils in KRN Ag<sup>7</sup> mice also correlated with Ly6c<sup>lo</sup> monocytes, which are required for neutrophil recruitment. Levels of CD11b<sup>+</sup>CD64<sup>+</sup>Ly6c<sup>lo</sup> macrophages in KRN Ag<sup>7</sup> synovium peaked in inflammation phase but remained lower than those of C57Bl/6 at all time points. Subdivision of macrophages into 4 populations based on expression of MHCII and CX3CR1 identified populations associated with both phases of disease. MHCII<sup>+</sup>CX3CR1<sup>-</sup> and MHCII<sup>-</sup>CX3CR1<sup>+</sup> macrophages were significantly higher and lower respectively than C57Bl/6 during inflammation, but during initial resolution at 6 months reached comparable levels to those of C57Bl/6. However this was not maintained, and levels of both populations returned to baselines by 18 months. Neither MHCII<sup>+</sup>CX3CR1<sup>+</sup> nor MHCII<sup>-</sup>CX3CR1<sup>-</sup> macrophages significantly changed.

**Conclusion:** Using KRN Ag<sup>7</sup> mice, that best recapitulate human disease, we have characterized the cellular dynamics in arthritis upon aging, which are distinct from those observed in non-arthritic mice. By identifying the critical populations, and further characterization of their transcriptional profile, we can provide insight into RA progression with age.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune disease characterized by progressive infiltration of the joints by T cells and other leukocytes, production of mediators of inflammation, and the eventual destruction of joints. T follicular helper (Tfh) cells are a unique subset of CD4<sup>+</sup> T cells, predominantly located in B cell follicles, and regulate the survival of B cells and antibody production in germinal centers. Our previous studies have showed that circulating Tfh cells were significantly increased in active RA patients, correlating with the percentage of plasmablasts, anti-CCP antibody titer, and disease activity in active RA patients, indicating that Tfh cells may play an important role in RA pathogenesis. The purpose of this study is to investigate the therapeutic potential of a small molecule inhibitor targeting Tfh cells in mice with collagen-induced arthritis (CIA).

### Methods:

CIA was induced in twenty-four DBA/1 mice by immunization with chicken type II collagen. Following the onset of clinical arthritis, mice were treated with a small molecule inhibitor (SMI-Tfh) selective blockage of Tfh cell signature transcription factor Bcl-6. Disease progression was monitored daily and recorded by arthritis severity scores weekly. Blood, spleen, and affected paws were collected at the end of the study. Tfh cells in spleen and blood were defined by their signature surface markers (CD4<sup>+</sup>CXCR5<sup>+</sup>ICOS<sup>+</sup>) via flow

cytometry and analyzed using FlowJo software. The immune cells were further confirmed in mice spleen by immunohistochemistry staining. Statistical analysis was carried out using GraphPad Prism software and the significance was evaluated by *t* test.

## Results:

Mice developed arthritis four weeks after immunization with type II collagen. Treatment with SMI-Tfh (50mg/kg) significantly reduced the disease progression/activity (as measured by paw swelling) in mice with CIA. SMI-Tfh significantly inhibited the frequency of Tfh cells in spleen ( $P < 0.01$ ), but not the frequency of circulating Tfh cells in CIA mice ( $P > 0.05$ ). In addition, SMI-Tfh also inhibited B cell proliferation induced by Tfh cells and antibody production *in vitro*.

## Conclusion:

The small molecule inhibitor SMI-Tfh selectively inhibits Tfh cells and abrogates progression/activity of inflammatory arthritis in CIA mouse model. Treatment with our small molecule SMI-Tfh in CIA mice provides a potential strategy for joint protection and may be beneficial in RA patients. This is first report that a small molecule targeting Tfh cells in RA may be an approach worth further investigation in RA.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster I

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CR6086, a selective EP4 antagonist, dose-dependently improves disease features in rheumatoid arthritis (RA) models in rodents. Indeed, recent studies highlight the role of the EP4 receptor in modulating autoimmunity and in counteracting bone erosion. Aim of the present study was to test CR6086 as an add-on medication with methotrexate (MTX).

**Methods:** DBA/1 male mice were immunized with bovine type II collagen (BCII) in CFA. On arthritis onset, animals were assigned to the following experimental groups: vehicle, oral CR6086 30 mg/kg/day, MTX 1 or 3 mg/kg/three times a week alone or in combination with daily CR6086 30 mg/kg. Edema measurement and clinical scores were blindly determined daily before drug administration. After 2 weeks of treatment, mice were sacrificed and serum BCII antibodies measured. Paw joints were blindly scored for histological features. Data were analyzed by ANOVA or by Kruskal-Wallis test followed by appropriate post-hoc comparison test.

**Results:** CR6086 strongly and significantly reduced score and edema within the first week of treatment compared to vehicle. MTX 3 mg/kg modestly reduced clinical signs over the second week of treatment, while MTX 1 mg/kg was inactive. CR6086/MTX combined treatments significantly reduced clinical score and edema within the first week of treatment. Figure 1 reports the AUC analysis of the whole treatment. Post-hoc pairwise comparisons showed that combined treatments were significantly superior to each single treatment ( $P < 0.05$  and  $P < 0.01$  vs. CR6086 and MTX alone, respectively).

Fig. 1. Clinical scores daily assigned to each mouse were evaluated at the end of treatments as AUC values. Depicted P values were calculated by Dunnett's multiple comparisons test vs. vehicle treated animals.

Histological features showed a similar treatment pattern (Fig.2), but the effects of CR6086 were so strong when given alone that we could not show a significant synergism with MTX but only a trend.

Fig. 2. Histological scores (cartilage degeneration, woven bone, osteolysis, synovial inflammation, synovial hyperplasia, and pannus) were blindly assigned to all 4 paws of the mice. Depicted P values were calculated by two-stage linear step-up procedure of Benjamini, Krieger and Yekutieli.

All treatments, but MTX 1 mg/kg, decreased BCII antibodies serum levels (Fig. 3).

Fig. 3. Serum levels of collagen II antibodies after two weeks of treatment. Depicted P values were calculated by Dunnett's multiple comparisons test vs. vehicle treated animals.

**Conclusion:** In a widely used animal model for RA, CR6086 was effective on all parameters examined both alone and combined with MTX. The superior overall efficacy of CR6086 vs. a classical immunosuppressant as MTX, at equally effective doses on BCII antibodies, outlines that CR6086 independently controls various pathological RA pathways. Moreover, the fact that CR6086 improved MTX effect strengthens its use in early RA in DMARD naïve patients, as presently investigated in clinical trials.

## An Evaluation of Absolute Neutrophil Count As a Biomarker of Inflammatory and Clinical Disease Activity in Baricitinib-Treated Patients

Iain B. McInnes<sup>1</sup>, Lee S. Simon<sup>2</sup>, Robert J. Moots<sup>3</sup>, Vipin K. Arora<sup>4</sup>, John D. Bradley<sup>4</sup> and David Muram<sup>4</sup>, <sup>1</sup>University of Glasgow, Glasgow, United Kingdom, <sup>2</sup>SDG LLC, Cambridge, MA, <sup>3</sup>University of Liverpool, Liverpool, UK, <sup>4</sup>Lilly and Company, Indianapolis, IN

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) patients (pts) tend to have higher absolute neutrophil count (ANC) values compared to healthy individuals.<sup>1</sup> Baricitinib (BARI), an oral, selective Janus kinase (JAK)1/JAK2 inhibitor,<sup>2</sup> reduced disease activity levels in RA pts with an inadequate response (IR) to methotrexate (MTX).<sup>3</sup> BARI also reduced neutrophil counts in these pts.<sup>3</sup> Herein we assessed the association between changes in ANC and the reduction in inflammation, as determined by high-sensitivity C-reactive protein (hsCRP) levels, and by inference clinical responses in pts receiving BARI 4-mg in the RA-BEAM trial.

**Methods:** RA-BEAM was a 52 week (wk) Phase 3 trial with RA pts randomized to placebo, BARI 4-mg once daily, or adalimumab 40-mg biweekly. Primary end-point of the trial was the proportion of pts achieving ACR20 at wk 12. This post hoc analysis evaluated the changes in observed ANC in BARI 4-mg treated pts with either  $\leq 15\%$  or  $\geq 70\%$  reduction in hsCRP from baseline to wk 12. Proportion of pts achieving low disease activity (LDA), as determined by Clinical Disease Activity Index (CDAI)  $\leq 10$ , or DAS28-hsCRP  $< 2.6$  at 12 wks was evaluated as a function of percent change in ANC from baseline to wk 8, at which time a peak decline in ANC was observed (Figure 1).

**Results:** Of the 487 pts in the BARI 4-mg treatment arm of the RA-BEAM study, 78 pts demonstrated  $\leq 15\%$  reduction in hsCRP and 298 pts had  $\geq 70\%$  reduction in hsCRP at 12 wks. The mean neutrophil count at wk 8 in pts with  $\leq 15\%$  reduction in hsCRP was higher when compared to pts with  $\geq 70\%$  reduction (Figure 2), suggesting that the decline in ANC was associated with reduction in the inflammatory process. The reduction in ANC was associated with an improved clinical response as demonstrated by the proportion of pts achieving LDA (CDAI  $\leq 10$ ) or DAS28-hsCRP  $< 2.6$  at 12 wks. In contrast, a smaller proportion of pts achieved LDA when an increase in ANC was observed (Figure 3). These observations were similar regardless of the use of concomitant oral corticosteroids.

**Conclusion:** The decline in ANC is associated with a reduction in the overall inflammatory process and may also be associated with disease activity.

## Association between Anti-Citrullinated Protein Antibody Status and the Incidence of Erosive Disease in Patients with RA

Leslie R Harrold<sup>1</sup>, Heather J. Litman<sup>2</sup>, SE Connolly<sup>3</sup>, E Alemao<sup>3</sup>, Sabrina Rebello<sup>4</sup>, W Hua<sup>2</sup> and Joel Kremer<sup>5</sup>, <sup>1</sup>University of Massachusetts Medical School, Worcester, MA, <sup>2</sup>Corrona, Southborough, MA, <sup>3</sup>Bristol-Myers Squibb, Princeton, NJ, <sup>4</sup>Corrona, LLC, Southborough, MA, <sup>5</sup>Albany Medical College and The Center for Rheumatology, Albany, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Background/Purpose:** RA is characterized by the production of autoantibodies including anti-citrullinated protein antibodies (ACPAs).<sup>1</sup> ACPAs are considered a prognostic indicator for more severe RA and more rapid disease progression.<sup>2,3</sup> Little is known regarding the incidence of erosions overall in a contemporary cohort of patients with access to biologics or the association with ACPA status. This analysis aimed to characterize the incidence of erosive disease and its association with ACPA serological status in patients with RA.

**Methods:** We identified patients aged  $\geq 18$  years with RA disease duration  $\leq 2$  years who were enrolled in the Corrona Registry (October 2001 to June 2016) with ACPA status available at or before their enrollment visit and no evidence of erosions on their first visit at which radiographic information was reported. To assess incidence of erosions, we followed patients until their first radiograph showed evidence of erosions or their last follow-up visit, whichever came first. The primary outcome was the incidence of erosions (calculated as the total number of first erosions divided by the total radiographic follow-up time), overall and by ACPA status (negative anti-cyclic citrullinated peptide [CCP]  $< 20$  vs positive anti-CCP  $\geq 20$ ), unadjusted and adjusted (for age and baseline disease activity using the CDAI). Cox proportional hazards modeling was used to assess the hazard ratio (HR) (with 95% CIs) of erosive disease.

**Results:** In total, 693 patients (452 ACPA positive and 241 ACPA negative) met the inclusion criteria. Most were women (70.6%), middle-aged (mean [SD] 55 [13.3] years), with moderate disease activity based on the CDAI (13.9 [13.0]). Prior use of  $\geq 1$  biologic/targeted synthetic DMARD had occurred in 29.3% of patients. In total, 187 first erosions over 1344.27 person-years of radiographic follow-up time were recorded with an incidence rate of 13.9 erosions/100 person-years of follow-up. The incidence of erosions among ACPA-positive patients was 14.8/100 person-years vs 12.2/100 person-years in those who were ACPA negative (unadjusted HR 1.21; 95% CI 0.88, 1.67;  $p=0.23$ ; Table). In adjusted analyses, ACPA status was associated with the incidence of erosions (HR 1.30; 95% CI 0.94, 1.80;  $p=0.11$ ), although the estimate included unity (Table).

**Table. Incidence Rate Overall and by ACPA Status**

	Total number of first erosions	Total number of person- years of radiographic follow-up time	Incidence rate of erosions (per 100 person- years)	Unadjusted HR (95% CI)	Adjusted* HR (95% CI)
Overall	187	1344.27	13.9		
By ACPA status					
ACPA+				1.21 (0.88, 1.67)	1.30 (0.94, 1.80)
	132	893.60	14.8		
				$p=0.23$	$p=0.11$
ACPA-	55	450.67	12.2	reference	reference

\*Adjusted for baseline CDAI score (0–10, >10–22, >22) and baseline age (18–<45, 45–<55, 55–<65, 65–90 years)

ACPA=anti-citrullinated protein antibody; HR=hazard ratio

## Conclusion:

In this contemporary cohort of patients with early RA, incident erosions were common. Our findings suggest further exploration of the association of ACPAs and the incidence of erosions is needed, and whether medications including biologic/targeted synthetic DMARDs influence the relationship.

## Factors That Drive Treatment Recommendation during Rheumatoid Arthritis Patient's Follow-up, Differ According to Physician Experience

César Sifuentes-Cantú<sup>1</sup>, Irazu Contreras-Yañez<sup>2</sup>, Lina Saldarriaga Rivera<sup>3</sup>, Ana Cecilia Lozada<sup>4</sup>, Marwin Gutierrez<sup>5</sup> and Virginia Pascual-Ramos<sup>1</sup>, <sup>1</sup>Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, <sup>2</sup>Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, <sup>3</sup>Instituto Nacional de Rehabilitación, Mexico, Mexico, <sup>4</sup>Division of musculoskeletal and rheumatic diseases, Instituto Nacional de Rehabilitación, Mexico City, Mexico, <sup>5</sup>Rheumatology, Instituto Nacional de Rehabilitación, Mexico City, Mexico

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The management plan for rheumatoid arthritis (RA) might be a relatively simple task if only disease activity is considered but might become more complex when additional factors are considered.

Previously, in a real clinical setting of RA outpatients, we explored the impact of musculoskeletal ultrasound, added to clinical evaluations in the treatment decision; we found that ultrasound had a greater impact in the trainee (TR) than in the senior rheumatologist (SR).

The aim of the present study was to investigate which factors impact the treatment recommendation in RA outpatients and to detect potential differences among 2 rheumatologists categorized by their experience, TR vs. SR.

### Methods:

Eighty-five consecutive and randomly selected RA outpatients underwent 170 assessments, 85 each by the SR and the TR. Initially, both physicians performed a complete rheumatic assessment which included disease activity as per DAS28 and recommended a treatment. Then, the patients underwent a musculoskeletal evaluation by an independent rheumatologist. In the final step, the TR and the SR integrated ultrasound findings with their previous evaluation and reviewed their recommendations. In addition, immediately after each patient encounter, both physicians were instructed to select and rate, which among the following factors were determinant in the final treatment proposal: clinical assessments, ultrasound findings, comorbidities, treatment related adverse events, costs/availability, patient's preference and DMARD maximum dose. In all the instances, the SR and the TR were blinded to each other assessments. Data were obtained on standardized formats. Descriptive statistics were used. The study was approved by the local IRB and all the patients signed informed consent.

### Results:

Patients were primary middle-aged (mean±SD: 45.1 ± 12.4 years) female (91.4%) and had disease duration of 7.5±3.9 years. The majority of the patients were in DAS28 remission (<2.6) and 24 (28.2%) showed some disease activity. All the patients were on DMARDs and 48% had additional low doses of oral corticosteroids.

Clinical assessments were rated as determinants in the totality of the clinical scenarios, followed by ultrasound findings in 84.7%, DMARD maximum dose in 41.2%, comorbidities in 23%, DMARD cost/availability in 21.2%, DMARD-related adverse events in 20% and finally, patient preference was rated as determinant in 14.1% of the clinical scenarios. Interestingly, the SR and the TR differed in the selection of the factors they considered determinant for the treatment proposal (**Figure**).

### Conclusion:

Disease activity drives the treatment decision during RA patients follow-up, although additional factors may be considered. Considerable variation was observed in how doctors rated those factors and these variations depended on physician's experience.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Forefoot deformities are commonly seen in patients with RA. It has been reported that nearly 90% of the patients have foot problems.<sup>1,2</sup> Patients with RA often suffer from callosity or metatarsalgia in the rheumatoid foot. Forefoot surgery is often necessitated in cases of painful forefoot deformities in which conservative treatment proves to be insufficient.<sup>3,4</sup> The purpose of this study is to investigate the differences in plantar pressure and background characteristics between the patients without scheduled forefoot surgery (group N) and the patients with scheduled forefoot surgery (group S), and to identify those characteristics that might be useful as indicators for conservative treatment.

**Methods:** Patients with RA were divided into 2 groups: group N and group S. The former consisted of 250 feet in 141 patients, and the latter consisted of 125 feet in 72 patients. DAS28, hallux valgus angle (HVA), the angle between the first and the second metatarsal bone (M1/2), the angle between the first and the fifth metatarsal bone (M1/5) and distribution of the site of callosity were evaluated as background characteristics. Distribution of peak pressure as plantar pressure was measured in 9 sections, including the first interphalangeal joint, the first through the fifth metatarsophalangeal joints (MTPJ), the medial and lateral midfoot, and the hindfoot. In addition, maximum peak pressure (MAXPP), minimum peak pressure (MINPP) and the difference value between MAXPP and MINPP ( $\Delta$  pressure) were also measured. The MAXPP and MINPP indicates the highest and lowest peak pressure value found among the peak pressure measurements of all 9 sections, respectively. Finally, cut-off values were calculated from the receiver operating characteristic curve for each item which differed significantly between the 2 groups.

**Results:** In groups N and S, the mean DAS was 3.7 and 3.0 ( $p < 0.001$ ), the mean HVA was 19.4° and 34.5° ( $P < 0.001$ ), the mean M1/2 was 11.5° and 14.1° ( $P < 0.001$ ), and the mean M1/5 was 30.3° and 33.1°, respectively. Callosities were seen at the second and third

MTPJ in half of all patients in group S. The mean peak pressure of group S at the first, second, third MTPJ, medial midfoot and hindfoot was significantly higher than that of group N ( $P < 0.001$ , 0.05, 0.01, 0.05 and 0.01). Significant differences between the 2 groups were also seen in MAXPP, MINPP and  $\Delta$  pressure ( $P < 0.001$ , 0.05 and 0.001). The cut-off values were 24.9° for HVA, 4.81 kg/cm<sup>2</sup> for MAXPP and 4.51 kg/cm<sup>2</sup> for  $\Delta$  pressure. At the cut-off values, sensitivities were 76.0%, 69.6% and 67.4%, and specificities were 71.2%, 57.2% and 60.8%, respectively. Assessing HVA and MAXPP in combination, sensitivity was 46.4%, and specificity was 90.8%.

**Conclusion:** The combined assessment of HVA and MAXPP appeared to be useful as an indicator for conservative treatment of rheumatoid forefoot deformity. It is important to keep MAXPP under 4.81 kg/cm<sup>2</sup> through drug treatment, orthotic treatment and physical treatment, in order to avoid forefoot surgery.

## Economic Burden Associated with Anti-Cyclic Citrullinated Peptide Antibody Positivity in Patients Newly Diagnosed with RA

J An<sup>1</sup>, Z Bider<sup>2</sup>, J Kang<sup>1</sup>, E Alemao<sup>3</sup>, SE Connolly<sup>3</sup> and TC Cheetham<sup>1</sup>, <sup>1</sup>Western University of Health Sciences, Pomona, CA, <sup>2</sup>Southern California Permanente Medical Group, Pasadena, CA, <sup>3</sup>Bristol-Myers Squibb, Princeton, NJ

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-cyclic citrullinated peptide (anti-CCP) antibody positivity has been suggested as a strong predictor of joint erosion as well as a potential biomarker for guiding treatment decisions. There are limited data evaluating the economic burden of anti-CCP positivity. We investigated the association between anti-CCP positivity and healthcare expenditures in newly diagnosed patients (pts) with RA.

**Methods:** A retrospective cohort study was conducted in adult pts with RA in Kaiser Permanente Southern California (Jan 2007 to Dec 2014). Individuals were followed from their first RA diagnosis (index) for 12 months. Pts were required to have two International Classification of Diseases, Ninth Revision, RA diagnosis codes of 714.0–714.8, a DMARD prescription, and continuous eligibility for 12 months prior to and after index date. Pt demographics, anti-CCP status, co-morbidity and healthcare resource utilization during the study period were collected. Nationally recognized direct medical costs were assigned to healthcare utilizations to calculate healthcare costs in 2015 US dollars. Difference-in-difference (DID) propensity score analyses were conducted to determine the association between anti-CCP positivity and 12-month cost outcomes. A generalized linear regression model with recycled prediction methods was used to quantify the differences of changes in costs ( $\delta_{dd}$ ) between the anti-CCP-positive (anti-CCP+) and anti-CCP-negative (anti-CCP-) groups.

**Results:** A total of 2448 newly diagnosed pts with RA were identified with a mean (SD) age of 55.5 (14.3) years; 75.7% were female. At baseline, 65.8% of pts were anti-CCP+ and 34.2% were anti-CCP-, where anti-CCP+ pts had fewer co-morbidities (median Elixhauser co-morbidity scores: 3 vs 4;  $p < 0.001$ ) versus anti-CCP- pts. During follow-up, more anti-CCP+ pts received  $\geq 1$  biologic DMARD (22.6 vs 12.9%;  $p < 0.001$ ) and had more frequent rheumatologist visits (median number: 5 vs 4;  $p < 0.001$ ) versus anti-CCP-

pts. During the 12-month follow-up, median (interquartile range) total healthcare expenditure for anti-CCP+ and anti-CCP– pts was \$6200 (\$3563–13,260) and \$7022 (\$3885–12,995), respectively. For the DID, when considering baseline costs, pt demographics and co-morbidities, anti-CCP positivity was significantly associated with higher prescription ( $\delta_{dd}=\$2499$ ;  $p<0.001$ ), laboratory testing ( $\delta_{dd}=\$183$ ;  $p<0.001$ ) and rheumatologist visit costs ( $\delta_{dd}=\$76$ ;  $p<0.001$ ). Total incremental cost associated with anti-CCP positivity was estimated as \$2163 ( $p=0.001$ ; Figure). No statistical differences were found in hospitalizations or emergency department-related costs.

**Conclusion:** In newly diagnosed pts with RA, the higher economic burden for anti-CCP+ pts was mainly driven by pharmacy costs. Future pt-reported outcomes and/or disease progression associated with the early economic burden may help guide treatment decisions.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

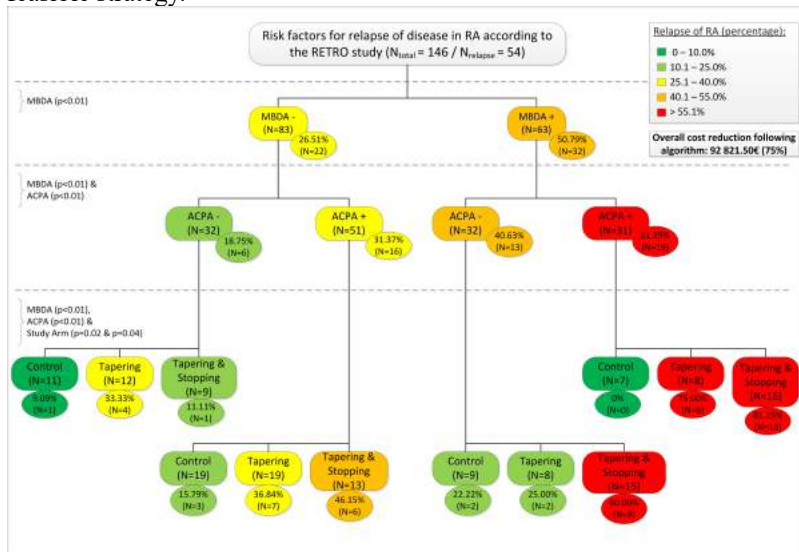

### Background/Purpose:

Achieving remission is the ultimate treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach the disease remission state (1), raising the question about tapering or stopping anti-rheumatic treatment and appropriate predictors (2). The purpose was to analyse the effect of a risk-stratified DMARD tapering algorithm based on multiple-biomarker disease activity (MBDA) score and anti-citrullinated protein (ACPA) status for successful DMARD tapering and treatment cost reduction in RA patients in sustained remission enrolled in the prospective randomized controlled RETRO study (3,4).

**Methods:** MBDA scores and ACPA status were determined in the baseline samples of 146. A patients in sustained remission. Patients either continued DMARDs (arm1), tapered dose by 50% (arm 2) or stopped DMARDs after tapering (arm 3) for one year according to the RETRO study protocol. Direct treatment costs (including testing costs at baseline) were evaluated every three months. MBDA and ACPA status were used as predictors creating a risk-stratified tapering algorithm based on relapse rates.

**Results:** RA patients with a low MBDA score (<30) and negative ACPA showed lowest relapse risk (19%). With either single positivity for ACPA or moderate/high MBDA scores (>30) relapse risk increased and was high in double-positive patients (61%). In MBDA negative (<30) and MBDA single-positive (>30) groups, DMARD tapering appears feasible. Considering only patients that did not flare, costs for synthetic and biologic DMARDs in the MBDA-negative and single-positive groups (n=41) would have been 123.751,29€ for full-dose treatment over one year. Tapering and stopping DMARDs in this low-risk relapse groups allowed a reduction of 92.821,50€ (-75%) of DMARD costs. Average reduction of DMARD costs per patient were 2.350,08€ in the double negative (MBDA- /ACPA-) and single negative (MBDA- /ACPA+) group and 1.761,43€ in the MBDA single positive (MBDA+ /ACPA-) group.

**Conclusion:** Combining MBDA score and ACPA status allows risk stratification for successful DMARD tapering and cost-effective use of biologic DMARD. Given that previous data of the RETRO have shown that patients relapsing after tapering their DMARDs respond well to their reintroduction, a stratified tapering and stopping of DMARDs is not only a cost economic but also clinically feasible strategy.

### **SESSION INFORMATION**

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Baricitinib (bari) is an oral selective inhibitor of Janus kinase (JAK) 1/JAK2.<sup>1</sup> In the European Union, bari is approved for the treatment of moderate to severe RA in adults. GlycA, a measure of glycosylated acute phase proteins, is an emerging inflammatory marker that may be useful for assessment of disease activity and is associated with subclinical cardiovascular (CV) disease in patients with RA.<sup>2,3</sup> The objective of this analysis was to assess GlycA levels in a Phase 2 and 3 (RA-BEAM) study in patients (pts) with RA treated with bari.

**Methods:** In the Phase 2 study, 301 pts were randomized 2:1:1:1 to placebo (PBO) or bari (1, 2, 4, or 8 mg) once daily (QD) for 12 weeks (wks). At Wk 12, pts initially assigned to PBO or bari 1 mg were rerandomized 1:1 to bari 2 mg twice daily or bari 4 mg QD; pts initially assigned to bari 2, 4, or 8 mg QD continued that treatment. In RA-BEAM, 1305 pts were randomized 3:3:2 to PBO, bari 4 mg QD, or adalimumab (ADA) 40 mg every 2 wks. GlycA levels were evaluated with nuclear magnetic resonance spectroscopy at baseline and Wks 12 and 24. In these post hoc analyses, change from baseline to week 12 in GlycA levels were compared between treatment groups without adjustment for multiple comparisons.

**Results:** Treatment with bari resulted in dose-dependent decreases in GlycA levels from baseline to Wk 12 in the Phase 2 study (-7.7% to -14.4% in the 1- and 8-mg treatment groups, respectively), with similar results at Wk 24 (Figure). In RA-BEAM at Wk 12, GlycA levels in pts treated with bari decreased significantly compared to PBO or ADA (Table 1). There were similar reductions in GlycA with bari regardless of baseline statin use (Table 2).

**Conclusion:** Bari decreases GlycA in a dose-dependent manner; reductions were seen regardless of baseline statin treatment. With recent studies suggesting GlycA as a marker for CV risk, these reductions in Phase 2 and 3 studies in an RA population may portend a reduction in overall CV risk. Further long-term data will be required to assess the possibility.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Maturation of autoantibody responses has been suggested to be a proxy for disease maturation. Autoantibody responses against post-translationally modified antigens are present in autoimmune diseases and antibodies directed against carbamylated proteins (anti-CarP antibodies) are a marker of RA. Anti-CarP antibody analysis in patients (pts) with early RA offers the opportunity to estimate whether specific intervention during such early stages of autoantibody development may have an impact on the maturation of the anti-CarP antibody response. We assessed the relationship between changes in anti-CarP isotypes and rates of seroconversion to negative (–ve) in pts with early RA. **Methods:** In the AVERT study (NCT01142726), pts with early RA were treated with abatacept (ABA)+MTX, ABA monotherapy or MTX alone.<sup>1</sup> Pts were anti-cyclic citrullinated peptide-2 positive (+ve) at baseline for study entry.<sup>1</sup> In this *post hoc* analysis, concentrations of anti-CarP isotypes were measured using custom ELISAs. Anti-CarP ELISAs for immunoglobulin (Ig)G, IgM or IgA isotypes were performed in pt serum at baseline, and at Days 85 and 365 on treatment. Baseline levels of each anti-CarP antibody isotype and % seropositivity were comparable across treatment arms. Adjusted mean change from baseline was calculated using a longitudinal repeated measures model. **Results:** At baseline, 51.3, 42.5 and 29.3% of all pts with

serum available in AVERT were +ve for IgG, IgM (indicative of an ongoing immunoresponse) and IgA anti-CarP isotypes, respectively. Overall, ~65% of pts were +ve for  $\geq 1$  anti-CarP antibody isotype. Median % change from baseline (25%, 75%) for anti-CarP isotype levels from baseline to Days 85 and 365 are shown (Table). Analyzing pts who were +ve at baseline for each of the isotypes, we observed that 19/48 (40%), 16/43 (37%) and 11/48 (23%) of pts +ve for the IgG isotype became -ve on ABA+MTX, ABA and MTX, respectively, at 1 year. For the IgM isotype, 26/48 (54%), 14/36 (39%) and 15/38 (39%) became -ve on ABA+MTX, ABA and MTX, respectively. For the IgA isotype, 12/26 (46%), 10/23 (43%) and 13/31 (42%) became -ve on ABA+MTX, ABA and MTX, respectively.

**Conclusion:** Concentrations of all anti-CarP isotypes (IgM, IgA, IgG) were numerically reduced by abatacept+MTX therapy compared with MTX or abatacept alone. Abatacept+MTX trended towards higher rates of seroconversion to -ve for all isotypes over 1 year of treatment. These results indicate that the extent of the anti-CarP antibody response can be modulated by intervention with abatacept on background MTX in anti-citrullinated protein antibody +ve pts with early RA.

## SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** This is the first study assessing the effect of subcutaneous tocilizumab (TCZ-SC) and/or conventional synthetic DMARDs (csDMARDs) on work productivity and activity impairment (WPAI) in paid workers (PWs) and homeworkers (HWs) among Japanese patients with RA.

**Methods:** FIRST ACT-SC was a real-world, prospective, observational study (Jan 2014 to Sep 2015 at 82 centers). Biologic-naïve patients receiving  $\geq 1$  csDMARD, both PWs and HWs, and with moderate/high disease activity were enrolled and treated with TCZ-SC +/- csDMARDs or csDMARDs alone. The primary endpoint was the percentage change in overall work impairment (OWI; assessed using the WPAI questionnaire) from baseline to 52 weeks among PWs. Inverse probability of treatment weighting using propensity score was used to adjust for patient background to compare the 2 groups. Depending on the patients' symptoms during the observation period, change of dose, change to another csDMARD, or addition of another csDMARD was allowed.

**Results:** In total, 377 and 347 patients were enrolled in the TCZ-SC +/- csDMARD and csDMARD-alone groups, respectively, of which 321 (mean  $\pm$  SD age, 57.7  $\pm$  14.0 years; female, 81.6%) and 307 (60.1  $\pm$  12.8 years; 85.7%) patients, respectively, were included in the modified intent-to-treat population. Of these, 233 (72.6%) and 224 (73.0%) patients, respectively, completed 52 weeks of follow-up. The primary and secondary endpoint results are summarized in the Table 1. Although disease activity (DAS28, SDAI, CDAI, etc.) and HAQ-DI improvements were better in the TCZ-SC group compared to the csDMARD group, the weighted percentage change in OWI from baseline was only  $-0.189$  in the TCZ-SC group at 52 weeks, and there was no difference between the 2 groups (weighted treatment difference,  $0.003$ ; 95% CI,  $-0.062$  to  $0.068$ ;  $P = 0.929$ ). In contrast, the improvement in percentage activity impairment in HWs and the overall group was significantly better in the TCZ-SC group compared to the csDMARD group at week 52 ( $P = 0.005$  and  $P = 0.003$ , respectively). TCZ-SC-treated HWs also showed significant improvement in overall quality of life (QOL), including EQ-5D, J-HAQ, and K6.

**Conclusion:** There was no significant difference in OWI between the 2 treatment groups. However, activity impairment, disease activity, and QOL in HWs and the overall group were significantly improved with TCZ-SC than with csDMARDs alone. Taken together, improvement in work productivity/activity impairment is determined by differences in TCZ-SC +/- csDMARDs and differences in PWs and HWs at baseline.

**Role of the Study Sponsor:** This study was supported by funding from Chugai Pharmaceutical Co., Ltd.

**Acknowledgments:** Medical writing assistance was provided by Mami Hirano, M.S., of Cactus Communications. Support for study management was provided by EPS Corporation.

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Baricitinib (BARI), an oral inhibitor of Janus kinase (JAK)1 and JAK2, is being developed for the treatment of RA. RA-BEGIN (NCT01711359) was a phase 3, double-blind, three-arm, multicenter study of BARI administered as monotherapy or in combination with methotrexate (MTX) to patients with early active RA who had no or limited treatment with MTX; MTX monotherapy was the active comparator. This analysis was conducted to identify factors associated with risk of radiographic progression in an early RA population after 52 weeks of treatment with BARI 4mg monotherapy, MTX monotherapy, or a combination of the two drugs.

**Methods:** Radiographic progression was defined as change from baseline (CFB) greater than the smallest detectable change (SDC) in van der Heijde-modified total Sharp score (mTSS) at week 52. The SDC in mTSS in the RA-BEGIN modified intent-to-treat population at week 52 was 1.4. Missing mTSS data at week 52 were imputed using linear extrapolation based on baseline data and the most recent radiographic data before the missed radiograph. Data for 39/584 patients with completely missing radiographic data were omitted from the analysis. The association of different baseline factors with radiographic progression was assessed using a multivariate logistic regression model including: treatment, age, gender, BMI, ACPA ( $\leq 10$ U/ml negative;  $>10$ U/ml positive), RF ( $\leq 14$ IU/ml negative;  $>14$ IU/ml positive), presence of joint erosions (yes/no), smoking habit (yes/no), hsCRP, HAQ-DI, mTSS, RA duration, CDAI, and geographic location.

**Results:** Radiographic progression at week 52 was seen in 21.9% (MTX), 14.9% (BARI 4mg) and 10.1% (BARI 4mg plus MTX) of patients. Female gender, smoking habit, higher hsCRP at baseline (Fig), higher CDAI at baseline (Fig) and lower BMI at baseline were significantly associated with an increased risk of radiographic progression (Tab).

**Figure. Adjusted probability of radiographic progression as a function of A. baseline hsCRP and B. baseline CDAI, estimated with a multivariate logistic regression model**

**A.**

Estimated odds ratio for baseline hsCRP is 1.018 ( $p < 0.001$ ). The odds of radiographic progression will increase by a factor of 1.018 when baseline hsCRP increases by one unit.

**B.**

Estimated odds ratio for baseline CDAI is 1.025 ( $p = 0.038$ ). The odds of radiographic progression will increase by a factor of 1.025 when baseline CDAI increases by one unit.

CFB, change from baseline; CDAI, Clinical Disease Activity Index; hsCRP, high sensitivity C-reactive protein; Rd, radiographic; SDC, smallest detectable change.

**Table. Assessment of radiographic progression estimated from a multivariate logistic regression model adjusted by baseline factors**

Odds ratio estimates				
	Odds ratio	Lower confidence interval	Upper confidence interval	p value
BARI 4mg vs MTX	0.567	0.305	1.028	0.066
<b>BARI 4mg plus MTX vs MTX</b>	<b>0.324</b>	<b>0.169</b>	<b>0.599</b>	<b>&lt;0.001</b>
Age	0.998	0.979	1.017	0.820
<b>Gender (female vs male)</b>	<b>2.283</b>	<b>1.202</b>	<b>4.577</b>	<b>0.015</b>
<b>Baseline BMI</b>	<b>0.941</b>	<b>0.890</b>	<b>0.991</b>	<b>0.025</b>
ACPA (positive vs negative)	1.191	0.448	3.812	0.745
RF (positive vs negative)	1.755	0.298	33.888	0.608
<b>Smoking habit (yes vs no)</b>	<b>1.923</b>	<b>1.031</b>	<b>3.544</b>	<b>0.037</b>
<b>Baseline hsCRP</b>	<b>1.018</b>	<b>1.009</b>	<b>1.027</b>	<b>&lt;0.001</b>
Baseline HAQ-DI	0.702	0.453	1.083	0.111
Baseline mTSS	1.006	0.994	1.016	0.319
RA duration	0.953	0.852	1.035	0.322
<b>Baseline CDAI</b>	<b>1.025</b>	<b>1.001</b>	<b>1.049</b>	<b>0.038</b>
Baseline joint erosions (positive vs negative)	1.441	0.808	2.631	0.224
<p>There was no evidence that any of the geographic locations differed from the others with respect to radiographic progression (Omnibus Type III p value = 0.653). Individual comparisons between the different geographic locations not shown.</p> <p>ACPA, anti-citrullinated protein antibody; BMI, body mass index; CDAI, Clinical Disease Activity Index; HAQ-DI, Health Assessment Questionnaire Disability Index; hsCRP, high sensitivity C-reactive protein; RF, rheumatoid factor.</p>				

**Conclusion:** In patients with early RA and no or limited previous use of MTX who were treated with MTX, Bari 4 mg, or Bari 4mg plus MTX, risk factors for radiographic progression can be identified. After multivariate adjustment, female gender, smoking, baseline hsCRP, CDAI and BMI showed a statistically significant association with radiographic progression.

### SESSION INFORMATION

**Session Date:** Sunday, November 5, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster I: Treatment Patterns and Response

**Session Type:** ACR Poster Session A

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Since the year 2016 Rheumatoid Arthritis (RA) patients in the Chilean public health system can access biologic treatment if they have active disease refractory to non biologic DMARDs (see inclusion criteria). At first only Abatacept was available

as first line biologic. The first patients that initiated biologic treatment in our center were those who had a long lasting active disease. Our main objective was to evaluate the response to treatment with Abatacept in the patients from our center.
