**Background/Purpose:** MR-based T1ρ relaxation time mapping allows non-invasive quantification of early cartilage deterioration, while high-resolution peripheral quantitative computed tomography (HR-pQCT) can detect early changes in bone erosion volume. It is unknown whether changes of cartilage T1ρ values are associated with concomitant bone erosion changes and reflect treatment response. Therefore, we used 3T MRI and HR-pQCT to investigate the changes of bone and cartilage damage in RA patients receiving methotrexate (MTX) and anti-tumor necrosis factor alpha (TNFα) therapy.

**Methods:** Twenty RA patients receiving MTX treatment were recruited into either a low DAS group (n=9, DAS28≤3.2) or a high DAS group (n=11, DAS28>3.2). At baseline, the high DAS group initiated supplemental anti-TNFα treatment in addition to ongoing MTX. All patients underwent MRI wrist scans and HR-pQCT scans of the MCP and wrist at BL and after 3 months (3M). DAS28 CRP was assessed at BL and 3M. Lunar, scaphoid and radius and global cartilage T1ρ values were measured. HR-pQCT-derived erosion volume at lunate, radius, scaphoid, MCP2 and MCP3 were semi-quantitatively measured. Longitudinal changes and associations were evaluated either via paired t-test or Pearson's correlations.

**Results:** Anti-TNFα therapy in the high-DAS group resulted in a significant decrease of DAS28 CRP score (p<0.001), which was accompanied by decreases in mean T1ρ values (reached significance in scaphoid T1ρ, P=0.031) and erosion volumes (reached significance in MCP3 and global) at all measurement sites (Table.1). The low DAS group in contrast, displayed an increasing trend in T1ρ values and erosion volumes (reached significance in radius and global) despite low disease activity (Table.1) Changes in T1ρ values and bone erosion volume were significantly positively correlated, and both were significantly correlated with changes in DAS28 CRP score (Figure 1).

**Conclusion:** Anti-TNFα therapy seems to simultaneously prevent bone and cartilage from further destruction and might even partially repair preexisting cartilage deterioration and bone erosions within first 3 months of therapy as indicated by our observed decrease in T1ρ values and erosion volumes in our cohort. Our observation that early changes in cartilage T1ρ values are associated with changes in clinical disease activity and erosion volume, recommends a more extensive investigation of T1ρ as a predictor of disease progression. Our data illustrate the powerful potential of multimodal imaging with MRI and HR-pQCT to evaluate early response to treatment in RA.

Table 1; Longitudinal changes of MRI and HR-pQCT data

	Low disease activity (N=9)				High disease activity (N=11)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Early initiation of DMARDs and targeted therapy to achieve remission are said to offer the best opportunity to prevent radiographic damage in early inflammatory arthritis (EIA). High-resolution peripheral quantitative computed tomography (HR-pQCT) provides superior resolution of bone compared to x-ray, and reliable quantification of joint space [1] and erosions [2]. We used HR-pQCT to quantify changes in joint space, erosion number and size, and bone microarchitecture in EIA patients during the first year of therapy.

**Methods:** We recruited 47 EIA subjects and performed HR-pQCT (XtremeCT I, Scanco Medical AG, Switzerland) scans of the 2<sup>nd</sup> and 3<sup>rd</sup> MCPs of their dominant hand at diagnosis and 1 year later and collected sociodemographic and disease characteristics and disease activity at both timepoints. Erosion number and size were assessed from HR-pQCT images by applying the erosion definition and margin landmarks proposed by SPECTRA [2]. Mean, maximum, and minimum joint space width as well as joint space volume were assessed in 3D [1]. Total bone mineral density (Tt.BMD) was assessed in the distal 12% of the 2<sup>nd</sup> and 3<sup>rd</sup> metacarpal heads.

**Results:** At baseline, 34 met classification criteria for RA [3] and 13 had undifferentiated arthritis. After 1 year several individuals were reclassified: 1 had adult onset Still's disease, 1 had Psoriatic Arthritis, and 3 had a self-limited arthritis. The majority received DMARD therapy (89%) and 27% progressed to biologic use. The mean DAS28 improved from 5.4 (SD 1.2) to 2.4 (SD 1.1), and the HAQ decreased from 1.20 (SD 0.72) to 0.41 (SD 0.51). Erosions by HR-pQCT were found in 34% (19) of subjects at baseline, with 32 erosions detected (mean axial width 1.2 (SD 0.7) mm, axial depth 1.8 (SD 1.1) mm, perpendicular width 1.4 (SD 0.9) mm, perpendicular depth 1.8 (SD 1.1) mm. This increased to 40 erosions at 1 year, with 23 subjects remaining free of erosions, 12 having a stable number and 8 having an increased number of erosions. However, only 3 erosions had a depth increase that exceeded the smallest detectable change. At the 3<sup>rd</sup> MCP, mean and minimum joint space width (mm) decreased by 0.06 (SD 0.11) and 0.082 (SD 0.20), respectively. In contrast there were no significant changes in joint space width or volume at the 2<sup>nd</sup> MCP joint. There were no significant changes in Tt.BMD in the 2<sup>nd</sup> or 3<sup>rd</sup> MC. Type of therapy, CCP, RF, or 1-year remission status did not influence change in Tt.BMD or joint space.

**Conclusion:** Joint space narrowing progressed and the number of erosions increased despite rheumatologic intervention. HR-pQCT provides greater sensitivity for detection of changes in joint space, erosions and bone microarchitecture.

Figure 1. Change in erosion over 1-year follow-up evaluated with HR-pQCT after registration and alignment with baseline image.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate the local inflammatory activity by using dynamic magnetic resonance imaging (MRI) and cartilage biochemical composition of the metacarpophalangeal joints (MCP) digits 2 and 3 by using Delayed Gadolinium-Enhanced MRI (dGEMRIC) in patients with early rheumatoid arthritis (eRA) treated with Methotrexat (MTX).

**Methods:** MCP joints of the index and middle finger of 28 patients with eRA from the AthroMark cohort were examined prior to MTX-therapy (baseline) as well as 3 and 6 months after initiation of MTX-therapy (follow up). Perfusion parameters and dGEMRIC index were calculated. OMERACT RA MRI score, including synovitis, edema and erosion subscores, and clinical parameters (CRP and DAS28) were registered at all time points.

**Results:** In follow-up measurements, the local perfusion in dynamic MRI decreased significantly between months 0 and 3 and between months 0 and 6. Decreasing of local perfusion correlates significantly with the DAS28 improvement at 3 months ( $p < 0.05$ ). The extent of local inflammation (MCP II or MCP III) was significantly correlated with dGEMRIC values at all time points ( $p < 0.05$ ). Furthermore, local inflammation and cartilage composite measurements showed significant correlation with edema subscore in follow up after 3 months and with RAMRIS and erosion subscore in follow up after 6 months ( $p < 0.05$ ).

**Conclusion:** In patients with eRA synovial local hyperperfusion measured by dynamic MRI correlated significantly with the local cartilage composite and decreased significantly after 3 and 6 months after initiating MTX-therapy. Dynamic MRI seems to be a useful parameter of therapy success, since DAS28, RAMRIS and edema/erosion

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Radiological studies to distinguish between dermatomyositis (DM) and polymyositis (PM) are few. We predicted that the magnetic resonance imaging (MRI) findings of skeletal muscle would differ between DM and PM because of the differences in the histopathological findings associated with the disorders. Our objective was to establish distinctive MRI characteristics of skeletal muscle in patients with DM or PM.

**Methods:** The MRI findings (short-tau inversion recovery [STIR] and gadolinium-enhanced fat-suppressed T1-weighted imaging [Gd-T1WI]) of proximal limb skeletal muscles in patients with DM (n = 53) or PM (n = 32) were evaluated. Differences in the percentage appearances of the following findings in the axial plane between DM and PM patients and between autoantibody-positive and autoantibody-negative PM patients were analyzed: structures with high signal intensity (HSI) (subcutaneous adipose tissue, fascia,

muscle); distributions of HSI areas in muscle (diffuse, patchy, peripheral); patterns of HSI in muscle (honeycomb, foggy, strong high signal intensity [SHSI] ).

**Results:** Among the 79 patients with abnormal MRI findings, 48 were diagnosed with DM and 31 were diagnosed with PM. Of these, Gd-T1WI was performed in 45 patients with DM and 27 patients with PM. Table 1 shows the differences in the percentage appearances of MRI findings between DM and PM patients. On STIR and Gd-T1WI images, the percentage appearances of the following characteristics were higher in DM patients than in PM patients: subcutaneous HSI, fascial HSI, peripheral distribution in muscle, honeycomb pattern in muscle. Patchy distribution and foggy pattern in muscle were higher in PM patients than in DM patients. There were no significant differences between the groups for diffuse distribution and SHSI pattern in muscle. Table 2 shows the differences in the percentage appearances of MRI findings between the autoantibody-positive and autoantibody-negative PM groups. The percentage appearances of subcutaneous and fascial HSI on STIR and Gd-T1WI images were higher in autoantibody-positive PM patients than in autoantibody-negative PM patients. Patchy distribution in muscle on Gd-T1WI was higher in autoantibody-negative PM patients than in autoantibody-positive PM patients.

**Conclusion:** Subcutaneous and fascial HSI, peripheral distribution in muscle, and honeycomb pattern in muscle are characteristic MRI findings in patients with DM, whereas patchy distribution and foggy pattern in muscle are characteristic MRI findings in patients with PM. MRI could be a useful tool for diagnosing DM and PM.

**Table 1:** Percentage appearances of characteristic findings on MRI in patients with DM or PM\*

<b>STIR</b>	<b>DM ( n = 48 )</b>	<b>PM ( n = 31 )</b>	<b>p-value<sup>†</sup></b>

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** According to the ASAS classification criteria for axial spondyloarthritis (SpA), the presence of structure changes of sacroiliac (SI) joints such as sclerosis, bone erosion, joint space widening or ankyloses can't be adopted to confirm active sacroiliitis on magnetic resonance imaging (MRI) in the absence of bone marrow edema (BME). Previous data indicated less than half Asian patients with axial SpA were characterized by BME. For patients with early phase of SpA, HLA-B27 is associated with early diagnosis and axial inflammation of SI joints on MRI, while serum c reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are incapable of predicting early sacroiliitis. Nonetheless, HLA-B27 is not associated with structural lesions of SI joints. All factors contribute to difficult defining early Asian SpA patients in the absence of serum HLA-B27 and obvious imaging inflammation. This study aims to define the prevalence of structure changes of SI joints on MRI in Taiwanese patients with non-radiographic axial SpA and identify how to confirm an early diagnosis of HLA-B27 negative axial spondyloarthritis.

**Methods:** Eighty patients with inflammatory back pain and morning stiffness and high disease activity (BASDAI $\geq$ 4) who had to be either serum HLA-B27 positive (27 patients) with  $\geq$ 1 SpA-feature or HLA-B27 negative with  $\geq$ 2 SpA-features (53 patients) were included in this prospective study. All patients were tested for X-rays of the pelvis before MRI examination and did not meet the definition for a positive radiograph according to the modified New York criteria. MRI of sacroiliac joints (MRI-SIJ) was performed with multiple sequence (Coronal and axial T1-weighted spin echo, coronal and axial short-tau inversion recovery). SI joints were evaluated for the prevalence of subchondral BME and structure changes, including sclerosis, bone erosion, joint space widening and ankylosis. All MRI-SIJ were scored according to the SPARCC score. All patients were tested for serum levels of ESR and CRP. Correlation analysis was performed among the different collected variables.

**Results:** Subchondral BME was present in 12 of 57 patients with HLA-B27 serum negative SpA (21.1 %), while 15 of 23 (65.2 %) HLA-B27 serum positive SpA patients had active BME on MRI ( $p = 0.02$ ). Patients with SpA and positive HLA-B27 were characterized by higher SPARCC scores, compared to serum negative patients ( $p < 0.001$ ). Structural changes of SIJ, including sclerosis, bone erosion and joint space widening were identified in 20 (86.9 %), 27 (100 %) and 10 (43.5 %) SpA patients with positive HLA-B27, respectively. These structural changes of SIJ on MRI were less common in HLA-B27 serum negative patients, as 30 (52.6 %), 50 (87.7 %) and 9 (15.8 %) of 23 patients, respectively. Among patients with high serum ESR or CRP, joint space widening developed accompanied with higher SPARCC scores ( $p = 0.024$  and  $0.019$ , respectively).

**Conclusion:** MRI is able to detect active sacroiliitis and structure changes of SI joints for patients with non-radiographic axial spondyloarthritis in the absence of serum HLA-B27. Structure changes on MRI-SIJ could be used alternatively for early diagnosis of SpA in Asian people whom are characteristic by less bone marrow edema.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To compare the prevalence of inflammatory posterior arch abnormalities (IPAA) on lumbar spine MRI between spondyloarthritis patients (SpA) and low back pain patients (LBP).

**Methods:** Design : Monocentric cross-sectional case-controlled study. Patients : SpA patients fulfilling the 2009 ASAS criteria who had a lumbar spine MRI were retrospectively selected from medical files. Chronic LBP patients with a lumbar spine MRI planned in the Toulouse Hospital Radiology Center were prospectively selected if they had no argument for a symptomatic back pain (e.g. tumor, infection,...). MRI : STIR and T1 sagittal images from 3 and 1.5 Tesla MRI going up to T8-T9 stages were reviewed by two experienced rheumatologists, blinded from the diagnosis and clinical data. IPAA (i.e.: pedicle edema, transverse and spinous process edema, interspinous process edema, costo-transverse or zygapophyseal joint arthritis) were collected in the two groups. Analyses : The prevalence of IPAA between SpA and LBP patients were compared by Chi2 or Fisher's exact test. Clinical data (age, sex, disease duration, BASDAI, CRP, BASFI) were compared in the SpA group according to the presence/absence of IPAA by Chi2 or Wilcoxon tests.

**Results:** Ninety-five patients were included in each group. Inter and intra-observer agreement was excellent ( $\kappa=0.938$ ). The prevalence of all IPAA was not significantly different between SpA and LBP groups (55.9% in SpA group versus 69.5% in LBP group,  $p = 0.97$ ). On the other hand, there was a significant difference in the prevalence of costo-transverse joint arthritis, pedicle edema, transverse and spinous process edema between the two groups (prevalence of these anomalies in SpA group: 27% versus 8% in LBP group,  $p = 0.006$ ). Costo-transverse joint arthritis and transverse process edema have a specificity and a positive predictive value of 100% for the diagnosis of SpA, with sensitivity of 17% and 3.2% respectively. Patients with IPAA in SpA group had a longer disease duration (11 years versus 8 years,  $p=0.02$ ), higher CRP level (medians : 11 versus 3,  $p=0.0002$ ), more often a MRI sacroiliitis (84% versus 47%,  $p=0.001$ ), more often psoriasis (27% versus 10.2%,  $p=0.04$ ) but received less NSAIDs (42% versus 69%,  $p=0.01$ ) compared to patients without IPAA.

**Conclusion:** Costo-transverse joint arthritis, pedicle edema and transverse process edema are more frequent and specific for the diagnosis of SpA. IPAA are frequently associated with biological inflammation and MRI sacroiliitis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** <sup>18</sup>F sodium fluoride (NaF) positron emission tomography (PET) allows quantitative assessment of osteoblastic bone synthesis in specific skeletal sites. Previous studies showed that increased <sup>18</sup>F NaF uptake at vertebral corners was linked with syndesmophytes formation in patients with ankylosing spondylitis (AS), but the association between bone metabolism measured by <sup>18</sup>F NaF PET and bone mineral density (BMD) has not been studied. Thus, we investigated whether baseline <sup>18</sup>F NaF uptake of vertebral bodies or vertebral corners on PET is associated with changes in BMD at the corresponding lumbar vertebrae in AS.

**Methods:** In 12 male AS patients, <sup>18</sup>F NaF PET/computed tomography (CT) was performed at baseline and dual energy X ray absorptiometry (DEXA) was performed at baseline and the 1-year follow-up. The maximum standardized uptake value (SUVmax) of the vertebral body and both upper and lower vertebral corners from the L1 to L4 were measured in the mid-sagittal plane of the <sup>18</sup>F NaF PET/CT image. By using the squared region of interest (ROI), the SUVmax of the vertebral body was acquired (Figure 1a). For the SUVmax of the corners, we used the arithmetic mean SUVmax of the upper and lower vertebral corners which were evaluated with 1cm-sized circular ROIs (Figure 1b). The BMD of the L1 to L4 were calculated from conventional DEXA. The association of the SUVmax of the vertebral bodies or corners with the changes in BMD during 1-year follow-up was analyzed at the lumbar vertebral level using generalized estimating equations (GEE) to adjust within-patient correlation for a total number of lumbar vertebrae.

**Results:** We analyzed 48 lumbar vertebrae in 12 AS patients. At the lumbar vertebral level, the mean (SD) baseline SUVmax of the vertebral body and the median (IQR) baseline SUVmax of the vertebral corners were 6.7(1.8) and 6.5(5.3-7.1), respectively. The mean (SD) BMD of each vertebra at baseline and 1-year follow-up were 1.18 (0.21) g/cm<sup>2</sup> and 1.19 (0.19) g/cm<sup>2</sup>, respectively. In correlation analyses, changes in BMD at lumbar vertebrae was positively correlated with the baseline SUVmax of the vertebral bodies ( $r=0.39$ ,  $p=0.036$ ) but not with that of the vertebral corners ( $r=-0.07$ ,  $p=0.657$ ). In multivariable GEE analysis, the baseline SUVmax of the vertebral bodies was significantly associated with changes in BMD at the lumbar vertebrae [ $B(SE)=0.009(0.004)$ ,  $p=0.017$ ], but that of vertebral corners did not showed this association [ $B(SE)=-0.003(0.002)$ ,  $p=0.174$ ]. The baseline BMD of the vertebra also showed significant associations with changes in BMD.

**Conclusion:** Baseline <sup>18</sup>F NaF uptake of the vertebral bodies but not that of the vertebral corners on PET was associated with 1-year changes in BMD at the lumbar vertebrae in AS patients. Our data suggests different mechanisms of bone metabolism between the vertebral bodies and corners that have separate effects on BMD in AS.

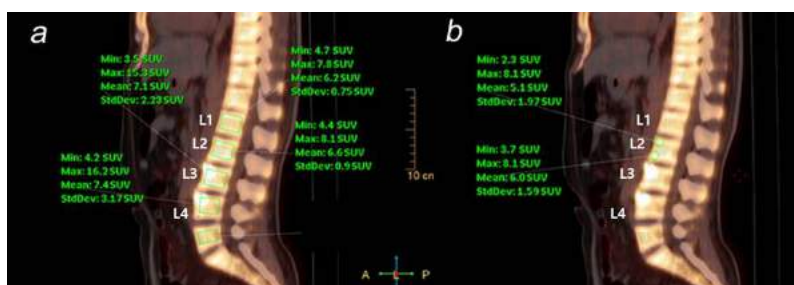

Figure 1. Representative example of the region of interest (ROI) used to obtain the maximum standardized uptake (SUVmax) value of the L1 to L4 in the mid-sagittal plane of the 18F sodium fluoride positron emission tomography /computed tomography image of a 42-year old patient with ankylosing spondylitis. The squared ROI for the vertebral body (a) and 2 round shaped ROIs for calculating arithmetic mean SUVmax of the upper and lower vertebral corners (b).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung diseases (ILD) are a group of illnesses that often complicate connective tissue diseases (CTD) such as rheumatoid arthritis (RA) or systemic sclerosis (SS), but the lung is the only affected organ in the idiopathic pulmonary fibrosis (IPF). Nonspecific interstitial pneumonia (NSIP) is the more frequent form in SS while usual interstitial pneumonia (UIP) predominates in RA patients and in the IPF form. ILD are one of the most important causes of mortality in CTD, but evaluating their prognosis remains difficult. Some studies suggested that 18-FDG-PET/CT could help to detect zones of activity in lung tissue in IPF and this in turn could predict the progress of the disease, but the results are inconclusive. Moreover, little is known about the value of 18-FDG PET uptake in ILD associated to RA or SS. The purpose of this study is to evaluate the predictive value of 18 FDG-PET/CT scan images in functional pulmonary progression of ILD associated to RA or SS.

**Methods:**

We conducted a 12 month prospective observational study on patients diagnosed with ILD associated to SS or RA between January 2015 and May 2017. ILD diagnosis was based on clinical assessment, pulmonary function tests (PFTs) and expert HRCT evaluation. This study was approved by the ethic research committee of our institution, and a formal written consent was obtained by all patients.

We performed three visits: basal, 6 month and 12 month visits. On all visits a general exploration, forced vital capacity (FVC) and diffusing capacity of the lungs for carbon monoxide (DLCO) were carried out. On basal and 6 month visits a 18 FDG-PET/TC were performed within a period of three months from the PFTs.

The patients selected continued with their treatment (corticosteroids, DMARDs or immunosuppressants).

The nuclear medicine physician identified the maximum and mean standardized uptake value (SUVmax and SUVmean) in the three areas with the most FDG uptake, and adenopathies uptake.

PET/CT images were reviewed by 2 combined radiologist/nuclear medicine physicians in consensus.

**Results:** We included 17 patients, 10 had UIP associated with RA and 7 NSIP related to SS. It appeared that RA patients had longer lung illness evolution and worse FVC than SS patients (table), in spite of not having found statistical differences. We detected significant statistical relation between the highest SUVmax and FVC ( $p=0.009$ ) or DLCO progression ( $p=0.006$ ) in SS patients, independently of the basal FVC and DLCO, and duration of lung illness in a multivariable linear mixed model. We didn't find any relation between SUVmax and FVC or DLCO progression in RA patients.

Rheumatoid arthritis (n=10) Systemic Sclerosis (n=7)

	Median (1st, 3rd Q.)	Median (1st, 3rd Q.)	P-value
	n (%)	n (%)	
Sex (female)	6 (60%)	6 (86%)	0.55
Age at visit(years)	61 (52-67)	53 (50-62)	0.23
Duration of disease (months)	64(10-102)	28 (17-176)	0.93
Duration of ILD (months)	40 (29-56)	16 (12-25)	0.35
FVC (L)	2.4 (2-3.12)	2.4 (2.12-2.67)	0.94
FVC (% predicted)	74% (68-97%)	96% (70-106%)	0.75
DLCO (% predicted)	54% (41-70%)	52% (44-75%)	0.93
SUVmax	2.95 (2.5-3.5)	2.5 (1.85-3.05)	0.39
Corticosteroids	8 (80%)	3 (43%)	0.28
DMARDs	6 (60%)	4 (57%)	1
Immunosupresants	3 (30%)	0 (0%)	0.34

## Conclusion:

In our cohort of patients with SS, 18 FDG PET/TAC can aid in predicting the progression of ILD associated disease, which does not occur in RA patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nailfold Capillaroscopy is a non-invasive diagnostic technique designed to evaluate small vessels of the microcirculation. The most important indication for capillaroscopy is Raynaud's phenomenon. The complexity and meticulous evaluation of the eight fingers is difficult to apply in daily practice given the limited availability of time to perform. For this reason it is necessary to develop simple and abbreviated techniques, to achieve an optimal and rapid evaluation of the patient. The objective of this study is determine the performance of the method of the 4<sup>o</sup> finger for the diagnosis of SD pattern in patients with Raynaud's phenomenon taking the eight finger pattern as a gold standard.

**Methods:** Cross-sectional study with blinded and independent measurements. Nailfold Capillaroscopy was performed on the four fingers of each hand, except thumbs. Another observer evaluated the 4th finger of the hands. The interobserver agreement was made before carrying out the study and was 100%. The 8-finger method (gold standard) was considered positive when at least one finger has SD pattern and the 4<sup>o</sup> finger method was considered positive when at least one of them presents the SD pattern. We included patients older than 18 years with a diagnosis of Raynaud Phenomenon and suspected autoimmune disease. Patients with thickening of the skin in the nailfold, digital lesion that made it difficult to assess (trauma, amputation, burns, etc.) and patients who did not consent to the procedure were excluded.

**Results:** We included 78 patients, 90% was female. The mean age was 53 years ( +/- 13.5). Sixty-three patients had a score of eight fingers positive (cases) and 15 had a score of eight fingers negative (controls). The sensitivity of the 4<sup>o</sup> finger evaluation method was 89% (95% CI: 82-96%) and 93% specificity (95% CI: 88-99%). The positive predictive value of this method was 98% (95% CI: 95-100%) and the negative predictive value was 67% (95% CI: 56-77%). The positive likelihood ratio was 13 (95% CI: 2-89).

**Conclusion:** The simplified method of the 4<sup>o</sup> finger showed good performance for the diagnosis of SD pattern compared to the standard method of evaluation of the 8 fingers.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Nailfold capillaroscopy plays an important role in diagnosing systemic sclerosis (SSc), with abnormal nailfold capillary appearance being included in the 2013 ACR/EULAR diagnostic criteria [1]. Common queries from clinicians who assess patients with suspected SSc are: which finger(s) should be imaged, and how many digits in total, given that assessing 8 fingers (excluding thumbs) takes time in a busy clinical practice? Our aim was to demonstrate the sensitivity of assessing different (combinations of) fingers for the presence of two markers of capillary abnormality: (1) presence of giant capillaries, and (2) overall image grade, compared to assessment of all 8 fingers.

### Methods:

Nailfold images (all fingers from each of 101 patients with SSc) and subsequent multi-observer assessments from a large study of quantitative capillaroscopy [2] were characterised by digit. Using custom software, observers counted giant vessels and graded the image overall (including normal/early/active/late). Patients were defined as “true case” for each of 2 parameters (giants, and image grade) if at least one of 8 fingers tested positive for the parameter (i.e.  $\geq 1$  giant vessels in one or more fingers, or one or more fingers given an ‘abnormal’ [early/active/late] grade). Seven single-finger, or finger combinations (derived from the middle and ring fingers), were then tested for sensitivity of achieving the correct result against the 8-finger “gold standard” true cases.

### Results:

For each of seven combinations of finger(s), sensitivity percentages for the two parameters are shown in Table 1. For the 8-finger “gold standard”, sensitivity against the diagnostic criteria was 53.0% (71 +ve cases from 134 assessments) and 73.1% (98 +ve cases from 134 assessments) for presence of giants and image grade, respectively. Pairs of fingers have higher sensitivity than single fingers in all cases, and the 4-finger combination shows a sensitivity of 85.9% and 91.8% for giants and image grade, respectively.

### Conclusion:

1. Assessing only middle and ring fingers on both hands detects abnormality in 85-90% of cases of established SSc (halving imaging time).
2. Assessing only ring fingers (sensitivity 73-80%) brings a 75% reduction in imaging time.
3. Some cases of abnormality will be missed by not examining all fingers.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies in systemic inflammatory joint diseases have suggested that Fluorescence Optical Imaging (FOI) is a reliable and sensitive tool for the detection of altered microcirculation as a proxy for inflammation. Inflammation is commonly present in hand osteoarthritis (OA), and plays a role for symptoms and disease progression. Feasible, sensitive and reliable tools to evaluate inflammation are important in hand OA trials. Our aim was to explore the inter-reader reliability of FOI in hand OA, which has not been assessed in any previous trials.

**Methods:** Hand OA patients with no systemic inflammatory joint disease or psoriasis were included in the Nor-Hand study. A fluorescence dye was administered intravenously (ICG-pulsion, 0.1 mg/kg body weight), and one image was obtained every second for 6 minutes using the Xiralite scanner. Two readers independently scored the FOI scans from 21 patients (19 women, mean (standard deviation) age 63.9 (5.6) years). Fluorescence enhancement in 32 joints including the bilateral distal (DIP), proximal interphalangeal (PIP), metacarpophalangeal (MCP), first carpometacarpal (CMC1) and wrist joints was scored on 0-3 scales. The readers evaluated three different phases (phase 1-3) based on the wash-in and wash-out of the dye and the prima vista mode (PVM; a composite of the 240 first images). We assessed the agreement between the two readers by calculating weighted kappa values at joint level as well as intraclass correlation coefficients (ICC) and smallest detectable difference (SDD) values for sum scores when using the two readers« average scores (=1.96\*standard deviation of the difference between readers/√2).

**Results:** Fluorescence enhancement was most commonly seen in phase 2 of the examination. Enhancement in phase 3 and especially phase 1, which is thought to represent active inflammation, was uncommon (Table). In phase 2, the readers agreed upon enhancement in 152/210 (72.3%) PIP and 83/168 (49.4%) DIP joints, but only 3/41 (7.3%) wrist joints. No enhancement was found in the CMC1 joints in any of the phases. The inter-reader ICC values were very good for the PVM and phase 2-3. In these phases, the inter-reader kappa values were good/very good for PIP joints and good for DIP joints. The reliability was lower for MCP and wrist joints. Fluorescence enhancement in phase 1 could not be reliably assessed.

	PVM	Phase 1	Phase 2	Phase 3
<b>Sum scores (32 joints)</b>				
Reader 1: Median (IQR)	15.0 (10.5, 19.5)	0.0 (0.0, 0.5)	23.0 (19.0, 27.5)	4.0 (0.5, 10.5)
Reader 2: Median (IQR)	12.0 (9.5, 18.0)	2.0 (0.0, 4.5)	24.0 (19.5, 30.5)	6.0 (2.0, 11.0)
ICC	0.89 (0.72, 0.96)	0.10 (-0.32, 0.50)	0.87 (0.72, 0.95)	0.89 (0.75, 0.95)
SDD	3.6	6.1	6.8	3.9
<b>Weighted kappa values across joint groups</b>				
DIP 2-5	0.63	0.47	0.69	0.74
PIP 1-5	0.84	0.21	0.81	0.74
MCP 1-5	0.62	0.13	0.43	0.33
CMC1	NA	NA	NA	NA
Wrist	0.55	0.59	0.07	0.00
PVM=Prima Vista Mode; IQR=Interquartile range; ICC=Intraclass Correlation Coefficients; SDD=Smallest Detectable Difference; DIP=distal interphalangeal; PIP=proximal interphalangeal; MCP=metacarpophalangeal; CMC=carpometacarpal; NA=Not appropriate due to grade 0 in all joints.				

**Conclusion:** In hand OA, signal alterations by FOI as a proxy for inflammation were most commonly found in DIP and PIP joints. FOI seemed insensitive for the detection of inflammation in CMC1 joints. The inter-reader reliability was good for all phases, except phase 1.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic sclerosis (SSc) is a condition causing impaired microcirculation with the risk of ischemic complications such as digital ulcers and pitting scars (DU/PS). Fluorescence optical imaging (FOI) is an imaging method that detects enhanced microcirculation as a sign of joint inflammation in both hands of patients with rheumatoid arthritis and other arthritides [1, 2]. FOI's impact to record disturbed microcirculation in the hands of patients with systemic sclerosis has not yet been sufficiently investigated [3]. The aim of this study is to find associations of disturbed microcirculation initially detected by FOI and the development of new DU/PS throughout a follow-up of 12 months.

### **Methods:**

Sixty-three patients with SSc were included and received FOI examination following the Xiralite-System guidelines (ICG 0.1mg/kg BW i.v.; 6 minute duration) as well as capillaroscopy at baseline. After a mean follow-up time of 12 months (min-max: 8-20 months), all participants were followed regarding the development of new ulcers and pitting scars.

### **Results:**

A disruption of microcirculation in FOI was defined as a lack of a sufficient fluorescent signal in at least one fingertip over the entire course of the examination and was found in 11 of 63 SSc patients. All of these patients had a history of DU/PS and frequently presented with a *late pattern* capillaroscopy (9 of 11) at baseline. Fingers with a disrupted microcirculation also showed a reduced capillary density to a greater extend (96.0%) than fingers with a sufficient signal in FOI (76.0%;  $p=0.0241$ ).

30 of 60 patients developed digital ulcers or pitting scars during follow up (3 drop outs due to death [ $n=2$ ] or withdrawal). 81.8% of patients with a disturbed microcirculation in FOI developed these complications during follow-up compared with 42.9% of patients without a disruption in FOI ( $p=0.0419$ ; OR=6.0 [95%CI 1.2 - 30.7]). A disruption of microcirculation especially increased the risk of developing DU/PS in the same finger: 20.1% of fingers with normal, but 65.4% with a missing FOI signal in the fingertip presented with an ischemic complication during follow-up ( $p<0.0001$ ; OR=7.5 [95%CI 3.3 - 17.3]).

### **Conclusion:**

Fluorescence optical imaging can reveal an impaired microcirculation in patients with systemic sclerosis, which is associated with microangiopathic changes as seen in capillaroscopy as well as the subsequent development of digital ulcers and pitting scars. Therefore, FOI might help to identify patients at risk for these complications.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Connective tissue diseases (CTD) can cause intrathoracic involvement, increasing patients morbidity and mortality. High-resolution computed tomography (HRCT) is a key method for evaluation of these manifestations. The aim of this study is to describe clinical features and to evaluate intrathoracic HRCT findings in patients with CTD.

### **Methods:**

Retrospective descriptive study, from January 2010 to December 2016. We evaluated HRCT findings in patients with CTD. We excluded patients under 18 years of age, pregnant, diagnosis of vasculitis, respiratory infections, drug toxicity, and previous thoracic surgery or radiotherapy. Data were analyzed using SPSS 17.0 software.

### **Results:**

Out of 199 patients, 96 had rheumatoid arthritis (RA), 29 systemic lupus erythematosus (SLE), 26 systemic sclerosis (SSc), 23 inflammatory myopathies (IM), 22 primary Sjögren's syndrome (pSS) and 3 mixed connective tissue disease (MCTD). The baseline characteristics of patients are shown in table 1.

**Table 1. Baselines features.**

<i>*p&lt;0.05.</i>						

The mean age was 58 years (range 18-84, SD ± 15.5) with a female predominance in all groups. In 10% of cases pleuropulmonary involvement was the first manifestation of CTD. HRCT findings and ILD patterns are shown in table 1 and 2 respectively.

**Table 2. HRCT findings in CTD.**

Diseases (n)	RA	SLE	SSc	IM	pSS	MCTD	TOTAL
HRCT findings n, (%)	(42)	(18)	(14)	(19)	(16)	(1)	
NSIP	17 (40.5)	11 (61.1)	9 (64.3)	15 (78.9)	10 (62.4)	1 (100)	63
UIP	22 (52.4)	—	5 (35.7)	2 (10.5)	3 (18.8)	—	32
COP	3 (5.8)	4 (22.2)	—	1 (5.3)	—	—	8
LIP	—	—	—	1 (5.3)	3 (18.8)	—	4
DAD	—	3 (16.7)	—	—	—	—	3
Patterns frequency	UIP>NSIP>COP	NSIP>COP>DAD	NSIP>UIP	NSIP>UIP>COP=LIP	NSIP > UIP =LIP	NSIP	
DAD: Diffuse alveolar damage; LIP: Lymphocytic interstitial pneumonia.							

Interstitial lung disease (ILD) was observed in 55.3% of patients.

There was a higher frequency of bronchiectasis in RA, esophageal dilation in SSc and pleural effusion in SLE ( $p < 0.05$ ).

Pleural involvement was the most frequent manifestation in SLE (48.3%) and esophageal involvement in SSc (69.2%).

In RA we observed bronchial involvement in 47.9% of patients and pleural in 17.7%. 43.8% of the patients with RA presented ILD; usual interstitial pneumonia (UIP) was the most frequent pattern in 52.4% followed by non-specific interstitial pneumonia (NSIP) in 40.5% and cryptogenic Organizing Pneumonia (COP) in 7.1%. All patients with RA and ILD in our sample had positive rheumatoid factor (RF). Only 2 patients with RA had rheumatoid nodules.

NSIP was the most frequent pattern of ILD in the remaining CTD (37.9% in SLE, 34.6% in SSc, 65.2% in IM, 45.5% pSS and 33.3% in MCTD).

Tomographic signs of pulmonary arterial hypertension (PAH) were evidenced in 40 patients, 30% with RA and 30% SSc. A statistically significant association was found between PAH and SSc ( $p = 0.0$ ) and among the findings of PAH in HRCT and SD pattern in capillaroscopy ( $p = 0.01$ ).

## Conclusion:

Intrathoracic manifestations are common in patients with CTD. A comprehensive knowledge of the pleuropulmonary involvement in CTD is important, because the prognosis and optimal therapy differ for each presentation.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

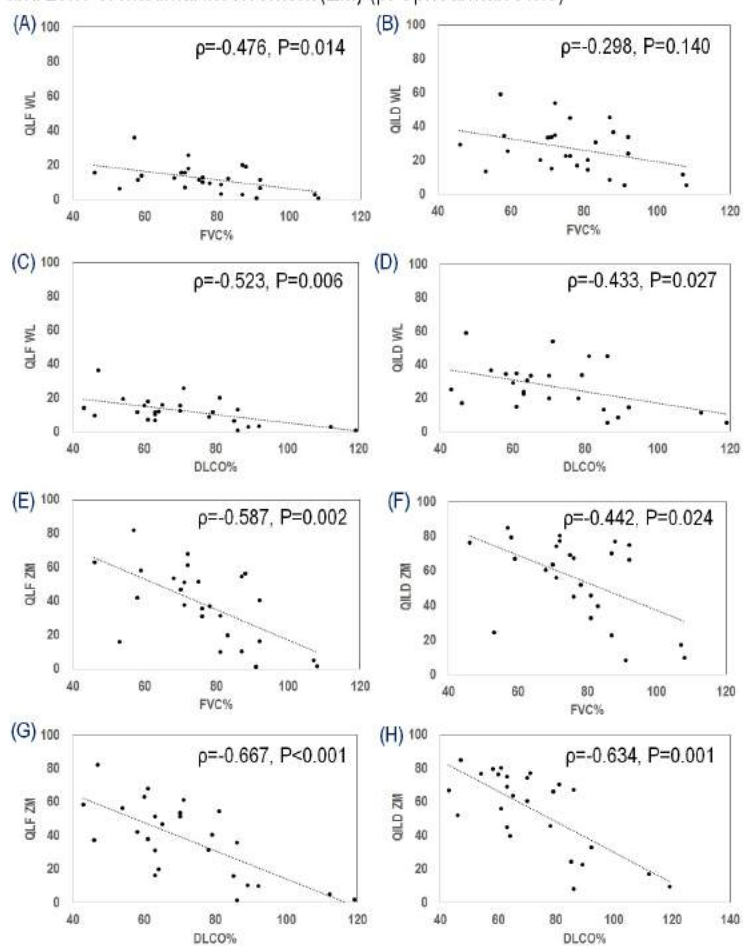

**Background/Purpose:** Quantitative analysis of fibrotic patterns provides an objective measurement of treatment efficacy in interstitial lung disease (ILD). We aimed to measure the extent of ILD in rheumatoid arthritis (RA) patients by computer-aided analysis of high-resolution chest CT (HRCT), and to identify correlation with the visual assessment by radiologist and results of pulmonary function test (PFT).

**Methods:** Twenty-six RA patients with ILD who had two HRCTs with matched PFT result within 3 months were enrolled in this retrospective study. Demographic, clinical, laboratory information were obtained through a medical chart review. Quantitative analysis of HRCT image was conducted by the Radiology Core at University of California at Los Angeles. Quantitation was expressed as parameters in detail such as ground-glass opacity (QGG), lung fibrosis (QLF), honeycombing (QHC), and their summation (QILD).

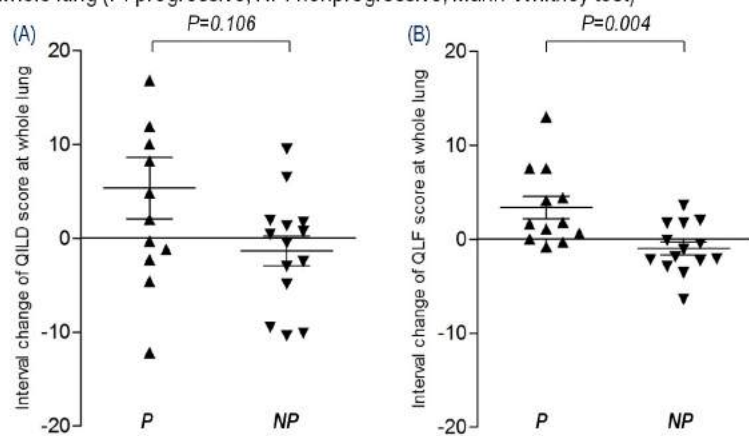

**Results:** Baseline demographics and clinical characteristics of the patients with rheumatoid arthritis-associated interstitial lung disease were not different when analyzed by interval progression evaluated by radiologist, except for body mass index (progressive group  $20.0 \pm 3.7$ ; non-progressive group  $25.5 \pm 3.6$  kg/m<sup>2</sup>,  $P = 0.001$ ), time interval between HRCTs (progressive group  $2.0 \pm 1.2$ ; non-progressive group  $1.1 \pm 0.6$  years,  $P = 0.047$ ), and all-cause mortality (progressive group 50.0%; non-progressive group 7.1%,  $P = 0.031$ ). Negative correlation between PFT results and QILD scores at whole lung or zone of maximal involvement were significant (Fig. 1). Correlation between the evaluation of radiologist and QILD scores at whole lung was significant on QLF score (progressive group  $3.38 \pm 4.15$ ; non-progressive group  $-1.01 \pm 2.64$ ,  $P = 0.004$ ) (Fig. 2). More involvement of ILD on upper and middle zone of lung (versus lower zone) would predict progression of ILD (Fig. 3).

**Conclusion:** QILD score provides reliable estimate of ILD status and prognosis in RA patients when compared to PFT and assessment of radiologist.

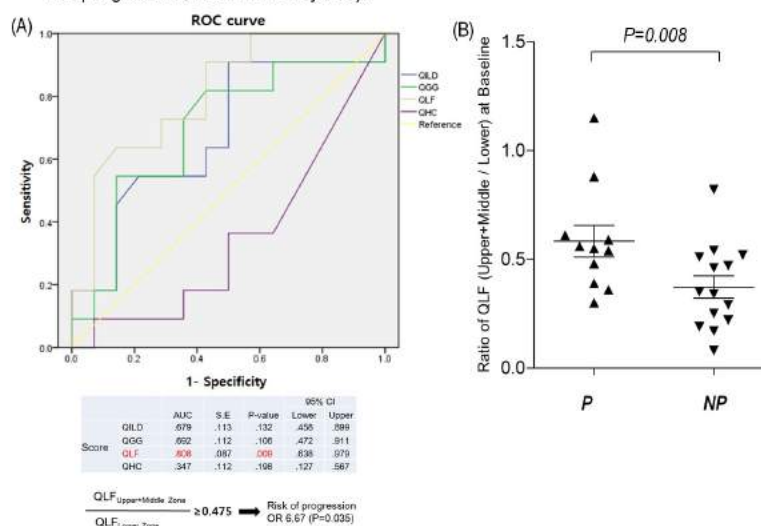

**Figure 1.** Correlation between PFT results and QILD scores at whole lung (WL) and zone of maximal involvement (ZM) ( $\rho$ : Spearman's rho)

**Figure 2.** Correlation between the evaluation of radiologist and QILD scores at whole lung (P: progressive, NP: nonprogressive, Mann-Whitney test)

**Figure 3.** Higher ratio of upper plus middle zonal QLF score compared to that of lower zone at baseline predicted ILD progression (P: progressive, NP: nonprogressive, Mann-Whitney test).

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Relapsing polychondritis(RP) is a rare rheumatic disease involving cartilaginous and proteoglycan rich structures. Clinical examination and radiological investigations have limitations in assessing the extent of disease. The study was done to evaluate the role of 18F-FDG PET CT in RP.

### Methods:

Thirteen patients who underwent PET CT examination for evaluation of the extent of the disease were included. The diagnosis of RP was made according to Damiani and Levine's modification of McAdam's criteria. PET CT was done at the time of diagnosis in 11 patients and at disease relapse in two. The FDG uptake along with CT findings were recorded. A follow up PET was done in 3 patients.

**Results:**

The details of findings are given in Table 1. Mean age was 36.8±12.9 yrs with a Male:Female ratio of 6:7. Out of 12 patients with aural pain/tenderness 5 had increased FDG uptake (SUV max 1.2-8.0) and it was bilateral in all. This gap between clinical findings and FDG uptake may be due to initiation of immunosuppressive therapy before the PET CT as necessitated by the clinical presentation. Non FDG avid thickening of ear was noted in one. Eustachian tube was involved in two patients. Of 8 patients with nasal pain/tenderness only 5 had increased uptake. Of the 4 patients with saddle nose deformity, only one had increased PET uptake in nasal cartilage. Increased FDG uptake was noted in tracheal cartilage in 2 and main bronchus in 4(SUV max 1.6-4.8). Out of four patients with increased FDG uptake in bronchi, three were symptomatic with stridor and breathlessness. Three patients had non FDG avid bronchial thickening on CT. One patient had asymptomatic involvement of aorta, superior mesenteric artery and renal arteries. Two patients with scleritis showed increased uptake in three or more sites. All the three patients on follow up PET showed a response to treatment with all showing persistent thickening with no uptake in involved sites.

**Conclusion:**

FDG PET is useful in assessing disease extent and picking up involvement in areas not accessible to clinical examination like airways and internal blood vessels. It is also useful in assessing treatment response in these patients

**Table 1:** showing the clinical characteristics, PET CT abnormalities and treatment outcomes in patients with relapsing polychondritis

S no	Age, Sex	Clinical symptoms and examination findings	PET abnormalities (SUV)			CT finding
			Ear nose throat	Airway	Other areas	
1	46,F	Collapsed nasal bridge, ear pain and tenderness, laryngeal tenderness, Stridor	None	Trachea(2.3), both main bronchii (1.6)	None	Wall thickening of bronchii

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Fluorodeoxyglucose (FDG)-positron emission tomography (PET) allows more direct assessment of inflammation than other imaging modalities by portraying metabolic activity. No standards exist for objective quantification of joint activity using PET, and many techniques rely on subjective initial assessments and use of a sample of voxels such as SUVmax or SUVpeak to characterize an entire region. The aim of this study was to compare the accuracy and reliability of novel methods of assessing global synovitis activity in patients with rheumatoid arthritis (RA) and healthy controls.

### Methods:

FDG-PET/CT scans were performed on 19 RA patients and compared to 19 asymptomatic age- and sex-matched control subjects using similar acquisition methods. Several methods of quantification were performed. Method A used a traditional subjective approach to only measure ÓactiveÓ joints and an adaptive thresholding algorithm with a lower threshold defined as 40% of the SUVmax in selected joints. Methods B utilized the average SUVmax in control subjects as a lower threshold to exclude only the expected background uptake (separately for each joint type). For both methods, the sum of the partial volume-corrected mean metabolic volume product (cMVPmean) for all ROIs represented the global synovitis score for each subject. RA patients were compared to controls and correlations with clinical indicators of disease activity were assessed among RA patients.

### Results:

Method B demonstrated superior inter-reader reliability ( $r = 0.982$ ) compared to method A ( $r = 0.636$ ). Patients with RA had much higher PET global activity scores than controls regardless of method (Figure). Method B correlated strongly with more objective clinical measures of systemic inflammation and disease activity. Method B also generally correlated more strongly with modified disease activity (M-DAS28) scores that exclude subjective components, compared to traditional disease activity scores (Table).

## Conclusion:

For quantification of synovial inflammation by PET/CT, a method of thresholding that eliminates calculated background activity is more accurate and reliable than methods that depend on the assessment of subjectively active joints using focal measurements. Further studies are needed to determine how these methods of quantification perform in longitudinal assessments to assess course of the disease and the effects of various interventions.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Tenosynovitis has been regarded as a feature of RA, although its true prevalence in early stages has not been firmly established. The aim of this work was to evaluate US findings of tenosynovitis in a cohort of ACPA+ patients.

## Methods:

Consecutive ACPA+ patients, without clinical synovitis (CS), underwent US of 9-paired tendons and 24-paired joints. Baseline assessment included: 1) demographic/clinical characteristics, 2) extensor carpi ulnaris and flexor tendons gray-scale (GS) and power-doppler (PD), 3) joint GS, PD and erosions. US findings were assessed with the OMERACT semi-quantitative score.  $\chi^2$ /Fisher's exact test for categorical and Student-t test/Mann-Whitney for continuous variables, were used to identify differences regarding the prevalence of US tenosynovitis, synovitis or progression to CS.

## Results:

A total of 146 individuals were included (71% women, mean(SD) age of 50(14) years) with 17 (11.6%) progressing to CS (all RA). This was predicted by the duration of early morning stiffness ( $p<.01$ ), presence of shared epitope ( $p=.02$ ) and high titres of RF ( $p<.01$ ) and anti-CCP ( $p<.01$ ) (table 1). The median (IQR) time to progression of CS was 6.5 (4.3-10.5) months.

Twenty subjects (13.7%) had changes of GS and/or PD tenosynovitis, the majority classified as GS=1. A positive trend was found towards the progression to CS [OR (95%)=3.2 (1.0-10.2),  $p=.06$ ]. The same association was seen between US synovitis and CS, with higher OR when PD was  $\geq 2$  [OR(95%)=4.2 (0.7-24.7),  $p=.15$ ] (table 2).

Of those 20 individuals, 7 had concomitant US synovitis in the respective anatomical joints. Even though a correlation between significant US synovitis (GS $\geq 2$  and/or PD $\geq 1$ ) and tenosynovitis (any finding) was not found, an association was seen for the subgroup of patients who presented only with PD synovitis [OR (95%CI)=4.5 (1.4-14.0),  $p=.01$ ]. This was reinforced when only PD $\geq 2$  synovitis was considered [OR (95%CI)=15.5 (2.6-91.5),  $p<.01$ ]. Tenosynovitis was anatomically separate to synovitis with one exception.

Finally, tenosynovitis was not significantly associated with any of the demographic or clinical characteristics.

## Conclusion:

To our knowledge this is the first study to assess tenosynovitis in a large cohort of ACPA+ patients; a low prevalence and a positive trend towards the progression to CS were found. The low prevalence of progression to CS and the absence of its association with US synovitis may suggest that this could represent the earliest stage of disease. Further studies with larger samples and with other methods (e.g. MRI) are warranted to confirm these results.

## Physician Experience and Patient's Disease Activity Affect the Impact of Musculoskeletal Ultrasound on the Treatment Decision in Rheumatoid Arthritis Patients

César Sifuentes-Cantú<sup>1</sup>, Irazu Contreras-Yañez<sup>2</sup>, Marwin Gutierrez<sup>3</sup> and Virginia Pascual-Ramos<sup>4</sup>, <sup>1</sup>Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, <sup>2</sup>Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, <sup>3</sup>Rheumatology, Instituto Nacional de Rehabilitación, Mexico City, Mexico, <sup>4</sup>Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In a real clinical setting of RA outpatients, we previously showed that musculoskeletal ultrasound (MUS) added to clinical evaluation impacted the treatment decision in 20% of the clinical scenarios evaluated; the impact was greater for the trainee in rheumatology (TR) than for the senior rheumatologist (SR). The aim of the present study was to explore if the results could be generalized to a higher number of physicians.

### Methods:

The population of physicians consisted of 10 SR (mean age: 46.2± 12.7 years, 3 of them with ≥5 years of experience, 4 with 6-14 years and 3 <5 years) and 12 TR (median age: 30.8±1.3 years); 94% and 16.7% of the TR and the SR, respectively, referred theoretical MUS training.

10 clinical vignettes included data abstracted from 10 RA outpatients, randomly selected from an ongoing cohort. Each vignette was shared with 6 TR and 6 SR, who were asked to give a first treatment recommendation based on traditional rheumatic assessments and in a second step, to confirm or not their previous recommendation after MUS findings were incorporated to the rheumatic assessments.

Each vignette included the following data: in the first sheet, patient socio-demographic characteristics, comorbidities, extended disease activity evaluation, previous RA treatment, comorbid conditions treatment and a space for the first treatment recommendation; in the second sheet, MUS information and a space for eventual RA specific treatment changes (**Figure**).

### Results:

Patients were middle-aged females (41.9±7 years old) with (mean±SD) disease duration of 7.5±3.4 years. Six of them had DAS28-ESR remission.

MUS added to the clinical evaluation induced a treatment modification in 26% of the 96 clinical scenarios evaluated, with similar percentage in TR (29.2%) and SR (22.9%), ( $p=0.64$ ). Within SR, the lesser experienced rheumatologist (<15 years) changed their treatment proposal after MUS finding more frequently (44%) than those with ≥15 years of experience (0%,  $p=0.002$ ); training in MUS did not impact treatment modifications.

MUS induced more treatment modifications in those clinical scenarios with DAS28-ESR active disease vs. remission patients 68% vs 32%,  $p=0.005$ . There was a higher (albeit not significant) percentage of disagreement in disease activity level between DAS28 and MUS in active vs. remission patients: 75% vs. 32.8%,  $p=0.51$ ). Then, we identified 48 clinical scenarios (50%) with disagreement in disease activity as per DAS28 and per MUS; of them 18 (37.5%) were in DAS28-ESR remission and 30 had active disease; there were a higher percentage of treatment modifications after MUS information was incorporated to clinical data in active clinical scenarios vs. remission clinical scenarios: 43.3% vs. 11.1%,  $p=0.026$ .

### Conclusion:

[illegible]

**View Abstract and Citation Information Online -** <http://acrabstracts.org/abstract/physician-experience-and-patients-disease-activity-affect-the-impact-of-musculoskeletal-ultrasound-on-the-treatment-decision-in-rheumatoid-arthritis-patients>

# Reliability of 8-Joint Ultrasonography Scores in Follow up of Biological Therapy in Patients with Rheumatoid Arthritis

## SESSION INFORMATION

**Session Title:** Imaging of Rheumatic Diseases Poster II**Session Time: 9:00AM-11:00AM**

The use of biological agents, or biologics, has revolutionized the treatment of rheumatoid arthritis (RA). Using power Doppler ultrasound, this study to evaluate the comparative efficacy of biologics for refractory RA patients has been a trend. However, there were no standard exam to follow up on rheumatoid arthritis therapy. The primary objectives were to explore the associations between a comprehensive ultrasonographic (US) assessment of joints, tendons and bursae and previously described reduced joint counts (8-, 7-, 12-, 28) as well as to assess the sensitivity to change of these different US joint combinations during biological treatment.

8-joint( bilateral elbow, wrist, MCP II and III) were involved in this study. 49 patients with rheumatoid arthritis (RA) were examined by US (B-mode (BM) and power Doppler (PD)) with use of a semi-quantitative (0 to 3) score of 34 joints, tendons/tendon groups at baseline and 1, 3, 6 and 12 months after initiating treatment with biological therapy. BM and PD scores for the different joint combinations were generated.

**Results:** The reduced 8-joint scores had high correlation coefficients with the 28-joint score at all examinations (range 0.87 to 0.94 for BM and 0.69 to 0.93 for PD, each  $P < 0.001$ ) and sum BM and PD scores of all the different joint combinations improved significantly during follow-up ( $P \leq 0.05$  to 0.001).

## Conclusion:

The reduced joint combinations were highly associated to the 28-joint score. Furthermore, all the joint combinations presently explored responded well to biological treatment. This indicates that an approach focusing on few joints and tendons gives equivalent information about the inflammatory activity in RA patients as a comprehensive US examination. The optimal combination of joints and tendons for a valid, reliable and feasible US measurement should be further explored to define a US score for follow-up of RA patients on biological treatment.

Table 1. Correlation coefficients between sum scores B mode (BM) of the different joint combinations

	BM 7-joint score	BM 12-joint score	BM 28-joint score
BM 8-joint score	0.872/0.809	0.891/0.870	0.945/0.892
BM 7-joint score		0.873/0.845	0.908/0.886
BM 12-joint score			0.937/0.926

Table 2. Correlation coefficients between sum scores power Doppler (PD) of the different joint combinations

	PD 7-joint score	PD 12-joint score	PD 28-joint score
PD 8-joint score	0.883/0.696	0.921/0.811	0.939/0.894
PD 7-joint score		0.931/0.711	0.947/0.820
PD 12-joint score			0.956/0.896

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A number of studies have demonstrated that musculoskeletal ultrasonography (MSUS) is more sensitive in diagnosing arthritis than clinical examination although, as underlined in a recent review, it remains controversial whether it can substantially improve discrimination in the setting of early arthritis (EA). In 2011, Gutierrez et al. published preliminary data showing a

high frequency of peritendon extensor tendon inflammation in patients with psoriatic arthritis (PsA), thus suggesting the potentially important role of US in the differential diagnosis of rheumatoid arthritis (RA) and PsA at metacarpophalangeal (MCP) joint level, and recommending additional research in order to confirm these data. Aim was to compare MSUS findings at MCP joint level in patients with early RA and early spondyloarthritis (SpA).

**Methods:** We retrospectively selected 35 patients who had been definitely diagnosed as having RA (2010 ACR/EULAR criteria) or axial/peripheral SpA (2009 ASAS criteria) within one year of their first visit from a consenting cohort of EA patients attending our Rheumatology Department between November 2012 and July 2016. Their demographic, clinical data and baseline MCP/wrist MSUS assessment data were recorded during the patients' first visit to our EA clinic by an experienced rheumatologist and a blinded experienced sonographer. All of the patients were scanned using an ESAOTE MyLAB 70 equipped with a 6-18 MHz linear array transducer, and the findings were scored in accordance with the OMERACT guidelines.

## Results:

The MSUS data of 20 RA patients (17 females and three males; median age 59 years, range 35-83 years; median time to a definite diagnosis 2.4 months, range 1-11 months) and 15 SpA patients (nine females and six males; median age 53 years range, 18-78 years; median time to definite diagnosis 1.7 months, range 1-8 months) were retrospectively analysed. At the time of their first visit at the EA clinic, all of the patients had at least one MCP joint with synovial fluid and/or synovial hypertrophy with a grey scale (GS) score of >1, and there were no statistically significant differences in the percentages of patients presenting at least one power Doppler (PD)-positive joint (55% of RA and 53% of SpA patients;  $p = 0.92$ ) and PD-positive tenosynovitis of the flexor tendons in at least one finger (10% of RA and 33% of SpA patients;  $p = 0.08$ ). There was a statistically significant difference in the percentage of patients with erosion in at least one MCP (25% of RA and 0% of SpA patients;  $p = 0.036$ ) and in the percentage of patients with PD-positive paratenonitis of the extensor tendons in at least one finger (30% of RA and 80% of SpA patients;  $p = 0.003$ ).

**Conclusion:** The patients with early RA showed a statistically higher percentage of erosions at the MCP MSUS evaluation of their first visit to the EA clinic than the patients with early SpA, who presented a higher percentage of PD-positive paratenonitis at the level of the extensor tendons than the patients with early RA. Larger studies are required to confirm the potential role of MCP MSUS in the differential diagnosis of early RA and early SpA.

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose :

MTP joints are seldom examined in routine clinical visits. As such, it is important to understand how the standard treatment of patients with early RA and their serological RF and ACPA status may affect active inflammation in the MTP joints. This study aimed to characterize 1) 1-year changes in power Doppler (PD) scores of patients with early RA treated as per standard of care, and 2) changes in PD scores based on serological RF and ACPA status.

## Methods :

Patients with early RA (ACR criteria) were examined at baseline, 6 weeks, 3 months, 6 months and 1 year. At baseline, all patients were DMARD naïve and treated as per standard of care. Except in a few cases, initial treatment involved mainly MTX and occasionally LEF. For the purpose of this study, subgroup analyses were conducted for patients who were characterized as being seronegative for both RF and ACPA (-/-), or seropositive for both RF and ACPA (+/+). At each visit, a rheumatologist imaged the 2<sup>nd</sup>-5<sup>th</sup> MTP joints of both feet using US, and graded PD semiquantitatively (score 0-3 per joint, max. score=24/patient). Paired t-tests compared baseline and 1-year PD, and PD between serology groups.

## Results :

Forty patients were enrolled [mean (SD) age=52.1(10.4) years, n=32 female]. At baseline, PD scores ranged from 0 to 17; at 1-year PD scores ranged from 0 to 5. Mean (SD) PD scores were significantly lower at 1-year [0.5 (1.1)] than baseline [2.3 (4.2)],  $p<0.05$ . Changes in the level of active inflammation developed rapidly: within 6 weeks, 8 patients improved (decreased  $PD\geq 2$ ) and 5 patients worsened markedly (increased  $PD\geq 2$ ). All except 1 of the patients who worsened improved by 3 months (patient stopped medication at 3 months, and improved once restarted). The mean baseline PD (SD) was significantly higher for +/+ patients [n=14, 5.3 (5.8)], than -/- patients [n=20, 0.5 (0.9)],  $p<0.05$ . Of all patients who maintained  $PD=0$  at all visits (n=12), 8 were -/- and 3 were +/+. Of 14 patients who had  $PD\geq 5$  at any visit, 9 were +/+ and 1 was -/-. In 20 patients who either maintained a low PD baseline score ( $\pm 2$  at each visit) or improved, serology was split (n=10 -/-, n=9 +/+). Patients who worsened (increased  $PD\geq 2$ ) after baseline (n=6) were split on serology as well (n=2 -/-, n=2 +/+). The two groups of patients followed similar courses of treatment, and their responses were both favourable: 39 patients had inflammation controlled ( $PD\leq 3$ ) at 1 year.

Figure 1: PD score at each study visit of patients who showed  $PD\geq 1$  at any time point (n=28).

## Conclusion:

Patients with early RA seropositive for RF and ACPA had, on average, more severe inflammation at baseline. However, serotype did not appear to affect patient response to standard initial treatment. Patients with severe inflammation at baseline and 6 weeks all improved by 3-6 months, and patients with low initial inflammation did not generally worsen, regardless of serology, and without considerable changes to treatment.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recently, a significant number of rheumatoid arthritis (RA) patients can reach low disease activity (LDA) by using biologics such as adalimumab. However biologics therapy can sometimes cause serious side-effects and is expensive. Therefore, it could be expedient to discontinue biologics after achieving sustained remission or LDA. Ultrasonography seems to be a good predictor of relapse in this respect in several studies. The PRIMULA (Prospective study of Remission Induction & Maintenance using ULtrasonography in rheumatoid Arthritis) study, is a multicenter prospective study to investigate if ultrasonography (US)-based evaluation could provide an additive value to composite measure-based evaluation for clinical relapse and radiological progression in RA patients who discontinued adalimumab after obtaining sustained LDA.

**Methods:** Thirty-one RA patients in sustained LDA (DAS28-CRP < 3.2 for more than 6 months) who had been receiving adalimumab plus MTX enrolled in the PRIMULA study were evaluated in this study. All patients underwent US evaluation of synovial hypertrophy (SH) and power Doppler (PD) signal presence. The joints were graded on grayscale (GS; 0-3) and power Doppler (PD; 0-3). Nineteen patients agreed to discontinue adalimumab and 12 continued. Trial visits were performed at week 13, 26, and 52. Modified total Sharp score (mTSS) was also evaluated at the enrollment and the end of study (at week 52). Relapse was defined when DAS28-CRP score elevated more than 3.2. The relationship between the integral value of each disease activity score (ESR, CRP, DAS28, SDAI, and US-SH and -PD score, etc.) and  $\Delta$ mTSS (0-52w) was analysed.

## Results:

Among the 19 discontinuation group patients, 8 cases relapsed during 1-year study period. There was no significant difference between the relapse group (n=8) and non-relapse group (n=11) in the baseline clinical composite measure (DAS28-CRP 1.3 vs. 1.3; p=0.68) and US score (GS and PD total score 3.4 vs. 3.5; p=0.64) (table 1). Only the integral value (0-52w) of CRP significantly correlated with  $\Delta$ mTSS (0-52w) (r=0.617, p=0.006) (table 2).

**Conclusion:** In this study, US provided limited additional value as a tool to predict patients' prognosis according to clinical disease activity and radiographic progression, after discontinuation of adalimumab in RA patients who achieved sustained LDA with adalimumab plus MTX.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Musculoskeletal ultrasound (MSUS) is increasingly being utilized in children. In order to provide objective assessments of arthritis, reliable scoring systems are needed. Yet, given the unique pediatric anatomy, adult scoring systems cannot simply be adapted for children. The aim of this study was to develop and assess reliability of a B-Mode and Doppler scoring system for arthritis in the pediatric knee.

**Methods:** As part of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) ultrasound group, six pediatric rheumatologists developed a set of standard views of the knee relevant for the assessment of arthritis in children. This was done through a comprehensive literature review followed by a practical exercise and consensus process. Similarly, a B-mode and Doppler scoring system was developed through both literature review and consensus process and subsequently validated by several practical exercises on images that were obtained based on the previously agreed standard views. Agreement between raters was determined using two-way single score intraclass correlation coefficients (ICC).

**Results:** A total of 21 possible views/images to assess the presence of arthritis in children were identified. After evaluation of the proposed views during a practical exercise, a total of 3 views were chosen for each B-mode and Doppler in a subsequent consensus process, all at 30 degrees of flexion: a suprapatellar view, a medial and a lateral parapatellar view. An initial scoring exercise included 218 images. ICC for all B-mode images was 0.66 (CI 0.58-0.73). ICC for all Doppler images was 0.53 (CI 0.37-0.67). There was excellent agreement for B-mode on suprapatellar images with ICC 0.78 (CI 0.70-0.85) and fair to good agreement for parapatellar images: medial ICC 0.52 (CI 0.37-0.67), lateral ICC 0.60 (CI 0.46-0.73). The ICC for Doppler was fair at 0.39 (CI 0.22-0.58), 0.57 (CI 0.38-0.75) and 0.54 (CI 0.32-0.73) for suprapatellar, medial and lateral parapatellar views respectively. After revision of the scoring system, 90 images were assessed in a second round. Results improved with the ICC for B-mode in the suprapatellar view now at 0.82 (CI 0.70-0.91, excellent). The ICC for Doppler on the suprapatellar view improved to 0.49 (CI 0.25-0.78 fair/good) and on the lateral parapatellar view to 0.64 (CI 0.37-0.87, good).

**Conclusion:** A novel B-Mode and Doppler scoring system for assessing arthritis of the pediatric knee was successfully developed through a consensus process. Preliminary results from practical exercises indicate overall good reliability but also illustrate the challenges in certain views especially with regards to Doppler scoring. With further refinement and validation, this scoring system could serve as a clinical tool and outcome measure for scientific purposes.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

Background/Purpose:

Early OA is a complex, poorly understood and still largely an uncharted “entity”. Thus, our purpose was evaluate the prevalence of findings suggestive of knee OA by MRI in middle-aged subjects *without* evidence of radiographic OA but *with* or *without* risk factors for OA.

Methods:

We selected 340 subjects from the Osteoarthritis Initiative, aged 45-55 years (51% women) with Kellgren Lawrence grade 0 in both knees, who had 3T knee MR images. Among them, 294 subjects had OA risk factors and 46 individuals were without risk factors (Table 1). Right knee MR images were assessed by one radiologist for osteophytes, cartilage damage, bone marrow lesions (BMLs), meniscal damage, synovitis-effusion and Hoffa synovitis using the MOAKS scoring system. Meniscal body extrusion was measured in mm, and we considered  $\geq 3$  mm as meniscal extrusion.

Results:

At least one MR-detected feature was found in 96% (281/294) of the subjects with OA risk factors and in 87% (40/46) of those without. Cartilage damage (82%), BMLs (60%), osteophytes (45%), meniscal body extrusion (32%), synovitis-effusion (29%) were the most common findings in subjects with OA risk factors, while cartilage damage (67%), osteophytes (46%), meniscal body extrusion (37%) and BMLs (35%) in subjects without. The prevalence of *any* abnormality was significantly higher in subjects *with* OA risk factors than in subjects *without* (prevalence ratio adjusted for age and sex 1.34 [95% CI 1.11, 1.62]), so was prevalence of subchondral cysts 2.11 (1.16, 3.84); BMLs 1.73 (1.15, 2.59), and cartilage lesions 1.22 (1.00, 1.50). Osteophytes, BMLs and subchondral cysts were observed more frequently in the patellofemoral joint than in the tibiofemoral compartments (Table 2).

Conclusion:

Our findings highlight the challenge to distinguish pathological features of knee OA from ‘normal’ ageing of the joint. Still, BMLs and cysts in particular were more frequently found in subjects having multiple OA risk factors than those without.

Table 1. Characteristics of the study participants.

	Subjects <i>with</i> OA risk factors (n=294)	Reference cohort (n=46)
Age, years, mean (SD)	50.4 (2.9)	50.3 (3.3)

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

Background/Purpose:

The introduction of MRI and ultrasound (US) atlases has improved reliability in rheumatoid arthritis. With an increased interest in the role of inflammation in osteoarthritis (OA), a similar US reference atlas could be useful for hand OA. Recent US studies of hand OA either apply a preliminary hand OA scoring system without image examples or an US atlas developed for RA patients. Hence, our aim was to standardize and explore the reliability of US assessments of inflammatory pathologies in patients with hand OA.

Methods:

The OMERACT (Outcome Measures in Rheumatology) US group in hand OA performed a Delphi exercise to agree on US-detected inflammatory pathologies including synovitis, effusion and power Doppler signals in hand OA finger joints. Still-images of interphalangeal joints with different grades of pathology were acquired and a set of 99 images was distributed in a web-based reliability exercise, with re-reading of 40 images after a week. Finally, the definitions were tested in a patient-based reliability exercise, where 6 experienced sonographers examined 12 patients with hand OA using GE Logic E9 machines. The 2nd–5th proximal and distal interphalangeal joints of the right hand were scored 0-3 for synovial hypertrophy and effusion (dorsal and volar side) and for Doppler activity (dorsal side). An US atlas was available during the exercise. Intraclass correlation coefficient (ICC) values were calculated with average-measure for inter-reader and single-measure for intra-reader reliability, defined as poor (<0.5), moderate (0.5–0.75), good (0.75–0.9) and excellent (>0.90).

Results:

US atlases of elementary lesions were developed (figure). The web-based reliability exercise (completed by 12 sonographers) showed excellent inter-reader and good to excellent intra-reader reliability for all variables (table). The patient-based reliability exercise showed moderate to good inter-reader and intra-reader reliability for all pathologies (table), with slightly better agreement for dorsal assessment of hypertrophy and effusion.

Conclusion:

Following a Delphi process, a semiquantitative scoring system with a complementary US atlas showed moderate to excellent reliability for sonographic assessments of inflammatory features in finger joints of hand OA patients. Our study demonstrates that ultrasound is a reliable tool for evaluating inflammation in hand OA patients.

Figure

Table

	Web-based reliability exercise		Patient-based reliability exercise

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The OMERACT ultrasound (US) Gout Task Force has defined four US elementary lesions to evaluate patients with gout: double contour (DC), aggregates, tophus and erosions. The objective of this study was to evaluate intra and inter-reader reliability of the US definitions of elementary lesions in gout and to assess the Influence of Sonographer Experience.

**Methods:** We conducted a cross-sectional study. Sixty-two sonographers from several countries and different degree of experience took part in an US reading exercise. All observers evaluated 50 ultrasound videos from patients with gout diagnoses. In addition, a group of 15 videos was displayed twice to assess intra-reader reliability. We evaluated the presence of the four elementary lesions described by OMERACT US Gout Task Force: double contour (DC), tophus, aggregates and erosion. Intra and Inter-reader reliability was calculated by the Cohen's kappa coefficient and classified according to Landis and Koch criteria. Sonographers were stratified according to US experience (defining High experience as at least  $\geq 5$  years of experience,  $\geq 100$  US assessments/month and  $\geq 10$  US in gout patients/month), evaluating differences in intra, inter – reader reliability and overall agreement. Bias-adjusted and prevalence-adjusted kappa (PABAK) was calculated to overcome prevalence bias in kappa estimates.

**Results:** A total of 3100 US assessment were performed. Prevalence of lesions were: Tophus (34%), Aggregates (29%), Erosions (22%) and DC (20%). The mean intra-reader values were good to excellent in all lesions (table 1). Mean Kappa inter-reader correlation coefficients, were fair for aggregates, moderate for tophus and erosions, and good for DC (Table 1). Adjusting for low-prevalence using PABAK estimates, inter-rater reliability increased to 0.42 (moderate), 0.49 (moderate), 0.69 (good) and 0.79 (good); respectively. There was not significant difference between experience and non-experience sonographers regarding to agreement and inter-rater reliability. Experience sonographers showed better intra-rater reliability for the detection of erosions (table 1).

**Conclusion:** The inter-rater reliability of the OMERACT US elementary lesions for gout is still a concern, especially in others than Double Contour. This results should be taken into account in the design of future multicenter studies.

**Table 1. Agreement and kappa estimates stratified by evaluator experience**

Group	US experience [median, (p25-75)]	US assessment per months [median, (p25-75)]	US assessment in gout patients per months [median, (p25-75)]	Reliability assessment (Intra or Inter rater)	Aggregates		DC		Tophus		Erosions

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In recent years, salivary gland ultrasonography (SGUS) has emerged as a promising tool for the diagnosis and prognostic stratification of patients with primary Sjögren's syndrome. However, more studies are needed to demonstrate its diagnostic usefulness before it can be used in daily clinical practice. Our objective is to evaluate the diagnostic and prognostic value of salivary gland ultrasonography (SGUS) in primary Sjögren's syndrome (pSS).

#### **Methods:**

Patients with primary SS (fulfilling the American-European Consensus Group criteria of 2002) and controls with secondary SS or sicca syndrome are evaluated using a simplified SGUS scoring system.

Parotid and submandibular glands on both sides were assessed for parenchymal inhomogeneity, which was performed by the same ecographist. Echostructural alterations of the salivary glands were graded from 0 to 3, with grades 0 (normal) and 1 (mild inhomogeneity) being interpreted as normal, and grades 2 and 3 as primary SS typical lesions. Associations between SGUS and clinical and laboratory disease were analyzed. Moreover, to test the accuracy for diagnosis of SGUS, we calculated sensitivity, specificity, PPV, NPV and positive/negative likelihood ratio.

#### **Results:**

Thus far, twenty-five patients have been included, thirteen with pSS and twelve with secondary SS/sicca syndrome. The hypoechoic lesions (score 2 or 3) were found in 76.9% of primary SS patients and in none of controls ( $p < 0.001$ ). Specificity and positive predictive value of abnormal SGUS was 100%, sensitivity and negative predictive values were 76.9% and 80%, respectively. The negative likelihood ratio was 0.23 and the positive likelihood ratio was  $> 10$ , which means that typical SS lesions would improve the probability of having primary SS. However, if the SGUS results negative, another diagnostic test are needed in order to avoid patient misclassification.

Patients with parenchymal heterogeneity, more frequently, had positivity for anti-Ro/SSA ( $p=0.022$ ), anti-La/SSB ( $p=0.005$ ) and rheumatoid factor ( $p=0.007$ ). Moreover, the presence of hypergammaglobulinemia, ( $p=0.001$ ), leucolymphopenia ( $p<0.001$ ), and elevated ESR ( $p<0.001$ ) was associated with typical pathologic SGUS. Consequently, the EULAR Sjögren's syndrome disease activity index (ESSDAI) was higher in patients with abnormal SGUS ( $p=0.025$ ). We could not detect an association with age, disease duration, ANA positivity, complement level, anemia and, suprisingly, extraglandular involvement.

#### **Conclusion:**

In our preliminary study, assessment of parenchyma dyshomogeneity with SGUS is highly specific in differentiating primary SS from idiopathic sicca syndrome or Secondary SS. Moreover, this technic can provide prognostic stratification in patients with primary SS.

## **Diagnostic Value of the Non-Observation of the Frontal Branch of the Temporal Arteries By Ultrasonography in the Diagnostic of Giant Cell Arteritis (GCA)**

Natacha Cambray<sup>1</sup> and Artur J de Brum-Fernandes<sup>2</sup>, <sup>1</sup>Rheumatology Division, Université de Sherbrooke, Sherbrooke, QC, Canada, <sup>2</sup>Rheumatology Division, Université de Sherbrooke, Rheumatology Division, Canada, Sherbrooke, QC, Canada

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Imaging of Rheumatic Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

The absence of the parietal branch of the temporal artery during an ultrasound evaluation may be due to a variance of the normal anatomy or to technical difficulties due to interference of hair. However, the significance of a complete absence of the frontal branch

without any obvious stenosis or sudden occlusion is not known. The objective of the present study was to determine if the non-observation of the frontal branch of the temporal arteries by ultrasonography had any diagnostic value in patients with a clinically suspected GCA, as defined by biopsy or the ACR classification criteria.

#### **Methods:**

From May 2011 to February 2017, 102 patients underwent an US evaluation of the temporal arteries for suspected GCA. US of the common, parietal and frontal branches of the TA were done with a MyLab70 device and Color Doppler technique, bilaterally. A definitive stenosis was diagnosed when the frontal branch had its diameter decreased or the blood flow increased by at least twofold; obstruction was diagnosed by the sudden loss of a proximally well-identified artery. Non-observation was defined when at least one of the frontal branches of the temporal arteries was not observed at all.

#### **Results:**

102 patients were included in the study: 71.6% of them were women and the average age was of 72 years ; 49% of the patients presented at least 3 ACR criteria for GCA. 18 patients underwent a temporal artery biopsy, 4 with positive results. A definitive stenosis or occlusion on US examination was found in 11 of our patients. In 12 other patients the frontal branch of one of the temporal arteries could not be identified during US examination.

Compared to the ACR criteria, the presence of a definite stenosis had a sensibility of 18,6%, a specificity of 93,6 %, a PPV of 72,7% and a NPV of 55,7%. The non-identification of at least one frontal branch had a very similar predictive value: sensitivity of 14%, specificity of 90,4%, PPV of 58,3% and NPV of 52,2% . Compared to the biopsy, the presence of a definite stenosis or occlusion had a sensitivity of 100%, a specificity of 84,6%, a PPV of 33.3% and a NPV of 100%, while the non-observation of the frontal branch of the TA showed 75%, 85,7%, 60% et 92,3%, respectively.

#### **Conclusion:**

In our cohort the non-observation of the frontal branch of the temporal arteries was highly predictive of GCA whether the disease was defined by ACR criteria or by biopsy. Its predictive values were very close to those found for stenosis or occlusion, suggesting that it may be a manifestation of the same phenomenon.

## Background/Purpose:

Tumor necrosis factor inhibitors (TNFi) signify a major advance in the treatment of rheumatoid arthritis (RA). However, treatment success initially remains uncertain as one third of patients do not respond adequately to TNFi. We investigated whether brain activity associated to arthritis measured by functional magnetic resonance imaging (fMRI) can function as a predictor of response to TNFi in RA patients.

## Methods:

This is an interim analysis of the first 50 patients of the PreCePRA trial, a multi-center, randomized, double-blind, placebo-controlled fMRI trial on patients with RA. [1] [2] Active RA patients failing csDMARDs with a DAS28-ESR>3.2 and at least three tender and/or swollen joints received a brain BOLD (blood-oxygen-level dependent) fMRI scan upon joint compression at screening. Patients were then randomized into a 12-week double-blinded treatment phase with 200mg Certolizumab-Pegol every two weeks (arm 1: fMRI BOLD signal >2000 voxel, i.e. 2 cm<sup>3</sup>; arm 2: fMRI BOLD signal <2000 voxel) or placebo (arm 3) or. DAS28-ESR low disease activity at 12 weeks was assigned as primary endpoint. A 12-week follow-up phase in which patients were switched from the placebo to the treatment arm followed the blinded phase. fMRI was carried out at screening as well as after 12 and 24 weeks of receiving Certolizumab-Pegol or placebo.

## Results:

In responders screening signal volume, i.e. sum of significantly coupled voxels after FDR thresholding, was higher compared to non-responders allowing discrimination between the two groups prior to treatment. In responders we detected a persistent decrease of BOLD volume at week 12 and 24 compared to screening ( $r^2=0.561$ ) whereas BOLD volume in non-responders persistently increased ( $r^2=0.589$ ).

**Conclusion:** Based on this interim analysis we conclude that high BOLD volumes in fMRI indicating high-level brain representation of pain in arthritis predict response to TNFi. These data represent the first encouraging results of the PreCePRA brain fMRI study supporting the concept that increased RA-related brain activity correlates with response to TNFi.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Imaging of Rheumatic Diseases Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recently, optical molecular imaging is expected to serve as the new technique for early diagnosis and treatment monitoring of rheumatoid arthritis (RA). "Manu-Scan" is the diffuse optical tomography detecting near infrared ray (wavelength 0.7-1.4um) beamed into patient's joint. This pilot study was aimed to assess the clinical utility of Manu-Scan in patients with hand RA.

**Methods:** In 14 RA patients and 3 healthy controls, Manu-Scan was performed twice with a one-week interval to detect repetitive error, targeting metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints. Enrolled subjects also underwent joint physical exam, magnetic resonance imaging (MRI), bone scan (BS), and single photon emission computed tomography (SPECT) at the same time. Manu-Scan score was measured by contrast ratio between maximum and minimum scattering factors inside the joint.

**Results:** Among 215 hand joints assessed using Manu-Scan, 166 (77%) joints within repetitive error less than 20% (137 in RA patients and 29 in healthy controls) were valid for evaluation. Manu-Scan scores in RA joints were significantly lower than those in control joints (median 2.05 vs 2.80,  $p < 0.001$ ). Manu-Scan scores were also lower in RA joints without tenderness or swelling ( $n = 44$ ) compared with control joints ( $p = 0.002$ ). In RA patients, Manu-Scan scores were negatively correlated with MRI grades ( $\rho -0.502$ ,  $p < 0.001$ ), BS grades ( $\rho -0.516$ ,  $p < 0.001$ ), and SPECT scores ( $\rho -0.178$ ,  $p = 0.038$ ). Moreover, even if RA joints were lesion-free on MRI ( $n = 69$ ), Manu-Scan had moderate to good discriminatory ability between RA and control, based on ROC curve analysis (AUC 0.763 95% CI [0.661, 0.864]).

**Conclusion:** Manu scan could be utilized as a novel imaging modality reflecting synovial inflammation without exposure to radiation in RA patients. Further large-scale trial is needed to confirm this finding.

## Pneumococcal Vaccination Rates: Improving Safety in Immunocompromised Patients

**Shanley O'Brien** and Paul Schmidt, Department of Internal Medicine, Division of Allergy, Clinical Immunology, & Rheumatology, Kansas University Medical Center, Kansas City, KS

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Streptococcus pneumoniae is the most common cause of bacterial pneumonia.<sup>1</sup> Invasive pneumococcal infections carry a 10% mortality rate, which is higher in the immunosuppressed.<sup>1</sup> The Infectious Diseases Society of America recommends pneumococcal vaccination in patients planning to start or already on immunosuppression.<sup>2</sup> This project's purpose is to improve the pneumococcal vaccination rate of patients on immunosuppression with the goal of decreasing morbidity and mortality from invasive pneumococcal disease.

**Methods:** In an adult rheumatology clinic in a tertiary care center, a best practice alert (BPA) was created within the electronic medical record (EMR). The BPA is triggered for patients taking an immunosuppressive medication who have not received both the pneumococcal conjugate vaccine and the pneumococcal polysaccharide vaccine within the last 5 years. Options within BPA include: a link to the Centers for Disease Control and Prevention website, an option to order either vaccine, and a link to document the vaccine if historically given. Educational sessions on vaccine guidelines were held periodically with both the clinic physicians and nursing staff. A survey of clinic physicians was conducted both prior to and after initiation of the BPA. Baseline data was collected prior to initiation of the BPA and quarterly thereafter to determine the rate of patients who had received 1, 2 or 3 vaccines. Fisher's exact test was utilized.

**Results:** Baseline data from January to March 2016 found that of 741 patients, 335 (45.2 percent) had received 0 pneumococcal vaccines, 205 (27.6 percent) had received 1 pneumococcal vaccine, 168 (22.6 percent) had received 2 pneumococcal vaccines and 33 (4.4 percent) had received 3 pneumococcal vaccines. The BPA was implemented in May 2016. Repeat data from January to March 2017 showed that of 741 patients, 224 (30.2 percent) had received 0 pneumococcal vaccines, 219 (29.5 percent) had received 1 pneumococcal vaccine, 247 (33.3 percent) had received 2 pneumococcal vaccines and 51 (6.8 percent) had received 3 pneumococcal vaccines. The total number who had received at least 1 pneumococcal vaccine improved significantly after the intervention [406 (54.7 percent) to 517 (69.7 percent); (p = <0.0001)]. The rate of physicians surveyed who "usually" or "always" discussed vaccines with patients on immunosuppression improved from 50% (4/8) to 88.8% (8/9).

**Conclusion:** A BPA within the EMR was successful in significantly improving pneumococcal vaccination rates for patients on immunosuppression. A limitation of this study is that it was conducted in a tertiary care center and may not be generalizable to all care settings. Obtaining vaccination history was a challenge throughout the project. Future directions for this project include adding a patient education arm or expanding the BPA for use in other specialty clinics or additional vaccine types.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patients with Systemic Lupus Erythematosus (SLE) lupus are up to 13 times more likely to develop invasive pneumococcal infections, resulting in increased morbidity and mortality. Vaccination against *S. pneumoniae* is therefore recommended in all patients with SLE, however, vaccination rates in routine rheumatology care remain low. Barriers to vaccination are lack of provider recommendation, concerns about vaccine efficacy and safety, lack of vaccine supply, incomplete immunization records and time. The aim of this study was to increase pneumococcal vaccination rates in patients with Childhood-onset SLE (c-SLE) from 3.6% to 50% in 1 year and 80% by the following year. This report describes the interim results at 9-months from the initiation of the project.

### Methods:

Patients with childhood-onset SLE followed in the pediatric rheumatology clinic at Nationwide Children's Hospital from 1/1/2015 to 8/31/2016 were included for the baseline analysis. Newly diagnosed patients with c-SLE were included for the ongoing study. A letter was sent to these patients and their primary care providers requesting an updated immunization record. An age-based algorithm was developed for pneumococcal conjugate (PCV13) and pneumococcal polysaccharide (PPSV23) vaccination based on current ACIP guidelines, followed by an education session for rheumatology providers and clinic staff. Pre-visit planning included: 1) Generating a weekly report of upcoming appointments for c-SLE patients, 2) Entering updated immunization records with the help of the clinical pharmacist in the electronic health record (EHR), identifying candidates for vaccination, and notifying the rheumatology team of vaccination opportunities on a weekly basis, and 3) Weekly monitoring by clinic nurses to ensure adequate vaccine stock.

### Results:

83 patients with c-SLE were seen in the pediatric rheumatology clinic in the baseline period, with a median age of 18.3 years (range 7-24). An additional 8 newly diagnosed patients were included in this analysis, with a total of 91 patients. Over the study period, the number of patients with updated vaccine records in the EHR increased from 25.6% to 65.1%. Vaccination rates for PCV13 increased from 8.4% to 49.4% ( $p<0.0001$ ) and PPSV-23 rates increased from 24.1% to 32.9%. A total of 20/91 (21.9%) were appropriately immunized with both vaccines, compared with 3.6% at baseline ( $p<0.0001$ ). Notably, 60.4% of patients had received at least 1 dose of pneumococcal vaccine as compared to 28.9% at the start of the study ( $p<0.0001$ ).

### Conclusion:

This study highlights the benefits of pre-visit planning in improving pneumococcal vaccination in patients with c-SLE. Access to updated immunization records in the EHR at the time of the visit facilitated timely decision making. Targeted vaccine recommendations prior to the visit minimized the time burden on providers and served as a reminder to order the vaccine. Future efforts will be directed at building clinical decision support in the EHR for vaccinations in high-risk individuals, evaluating vaccine immunogenicity and expanding the service to patients with other pediatric rheumatic diseases.

## Compliance with Pneumococcal Vaccination in Rheumatic Disease Patients on Immunosuppressive Medications

Zainab Shahnawaz<sup>1</sup>, Fatme Allam<sup>2</sup> and Andras Perl<sup>3</sup>, <sup>1</sup>Medicine/Rheumatology, SUNY Upstate Medical University, Syracuse, NY, <sup>2</sup>SUNY Upstate Medical University, Syracuse, NY, <sup>3</sup>Medicine, SUNY Upstate Medical University, Syracuse, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Background/Purpose:**

The 2012 recommendations of the Centers for Disease Control (CDC) advise that adults aged  $\geq 19$  years with immunocompromising conditions including patients on iatrogenic immunosuppression should receive a dose of Pneumococcal Conjugate Vaccine (PCV13) first, followed by a dose of Pneumococcal Polysaccharide Vaccine (PPSV23) at least 8 weeks later (1). A second PPSV23 dose is recommended 5 years after the first PPSV23 dose for patients aged 19–64. Additionally, those who received PPSV23 before age 65 years for any indication should receive another dose at age of 65 years, or later if at least 5 years have elapsed since their previous PPSV23 dose. The preceding, 2008 recommendations suggested to vaccinate with PPSV23 alone (2). This project was initiated to evaluate compliance with the 2012 and 2008 guidelines at the Veteran's Affairs (VA) Medical Center in Syracuse, New York.

**Methods:**

This study included patients with the diagnoses of rheumatoid arthritis, systemic lupus erythematosus, or granulomatosis with polyangiitis who were treated with methotrexate, azathioprine, adalimumab, tofacitinib, apremilast, rituximab, mycophenolate mofetil, anakinra, etanercept, sekukinumab, ustekinumab, certozilumab or cyclophosphamide. Compliance rate in our cohort was compared to previously published studies with chi-square test using GraphPad software (San Diego, CA). Two-tailed  $p < 0.05$  was considered significant.

**Results:**

The records of 3095 cases between 1/1/2014-1/1/2017 were examined. 414 of 3095 cases were treated with immunosuppressants. Only 138/414 (33%) of the patients were immunized appropriately following the 2012 guidelines (1). 155/414 patients (37%) received PPSV23 alone, which follows the 2008 guidelines (2). 271/414 patients (65%) received PCV13 alone, while 288/414 patients (70%) received PCV13 or PPSV23. As reference points for our study, we were unable to find publications that evaluated compliance with 2012 CDC recommendations. However, we found three studies that assessed pneumococcal vaccination in similar cohorts (Table 1). Compliance with 2008 CDC guidelines was significantly lower in study No. 1 but greater in studies No. 2 and 3 as compared to our cohort at 37%.

**Table 1. Compliance rate of 37% at the Syracuse VA with 2008 CDC guidelines (2) is compared to three studies documented in the literature.**

Study No.	1	2	3
Reference	<a href="#">Arthritis Rheum.</a> 2009; 61:1505-10.	Rheumatology 2011; 50:366-372.	<a href="#">Open Forum Infect Dis.</a> 2015; 2: ofv119.
Vaccinated	99 (19%)	1491 (54%)	1449 (50%)
Not Vaccinated	420	1272	1449
Total	519	2763	2898
P value vs 37%	<0.0001	<0.0001	<0.0001

**Conclusion:**

This study demonstrates that the 66% majority of rheumatic disease patients on immunosuppressants at the Syracuse VA were not receiving adequate pneumococcal vaccination as recommended by the CDC (1). Therefore, quality improvement is necessary to enhance compliance with current CDC recommendations. Follow-up studies are warranted given the significant morbidity and burden to society inflicted by non-compliance with pneumococcal vaccination guidelines.

# Improved Provider Awareness and Delivery of Zoster Vaccination in Patients with Rheumatoid Arthritis Contemplating Biologic Therapy: Need to Target Eligible Patients Prescribed for Vaccination Post-Clinic

Gina Prakash<sup>1</sup>, Kenneth O'Rourke<sup>2</sup> and Stephen Mullis<sup>3</sup>, <sup>1</sup>Department of Internal medicine, Section on Rheumatology and Immunology, Wake Forest School of Medicine, Winston Salem, NC, <sup>2</sup>Department of Internal Medicine, Section on Rheumatology and Immunology, Wake Forest School of Medicine, Winston-Salem, NC, <sup>3</sup>Department of Internal Medicine, Section on Rheumatology and Immunology, Wake Forest School of Medicine, Winston Salem, NC

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Vaccination against herpes zoster (shingles) can reduce the frequency of infection, the severity of shingles should it occur, and the frequency of post-herpetic neuralgia. As active biologic therapy is currently considered a contraindication to vaccination against shingles with a live virus zoster vaccine (LVZV), provider awareness of this situation may promote vaccination rates in eligible patients for whom biologic therapy is contemplated. Factors such as determining vaccine cost may limit point-of-care (POC) vaccination in eligible patients.

## Methods:

In patients with a coded diagnosis of rheumatoid arthritis (RA) chart documentation assessed how frequently LVZV was addressed prior to initiation of biologic therapy. Following an educational intervention, a reminder and documentation system was implemented using a sheet given to all patients at the time of clinic intake, including a decision tree for providers to determine the need for vaccination based on age, prior vaccine status, diagnosis, and potential contraindications. A senior rheumatology fellow reviewed all charts. Pre-intervention consecutive charts from patients attending the rheumatology outpatient clinics in 2016 from 5/1 thru 5/31 were retrospectively reviewed. Inclusion criteria were patients coded with RA, age >50 years, and on biologic therapy. Exclusion criteria included patients already on biologics prior to established care in our clinic, or contraindication to LVZV per CDC guidelines. The post-intervention study prospectively reviewed charts on the same eligible consecutive patients seen in 2017 from 5/10 thru 5/26.

## Results:

Of 168 consecutive charts retrospectively reviewed pre-intervention, only 76 met eligibility criteria. In 0 charts was there provider documentation about the need for vaccination. Although nursing and/or medication documentation noted LVZV was appropriately given in 19%, there was no provider documentation as to why or if it actually was given. The percentage of vaccinated patients being seen solely by attendings were slightly higher compared to those seen by fellows.

All patients representing the 116 consecutive charts, which were reviewed post-intervention, were screened with the reminder sheet: only 16 met eligibility criteria for LVZV. Only 2 of the eligible patients received LVZV or a prescription for it accompanied by documentation by the provider in the record that the vaccine was given. 8 of the eligible patients were given a prescription for LVZV vaccination (4 seen by attendings, 4 by fellows), but there has been no documentation of the provider subsequently receiving confirmation that patients so prescribed actually received the vaccine. 6 of the eligible patients already had received LVZV previously as recorded in the clinic reminder sheet, but in only 4 patients was subsequent chart documentation found.

## Conclusion:

In eligible RA patients the documentation of completed LVZV remains low. The majority of eligible patients required a prescription for vaccination after POC, but there has been no confirmation that any received it. Efforts at increasing vaccination rates should be directed at providing a system to report back successful receipt of vaccination post-visit.

El Miedany<sup>1,2</sup>, Maha El Gaafary<sup>3</sup>, Nadia El Aroussy<sup>1</sup>, Sally Youssef<sup>4</sup> and Deborah Palmer<sup>5</sup>, <sup>1</sup>Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt, <sup>2</sup>Rheumatology, Darent Valley Hospital, Dartford, United Kingdom, <sup>3</sup>Community, Environmental and Occupational Medicine, Ain Shams University, Abbassia, Egypt, <sup>4</sup>Rheumatology & Rehabilitation, Ain Shams University, Cairo, Egypt, <sup>5</sup>Rheumatology, North Middlesex University Hospital, London, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

To assess the value of sharing the real-time ultrasound (US) images of the inflamed joints/ tendons with inflammatory arthritis patients and its impact on: 1. patient motivation; 3. medication adherence; 3. Control of disease activity; and 4. Patient cost-benefit decision.

### Methods:

Observational longitudinal study which included 121 patients, diagnosed to have active RA (62-patients, DAS-28 >3.2), or psoriatic arthritis (59-patients) who were treated according to Treat-to-Target approach. At baseline, 3-, 6- and 12-month every patient completed: A. PROMs questionnaire [1]; B. Beliefs about Medicines Questionnaire (BMQ) [2] to assess the cost-benefit analysis made by patients regarding the necessity versus concern of medication; C. Patient Motivation Measure [3]; D. Compliance Questionnaire-Rheumatology (CQR) [4] to measure medication adherence. US joint/ soft tissue examination was carried out based on patient reported joint/ enthesitis tenderness. All the US findings which were explained through direct clinician-patient interaction. Scores of US disease activity were recorded semi-quantitatively.

Control group: 118 of age and sex matched group of patients living with inflammatory arthritis (61 RA and 57 Psoriatic arthritis) treated per Treat-to-Target in standard outpatient setting. The patients were subjected to the same clinical assessment and completed the same questionnaires at the same time intervals. However, they were not subjected to US guided education.

Appropriate tests of significance were used to compare the study statistics. Pearson correlation coefficients were used to test the relationship between patient beliefs and medication adherence.

### Results:

Incorporation of US-guided patient education improved patient motivation and adherence to therapy. Patient motivation scores showed the highest significant changes in response to the US-guided education at 3-, 6-, and 12-months of follow up ( $p < 0.001$ ). This was paralleled by similar significant improvement in the DAS-28 score ( $P < 0.01$ ) at both 3- and 6-months of follow up.

Patient cost-benefit decisions shifted positively in the group who had US guided education. The shift was in favour of "belief in the necessity" of medication with a mean  $\pm$  SD cost-benefit ratio at 3-month of  $2.72 \pm 3.41$  which increased at 6-month to  $4.92 \pm 4.84$ , whereas at 12-month  $9.83 \pm 4.62$ ,  $P = 0.01$ . Similar improvement was noted in the CQR score as well as functional disability and quality of life measures.

### Conclusion:

US-guided patient education helped to improve the patient motivation and those patients with better understanding of the treatment benefits were more inclined to accept risks in the pursuit of successful disease control. Results highlighted that inflammatory arthritis patients who were well informed about the risks and benefits of medication showed better cost-benefit analyses. The patients would be more adherent to medication if they visualized the necessity of medication outweighed concerns about adverse effects.

## Online Viewing of Labs in RA Patients Is Not Associated with Clinically Significant Change in ESR over 18 Months Compared to Non-Viewers

Sheryl Mascarenhas<sup>1</sup>, Shuvro Roy<sup>2</sup>, April Pinto<sup>2</sup> and Preeta Gupta<sup>2</sup>, <sup>1</sup>Rheumatology, The Ohio State University, Columbus, OH, <sup>2</sup>The Ohio State University, Columbus, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** As part of passage of the Affordable Care Act in 2010, Meaningful Use Core Measures were outlined to improve electronic medical record (EMR) systems. One of these such measures is enabling patients to electronically view laboratory results. Allowing patients to view and track their labs can improve patient engagement in their medical care. However whether increased electronic patient engagement results in better clinical outcomes is not yet known. We reviewed whether viewing labs amongst rheumatoid arthritis patients resulted in improvement in laboratory results over an 18 month period.

**Methods:** Data was obtained from a retrospective chart review of rheumatoid patients seen at the Ohio State University Rheumatology Clinics. The cohort included patients who had an ICD-9 or ICD-10 diagnosis consistent with rheumatoid arthritis. The most recent sedimentation rate (ESR) and an ESR 18 months prior were recorded as the two outcome measures. Patients were divided into a group who had viewed their labs online and a group that did not, which could be determined from our EMR tracking system. The difference between the ESR over the 18 months was calculated and a one tailed t test was done between the 2 groups.

**Results:** 173 patients were included in the study with 111 of the patients not viewing their labs online (Non-viewers) and 62 having viewed the labs online (viewers). 138 of the patients were female (79.8%), with a mean age of  $56.6 \pm 12.4$  years. Baseline ESR were similar between both groups. At 18 months there was a statistically significant difference ( $p=0.039$ ) in the ESR of  $31.68 \pm 27.12$  mm/hour in Non-viewers compared to  $23.87 \pm 19.61$  mm/hour in Viewers. However the degree of change in the ESR over the 2 data points was not statistically significant ( $p=0.29$ ). The change in ESR over 18 months in the Non-viewers was  $-6.16 \pm 22.42$  mm/hour compared to  $-8.16 \pm 23.93$  mm/hour in Viewers.

**Conclusion:** To our knowledge this is the first study evaluating whether patient viewing of labs online results in a change in laboratory results overtime in rheumatoid arthritis patients. After 18 months the ESR did improve in both populations, however the degree of change in ESR over the course of 18 months in those who viewed labs online and those who did not was not statistically significant.

### Table 1. Patient Demographics

	<u>Non-Viewers</u>	<u>Viewers</u>
Total	111	62
Age (years)	57.22 ( $\pm 12.68$ )	55.5 ( $\pm 11.83$ )

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient engagement has become a growing focus in healthcare, catalyzed with the passage of the Affordable Care Act in 2010. Stage 2 of the Meaningful Use has criteria dependent on a patient portal, however whether electronic patient engagement translates into better clinical outcomes is yet to be determined. To begin an evaluation into this we reviewed outcomes in rheumatoid arthritis patients who had signed up for the patient portal compared to those who did not.

**Methods:** Data was obtained from a retrospective chart review of rheumatoid patients seen at the Ohio State University Rheumatology Clinics. The cohort included patients who had an ICD-9 or ICD-10 diagnosis consistent with rheumatoid arthritis. Patient outcome measures including the most recent sedimentation rate (ESR), Rapid 3, and swollen joint count were recorded along with demographic data. Two tailed t tests for these outcomes were done between each the group who had signed up for the patient portal and those that did not.

**Results:** 132 patients were included with 66 having signed up for the patient portal (Users) and 66 not signed up for the patient portal (Non-users). 103 (78.0%) of patients were female, with a mean age of 55 with a standard deviation of 13.79 years. Outcome measures

between the patients who signed up for the patient portal compared to those who had not  $14.77 \pm 7.57$  compared to  $13.48 \pm 7.73$  ( $p=0.33$ ) for Rapid 3 scores,  $1.97 \pm 2.25$  compared to  $2.86 \pm 4.06$  ( $p=0.16$ ) for swollen joint count, and  $39.88 \pm 29.76$  mm/hour compared to  $30.61 \pm 22.04$  mm/hour ( $p=0.04$ ) for ESR.

**Conclusion:** To our knowledge this is the first study to examine whether electronic patient engagement is associated with a change in clinical outcomes in rheumatoid arthritis. This initial study cohort does not demonstrate any clinically significant change in several key outcome measures in rheumatoid arthritis, particularly Rapid 3 scores, swollen joint counts. However there was a statistical difference between the ESR, with more favorable values in patients using the patient portal. This data suggests further study is needed to better understand if electronic patient engagement does have an effect on clinical outcomes in RA.

Table 1. Patient Demographics

	Non-Users	Users
Total (n)	66	66

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low health literacy has been associated with poor health outcomes and increased hospital admissions. Adherence to medication has been shown to significantly impact mortality, morbidity, and health care utilization in SLE. The relationship between medication adherence and health literacy has not been evaluated in SLE. Accordingly, the current study aims to assess the relationship between health literacy and adherence to HCQ in a multiethnic, urban SLE population.

**Methods :** SLE patients from the Columbia Lupus Center meeting ACR/SLICC criteria, treated with HCQ for >6 months, that had self-reported adherence, were included in study. Health literacy was assessed in English or Spanish using the validated Pfizer Health Literacy Questionnaire (HLQ), ÒNewest Vital SignÓ. Limited health literacy is defined as an HLQ score of 0-3, and adequate health literacy as a score of 4-6. HCQ testing was done by high performance liquid chromatography on whole blood by Exagen Laboratory. Adherence was defined as a HCQ level of >/= 500ng/ml. We evaluated the relationship between HLQ score, patient demographics, disease characteristics and HCQ levels. A significant association was considered at p</=0.05.

**Results :** The study included 67 lupus patients, average age 37 (range 19-66)91% female, 58% Hispanic, and average SLEDAI of 4.5 (range 0-15). 60% (n=40) of the population had limited health literacy, with HLQ scores of 0-3. Limited health literacy was significantly associated with Hispanic ethnicity, being Spanish speaking only (language barrier), having a household income below the poverty line, and less than high school education (Table 1). Younger patients and those with longer disease duration were more likely to have adequate health literacy. HCQ adherence, disease activity scores and SLE disease characteristics, such as organ involvement or current/recent use of steroids, were not associated with health literacy (Table 2).

**Conclusion :** Limited health literacy is significantly associated with markers of low socioeconomic status (SES) such as low level of education, language barrier, and poverty. There was no association between health literacy and medication adherence or disease activity. These data suggest that in an urban, multiethnic SLE population alternative factors affect compliance. Further study into these alternative factors is likely to help improve adherence.

## New Guidelines on Hydroxychloroquine Dosage – Where Are We?

**Shriyanka Jain**<sup>1</sup> and John Waterman<sup>2</sup>, <sup>1</sup>Division of Rheumatology, University of Connecticut, School of Medicine, Farmington, CT, <sup>2</sup>Rheumatology, Connecticut VA Healthcare System, Newington, CT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Hydroxychloroquine (HCQ) is a widely-used medication in many rheumatologic conditions. The most worrisome toxicity is irreversible damage to retinal pigment epithelium which can lead to blindness. The most recent 2016 guidelines from the American Academy of Ophthalmology (AAO) recommend the dose of HCQ  $\leq 5$  mg/kg real body weight to minimize toxicity<sup>1</sup>. According to these new guidelines, the risk of HCQ retinal toxicity is less than 1 % in the first year of therapy and less than 2 % up to 10 years of therapy. There is an increased risk of HCQ retinopathy with increase in the cumulative dose. Per the prior 2011 AAO guidelines the recommended maximum dose to minimize HCQ retinal toxicity was 6.5 mg /kg based on ideal body weight<sup>2</sup>. The advantage of the real body weight formula is that it distributes the risk evenly on a broad range of body habitus.

### **Methods:**

We identified, patients on HCQ in year 2016 at VA Connecticut Health Care System. Primary outcome was to identify patients whose dose exceeded the maximum recommended dose as per the 2016 guidelines. Data on indications for medication use, dose, ideal weight, real weight, duration of therapy and adherence to the last 3 years screening ophthalmologic exams were obtained. We also looked at the number of patients who were discontinued from HCQ use due to retinal toxicity.

### **Results:**

There were 102 patients who were prescribed HCQ in the year 2016. 89 patients were actively on HCQ. The average age was 64.7; (69/89) were male. 46/89 had RA. 12/89 had SLE. Other diseases included ScLE, MCTD, UCTD, Sjogren's syndrome, hepatitis C related arthritis. 45/77 of patients had 3 ophthalmology screening in past 3 years for toxicity. The average duration of HCQ use varied from <1 year to 20 years. There were 19/89 (21.3%) patients who were receiving more than 5 mg/kg/day of HCQ. HCQ was discontinued in one patient due to HCQ retinal toxicity during the observation period. He had been on HCQ for 13 years.

### **Conclusion:**

Our study revealed, 19/89 (21.3%) patients who were receiving more than currently recommended daily doses of HCQ based on the 2016 AAO guidelines potentially placing them at increased risk for HCQ retinal toxicity. With the new guidelines for HCQ dosing it becomes imperative for rheumatologists to assess the weight of their patients and adjust the dose of HCQ downward if the patient weights <80 kg.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hydroxychloroquine (HCQ) is used widely for the treatment of inflammatory arthritides and systemic lupus erythematosus. Recent publications have shown that HCQ toxicity is not as rare as previously thought among long-term users of the drug, with overall prevalence in a large demographic study around 7.5%. The risk of toxicity was greatly dependent on daily dose. Furthermore, HCQ retinopathy is not reversible and cellular damage may progress even after the drugs are stopped. The purpose of our study was to determine whether appropriate HCQ dosing and toxicity screening is elicited during regular clinical encounters for patients with inflammatory arthritis and connective tissue diseases.

**Methods:** A prospective clinical audit was conducted at nine Canadian rheumatology practices in eastern Ontario. Audit standards were based on the American College of Rheumatology (ACR) and American Academy of Ophthalmology (AAO) recommendations. Best practice standards included appropriate weight based dosing of hydroxychloroquine and subsequent monitoring for toxicity. We audited 100 appropriate patient encounters, spread out over nine practices using a standardized screening form.

**Results:** Among the 100 patients enrolled in the study, 80% were female with an average age of 58 years. Patients were on hydroxychloroquine for an average duration of 73 months, with rheumatoid arthritis (61%) and systemic lupus erythematosus (23%) being the most common diagnoses as per the ACR classification criteria. A total of 62 patients were considered high risk for retinal toxicity based on AAO criteria including age, duration of use, renal or liver dysfunction and pre-existing retinal disease.

Three out of four audit standards were not met. No patients in our audit had hydroxychloroquine retinopathy and therefore, the last standard could not be assessed. Only 70% of patients were being appropriately dosed based on body weight. Furthermore, 17% of patients were on a prescription dose that was greater than 10% of the recommended dosage. Only 87% of patients had a baseline ophthalmologic exam in the first year of treatment, while guidelines suggest all patients should have one. Within the hydroxychloroquine retinopathy high-risk cohort, only 91% of patients were getting yearly eye exams.

**Conclusion:** Our guideline-based standards of appropriately dosing hydroxychloroquine and monitoring for retinopathy are not being met in typical patient encounters. The current system can be improved and the next step is to provide clinicians with a weight-based dosing chart that includes monitoring requirements. This intervention will be applied over three months and a re-audit will be conducted. The results will be compared to pre-intervention outcomes.

## **Rheumatologists' Compliance with Screening for Viral Hepatitis B and C Prior to Initiation of Methotrexate Treatment Needs Quality Improvement**

Farheen Jaffari<sup>1</sup>, Andras Perl<sup>2</sup> and Fatme Allam<sup>3</sup>, <sup>1</sup>Rheumatology, SUNY Upstate, Syracuse, NY, <sup>2</sup>Medicine, SUNY Upstate Medical University, Syracuse, NY, <sup>3</sup>SUNY Upstate Medical University, Syracuse, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The risk of viral hepatitis reactivation in patients undergoing immunomodulating therapy is being increasingly recognized. The American College of Rheumatology guidelines recommends screening for hepatitis B virus (HBV) and hepatitis C virus (HCV) infections prior to initiation of Methotrexate (Arthritis Rheum. 2003; 49: 843–845; Arthritis Rheum. 2008; 59: 762–784). In this Quality Improvement (QI) study, we evaluated screening practices at the Veterans Affairs (VA) Medical Center in Syracuse, New York.

## Methods:

To perform quality assessment as the first step of the Plan-Do-Study-Act QI methodology (BMJ Qual Saf.2014; 23:290–8), we extracted records of 299 patients receiving methotrexate for rheumatologic diseases at the Syracuse VA between 2011-2016. The patient records were then retrospectively examined to assess if they had undergone screening for HBV and HCV infections prior to initiation of methotrexate. The inclusion criteria were defined as: 1) age > 30 years; 2) initiation of methotrexate within the 5 years preceding the study period; and 3) methotrexate dosages < 30 mg per week. Compliance rate from the current study at the Syracuse VA was compared to two previously published studies with chi-square test using GraphPad software (San Diego, CA). Two-tailed p <0.05 was considered significant.

## Results:

From a total of 299 patients treated with methotrexate at the Syracuse VA, only 104 (34%) were screened for both HBV and HCV infections prior to therapy initiation. In comparison to peer-reviewed literature, there was considerable variability in screening rates.

Table 1: HBV and HCV screening at the Syracuse VA and its comparison to the literature.

Study	Tested	Not tested	Compliance	Chi-square p
Syracuse VA	104	195	34.7%	-
Clin Rheumatol 2014; 33: 1823	6	79	7%	< 0.0001
Clin Exp Rheumatol. 2016; 34:473-9	861	475	64.4%	< 0.0001

## Conclusion:

Our study clearly indicates that QI aimed at increasing compliance with ACR guidelines among rheumatologists regarding the risks of viral hepatitis reactivation in patients treated with immunosuppressant medications is warranted. We propose a QI initiative that testing for HBV and HCV should be prompted when electronically ordering methotrexate in patients with rheumatic diseases.

## HLA-B27 Testing in Patients $\geq$ 45 Years of Age and Subsequent Diagnosis of Late Onset Spondyloarthritis

**Marc W. Nolan**<sup>1,2</sup>, Morgan M. Brown<sup>3</sup> and Elie Gertner<sup>1,2</sup>, <sup>1</sup>Section of Rheumatology, Regions Hospital, St. Paul, MN, <sup>2</sup>Division of Rheumatology, University of Minnesota Medical School, Minneapolis, MN, <sup>3</sup>HealthPartners Institute, St. Paul, MN

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In 2015, the Canadian Rheumatology Association published their Choosing Wisely recommendations regarding HLA-B27 testing. One of the criteria that triggers testing is inflammatory back pain in patients < 45 years old (y/o). This was chosen based on ASAS criteria for axial and peripheral SpA which were validated in patients under 45 y/o. However, studies have indicated that 3-10.6% of patients with SpA diagnosis occur in patients  $\geq$  45 y/o, hinting at a “late onset” SpA group. We sought to assess the utility of HLA-B27 testing in patients  $\geq$  45 y/o to determine how many were eventually diagnosed with SpA.

### Methods:

Retrospective analysis of all patients  $\geq 45$  y/o who had HLA-B27 testing by a non-rheumatology provider (PCP, Ophthalmology, Orthopedics) at Regions Hospital/ Health Partners, a large academic vertically and horizontally integrated health care system, from 1/1/2014 - 7/1/2015. Chart review identified features of SpA (defined as inflammatory back pain  $> 3$  months with onset  $< 45$  y/o, peripheral synovitis, enthesitis, dactylitis, psoriasis, or uveitis) that were present at the time of HLA-B27 testing. We assessed if imaging (Xray, CT, or MRI) identifying sacroiliitis  $\pm 6$  months from HLA-B27 order was present, the presence of inflammatory markers (ESR or CRP)  $\pm 1$  month from the HLA-B27 order, and if an eventual diagnosis of SpA was made. Data were analyzed to generate descriptive information regarding frequency, and logistic regression was used to identify which features of SpA and SpA subsets are identified in HLA-B27 tested patients  $\geq 45$  y/o.

## Results:

Over the 18 months, 291 HLA-B27 tests were ordered by non-rheumatologists. The age ranged from 1 to 92 years. 141/291 tests were in individuals  $\geq 45$  y/o [63 tests  $> 50$  y/o, 44 tests  $> 55$  y/o]. Diagnosis of a SpA was made in 11/141 (7.8%) (8 AS, 3 PsA) whereas 32 total diagnoses of SpA were made in the entire group (regardless of age). Thus, 11/32 (34.4%) of SpA diagnosis occurred in patients  $\geq 45$  y/o. At a 95% confidence level, psoriasis (OR 14.66) and back pain (OR 13.98) were the significant predictors for SpA in the group  $\geq 45$  y/o (Table 1). There were insufficient numbers to evaluate the predictive value of the other symptoms in the group  $\geq 45$  y/o. In the entire group, back pain was also the most significant predictive factor (OR 28.5) for a diagnosis of SpA. Thus inflammatory back pain can trigger evaluation for SpA regardless of age.

## Conclusion:

In this study, of the 291 non-rheumatologist ordered HLA-B27 tests, 11/141 (7.8%) of patients  $\geq 45$  y/o eventually received a SpA diagnosis which represents 1/3 of the eventual SpA diagnoses. This significant amount of late onset SpA combined with the highest OR being back pain emphasizes the importance of being aware of late onset SpA as well as considering inflammatory back pain regardless of age as a feature for SpA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disease progression and therapy response in patients with rheumatoid arthritis (RA) is currently evaluated using clinical and functional assessments that include subjective measurements such as DAS28, HAQ, and the Michigan Hand Outcome Questionnaire (MHQ). Studies have been conducted to determine potential associations between radiological imaging, DAS28, and HAQ. There are limited studies that investigate the connection with MHQ. Our study aims to explore if radiological studies using magnetic resonance imaging (MRI) and high-resolution peripheral quantitative computed tomography (HR-pQCT) demonstrate any association with the more hand-focused MHQ score.

**Methods:** Patients were screened and separated into two groups based on their disease activity determined by DAS28: Group I: low disease activity (DAS28  $\leq 3.2$ ) and Group II: high disease activity (DAS28  $> 3.2$ ). Following current guidelines set by the American College of Rheumatology (ACR); group I continued their current treatment using methotrexate, while group II were initiated on an anti-TNF $\alpha$ . At baseline (immediately before anti-TNF $\alpha$  initiation for group II) and 3-months, each patient underwent clinical (DAS28), functional (MHQ and HAQ), and structural (imaging of dominant hands/wrists via 3 Tesla MRI and HR-pQCT) assessments. Bone marrow edema pattern, synovitis, and erosion were graded using the RA MRI score (RAMRIS) system. Bone erosion volumes were calculated using HR-pQCT images. Measures at baseline and 3-months were compared using paired t-test. The association between changes in MHQ and imaging measures from baseline to 3-months were evaluated using Pearson's correlation coefficient.

**Results:** Twenty patients were studied (9 group I and 11 group II, Table 1). Significant increases in MHQ (suggesting improvement) and significant decreases of DAS and erosion volumes from baseline to 3-months were observed in group II (Table 1); while significant increases in DAS28-CRP and erosion volumes were observed in group I. 3-month changes in bone erosion volume and edema had a significant correlation with changes in MHQ score (Figure 1 top). Significant correlations with 3-month changes in MHQ and DAS28 and HAQ were also found (Figure 1 bottom).

**Conclusion:** Advanced imaging measures such as bone erosion volume and bone marrow edema show great potential to serve as biomarkers to determine disease progression, therapy response, and specific hand functions in patients with RA. The study is recruiting more patients and will follow up patients at 12-months to evaluate potential imaging markers that may predict hand functional outcomes.

**Table 1: Patient Demographic and Clinical Information**

	Group I		Group II	
	Baseline	3-Months	Baseline	3-Months
Age (years)	61.6 (13.1)	-	48.8 (15.3)	-
Females, %	66.7	-	84.6	-
BMI (kg/m <sup>2</sup> )	24.4 (5.5)	-	30.0 (5.5)	-
MHQ	79.8 (20.2)	81.6 (23.2)	43.8 (15.1)	65.3* (21.2)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Participation, including work disability, is an important patient centred outcome and is in the middle ring of the Outcome Measures in Rheumatology (OMERACT) psoriatic arthritis core set of domains. The Work Productivity and Activity Index Specific Health Problem (WPAI-SHP) is a feasible, patient reported measure of work disability but there is little data on the validity of the WPAI-SHP in PsA. We set out to determine the validity of the WPAI-SHP and the minimally important difference (MID) for improvement in PsA.

### Methods:

LOPAS II is a UK multicentre observational study of work disability in PsA. Working patients were included for analysis. Construct validity was determined by correlation with other clinical and patient reported outcomes using spearman correlation coefficients. Responsiveness was calculated using the standard error of the mean (SEM). The MID was determined by the health based anchor method (mean change in score amongst patients who improved) and the receiver operating characteristic curve (ROC) method.

### Results:

Analyses were undertaken on 177 of 229(77.3%) working participants with complete data at baseline and three months follow up. The mean age was 48 years and median disease duration 6.0 years (IQR 2.0 – 12.0). The mean change of presenteeism was -7.9 (sd30.0), SEM 16.2 and SRM -0.26. Correlations with other outcomes are reported in table 1. Amongst 105 (59.3%) patients who reported no change between baseline and follow up the mean change in WPAI was; absenteeism 2.9 (sd30.7), presenteeism 4 (26.5), productivity loss 7.7 (27.2), activity impairment 1.9 (24.4). The MID for improvement amongst 72 (40.7) patients who reported improvement was; absenteeism -6.1 (26.2), presenteeism -20.8 (28.2), productivity loss -21.7 (30.8) and activity impairment -27.2 (29.5). The MID using the ROC method for presenteeism, productivity loss and activity impairment was -5.0 (AUC 0.75), -11.3 (AUC 0.76) and -25.0 (AUC 0.79) respectively (Figure 1).

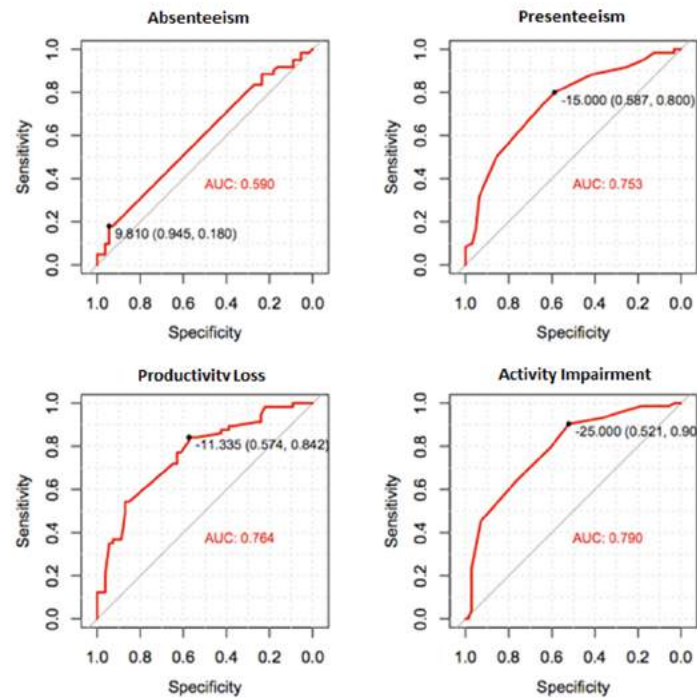

Conclusion:

We report data on the validity of the WPAI-SHP in PsA and an estimate of the MID for improvement. Presenteeism and productivity loss are moderately correlated with clinical measures. Responsiveness was small to moderate amongst the group as a whole.

Table 1 Spearman correlation coefficients of the WPAI-SHP and clinical, composite and patient reported outcomes at baseline.

Outcomes	WPAI absenteeism	WPAI presenteeism	WPAI productivity loss	WPAI activity impairment
DAPSA	0.20	0.34	0.39	0.45
RAPID3	0.32	0.54	0.62	0.77
HAQ	0.31	0.42	0.51	0.61
EQ5D	-0.29	-0.42	-0.44	-0.59
FACIT fatigue	-0.40	-0.44	-0.53	-0.61
Global VAS	0.26	0.47	0.52	0.70
Pain VAS	0.26	0.51	0.57	0.65

Improving Quality of Care for Rheumatoid Arthritis Patients in an Underserved Area

Qingying Lai<sup>1</sup> and Beverly Johnson<sup>2</sup>, <sup>1</sup>Internal Medicine, Jacobi Medical Center, Bronx, NY, <sup>2</sup>Department of Rheumatology, Jacobi Medical Center, Bronx, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The American College of Rheumatology (ACR) has endorsed a set of quality measurements for patients with rheumatoid arthritis (RA). Our patient population was at two city hospitals which serve a large underserved population. This study is aimed to use these ACR quality measurements to assess the quality of care of RA patients in this population.

### Methods:

This is a retrospective study conducted by chart review of patients with an ICD-9 or ICD-10 diagnosis code of RA that visited rheumatology clinic of two public hospitals in an underserved area between July 1st, 2015-July 1st, 2016. All patients met ACR criteria for RA. We measured five ACR endorsed quality measurements (see Table 1) and compared between patients of different socioeconomic status (SES) and different provider type (trainees and attendings).

### Results:

240 patients were seen in rheumatology clinic of the two public hospitals during the targeted time period, 89% of whom were of low SES defined as having Medicare/Medicaid or no insurance. Almost all patients were on DMARD (95.8%) during the index clinic visit and 35% were on biological DMARD. The majority of the patients (7/11) not on DMARD were of low SES and were not on DMARD due to documented non-compliance and poor follow-up. All patients (83/84) with increased disease activity had changes in regimen except for one who refused changes. Among the 28 patients who were started on biological DMARD during the targeted year, 25% (7/28) had no tuberculosis (TB) screening documented within the prior 12 months (3 had TB screening more than 12 months prior, 2 were documented after initiation of biological DMARD and 2 had no documentation). Less than half of the patients (43%) had Clinical Disease Activity Index (CDAI) documented in  $\geq 50\%$  of the clinic encounters. Attendings had a slightly better percentage of CDAI documentation than trainees (49% vs 40%) but the difference was not statistically significant (chi-square test,  $p=0.206$ ). Only 7% of patients were on prednisone  $> 10\text{mg}$  daily for more than 3 months and most of them (10/13) had a documented glucocorticoid taper plan.

### Conclusion:

Providing high quality of care to patients with rheumatoid arthritis in an underserved area is challenging. Our providers did a good job of initiating DMARD, escalating treatment in the face of high disease activity and decreasing high prednisone doses. In these areas, the main limitation was low SES with medication non-compliance. Areas for improvement are reaching 100% screening for TB prior to starting biologics and to achieve higher disease activity documentation rate. Based upon this study, a prospective intervention will be started in the clinics to improve TB screening and documentation of disease activity as an ongoing divisional QI project.

Table 1: ACR Endorsed Quality Measurement

- 1 Percentage of patients with diagnosis of RA who were prescribed DMARD therapy within 12 months
- 2 Percentage of patients with increased disease activity have changes in regimen (e.g. Change DMARD/glucocorticoid dose, add additional DMARD et al.)
- 3 Percentage of patients who have TB screening documented within 12 months prior to receiving first course of biological DMARD
- 4 Percentage of patients have  $\geq 50\%$  total number of outpatient encounters with disease activity assessment
- 5 Percentage of patients being on prolonged doses of prednisone  $> 10\text{mg}$  daily have documented glucocorticoid management plan

## Practice Improvement Utilizing Six Sigma and Health Informatics in an Academic Setting

**Puneet Bajaj**<sup>1</sup>, Shilu Varghese<sup>2</sup>, Allison Sunleaf<sup>2</sup>, Paul Padilla<sup>2</sup>, Shannon Scielzo<sup>2</sup>, Sherene Philip<sup>2</sup>, Justin Haridas<sup>2</sup>, Clarie Wang<sup>2</sup>, Vaishnavi Kannan<sup>2</sup>, Jeffrey Lewis<sup>2</sup>, Deepa Bhat<sup>2</sup>, Jacqueline Mutz<sup>2</sup>, Duwayne Willett<sup>2</sup>, Jason Fish<sup>2</sup> and David Karp<sup>2</sup>, <sup>1</sup>Rheumatology, UT Southwestern Medical Center, Dallas, TX, <sup>2</sup>UT Southwestern Medical Center, Dallas, TX

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

For projects such as the ACR Rheumatology Informatics System for Effectiveness (RISE) to succeed for quality improvement, practice benchmarking, & research, the data included must be high fidelity and represent the majority of patients in participating practices. To prepare a large academic practice for RISE participation, we synergistically harnessed the power of institutional informatics coupled with systems engineering. We focused on two Rheumatoid Arthritis (RA) assessments: Routine Assessment of Patient Index Data (RAPID3) & Clinical Disease Activity Index (CDAI). Baseline data was extremely low (13% & 27% respectively). The aim was to improve compliance for these instruments in the Rheumatology clinics to > 75% by December 2016.

### Methods:

High quality data was extracted from our RA registry established in April 2015. Inclusion criteria: RA patients seen by a rheumatology provider twice in the last 24 months & at least once in last 12 months. By Feb 2017, the registry had 543 patients. The project team utilized Six Sigma DMAIC (Define, Measure, Analyze, Improve & Control) data-driven improvement cycle for problem-solving & process improvement. Tools & techniques included brainstorming, project charter, process maps, fishbone diagrams, Pareto chart, & feedback communications. Interventions were aimed towards standardization of clinic work flow, and motivating better EMR documentation practices.

### Results:

We examined growth of compliance (proportion of completed assessments) over time. We found very strong effect sizes ( $r > .90$ ,  $p < .001$ ) for both completion of the Rapid3 & CDAI (average growth rates over 3% a month). Their compliance was also highly related; but Rapid3 compliance was not the sole explanatory variable for CDAI compliance as demonstrated by mediational analyses.

We have created modified control charts (Tables 1 & 2). Given our goal to demonstrate differences over time, the standard error of difference (SED;  $(\sigma/N)^{1/2} \cdot 1.96$ ) within month was calculated and used to create the bounds around the observed compliance rates. Any month's proportion rate outside of other months' SED bounds is statistically different at  $\alpha = .05$ .

### Conclusion:

Combining the power of informatics & systems engineering led to impressive improvements in provider behaviors. This methodology helped to identify opportunities to overcome barriers & to motivate providers. High quality processes facilitated high quality data, and vice versa. Performance expectations were clear, improvements were sustained, and we have believable long-term RA outcomes data that can be used to improve outcomes at the practice level.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prompt identification and referral of patients with suspected inflammatory arthritis to a rheumatology clinic are crucial for early diagnosis and treatment. In the referral letter to our Early Arthritis Clinic (EAC), the physician should refer, out from seven possible criteria, the ones motivating the referral. The objectives of our study were: 1) to assess the level of agreement between the referring physician and the rheumatologist, regarding the presence of referral criteria; 2) to identify the set of criteria that best predicts the presence of inflammatory arthritis.

**Methods:** Unicentric retrospective observational study, including patients observed in the EAC until May/2016. Subjects were excluded if they had been referred to the EAC by a rheumatologist and if we couldn't access the referral letter or the medical records from the first visit to the EAC. Demographic data, provenience, referral criteria and the final diagnosis were retrieved from individual clinical files and the Portuguese Registry of Rheumatic Patients – Reuma.pt. For the referral criteria, the agreement between the referring physician and the rheumatologist in the first EAC visit, was assessed using the Cohen's Kappa. In the second step, we created four new variables, each one corresponding to a set of criteria, as indicated by the referring physician. ROC curves were drawn by a nonparametric method in order to identify the set that best predicts the presence of inflammatory arthritis.

**Results:** We included 132 patients, 66% females, mean age 52±17 years; Referred from primary care (72%), emergency department (17%) and other hospital specialties (11%). An inflammatory arthritis was diagnosed in 73% of the cases. Table 1 shows the level of agreement between the referring physician and the rheumatologist, regarding the presence of each of the referral criteria. Table 2 shows the area under the curve for each set of criteria.

**Conclusion:** Among the clinical criteria, there was poor agreement regarding the presence of arthritis and no significant agreement regarding the characterization of the arthralgia as inflammatory, the morning stiffness and the squeeze test. The weak performance of all sets of criteria in predicting inflammatory arthritis is probably due to deficient recognition of each criterium. These results suggest the need for improving education among the physicians referring patients to the EAC.

Table 1: Agreement between the referring physician and the rheumatologist, regarding the presence of each of seven criteria.

Referral criteria	N Ref/Rheum	kappa	CI 95%	p
Arthritis (N=122)	83/82	0.23	0.05-0.41	0.01
Squeeze (N=80)	23/36	0.03	-0.17-0.24	0.75
Inflammatory arthralgia (N=131)	95/112	-0.01	-0.17-0.15	0.90
Morning stiffness > 30' (N=107)	51/80	0.01	-0.02-0.30	0.09
Rheumatoid Factors (N=117)	31/27	0.59	0.42-0.76	0.00
Elevated Erythrocyte Sedimentation Rate (N=125)	63/65	0.33	0.16-0.49	0.00
Elevated C reactive Protein (N=124)	60/74	0.30	0.13-0.46	0.00

Table 2: Area under the curve for each set of criteria, as indicated by the referring physician.

Set of criteria	AUC	CI 95%	p
All_Criteria	0.577	0.478 – 0.677	0.177
Clinical_Criteria	0.465	0.356 – 0.574	0.543
Clinical+ESR+CRP_Criteria	0.544	0.442 – 0.647	0.439

## Adherence to American College of Rheumatology Guidelines for Prevention of Glucocorticoid-Induced Osteoporosis in Patients with Polymyalgia Rheumatica

Brittany Frankel<sup>1</sup>, Angela Christensen<sup>2</sup> and Monica Guma<sup>3</sup>, <sup>1</sup>Internal Medicine, University of California, San Diego, San Diego, CA, <sup>2</sup>Rheumatology, University of California, San Diego, San Diego, CA, <sup>3</sup>University of California, San Diego, San Diego, CA

First publication: September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

American College of Rheumatology (ACR) 2010 guidelines recommend that any patient initiating glucocorticoid therapy with an anticipated duration of  $\geq 3$  months should receive a baseline assessment of bone mineral density (BMD), assessment of osteoporosis risk factors, vitamin D supplementation, and counseling on calcium intake and lifestyle modification. Prior studies suggest that implementation of glucocorticoid-induced osteoporosis (GIOP) prevention measures is often suboptimal. Polymyalgia rheumatica (PMR) is a common rheumatologic condition for which most patients receive  $> 3$  months of prednisone. As such, we utilized this population to investigate compliance with GIOP prevention measures within our healthcare system's rheumatology clinics.

### Methods:

A retrospective review of the electronic health record (EHR) was conducted to identify patients with a documented diagnosis of PMR and at least 2 rheumatology clinic encounters. A total of 170 patient charts were reviewed. 55 patients met inclusion criteria, which required presence of a new diagnosis of PMR at the time of any rheumatology clinic visit, PMR diagnosis no earlier than November 2010 (date of 2010 ACR GIOP guideline publication), and absence of osteoporosis at the time of PMR diagnosis. The EHR was reviewed directly to obtain data.

### Results:

Mean age was 69.5 years, 55% were male, 76% were Caucasian, and mean BMI was 26.9. 64% had a primary care provider within our healthcare system. All patients were treated with  $\geq 3$  months of prednisone. Median duration of prednisone use was 20 months (range 4 to 75 months). Median initial dose of prednisone was 20mg/day (range 5 to 80mg/day). Per 2010 ACR guidelines, a baseline dual-energy X-ray absorptiometry (DXA) scan was indicated in all patients. Only 24% of patients had a documented DXA scan between 5 years before and 3 months after PMR diagnosis, although DXA scans obtained outside of our health system may not have been available for review. Among DXA scans ordered within 3 months of diagnosis, 20% were recommended by a rheumatologist, and the rest were ordered by a primary care provider. Recommendations for calcium intake were documented in 42% of patients. Vitamin D supplementation was documented in 55% of patients. Per 2010 ACR guidelines, prophylactic antiresorptive therapy was indicated in at least 96% of patients. However, only 18% were treated with a bisphosphonate at any point after PMR diagnosis. A repeat DXA 1 year or more after PMR diagnosis was obtained in 29% of patients. 20% of these patients developed osteoporosis by T score definition. Although bisphosphonates were indicated at the time of steroid initiation in all patients who developed osteoporosis, none were started on bisphosphonates until 1 year after PMR diagnosis.

### Conclusion:

Rates of implementation of GIOP preventative and treatment measures among patients with PMR are suboptimal in our healthcare system. The authors plan to implement an EHR template to remind rheumatology providers to order a DXA and counsel on GIOP prevention. We are also investigating the feasibility of an EHR pop-up to prompt providers to order a baseline DXA when glucocorticoids are ordered for  $> 3$  months for patients who do not have a baseline DXA on file.

# Secondary Prevention of Cardiovascular Disease Is Incomplete in a Systemic Lupus Erythematosus Population-Based Cohort

Suzana John<sup>1</sup>, Cristina Drenkard<sup>2</sup>, Gaobin Bao<sup>2</sup> and S. Sam Lim<sup>2</sup>, <sup>1</sup>Rheumatology, Emory University, Atlanta, GA, <sup>2</sup>Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Cardiovascular disease (CVD) is a common cause of morbidity and mortality in systemic lupus erythematosus (SLE). We know that a combination of traditional cardiovascular disease (CVD) risk factors and dysregulation of the immune system play a role in the pathogenesis. Strict adherence to established preventive measures in these patients is important. This study evaluated secondary prevention of CVD in a large population-based SLE cohort.

## Methods:

Georgians Organized Against Lupus (GOAL) is a population-based cohort of patients with validated SLE surveyed annually and matched to the Georgia Hospital Discharge Database to capture all hospitalizations throughout the state. Those with CVD were identified from responses to the validated Self-Administered Brief Index of Lupus Damage. CVD related hospitalizations were identified based on the first 3 admission codes.

## Results:

164 out of 685 respondents had CVD. Patients with CVD were more often older, black, poor, unemployed and on Medicare/Medicaid. Blood pressure was monitored very well. Most but not all received an annual check-up and cholesterol monitoring. Measures that were met the least included not smoking, adequate physical activity and aspirin adherence. Smokers were more often on Medicare/Medicaid than non-smokers ( $p=0.015$ ).

## Conclusion:

SLE patients with known CVD are at high risk for recurrent cardiovascular events and mortality, making prevention a crucial and cost effective priority. There continues to be significant room for improvement in many preventive measures. Further study may direct education and resources to improve performance in these areas.

Table 1: Socio-demographic description of the GOAL Cohort

Descriptors	GOAL Cohort (N=685)	CVD status		
		Non-CVD (n=519)	CVD (N=164)	P Value

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The primary objective of this study was to better characterize the prescribed rates of aspirin prophylaxis for ischemic considerations in patients diagnosed with Giant Cell Arteritis (GCA). Secondary objectives included utilizing this functionality of the electronic health record to further characterize rates of biopsy-proven diagnoses, initial and alternative therapies offered, and incidence of ischemic events in patients diagnosed with GCA.

**Methods:** This study utilized the SlicerDicer capability of the Epic electronic health record at the University of California, San Diego. Encounters were reviewed individually to determine if patients met ACR criteria for the diagnosis of GCA. The above objectives were accomplished by reviewing all documentation regarding the indication of aspirin use in these patients, whether related to GCA or for other indications.

**Results:** 92 patients were identified through the overall query of the tracking tool for GCA of which 40 met ACR criteria for diagnosis of GCA. We found 52.5% (21 of 40) patients were identified to be prescribed aspirin with only 5 patient charts with distinct documentation for the indication of GCA. Two additional patients were on other forms of anticoagulation. Five patients suffered either strokes or transient ischemic attacks, of which 4 of 5 were before or the presenting feature of GCA. One was secondary to inappropriately stopping anticoagulation for atrial fibrillation. Only three of the four were prescribed aspirin prior to the documented event. Of note, two patients were noted to have either active or history of gastrointestinal bleeds with aspirin started after a prolonged period. Lastly, 22.5% of patients failed prednisone as the initial therapy and required alternative treatments.

**Conclusion:** Our data demonstrated that 52.5% of patients who met ACR criteria for GCA were on ischemic prophylaxis therapy with aspirin and only 12.5% of these patients had documentation for why or why not aspirin was recommended. The majority of cerebral ischemic events preceded or served as a presenting manifestation of GCA in this cohort. Our data indicates that we have opportunity to improve the number of patients on prophylaxis with aspirin for ischemic disease in GCA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Practice improvement research routinely measures patient satisfaction and disease-specific outcomes but seldom considers the satisfaction of physicians who deliver the care. Studies suggest that physician dissatisfaction may pose a barrier to implementing quality improvement efforts. There is a paucity of succinct measures of physician satisfaction. As part of a Performance Improvement Project, in an academic rheumatology practice and an affiliated practice, we developed and piloted a simple questionnaire.

**Methods:** Thirty five rheumatologists in the academic or private setting were sent opened-ended questions to determine the factors that made them satisfied or dissatisfied with respect to their rheumatology practice. From the responses we formed a 14 questions 0 to 10 scale centering on satisfaction and dissatisfaction. We then administered the questionnaires to a small pilot of 30 rheumatologists in academic and/or private setting.

**Results:** Our sample included 30 rheumatologists, from whom 60% were faculty members, 27 % were fellows, 53% (N=16) were males and the majority (77%) were salaried. Racial distribution was 57% white, and 40% Asian, with 7% Hispanic/Latino ethnicity. The most common practice setting was academic medicine (80%, N=24), followed by multi-specialty group (10%, N=3), private practice (7%, N=2), and rheumatology group (3%, N=1). Forty percent (N=12) and 37% (N=11) had been in practice <5 and >30 years, respectively. Coefficient Alpha for each factor was 0.54 (raw) 0.66 (standardized) for satisfaction and 0.60 (raw) and 0.60 (standardized) for dissatisfaction. Based on the results of this survey, mean satisfaction factor in rheumatologists was high (8.6±0.99). 91.3% of rheumatologists (N=21) had mean satisfaction factor >8 (range 5.5-9.9). The ability to make a difference in patient's life and having the opportunity to work with great colleagues were the strongest contributors to physicians' satisfaction (mean 9.2±1.1 and 9.4±0.8, respectively). Time spent on documentation and getting inappropriate referrals that are not in the scope of practice were among the strongest contributors to physicians' dissatisfaction (mean 3±1.9 and 3.9±1.3, respectively). None of the items were highly correlated with each other.

**Conclusion:** A simple and practical questionnaire to measure physician satisfaction was developed and successfully piloted on a predominately academic sample of rheumatologists. The strongest correlates of physician satisfaction were the “ability to make a difference in a patient's life” and to “work with great colleagues” whereas the greatest correlates of dissatisfaction were “time spent on documentation” and “inappropriate referrals.” It is hoped that with further testing on a larger sample, this scale will serve as a means to identifying potential barriers to the implementation of performance improvement projects in the practice of Rheumatology.

## Development and Implementation of a “Data-in-Once” Model for a Pediatric Rheumatology Learning Health System

Tzielan Lee<sup>1</sup>, Sharon Bout-Tabaku<sup>2</sup>, Joshua Conkle<sup>3</sup>, Karan Iyer<sup>4</sup>, Chris Servick<sup>2</sup> and Esi Morgan<sup>3</sup>, <sup>1</sup>Pediatric Rheumatology, Stanford University, Palo Alto, CA, <sup>2</sup>Nationwide Children's Hospital, Columbus, OH, <sup>3</sup>Cincinnati Children's Hospital, Cincinnati, OH, <sup>4</sup>Stanford University, Stanford, CA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Medical institutions are adopting electronic health records (EHR) in accordance with Meaningful Use making it possible to standardize and capture patient data for registries that serve Learning Health Systems (LHS). LHS leverage clinical data to generate new evidence and knowledge improving clinical practice; ensuring quality, safety, and value; and driving innovation in health care.

The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is an 18 center learning network designed to improve the outcomes of rheumatic disease care. Teams collect and analyze point of care data on process and outcomes that guide improvement activities. Currently for most centers, data collection and entry is manual and duplicative: (1) patients and providers fill out paper forms; (2) providers document clinical visits in multiple areas within the EHR; (3) staff complete paper case report forms (CRF); and (4) staff enter data from CRFs into the registry database. This time and resource consuming process increases the risk for data entry errors, is very expensive, and delays optimal evidence based care.

We describe a PR-COIN and EHR vendor (Epic Systems Corporation) collaboration to design, build, and implement a technical architecture to make clinical documentation efficient, standardize data collection, enhance data display and access, to improve patient care and facilitate research.

### **Methods:**

Development entailed direct interaction of the EHR vendor with three institutions' information systems departments. Over a course of two years, twice monthly meetings occurred to discuss collection form and note template builds, data element standardization, and process workflows. Our goals were: (1) to support a "data-in-once" strategy for registry data collection while integrating data capture into routine patient clinical visit documentation; (2) to develop automated pre-visit planning reports within the EHR that support evidence based chronic care patient management.

### **Results:**

Components of the "data-in-once" build included: (1) point of care seamless discrete standardized data exchange between the clinical documentation and PR-COIN registry data collection elements within the EHR; (2) capability for ongoing electronic transfer of the EHR PR-COIN registry data to the external PR-COIN registry. Automated pre-visit planning reports are strategically localized in the EHR for ease of access and use. Three institutions are piloting system implementation with subsequent roll-out planned to other users in the learning network.

### **Conclusion:**

Learning health systems can be the foundation for improved quality of clinical care and patient outcomes. Successful implementation and utilization of registries rely on integration into the clinical process and a coordinated effort to analyze workflows and define build requirements. Using the EHR platform to obtain registry data directly from the patient care process, we developed a method to efficiently and unobtrusively collect patient data. This effectively accelerates the rate of useful data accumulation for analysis and provides visually enhanced presentation of clinically meaningful data to users.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Measures and Measurement of Healthcare Quality Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Value based health care has gained worldwide attention due to the refocusing vision of creating value around and for patients. The latter is obtained by measuring healthcare outcomes/quality relative to the cost. Besides measuring these parameters, another crucial element in the evaluation of value-based reimbursement decisions depends on adequate registration. Therefore, in this study we aimed to objectify the degree of misregistration by comparing the received diagnosis of rheumatoid arthritis from a rheumatologist-driven, scientific (ACR/EULAR-2010 criteria for RA), and financial (ICD-10) perspective.

**Methods:** All patients who received the diagnosis Rheumatoid Arthritis (RA) between 2000-2016 within our hospital, were identified according to the Diagnosis Treatment Code (DTC) RA, which is a financial instrument that corresponds to the ICD-10 system (corresponding codes for RA: ICD-10 M05.79/M05.89/M06.09/M06.89). Clinical and demographic data were extracted from digital patient records in which 10% of the data were randomly cross-checked. The collected variables at time of RA diagnosis included number and type of swollen/painful joints, inflammatory markers, rheumatoid factor (RF), ACPA, disease duration and patients primary/secondary/tertiary diagnosis according to the rheumatologist. Additionally, patients were classified according to the ACR/EULAR 2010 criteria for RA. The degree of discordance was determined by descriptive statistics.

**Results:** A total number of 1641 patients were identified by DTC RA. The majority of the population was female (73%) with a mean age of 55 at time of RA diagnosis. According to the rheumatologist 371(23%) patients did not had RA. From the remaining 1270 patients who received the diagnosis RA according to the rheumatologist, 272(17%) did not fulfill the ACR/EULAR 2010 criteria (Figure 1). The patients who did not fulfill the ACR/EULAR 2010 criteria had less inflammation, were more often RF and/or ACPA negative, and had less involved joints, in terms of patient characteristics there was no significant difference within the groups. Approximately 10% of the data were missing at random.

**Conclusion:** For the measurement of healthcare quality and outcomes within a VBHC system, the patient population needs to be clearly defined and identified from hospital data sources. ICD-10 allows for baseline stratification. In this study we compared the financial DTC-RA registration, clinical diagnosis and ACR/EULAR classification criteria, and found a total discrepancy of 40%. Unfortunately from these descriptive analyses, it can be concluded that the ICD-10/DTC-RA codes are not the most reliable source of information on which the patient selection should be based. It is expected that this degree of misregistration for RA will have an impact on the value-based driven reimbursement system which we are currently investigating.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Measures and Measurement of Healthcare Quality Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Valid measures of appearance concern are needed in systemic sclerosis, a rare, disfiguring rheumatologic disease. The Derriford Appearance Scale-24 (DAS-24) is a self-report measure that assesses appearance-related distress related to visible differences. There is uncertainty regarding the DAS-24 factor structure, possibly due to its scoring method of the 14 items with a “not applicable” response option.

**Methods:** Patients with systemic sclerosis ( $N = 950$ ) completed self-report measures at enrollment to the *Scleroderma Patient-centered Intervention Network (SPIN) Cohort Study*. DAS-24 items marked “not applicable” were scored two ways: (1) “not applicable” scored as 0, per standard DAS-24 scoring; (2) “not applicable” treated as missing. Internal consistency reliability was evaluated using Cronbach’s alpha. The one-factor DAS-24 model was evaluated using confirmatory factor analysis. Convergent validity was evaluated using bivariate correlations with social interaction anxiety, depressive symptomatology, fear of negative evaluation, and satisfaction with appearance.

**Results:** Internal consistency reliability was high ( $\alpha = .92$ ). When items marked by respondents as “not applicable” were scored as 0, the one-factor model fit poorly (CFI = .896, RMSEA = .096). When items marked by respondents as “not applicable” were treated as missing data, the one-factor model fit well (CFI = .958, RMSEA = .065). Convergent validity analyses revealed strong correlations that were similar across scoring methods (Standard  $r$ s: .44-.68; Missing  $r$ s: .47-.72).

**Conclusion:** Treating “not applicable” responses as missing improved the measurement model, but did not yield substantively different relationships with theoretically related constructs. It is unlikely that using standard DAS-24 scoring greatly impacts the practical interpretation of scores. Indications of item redundancy and poorly performing items suggest that the DAS-24 could be improved and potentially shortened.

## Analysis of Data Collected from Right and Left Limbs: Accounting for Dependence and Improving Statistical Efficiency in Musculoskeletal Research

**Sarah Stewart**<sup>1</sup>, Janet Pearson<sup>2</sup>, Keith Rome<sup>3</sup>, Nicola Dalbeth<sup>4</sup> and Alain Vandal<sup>5</sup>, <sup>1</sup>School of Podiatry, Auckland University of Technology, Auckland, New Zealand, <sup>2</sup>Auckland University of Technology, Auckland, Niger, <sup>3</sup>School of Clinical Science, Health & Rehabilitation Research Institute, AUT University, Auckland, New Zealand, <sup>4</sup>University of Auckland, Auckland, New Zealand, <sup>5</sup>Counties Manukau District Health Board, Auckland, New Zealand

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Measures and Measurement of Healthcare Quality Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Statistical techniques used in musculoskeletal research often inefficiently account for paired-limb measurements or the relationship between measurements taken from multiple sites within limbs. This study compared three commonly used analysis methods with a multivariate mixed-effects model which accounts for the association between limbs, sites, and trials and that utilises all information available from repeated trials.

**Methods:** Four analysis models were applied to an existing data set containing peak plantar pressure data, a continuous variable. The original study compared pressure during barefoot walking in people with gout (n = 25) or people with asymptomatic hyperuricaemia (n = 27) with normouricaemic controls (n = 34). Pressure data was collected for both feet over three walking trials. Peak pressure was calculated for each of 7 masked regions of the plantar foot (heel, midfoot, 1st metatarsal, 2nd metatarsal, metatarsals 3 to 4, hallux and lesser toes). The data set was analysed using the following 4 approaches: Model 1 analysed right foot data; Model 2 analysed data from a randomly selected foot; Model 3 averaged right and left foot data; Model 4 used all available data in a mixed-effects regression model which accounted for repeated measures taken for each foot, foot site and trial. Two comparisons were considered for all analyses: gout vs. normouricaemic control and asymptomatic hyperuricaemic vs. normouricaemic control. Age and body mass index were included in all analyses as covariates. For the purpose of model comparison, confidence interval widths for the mean differences between groups for each foot site were used as a criteria for statistical efficiency.

**Results:** Estimated mean differences in peak pressure between diagnostic groups for Analysis Models 1 to 3, were similar across all analysis methods, while the confidence interval widths for the mean differences were consistently smaller for Analysis Model 4 (Figure 1). The mean peak pressure estimates for each diagnostic group, for Analysis Models 1 to 3, were also similar across analysis methods, while confidence interval widths were again consistently lowest in Analysis Model 4. Model 4 also revealed significant between-group differences which were not detected in Models 1-3.

**Conclusion:** Adoption of a multivariate mixed-effects linear regression model efficiently addresses the issue of between-limb dependence in musculoskeletal research through retaining individual side and trial data, and utilising the relationship between site measurements on the same foot. The improved efficiency and power generated from this model produces more precise estimates compared to alternative approaches which discard or average data to take into account the paired nature of the data, and which model site measurements independently.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Measures and Measurement of Healthcare Quality Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Selecting the best model in an epidemiologic analysis is challenging as it addresses problems like confounding and allows the estimation of unbiased results. Stepwise selection is the most commonly used method but also the most criticized, as it relies on an arbitrary threshold, the probability of removal, to decide which variables will be included in the model. Modern shrinkage techniques such as the Least Absolute Shrinkage and Selection Operator (LASSO) may address this issue. Using a rheumatology patient registry, we compared the LASSO method with traditional regression model techniques including stepwise and change-in-estimate.

### Methods:

LASSO can be used with several statistical models including generalized linear models and proportional hazards models. In the latter, it maximizes the partial likelihood of regression coefficients subject to a constraint imposed on the sum of the absolute value of all regression coefficients. It excludes variables without formal statistical testing by correcting the extremes in the distribution and shrinking unstable estimates to zero. The constraint can be estimated via cross-validation. We illustrate this technique in a sample of patients enrolled in the National Data Bank for Rheumatic Diseases from 2001 to 2016. We applied survival methods to assess the risk of serious infections (SI) in patients with RA compared to non-inflammatory rheumatic disease (NIRD) controls. Variables included demographics, clinical status, disease severity and prednisone use.

## Results:

20,361 RA and 6176 NIRD patients contributed to 81,499 and 20,665 patient-years of exposure, having had 1600 (7.9%) and 276 (4.5%) SI, respectively (incidence rate ratio: 1.5 [1.3-1.7]). Baseline characteristics by disease (RA:NIRD) were age (58:63 yrs), female sex (79:80%) and HAQ (1.11: 1.10). The LASSO HR of SI comparing RA vs NIRD was 1.15 (0.99 – 1.32), being prednisone, vaccination, and prior infections the variables with the highest impact (Figure). Similar results were obtained with stepwise, selecting almost the same covariates. However, when using different thresholds, slightly different models were obtained (Table).

## Conclusion:

Identical estimates were obtained across methods, not imposing arbitrary thresholds with LASSO. Although LASSO has many positive attributes, such as being very powerful when variables exceed observations, it is still rarely applied in epidemiologic studies. It is a valid alternative to the popular stepwise, as it is less variable and yields interpretable models.

<b>Table.</b> Best Cox models selected for serious infections accordingly to several selection techniques.		
<b>Method</b>	<b>HR (RA vs NIRD)</b>	<b>Other variables selected</b>
LASSO	1.15 (0.99-1.32)	Ethnicity (white vs. other), sex, smoking status, age, disease duration, residency (urban vs. rural), prior infections, RD comorbidity index, HAQ, pain, education, prednisone, vaccination, diabetes
Change-in-estimate  (10% change)	1.13 (0.98-1.30)	Prednisone
Change-in-estimate  (2% change)	1.17 (1.01-1.34)	Prednisone, pain, age, education
Stepwise  (20% removal probability)	1.14 (1.0-1.31)	Ethnicity (white vs. other), sex, smoking status, age, disease duration, residency (urban vs. rural), prior infections, RD comorbidity index, HAQ, pain, education, prednisone, vaccination, diabetes
Stepwise  (10% removal probability)	1.15 (1.0-1.32)	Ethnicity (white vs. other), sex, smoking status, age, disease duration, prior infections, RD comorbidity index, HAQ, pain, education, prednisone, vaccination, diabetes

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gouty arthritis, caused by the deposition of monosodium urate (MSU) monohydrate crystals at joints, is comprised of multiple inflammatory processes in synovium, tendons, cartilages and bone. In addition to traditional serum tests including c reaction protein (CRP), erythrocyte sedimentation rate (ESR), uric acid and blood white cell counts, musculoskeletal ultrasonography (MSKUS) is a convenient, costless and straightforward tool to identify anatomical location and severity of inflammation, which guided clinicians appropriate treatment. Here, we retrospectively investigated how rheumatologists applied MSKUS in detecting and treating acute and chronic tophaceous gouty arthritis. We further analysed serum inflammatory markers, biochemistic results and blood cell counts and compared MSKUS manifestations to identify whether renal insufficiency influenced uric acid deposition at joints of patients with gouty arthritis.

**Methods:** This is a retrospective review of clinical and ultrasonographic findings in 280 patients with gouty arthritis from August 2004 to May 2017. All patients met the criteria of 2015 American College of Rheumatology/European League Against Rheumatism.

Ultrasonographic manifestations include joint effusion, synovial proliferation, tenosynovitis, Baker's cyst, double contour sign (DCS), and tophi-like lesion (TLL). Patients received blood tests including serum white blood cell count (WCC), serum uric acid, CRP, ESR, estimated glomerular filtration rate (eGFR) and we collected synovial fluid WCC from arthritis sites. Differences were analysed by independent *t* tests, phi coefficient, Pearson correlation coefficient and Cramer's V Coefficient.

**Results:** Joint effusion, synovial proliferation, tenosynovitis, Baker's cyst, DCS, and TLL were detected in 75.7%, 45.3%, 20.0%, 9.2%, 42.8% and 23.9% of joints, respectively. Patients with acute gouty arthritis and leucocytosis would have higher serum CRP ( $p < 0.01$ ). Patients with synovial proliferation, tenosynovitis, or DCS had lower synovial fluid WCC ( $p = 0.04$ ,  $0.04$ , and  $< 0.01$ , respectively). Patients with synovial proliferation had higher prevalence of joint effusion, Baker's cyst and double contour sign ( $p < 0.01$ ,  $< 0.01$ , and  $< 0.01$ , respectively). Patients with TLL had lower serum UA ( $p = 0.013$ ). Patients with renal insufficiency (eGFR  $< 90$ ) were characterized by higher prevalence of Baker's cyst ( $p = 0.02$ ).

**Conclusion:** We would recognize Baker's cyst, DCS, and TLL as MSKUS manifestations of chronic gout. Synovial proliferation and tenosynovitis can exist in both acute or chronic gouty arthritis. Synovial proliferation was considered as a transformational change between acute and chronic gout. Patients with chronic kidney disease have an increasing risk of development of Baker's cyst. Early treatment of patients with gouty arthritis and chronic kidney disease help prevent development of chronic joints destructions.

## Computed Tomography Dependent Diagnosis of Crowned Dens Syndrome; A Cervical Manifestation of Patients with Calcium Pyrophosphate Dihydrate Crystal Deposition Disease

Ammar Haikal<sup>1</sup>, Brian Everist<sup>2</sup>, Pim Jetanalin<sup>3</sup> and Mehrdad Maz<sup>3</sup>, <sup>1</sup>Department Internal Medicine, Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS, <sup>2</sup>Department of Radiology (MSK), Department of Radiology (MSK), University of Kansas Medical Center, Kansas City, KS, <sup>3</sup>Allergy, Clinical Immunology, and Rheumatology, Division of Allergy, Clinical Immunology and Rheumatology, Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Crowned Dens Syndrome (CDS), a variation of *Calcium Pyrophosphate Deposition Disease (CPPD)*, is a radiologic-clinical entity defined by the association of radiological calcifications around the odontoid process and periodic cervico-occipital pain. The true incidence and prevalence of CDS in the general population or in those with CPPD remain unknown. Here, we discuss 34 patients as one of the largest reported series.

**Methods:** This is a retrospective chart and *radiology registry* imaging study review from a single tertiary medical center from 11/1/2005-10/31/2015. 191 patients with a diagnosis of CPPD and/or CDS were identified. *Terms used in the search included pseudogout, CPPD, CDS, chondrocalcinosis and calcification.* 57 patients had at least one c-spine CT performed for a variety of indications. The CTs were analyzed by a musculoskeletal radiologist for the presence of odontoid calcifications.

**Results:** Of the 191 patients with CPPD, 57 had c-spine CTs obtained; 34 of whom (34/57, 59.64%) had odontoid calcifications. Only 12/34 patients were formally diagnosed with CDS by rheumatologists. The others (22/34) were either not seen by a rheumatologist or were not diagnosed with CDS if seen by other specialists. The median age of diagnosis was 78.5 years, with majority (73.52 %) over 70 y/o and 24/34 (70.58%) were female. 17/34 patients (50%) were symptomatic; defined as presence of acute to sub-acute neck pain within 6 weeks of performing the c-spine CT. The majority of the patients (82.35%, 28/34) had additional sites of chondrocalcinosis on joint radiographs; 8 patients (28.57%) had 3 or more sites of chondrocalcinosis in typical CPPD locations. Six patients did not have any joint radiographs. 16/34 patients (47.05%) who had CDS and chondrocalcinosis elsewhere, also carried

metabolic diseases, including: hyperparathyroidism (2), hypothyroidism (10), hypomagnesemia (2) and hypophosphatemia (2). None of the patients had a documented history of hemochromatosis or evidence of iron overload based on laboratory tests.

**Conclusion:** Crowned Dens Syndrome is an under-recognized entity, which should be considered in elderly patients with neck pain in the setting of CPPD. Our data demonstrates a high percentage (about 60%) of patients with CPPD who had c-spine CT findings consistent with CDS. This underscores the importance of performing c-spine CTs when evaluating patients with neck pain and CPPD or chondrocalcinosis in other joints, as radiographs and MRI may not be diagnostic of CDS.

Periodontoid curvilinear calcifications on noncontrast c-spine CT of the transverse ligament seen in both sagittal (A) and axial (B) planes.

## Rapid Tophus Resolution in Chronic Refractory Gout Patients Treated with Pegloticase

**Brian F. Mandell**<sup>1</sup>, Herbert S. B. Baraf<sup>2</sup>, Anthony Yeo<sup>3</sup> and Peter E. Lipsky<sup>4</sup>, <sup>1</sup>Rheumatology, Cleveland Clinic, Cleveland, OH, <sup>2</sup>The Center for Rheumatology and Bone Research, Wheaton, MD, <sup>3</sup>Horizon Pharma, Lake Forest, IL, <sup>4</sup>AMPEL BioSolutions, LLC, Charlottesville, VA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It has been suggested that the velocity of resolution of tophi in chronic tophaceous gout is related to serum uric acid (sUA) levels.<sup>1</sup> However, few subjects with a persistent sUA <4.0 mg/dL have been studied. Pegloticase is a recombinant uricase conjugated to polyethylene glycol approved in the U.S. for chronic refractory gout that profoundly decreases sUA in responders to <1 mg/dL.<sup>2</sup> The results from the pegloticase randomized clinical trials (RCTs) permitted determination of the impact of persistent, very low sUA levels on the velocity of tophus resolution.

**Methods:** This analysis used results from two RCTs of 6-months duration.<sup>2,3</sup> Photographs were taken of hands, feet and up to 2 other locations. Serial standardized digital images of tophi were analyzed by a blinded reader using computer-assisted quantitative measurement software. Subjects were defined as responders and non-responders (NRs) based upon persistent sUA lowering.<sup>2</sup>

**Results:** A total of 952 tophi were analyzed in 87 subjects; 341 in 30 responders; 361 in 36 NRs receiving pegloticase infusions; and 250 in 21 subjects receiving placebo infusions. At baseline, the mean tophus areas were  $644.7 \pm 789.2 \text{ mm}^2$  (mean  $\pm$  SD) in responders,  $820.0 \pm 1349 \text{ mm}^2$  in NRs, and  $777.2 \pm 1056.0 \text{ mm}^2$  in placebo-treated subjects (3 group comparison, not significantly different). Achievement of tophus resolution in the three groups is summarized in Figure 1. By regression analysis, the velocity of tophus reduction over 6 months of treatment was  $66.4 \text{ mm}^2/\text{mo}$  in responders ( $P < 0.0001$  comparing all visits). The mean time for complete resolution of tophi in responders was 9.7 mo (range 5.2  $\bar{D}$  23.1 mo). By contrast, in NRs, the velocity of resolution was  $-74.9 \text{ mm}^2/\text{mo}$  from dose 1 to dose 7 ( $P < 0.0001$ ) and  $+23.5 \text{ mm}^2/\text{mo}$  from dose 7 to the final dose ( $P > 0.05$ ), reflecting the loss of urate lowering effect in the NRs during the latter 3 months. The sUA AUC during the 6 months of the RCT was calculated for all subjects. There was a significant negative correlation between the velocity of tophus resolution and sUA AUC ( $r = -0.31$ ,  $P = 0.0032$ ) Figure 2. Baseline age, BMI, gender, race, total tophus area and tophus location did not significantly influence velocity of tophus resolution.

**Conclusion:** Pegloticase treatment causes a rapid resolution of tophi in responders. However, there is considerable heterogeneity in the velocity of tophus reduction.

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The OMERACT US subtask force “US in CPPD” has recently created the definitions for US identification of crystal deposits in joints and tested the reliability between different observers[1]. Those criteria were however validated only at the knee. The Objectives were to assess the inter- and intra-observer reliability of US on detecting CPPD in the triangular fibrocartilage complex (TFCC) of the wrists, fibrocartilage of the acromio-clavicular (AC) joint and hip labrum (HL) and hyaline cartilage (HC) of the metacarpal heads (MC) and femoral head.

**Methods:** The OMERACT US criteria for identification of CPPD have been used for this exercise[2] using a two steps approach. First, a panel of US experts gave a dichotomous score (presence/absence of CPPD) of 120 images of sites under investigation using a web based platform. The assessment was carried out twice in order to calculate both the inter and intra-observer reliability. In the second step, the experts met for a patient based assessment of CPPD in a workshop. Bilateral evaluation of TFCC, AC joints, HL and HC of the hip and HC of the II and III MC of 8 patients was carried out twice in the same day by 18 US experts. Eight US machines (3 GE, 1 Samsung and 4 Esaote) equipped with high resolution linear probes were used for the workshop

### Results:

Reliability values of the web based exercise (both intra and inter) were high demonstrating that definitions were clear for all participants for all sites. The results of the patient based exercise are presented in table 1. The TFCC of the wrist demonstrated to be the most reliable site for the assessment of CPPD followed by the AC joint. Other sites demonstrated lower kappa values and thus are not considered reliable for assessment of CPPD

Section	Mean prevalence	Mean observed agreement	Mean kappa	PabaK*
<b>Inter-Reader Agreement</b>				
1) ALL	48,2	0,71	0,43	0,42
2) Fibrocartilage	72,7	0,75	0,39	0,51
3) Hyaline cartilage	23,7	0,67	0,09	0,34
4) Hand	22,6	0,69	0,12	0,38
5) Wrist Fibrocartilage	95,1	0,91	0,01	0,82
6) Acromion-Clavicular Joint	61,1	0,75	0,51	0,51
7) Hip	43,7	0,61	0,23	0,23
7a) Hip Labrum	61,8	0,6	0,16	0,19
7b) Hip Cartilage	25,7	0,63	0,04	0,26
<b>Intra-Reader Agreement</b>

2) Fibrocartilage	73,1	0,85	0,57	0,71
3) Hyaline cartilage	23,4	0,86	0,53	0,73
4) Hand	23	0,84	0,48	0,69
5) Wrist Fibrocartilage	95,1	0,93	0,66	0,87
6) Acromion-Clavicular Joint	62,5	0,88	0,68	0,76
7) Hip	42,9	0,82	0,58	0,66
7a) Hip Labrum	61,7	0,73	0,32	0,47
7b) Hip Cartilage	23,9	0,91	0,67	0,83
Strength of agreement: < 0.20 Poor. 0.21 - 0.40 Fair. 0.41 - 0.60 Moderate. 0.61 - 0.80 Substantial. 0.81 - 1.00 Excellent				
*Pabak: Prevalence-Adjusted Bias-Adjusted Kappa				

### Conclusion:

the TFCC of the wrist is the most reliable site for assessing CPPD. By adding these results to the previous exercise[2], we can confirm that the new OMERACT US definitions for assessing CPPD can be applied reliably at the knee (meniscus and HC), TFCC of the wrist

and AC joints. These peripheral sites are the most frequently involved in CPPD. The next step of the OMERACT “US in CPPD” subtask force, will be to test the value of these findings in a longitudinal observational study.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Musculoskeletal ultrasound (MS-US) has not been validated as a reliable technique to evaluate joint inflammation in an acute gout rabbit model. Rabbit has been used to accurately reproduce human acute gout. Thus, validating ultrasonographic imaging in this animal model would be important to use this technique for sequential evaluation of synovium damage, synovial fluid effusion, crystal deposits, and the efficacy of new pharmacological options.

### Methods:

Monosodium urate (MSU) crystals were used to induce acute gout in 10 New Zealand white rabbits through bilateral intra-articular injections, while 3 controls received vehicle injection. Both rabbit knees were assessed by B-mode and power Doppler (PD) US blindly to the type of injection, both 24 and 72 h after the injections. All US examinations were carried out with a commercially available real-time scanner (LOGIQ e R7, GE Medical Systems) equipped with a 22 MHz linear transducer (6-15 MHz). B-mode and PD machine settings were optimised as follows: B-mode gain of 47 dB, dynamic range 72 dB, Doppler frequency of 14.3 MHz, Doppler gain of 28 dB, low-wall filters, and pulse repetition frequency of 700 Hz. B-mode global distension (GD), synovial fluid (SF) and synovial thickening (Sth); and PD-detected synovial blood flow (PD) were semiquantitatively scored (0-3) at the lateral recess of the knees. Additionally, the presence of MS-US features of MSU crystal deposit was investigated. Progression of joint swelling was followed by knee perimeter measurements. After 72 h, all rabbits were euthanized, and synovial membranes were fixed and embedded in paraffin for histological and immunohistochemical evaluation, and processed for protein expression studies.

### Results:

We showed that MS-US was able to discriminate between the MSU crystal injected group and the control vehicle injected group for the different inflammatory findings both at 24 and 72 h ( $p < 0.05$ ). A statistically significant positive correlation was found between the increment in knee perimeter and GD MS-US at 24h (Spearman's correlation coefficient  $r = 0.579$ ,  $p = 0.0019$ ). Sth MS-US score also showed a significant correlation with the global histopathological score in synovium paraffin sections measured by Krenn's score (Spearman's correlation coefficient  $r = 0.466$ ,  $p = 0.018$ ). Furthermore, PD intra-synovial US signal significantly correlated with the

synovial tissue vascularization measured by % CD31 immunohistochemical positive staining ( $r=0.463$ ,  $p=0.017$ ). Additionally, we observed that GD MS-US significantly correlated with the protein levels of IL1 $\beta$  in the synovial membranes measured by western-blot studies (Spearman's correlation coefficient  $r=0.529$ ,  $p=0.0078$ ).

## Conclusion:

Our results indicate that MS-US imaging measurements correlate with joint swelling, histological inflammation and vascularization of the synovium. Furthermore, MS-US could also serve as an indicator of the inflammatory degree in relation to the level of some pro-inflammatory cytokines, such as IL-1 $\beta$ , involved in the pathogenesis of gout. Therefore, ultrasonography analysis can be considered a feasible valid method for assessing the evolution of synovial inflammation in experimental gouty arthritis in rabbits.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACRC Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Serum uric acid (sUA) is a useful indicator of the risk of developing gout. However, most patients with elevated sUA levels do not have gout. Dual-energy computed tomography (DECT) scan is a relatively sensitive and specific imaging tool used to measure and visualize urate deposits in the joints. Prior research shows presence of subclinical urate deposits in nearly one-quarter of patients with severe hyperuricemia (*i.e.*, sUA >9 mg/dl) without gout. We conducted a cross-sectional study to identify urate deposits using DECT and examine whether an association exists between sUA levels and total volume of urate deposits in patients with asymptomatic hyperuricemia.

**Methods:** We recruited adults aged  $\geq 40$  years with sUA levels  $\geq 6.5$  mg/dl and metabolic syndrome according to the National Cholesterol Education Program-Adult Treatment Panel III criteria. We excluded patients with gout, end-stage renal disease, renal replacement therapy, active malignancy, and use of xanthine oxidase inhibitors, colchicine or probenecid. All patients underwent a measurement of sUA level and DECT scan of a foot. A fellowship trained MSK radiologist processed and reviewed the DECT images and determined total volume of urate deposits. We used logistic regression to assess the association between sUA and presence of urate deposits and linear regression to examine the association between sUA and total volume of urate deposits.

**Results:** A total of 46 subjects participated in this study. The mean age was 62 ( $\pm 8$ ) years, 41% were male and mean sUA level was 7.8 ( $\pm 1.0$ ) mg/dl. Seven of 46 (15%) patients had urate deposits in the feet. The mean total volume of urate deposits was 0.13 ( $\pm 0.14$ ) cm<sup>3</sup>. On univariable analysis, age had significant association with presence of urate deposits but sUA, male sex, body mass index, presence of diabetes, and renal function did not (Table). sUA had a modest linear association ( $\beta$  coefficient=0.11,  $p=0.09$ ), albeit statistically not significant, with total volume of urate deposits (Figure).

**Conclusion:** In this cross-sectional study, 15% of patients with elevated sUA but no known gout had urate deposits in the foot DECT scan. There were no clear patient factors other than older age associated with presence of urate deposits on DECT scans. While the clinical significance of these urate deposits is unclear, it is possible that these patients may develop gouty arthritis or they may have

“resistance” to reacting against urate depositis. Further research on why certain patients with hyperuricemia develop gout may present important clues to gout prevention.

**Table. Association between clinical characteristics and presence of urate deposits on DECT scans among patients with asymptomatic hyperuricemia (n=46)**

Patient characteristics	Univariable OR (95% CI)	sUA-adjusted OR (95%CI)*
Serum uric acid (sUA)	1.36 (0.63-2.95)	-
Age, years	1.20 (1.03-1.39)	1.21 (1.03-1.42)
Male sex	1.08 (0.21-5.49)	1.06 (0.21-5.45)
Body mass index	0.97 (0.85-1.11)	0.94 (0.81-1.10)
Type 2 diabetes	0.97 (0.19-4.93)	0.87 (0.16-4.60)
Serum creatinine	0.92 (0.08-11.19)	0.60 (0.04-8.22)

## A Study on Febuxostat Prescribing Practices for Patients with Chronic Gout Previously Managed with Allopurinol at the Veterans Affairs Puget Sound

Percy Balderia and Elizabeth R. Wahl, Rheumatology, University of Washington School of Medicine, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** American College of Rheumatology (ACR) guidelines recommend use of either allopurinol or febuxostat as first-line approaches to urate lowering therapy in gout. Prior studies of managed care cohorts have shown that patients are commonly switched to febuxostat before their allopurinol dose has been optimized. While each is effective, their cost differential (8 cents/pill compared to 5 dollars/pill at our facility) suggests there may be good reason to favor allopurinol use within a health system. To identify potential areas for improvement for allopurinol and febuxostat use, we sought to better understand current febuxostat prescribing practices at our facility among patients with chronic gout who were initially on allopurinol.

**Methods:** Data were extracted from the local pharmacy prescription database to identify all patients  $\geq 18$  years of age, seen at our facility, and prescribed febuxostat between 1/1/13 and 8/31/16. We conducted a retrospective chart review to identify the daily dose of allopurinol before febuxostat prescription. Additionally, the type of prescribing physician (rheumatologist, non-rheumatologist), reason for prescribing febuxostat (inadequate response to other medications, kidney dysfunction, allopurinol hypersensitivity), uric acid level, estimated glomerular filtration rate (GFR) at time of switch, presence of tophi, and demographic data were recorded.

**Results:** Sixty-four patients with chronic gout were switched from allopurinol to febuxostat. Forty-two patients were switched due to adverse drug events (most commonly rash,  $n = 17$  or gastrointestinal symptoms,  $n = 8$ ) and 22 due to inadequate response.

**Table 1.** Characteristics of Patients Switched to Febuxostat Due to Inadequate Response to Allopurinol

Characteristic	Result
	<b>n = 22</b>
Age in y: median (IQR)	63 (9.3)
Male: n (%)	21 (95.5)
Tophaceous gout: n (%)	6 (27.3)
Allopurinol duration in months: median (IQR)	49 (41.5)
Documented trial of probenecid: n (%)	3 (13.6)
Uric acid level in mg/dL: median (IQR)	9.2 (3.3)

**Table 2.** Allopurinol Dosing Prior to Switching to Febuxostat According to Estimated Glomerular Filtration Rate

Estimated GFR in mg/dL/m <sup>2</sup> : range (n)	Daily Dose in mg: median (IQR), range
$\leq 30$ (10)	300 (175), 100-450
$>30 - \leq 60$ (8)	300 (100), 50-825
$>60$ (4)	600 (100), 600-800

**Conclusion:** In our facility, most of the patients were prescribed febuxostat due to adverse effects from allopurinol. Among those switched due to inadequate response, almost two-thirds had a dose of 300 mg/day or less.

**Disclosure:** P. Balderia, None; E. R. Wahl, None.

# Allopurinol Dose-Titration Patterns Relative to Serum Uric Acid Levels in Gout Patients: US Electronic Health Record Data

**An-Chen Fu,** Douglas C.A. Taylor and David S. Reasner, Ironwood Pharmaceuticals, Inc., Cambridge, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is the most common form of inflammatory arthritis and is caused by elevated serum uric acid (sUA). Allopurinol is a first-line urate-lowering therapy for patients with gout and the American College of Rheumatology guidelines recommend allopurinol dose titration to lower and maintain sUA levels <6 mg/dL. Understanding the gap between treatment guidelines and real-world dose titration patterns in patients with gout may ultimately lead to better disease management and control. Hence, the aim of this study was to understand real-world allopurinol dose-titration patterns relative to sUA levels.

**Methods:** This was a retrospective study using de-identified Humedica electronic medical record data from 2007 to 2015. The study cohort included gout patients (International Classification of Disease, Ninth Revision, Clinical Modification [ICD-9-CM: 274.xx]), aged  $\geq 18$  years on the first gout diagnosis, with at least 1 sUA result and 2 allopurinol prescriptions. An sUA episode within the study cohort was defined as allopurinol initial dosage (ID) prior to (closest) and titrated dosage (TD) after (within 30 days of) an sUA test. Study measurements included dosage (strength/day) by imputing allopurinol strength, and dose frequency, dose titration was categorized as up-titration, down-titration, or no-dosage-change by comparing ID and TD for each episode (up-titration: ID < TD; down-titration: ID > TD, no-dose-change: ID = TD). Uncontrolled episodes were defined as episodes with sUA levels  $\geq 6$  mg/dL. Prescriber's specialty was identified from the TD prescription. Descriptive episode-level and patient-level analyses were performed.

**Results:** All sUA episodes (n=64,609) selected in this analysis were from 40,143 unique patients (mean age of 64 years, 73% male, and 82% Caucasian). Of all sUA episodes, 57% were uncontrolled (sUA  $\geq 6$  mg/dL). A total of 71% uncontrolled episodes had no-dosage-change (n=26,123), 21% had up-titration (n=7,823), and 7% had down-titration (n=2,704). Among no-dosage-change sUA episodes, episodes with lower dosages were uncontrolled at higher rates. Seventy-eight percent of dosage-change episodes were uncontrolled, of which 100 to 300 mg/day was the most frequent (39%) dose titration. Overall, the most frequent TD was 300 mg/day (52%) followed by 100 mg/day (36%), >100 & <300 mg/day (8%), >300 mg/day (3%), and <100 mg/day (<1%). Prescriber specialty at the time of a TD prescription was mostly primary care (77%), followed by rheumatology (13%), others/unknown (9%), and nephrology (2%). Among uncontrolled episodes, rheumatologists dose-titrated allopurinol more often than other specialists (rheumatologists [46%], nephrologists [29%], others/unknown [29%], and primary care physicians [26%]).

**Conclusion:** Contrary to current guidelines from the American College of Rheumatology, allopurinol dose was generally not titrated, regardless of sUA levels. This current lack of titration suggests a need for more active management of patients with gout and uncontrolled sUA, including consideration of new treatment options in addition to allopurinol.

## **Pseudogout Among Patients Fulfilling a Billing Code Algorithm for Calcium Pyrophosphate Deposition Disease (CPPD)**

Sara K. Tedeschi, Daniel H. Solomon and Katherine P. Liao, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Calcium pyrophosphate deposition disease (CPPD) has a spectrum of manifestations, of which pseudogout is the most acute inflammatory phenotype. Studies focusing on pseudogout are limited by a paucity of algorithms to identify this condition in large datasets. To our knowledge, there is only one published algorithm for CPPD, developed at a Veterans' Administration Medical Center to identify "definite or probable CPPD" per Ryan and McCarty's diagnostic criteria.<sup>1</sup> The algorithm includes  $\geq 1$  ICD-9 code 275.49 (other disorders of calcium metabolism) or 712.1-712.39 (chondrocalcinosis due to dicalcium phosphate crystals, pyrophosphate crystals, or cause unspecified). We examined characteristics of patients fulfilling this algorithm at a tertiary care academic medical center, with a focus on subjects clinically manifesting as pseudogout.

**Methods:** Following the published methods, we applied the algorithm to patients with  $\geq 1$  encounter at our center over 2 years (1/1/15-12/31/16). 100 patients were randomly selected for medical record review from date of 1st qualifying ICD-9 code through present. We

evaluated each record for 2 phenotypes: 1) “definite or probable CPPD”<sup>1</sup>, defined as joint pain, and either synovial fluid with calcium pyrophosphate crystals or radiographic chondrocalcinosis in any joint, or both; 2) pseudogout, defined as synovitis and synovial fluid aspirate with calcium pyrophosphate crystals. We recorded information on demographics, healthcare utilization, musculoskeletal diagnoses, and evaluation and treatment.

**Results:** 68% of patients had one or both phenotypes; 32% met neither definition (**Table**). 18 patients (18%) had pseudogout, all of whom also met the definition of “definite or probable CPPD”. 50 patients (50%) had “definite or probable CPPD” but not pseudogout. Overall 73% had osteoarthritis per x-ray reports or notes, with the highest frequency (90%) among “definite or probable CPPD” only, compared to 72% of pseudogout patients. Synovial fluid aspiration was performed in 25% of patients and was positive in all with crystal-proven pseudogout by definition, but not positive in any others. Among 92 patients with x-rays, chondrocalcinosis was noted in 61% and in 100% of patients with “definite or probable CPPD” only. Chondrocalcinosis was present in <1/3 of patients with both x-rays and crystal-proven pseudogout; among these, it was present in <20% of symptomatic joints.

**Conclusion:** Among subjects identified using a published CPPD algorithm, 18% had crystal-proven pseudogout, of whom <20% had x-ray chondrocalcinosis in the affected joint. These findings highlight a need for improved understanding of pseudogout and improved approaches to identify this acute phenotype of CPPD.

Merriman<sup>4</sup> and Nicola Dalbeth<sup>1</sup>, <sup>1</sup>University of Auckland, Auckland, New Zealand, <sup>2</sup>University of Otago, Dunedin, New Zealand, <sup>3</sup>University of Otago, Christchurch, New Zealand, <sup>4</sup>Biochemistry Dept, PO Box 56, University of Otago, Dunedin, New Zealand

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** For most people with gout, reduced renal clearance of uric acid is a key contributor to hyperuricemia. It is increasingly recognized that gout has a genetic basis, and that renal clearance of uric acid is also genetically determined. However, the factors that contribute most to reduced renal clearance of uric acid are unknown. The aim of this study was to examine clinical and genetic factors associated with fractional excretion of uric acid (FEUA), including in the New Zealand Maori and Pacific population which has high prevalence of hyperuricemia and gout.

**Methods:** New Zealand Maori, Pacific and European participants in the Genetics of Gout in Aotearoa study with available genotyping and FEUA data were included in this analysis (n=1713, 896 with gout and 817 without gout). All participants completed a study visit which included clinical assessment and collection of blood and urine for urate and creatinine testing. FEUA was calculated as the urate clearance/creatinine clearance, expressed as a percentage. Participants with chronic kidney disease stage 5 were excluded from the analysis. Associations with FEUA were tested using linear regression models. The top 10 loci previously associated with FEUA in a European population by GWAS (Kottgen, Nature Genetics 2013) were analysed. For genetic analysis, P for experiment-wide significance was 0.005.

**Results:** The mean (SD) FEUA in the entire study group was 5.5 (2.7)%. Maori or Pacific participants had lower FEUA compared to European participants (mean (SD) FEUA 5.0 (2.6)% vs. 5.9 (2.7)%, P for difference=2x10<sup>-12</sup>). The number of *SLC2A9* rs11942223 risk alleles was associated with FEUA in European participants (age and sex-adjusted P=3 x 10<sup>-8</sup>). Most (89%) Maori or Pacific participants had two *SLC2A9* rs11942223 risk alleles, and no association between *SLC2A9* and FEUA was observed in Maori or Pacific participants (age and sex-adjusted P=0.15). No other tested loci met experiment-wide significance for association with FEUA. In European participants, gout status, diuretic use, male sex, body mass index, and number of *SLC2A9* risk alleles were independently

associated with FEUA, and these five variables accounted for 37% of the variance of FEUA in the regression model (Table). In contrast, in Maori or Pacific participants, these variables contributed to 19% of the variance of FEUA in the regression models (Table).

**Conclusion :** Both genetic and non-genetic factors contribute to renal clearance of uric acid. *SLC2A9* exerts population-specific effects on FEUA, with effects observed in European, but not Maori or Pacific people.

Table: Predictors of FEUA in linear regression analysis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several studies have shown the relationship between gout and increased cardiovascular risk and mortality. Hyperuricemia and crystal-induced synovitis are associated with endothelial dysfunction and patients with gout may be at increased risk of early atherosclerosis. Many reports have indicated that endothelial dysfunction plays a key role in affecting cardiovascular and renal function. The flow-mediated dilation (FMD) test is the most commonly used non-invasive assessment of vascular endothelial function and is associated with an increased risk of vascular events. There is a lack of studies with FMD assessment in patients with gout.

**Methods:** Prospective cohort study with collection of demographic and clinical data and cardiovascular treatments received. BMI, serum uric acid, ESR, high-sensitivity CRP [hsCRP], ferritin, cholesterol, triglycerides, vitamin D and homocysteine were measured.

Patients were referred to Vascular Surgery Department for flow-mediated dilation assessment with high-resolution two-dimensional ultrasound imaging of the brachial artery. Endothelial dysfunction was defined as pathological values of FMD below 10 (severe if less than 5). All patients met the ACR classification criteria for gout.

**Results:** One hundred and fifty patients, 97% men and 3% women. Average age: at time of study 56 (23-92); at diagnosis 47 years (15-79); at symptoms onset 45 years (15-77). 22.5% had tophi, 11.3% urate kidney stones, 42% gout family history, 41% cardiovascular disease family history. Hypertension 47.3%; diabetes mellitus 4.6%; dyslipidemia 56.7%; smokers 20.6%, quitters 37.6%; 75% overweight/obesity, mean BMI 28 (19-40). One patient had suffered stroke; 4 thrombosis; 17 ischemic heart disease (11 angina, 6 myocardial infarction). Analytical parameters: ESR 10 mm/h (1-68), hs-CRP 2.7 mg/dL (0.1-57.7); serum uric acid 6.9 mg/dL (2.4-11.8); ferritin 259 ng/ml (11-2000); cholesterol: 187 mg/dL (102-321), triglycerides 145 mg/dL (53-603); vitamin D 24.7 ng/mL (5.6-23.6; 29% <20); homocysteine 24.7 mmol/L (4-40; 32% >15 mmol/L). FMD was assessed in 147 patients with a mean value of  $-0.60 \pm 0.52$ . The 81% of subjects showed pathological values indicating endothelial dysfunction, severe in 52%. In the multivariate analysis, the only analytical determinant of endothelial dysfunction was the serum vitamin D concentration, which showed a negative correlation with FMD.

**Conclusion:** There is a high prevalence of traditional cardiovascular risk factors and cardiovascular diseases in our cohort. Most of our patients with gout have endothelial dysfunction measured by FMD, and that is severe in more than a half of them. Vitamin D deficiency is common and correlates with pathological values of FMD in gout. Cardiovascular risk should be periodically assessed in gout and we will continue studying the potential value of FMD as a marker of endothelial dysfunction in patients with this rheumatic disease.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout duration and serum urate (SU) levels are thought to influence development of tophi and chronic inflammatory gouty arthropathy, but the extent to which either one or both contribute to their development is not clear. We evaluated the relation of SU and of gout duration to the presence of tophus, urate deposition, and inflammation in a large cohort of crystal-proven gout subjects.

**Methods:** We used data from the 509 crystal-proven gout subjects in the Study for Updated Gout Classification Criteria (SUGAR) cohort to evaluate the effect of highest-ever recorded SU and gout duration (years since 1<sup>st</sup> flare) separately, as well as in combination to examine their joint effects on tophi, urate deposition, and inflammation. Subjects were enrolled irrespective of flare status. Radiographs of the hands and feet, and ultrasound (US) of a clinically affected joint were obtained. Tophi were evaluated as clinically evident tophi, as well as imaging evidence of tophus (based on X-ray or US). Urate deposition was determined based on US evidence of urate deposition (double-contour sign), and inflammation was assessed as power Doppler signal on US indicative of synovitis. We assessed

the relation of highest SU, gout duration, and their combination using logistic regression, adjusting for age, sex, and ethnicity. Relative Excess Risk due to Interaction (RERI) was assessed using a linear additive risk-ratio model.

**Results:** Study sample included ~87% males, ~66% Caucasians, mean age of 60 years. Highest SU ranged from 2.6-19.2 mg/dL, and gout duration from 0-54 yrs. Higher levels of SU and longer duration of gout were significantly associated with clinical tophus, imaging evidence of tophus and double-contour sign, but not with power Doppler signal (**Table 1A**). The combination of higher SU and longer gout duration had the strongest association with the 4 outcomes, followed by longer disease duration regardless of highest SU for tophi and urate deposition, while for synovitis effects were similar regardless of the combination of SU with gout duration compared with low SU and shorter gout duration (**Table 1B**). However, we did not find any evidence of an additive interaction (**Table 1C**).

Relative Excess Risk due to Interaction (RERI) (95% Bayesian Probability Interval)								
	-0.7 (-3.1, 0.8)		-0.4 (-1.0, 0.9)		-0.6 (-1.7, 0.1)		-0.5 (-1.9, 0.3)	

\*All analyses were adjusted for age, sex, and ethnicity.

**Conclusion:** Both gout duration and highest-ever recorded SU levels were each associated with clinical and imaging evidence of tophus and with US-evidence of urate deposition, but not clearly with evidence of synovitis (power Doppler). The combination of high SU and longer gout duration resulted in the highest risk of tophaceous disease, but there not appeared to be a potentiation of individual effects. These data highlight the importance of managing the hyperuricemia of gout to minimize the adverse clinical features of the disease.

## The Nomenclature of Gout: A Content Analysis of Contemporary Medical Journals

David Bursill<sup>1,2</sup>, William J. Taylor<sup>3</sup>, Robert Terkeltaub<sup>4</sup> and Nicola Dalbeth<sup>5</sup>, <sup>1</sup>Medicine, University of Auckland, Auckland, New Zealand, <sup>2</sup>School of Medicine, University of Adelaide, Adelaide, Australia, <sup>3</sup>University of Otago, Wellington, New Zealand, <sup>4</sup>Rheumatology, VA San Diego Healthcare System, San Diego, CA, <sup>5</sup>University of Auckland, Auckland, New Zealand

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout has been recognized and described since antiquity. However, the terms used to describe the disease lack standardization. The aim of this study was to identify and categorise the labels used for the basic disease elements of gout in

contemporary medical literature.

**Methods:** We analysed articles from the ten highest ranked general rheumatology and five highest ranked general internal medicine journals according to 2015 Thomson-Reuters Journal Citation Reports for the period January 2012 to January 2017. For each journal, relevant articles were identified by the search terms ‘gout’ and/or ‘hyperuricemia’ using MEDLINE. No exclusion criteria were applied. Labels were extracted from each article and categorised according to the descriptions given to the basic disease elements as shown in table 1. A label was determined to be ‘unique’ if it used different words or phrases to describe an element.

**Results:** There were 549 articles from 15 journals over the five-year period. A total of 3,220 labels were identified, of which 342 were unique. Table 1 shows the number of unique labels identified for each element, and the most commonly used label. For a few elements, there was consistency in the label used; for example, 99.0% of articles describing ‘an elevated circulating level of the final enzymatic product generated by xanthine oxidase in purine metabolism in humans’ used the label ‘hyperuric(a)emia’, and 92.5% of articles describing ‘a discrete collection of pathogenic crystals with associated host-response tissue’ used the label ‘tophus’. However, for most elements, a wide range of labels was used with no dominantly used label (Table 1). The element ‘an episode of acute inflammation triggered by the presence of pathogenic crystals’ had the largest number of unique labels; 162 unique labels were identified, and 33.6% articles used at least 4 unique labels for this element. For ‘the circulating form of the final enzymatic product generated by xanthine oxidase in purine metabolism in humans’, there were two widely used labels; ‘uric acid’ (63.0% articles) and ‘urate’ (62.5% articles); with both labels used interchangeably in 25.9% articles.

**Conclusion:** The existing nomenclature of gout disease elements is imprecise and inconsistent. This imprecision may be a barrier to effective communication in both clinical and research settings. Consensus regarding the nomenclature of disease elements is required.

**Table 1 – Unique labels identified for the basic disease elements of gout in 549 disease-relevant articles**

<b>Disease Element</b>	<b>Number of Unique Labels Identified</b>	<b>Most frequently used label (% articles)</b>
The pathogenic crystals in gout	28	Monosodium urate crystals (73.1%)
The circulating form of the final enzymatic product generated by xanthine oxidase in purine metabolism in humans	9	Uric acid (63.0%)
An elevated circulating level of the final enzymatic product generated by xanthine oxidase in purine metabolism in humans	7	Hyperuric(a)emia (99.0%)
A discrete collection of pathogenic crystals with associated host-response tissue	18	Tophus (92.5%)
A discrete collection of pathogenic crystals with associated host-response tissue, detectable on physical examination	27	Subcutaneous tophus (44.1%)
An episode of acute inflammation triggered by pathogenic crystals	162	Acute gout (33.6%)
The condition in which there is an absence of clinically evident inflammation after or between episodes of acute inflammation	16	Intercritical period (42.1%)
Persistent inflammation induced by pathogenic crystals	34	Chronic gout (58.4%)
The presence of pathogenic crystal deposition on imaging	11	Urate deposition (63.3%)
The presence of structural bone damage due to gout	30	Erosion (54.0%)

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

#### Background/Purpose:

Hyperuricemia and gout are associated with increased risk of cardiovascular disease. The aim of the study was to evaluate the correlation between cardiovascular risk and total urate volumes measured by dual energy computed tomography (DECT).

#### Methods:

DECT datasets from 91 crystal-proven gout patients were analyzed retrospectively. The total volumes of uric acid deposition were quantified using automated volume assessment software. The 10-year cardiovascular risk using Framingham risk score (FRS) and metabolic syndrome (MS) based on National Cholesterol Education Program were estimated.

#### Results:

Fifty five patients with positive results on DECT and 36 patients with negative results on DECT were assessed. Patients with positive DECT showed significant higher systolic blood pressure, diastolic blood pressure, and fasting glucose and higher prevalence of chronic kidney disease, compared with those with negative DECT. The total urate volumes were significantly correlated with FRS and the number of component of metabolic syndrome ( $r = 0.22$ ,  $P = 0.036$  and  $r = 0.373$ ,  $P < 0.001$ , respectively).

#### Conclusion:

This study demonstrated the correlation between total urate volumes on DECT and cardiovascular risk. Higher urate burden could affect unfavorable cardiovascular outcomes.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

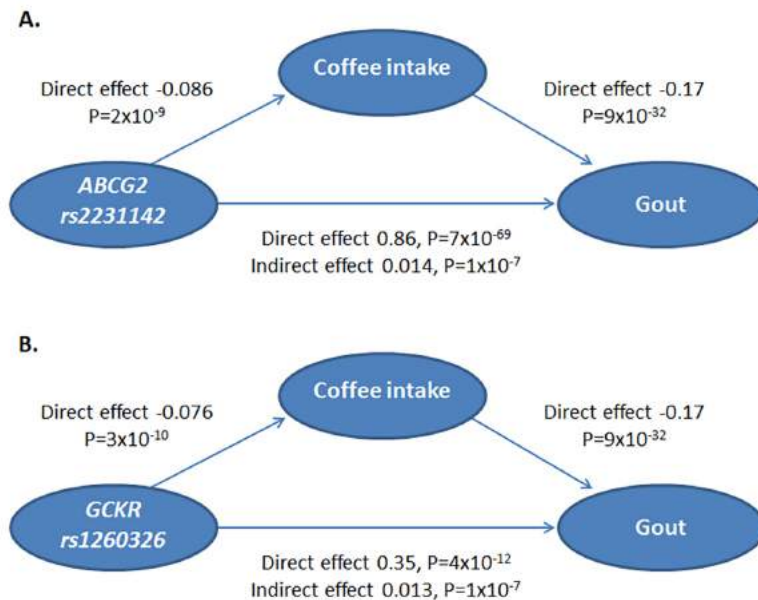

**Background/Purpose:** Increased coffee intake is associated with reduced serum urate concentrations and lower risk of gout. Recent genome wide association studies (GWAS) have shown that genetic variants influence both coffee intake and serum urate. Specific alleles of SNPs in the *ABCG2*, *GCKR*, *MLXIPL* and *CYP1A2* genes have been associated with reduced coffee intake and increased serum urate in separate GWAS. The aim of this study was to determine whether these SNPs influence the risk of gout through their effects on coffee consumption.

**Methods:** This research was conducted using the UK Biobank Resource (approval number 12611). Data, including genome-wide genotypes, were available for 130,966 European participants, aged 40-69 years. A validated case definition of ‘self-reported gout or urate-lowering therapy use’ was used to determine gout status. Gout status and coffee intake (cups per day) were tested for association with four SNPs: *ABCG2* (*rs2231142*), *GCKR* (*rs1260326*), *MLXIPL* (*rs1178977*) and *CYP1A2* (*rs2472297*) using regression models, adjusted for age, sex, body mass index, hypertension, kidney disease, diabetes mellitus, and intake of additional dietary factors. Total, direct or indirect standardized effect estimates of the causal association with gout were calculated and Sobel’s test was used to determine whether the indirect effect of each SNP on gout risk, mediated through coffee consumption, was significant.

**Results:** Coffee consumption was inversely associated with gout (multivariate adjusted odds ratio (95% CI) per cup consumed per day 0.85 (0.82 - 0.87),  $p = 9 \times 10^{-32}$ ). The urate-increasing *ABCG2*, *GCKR*, *MLXIPL* and *CYP1A2* alleles were associated with reduced daily coffee consumption, with the strongest associations for *CYP1A2* (beta -0.35,  $p = 8 \times 10^{-40}$ ), and *MLXIPL* (beta -0.23,  $p = 3 \times 10^{-8}$ ), and weaker associations for *ABCG2* (beta -0.11,  $p = 2 \times 10^{-9}$ ) and *GCKR* (beta -0.10,  $p = 3 \times 10^{-10}$ ). *ABCG2* and *GCKR* were associated with gout at genome-wide significance (multivariate adjusted  $p < 5 \times 10^{-8}$  for both), but the association of *MLXIPL* and *CYP1A2* did not achieve experiment-wide significance (multivariate adjusted  $p > 0.0125$  for both). In mediation analysis, the direct effects of *ABCG2* and *GCKR* accounted for most of the total effect on gout risk, with much smaller indirect effects mediated by coffee consumption (Figure).

**Conclusion:** Lower coffee consumption is associated with gout. Although alleles at several SNPs associate with both lower coffee consumption and higher risk of gout, these SNPs largely influence gout risk directly, rather than indirectly through effects on coffee consumption.

**Figure. Mediation analysis of A. *ABCG2* and B. *GCKR* with gout, mediated by coffee consumption.** Multivariate-adjusted standardised path coefficients are shown. The direction of the path analysis from SNP to gout risk was pre-specified.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are significant correlations between serum uric acid (sUA) and blood pressure (BP) in individuals with and without gout.<sup>1</sup> Limited data suggest that lowering sUA may decrease BP<sup>2</sup>, but a metaanalysis suggests no consistent effect<sup>3</sup>. Pegloticase is a recombinant uricase conjugated to polyethylene glycol approved for chronic refractory gout that decreases sUA to <1 mg/dL.<sup>4</sup> The results from the pegloticase randomized clinical trials (RCTs) permitted determination of the impact of persistent, very low sUA levels on BP in subjects with chronic refractory gout.

**Methods:** This analysis used results from 2 6-month RCTs in which subjects were treated with 8 mg pegloticase every 2 or 4 weeks (q2 or q4) or placebo.<sup>4</sup> sUA responders maintained sUA <6 mg/dL.<sup>4</sup> Sitting BP was measured at each visit and estimated glomerular filtration rate (eGFR) was determined at baseline and after 3 and 6 months.

**Results:** Serial blood pressure measures were obtained in 173 subjects during the course of the RCTs. Significant reductions in mean MAP from baseline to 6 months were noted in q2 responders (P=0.0029) (Figure 1), whereas reductions in mean MAP in other groups were not significant. Notably, 18/29 (62.1%) of q2 sUA responders experienced persistent reductions in MAP (p=0.01 compared to other groups). Of the q2 sUA responders exhibiting persistent decreases in MAP, there were no significant differences in baseline age, gender, race, BMI, history of hypertension, gout duration, MAP, sUA, cholesterol, eGFR or urinary UA /creatinine ratio compared with those who did not lower MAP. There were no significant changes in eGFR in sUA responders to pegloticase treatment over the course of the study (Figure 2) and there was no significant correlation between change from baseline MAP and eGFR in these subjects (r=-0.16, P=0.43) (Figure 3).

**Conclusion:** sUA responders to pegloticase experienced significant reductions in MAP that were independent of changes in renal function.

## Previous Prescription of Allopurinol Reduces the Risk of Nsaids-Related Acute Kidney Injury in Patients with Gout

**Fernando Perez-Ruiz**<sup>1</sup> and Sandra Chinchilla<sup>2</sup>, <sup>1</sup>BioCruces Health Research Institute, Barakaldo, Spain, <sup>2</sup>Rheumatology Division, Hospital Universitario Cruces, Baracaldo, Spain

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** untreated or undertreated gout is characterized by recurrent episodes of acute inflammation of joint structures, called gout flares, and flares are commonly treated with non-steroidal anti-inflammatory drugs (NSAIDs). To evaluate risk factors associated with acute kidney injury (AKI) attributed to NSAIDs in a cohort of patients who were exposed to NSAIDs to treat gout flares prior to urate-lowering therapy.

**Methods:** retrospective analysis of a nested prospective cohort of 983 gout patients in whom general variables (age, gender, renal function, ethanol intake, hypertension, hyperlipidemia, diabetes, vascular events, diuretic use) and also variables related to gout and severity of gout (serum urate levels, number of flares per year, presence of tophi, joint distribution, X-ray involvement, previous prescription of urate-lowering therapy) are available for analysis. Outcomes considered were loss of renal function attributed to NSAIDs prescription following the KDIGO AKI Work Group and staging. Variables associated to increased risk in Kaplan-Meier survival analysis were tested with multivariate Cox survival analysis, using time from onset of gout to the event as time exposed to NSAIDs.

**Results:** 55/983 patients (5.59%, 0.82 per 100 patient-yr) experienced an episode of AKI: 31, 13, and 11 patients showed Grade 1, Grade 2, and Grade 3 AKI. Among the gout-related variables, the number of flares in the year previous to the renal event and polyarticular joint distribution were associated with higher risk of renal events. Other general variables previously described in the literature, as the presence of previous chronic renal disease, the use of diuretics, and prevalent vascular events were also independently associated to increased risk of AKI. Interestingly, patients who had been previously prescribed allopurinol (other medications were uncommonly prescribed) showed a lower risk of acute renal events (Table).

	<b>AKI uncorrected</b>	<b>AKI corrected</b>	<b>p</b>
<b>Diabetes</b>	1.127 (0.611-2.078)	0.996 (0.541-1.831)	0.996
<b>Age (yr)</b>	1.003(0.977-1.030)	1.002 (0.976-1.029)	0.876
<b>Gender (male)</b>	0.551 (0.190-1.601)	0.593 (0.205-1.761)	0.335
<b>Hypertension</b>	1.396 (0.621-3.141)	1.448 (0.663-3.163)	0.353
<b>Diuretic use</b>	1.963 (0.988-3.898)	<b>2.168 (1.130-4.161)</b>	<b>0.020</b>
<b>CKD 3-4</b>	2.755 (1.435-5.286)	<b>2.695 (1.404-5.172)</b>	<b>0.003</b>
<b>Previous vascular event</b>	2.173 (1.708-4.383)	<b>2.453 (1.259-4.782)</b>	<b>0.008</b>
<b>Polyarticular gout</b>	3.560 (1.233-10.282)	<b>3.90 (1.358-11.216)</b>	<b>0.011</b>
<b>Flares (&gt;2 per year)</b>	2.489 1.194-5.187)	<b>2.723 (1.030-5.693)</b>	<b>0.008</b>
<b>Not on allopurinol</b>	3.634 (1.880-7.022)	<b>3.921 (2.056-7.476)</b>	<b>0.000</b>

**Conclusion:** the number of flares and extensive joint distribution, variables related to gout clinical severity and surrogates for NSAID prescription, were associated with higher risk for renal injury in patients with gout, while previous prescription of allopurinol was

associated with lower risk. We are uncertain if this finding is related to the use of allopurinol or a signal of better standard of healthcare that may reduce the risk of events indirectly.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite the well known risk of hyperuricaemia in Sickle Cell Disease (SCD), it has not been determined if these patients are more prone to gout than the general populace. We studied the frequencies of gout between patients with SCD and controls with haemoglobin AA genotype and determined the factors associated with gout in SCD.

**Methods:** A prospective study of 104 patients with haemoglobin SS or SC and 104 age and sex-matched control participants with haemoglobin AA was conducted at the University of Ilorin Teaching Hospital, Nigeria. Clinical and demographic information were obtained from each participant and 10 ml of venous blood was taken for determination of haemoglobin genotype, serum uric acid and creatinine. Joint aspiration was done in all individuals presenting with articular pain and swelling. This sample was examined by polarized microscopy for monosodium urate crystals.

**Results:** The mean age of the patients was 27.4±8.3 years. Eight (7.7%) of the patients had genotype SC while the remaining 96 (92.3%) had SS. Hyperuricaemia was found in 28 (26.9%) and 2 (1.9%) individuals with SCD and controls respectively (p0.001). Six (5.8%) cases of gout were found among the SCD patients and none among the controls (p=0.029). None of the gouty individuals had ever been diagnosed with gout before and they all had serum uric acid in the hyperuricaemic range. Four (66.7%) of them were males giving a male-female ratio of 2:1. The pattern of articular involvement was monoarticular in 2 (33.3%), oligoarticular in 3 (50%) and polyarticular in 1 (16.7%). The knee was the most frequently affected joint seen in 4 patients. Five (66.7%) individuals reported having had painful and swollen joints on more than two occasions in the past while only one (16.7%) reported a single previous episode. One (16.7%) patient had subcutaneous tophi. Factors associated with gout in SCD were age, hyperuricaemia, more than two SCD crises in the past year and more than two hospital admissions in the past year (p 0.05 in each case).

**Conclusion:** Gout is more frequent in SCD than in individuals with HbAA genotype and many episodes of gouty attacks may have been mistaken for vaso-occlusive crises thereby delaying correct diagnosis and leading to mounting morbidities.

## Evidence-Based Development of Criteria for Complete Response in Patients with Chronic Refractory Gout

Naomi Schlesinger<sup>1</sup>, Puja Khanna<sup>2</sup>, Anthony Yeo<sup>3</sup> and Peter E. Lipsky<sup>4</sup>, <sup>1</sup>Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, <sup>2</sup>Rheumatology, University of Michigan, Ann Arbor, MI, <sup>3</sup>Horizon Pharma, Lake Forest, IL, <sup>4</sup>AMPEL BioSolutions, LLC, Charlottesville, VA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A Delphi exercise reached consensus on a definition for gout remission that included serum uric acid (sUA) <6 mg/dL, no flares, resolution of all tophi, limited pain, and low disease impact by patient global assessment (PGA).<sup>1</sup> The frequency with which these criteria are achieved in response to treatment has not been assessed. Our study evaluated these criteria using results from patients with chronic refractory gout who received pegloticase (8 mg every 2 weeks), a mammalian recombinant uricase conjugated to polyethylene glycol approved for treatment of adults with chronic gout refractory to oral urate lowering therapy<sup>2</sup>.

**Methods:** The results from two identical randomized controlled trials (RCTs) of pegloticase were analyzed.<sup>2</sup> Patients received 6 months of treatment with 8 mg of pegloticase or placebo, and responders were defined as those with persistent urate lowering<sup>2</sup>. Overall, 42% (n=36) of the patients who received pegloticase 8 mg every 2 weeks were responders in the RCTs and 34 continued in the open-label extension. Initially, individual patient data was reviewed to establish the frequency with which pegloticase responders met the proposed remission criteria.<sup>1</sup> Subsequently, using mixed modelling, we determined the best criteria for a “complete response” (CR) using a repeated-measures, mixed-effects model to relate the time when a patient's response was noted, assessed by patient global assessment (PGA), SF-36 bodily pain scores, visual analog scale pain levels, numbers of tender and swollen joints, number of flares, and the degree of tophus resolution controlling for repeated measures. Variables were eliminated by dropping the least statistically significant item. All components of the final model were statistically significant.

**Results:** Of 34 pegloticase responders, 29 (85.3%) met the published criteria for remission. However, comparison of various components of the composite criteria indicated weak or absent correlations. Mixed effects modelling defined the following criteria for a CR: sUA <6 mg/dL, resolution of all measured tophi, PGA ≤1, swollen joint count ≤1, and tender joint count ≤1. The mean time from the beginning of the RCT to reach CR criteria was 11.5 months. All patients who achieved a CR maintained it until the end of follow-up. The mean duration of CR was 507.4 days and there was a significant inverse relationship between the time to CR and the duration of the response (P=0.0008).

### Conclusion:

These results defined criteria for a CR in individuals with chronic refractory gout treated with pegloticase, suggesting that, the majority of patients who persistently lower sUA, reach criteria for CR, and do so within 1 year from the initiation of therapy. CR persisted for the length of treatment.

This composite CR index can serve as an evidence-based target goal for a “Treat to Target” strategy in clinical practice and in future clinical trials.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hyperuricemia, abnormally elevated level of serum uric acid, is associated with gout as well as other diseases including metabolic syndrome, hypertension, diabetic kidney disease. In particular, hyperuricemia has causative link with gout, a metabolic disease characterized by deposition of sodium urate crystals in the joints and recurrent attacks of painful inflammatory arthritis. The therapeutic options for hyperuricemia/gout include xanthine oxidase inhibitors and uricosurics. Benzbromarone, probenecid and lesinurad are clinically available uricosurics, which increase the renal urate excretion by inhibiting URAT1, the transporter responsible for urate reabsorption. However, they are not widely used due to safety concern. In this study, we describe a novel URAT1 inhibitor, TEI-A, with a potent and highly selective properties.

**Methods:** Human URAT1-overexpressing cells were treated with TEI-A, benzbromarone or lesinurad, and the uptake amounts of the specific substrates were measured to determine the inhibitory activities against the transporters. To determine the selectivity of TEI-A to URAT1, OAT1, OAT3 or OAT4-overexpressing cells, or ABCG2-overexpressing vesicles were treated with TEI-A, and the uptake amounts of the specific substrates were measured. Male tufted capuchin monkeys were administered once orally with TEI-A (0.1-10 mg/kg), benzbromarone (3-30 mg/kg) and lesinurad (30 and 100 mg/kg). The fractional excretion of uric acid and serum uric acid level up to 24 hours after dosing were measured to determine uricosuric effects.

**Results:** In *in vitro* assays, TEI-A showed concentration-dependent inhibition of human URAT1-specific uptake of uric acid with IC<sub>50</sub> value of 14.3 ± 0.5 nmol/L. Inhibitory activity of TEI-A against URAT1 was 18-fold and 1600-fold stronger than those of benzbromarone and lesinurad, respectively. In addition, TEI-A showed highly selective to URAT1 over OAT1, 3, 4 and ABCG2. In tufted capuchin monkeys, TEI-A dose-dependently increased fractional excretion of uric acid up to 24 hours after dosing. Uricosuric effects of TEI-A were significantly stronger than those of benzbromarone and lesinurad. TEI-A also lowered serum uric acid level in tufted capuchin monkeys.

**Conclusion:** TEI-A is a potent and highly selective URAT1 inhibitor, and has greater uricosuric effects than benzbromarone and lesinurad in monkeys. TEI-A is a promising candidate for the treatment of patients with hyperuricemia and gout.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

URC102, a novel and potent inhibitor of human uric acid transporter 1 (hURAT1), is currently under clinical development to treat patients with gout. In preclinical studies, URC102 inhibited URAT1 more selectively leading to more potent uricosuric and hypouricemic effects than conventional uricosuric agents such as benzbromarone. A phase I study was performed to evaluate the pharmacokinetics (PK), pharmacodynamics (PD), safety and tolerability profiles of URC102 after single and multiple oral administrations.

## Methods:

A randomized, double-blind, placebo-controlled, single and multiple dose-escalation study was conducted in healthy male volunteers. Thirty-one healthy Koreans randomly received a single oral dose of placebo or URC102 1, 3, 10 or 30 mg and twenty-four Caucasians received 1, 3 and 10 mg in the fasting state. Furthermore, 44 healthy Koreans received repeated doses of placebo or URC102 1, 3, 5, 7 or 10 mg for 7 consecutive days. Blood and urine samples were collected up to 168 hours post-dose in the single ascending dose study, and up to 312 (blood) and 168 (urine) hours post-dose in the multiple dose study. Serum uric acid, urinary uric acid output, and fractional excretion of uric acid were the PD variables. Safety and tolerability were also evaluated based on monitoring of physical conditions, vital signs, electrocardiograms, and clinical laboratory tests.

**Results:** The maximum plasma concentration ( $C_{max}$ ) and the area under the plasma concentration-time curve up to the last measurable time ( $AUC_{last}$ ) increased as the dose increased in both single (1 to 30 mg) and multiple ascending dose (1 to 10 mg) studies. URC102 was rapidly absorbed after single and repeated doses (time to reach  $C_{max}$  or  $T_{max}$  less than 2 and 1 to 6 hours, respectively). Blood or urine PK characteristics of URC102 were not significantly different between Koreans and Caucasians. The serum uric acid levels were rapidly reduced after single and repeated administrations of URC102. The maximum mean decrease in serum uric acid from baseline was more than 70% after repeated oral doses of URC102 at 5 to 10 mg. No serious AE was reported, and all AEs were resolved.

## Conclusion:

Orally administered URC102 was well tolerated over the dose range of 1 to 10 mg after single and multiple once-daily administrations for 7 days, and showed a linear PK profile in the ranges of 1 to 30 mg (single dose) and 1 to 10 mg (multiple doses). URC102 was effective in lowering serum uric acid levels.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Gout is the most common form of arthritis worldwide. Hyperuricemia is a crucial risk factor resulting in accumulation of uric acid (s-UA) crystals in tissues and in a subset development of clinical gout. The relative importance of other risk factors, some of which are associated with s-UA levels, is slightly more controversial. The aim of this preliminary analysis, were to identify such predictors for clinical gout in a population survey, the Malmö Preventive Project (MPP)- a large-scale screening and case-finding program for cardiovascular risk factors, alcohol abuse and breast cancer in the city of Malmö, Sweden.

**Methods:** Overall, 33.346 individuals (67% male, mean age 45.7 years at inclusion, mean follow up 28.2 years) participated. The study population was screened between 1974 and 1992. A baseline health screening included: 1. *Questionnaire* with 260 questions (socioeconomic factors, alcohol consumption, smoking, physical activity, dietary habits, history of gout and other co-morbidities) 2. *Physical examination* (including weight, height, BMI, and blood pressure) and 3. *Laboratory tests* (serum urate, fasting glucose, s-creatinine). Endpoint was defined as the date of first gout diagnosis, death, moving from the area, or December 31<sup>st</sup> 2014. In order to identify all gout diagnoses (using ICD-codes) given at visits to physicians in primary care, in specialized in-patient (from 1974) and out-patient specialized care (from 2001); MPP cohort was linked to regional health care register and to the national patient register, respectively. Individuals with a history of gout before the inclusion in MPP (n=11) were excluded from the analysis. Possible baseline predictors of developing gout were analysed using Cox-regression model.

**Results:** Of 33.346 individuals participating in MPP project, 1275 (3.8%) were diagnosed with clinically gout over 30 years follow up. Subjects with higher s-UA at baseline (age- and sex-adjusted) had a significantly increased risk of developing gout. In addition, results from the multivariate analysis identified higher age, male sex, higher baseline BMI, systolic blood pressure, current smoking for  $\geq 10$  years and daily alcohol drinking as independent predictors of incident gout (Table).

**Conclusion:** In addition to hyperuricemia, increased age, male sex, hypertriglyceridemia, concomitant hypertension, smoking and daily drinking were independent predictors for development of gout in this large cohort of middle-aged individuals.

Table: Baseline predictors of development of gout over 30 years

	Mean (SD)	HR (95% CI) (age/sex adjusted)	HR (95% CI)* (multivariate analysis)
Age	45.7 (7.4)	1.5 (1.4-1.6)	<b>1.4 (1.3-1.6)</b>
s-UA ( $\mu\text{mol/L}$ )	300.8 (70.1)	2.0 (1.9-2.0)	<b>1.8 (1.8-1.9)</b>

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

URC102 is a novel URAT1 inhibitor under clinical development for the treatment of hyperuricemia with gout. A series of double-blind, placebo-controlled, randomized, multicenter, phase 2 studies investigated the efficacy, safety, and dose-response relationship of URC102 in patients with gout (NCT02290210 and NCT02557126).

### **Methods:**

Korean male patients aged  $\geq 20$  and  $< 70$  years with gout and serum uric acid (sUA) levels  $\geq 7.0$  mg/dL and  $\leq 10.0$  mg/dL at screening were randomized to orally (QD) receive placebo or URC102 at 0.25 mg, 0.5 mg, 1 mg, and 2 mg (first study with low-dose URC102) and placebo or URC102 at 3 mg, 5mg, 7 mg, and 10 mg (second study with high-dose URC102) for 14 days. Efficacy was evaluated by analyzing the trend of sUA reduction, defined as percentage changes of sUA for 2 weeks with reference to baseline, after administration of URC102. Safety was assessed with adverse events (AEs), physical examinations, and laboratory findings throughout the studies.

### **Results:**

Sixty-four (first study) and 76 (second study) patients with gout were randomized. The mean percentage changes ( $\pm$  standard deviation) of sUA on Day 15 was -3.96 ( $\pm 15.77$ )%, -3.28 ( $\pm 10.39$ )%, -10.63 ( $\pm 10.09$ )%, -13.15 ( $\pm 20.30$ )%, and -29.52 ( $\pm 8.45$ )% in the placebo,

URC102 0.25 mg, 0.5 mg, 1 mg, and 2 mg groups, respectively (first study), and -1.20 ( $\pm 7.75$ )%, -28.31 ( $\pm 15.17$ )%, -44.02 ( $\pm 20.11$ )%, -49.05 ( $\pm 10.76$ )%, and -54.31 ( $\pm 12.38$ )% in the placebo, URC102 3 mg, 5 mg, 7 mg, and 10 mg groups, respectively (second study). AEs that occurred with a frequency of 10% or more, regardless of causality, were arthralgia and pain in extremity (first study) and gout and arthralgia (second study). Most of the AEs were mild in severity, and there were no significant differences in the frequency of AEs between the placebo and URC102 treatment groups. Two serious AEs, animal bite and traffic accident, were reported, but the causality to the study drug was unrelated in both events.

#### Conclusion:

URC102 decreased sUA levels in a dose-dependent manner in Korean patients with gout. All doses of orally administered URC102 for 14 days were well tolerated. Further long-term clinical studies in larger populations are warranted to evaluate the effectiveness of URC102, which could be a new effective treatment option as a urate-lowering therapy.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Accumulating evidence indicates that gut microbiota interact with gout but it is still unknown how the uric acid lowering treatment (ULT) affects to the gut microbiome. This study was performed to investigate the effect of ULT on gut microbiome composition.

**Methods:** Stool samples from asymptomatic hyperuricemic patients (asHU, n = 3) and three groups of gout patients, i.e. a group of acute gout patients before ULT (noULT, n = 14), a group of gout patients after the 30-day-ULT (30ULT, n = 9) and a group of chronic gout patients having the > 6-month-ULT (cULT, n = 18), were collected and analyzed using 16S rRNA gene-based pyrosequencing. The composition of gut microbiota and the abundant phylogenetic types were evaluated.

**Results:** *Firmicutes/Bacteroidetes* ratio in the cULT group was higher compared to those in noULT and 30ULT groups. We identified four robust enterotypes, which was affected by ULT. For the 30ULT group, proportion of patients with *Bacteroidaceae* dominant gut type were reduced and we observed enhanced prevalence of *Ruminococcaceae-Prevotellaceae* dominant gut type than in the noULT group. *Ruminococcaceae-Prevotellaceae* dominant gut type in the cULT group was not enriched as in the 30ULT group. In any group of gout patients, notable bacterial families presented significantly differed proportions: *Veillonellaceae*, *Pedospira*\_f, GQ396871\_f, *Polyangiaceae*, EU335275\_f, *Natronincola*\_f, FQ032818\_f, *Fucaceae* in family level and *Bradyrhizobium*, *Natronincola*\_f\_uc\_s, *Lactobacillus casei* group and DQ905770\_s in species level.

**Conclusion:** This study suggest that fecal microbiome may change after ULT in gout patients. Further research is warranted to uncover the potential links between the specific microbes and uric acid processing in human intestine.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Previous studies of hyperuricemia and dementia have provided contradictory findings, ranging from reduced to increased risk. Our objective was to assess the comparative effectiveness of allopurinol vs. febuxostat for preventing incident dementia in elderly.

**Methods:** In a retrospective cohort study using Medicare claims data, we included patients newly treated with allopurinol or febuxostat (baseline period of 365 days without either medication). We used 1:5 propensity-matched Cox regression analyses to compare the hazard ratio (HR) of incident dementia with allopurinol vs. febuxostat, assessing use, dose and duration.

**Results:** We found 42,704 new allopurinol or febuxostat treatment episodes in 35,030 patients, of which 2,591 ended in incident dementia. Crude rates of incident dementia per 100,000 person-days were lower with higher daily dose: allopurinol <200, 200-299 and <sup>3</sup>300 mg/day with 12, 9 and 8; and febuxostat 40 mg and 80 mg/day with 9 and 8, respectively. In propensity-matched analyses, compared to allopurinol <200 mg/day, higher allopurinol doses (200-299 mg/day and <sup>3</sup>300 mg/day) and febuxostat 40 mg/day dose were associated with lower HR of dementia, 0.80 (95% CI, 0.64, 0.98), 0.59 (95% CI, 0.50, 0.71) and 0.64 (95% CI, 0.47, 0.86), respectively;

febuxostat 80 mg/day was not associated, 0.66 (95% CI, 0.36, 1.19). Compared to allopurinol use for 1-180 days, longer febuxostat or allopurinol use durations were not significantly associated with differences in HR of dementia, ranging 0.76 to 1.14.

**Conclusion:** Higher allopurinol dose and febuxostat were more effective than low-dose allopurinol in preventing dementia in elderly patients. Future studies need to examine the mechanism of this benefit of febuxostat and higher-dose allopurinol.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although the cardinal feature of gout is inflammatory arthritis, it is also a metabolic condition closely associated with an elevated uric acid burden and insulin resistance. Thus, gout and hyperuricemia are associated with major cardiovascular (CV)-metabolic-renal comorbidities and their sequelae. Statins confer both CV and survival benefits in both individuals with and without CVD; however, the impact of statins in gout remains unknown. We examined the potential survival benefit of statin use among gout patients in a general population context.

**Methods:** We performed an incident user cohort study with time-stratified propensity score matching using an electronic medical record database representative of the UK general population. The study population included individuals aged  $\geq 20$  years who had a diagnosis of gout between January 1999 and December 2014. To account for potential confounders, we compared propensity score-matched cohorts of statin initiators and non-initiators within 1-year cohort accrual blocks. The variables used to create the propensity score model included disease duration, body mass index, lifestyle factors, duration of gout, CV comorbidities, and medication use, including anti-gout medications. We estimated the mortality hazard ratio of statin initiation using Cox proportional hazard models and the mortality rate difference using an additive hazard model.

**Results:** After propensity score matching, the baseline characteristics were well-matched between the two groups. Among 17,018 statin initiators, 2,503 deaths occurred during the follow-up period (mean=5.0 years), resulting in an all-cause mortality rate of 23.97/1000 person-years (PY). The corresponding number of deaths and all-cause mortality rate among the 17,018 matched comparators during the follow-up period (mean=4.6 years) were 2,025 and 31.67/1000 PY, respectively. As such, all-cause mortality during the follow-up period was lower among the statin initiators than among the comparators (see **Figure**). Compared with non-initiators, statin initiators experienced a 16% lower relative rate of all-cause mortality (HR=0.84, 95% CI 0.79 to 0.89) and a rate difference of 7.7 (95% CI 6.1 to 9.3) fewer deaths per 1000 PY. The protective association between statin initiation and all-cause mortality persisted across subgroups,

including age (age <60, HR=0.85; age 60-70, HR=0.81; age >70, HR=0.85), sex (males, HR=0.82; women, HR=0.88), and socioeconomic status (low, HR=0.82; high, HR=0.86).

**Conclusion:** In this general population-based cohort study, we found that statin initiation is associated with a lower risk of mortality among gout patients. The magnitude of this inverse association (i.e., a 16% reduction) appears at least comparable to or greater than that found in the general population where statins are used for primary prevention.

## Hypersensitivity Reactions with Allopurinol and Febuxostat in Adults 65 Years or Older: A Study Using the Medicare Claims Data

Jasvinder A. Singh<sup>1</sup> and John Cleveland<sup>2</sup>, <sup>1</sup>Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Rheumatology, University of Alabama at Birmingham (UAB), Birmingham, AL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Clinicians using allopurinol are always concerned about the risk of rare hypersensitivity reaction. Allopurinol and febuxostat are the two most common urate-lowering agents used for the treatment of hyperuricemia in gout. Population-based studies to estimate the risk of hypersensitivity reactions with allopurinol and febuxostat have not been done. Our objective was to describe the risk of hypersensitivity reactions with allopurinol and febuxostat.

**Methods:** We used the 5% Medicare Beneficiary sample (>65 years) from 2006-2012 to identify people with a new filled prescription for allopurinol or febuxostat or colchicine, with a baseline period of 365 days without either medication. We used Cox regression analyses to compare the hazard ratio (HR) of incident hypersensitivity reactions with allopurinol or febuxostat vs. colchicine use.

**Results:** Of the 68,230 new medication exposure episodes, 363 ended in a hypersensitivity reaction. Crude incidence rates of hypersensitivity reactions were as follows: allopurinol, 23.7; febuxostat, 30.7; and colchicine, 25.6 per 1,000 person-years. Incidence of hypersensitivity reactions was highest in the first 30 days of exposure to allopurinol or febuxostat, with a progressive reduction later. In multivariable-adjusted analyses, compared to colchicine, allopurinol, febuxostat and febuxostat + colchicine combination were associated with significantly higher hazard ratios of hypersensitivity reactions, 1.32 (95% CI, 1.10, 1.60) and 1.54 (95% CI, 1.12, 2.12)

and 2.17 (95% CI, 1.18, 3.99), respectively. In multivariable-adjusted analyses limited to allopurinol users, compared to allopurinol start dose of <200 mg/day, allopurinol start dose of ≥300 mg/day and diabetes were associated with significantly higher hazard of hypersensitivity reactions, 1.27 (95% CI, 1.12, 1.44), and 1.21 (95% CI, 1.00, 1.45).

**Conclusion:** In people 65 years or older, allopurinol and febuxostat increased the risk of hypersensitivity reactions. In allopurinol users, allopurinol start dose and diabetes increased this risk. Future studies need to examine as to why a higher start dose increases hypersensitivity risk.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Calcific tendinopathy represents 10 to 42% of chronic painful shoulders. These calcium deposits are composed of carbonated apatite. Although the disease is frequent, its origin stays still largely unknown. Molecular and cellular mechanisms involved in this pathological mineralization process are not currently identified. The objective of the study was to analyze calcified tendon samples to understand the organization of the deposits and to characterize the cells potentially involved in their formation.

### **Methods:**

Samples were collected from cadaveric subjects. Ultrasound was first used to detect calcified tendons. Then, tendons were collected and fixed in formalin 4% during 48h. Samples were then decalcified in EDTA, dehydrated and embedded in paraffin. Some samples were not decalcified to allow a better characterization of the calcific deposits. Hematoxylin and eosin (HE), Safranin O/Fast Green (SO/FG) and Von Kossa (no decalcified samples) staining were performed. Immunohistochemistry using anti-Runx2, anti-Sox9, anti-Collagen II and X, anti-CD31 and CD68 has been performed to characterize the cells and tissue around the calcifications. We used also anti-TNAP (Tissue Nonspecific Alkaline Phosphatase) and ENPP1 (Ectonucleotide Pyrophosphatase/Phosphodiesterase 1) antibodies. Indeed, these two enzymes are essential in the physiological mineralization: extracellular inorganic pyrophosphates are provided by ENPP1 then hydrolyzed by TNAP to promote mineralization.

### **Results:**

Six samples were collected (1 normal and 5 calcified). On HE staining, voluminous calcium deposits were encapsulated by a fibrocartilaginous tissue. In one sample, we observed an intra-tendinous osseous metaplasia. This fibrocartilaginous area presented a red

coloration (proteoglycan specific) on SO/FG staining but was collagen II negative whereas the fibrocartilage at the tendon attachment was strongly positive. Within this area, cells with round nuclei and pericellular lacunae and different from tenocytes were observed as previously described (Uthoff, 1975). These cells expressed Runx2 and Sox9 suggesting a chondrocyte differentiation but only a small number of them expressed type X collagen, hypertrophic chondrocytes-specific marker. These cells also expressed ENPP1 and TNAP. Interestingly, extracellular TNAP deposits were also present at the periphery of the deposits. We identified vessels surrounding the deposits on 4 of the 5 calcified samples. Finally, no CD68 positive cells were detected around the deposits.

#### Conclusion:

Histological analyses of whole calcified tendon tissues showed a fibrocartilaginous area surrounding the calcium deposits. Chondrocyte-like cells present within this area expressed ENPP1 and TNAP suggesting their crucial role in the deposition of apatite crystals. An osseous metaplasia was seen in one sample but probably does not represent the main mineralization process involved in the disease. Further analyses are necessary to understand the origin of these cells and the regulatory factors involved in their differentiation.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Elevated serum uric acid (sUA) is an established risk factor for gout. Its role in the development of dementia is controversial, low levels of sUA has been suggested to increase the risk for dementia because of its reduction impairs antioxidants capacity, on the other hand, high levels of sUA are associated with increased cardiovascular risk which might increase the risk for vascular dementia (VaD). We therefore examined the possible association of sUA with the risk of Alzheimer's disease (AD) and VaD in a population-based cohort of women.

**Methods:** Longitudinal analyses were conducted in the Prospective Population Study of Women in Gothenburg, Sweden. In 1968, 1462 women 38–60 years old randomly selected from the population census, were examined with a wide range of possible predictors for dementia. Re-examination occurred in 1974, 1980, 1992, 2000, 2005, 2009, and 2012 (with sUA being collected only in 1968 and 1992). Subjects with dementia or stroke before baseline were excluded ( $n=38$ ). Follow-up was defined from baseline to either the date of developing dementia, date of death, or end of data collection (31<sup>st</sup> of December 2012), whichever came first. Dementia was diagnosed according to Diagnostic and Statistical Manual (DSM – III) of Mental Disorders criteria based on information from neuropsychiatric examinations, informant interviews, hospital records and registry data. Multivariate proportional-hazards analyses were used to assess sUA in a time-dependent fashion as a predictor for AD and VaD in separate models, since the effect may differ between dementia subtypes. Analyses were adjusted for socioeconomic status and level of education at baseline and for age, body mass index (BMI), alcohol consumption, smoking status, triglycerides, cholesterol and hypertension in a time-dependent fashion.

**Results:** At baseline, women were on average 46.8 (SD 6.2) years old and had a mean sUA of 234.5  $\mu\text{mol/L}$  (SD 75.5). During the 44-year follow-up, 153 women developed AD and 48 developed VaD. Women in higher sUA tertiles (compared to lower) were older and had a worse metabolic profile, with a higher BMI, blood pressure, cholesterol and triglycerides concentration. Table 1 shows the results of the age and fully adjusted analyses. In fully adjusted analyses, an increase in sUA concentration (per SD) was associated with a

decreased risk for AD (HR 0.78; 95% Confidence Interval (CI) 0.63 to 0.96). For VaD, women in the lowest *and* highest tertiles had an increased risk for VaD (HR 3.41; CI 1.36 to 8.54) and (HR 2.61; CI 1.00 to 6.88), respectively, compared to women in the middle tertile.

**Conclusion:** In a population-based cohort study we found that a lower sUA level was associated with an increased risk for developing AD in women. For VaD, we found an increased risk among women with low and high sUA levels. If these findings are confirmed in men and other populations the inverse association between AD and sUA should be addressed in treatment of hyperuricemia.

**Table 1.** Time-dependent cox-proportional hazard ratios for incidence dementia per 1 SD increase in serum uric acid and according to tertiles.

## Synovial Fluid Leukocyte Count and Its Association with Crystal Deposition in Asymptomatic Hyperuricemia

**Mariano Andrés**<sup>1,2</sup>, José Antonio Bernal<sup>3</sup>, María Dolores Arenas<sup>4</sup> and Eliseo Pascual<sup>1,5</sup>, <sup>1</sup>Sección de Reumatología, Hospital General Universitario de Alicante, Alicante, Spain, <sup>2</sup>Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain, <sup>3</sup>Reumatología, Hospital Universitario del Vinalopó, Elche, Spain, <sup>4</sup>Unidad de Nefrología, Hospital Vithas Perpetuo Socorro, Alicante, Spain, <sup>5</sup>Emeritus Professor, Universidad Miguel Hernández, Elche, Spain

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Articular and periarticular deposits of monosodium urate (MSU) crystals in asymptomatic hyperuricemia (AH) may associate with more severe forms of atherosclerosis [Andrés 2016]. This likely relates with crystal-driven subclinical inflammation, a phenomenon well described in gout [2] but to date not assessed in AH. The aim of the present study was to assess the synovial fluid (SF) leukocytes count in patients with AH depending on the presence of crystals.

**Methods:** Consecutive patients with AH were selected from nephrology clinics. Hyperuricemia threshold was established at serum uric acid (SUA)  $\geq 7$  mg/dL; those on current urate-lowering therapy were excluded. Ultrasound (US) of knees, ankles and first metatarsophalangeal joints was performed blinded to clinical and laboratory data, to perform US-guided aspiration and obtain SF samples. Samples were jointly analyzed in fresh by two observers, using a compensated polarized light microscope equipped with two viewing stations. The second observer was also unaware of US findings. The presence of leukocytes and crystals was established by consensus. SF leukocyte count was performed using a Neubauer counting camera. Mann-Whitney's U and Kruskal-Wallis' H were used for comparisons between groups.

**Results:** A total of 30 patients have been assessed, with SF samples available from 27 (three showed no joint effusion at US). Median age was 70 years (p25-75 59.8-75.5), and 16 of them (60%) were males. Median (p25-75) SUA and estimated glomerular filtration rate were 8.1 mg/dL (7.6-8.5) and 37.0 mL/min (31.0-47.5), respectively. Seven (25%) were on diuretics. After microscopy evaluation, MSU crystals were found in four patients (14.8%), calcium pyrophosphate (CPP) crystals in five (18.5%), and no crystals in 18 (66.7%). Groups were similar in SUA levels and renal function. Figure shows median leukocytes count according to crystal group: 200/mm<sup>3</sup> (138-540) in MSU group; 60/mm<sup>3</sup> (50-235) in CPP group; and 30/mm<sup>3</sup> (10-53) in those with no crystal at SF. A statistically significant difference was found between the three groups ( $p=0.001$ ), and comparing MSU crystals and no crystals groups ( $p<0.001$ ); no difference was found between MSU and CPP groups, nor between CPP and no crystals groups.

**Conclusion:** MSU crystal deposition in patients with AH leads to higher SF leukocyte count, indicating low-grade inflammation. Despite low numbers, this significant finding adds evidence to the potential deleterious role of silent crystal deposits in AH patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The prevalence of total knee arthroplasty (TKA) and total hip arthroplasty (THA) has risen considerably in the U.S. There has been a relative lack of investigation into the incidence of post-implant CPDD (pseudogout) at prosthetic joint sites. We retrospectively reviewed cases of post-implant pseudogout treated at our tertiary care center. All patients met the ACR criteria for pseudogout. Our goal was to describe the demographics, clinical presentation, management, and outcomes of this cohort.

**Methods:** All patients >18 y.o with post-implant pseudogout at a prosthesis site, who were evaluated at our medical center between January 1, 2000 and June 30, 2016, were identified. Implant associated pseudogout was defined as CPPD crystals found in synovial fluid aspirates taken from periprosthetic fluid. Variables pertaining to patient demographics, presentation, management, and outcomes were abstracted and aggregated.

**Results:** There were 22 patients (15 male, 7 female) who met inclusion criteria. The average age for this cohort was 71 (Range: 51-84). Nine patients had concomitant negative joint fluid cultures, while 13 patients had concomitant positive joint fluid cultures. The most common implant was TKA, accounting for 13 (59.1%) of all cases of pseudogout. The most common indication for prosthetic placement was degenerative joint disease.

Clinical presentation for patients without concomitant infection included pain (100%), swelling at the joint (88.9%), redness (33.3%), fever (22.2%), and decreased joint range of motion (100%). Findings were mostly similar for patients with evidence of concomitant infection, however none of the patients without concomitant infection exhibited tachycardia or drainage from the prosthesis site. Various management steps and findings for the cohort are summarized in the table below.

Ten patients in the overall cohort (45.5%) had either relapse or continuation of symptoms after treatment. Of the 7 patients who received subsequent surgical intervention at the affected joint, 6 had evidence of concomitant infection.

**Conclusion:** Our study suggests strong resemblance in presentation between post-implant pseudogout and commonly encountered PJI, based on similar exam and lab findings (pain, swelling, redness, decreased ROM, elevated ESR/CRP/PMN%). Tachycardia and purulent drainage might hold some utility in distinguishing between the two conditions. Still, more conclusive tests including synovial fluid aspiration with crystal and culture analyses are needed for this. Unfortunately, many patients receive antibiotics prior to establishment of an etiologic diagnosis, as seen in more than half of our pseudogout patients with negative synovial fluid cultures. Future research should explore paired comparisons between post-implant patients with pure pseudogout & PJI, matched on the basis of variables such as age, gender, and implant site.

<b>Table 1: Management of Patients with CPPD</b> <b>Documentation at Prosthetic Joint.</b> Values are presented as mean $\pm$ SD, median [min-max] or n (%).			
	Entire Cohort (n= 22)	Patients with concomitant positive synovial fluid cultures (n=13)	Patients with concomitant negative synovial fluid cultures (n=9)
Time from symptom onset to CPPD finding (days)	2.5 [0-96]	1 [0-11]	7 [1-96]

## The Inflammation Induced By Four Types of Calcium Pyrophosphate Crystals Depends on Their Capacity to Stimulate NF- $\kappa$ b and MAPK Pathways

Félix Renaudin<sup>1</sup>, Laure Campillo-Gimenez<sup>2</sup>, Pierre Gras<sup>3</sup>, Christèle Combes<sup>4</sup>, Martine Cohen-Solal<sup>1</sup>, Frederic Liote<sup>5</sup> and **Hang-Korng Ea<sup>1</sup>**, <sup>1</sup>INSERM UMR1132, Paris Diderot University, Paris, France, <sup>2</sup>Inserm UMR1132 Bioscar, Paris, France, <sup>3</sup>CIRIMAT, INPT-UPS-CNRS, Toulouse, France, <sup>4</sup>ENSIACET, CIRIMAT, INPT-UPS-CNRS, Toulouse, France, <sup>5</sup>University Paris Diderot, Paris, France

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Calcium pyrophosphate (CPP) crystal-induced inflammation is mainly driven by interleukin (IL)-1 $\beta$ . IL-1 $\beta$  production involves a two-step process including the formation of pro-IL-1 $\beta$  through NF- $\kappa$ B activation and its' maturation through NLRP3 inflammasome activation. Two CPP crystal phases, namely monoclinic and triclinic CPP dehydrated (m- and tCPPD) crystals are identified in synovial fluids. They display different inflammatory potentials.

We aimed to assess the inflammatory properties of different CPP crystal phases and the intracellular pathways involved in CPP crystal-induced IL-1 $\beta$  production

### Methods:

Four synthesized and pyrogen-free CPP crystals (aCPP (amorphous), mCPPD or tetrahydrated (mCPPT) and tCPPD) (Gras P et al. 2014) and monosodium urate crystals (MSU) were used, *in vitro*, to stimulate THP-1 cell line or mouse bone marrow-derived

macrophages (BMDM) in the presence or not of pharmacological inhibitors: Bay-117085 (Bay, NF- $\kappa$ B inhibitor); SB203580 (SB, MAPK p38 inhibitor); SP600125 (SP, JNK inhibitor) and PD98059 (PD, p42/44 MAPK inhibitor). The expression of pro- and anti-inflammatory cytokine genes was assessed by qRT-PCR, IL-1 $\beta$  and IL-8 production by ELISA and MAPK activation by immunoblot. NF- $\kappa$ B activation was assessed in THP-1 cell line containing a gene reporter plasmid. *In vivo*, we used air pouch model to assess the effects of NF- $\kappa$ B inhibition in CPP crystal-mediated inflammation.

## Results:

*In vitro* mCPPD crystals were the most inflammatory CPP crystals and induced a higher production of mature IL-1b and IL-8 and a higher expression of inflammatory cytokine genes (IL-1 $\beta$ , IL-6, IL-8, IL-33, TNF, COX-2) than tCPPD, mCPPT and MSU crystals. aCPP crystals did not have inflammatory property. Similarly, mCPPD crystals induced a higher activation of NF- $\kappa$ B, a higher production of NLRP3 inflammasome and a stronger phosphorylation of p38, p42/44 and JNK MAPKs. Inhibition of NF- $\kappa$ B with Bay completely abrogated mature IL-1b and IL-8 secretion and pro-IL-1 $\beta$  synthesis induced by all CPP crystals. Inhibition of JNK and p42/44 MAPK with SP and PD, respectively, decreased both IL-1 $\beta$  secretion and NF- $\kappa$ B activation induced by CPP crystals. *In vivo* IL-1 $\beta$  and IL-8 production and neutrophil infiltration induced by mCPPD crystals were dramatically decreased by NF- $\kappa$ B inhibitor.

## Conclusion:

Our results suggested that the inflammatory potential of different CPP crystals relied on their capacity to activate MAPK pathways and NF- $\kappa$ B. Studies are ongoing to investigate the underlying mechanisms.

Patients with Early Onset Gout develop Earlier Severe Joint Involvement  
and Metabolic Comorbid Conditions

### Background/Purpose:

Early onset gout might encompass more severe cases along with genetic defects, leading to early management as pointed out by recent guidance from the US or Europe. The objective of this study was to compare disease characteristics and comorbidities of patients suffering from gout with early onset (EOG) before the age of 40 to the general population of gouty patients.

### Methods:

Patients from the cross-sectional national GOSPEL cohort having suffered from the first symptoms of gout before the age of 40 were included in the EOG group and compared to those with an onset after 40 included in the common gout (CG) group.

## Results:

A total of 120 (12.2%) patients was included in the EOG group (aged 49.5 ( $\pm$ 11.9) years) and 865 patients in the CG group (aged 64.4 ( $\pm$ 10.1) years). Patients with EOG presented with a higher prevalence of polyarticular flares ( $p<0.01$ ), but had similar proportions of patients having had at least 2 flares over the past year ( $p=0.16$ ), similar prevalence of gout arthropathy ( $p=0.79$ ) and tophi ( $p=0.53$ ). A total of 68.9% among EOG patients were treated with urate lowering therapy (ULT) compared to 67.9% in the CG group ( $p=0.91$ ), but only 19.1% in the EOG had an SUA level below 6.0mg/dL versus 29.8% in the CG group ( $p<0.05$ ). More patients of the CG group were suffering from moderate to severe CKD ( $p<0.01$ ). A similar proportion of patients suffered from diabetes mellitus in the EOG (12%) and CG (15.5%) groups ( $p=0.38$ ) and prevalence of each item composing the metabolic syndrome did not differ significantly between groups. However, in EOG patients, cardiovascular comorbidities were present before gout onset (figure 1).

## Conclusion:

In this large French cohort, EOG patients develop similar joint involvement and comorbid disorders than CG patients, but earlier in life.

Figure 1: Time to diagnosis of cardiovascular comorbidities from the first manifestations of gout in early and common gout groups. \*  $p<0.05$

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Gout is an inflammatory disorder related to hyperuricemia and abnormal deposition of monosodium urate crystals in joints or other tissues. The relationship between serum uric acid and asthma is controversial in the literature. While some studies found it an initiator and amplifier of asthma, others had the opposite results. Most previous studies involved either animal models or small patient samples. In our study, we analyzed the association of asthma and gout in hospitalized patients

## Methods:

We conducted a cross-sectional study using data from National Inpatient Sample (NIS) for the year of 2014. Diagnosis for asthma, subtypes of asthma (i.e. allergic asthma, non-allergic asthma, exercise-induced bronchospasm and cough variant asthma) and gout were identified using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. STATA software package was used for statistical analyses. Multivariate logistic regression models were created to adjust for potential confounders such as age, gender, race, insurance type, current tobacco abuse and obesity. Patients younger than 18 years old were excluded from the study. For asthma exacerbations, we also studied exacerbations related to acute respiratory infections (ARI) and status asthmaticus.

## Results:

A total of 858,750 hospitalizations with a diagnosis of gout and 2,331,616 hospitalizations with a diagnosis of asthma were included in the study. Compared with those without gout, asthma patients with gout are more likely to be older (mean age 67.6 vs 54.9), male (50.5% vs 29.2%), more African American and less Hispanic (26.8% and 5.0% vs 21.3% and 10.2%), less smoker (10.3% vs 19.1%) and more obesity (33.8% vs 23.7%). The adjusted OR for all types of asthma and gout was 1.15 (95% CI 1.13 - 1.17,  $p < 0.001$ ). For asthma subtypes, the adjusted OR was statistically significant only for allergic asthma (OR 1.16, 95% CI 1.01 - 1.35,  $p = 0.035$ ). There was no difference for non-allergic asthma (OR 0.78, 95% CI 0.47 - 1.32,  $p = 0.363$ ), exercise-induced bronchospasm (OR 0.93, 95% CI 0.55 - 1.56  $p = 0.776$ ), and cough variant asthma (OR 1.43, 95% CI 0.89 - 2.29,  $p = 0.136$ ) in patients with gout. For patients with asthma exacerbations, gout was associated with a lower risk of overall exacerbations (OR 0.87, 95% CI 0.83 - 0.91,  $p < 0.001$ ), ARI-related exacerbations (OR 0.78, 95% CI 0.66 - 0.92,  $p = 0.003$ ) and status asthmaticus (OR 0.59, 95% CI 0.46 - 0.77,  $p < 0.001$ ). There was no difference for exacerbations from allergic asthma (OR 0.76, 95% CI 0.52 - 1.10,  $p = 0.142$ ) in patients with gout.

## Conclusion:

Our study suggested that gout is a risk factor only for allergic subtypes of asthma, and that it may be a protective factor for asthma exacerbations except for the allergic subtype. This unexpected finding may be due to the unique biochemical properties of uric acid, being both pro-inflammatory and anti-oxidant and also the heterogeneity for different subtypes of asthma. However, we also cannot rule out the effects of systemic steroid, which is one of the short-term treatment for acute gouty arthritis, as a possible confounder. Whether a target level of uric acid in gout patients with allergic and non-allergic asthma needs to be individualized warrants further investigations.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To better understand the variation in calcium pyrophosphate (CPP) crystal, size, shape and appearance under compensated polarized microscope, synovial fluid crystals were examined by 4 independent raters.

**Methods:** Over a 4-month period, synovial fluid samples were de-identified and collected from the university clinical laboratory when found to be positive for CPP crystals. All samples were centrifuged for 5 minutes (prior to clinical lab examination) and stored at 4°C. For this research effort, slides were dry mounted for enhanced stability.

Two experienced raters and two novice raters were trained using an atlas with sample CPP crystal images and a standardized protocol for describing each crystal's shape, birefringence strength, color, and the raters' certainty that the object was a CPP crystal. Raters examined each slide until a minimum of 10 CPP suspected crystals were identified and photographed with 100x objective, or a maximum of 30 minutes was reached.

For the purpose of crystal measurement, Adobe Photoshop CS6 was used to apply a high pass linear light filter to digital images to provide enhanced resolution and line discrimination. Crystal area ( $\mu\text{m}^2$ ), length ( $\mu\text{m}$ ), and width ( $\mu\text{m}$ ) (for rods), and diagonals ( $\mu\text{m}$ ) (for rhomboids) were measured. Crystals rated with low certainty (1 on 1-3 scale) or crystals that had atypical shape or uncharacteristically bright birefringence were excluded. All remaining crystals were reviewed by a national CPP crystal expert (AR) for final inclusion in the dataset.

**Results:** Synovial fluid from 16 joint aspirates was reviewed by 4 raters. Of the 564 potential crystals identified by the 4 raters, the expert rater confirmed 293 (52%) were definite CPP crystals. Crystals that were rejected were more likely to be smaller, rhomboid, yellow rather than blue, and have weaker or no birefringence. After the brief training session, there were few differences in either the number of definite crystals or accuracy of crystal identification between the more experienced and lesser experienced raters.

Of the 293 definite crystals, 185 (63%) were categorized as rods with median area of  $3.8 \text{ mm}^2$ , (range,  $1.0 - 22.9 \text{ mm}^2$ ), and 108 rhomboids (37%) with median area of  $5.8 \text{ mm}^2$ , (range,  $0.9 - 27.0 \text{ mm}^2$ ),  $p < 0.005$ . The expected frequency of color distribution ought to be 50:50; however, 60% of confirmed crystals were blue (suggesting that the yellow-orange crystals were not as easily identified). Compared to rhomboids, rods were more likely to be scored as having low birefringence (35% vs. 9%). Only 4 (1.4%) non-birefringent confirmed crystals were identified. Rod median length was 3.8 mm (range,  $1.0 - 14.3 \text{ mm}$ ), median length to width ratio 3.4 (range,  $1.1 - 13$ ). Rhomboid median (maximum) diagonal length, 3.6 mm (range,  $1.0 - 9.0 \text{ mm}$ ), median (minimum) diagonal length, 2.6 mm ( $0.9 - 7.0 \text{ mm}$ ) and median acute angle of  $74^\circ$  (range,  $41^\circ$  to  $90^\circ$ ).

**Conclusion:** After a brief training session, less experienced raters performed similarly to more experienced raters. CPPD crystals that are smaller, show weaker birefringent or are aligned perpendicular to the short-axis of polarization are harder to identify. There is significant variation in crystal size, shape and appearance under polarized microscopy.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Common dysfunctional variants of ABCG2, a high-capacity urate transporter gene, that result in decreased urate excretion, are major causes of hyperuricemia and gout. In the present study, we describe the first detailed analysis of disease-relevant functional allelic variants in the *ABCG2* gene.

## Methods:

The main cohort recruited from the Czech Republic consisted of 155 gout patients, 115 normouricemic controls were used for comparison. We amplified, directly sequenced, and analyzed 15 ABCG2 exons. The associations between genetic variants and clinical phenotype were analyzed using the t-test, Fisher exact test and logistic and linear regression approach. Data from a NZ Polynesian sample set and the UK Biobank were included for the p.V12M analysis.

## Results:

In the *ABCG2* gene, 18 intronic (one dysfunctional splicing<sup>1</sup>) and 12 exonic variants were detected: 10 were non-synonymous (two common, eight rare including one novel): p.V12M, p.Q141K, p.R147W, p.T153M, p.F373C, p.T434M, p.S476P, p.S572R, p.D620N, and p.K360del. The p.Q141K (*rs2231142*) variant had a significantly higher minor allele frequency (0.23) in the gout patients compared to the European-origin population (0.09) and was significantly more common among gout patients than among normouricemic controls (OR = 3.15, p<0.0001). Patients with non-synonymous allelic variants had an earlier onset of gout (41.5 vs. 48 years, p=0.0478) and a greater likelihood of a familial history of gout (42% vs. 26%, OR = 2.02, p=0.043). In a meta-analysis p.V12M exerted a protective effect from gout (p<0.0001).

## Conclusion:

Genetic variants of ABCG2, common and rare, increased the risk of gout. Non-synonymous allelic variants of ABCG2 had a significant effect on earlier onset of gout and the presence of a familial gout history. ABCG2 should thus be considered a common and significant risk factor for gout.

## Background/Purpose:

Dual-energy computed tomography (DECT) is advanced imaging modality that shows the deposition of monosodium urate (MSU) crystal in tissue as a color signal. In the 2015 American College of Rheumatology/European League Against Rheumatism gout classification criteria, DECT was included as one of the imaging modalities for diagnosis. The MSU crystal deposit around the symptomatic joint is considered as positive finding, but the clinical significance of urate deposition around the tendon is still unclear.

The aim of this study was to compare the clinical characteristics and DECT findings in people with MSU crystal deposition in the joints and people with urate deposition only in the tendons.

## Methods:

DECT was performed in 71 patients who complained of recurrent painful swelling of the foot and/or ankle joints, and 35 of them showed MSU crystal deposition in the joints on DECT. The patients were divided into two groups according to the location of uric acid deposition on DECT. We analyzed the differences in clinical features and imaging findings between the two groups.

## Results:

The mean age of the patients was  $50 \pm 14$  years, and 67 patients (94%) were male. All of patients who had shown the deposition of uric acid crystals in joints on DECT had history of typical gout attacks, but 29 (81%) of those only in tendons on DECT had experienced typical gout attacks ( $p=0.011$ ). The overall mean uric acid level in all patients was as high as  $7.5 \pm 2.2$  mg/dL. The uric acid level was found to be higher in patients with joint involvement, but this difference was not statistically significant. The concordance rate between the symptomatic sites and the urate deposition sites was 91% in patients with joint deposition, but the rate was only 6% in patients without joint deposition ( $p<0.001$ ). There were 4 patients (11%) who showed gouty erosion without MSU crystal deposition in joints on DECT.

## Conclusion:

The MSU crystal deposition in the tendon was not correlated well with clinical features. However, in some patients, MSU crystal deposition may be observed only in the tendon, even with gouty erosion in joints. Therefore, careful interpretation of the DECT is necessary.

## Arhalofenate Acid Inhibits Urate Crystal-Induced Inflammatory Responses through Activation of AMP-Activated Protein Kinase (AMPK) Signaling

Charles McWherter<sup>1</sup>, Robert Terkeltaub<sup>2,3</sup> and Ru Liu-Bryan<sup>3,4</sup>, <sup>1</sup>CymaBay Therapeutics, Inc., Newark, CA, <sup>2</sup>Rheumatology, VA San Diego Healthcare System, San Diego, CA, <sup>3</sup>Medicine-Rheumatology, University of California, San Diego, La Jolla, CA, <sup>4</sup>VA San Diego Healthcare System, San Diego, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACRR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Arhalofenate is an investigational drug with dual uricosuric and anti-inflammatory properties. Arhalofenate reduced the risk of acute flare while lowering serum urate levels in gout patients in a phase II trial. Previous studies demonstrated that arhalofenate (or its active acid form) suppresses the production of IL-1 $\beta$  in response to urate crystals in macrophages *in vitro* and in a mouse air pouch model *in vivo*. In this study, we characterized the molecular mechanism of action of arhalofenate acid, studying urate crystal-induced inflammatory responses in macrophages *in vitro*.

**Methods:** Bone marrow derived macrophages (BMDMs) were stimulated with urate crystals in the presence or absence of arhalofenate acid. IL-1b release was measured from conditioned media by ELISA analysis. Western blot was carried out to examine expression of NLRP3, pro-caspase-1 and cleaved caspase-1 (for NLRP3 inflammasome activation); phosphorylation and expression of the nutritional biosensor AMPKa (AMP-activated protein kinase), the NAD<sup>+</sup>-dependent protein deacetylase SIRT1, the PPARg co-activator and master regulator of mitochondrial biogenesis PGC-1a, the nuclear-encoded mitochondrial transcription factor A TFAM, cytosolic thioredoxin 1 (TXN1), nuclear thioredoxin 2 (TXN2), thioredoxin-interacting protein (TXNIP) involved in NLRP3 inflammasome activation; microtubule-associated protein 1 light-chain 3 (LC3) and p62 (an adaptor contributing to autophagic degradation of ubiquitinated substrates and damaged organelle such as damaged mitochondria) for autophagy.

**Results:** Arhalofenate acid attenuated urate crystal-induced IL-1b production in BMDMs via inhibition of NLRP3 inflammasome activation, evidenced by inhibition of protein expression of NLRP3 and cleaved caspase-1 (p10). In addition, arhalofenate acid dose-dependently increased phosphorylation of AMPKa, as well as expression of SIRT1 that was dependent on AMPK, since arhalofenate acid failed to increase SIRT1 expression in AMPKa1 knockout (KO) BMDMs. Arhalofenate acid was also unable to significantly inhibit urate crystal-induced IL-1b production in AMPKa1 KO, compared to WT BMDMs, indicating that AMPK mediated inhibitory effect of arhalofenate acid. Moreover, urate crystals concurrently reduced phosphorylation of AMPKa, expression of SIRT1, PGC-1a, TFAM, TXN1, TXN2, but induced expression of TXNIP, all of which were reversed by arhalofenate acid in BMDMs, implicating a role for arhalofenate acid in maintaining mitochondrial function, limiting oxidative stress and preventing TXNIP-mediated inflammasome activation. Furthermore, arhalofenate acid was able to not only promote induction of autophagy but also accelerate autophagic flux.

**Conclusion:** Arhalofenate acid, the active form of arhalofenate, is anti-inflammatory via activation of AMPK and downstream signaling in macrophages, thereby increasing cellular resistance to stresses induced by urate crystals, mediated by maintaining mitochondrial integrity and cellular quality control through autophagy. These effects likely contribute to gout flare risk reduction by arhalofenate.

## Utility of Anakinra in Acute Crystalline Diseases: A Retrospective Study Comparing a University Hospital with Veterans Affairs Medical Center

Julianna Desmarais<sup>1</sup> and Cong-Qiu Chu<sup>2</sup>, <sup>1</sup>Department of Arthritis and Rheumatic Diseases, Oregon Health & Science University, Portland, OR, <sup>2</sup>Rheumatology, Oregon Health & Science University, Portland, OR

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anakinra is an IL-1 blocking medication used off label to relieve acute inflammation from gout and pseudogout. The efficacy and safety of this treatment in the inpatient setting have not been well evaluated.

**Methods:** Patients with crystal-induced arthritis who were hospitalized at Oregon Health & Science University (OHSU) Hospital and the VA Portland Health Care System (VA) since 2008 were included. Patient characteristics, comorbidities, medications prior to anakinra use, reason for anakinra use, number of doses of anakinra (one dose was 100 mg subcutaneous injection), adverse events, and response to treatment were analyzed. A response to treatment was defined as a pain score improvement of 2 on a 0-10 pain scale, functional improvement such as ability to bear weight on affected limb when unable to initially, or a documented clinical response such as "great improvement." For pain improvement, a student's *t* test was used to calculate significance.

**Results:** A total of 79 gout patients were identified who had 101 flares. There were 11 patients with pseudogout who had 14 flares. Three patients had both processes on joint aspiration. The average patient age was 64 (61 at OHSU, 69 at the VA), with an average of 3.9 joints flaring. At both OHSU and the VA around half of all patients had comorbidities such as diabetes, congestive heart failure, and chronic kidney disease that affected the choice of their crystal induced arthritis treatment. At OHSU each patient received an average of 4.6 doses of anakinra, while at the VA the average number of doses of anakinra was 3.3. All of the patients except two had a response to

anakinra. Ninety percent of the patients responded within 2 days after initiation of anakinra at both hospitals when evaluating function, pain, and/or clinical response. Anakinra was well tolerated. No adverse reactions to anakinra were reported.

**Conclusion:** Anakinra is an effective and safe medication for the use of gout and pseudogout in hospitalized patients in the academic and VA settings who have acute crystal induced arthritis, particularly in those who have comorbidities that would limit the use of other acute gout medications.

## **Initial Phase 2 Clinical Data of SEL-212 in Symptomatic Gout Patients: Monthly Dosing of a Pegylated Uricase (Pegsiticase) with Svp-Rapamycin Enables Sustained Reduction of Serum Uric Acid Levels By Mitigating Formation of Anti-Drug Antibodies**

Earl Sands<sup>1</sup>, Alan J. Kivitz<sup>2</sup>, Wesley DeHaan Ph.D.<sup>1</sup>, Lloyd Johnston<sup>1</sup> and Takashi Kei Kishimoto<sup>1</sup>, <sup>1</sup>Selecta Biosciences, Watertown, MA, <sup>2</sup>Department of Rheumatology, Altoona Center for Clinical Research, Duncansville, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Pegylated uricases are promising therapies for the treatment of severe chronic gout, particularly for the rapid resolution of tophi. However uricases are limited by the induction of anti-drug antibodies (ADAs) that can compromise efficacy and safety. We have developed SEL-212, a novel combination product consisting of pegsiticase co-administered with synthetic vaccine particles encapsulating rapamycin (SVP-R). Preclinical studies have shown the ability of SVP-R to induce durable, antigen-specific immune tolerance to a range of co-administered biologic drugs. A Phase 1 study of SEL-212 demonstrated mitigation of ADAs and sustained control of serum uric acid (sUA) for at least 30 days after a single dose. Here we report initial data on the safety, tolerability, and effects on sUA, ADAs, and gout fares of repeated monthly doses of SEL-212 from an ongoing Phase 2 clinical study in symptomatic gout patients.

### **Methods:**

Patients with symptomatic gout ( $\geq 1$  tophus, gout flare within 6 months, and/or gouty arthropathy) and elevated sUA (sUA  $\geq 6$ mg/dL) were enrolled in SEL-212 treatment cohorts (N=6-10 patients/cohort) of fixed doses of pegsiticase (0.2mg/kg or 0.4mg/kg) alone or co-administered with SVP-R (0.05, 0.08, or 0.1mg/kg). SEL-212 was infused in 28-day cycles x3 doses followed by challenge with pegsiticase alone on 28-day cycles x2 doses. Safety, tolerability, sUA, and ADAs were monitored, and clinical data were collected.

### **Results:**

As of 12 June 2017, 60 patients had been dosed. A dose range matrix of pegsiticase and SVP-R enabled the identification of the minimum effective monthly dose (MED) as 0.4mg/kg pegsiticase+0.08mg/kg SVP-R. At the MED, 5/6 initial evaluable patients demonstrated sustained sUA levels  $< 0.1$  mg/dL with no or low ADA titers through 5 monthly doses, including two challenges with pegsiticase alone, and 4/6 demonstrated evidence of immune tolerance induction (Figure 1). In contrast, all patients treated with 0.4 mg/kg pegsiticase alone developed ADAs after the first dose and lost control of sUA by 14-21 days. Flare rates in the first 3 months were low for patients treated with SEL-212 (22%) versus those treated with pegsiticase alone (50%). SEL-212 was generally well tolerated at the clinically active doses. Of 7 observed serious infusion reactions, 4 were associated with patients receiving pegsiticase alone or the lowest dose of SEL-212, as expected, and two were related to dosing errors.

### **Conclusion:**

SEL-212 has been well-tolerated, and, unlike pegylated uricases alone, has mitigated immunogenicity, reduced flare rate and enabled repeated monthly dosing with sustained control of sUA levels in gout patients.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Carpal tunnel syndrome (CTS) is the most common peripheral entrapment neuropathy and has been associated with systemic conditions such as rheumatoid arthritis, hypothyroidism, and obesity, as well as occupational tasks involving repetitive manual activities. The most common treatments for CTS have several drawbacks, such as invasiveness (surgery), lack of long-term efficacy (corticosteroid injections), or low compliance (braces). To overcome these shortcomings, an unobtrusive and non-invasive device was developed to treat CTS by relieving pressure on the median nerve. This carpal tunnel tissue manipulation device (CTMD) is

attached to the volar aspect of the wrist and applies a consistent level of tension to the underlying tissue. A pilot clinical trial was performed to investigate the feasibility, safety and efficacy of the CTMD to relieve symptoms of and potentially treat CTS.

**Methods:** Subjects with mild to severe unilateral or bilateral CTS, confirmed using electrodiagnostic testing and AANEM criteria, were enrolled into the study. Subjects with concomitant ulnar or radial neuropathies, diabetes, thyroid disease, or connective tissue diseases were excluded. The CTMD was worn on the affected wrist(s) for 8-10 hours daily for 28 days, followed by 8 weeks of no CTS treatment. The primary outcome measure was the Symptom Severity Scale (SSS) score of the Boston Carpal Tunnel Questionnaire (BCTQ). The BCTQ was administered at 0, 2, and 4 weeks into treatment, and 8 weeks post-treatment. Data for bilateral subjects were evaluated only for the wrist with higher CTS severity and higher BCTQ score.

**Results:** Eleven (11) subjects were enrolled: mean age 51.4 years ( $\pm 11.1$ ), 64% female, 7 treated for unilateral CTS and 4 for bilateral CTS. Subjects' average SSS score reduced from baseline by  $0.63 \pm 0.56$  points at 2 weeks and by  $0.59 \pm 0.68$  points at 4 weeks ( $p < 0.05$ ). Subjects' scores continued to improve 8 weeks post-treatment, resulting in an overall improvement in SSS of  $0.79 \pm 0.74$  points ( $p < 0.01$ ). Although a history of connective tissue disorders was an exclusion criteria, it was later found that two subjects had or possibly had arthritis. One subject had wrist arthritis and unilateral CTS but showed improvement of 0.91 points 8 weeks post-treatment. In contrast, the other subject had unconfirmed RA and bilateral CTS and experienced a 0.46 point degradation 8-weeks post-treatment. Unilateral CTS subjects' average SSS score improved more than bilateral subjects at each timepoint and most significantly at 8 weeks post-treatment ( $1.2 \pm 0.5$  points vs.  $0.09 \pm 0.41$  points).

**Conclusion:** At least 4 weeks of daily wear of the CTMD improved severity of CTS symptoms in patients with unilateral CTS. These results suggest that the CTMD may have a lasting effect up to 8 weeks post-treatment. Bilateral CTS patients may respond differently to treatment than unilateral CTS patients. An extended, randomized, placebo-controlled study is proposed to investigate long-term effects.

## Comparison of Clinical and Laboratory Features of Patients with and without Allergic Conditions in IgG4-Related Disease: A Single-Center Experience in Japan

Takako Saeki, Tomoyuki Ito, Maasa Tamura, Seiichi Yoshikawa and Hajime Yamazaki, Department of Internal Medicine, Nagaoka Red Cross Hospital, Nagaoka, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although patients with IgG4-related disease (IgG4-RD) sometimes have accompanying allergic conditions, few data on the relationship between allergic conditions and IgG4-RD have been available. In the present study, we compared the clinical and laboratory features of IgG4-RD patients with and without allergic conditions.

**Methods:** We retrospectively examined the clinical and laboratory features of 45 patients with definite IgG4-RD, collected from all departments of Nagaoka Red Cross Hospital between January 2004 and March 2016, with reference to the presence of allergic conditions.

**Results:** Of the 45 patients, 18 (40%) had allergic conditions [allergic rhinitis (n=12) and bronchial asthma (n=10)] at the time of IgG4-RD diagnosis. In the allergic group, the proportion of females was significantly higher (61% vs. 30%,  $p=0.036$ ) and the age at diagnosis was significantly lower [mean 62 yr (42-85) vs. 72 yr (60-86),  $p=0.003$ ] in comparison with the non-allergic group. Kidney disease was evident more frequently in the non-allergic group, and there was no significant difference in the frequency of involvement of other organs. The ratio of the total number of affected organs in the upper body (head, neck and thoracic area) to that in the whole body was  $83 \pm 24\%$  in the allergic group and  $55 \pm 33\%$  in the non-allergic group ( $p=0.006$ ). There was no significant inter-group difference in the absolute number of peripheral blood eosinophils, or the levels of serum IgG4 and IgE.

**Conclusion:** The present findings suggest that eosinophilia, and high serum levels of IgE and IgG4 are common features in IgG4-RD patients regardless of allergy, although there may be some clinical differences according to the concomitant allergic conditions that are present.

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** : Mixed connective tissue disease (MCTD) is characterized by overlapping features of SLE, SSc, PM/DM and rheumatoid arthritis together with the presence of high-titre of anti-RNP antibodies. Its most common clinical manifestations are Raynaud's phenomenon, arthritis, sclerodactyly, edema in the hands and myositis. However, organ involvement is more extensive than first descriptions reported. The disease can be serious with development of pulmonary, kidney, cardiovascular, gastrointestinal and neurological manifestations. The objective of the present study was to evaluate the frequency and the different types of organ damage in a well characterized cohort of patients with MCTD.

**Methods:** Ambispective study of 42 MCTD patients, all of them fulfilling the diagnostic criteria proposed by Alarcon-Segovia (J Rheumatol 1989;16:328-34), with a minimal follow-up after the first clinical presentation of at least 2 yr. The endpoint of patient follow-up was the date of the last clinic visit.

**Results:** At the end of the follow-up period (median  $\pm$  SD: 117.3  $\pm$  63.1 months; minimum, maximum: 28-432 months), 69% of patients (29/42) had 1 or more organ involvement.

Esophageal dysmotility and reflux disease was the most prevalent complication, being observed in 43% (18/42) of cases. Pulmonary abnormalities were also common, being found in 38% of patients (16/42). The most frequent lung manifestations were diffuse interstitial lung disease in 24% (10/42) of patients (including 6 cases of nonspecific interstitial pneumonitis, 3 cases of usual interstitial pneumonitis and 1 case of lymphocytic interstitial pneumonia), and pleuritis in 19% (8/42). Other pulmonary complications include primary pulmonary hypertension in 12% of patients (5/42) and shrinking lung syndrome in 2% (1/42).

Neurological disease was observed in 19% (8/42) of patients (including 4 cases of trigeminal neuropathy, 1 with dyskinesias, 1 with sensory peripheral neuropathy, 1 case of intracranial haemorrhage, and 1 with CNS vasculitis), cardiac involvement in 12% (5/42) (4 cases of pericarditis which was usually mild, and 1 case of myocarditis), and renal involvement in 10% (4/42), (2 mesangial glomerulonephritis [GN], 1 focal proliferative GN, and 1 diffuse proliferative GN).

**Conclusion:** MCTD is a well-defined entity with a wide spectrum of clinical manifestations. Long-term follow-up reveal that some patients may have mild self-limited disease, whereas others may develop severe major organ involvement which does not always have a good prognosis

## **Traditional Disease Modifying Anti-Rheumatic Drugs (tDMARDs), Hydroxychloroquine (HCQ) and/or Sulfasalazine (SSZ), Are Rapidly Effective in Immune Checkpoint Inhibitors-Induced Inflammatory Arthritis**

Jessie Alperin<sup>1</sup>, Jeffrey Sarazin<sup>2</sup>, Leslie Fecher<sup>3</sup>, Christopher Lao<sup>3</sup>, Seetha Monrad<sup>4</sup>, David Fox<sup>1</sup> and **Elena Schioppa**<sup>5</sup>, <sup>1</sup>University of Michigan Medical System, Ann Arbor, MI, <sup>2</sup>Rheumatology, University of Michigan Medical System, Ann Arbor, MI, <sup>3</sup>Oncology, University of Michigan Medical System, Ann Arbor, MI, <sup>4</sup>Internal Medicine/Rheumatology, University of Michigan Medical System, Ann Arbor, MI, <sup>5</sup>Internal Medicine, University of Michigan Medical System, Ann Arbor, MI

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Immune checkpoint inhibitor (ICI) therapy is widely used in the treatment of metastatic melanoma and non-small cell lung cancer and it is under investigation for multiple other cancers (lymphoma, head and neck cancers, renal cell carcinoma, urothelial carcinoma, and breast cancer). ICIs can cause a variety of immune-related adverse events, including inflammatory arthritis (IA), which is an increasingly recognized complication. A variety of interventions directed at ICI-induced IA, including corticosteroids and biologic DMARDs, have already been published with variable efficacy, but the long term side effects of glucocorticoids and malignancy risk are important challenges in this population.

**Methods:** We performed a retrospective chart review of all the cases of ICI-induced inflammatory arthritis referred to the Rheumatology service in a single academic center from January 2015 through May 2017 who have had at least one follow-up visit after treatment initiation. We abstracted demographic data, type of ICI used, swollen and tender joint counts, imaging (radiographic and/or high power Doppler ultrasound), laboratory data (C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)), serological data (Rheumatoid Factor (RF), anti-nuclear antibody (ANA) and anti-CCP antibodies), side effects from DMARDs and patterns of rheumatic treatment.

**Results:** Six patients who had a 2-month follow up were identified: age  $63 \pm 3.8$  years, BMI of  $31 \pm 7.3$  kg/m<sup>2</sup>, 5 males and 1 female, all Caucasian with stage IV metastatic melanoma (see Table); four patients developed IA after <5 months of exposure to ICI ( $7.8 \pm 5.6$  months); 2 patients developed IA 15 months after initiation of ICI with ulnar styloid erosions seen on radiographs. All patients received combinations of ipilimumab (Ipi) and/or nivolumab (Nivo) or Pembrolizumab (Pembro) prior to developing IA. At the time of our analysis, 4 patients had stopped ICIs. None of the patients had evidence of other immune/inflammatory disorders. ANA, RF and CCP were negative. Five patients received HCQ (6.5 mg/kg) and SSZ (maximum dose of 2 grams/day), and one received HCQ monotherapy; 4 patients required steroids at maximum dose of 30 mg daily; five patients completely tapered steroids by the second follow up visit; one patient had rash with SSZ. One patient achieved partial remission and 5 patients achieved complete remission of IA within 2 months.

Patient	Age(y)/ Gender	ICI	Time ICI to IA (months)/ Ongoing(Y/N)	tDMARD	Erosions	Pre-DMARD			Post-DMARD		
						joints	ESR	CRP	joints	ESR	CRP
1	66/M	Pembro, Ipi	5/Y	PLQ+SFSZ	N	2 L	19	1.5	0	n/a	2.1
2	61/M	Nivo, Ipi	5/N	PLQ+SFSZ	N	>10 S+L	23	6.3	0	2	2.1
3	59/M	Ipi, Pembro	15/N	PLQ+SFSZ	Y	4 S+L	23	0.8	1 S	22	0.2
4	65/M	Ipi+Nivo	2/Y	PLQ+SFSZ	N	6, S+L	64	1.9	0	58	1.3
5	59/F	Nivo	15/N	PLQ+SFSZ	N	2 L	54	2.8	0	11	0.9
6	68/M	Ipi+Nivo	5/N	PLQ	Y	>10 S+L	43	3.8	0	n/a	n/a

M=male; F=female; S=small; L=large

**Conclusion:** Combination non-immunosuppressive tDMARDs is a valid alternative in managing ICI-related IA, and it is rapidly effective and well tolerated. Our small series suggests a potential risk for erosive IA in patients managed on corticosteroids alone. Prospective registries are needed to stratify the risk for developing ICI-induced IA and to assess comparative effectiveness among traditional and biologic DMARD regimens.

## Nailfold Capillaroscopy Is an Opportunity for Telerheumatology

Jacob R. Stever<sup>1</sup>, Nicholas Lebedoff<sup>2</sup>, Tracy M. Frech<sup>3</sup>, Lesley A. Saketkoo<sup>4</sup> and Marcus Snow<sup>5</sup>, <sup>1</sup>Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, <sup>2</sup>Internal Medicine, University of Utah, Salt Lake City, UT, <sup>3</sup>Division of Rheumatology, University of Utah, Salt Lake City, UT, <sup>4</sup>Rheumatology, Tulane University School of Medicine, New Orleans, LA, <sup>5</sup>Internal Medicine, University of Nebraska, Omaha, NE

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The 2013 classification criteria for systemic sclerosis (SSc) provide 2 points (towards a 9 point diagnosis) for patients who have abnormal capillaroscopy. In the United States (U.S.), formal capillaroscopy training programs do not exist as part of fellowship training for assessment of patients complaining of Raynaud's phenomenon. There is an effort in the European Union League Against Rheumatism (EULAR) microcirculation group to introduce training and certification for capillaroscopy in the United States (U.S.). The purpose of this project was to assess if U.S. trainees at a single center could effectively use nailfold videocapillaroscopy (NVC) with non-formal educational training provided by a local expert and through remote store-it-forward telehealth send images for additional teaching at other U.S. SSc centers. Additionally, the quality of dermatoscope images were compared to NVC to assess the role of this device for image capture.

**Methods:** Two trainees (JS and NL) had health related training in capillaroscopy, which involved observation and then hands-on performance of nailfold video capillaroscopy (NVC, Optilia®) and dermatoscope (Dermalite®) capillaroscopy on SSc registry patients. Subsequently 20 SSc patients had two NVC (Optilia®) and dermatoscope (Dermalite®) capillaroscopy on 8 digits obtained (Figure 1). These 153 images (2 patients had multiple auto-amputation) were interpreted by the two trainees and then sent to 2 U.S. members of the EULAR microcirculation group to determine whether normal versus abnormal could be effectively obtained and determined by dermatoscope, and whether trainees could identify abnormal features of NVC.

**Results:** The inter-rater reliability of the 153 NVC images was 0.82. Based on the NVC images all 20 patients would have been appropriately referred to a SSc center for further evaluation, but 29 images had additional abnormality features (micro-hemorrhage and neo-angiogenesis) found by the expert reviewers. Dermatoscope was able to recognize abnormal capillaroscopy in 13 of the 20 patients (65% of the time; Figure 1).

**Conclusion:** Store-it-forward capillaroscopy image capture with expert read is a potential modality to integrate nailfold capillaroscopy into U.S. fellowship training programs. While NVC is the gold-standard device for capillaroscopy, dermatoscope can be effectively used to evaluate the complaint of Raynaud's phenomenon. This pilot suggests that nailfold capillaroscopy is an opportunity to integrate telehealth technology into rheumatology practice and educational curriculums.

## Clinical Significance of KL-6 and SP-D As Serum Markers for Interstitial Lung Disease in Patients with Connective Tissue Disease

Kyung-Eun Lee<sup>1</sup>, Ji-Hyoun Kang<sup>2</sup>, Dong-Jin Park<sup>2</sup> and Shin-Seok Lee<sup>2</sup>, <sup>1</sup>Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South), <sup>2</sup>Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the association between serum levels of Krebs von den Lungen-6 (KL-6) and surfactant protein-D (SP-D) and the clinical manifestations and severity of interstitial lung disease (ILD) in patients with connective tissue disease (CTD).

**Methods:** Eighty patients with various CTDs were included, as follows: 33 with rheumatoid arthritis (RA), 19 with systemic lupus erythematosus (SLE), 10 with systemic sclerosis (SSc), 9 with Sjogren's syndrome (SS), and 9 with inflammatory myositis. KL-6 and SP-D levels were measured using an enzyme-linked immunosorbent assay and defined as abnormal if KL-6  $\geq 500$  U/mL and SP-D  $\geq 110$  mg/mL. All patients were simultaneously evaluated for parameters related to disease activity using laboratory tests and a pulmonary

function test, and interstitial lung abnormalities (ILA) using chest computed tomography (CT). Patients were subclassified according to ILA score: 0 for no ILD, 1 for indeterminate ILD, 2 for mild ILD, and 3 for advanced ILD based on chest CT scans.

**Results:** In all, 29 patients had radiologically advanced ILD, 18 had mild ILD, 18 had indeterminate ILD, and 15 had no ILD. A higher ILA score was associated with more severe dyspnea, and decreased volume and percent of functional vital capacity, forced expiratory volume in 1 s, and diffusion capacity of carbon monoxide. As clinical manifestations, a higher ILA score was associated with a higher GAP index but not with the parameters of disease activity. A higher ILA score was associated with higher levels of KL-6 and SP-D and a higher percentage of subjects with abnormal levels, and this was more pronounced in SLE, SSc, and SS than in RA.

**Conclusion:** Serum levels of KL-6 and SP-D are associated with the radiological severity of ILD. Hence, these can serve as markers for ILD severity, especially in SLE, SSc, and SS.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Acute anterior uveitis (AAU) is the most common form of uveitis. One third of AAU patients may present recurrences, some requiring systemic disease-modifying antirheumatic drugs (DMARDs). The aim of this study was to perform a systematic and critical literature review on the use of synthetic and biologic DMARDs in AU.

**Methods:** A systematic literature review was performed. Studies were identified by sensitive search strategies in the main bibliographic databases (Medline, Embase and Cochrane Library) up to July 2016. Mesh terms and text word were used. We selected articles that analyzed, in AU patients, the efficacy or safety of DMARDs and biologic therapies including: flares, time to flare, visual acuity, corticoid sparing (CS) effect, etc. Any type of study except case series or case reports with less than 10 patients was eligible. Two reviewers (AG and EL) screened the titles and abstracts of the retrieved articles independently. Both reviewed the selected articles in detail and collected data from the studies by using ad hoc standard forms. A hand search was completed by reviewing the references of the included studies. Quality was graded using the Jadad scale and the Oxford Centre for Evidence-based Medicine Levels of Evidence. Evidence and results tables were produced.

**Results:** A total of 14 articles included, 2 randomized controlled trials and 12 observational studies, with low or moderate quality. The mean duration/follow-up, number (n) and patients characteristics were highly variable. The definition of the anatomic classification of AUs was generally not clear. Systemic DMARDs were used, including Methotrexate (MTX), Azathioprine (AZA), Cyclosporine A (CsA) and anti-TNF $\alpha$  (Adalimumab (ADA), Golimumab (GLM)), at usual dosage prescription. Number of flares, disease activity and corticoid sparing (CS) effect were the most common outcomes, with big differences between studies in variables included and their definitions. MTX showed efficacy in disease remission, n of flares, time between flares, lower activity and CS effect. SSZ showed lower

n of flares and improvement in visual acuity (VA) in AS-associated AAU patients. AZA (low quality RCT) showed no differences in VA, Tyndall, flares or IOP. A prospective OS showed lower activity and CS effect. CsA (moderate quality OS) showed efficacy improving activity and as CS agent (mid/long term). Anti-TNF $\alpha$ : ADA, (2 OSs) with SpA-associated AU patients lowered n of flares (mid/long term), can improve VA, Tyndall and be used as CS agent. GLM in AU patients refractory to DMARDs (some to other biologics), showed CS effect in 2 studies. One showed improvement in VA and Tyndall, but not in OCT or n of flares. Adverse events recorded were those usually registered for all these drugs.

**Conclusion:** MTX showed efficacy in idiopathic and systemic disease-associated (SDA) AU.(EL 2c; RG B), SSZ showed efficacy in idiopathic and SDA AU.(EL 3a; RG B-C), AZA seems to be effective in naïve and DMARDs-refractory AU (EL 3a; RG C), CsA showed efficacy in idiopathic and SDA AU (EL 2c; RG B-C), ADA showed efficacy in idiopathic and SDA AU, naïve or DMARDs-refractory AU (LE 2c; RG B), GLM showed efficacy in DMARD-refractory AU (2nd line and further) and other biologic therapies (EL 3a; RG B-C).

## Elderly – Onset Sarcoidosis: a Single Center Comparative Study

Senol Kobak<sup>1</sup>, Fidan Yildiz<sup>2</sup>, Huseyin Semiz<sup>3</sup> and Mehmet Orman<sup>4</sup>, <sup>1</sup>Rheumatology, Istinye University Faculty of Medicine, Istanbul, Turkey, <sup>2</sup>Chest Diseases, Medicalpark Hospital, İzmir, Turkey, <sup>3</sup>Internal Medicine, Ege University Faculty of Medicine, İzmir, Turkey, <sup>4</sup>Statistics, Ege University Faculty of Medicine, İzmir, Turkey

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Sarcoidosis is a chronic granulomatous inflammatory disease characterized with non-caseified granuloma formation. It is rarely affects patients older than 65 years old..The purpose of this study is to compare and evaluate the demographic, clinical and laboratory features of elderly-onset(EOS) and young-onset sarcoidosis(YOS) patients.

### Methods:

One hundred and thirty one patients diagnosed with sarcoidosis according to clinical, radiologic and histopathological evaluation were included in this study.The patients with initial symptoms started after age 65 were accepted as EOS. Demographic, clinic, radiologic, and laboratory data and the medication which the patients recieved were recorded and retrospectively evaluated.

### Results:

Twenty(15.3%)of 131 patients were diagnosed as EOS, and 111(84.7%) patients were evaluated as YOS. Fifteen of 20 EOS patients were female and 5 of them were male. Average duration of the disease was determined as 38.4months for YOS and 22.5months for EOS(p=0.556).Delay of the diagnosis was 12months for YOS while it was 3months for EOS(p=0.001).Higher rates of fatigue, comorbid diseases and more Hydroxychloroquine(HQ) use were detected in EOS patients comparing to YOS(p=0.010, p=0.003 and p=0.039 respectively).There was obviously more disease modifying anti-rheumatic drugs(DMARDs) use by YOS group but statistical difference wasn't significant. The 3-year survival rate after diagnosis of sarcoidosis was %95 in the EOS group, compared with %100 in the YOS group

### Conclusion:

In this study we showed that YOS and EOS patients may be presented with different clinical, and laboratory features. EOS patients are characterized with higher rates of fatigue and comorbid diseases, less inflammatory sign and delayed diagnosis, and less DMARDs

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

There are no validated classification criteria for relapsing polychondritis (RP). Given that some manifestations of RP are organ- or life-threatening, it is imperative that classification criteria in RP have adequate sensitivity to identify cases early during the disease. The objective of this study was to use consensus procedures to select a set of items with potential utility to classify RP, focusing on items related to disease activity and organ damage.

### **Methods:**

An international, multidisciplinary group of physicians with experience managing RP was formed. Based on a systematic review of publications reporting on observational cohorts, case series, and case reports data in RP, combined with clinical experience, a list of potential candidate items for classification criteria was generated. All group members were invited to participate in an online Delphi exercise for item reduction. Survey participants rated each potential candidate item on a scale of 1-10 (ranging from 1=completely inappropriate to 10=completely appropriate for inclusion as a potential classification criteria item in RP). Items with a median response score of  $\leq 4$  were eliminated from further consideration. Items with a median score of  $\geq 7$  were retained. Items with a median score  $>4$  and  $<7$  were termed indeterminate and will be subject to 1-2 additional Delphi rounds

### **Results:**

A list of 142 candidate items was generated related to patient-reported symptoms, physician-observed findings, laboratory, and imaging assessments in RP. The first round of the Delphi survey led to a response rate within 16 days of 81% (25/31). Respondents were from 6 countries (United States=15; France=3; Japan=3; Canada=2; United Kingdom=1; India=1) representing multiple subspecialties (Otolaryngology=4; Pulmonology=3; Adult Rheumatology=14; Pediatric Rheumatology=4). Based on survey responses, 49 items were retained, 34 were eliminated, and 59 were indeterminate. Most retained items were related to the respiratory, head/eyes/ears/nose/throat, and musculoskeletal systems (**Figure**). Items related to damage (e.g. deformed ear, tracheomalacia) were consistently rated higher than features of active disease (but non-damage) (e.g. red ear, anterior neck tenderness). The only laboratory items retained were a negative test for anti-neutrophil cytoplasmic antibody and a positive test for anti-collagen II antibody.

## Conclusion:

This consensus exercise generated a preliminary set of candidate items for use in developing classification criteria for RP through prospective data collection. The final rounds of the Delphi will help refine what will be an extensive set of candidate items related to disease activity or damage. Development of classification criteria that represent the broad spectrum of clinical presentations in RP will facilitate the design and implementation of clinical trials in this complex disease.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To study the clinical characteristics of IgG4-RD patients in China

**Methods:** Patients were recruited from a prospective cohort study of IgG4-RD in Peking Union Medical College Hospital between 2011 and 2016, who were followed-up for more than 6 months. The demographic characteristics, organ involvements, the laboratory examinations and treatment were analyzed

**Results:** A total number of 346 patients were enrolled, including male 230 (66.5%), female 116 (33.5%). The age of disease onset was  $53.8 \pm 14.2$  years old. The mostly common related organ onset was lymphadenopathy (56.4%), submandibular glands (52.6%). Other affected organs included: swelling of the lacrimal glands (46.5%), autoimmune pancreatitis (38.4%), pulmonary involvement (28.0%), sclerosing cholangitis (25.4%), naso-sinusitis (23.4%), salivary swelling were (21.7%), retroperitoneal fibrosis (19.9%), large arteries involvement (9.5%), kidney involvement (6.9%), skin lesions (6.4%). Rarely involved organs were thyroid glands, pituitary glands, gastrointestinal tract, pachymeningitis, pericardium, sclerosing mediastinitis and orchid. The majority of patients had multi-organ involvement, 74.3% of patients with 3 and more organs involvement 18.2% and 7.5% of patients with 2 and single organ involvement respectively. The average IgG4-RD responder index (IgG4-RD RI) was  $13.21 \pm 5.7$ . History of allergy was found in 172 (49.7%) patients. Of the laboratory tests, elevated serum IgG4 levels were found in 285 (94.1%) patients, and positively correlated with IgG4-RD RI. Of treatment, 33.5% patients received treatment of glucocorticoids, 52.6% patients were treated with glucocorticoids combined with immunosuppressors, 3.2% patients were treated with immunosuppressors, and 9.0% patients received no drugs at baseline evaluation. Most patients improved after regular drug treatment.

**Conclusion:** IgG4-RD is a systemic fibro-inflammatory disease with multiple organs involvement. The mostly common related organs respectively were lymph node, submandibular glands, and pancreas. Glucocorticoids and immunosuppressors were effective treatment strategies of IgG4-RD.

## **The Difference between International Criteria for BD (ICBD) and the BD Criteria of International Study Group (ISG) in Our Behcet's Disease (BD) Patients Who Fulfilled Japanese BD Criteria**

**Tsuyoshi Kobashigawa**, Yuki Nanke, Hisashi Yamanaka and Shigeru Kotake, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In Japan, we have a criteria for BD since 1988. (International Journal of Tissue Reactions. 1988; 10; 59-65.) In Japanese patients diagnosed according to this Japanese BD criteria, the recent number of patients with the ocular lesions decreased compared with those with of the passed time; however, those the intestinal lesions increased. Moreover, a new international criteria for Behcet's disease (ICBD) was proposed in 2006. (Clinical and Experimental Rheumatology. 2006; 24; S13, S14-15.) In ICBD the intestinal lesions were excluded as well as the criteria of international study group (ISG) in 1990 (Lancet. 1990; 335; 1078-80.). The purposes of this study are to analyze the clinical features of BD with comparison among four 5-year-patient groups, and to search which criteria was useful for Japanese BD patients between ISG and ICBD.

**Methods:** We enrolled our 264 (67.2%) BD patients out of 393. We diagnosed the patients having BD with Japanese BD criteria. We divided our patients to four groups with ones arriving period of 5 years: 49 BD patients were arrived at our clinic and started following until 2000, 70 patients from 2001 to 2005, 77 from 2006 to 2010, and 69 from 2011 to 2015, and compared symptoms of BD among four groups. We then analyzed the escape rate of our Japanese BD patients when we evaluated between ISG and ICBD. Moreover, we compared each rate, which criteria will be more usefull for Japanese BD patients comparing escape rate with chi square test.

**Results:** The characteristics of our 264 BD patients were as described below: 264 recurrent oral aphtous ulcers (100.0%), 206 genital ulcers (78.0%), 103 ocular manifestations (39.0%), 246 skin manifestations (93.2%), 161 arthritis (61.0%), 7 pathergy tests (2.7%), 71 intestinal lesions (26.9%), 23 neural lesions (8.7%), 22 vascular (8.3%), 11 epidemittis (4.20%), 75 male (28.4%), 136 HLA-B5 (51.5%), 86 HLA-B51 (32.6%), 16 HLA-A26 (6.1%). There was no significant differentiations among periods. The escape rate of our BD patients using ISG was 12.9% (n=34) and that using ICBD was 23.4% (n=15), and statistical analyses showed that ICBD may be useful criteria for Japanese BD patient (chi's  $P < 0.005$ :  $p = 0.0044$ ).

**Conclusion:** The clinical features of our BD patients did not change among four 5-year periods. In our BD patients diagnosed with Japanese BD criteria, the diagnosing criteria for BD called ICBD was better item than ISG.

### PROBLEMS IN THE DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER (FMF) IN TURKEY

**Background/Purpose:** The diagnosis of FMF can be missed or delayed even in a country like Turkey, an endemic region for FMF (1). We compared the duration of delay in diagnosis before and after year 2000, and assessed the problems related to a late diagnosis of FMF.

**Methods:** We studied 177 (104 F, 73 M) consecutive patients with FMF seen at our rheumatology outpatient clinic. Patients completed a self-administered questionnaire that assessed initial symptoms, previous diagnoses and treatments received before a formal diagnosis of FMF. Patients were divided in 2: Group 1, which included 128 patients seen for the first time by a physician before 2000 and Group 2, which included 49 patients seen in or after year 2000.

**Results:** The median age of the patients was 33 years [IQR:26-43]. The initial symptom was abdominal pain in the majority (n = 156, 88 %), followed by fever (n=139, 79%), arthritis (n=123, 69%) and pleuritic pain (n=53, 30%).

The median age at initial symptom was 8 years (IQR:5-14). The median delay in diagnosis was 11 years (IQR:4-18). This was significantly shorter in Group 2 (med. 4 years) than that observed in Group 1 (med. 15 years) as shown in Table.

A total of 146 patients (82 %) were diagnosed with one or more diseases other than FMF. These were appendicitis (n=79, 45 %), acute rheumatic fever (n=65, 37 %), gastro-intestinal diseases (n= 42, 23 %), inflammatory arthritis (n=28, 16 %), kidney stones (n=18, 10

%), gynecological diseases (n=15, 8 %) and others (n= 14, 8 %). As shown in Table, the frequency of patients with misdiagnosis, was lower in Group 2 (76 %) compared to Group 1 (85 %).

A total of 88 patients (50 %) received other long-term treatments, mainly monthly penicillin (n=48), prior to colchicine. There were 53 surgical interventions in 48 patients (27%), before the diagnosis of FMF, the most common being appendectomy in 45, followed by gastrointestinal tract surgeries (2 gastrectomies, 2 cholecystectomies, 2 intestinal herniation operations) in 6. It was noted that, the frequency of surgical operations was somewhat less in Group 2 (22 %) compared to Group 1 (30%) (Table).

The presence or absence of MEFV mutations was assessed in 69 patients (39 %) before the diagnosis or after to confirm the diagnosis. As expected, this was significantly more frequent in Group 2 (51 %) compared to Group 1 (34 %) (Table).

73 patients (41%) were diagnosed as FMF only after it was found out someone else in the family or a friend had a similar diagnosis. The frequency of these patients was similar when Group 1 and 2 were compared

**Table: Demographic and clinical characteristics of patients**

	Group 1, (n=128)	Group 2, (n=49)	p
Male/Female	48/80	25/24	Non-significant
Current age, med [IQR]	40[31-51.5]	32[24.5-38]	<0.001
Delay in dx, med [IQR]	15 [8-22]	4 [1-9]	<0.001
Misdiagnosed, n (%)	109 (85)	37 (76)	0.013
Appendicitis, n (%)	59(46)	20(41)	
ARF, n (%)	54(42)	11(9)	
Gastro-intestinal diseases, n (%)	30(23)	12(9)	
Inflammatory arthritis , n (%)	22(17)	6(12)	
Kidney stones , n (%)	15(12)	3(6)	
Gynecological diseases , n (%)	11(9)	4(8)	
Others , n (%)	14(11)	-	
Surgery before dx, n (%)	37(30)	11(22)	0.3
Appendectomy	34(27)	11(22)	
Gastrointestinal Surgery	6	-	
Gynecological surgeries	1	-	
Others	1	-	
Penicilin treatment, n (%)	43(34)	5(10)	0.002
Dx'ed after seeing another person's dx, n (%)	50(39)	23(47)	0.5
MEFV Gene analyses available	44(34)	25(51)	0.035

**Conclusion:** Although there is considerable decrease in delayed diagnosis of FMF, there is still a significant amount of misdiagnoses after the year 2000, even in a geography where FMF is highly prevalent.

# Exposure to Fine Particle Air Pollution and Anti-Nuclear Antibodies (ANA) in a Large Population-Based Sample

Sasha Bernatsky<sup>1</sup>, Audrey Smargiassi<sup>2</sup>, Lawrence Joseph<sup>3</sup>, Patrick Belisle<sup>3</sup> and Marvin J. Fritzler<sup>4</sup>, <sup>1</sup>Divisions of Rheumatology and Clinical Epidemiology, Research Institute of the McGill University Health Centre, Montreal, QC, Canada, <sup>2</sup>Université de Montreal, Montreal, QC, Canada, <sup>3</sup>Research Institute of the McGill University Health Centre, Montreal, QC, Canada, <sup>4</sup>Medicine, University of Calgary, Calgary, AB, Canada

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fine particle air pollution (PM<sub>2.5</sub>) has been associated with many conditions including systemic autoimmune rheumatic diseases. Our work has previously suggested an association between estimates of exposure to industrial emissions of PM<sub>2.5</sub> and anti-Cyclic Citrullinated Peptide (CCP), but no one to date has assessed anti-nuclear antibodies (ANA). Our purpose was to determine the association of ANA with estimates of exposure to PM<sub>2.5</sub> (industrial emissions recorded by Environment Canada, and estimates from satellite imagery).

**Methods:** We assessed 2304 subjects from a large general population cohort, drawn from four census metropolitan areas in the province of Quebec, Canada. Within these 2304 patients, we performed multivariable logistic regression models for the outcome of positive ANA, assessing for independent effects of PM<sub>2.5</sub> exposure (PM<sub>2.5</sub> emissions and PM<sub>2.5</sub> satellite estimates), adjusting for age, sex, smoking, and self-reported French Canadian ancestry. Exposures were determined from baseline six digit postal code of residence, to industrial PM<sub>2.5</sub> emitters, estimated using Environment Canada's National Pollutant Release Inventory. Our analyses assessed tons of PM<sub>2.5</sub> annual industrial emissions, distance to major industrial emitters (industry emitting more than an average of 100 tons of PM<sub>2.5</sub>) and regional satellite PM<sub>2</sub>.

**Results:** In multivariate analyses, the only variable convincingly associated with ANA positivity was older age (1.020, 95% CI 1.007, 1.033). Our primary multivariate estimate of the odds ratio (OR) related to ANA positivity was 1.001 (95% CI 1.000, 1.002) for PM<sub>2.5</sub> emissions. No clear association was seen with distance to emitters in any of our models, nor with PM<sub>2.5</sub> from satellite images, though many of our estimates being relatively imprecise and did not preclude an effect of air pollution on ANA positivity.

**Conclusion:** In these preliminary analyses, we did not see strong associations of ANA positivity with PM<sub>2.5</sub> exposure. We are currently exploring additional models and considering the effects of other air pollution exposures, including nitrogen dioxide (NO<sub>2</sub>) and ultrafine particles, in a larger sample.

## Epidemiology of Interstitial Pneumonia with Autoimmune Features

Robert Mango<sup>1</sup>, Ashima Makol<sup>2</sup>, Cynthia S. Crowson<sup>3</sup>, Jay H. Ryu<sup>4</sup> and Eric L. Matteson<sup>2</sup>, <sup>1</sup>Internal Medicine, Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN, MN, <sup>2</sup>Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN, <sup>3</sup>Health Sciences Research, Mayo Clinic College of Medicine and Science, Rochester, MN, <sup>4</sup>Division of Pulmonary and Critical Care Medicine, Mayo Clinic College of Medicine and Science, Rochester, MN

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interstitial pneumonia with autoimmune features (IPAF) is a subset of interstitial lung disease (ILD) with clinical features suggestive of, but not sufficient for, a diagnosis of a connective tissue disease (CTD). Previous reports suggest it has a prognosis intermediate between that of idiopathic pulmonary fibrosis (IPF) and that of CTD related ILD (CTD-ILD). The epidemiology and progression of IPAF in a population based cohort has not been defined.

**Methods:** All residents of a geographically-defined area who first met the Fischer criteria for IPAF (Eur Respir J 2015; 46; 976-987) in 2000-2015 were identified. Manual chart review of all patients with ILD with abnormal serologies listed in the IPAF criteria, or with at least one rheumatology evaluation was performed. Those with a diagnosis of a CTD prior to or within 6 months after ILD diagnosis were excluded. Baseline serologies, clinical characteristics, comorbidities, ILD subtype, pulmonary function tests, and echocardiograms were collected. Incidence rates were calculated and adjusted to the US white 2010 population. Mortality was estimated by Kaplan-Meier methods. The performance of GAP and ILD-GAP prognostic models was assessed using standardized incidence ratios (SIR).

**Results:** We identified 17 cases meeting classification criteria for IPAF (7 [41%] female; mean age: 72.5 years; range 35-89), with an estimated incidence of 1.2 per 100,000 (95% CI 0.6 – 1.8). The incidence increased over time ( $p=0.024$ ), perhaps reflecting increasing surveillance for CTD-ILD. Based on high resolution chest CT, there were 10 (59%) with nonspecific interstitial pneumonia (NSIP), 6 (35%) with usual interstitial pneumonia (UIP), and 1 with organizing pneumonia. Seven patients (41%) were never seen by a rheumatologist but met criteria based on serologies. Antinuclear antibodies were positive in 8 patients (73%). Six patients (40%) had a DLCO < 40% or were too ill to perform DLCO at the time of meeting IPAF criteria, and these were over-represented in the UIP group ( $p = 0.036$ ). Only 4 patients (24%) had pulmonary hypertension. None of the patients progressed to a diagnosis of a CTD. During a median of 2.6 years of follow-up, 10 patients died (5 year survival rate: 36%; 95% CI 18- 71; median: 1.5 years). Both the GAP and ILD-GAP models underestimated mortality (SIR for GAP: 2.16; 95% CI: 1.12-4.15; SIR for ILD-GAP: 4.79; 95% CI: 2.49-9.21). In subgroup analysis, this appeared to be due to underestimation for patients with UIP.

**Conclusion:** The incidence of patients with ILD meeting criteria for IPAF in this first ever population based study was 1.2 per 100,000, although it may be increasing over time. Patients are generally older, with mean age at the time of meeting IPAF criteria of 72.5 years. Mortality in this population-based cohort was higher than previously published estimates for IPF or CTD-ILD. The GAP and ILD-GAP prognostic models underestimated mortality, particularly in patients with a UIP pattern. Overall, outcomes in this population-based cohort were significantly worse than those previously reported for IPAF cohorts at tertiary care centers.

## Immune-Related Adverse Events in Cancer Patients Treated with Immune Check Point Inhibitors: A Single Center Experience

Taylor Doberstein<sup>1</sup>, Aneet Kaur<sup>1</sup>, Elizabeth Field<sup>2</sup> and Namrata Singh<sup>3</sup>, <sup>1</sup>Internal Medicine, University of Iowa, Iowa City, IA, <sup>2</sup>Iowa City VA, Iowa City, IA, <sup>3</sup>Internal Medicine, University of Iowa Hospitals and Clinics and Iowa City VA, Iowa City, IA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The immune checkpoint inhibitors (ICIs) anti-CTLA4 (cytotoxic T-lymphocyte associated protein 4) and anti-PD1 (programmed death cell protein 1) have revolutionized cancer treatment. ICIs interrupt immune inhibitory pathways, thereby discharging CD8-mediated killing of cancerous tissue (1). However, ICIs also can provoke powerful autoimmune reactions in other organ systems (2). As ICI use becomes more widespread, more immune-related adverse events (IrAEs) are being reported. Our aim was to investigate the incidence and nature of IrAEs in cancer patients treated with anti-CTLA4 or anti-PD1 at our institution.

**Methods:** We performed a retrospective chart review of all patients treated for cancer with anti-PD1 (pembrolizumab or nivolumab) or anti-CTLA4 (ipilimumab) at the University of Iowa Hospitals and Clinics between January 2014 to April 2016. Demographic data, cancer type and stage, autoimmune diagnosis and symptoms, and drug treatment information were extracted. IrAEs included any new autoimmune disorder (i.e. inflammatory arthritis) or disease flare of pre-existing autoimmune disorder that occurred after start of ICI treatment.

**Results:** We identified 220 patients prescribed pembrolizumab, nivolumab, or ipilimumab. Fifteen percent (33/220) developed IrAE, 16 with anti-CTLA4 (Table 1) and 17 with anti-PD1 (Table 2). Two patients on anti-PD1 developed new onset inflammatory arthritis and were successfully treated with corticosteroids and methotrexate. Twelve patients were diagnosed with colitis, 9 with thyroid disorder or worsening of previously stable thyroid disease, 4 with pneumonitis, 2 with hypophysitis, 1 with myasthenia gravis flare, 1 with optic neuritis, 1 with psoriasis flare, and 1 with adrenal crisis. The severity of IrAEs required discontinuation of cancer therapy in 39% of those with IrAEs and 5.9% of all ICIs-treated patients.

**Conclusion:** Gastrointestinal and thyroid IrAEs were by far the most common, accounting for nearly two-thirds of all IrAEs. Only 2 patients developed inflammatory arthritis, and corticosteroids and methotrexate controlled symptoms in both. Additional studies are needed to determine whether one can maintain more patients on ICI treatment by earlier referral to specialist for appropriate intervention of IrAEs.

Table 1. Patient demographics, cancer type and stage, IrAE reported, and its treatment while on anti-CTLA4

<u>Patient</u>	<u>Gender</u>	<u>Age</u>	<u>Medication Received</u>	<u>Cancer Type</u>	<u>Stage</u>	<u>IRAE Reported</u>	<u>Treatment</u>

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Polymyalgia rheumatica (PMR) is an inflammatory rheumatic disorder which usually affect patients over 65 years old. Different poor prognostic factors are involved in prednisone response including rapid decrease of prednisone dose or female sex. To date, there is no data relating the impact of the age on therapeutic response in PMR. The aim of this study was to compare, in case of PMR, the response to prednisone in patients younger than 60 to patients over 65 years old.

## Methods:

This was a retrospective, monocentric study. We included patients with PMR, meeting ACR 2012 criteria. Patients were classified into two groups, one group with patients less than 60 years, and one group with patients over 65 years. We registered demographic, clinical, biological, and imaging data as well as therapeutic response profile. The local inflammation was evaluated with PET scan, by studying each anatomical site usually affected by PMR. Then, the rate of inflammation was scored from 0 to 3, according to the intensity of uptake compared to liver. The treatment was standardized. The initial dose of prednisone was of 0.3mg/kg/j during the two first weeks, then, the dose was slowly decreased by 10 % each month. The main endpoint was a steroid dependence defined by the recurrence of PMR symptoms and / or the increase of CRP at two times during the decrease of prednisone.

## Results:

We included 14 patients younger than 60 years old (average age 54 $\pm$ 0.8 years) and 28 patients older than 65 years old (average age 75.8  $\pm$  1.5 years). The population younger than 60 years was mainly male (60% VS 27 %,  $p < 0.05$ ). Both groups were similar in terms of morning stiffness (2,1  $\pm$  0,4 VS 1,9  $\pm$  0,3 hours;  $p > 0.05$ ), disease duration (4,2  $\pm$  0,8 VS 4,1  $\pm$  0,6 months;  $p > 0.05$ ), leukocytes rate (8,3  $\pm$  1,37 VS 8  $\pm$  0,7 G/L;  $p > 0.05$ ) and percentage of antinuclear antibodies rate over 1/320 (20 % VS 10%;  $p > 0.05$ ). However, regarding to local inflammation, the intensity of FDG uptake highlighted by the Pet scan was lower among young patients (score of 16,9  $\pm$  1,7 VS 26,5  $\pm$  3,0;  $p < 0.05$ ). Furthermore, we observed a significant difference concerning therapeutic response according to the age: 60% of the young patients developed a steroid dependence compared to 20% in group of old patients ( $p < 0.05$ ). Moreover, the introduction of methotrexate was necessary for 35% of the young patients against 6.5% ( $p < 0.05$ ).

## Conclusion:

Our study is the first to show the age as a bad prognosis factor in case of PMR. This difference is independent to the systemic and local inflammation (assessed by the PET score) is more important in elderly people. Young patients with PMR are mostly men and are more dependent on steroids. Thus, methotrexate could be straightaway proposed, particularly in patient younger than 60 years old.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Familial Mediterranean fever (FMF) is an autoinflammatory disease. Colchicine is used in FMF patients for preventing attacks and amyloidosis. There were conflicting reports as to existence of proarrhythmic electrocardiographic (ECG) findings in FMF(1,2). Furthermore, studies showed that colchicine might be protective in non FMF patients against atrial fibrillation(3). Besides, its effect on FMF patients was not evaluated. In the present study, in order to evaluate effect of colchicine treatment on arrhythmia risk in FMF patients, we assessed ECG of the new diagnosed FMF patients for arrhythmatogenic anomalies at baseline and after one year of colchicine treatment.

**Methods:** Twenty eight new diagnosed FMF patients who fulfilled Modified Tel-hashomer criteria were recruited to study. After baseline measurements, colchicine treatment was started. ECG, laboratory parameters, demographic and disease related parameters of the patients were obtained at the first visit and after one year of treatment. We evaluated the risk of atrial arrhythmia with P dispersion and risk of ventricular arrhythmia with Tp-E, Tp-E/Qt, Tp-E/Qt<sub>c</sub> (2). P dispersion  $\geq 40$  ms was accepted as arrhythmatogenic anomaly for atrial arrhythmias(2).

**Results:** Demographic, laboratory and disease related characteristics of the patients at baseline were shown in Table 1. There was no statistical difference between the number of patient with arrhythmatogenic P dispersion at baseline and after one year of treatment. Furthermore, Tp-E, Tp-E/Qt values decreased with treatment (Table 2).

Table 1. Demographic, laboratory and disease related characteristics of the FMF patients at baseline

	Patients (n=28)
Gender (M/F)	8/20
Age	31.4± 8.2
Age at first attack	6.2±3.7
BMI (kg/m <sup>2</sup> )	26.4±3.4
Smoking (%)	7 (25.0%)
Co-morbid illnesses* (%)	3 (10.7%)
Frequency of attacks (/year)	10.6±7.0
Duration of attacks (day)	3.3±1.5
Main FMF symptom	
Peritonitis (%)	21(75.0%)
Fever (%)	2(7.1%)
Musculoskeletal symptoms (%)	5(17.9 %)
Creatinine (mg/dL)	0.62±0.17
ALT (IU/L)	21.68±10.39
AST(IU/L)	20.93±7.93
Albumin (g/dL)	4.55±0.26
CRP (mg/L)	19.17±31.97
Sedimentation rate (mm/h)	23.75±16.60
Spot urine protein/creatinine	0.14±11.22
WBC (/mcL)	7182.14±1701.86
Hemoglobin (g/dL)	12.55±1.81
Platelet (x10 <sup>3</sup> /mcL)	266.43±89.19
Documented tachycardia (%)	6(21.4%)
BMI: Body mass index; ALT: Alanin aminotransferase; AST: Aspartate aminotransferase; CRP: C-reactive protein; WBC: White blood cell  *Hypertension, hypothyroidism, hyperthyroidism cardiovascular diseases, coronary artery diseases, cerebrovascular diseases, chronic renal disease, chronic obstructive pulmonary disease, diabetes mellitus	

Table 2. Electrocardiographic findings and disease parameters of the patients at baseline and after one year of colchicine treatment

	Pretreatment ( n=28)	Treatment* (n=28)	P value

CRP (mg/L)	19.17±31.97	9.46±17.12	0.059
Sedimentation rate (mm/h)	23.75±16.60	16.79±14.93	<b>0.006</b>
Frequency of attacks (/year)	10.60±7.00	0.80±1.24	<b>&lt;0.001</b>
Colchicine dosage (mg)**		1.23±0.31	
* Electrocardiographic measurements and disease parameters of the patients evaluated after one year of colchicine treatment  **Actual colchicines dosage at the first year of the treatment  p<0.05 shown with bold numbers			

**Conclusion:** We found that colchicine treatment may have no effect on atrial arrhythmia risk. Furthermore, it might have favorable effect on ventricular repolarization indices and might be protective against ventricular arrhythmias and sudden death in FMF patients.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hyperferritinemia is associated with inflammatory conditions, such as rheumatologic diseases. Objectives: To determine which diseases are associated with hyperferritinemia in a tertiary hospital; to compare ferritin levels between these different entities and to evaluate relationship between levels of ferritin and mortality in these patients.

**Methods:** A retrospective study was carried out in which all patients over 18 years with at least one determination of serum ferritin equal to or greater than 1000 ng/ml were identified in the laboratory database of our hospital between 2006 and 2016. Corresponding electronic medical records were reviewed and demographic data and clinical data were collected. Mortality was assessed at the end of follow-up. A descriptive statistical analysis and logistic regression analysis were performed in order to identify variables associated with mortality.

**Results:** 1979 patients were included, 1235 men with a mean age of 63.2 years (SD 17.2). Only 36 patients (1.8%) presented a rheumatologic diagnosis as the only cause of high levels of ferritin. Still's disease and systemic Vasculitis being the main diagnoses. Table 1 shows patients' characteristics grouped according to whether the elevation of ferritin was associated with a rheumatic disease or not. Median serum ferritin and transferrin saturation in both groups were similar. Mortality was lower for rheumatologic causes (5.9% vs 37.2%,  $p < 0.001$ ). Variables that were associated with mortality in multivariable logistic regression analysis were: maximum ferritin value (OR 1.0004, 95% CI 1.0003-1.0004,  $p < 0.001$ ) and age (OR 1.03, 95% CI 1.02-1.04,  $p < 0.001$ ), whereas rheumatologic diagnosis was a protective factor for mortality (OR 0.11, 95% CI 0.03-0.47,  $p = 0.003$ ). ROC curve for ferritin and mortality showed an area under the curve of 0.59 (95% CI 0.58-0.62). Ferritin levels greater than 3000 ng/ml showed a specificity of 89.2% and a sensitivity of 19.7% for mortality, regardless of cause.

**Conclusion:** rheumatologic diseases, although representing a smaller percentage of the causes of elevation of ferritin above 1000 ng / ml, were associated with lower mortality than the non rheumatologic causes of hyperferritinemia. Serum ferritin levels were significantly associated with increased mortality regardless of the underlying cause.

Table1 Patients' characteristics grouped by cause of Hyperferritinemia

	Only rheumatologic disease (n=35)		Other causes of ferritin elevation (n=1944)		p

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Colchicine is the main therapy for familial Mediterranean fever (FMF). However, about 5-10% of FMF patients are colchicine-resistant (1). The reason for colchicine resistance in FMF patients remains obscure. ABO genes are distributed differently among socioeconomic groups, and socioeconomic status is one of the risk factors for disease severity in FMF. To date, no report has evaluated this relation. Our aim was to investigate the association between blood groups and colchicine resistance in FMF patients.

**Methods:** This is a single-center, cross-sectional study. Between January and December 2016 385 FMF patients were assessed by the Adult and Pediatric Rheumatology outpatient clinics and 297 patients had blood groups (ABO and Rh) results. The blood groups in 1000 volunteer donors who admitted to the Turkish Red Crescent Blood Service in Ankara in 2015 were enrolled as healthy control group. Demographic and clinical data collected for each patient. Response to colchicine was evaluated by two experts (YB and UK). The patients were grouped into two groups: colchicine-responsive patients (Group CR) and colchicine-unresponsive patients (Group CUR).

**Results:** 297 patients were included in the study. As expected, the acute phase reactants were higher and arthralgia/arthritis, pleuritic chest pain, and erysipelas-like erythema were more frequent in group CUR ( $p<0.05$ ). FMF patients had frequently blood group "A" than healthy controls (152/297 (51.2%) vs 420/1000 (42.0%),  $p=0.006$ ). Patients with blood group "A" had 1.5 folds higher FMF compared to "non-A" blood group [OR 1.50 (95% CI 1.11-1.87)], particularly having "A" Rh (+) blood group [OR 1.47 (95% CI 1.13-1.91)]. Furthermore, patients with blood group "A" had a better response to colchicine treatment than "non-A" blood group OR 2.21 (95% CI 1.15-4.27). On the contrary, patients with blood group "O" had prominently associated with unresponsive to colchicine (Table 1).

**Table 1.** Comparison of blood groups between colchicine unresponsive and responsive familial Mediterranean fever (FMF)<sup>a</sup> patients

ABO / Rh blood group	Colchicine unresponsive FMF <sup>a</sup> patients (n=46)	Colchicine responsive FMF <sup>a</sup> patients (n=251)	Odds ratio (95% CI)	P value
O	21 (45.7)	71 (28.3)	2.12 (1.12-4.04)	0.019
Non- O	25 (54.3)	180 (71.7)		
O Rh (-)	6 (13.0)	7 (2.8)	5.31 (1.69-16.62)	0.002
Non- O Rh(-)	40 (87.0)	244 (97.2)		

**Conclusion:** It is well known that blood group A is associated with some of the Cancer such as stomach (2). It may also be related to inflammatory diseases (3). Our results may support associations of blood groups and inflammatory diseases. We demonstrated the blood subgroups and colchicine responses, as well. ABO blood group phenogroups may be used in combination with other risk factors to identify FMF patients at high risk for colchicine resistance.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although recognized only 10 years ago, anti-N-Methyl-D-Aspartate receptor encephalitis (anti-NMDAR encephalitis) has become a leading cause of encephalitis with an identifiable etiology in pediatric patients<sup>1</sup>. The clinical presentation of patients with this disorder is quite variable but typically involves acute onset of symptoms with a characteristic progression including movement disorders, psychiatric symptoms, autonomic instability and seizures<sup>2</sup>. Despite efforts to fully understand this disorder, there continue to be gaps in our knowledge.

**Methods:** This was a retrospective chart review of patients admitted to a mid-sized tertiary pediatric hospital for medical or rehabilitative services with a diagnosis of anti-NMDAR encephalitis over a 41 month period. Only patients with laboratory evidence of anti-NMDAR encephalitis between the ages of 24 months and 18 years were included in this study.

**Results:** 12 patients met our inclusion criteria ranging in age from 2 years to 17 years of age with a median age of 9. These patients represent 12.5% of the patients with a diagnosis of encephalitis at our hospital during this time frame. 58% were female. Multiple ethnicities and socioeconomic backgrounds were represented. All but one patient presented with sudden onset of unexplained behavioral change from baseline. Mean time to diagnosis was 17 days. Eleven out of twelve patients had a minimum of 3 of the 8 characteristic symptoms noted in 90% of patients<sup>3</sup>. One patient died of overwhelming sepsis while immunosuppressed. Only one patient was found to have an associated tumor. 41% of patients required a PICU admission. All of the patients required inpatient rehabilitation. 75% of patients required gastrostomy tube placement. 25% of patients have returned to baseline and another 16% demonstrated functional gains by the most recent follow up. Many are still in the initial 12-24 months of recovery so their outcomes are still undetermined. 3 of the 12 patients in our study had pre-existing cognitive deficits or propensity for them; these patients were noted to all have incomplete recovery.

**Conclusion:** Though previously described, anti-NMDAR encephalitis may be more common than we recognize. In this study we present 12 cases of anti-NMDAR encephalitis treated at a single center pediatric tertiary care institution. We found no correlation of time to diagnosis with ethnicity or socioeconomic status. Our series corroborates the current literature with most patients presenting with acute unexplained behavioral change. Many patients required intensive care management. Their recovery is prolonged and almost invariably requires inpatient rehabilitation and often gastrostomy tubes. This suggests that management at a tertiary care center and early physical medicine and rehabilitation consultation is recommended. Recovery for these patients is mixed, and though our study is too small to reach statistical significance, we did note a trend in patients with pre-existing cognitive deficits or propensity for them who seem to have diminished recovery compared to patients with no prior history suggesting the need for further research in this area.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Peripheral ulcerative keratitis (PUK) is a severe inflammation of the outer portions of the cornea that may lead to perforation. It may be associated to rheumatic diseases. The treatment is based on systemic corticosteroids and conventional immunosuppressive drugs. In refractory cases biological therapy may be needed. Our aim was to compare anti-TNF $\alpha$  vs Rituximab (RTX) in refractory PUK.

### Methods:

Multicenter study of 24 patients with PUK. All of them presented inadequate response to corticosteroids and at least 1 systemic traditional immunosuppressive drug.

Anti-TNF $\alpha$  were used in 17 patients: Adalimumab (n=9) 40 mg/sc every 1-2 weeks, infliximab (IFX) (n=7) 3-5 mg/kg iv/4-6 weeks, etanercept (n=1) 50 mg/week. RTX was used in 7 patients 1-2 g i.v. every 6 or 12 months.

The main outcomes were Best Corrected Visual Acuity (BCVA), signs of inflammation (scleritis and episcleritis), progression to corneal thinning, central keratolysis and ocular perforation.

Comparisons were made between baseline and 1<sup>st</sup> month, 6<sup>th</sup> month and 1<sup>st</sup> year (STATISTICA, StatSoft Inc. Tulsa, Oklahoma, USA). Quantitative variables were expressed as mean $\pm$ SD or median [IQR], accordingly to its distribution. They were compared with the Student t or the Mann-Whitney U test respectively. Dichotomous variables were expressed as percentages and compared by the chi-square test.

### Results:

We studied 24 patients/32 affected eyes. The underlying diseases in the anti-TNF $\alpha$  group were Rheumatoid Arthritis (RA) (n=14), Psoriatic Arthritis (n=2) and Behçet Disease (n=1); and in the RTX group: RA (n=5), granulomatous polyangiitis (n=1) and microscopic polyangiitis (n=1).

At baseline there were no significant differences between both groups in general features or in ocular involvement (**TABLE**). Before biological therapy they had received the following systemic drugs (anti-TNF $\alpha$  vs RTX) i.v. metilprednisolone (2 vs 4), doxycycline (7 vs 1), ascorbic acid (2 vs 0), MTX (11 vs 4), AZA (1 vs 2) and others (7 vs 3). In addition, 10 patients, in both groups, had to be undergoing to surgery: amniotic membrane (n=5), penetrating keratoplasty (n=2), conjunctival resection (n=2), tissue adhesives (n=2), conjunctival flap (n=1) and lamellar keratoplasty (n=1).

Once the treatment was initiated the ocular evolution was similar (**TABLE**).

After a mean follow-up of 22.53 $\pm$ 22.60 (anti-TNF $\alpha$ ) and 22.28 $\pm$ 8.28 months with RTX the following severe side effects were observed: supraventricular tachycardia (n=1) with RTX and pulmonary Tuberculosis (n=1) with IFX.

### Conclusion:

In this study, anti-TNF $\alpha$  therapy and RTX seem to be equally effective for the treatment of peripheral ulcerative keratitis associated to rheumatic diseases refractory to conventional treatment.

## **Familial Mediterranean Fever in Chinese Adult Patients**

**Di Wu** and Min Shen, Rheumatology, Peking Union Medical College Hospital, Beijing, China

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose :**

Familial Mediterranean fever (FMF) is the most common monogenic autoinflammatory disease (AID) worldwide. There have been hardly any cases reported in Chinese population. We aimed to describe the first cohort of adult FMF patients in Chinese population.

### **Methods:**

We prospectively evaluated clinical and genetic features of adult patients suspected of FMF at the our adult AID center from April 2015 through April 2017. Patients were diagnosed clinically according to Tel-Hashomer criteria. Whole exome sequencing by Next Generation Sequencing was performed in every patient.

### **Results:**

During the study period, a total of 11 adult patients were diagnosed as FMF. The male to female ration is 8:3. The median age at disease onset was 31 years. All patients were of Chinese Han ethnicity without positive family history. All patients had intermittent self-limiting febrile episodes. Two patients had fever duration of less than 3 days, 7 patients had fever duration of 3 to 7 days. The interval between attacks ranged from weeks to years. During attacks, 7 patients developed generalized abdominal pain; 3 patients experienced chest pain with clear evidence of pleuritis, 2 of which also have evidence of pericarditis; 4 patients had arthritis involving large joints; none of the patients reported erysipelas-like skin lesion. Other manifestations included: pharyngitis, headache, aphthous stomatitis, unilateral conjunctivitis, bilateral sacroiliitis, ulcers in the stomach and small intestines. No patient had evidence of amyloidosis. Every patient carried at least one mutation in MEFV gene (1 homozygous, 6 heterozygous, 4 compound heterozygous). Allelic frequencies were E148Q (22.7%), R202Q (22.7%), G304R (18.2%), P369S/R408Q (9.1%), E148V (4.5%), M694V (4.5%). All patients had good response to low to moderate dose of colchicine, whereas the response to low to moderate dose of glucocorticoid varied considerably.

### **Conclusion:**

Our registry suggested for the first time that FMF could be identified among adult Chinese patients suffered from intermittent fever of unknown cause. The incomplete or atypical clinical manifestations of our patients compared to patients with Mediterranean origins may be related to low-penetrance and heterozygous mutations.

## Interstitial Pneumonia with Autoimmune Features (IPAF): Are There Definable Subsets?

Sepehr Mesdaghinia<sup>1</sup>, Julio Arturo Huapaya<sup>2</sup>, Brainerd Ewarlen<sup>2</sup> and Virginia D. Steen<sup>1</sup>, <sup>1</sup>Rheumatology, MedStar Georgetown University Hospital, Washington, DC, <sup>2</sup>Medicine, MedStar Georgetown University Hospital, Washington, DC

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

#### - Background/Purpose:

Interstitial lung disease (ILD) can be an early manifestation of an occult connective tissue disease (CTD). It is important to separate these patients from Idiopathic pulmonary fibrosis (IPF), since the outcome and treatment are different. Recently, an international task force proposed criteria for patients with ILD and at least one feature from clinical, serologic or morphologic domains, calling it 'Interstitial Pneumonia with Autoimmune Features (IPAF)' (Fischer, 2015). We carefully reviewed ILD patients seen since 2008 to see if they had features suggestive of CTDs and also a possible flavor to help define subsets.

#### - Methods:

We identified 374 patients with ILD who were seen at rheumatology and pulmonary clinics. Patients with clear IPF or a definable CTD were excluded (n=276) and the remaining 98 patients were thoroughly reviewed for the demographic, clinical, laboratory, and radiographic features. Those featured were entered in Excel database and analyzed from different aspects.

#### - Results:

Of these 98 patients with ILD, 66 met criteria for IPAF, 14 patients met criteria for a CTD, 3 patients had IPF and 15 patients did not meet criteria for IPAF primarily due to lack of rheumatologic evaluation or complete serologic testing. Among 15 patients without IPAF, 4 patients had elevated CPK and aldolase that could not be used towards IPAF criteria. In comparison with IPF, our IPAF patients were younger (mean age 60.7). There were more women and African Americans (74% and 46% respectively) and smoking history did not seem to be a major contributing factor (only 32%), (Table 1). Table 2 describes the features (domains) that led to the diagnosis of IPAF. Among these IPAF patients, 77% had features suggestive of a specific CTD with scleroderma the most frequent at 41% (Table 3). Some patients did not have enough features to suggest a possible CTD (23%).

**- Conclusion:**

IPAF is an important subgroup of patients who need to be better characterized. These patients are more commonly female and have serologic abnormalities. Further consideration may be helpful to include some other features in the criteria (e.g. elevated muscle enzymes). A large portion of patients with IPAF (77%) appeared to fit into a CTD subgroup which could be helpful in determining the best treatment.

Table 1- Characteristics of IPAF patients in our study in comparison to IPF from literature

Characteristics	IPAF (%)	IPF %
Mean Age (years)	60.7	66
Female	49 (74)	40
Male	17 (26)	60
White	22 (33.3)	N/A
African American	31 (47)	N/A
Asian	4 (6)	N/A
Hispanic	5 (8)	N/A
Never Smoker	45 (68)	28
Former Smoker	20 (30)	72
Active smoker	1 (1.8)	-

Table 2- IPAF features seen in our patients

Domains	Total (n=66)
Clinical	48
Serologic	61
Morphologic	65
Clinical and Serologic	45
Clinical and Morphologic	47
Serologic and Morphologic	60
All three domains	42
Total	66

Table 3- Possible CTD subsets of IPAF patients based on clinical and laboratory features

Possible CTD subset	Frequency	Percent (%)	Clinical and Laboratory Features (Number)
SLE like	9	13	Raynaud's (3), malar rash (1), arthritis (3), alopecia (2), ANA (8), ds-DNA (5)
RA like	6	9	Polyarthritis (6), morning stiffness (4), RF(3), CCP (2)
Sjogren's like	5	7	Sicca symptoms (3), parotid swelling (1), hypergammaglobulinemia (1), SSA (4), SSB (2), SSA and SSB (2)
Scleroderma like	27	41	Skin thickening (7), Raynaud's (14), swollen fingers (6) telangiectasias (5), digital ulcers (1), abnormal nailfold capillaroscopy (5), ANA (21), nucleolar ANA (11), Scl-70 (9), Centromere (1)
Myositis like	4	6	Muscle weakness (1), Gottron's (2), mechanic's hands (1), elevated CPK (2), elevated aldolase (1), Jo-1 (2), PM/SCL (1)
No definable subset	15	23	Raynaud's (6), arthritis (2), morning stiffness (3), muscle weakness (1), CPK (2), aldolase (2), ESR (5), CRP (3), ANA (11), RNP (1), RF (2), SSA (3), SSB (1)

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

### Background/Purpose:

Mast cells are immune cells often residing in connective tissue, best known for their role in allergic and anaphylactic responses<sup>1</sup>. Mast cell activation syndrome (MCAS) is a relatively newly recognized group of immune disorders in which patients have a normal number of “hyperresponsive,” mast cells which degranulate inappropriately and excessively. Clinical presentations of MCAS include: flushing, physical/cholinergic urticaria, angioedema, hypotension, diarrhea, and rhinitis<sup>1</sup>.

Several investigators have recently noted a possible link between MCAS and Ehlers-Danlos (EDS)/joint hypermobility syndrome<sup>1,2</sup>. Cheung et al. surveyed patients with both postural orthostatic tachycardia syndrome and hypermobility, and found 66% had MCAS symptoms. We aimed to evaluate the incidence of MCAS in hypermobile patients seen at our clinic over a 6-month period.

### Methods:

The study sample consisted of hypermobility patients seen by an individual provider at a rheumatology clinic in Spokane, WA over a 6 month period (Nov, 2016 to May, 2017). A cohort of 36 hypermobile patients with MCAS were identified through a search of the electronic health record system for a cross-section between: 1) Hypermobility/EDS (ICD-10 M35.7, M24.80, and Q79.6); and 2) idiopathic MCAS (ICD D89.42).

A second cohort (from the same 6-month period) of non-hypermobile patients with features of MCAS were found using an expanded set of ICD diagnosis codes for features associated with MCAS, as described by Seneviratne et al.<sup>1</sup>: D89.42 (idiopathic MCAS), I95.1 (Orthostatic hypotension), J30.9 (Allergic rhinitis), J45.909 (Asthma), K12.0 (Aphthous stomatitis), K21.0 (GERD), L29.8 (Pruritis), L50.X (Urticaria), R00.0 (Tachycardia), R10.9 (Unspecified abdominal pain), R14.0 (Bloating), R19.7 (Diarrhea), and R55 (Syncope).

### Results:

During this 6-month period, the provider saw a total of 1010 distinct patients. The first cohort was comprised of 36 patients (3.6% of total, 45.6% of hypermobile patients) with both hypermobility and possible MCAS. 33/36 (91.7%) were female, median age 48. A total of 79 patients – including the first cohort – met criteria for hypermobility with a Beighton score of  $\geq 5/9$  on exam.

The second cohort of non-hypermobility patients with possible MCAS found 118 distinct patients (12.7% of non-hypermobile patients) who had one of the ICD codes associated with MCAS. Only 5 (0.5%) patients had been diagnosed with MCAS without meeting criteria for hypermobility.

### Conclusion:

Our preliminary data demonstrate a higher incidence rate of MCAS features in our patients with joint hypermobility compared to the non-hypermobile population. This suggests a positive correlation between MCAS and joint hypermobility. Many hypermobile patients tend to be referred to rheumatology, and if a correlation between hypermobility and MCAS exists, MCAS may be an under-recognized phenomenon in our practices.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Connective tissue diseases (CTDs) are systemic autoimmune disorders that can compromise the lung. Interstitial lung disease (ILD) is one of the mayor forms of lung involvement in CTDs. Main CTDs with lung involvement are Rheumatoid Arthritis (RA), Systemic Sclerosis (SSc) and Idiopathic Inflammatory Myopathies (IIM) spectrum. ILD can be the first or the only manifestation of a CTD. Some ILD patients who don't meet specific CTD classification criteria but have autoimmune findings have been classified as interstitial pneumonias with autoimmune features (IPAF). CTD related ILD (CTD-ILD) have the same patterns than idiopathic ILD, with predominance of non-specific interstitial pneumonia (NSIP). Response to immunosuppressive (IS) therapy and prognosis of CTD-ILD can be better than idiopathic ILD and it may be necessary to treat extra-thoracic disease, so oportune diagnosis of an underlying CTD is essential. The aim of this study is to describe the clinical and radiological features of a historical cohort of patients with CTD-ILD in a specialized pneumo-rheumatology clinic.

**Methods:** The study was conducted at the Instituto Nacional del Tórax in Santiago, Chile, a national referral center for ILD. It is a retrospective study of a historical cohort started in 2012 by the authors. All patients were evaluated in a multidisciplinary team. Descriptive statistics were done. For comparison alfa 0,05 two tails was used; for multiple comparisons Bonferroni correction was used. Analysis was done in Stata 14.0

**Results:** 219 patients were included in the study. Their main clinical and radiological characteristics are summarized on Table 1. All patients are hispanic, with female predominance (84,5%). Main CTDs were RA, SSc and IIM. 15 patients (6,8%) met IPAF criteria. NSIP was the overall predominant ILD pattern (Table 1, Graphic 1). In 34,7 % of patients diagnosis of ILD was done before CTD, in 27,4 % diagnosis of CTD/ILD was concomitant and in 38 % ILD was diagnosed after CTD. Mean FVC and DLCO at ILD diagnosis were 75% and 47,7% respectively. 49 patients (22%) didn't get IS therapy due to mild and stable lung disease. 20 patients (9,1%) died in the period of observation. Main first line IS were Azathioprine, Mycophenolate or Cyclophosphamide.

**Conclusion:** Our cohort show the same kind of CTDs with lung involvement and related ILD patterns described in other series and worldwide literature. There might be an increase in ILD patients meeting IPAF criteria in the future.

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent inflammatory attacks. Attacks are accompanied by substantial increase in acute phase reactants such as C-reactive protein (CRP) and serum amyloid A (SAA) which usually decrease once the attack subsides. CRP and SAA have been considered as the most sensitive acute phase markers. We aimed to compare the behaviour of SAA and CRP in four different clinical conditions, in order to evaluate their role and possible differences during the course of FMF. Here we report our preliminary results on SAA and CRP response in a group of patients with FMF, sepsis, appendicitis and healthy controls.

## Methods:

Our study has a prospective design and is performed in a single institution. Blood samples were drawn from 15 FMF patients during attacks and control samples were obtained once the attacks subsided. We also included 17 patients with acute appendicitis and samples were drawn before and after the appendectomy. We also included 43 cases with sepsis. Among these 43, serial blood testing was performed for 19 cases. We also included 20 healthy controls without a proven medical condition. Serum CRP levels were measured via Enzyme Immunoassay (ELISA) method. Cut-off level was determined as 8 mg/L. **Results** were given as x-folds of normal. Serum Amyloid A levels were measured by using nephelometric method. Cut-off level was determined as 6.8 mg/L.

**Results:** During the FMF attack, mean SAA level was  $50 \pm 34.96$ , whereas it was  $0.92 \pm 1.10$  during the attack-free period ( $p < 0.01$ ). CRP was also decreased from  $26.32 \pm 13.9$  to  $3.61 \pm 2.67$  once the attacks subsided ( $p < 0.01$ ). For the group with acute appendicitis, preoperative and postoperative mean SAA levels were  $51.70 \pm 63.09$  and  $0.82 \pm 0.89$ , respectively ( $p < 0.001$ ). For this group, mean CRP was also decreased following the operation from  $21.75 \pm 12.47$  to  $3.31 \pm 3.40$  ( $p < 0.01$ ). In sepsis group mean SAA and CRP levels were  $43.42 \pm 40.92$  and  $27.92 \pm 12.23$ , respectively. Whereas in healthy controls mean SAA level was  $0.63 \pm 0.25$ , while mean CRP level was  $0.53 \pm 0.2$ . With regards to the correlation between SAA and CRP, analysis was performed for each setting. In FMF group, SAA and CRP were correlated both during and after the attacks ( $r = 0.806$ ,  $p < 0.001$ ). Also in acute appendicitis group, CRP and SAA were positively correlated ( $r = 0.877$ ,  $p < 0.001$ ) both preoperatively and postoperatively. In addition to the finding that CRP and SAA were also positively correlated in sepsis group ( $r = 0.278$ ,  $p = 0.012$ ), for the 19 sepsis cases in which serial measures were performed, this correlation was sustained for three consecutive days ( $r = 0.610$ ,  $p = 0.009$ ;  $r = 0.596$ ,  $p = 0.012$ ;  $r = 0.574$ ,  $p = 0.016$ ; day 1, 2 and 3, respectively).

**Conclusion:** We report that, SAA and CRP levels were correlated in various disease settings. Given the fact that, none of our patients had higher than normal SAA levels despite normal CRP, these two markers seem to have, if any, only minute behavioural differences when it comes to following an FMF case in clinical practice. Although our results are grounded on our preliminary data, both CRP and SAA seem to be effective and efficient to follow a case with FMF.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Diabetes is a metabolic disease that is characterized by chronic and persistent hyperglycemia that eventually results in microvascular and macrovascular complications. These vascular complications are well evaluated, and their association with glycemia is well defined. However, little attention has been paid to the relationship between diabetes and tendinopathies still remains unclear. We hypothesized that chronic hyperglycemia can affect morphologic or functional changes in hand tendons in type 2 diabetes. We aimed to identify whether chronic hyperglycemia can influence the morphologic changes in flexor digitorum tendons and to predict the clinical predictors of tendinopathies in patients with diabetes.

**Methods:** A total of 80 consecutive patients with Type 2 diabetes mellitus (T2DM; from 20 to 70 ages) and 40 age-matched controls were included. Demographics, diabetes-associated variables, carotid intima-media thickness, and data of lipid markers were collected.

Serum level of malondialdehyde (MDA), and adiponectin were measured by ELISA. The morphologic changes of flexor digitorum tendons were assessed by ultrasonography. Serum samples were obtained from all the enrollee at the time point of ultrasonography study. The study was carried out at the diabetes clinic of Bucheon St. Mary's Hospital, Catholic University of Korea, from March 2014 to April 2015. All subjects were informed and gave their written consent.

**Results:** Fifty-three (67%) patients with type 2 diabetes showed pathologic changes of flexor digitorum tendon, whereas only 4 (10%) subjects in control group did. The duration of diabetes tended to be longer in patients with flexor digitorum tendinopathy (FDT) compared with those without FDT. Body mass index (BMI) was significantly higher in patients with FDT than those without FDT. There was no difference in prevalence of macrovascular and microvascular complications, cholesterol profiles, HOMA-IR, and QUICKI between the the patients with FDT and those without FDT. Serum levels of adiponectin in type 2 diabetes patients with FDT were significantly lower than those of control group, but not in type 2 diabetes patients without FDT. Serum MDA levels were higher both in diabetes patients with FDT and those without FDT than controls. But, there was no difference in serum MDA level between the patients with FDT and those without FDT. Logistic regression analysis revealed that BMI, disease duration and abdominal obesity are predictor of morphologic changes of flexor digitorum tendons.

**Conclusion:** The morphologic changes of flexor digitorum tendons were first studied. Morphologic changes of flexor tendons in patients with type 2 diabetes might reflect the chronic burden of oxidative stress in tendons due to hyperglycemia.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Immune checkpoint inhibitors (ICIs), including anti-programmed cell death 1 (anti-PD 1) antibodies, are established therapies for advanced malignancies, including melanoma, and non-small cell lung cancer (NSCLC). The adverse event (AE) profile of anti-PD 1 antibodies includes immune-related adverse events (irAEs) spanning several organ systems, many of which have defined management pathways. However, no consensus exists for the management of rheumatological (Rh) irAEs, including inflammatory arthritis, PMR and myositis, which affect 5-10% of patients receiving anti-PD 1 antibodies. Equally, there is a paucity of data presenting management options for flares of pre-existing rheumatic disease whilst undertaking anti-PD 1 therapy.

### **Methods:**

We conducted a single centre retrospective study of patients treated with anti-PD 1 antibodies pembrolizumab (P) and nivolumab (N), who developed Rh irAEs, experienced flares of existing rheumatic disease, or experienced stability of existing rheumatic disease. Clinical and demographic data were obtained, including anti-PD 1 response (timing, durability and reason for cessation), rheumatologic presentation (including temporal relationship to anti-PD 1 therapy), rheumatologic treatment and response.

### **Results:**

Eighteen patients (12 male, 6 female; median age 71.5 years) were included. All had metastatic malignancy (14 melanoma, 2 NSCLC, 2 head and neck squamous cell carcinoma). Anti-PD1 monotherapy (P or N) was used in 17 patients, 1 of whom had previously received

the anti-cytotoxic T-lymphocyte-associated protein 4 (anti-CTLA4) antibody ipilimumab (I). One patient received combination N-I.

Thirteen patients developed de novo Rh irAEs (7 inflammatory arthritis, 1 PMR, 4 myositis, 1 fasciitis). Three experienced flare of Rh disease (all PMR). Two patients had no flare of their existing Rh disease (1 PMR, 1 with JIA/SSc). The median time to Rh irAE was 10.9 weeks (range 0.7-113). All myositis cases manifested within 4 weeks.

Twelve of the 16 irAEs required prednisone, all at doses  $\geq 10$ mg/day. DMARDs were used in 5 cases, including HCQ in 4, MTX in 1, and SSZ in 1. One case received intravenous immunoglobulin.

Of the 18 patients, 7 completely responded to anti-PD 1, 7 partially responded, 3 had stable disease, and 1 progressive disease. Responses have been maintained despite Rheumatologic therapy. Median duration of response has not been reached.

### Conclusion:

Rh irAEs to anti-PD 1 therapy present a new challenge for Rheumatologists and Oncologists. Both de novo disease, and flare, can occur. Our cohort demonstrated a high rate of response to anti-PD 1 therapy, including when Rheumatologic therapy was initiated. Prospective analysis is required to further characterise this set of diseases.

## Quality, Content and Readability Assessment of Patient Education Websites Relating to Ehlers-Danlos Syndrome

Ahmed Omar<sup>1,2</sup>, Laura Passalent<sup>3</sup>, Leslie Soever<sup>4</sup>, Medha Soowamber<sup>5</sup> and Simon Carrette<sup>6</sup>, <sup>1</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Rheumatology, Mount Sinai Hospital, Toronto, ON, Canada, <sup>3</sup>Allied Health, Toronto Western Hospital, Toronto, ON, Canada, <sup>4</sup>Toronto General Hospital, Toronto, ON, Canada, <sup>5</sup>University Health Network, Toronto, ON, Canada, <sup>6</sup>Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ehlers-Danlos Syndrome (EDS) is a heritable connective tissue disease that presents in myriad ways. Education is an essential component in managing this complex condition. Patients are increasingly relying on the internet to obtain health information. There is a lack of data looking at the quality of EDS patient education websites. In this study, we aimed to address this gap by assessing the quality, content and readability of existing websites specific to EDS.

**Methods:** The term "Ehlers Danlos Syndrome" was searched in Google.com and Bing.com. 60 results were retrieved from each search engine. Duplicates were removed and physician, commercial, news and video specific websites were excluded. Two independent readers analyzed the websites for website quality using two validated tools (DISCERN quality assessment instrument and The Health on the Net (HON) foundation certification). Web site content was scored by a self-developed content analysis tool based on established evidence and EDS standards of practice. Website Readability was assessed via the Flesch-Kincaid Reading Grade Level (FKGL) and Flesch Reading Ease Score (FRES).

**Results:** Of the 120 websites identified, 29 websites remained after the exclusion criteria were applied. Inter-observer reliability between the two readers was substantial, with ICC scores of 0.76 (95% CI=0.50, 0.89) and 0.71 (95% CI=0.40, 0.86) for total content and DISCERN scoring respectively. The mean content score was low at 31.55 out of a total of 80 (SD=17.92). Although most websites reported symptoms and diagnosis information, treatment content scores were generally lower. Only 37.93% mentioned self-management approach. The psychological component was especially neglected with 65.52% of websites failing to address this topic. The mean DISCERN score was poor at 36.21 out of a total of 80 (SD=11.71). 65.50% of websites had poor DISCERN scores, and only 6.90% reached the good to excellent range. Only 24.14% of the websites had the HON foundation certification seal. Regarding readability, the average FKGL was high at 11.42 (SD=0.91), with none of the website achieving the recommended FKGL scores of  $\leq 6$ . The FRES was

low at 38.68 out of a total of 100 (SD=9.60), the recommended score is  $\geq 80$ .

**Conclusion:** Although most of the websites studied provided a general description of EDS, most failed to achieve the required quality, this is especially so for treatment advice. Readability scores also did not meet the recommended standards. Future online patient education endeavours specific to EDS need to address these shortcomings and include more treatment advice, especially as self-management is an essential component of EDS care

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Circulating autoantibodies precede clinical onset of several autoimmune diseases. The characteristics of the so-called pre-clinical stage of autoimmune diseases are poorly understood. Anti-mitochondria autoantibodies (AMA) occur in >95% Primary Biliary Cholangitis (PBC) patients. AMA-positive subjects with normal liver enzymes are occasionally suspected in the indirect immunofluorescence (IIF) assay on HEp-2 cells and further confirmed on specific AMA assays. The liver histological status in biochemically normal (BN) AMA-positive individuals (BN/AMA) is not determined. The Enhanced Liver Fibrosis (ELF) score is a surrogate marker for assessing liver fibrosis state. We prospectively followed-up the autoantibody response, serum liver enzymes and ELF score in AMA/BN and PBC patients along a 7-year period.

**Methods:** 327 samples from 35 PBC patients and 59 BN/AMA were prospectively obtained along an average interval of 4.09 (range: 0.50–7.10) and 3.59 (0.50–7.40) years, respectively. Samples were tested by IIF on rat kidney (IIF-AMA), western blot with rat liver (WB-AMA) and ELISA for PBC-associated autoantibodies against pyruvate dehydrogenase (anti-PDC-E2), nuclear envelope protein gp210, protein sp100, and centromeric proteins CENP-A/B. Anti-PDC-E2 avidity was determined by 6M urea-elution modified ELISA. Alkaline phosphatase (ALP), gamma glutamyl transferase ( $\gamma$ GT) and ELF score were measured by automated methods.

**Results:** PBC patients had higher ELF score ( $p < 0.001$ ), ALP ( $p < 0.001$ ),  $\gamma$ GT ( $p < 0.001$ ), and anti-PDC-E2 ( $p < 0.001$ ) serum levels, as well as higher anti-PDC-E2 avidity ( $p = 0.022$ ) than BN/AMA. Along the follow-up, there was an increase in anti-PDC-E2 ( $p < 0.001$ ) and IIF-AMA ( $p < 0.001$ ) serum levels in BN/AMA, but not in PBC patients. There was increase in anti-PDC-E2 avidity ( $p < 0.001$ ) and ELF score ( $p < 0.001$ ) in both groups. There was a positive temporal correlation between: 1) ELF score and anti-PDC-E2 levels in BN/AMA ( $r = 0.239$ ;  $p < 0.001$ ) and in PBC patients ( $r = 0.268$ ;  $p = 0.004$ ); 2) ELF score and IIF-AMA in BN/AMA ( $r = 0.465$ ;  $p < 0.001$ ); and 3) ELF score and anti-PDC-E2 avidity in PBC ( $r = 0.341$ ;  $p < 0.001$ ). Along time, there was an increase in the number of recognized autoantigen targets in 39% BN and 49% PBC patients. BN/AMA depicted four divergent patterns of longitudinal behavior regarding anti-PDC-E2 serum levels and ELF score: ascending, descending, stable and erratic.

**Conclusion:** Along time, AMA/BN asymptomatic individuals undergo progressive expansion and intensification in the humoral autoimmune response. This process correlates with increase in serum liver fibrosis biomarkers indicating an ongoing silent inflammatory process in the liver. This represents an opportunity case for early therapeutic intervention and prevention of development of autoimmune diseases. However, there is heterogeneity in the longitudinal behavior among AMA/BN individuals, and not all AMA/BN individuals may evolve to overt PBC.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Retroperitoneal fibrosis (RPF) is a periaortic sclerotic disease that encases adjacent structures, particularly the ureters. Because it is unclear whether RPF is associated with malignancy, we examined standardized incidence ratios (SIRs) of cancers in patients with RPF compared with age- and sex-matched general population. Subsequently, the characteristics of patients with RPF accompanied by malignancy were analyzed.

### Methods:

Medical records of 111 patients diagnosed as having RPF by computed tomography, positron emission tomography (PET), and/or histological evaluation were reviewed. Forty one cases of cancers, which were confirmed by biopsies, were identified in 35 patients with RPF. Cancer incidence rates were calculated and compared with that observed in the Korean general population, computing the standardized incidence ratios (SIRs), which were then stratified according to RPF-cancer intervals.

### Results:

The mean  $\pm$  SD age at RPF diagnosis was  $59.2 \pm 15.0$  years, and 69.4% of the patients were male. Ninety two cases (82.9%) showed peri-aortitis, and 65 cases (58.6%) presented with hydronephrosis. The cancer SIR (95% confidence intervals) in patients with RPF relative to age- and sex-matched individuals in the general population was 3.18 (2.23-4.41) [2.65 (1.70 - 3.94) in men; 5.34 (2.76 - 9.32) in women]. The most frequent cancer was unspecified urinary organ cancers with SIR of 733 (238 – 1711). SIRs of multiple myeloma [27.6 (3.34 – 99.6)], renal cell cancers [9.53, (1.15-34.4)] and adenocarcinoma of unknown primary cancers [16.9, (2.05 - 61.1)] were also significantly higher than in the general population. When stratified by RPF-cancer intervals, SIR was 10.4 (6.59 - 15.60) within 1 year of RPF diagnosis, while no significant increase in SIR was found out of 1 year around RPF diagnosis. Among malignancies (n=23) within 1 year of RPF diagnosis (RPF with concurrent cancers), predominant cellular origin was epithelial cells, such as transitional cell carcinoma (n=4) and adenocarcinoma (n=13). Although RPF patients with concurrent cancers were significantly older at the diagnosis of RPF than RPF patients without concurrent cancers ( $65.6 \pm 12.3$  vs  $57.5 \pm 15.2$  years, respectively;  $p=0.017$ ), there was no significant differences in the laboratory findings including erythrocyte sedimentation rate, C-reactive protein, and immunoglobulin G4. Moreover, the maximum standardized uptake values at RPF measured by PET were not significantly different between RPF patients with concurrent cancers (n=3) and those without (n=16) ( $5.17 \pm 0.40$  vs  $4.93 \pm 2.14$ , respectively).

### Conclusion:

RPF was strongly associated with cancers within 1 year of RPF diagnosis. Our results indicate that cancer screening should be performed in patients with RPF, particularly in the aged patients.

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Protein-losing enteropathy (PLE) is a rare condition characterized by a loss of serum protein into the gastrointestinal tract resulting in hypoproteinemia, which can be complicated by edema, ascites, pleural and pericardial effusions, and malnutrition. Although rare, PLE may complicate a variety of diseases, most commonly cardiac or gastrointestinal conditions, and less infrequently, systemic autoimmune diseases (SAD).

**Methods:** In January 2016, we created a retrospective multicenter collection of cases of PLE reported in patients with SAD through the Spanish Autoimmune Diseases Study Group (GEAS-SEMI), and we carried out a systematic literature review. PLE was clinically diagnosed in patients presenting with hypoalbuminemia due to gastrointestinal loss after discarding urinary protein loss and reduced protein synthesis (malnutrition, liver disease, etc). Patients in whom evidence of protein leakage from the gastrointestinal tract as detected by 99 m Tc-HSA scintigraphy were classified as definite PLE, and those patients in which this examination was not performed were classified as probable PLE.

**Results:** A total of 263 patients with SAD-related PLE (6 patients from the Registry and 210 from the literature review) were included (80% were women, with a mean age at diagnosis of disease of 41.1 years, range 16-79 years); 226 (86%) of cases were reported from Asian countries (64% from China), 24 from European countries and 13 from America (7 from US). The main underlying SAD was systemic lupus erythematosus (SLE) in 202 (77%) cases, followed by Sjögren syndrome in 18 (7%) and sarcoidosis in 15 (6%). The main signs and symptoms at presentation were peripheral edema in 192 (85%) patients, pleural effusion in 129 (57%), ascites in 120 (53%) and diarrhea in 96 (43%) patients. Internal organ involvement CNS (in 8 (16%), pulmonary in 23 (46%) and renal in 15 (30%). The main analytical markers consisted of hypercholesterolemia (90%), hypertriglyceridemia (85%) and positive alpha1-antitrypsin in stool (68%). The main gastrointestinal endoscopic finding consisted of edematous mucosa either in upper endoscopy (67/129, 52%) and lower endoscopy (74/139, 53%). One hundred and eighty-two (69%) patients were classified as definite PLE and 81 (31%) were classified as probable PLE. Therapies included corticosteroids in 162 patients and immunosuppressive agents in 171 (mainly

cyclophosphamide and azathioprine); biological agents were used in 5 patients (rituximab in 4, infliximab in 1). After a mean follow-up of 15 months, 77% of patients had a complete response, 6% developed a disease relapse, and 4% died.

**Conclusion:** A very specific epidemiological and clinical profile was observed for protein-losing enteropathy associated with systemic autoimmune diseases, with nearly 90% of cases reported from Asian countries (two out of three cases from China), and nearly 80% reported in patients with underlying SLE. Patients were overwhelmingly treated with corticosteroids and immunosuppressive agents with a complete response of nearly 80% of cases and a global mortality of less than 5%.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mixed connective disease is a multi-system disorder with overlapping features of SLE, rheumatoid arthritis, scleroderma and polymyositis/dermatomyositis with high titres of U1 RNP. Arthritis is a common manifestation that can be erosive and deforming. However, it is unclear whether clinical arthritis in MCTD is more common than SLE and there is little data comparing detection of synovitis by ultrasound in the two diseases.

**Methods:** In this cross-sectional study, we used the Kasukawa criteria for the diagnosis of MCTD and SLICC criteria for SLE patients. Patients were matched for gender and disease duration. U1-RNP was done in MCTD patients by Fluorescence Enzyme Immuno Assay in a 1:10 dilution and ANA by ELISA with a 1:200 dilution of sera. History of arthralgia/arthritis and clinical evaluation for swelling, tenderness, limitation of movements and deformities was done. Functional disability was assessed using the Indian Health assessment questionnaire. Hand radiographs of patients were assessed by for erosions. In addition, ultrasound (9-14 Mhz linear probe) of the non-dominant wrist, metacarpal joints for synovitis and teno-synovitis of flexor and extensor wrist compartments was assessed using the OMERACT definition.

**Results:** Forty patients were recruited in both groups, with similar gender distribution (F:M=38/2, 38/2), disease duration (3.7±2.3, 4.7±3.1, p=0.1) but slightly younger in age (31.8±13.3, 36±10.2, p=0.01) in MCTD than SLE. ANA was positive in all patients in both groups, and U1RNP was positive in all MCTD patients. History suggestive of inflammatory arthralgia/arthritis (100 vs 75%, p = 0.001) and current arthritis on examination (65 vs 37.5%, p=0.03) was significantly higher in MCTD than SLE (Table 1). PIP (30 vs 10%, p=0.025) and wrist (61.8 vs 32.5%, p = 0.007) involvement were significantly more in the MCTD. (Table 1) Use of methotrexate was also significantly more in the MCTD group (20% vs 5% p= 0.043). However, on Ultrasound there was no significant difference in presence of synovitis (p= 0.32) or teno-synovitis (p=0.51) and there was no difference in the functional disability measured by Indian Health assessment questionnaire (0.73 vs 0.74, p=0.7). Deformity was more common in MCTD (10 vs 0%), however, erosions were uncommon in both. Rheumatoid factor was positive more in patients with MCTD than SLE (34.4 vs 6.3%, p=0.005)

**Conclusion:** In this study we observed clinical arthritis to be significantly higher in MCTD patients in comparison with SLE, however, an equally high presence of synovitis on Ultrasound.

**Table 1: clinical arthritis**

Joints/ arthritis	MCTD (%)	SLE (%)	p value
Atleast one tender joint	65	37.5	0.014
Atleast one swollen joint	47.5	15	0.002
PIP	27.5	42.5	0.16

## Identification of Long-Term Prognostic Factors for Relapse or Exacerbation in Patients with Pulmonary Sarcoidosis: A Single Center Long-Term Observational Cohort Study

Okinori Murata<sup>1</sup>, Atsuko Kudo<sup>2</sup> and Katsuya Suzuki<sup>3</sup>, <sup>1</sup>Department of Pulmonary medicine, Hachinohe Red Cross Hospital, Hachinohe, Japan, <sup>2</sup>Hachinohe Red Cross Hospital, Hachinohe, Japan, <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sarcoidosis is a systemic granulomatous disease that can affect multiple organs, and in particular lung involvements are common and found in more than 90% of the patients [1]. Spontaneous remission is often observed within 2 years [2] and chest radiographic stage, skin involvements, over 40 years old or smoking history are reported as poor prognostic factors in pulmonary sarcoidosis [3, 4]. However, there were no comprehensive reports of factors of relapse or exacerbation and characteristics of favorable patients without treatment in the long-term period more than 2 years. Aim of study is to identify prognostic factors for relapse or exacerbation in patients with pulmonary sarcoidosis in the long-term period.

**Methods:** Ninety-three patients who had visited at our division of Hachinohe Red Cross Hospital between January 2007 and December 2016 and clinically diagnosed as pulmonary sarcoidosis, were enrolled. They were divided into two groups, which presented relapse or exacerbation, and spontaneous remission. Clinical, laboratory and imaging data were collected from medical records and statistically analyzed.

**Results:** In 93 patients, 77% were women and mean age at diagnosis was  $50.1 \pm 16.6$  years old. Mean observation period was  $9.9 \pm 8.8$  years. Numbers of patients who had previously reported short-term prognostic factors are following: chest radiographic stage (Stage 0: n=3, Stage I: n=29, Stage II: n=36, Stage III: n=15, Stage IV: n=10), skin involvement (n=9), age over 40 years old (n=66), and smoking history (n=31). Overall relapse or exacerbation rate was 18.3% (n=17) and mean period to relapse or exacerbation was  $8.5 \pm 8.4$  years. Then, we purified 64 patients who were observed for more than 5 years, and relapse or exacerbation was found in 7 patients. When compared characteristics at diagnosis between two groups, decrease of peripheral number of lymphocytes, frequency of bilateral hilar lymphadenopathy, or less than 3.5 in the ratio of CD4/CD8 in bronchoalveolar lavage fluid (BALF) were significantly highlighted in relapse or exacerbation group ( $P=0.019$ ,  $0.042$ , and  $0.018$ , respectively).

**Conclusion:** Our long-term observational cohort study identified incidence rate and unique prognostic factors of relapse or exacerbation in patients with pulmonary sarcoidosis. This information could contribute to more appropriate medical administration in long term period.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Immune checkpoint inhibitors (ICIs), by inhibiting immunosuppressive molecules overexpressed in the tumoral environment such as CTLA-4 or PD1, increase the anti-tumor immune response and have been approved for an increasing number of cancers. However, they are responsible for immune related adverse effects (IRAEs), and patients with preexisting autoimmune diseases (PAD) have been excluded from clinical trials evaluating those molecules. The aim of this study was to evaluate their safety in routine practice in patients with PAD and the anti-tumoral response in this population.

**Methods:** Three national expert networks, focusing respectively on skin cancers, thoracic cancers, and inflammatory diseases, participated in the study. All patients who received an ICI despite a PAD were included in this nationwide retrospective study.

**Results:** 31 patients were included in the study (19 men (61%), median age of 66). Most frequent PADs were rheumatoid arthritis (n=9; 29%), psoriasis (n=6; 19%), lupus (n=4; 13%), ulcerative colitis (n=3; 10%), and spondyloarthritis (n=3; 10%). Eleven patients were receiving an immunosuppressive therapy when the ICI was initiated, and 10 had an active disease at that time. Neoplasm types were melanoma (n=16; 52%), non-small-cell lung carcinoma (n=12; 39%), and urologic neoplasms (n=3; 9%), with a median disease duration of 19 months. The majority of the patients (30/31) received an anti-PD1 drug, for a median duration of 4 months. PAD flares were frequent (n=18; 58%) but mostly mild: CTCAE grade 1-2 (n=12; 67%), grade 3-4 (n=3; 17%). 14 patients (78%) received

corticosteroids or NSAIDs, and 3 (17%) methotrexate or acitretine for the treatment of these flares. IRAEs not associated with PAD appeared in 10 patients (32%): arthralgia (n=5), colitis (n=2), thyroiditis (n=2), vitiligo (n=2) with mild severity. None of the patients received TNF blockers, neither for a flare nor for an IRAE. 5 patients discontinued the immunotherapy because of an adverse effect. Regarding the cancer response rate, 4 patients over 11 who were taking an immunosuppressive treatment were responders (36%), versus 12 over the 20 other patients (60%).

**Conclusion:** PAD flares are frequent during ICI therapy and other IRAEs are also possible, usually easily managed with corticosteroids only. Anti-tumor response could be reduced when an immunosuppressor is ongoing at the beginning of the ICI, within the limit of the number of patients analyzed so far. Overall, the tolerance of ICIs in patients with PAD seems acceptable, but a multidisciplinary follow-up with the PAD referral physician is appropriate to manage frequent PAD flares and/or IRAEs.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with sarcoidosis refractory to standard treatment are a therapeutic challenge and are often managed by a variety of specialists due to the heterogeneity of disease manifestations. Treatment options for symptomatic sarcoidosis have improved in recent years and we are now using tumor necrosis factor (TNF) inhibitors for moderate or severe disease. Currently treatment response in pulmonary sarcoidosis is assessed via pulmonary function, chest imaging, and quality of life measures. Our objective was to evaluate the safety and efficacy of TNF inhibitors in multi-system sarcoidosis.

**Methods:** A systematic English literature review and meta-analysis using PubMed was performed on published studies and case series. Search strategy involved screening for articles between 1996 and 2017 which reported use of TNF inhibitors (etanercept (ETN), adalimumab (ADA), infliximab (INF), golimumab or certolizumab) for the treatment of biopsy proven sarcoidosis. We selected studies that directly assessed the effects of TNF inhibitors on treatment outcomes in systemic sarcoidosis. We excluded case reports, sarcoidosis that developed while on a TNFi, and disease limited to cutaneous involvement. Data regarding disease phenotype, past therapies, treatment outcomes, and adverse events were extracted by two reviewers and is undergoing assessment to be pooled in a meta-analysis.

**Results:** There were 470 abstracts identified. Selection was made of 102 original articles using TNF inhibitors in sarcoidosis. Fourteen studies were evaluated: five comparative trials and nine observational. The most robust studies were comparative trials in patients with pulmonary sarcoidosis. 450 cases of biopsy proven sarcoidosis underwent treatment with TNF inhibitors. Variation in objective results (including pulmonary function tests) was seen. Adverse events leading to discontinuation were infrequent. Observational studies assessed patients with more wide ranging phenotypes including cutaneous, ocular, central nervous system (CNS), cardiac, pulmonary, liver, and musculoskeletal manifestations. Clear benefit with INF in neurosarcoidosis (when used with mycophenolate) and in multi-system sarcoidosis was seen. Both INF and ADA led to improved outcomes in uveitis. In one open label study, INF led to improvement in FDG PET in a majority of patients and improvement in FVC by 6.6%. ADA improved or stabilized FVC in all patients with severe, symptomatic pulmonary sarcoid and led to improved 6MWT, Borg dyspnea score, and both patient and physician global assessment. An open label study with ETN for stage II and III pulmonary sarcoid was terminated early due to frequency of treatment failure. Case series support use in a wide range of extra-pulmonary organ systems, most notably neurosarcoidosis.

**Conclusion:** Current results from randomized and open label studies appear to support use of monoclonal antibody TNF inhibitors, for use in extra-pulmonary sarcoid disease, with particularly compelling evidence for use in uveitis and neurosarcoidosis.

## **A Systematic Review of the Management of Patients with Preexisting Rheumatologic Diseases Receiving Checkpoint Inhibitors for Cancer**

**Noha Abdel-Wahab**<sup>1,2</sup>, Mohsin Shah<sup>1</sup>, Maria A. Lopez-Olivo<sup>1</sup> and Maria Suarez-Almazor<sup>1</sup>, <sup>1</sup>Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX, <sup>2</sup>Rheumatology and Rehabilitation Department, Assiut University Hospitals, Assiut, Egypt, Assiut, Egypt

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The incidence and management of rheumatologic immune-related adverse events (irAEs) as a consequence of the checkpoint inhibitor (CPI) therapy in patients with cancer has been investigated, but no studies have synthesized the management of preexisting rheumatologic diseases in patients receiving CPI. We systematically review all reported cases describing the use of CPI in patients with a preexisting rheumatologic disease.

**Methods:** We searched 5 electronic databases through November 2016 and handsearched the references of relevant articles. We collected data on the specific CPI received, disease activity and anti-rheumatic modifying drugs while receiving CPI, and development and management of irAEs.

**Results:** Eleven publications met inclusion criteria, reporting on 30 cases (18 rheumatoid arthritis (RA)/inflammatory arthritis (IA); 3 seronegative spondyloarthropathy (2 psoriatic and 1 reactive arthritis); 3 sarcoidosis; 2 systemic erythematosus lupus (SLE); 2 vasculitis; 1 rheumatic fever; 1 Sjögren's syndrome). Age of the cases ranged from 30 to 84 years. All had melanoma. Of the 18 patients with RA/IA, 16 received ipilimumab, 1 nivolumab, and 1 pembrolizumab. Sixteen patients had active arthritis before starting CPI and 6 were kept on treatment (steroids, hydroxychloroquine, or leflunomide) while receiving CPI. Fifteen of 18 had irAEs (8 flare, 2 colitis, 1 autoimmune thyroiditis, 4 flare plus colitis or hypophysitis). Nonsteroidal anti-inflammatory drugs or steroids were used to treat all irAEs which resulted in improvement. However, infliximab and surgical resection were required for a patient with exacerbation of colitis after steroids tapering and CPI discontinuation was recommended in 5 patients. One patient with inactive RA was maintained on methotrexate and prednisolone, with no irAEs. Of the 3 patients with seronegative spondyloarthropathy, all received ipilimumab. Two patients with psoriatic arthritis had active disease, and one was maintained on methotrexate with no irAEs reported. The other patient stopped methotrexate prior to receiving the CPI and had worsening of plaques and de novo colitis that required steroids. No irAEs were reported in the patient with reactive arthritis. Of the 3 patients with sarcoidosis, all received ipilimumab. Only one had active disease and was maintained on steroids while receiving CPI. All had irAEs (2 flare and 1 glaucoma) and improved with increasing steroids dose. The 2 patients with SLE, received ipilimumab. One had active disease, and both were maintained on hydroxychloroquine and/or steroids. None developed adverse events. irAEs were reported in one patient each with Behcet, eosinophilic granulomatosis with polyangiitis, and Sjögren's, but none for the rheumatic fever.

**Conclusion:** Flares and irAEs in patients with rheumatologic disease receiving CPI can be managed, often not requiring therapy discontinuation. No difference was noted in the occurrence of irAEs in patients with active versus non-active preexisting diseases. CPI can be offered to these patients considering risk-benefit ratios and patient preferences.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases Poster II

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Suppurative Hidradenitis (SH) is an inflammatory skin disease with often disappointing response to treatment. It is a disorder of apocrine glands (axillary, inguinal and anogenital regions) with infection and multiple inflamed nodules, cysts, abscesses and sinus tracts. It has been associated in a 1-4% with spondyloarthropathies and inflammatory bowel disease, possibly due to an innate immune system deregulation. The use of biological disease-modifying antirheumatic drugs (bDMARD) specifically tumor necrosis factor inhibitors has been described as a therapeutic alternative achieving good clinical results in these patients. Objective: To evaluate the prevalence of SH using the SH-questionnaire in patients diagnosed with chronic arthritis treated with bDMARD.

## Methods:

This cross-sectional study included 325 patients with a diagnosis of chronic arthritis. Those were recruited from Biological Therapy Unit at the Hospital General Universitario Gregorio Marañón and consecutively attended from January to March of 2015. All patients were treated with full or tapered bDMARD for at least 1 year. The bDMARD dosage tapering had been made in patients with a maintained remission according to their attending rheumatologist and the patient approval. None of patients had a previous SH diagnosis. All patients self-completed the validated SH-questionnaire (*Esmann S, et al. Br J Dermatol. 2010 Jul;163(1):102-6*), it was considered positive with an affirmative answer and lesions in >1 anatomical location. Patients were classified in peripheral arthritis (PerAR) [rheumatoid arthritis (RA)], psoriatic arthritis (PsA) and peripheral spondyloarthropathies (PerSpA)] and axial spondyloarthropathies (AxSpA). The clinical evaluation was always performed by the same observer. Demographic, clinical and laboratory variables were collected and clinical indices related to each pathology were calculated (DAS28-ESR, DAS28-CRP, SDAI, CDAI, BASDAI, BASFI, ASDAS-CRP).

## Results:

SH-positive was observed in 25/325 (7.7% vs. 92.3%) patients. Of these 25 patients, 12 (48%) were female and 13 (52%) were male. The mean age was 52 years (SD  $\pm$  12.9) and mean time since diagnosis was 14 years (SD  $\pm$  9.3). Twenty-four out of 25 patients had anti-TNF treatment (ETN=10, GOL=7, ADL=6, CTZ= 1). We found that 84% of patients had full and 16% had tapered bDMARD dosage. According to pathology, 13 had PerAR and 12 had AxSpA diagnosis (5.8% vs. 11.8%,  $p=0.062$ ). Comparing the subtypes of PerAR, we found that 6 patients had PsA and 5 had RA. Evaluating the clinical activity disease, we found 9/13 patients in the PerAR group with clinical remission according to DAS28-ESR and CDAI ( $p=0.02$  for both). Additionally, we found only 4/12 patients in remission in the AxSpA group by BASDAI, BASFI and ASDAS-PCR ( $p=0.006$ ,  $p=0.005$ ,  $p=0.004$ , respectively).

## Conclusion:

We found more SH-positivity in the AxSpA than in the PerAR group, which is consistent with published data. A bDMARD tapered dosage was related to SH-positivity which might be linked to persistent and undetectable inflammation.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Idiopathic inflammatory myopathies (IIM) comprise a heterogeneous group of autoimmune conditions characterized by muscle non-suppurative inflammation, progressive muscle weakness and a variety of extra-muscular manifestations. Joint involvement can be considered to be part of the IIM systemic manifestations, together with a possible gastrointestinal, cardiovascular and/ or pulmonary involvement. Although articular involvement in the IIM, including inflammatory arthralgia and arthritis, has been described as variable and non-specific with a chronic course it might be an early symptom of dermatomyositis in up to 30% of cases and in those patients with overlap syndromes. We aim to evaluate and to identify joint manifestations in IIM patients.

**Methods:** We evaluated a cohort of 479 patients that included 12 hospitals in the Community of Madrid belonging to the IIM registry of the Society of Rheumatology of Madrid (SORCOM-REMICAM) with diagnosis from January 1980 to December 2014. All patients were diagnosed of IIM according to Bohan and Peter criteria (*Bohan A, Peter JB. N Engl J Med 1975 Feb 13;292(7):344-7*). The presence of arthralgia and arthritis was considered. IIM were classified as dermatomyositis (primary and secondary dermatomyositis) (DM) and polymyositis (PM) including the rest of the patients (classification I). Also, IIM were classified (II) as primary polymyositis (PPM), primary dermatomyositis (PDM), overlap syndrome (OSd), juvenile myopathies (JM), cancer-associated myopathies (CAM), autoimmune necrotizing myopathy and inclusion body myositis (these were grouped as other myositis; OM).

**Results:** We found 70 (18%) patients with acute arthritis (<6 weeks), 74 (19%) patients with chronic arthritis (> 6 weeks) and 245 (65%) patients without any joint manifestations. Using the Tanimoto et al. criteria (1), the presence of erosive arthritis was observed in 149/479 (38.3%) of the patients. When comparing the joint manifestations in the PM and DM groups (n=250, 52.2% vs. n=229, 47.8%) no statistically significant differences were observed. However, assessing joint manifestations according to classification II, we observed that the highest prevalence was found in the OSd group, followed by the PDM group (p=0.0001). The group with less joint manifestations was JM compared to OSd and PDM (45% vs. 90% and 71%, respectively).

**Conclusion:** The presence of joint manifestations associated with IIM in our cohort is higher compared to other studies described in the literature so far and emphasize the importance of an accurate joint examination in these patients. The OSd group showed more joint manifestations which might be explained by the coexistence of SLE and MCTD patients in this group. Currently, no association between the clinical subtypes of IIM, overall, these results are encouraging and suggest that joint assessment in follow up may be helpful in differentiating subtypes of IIM.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To describe the clinical and serologic features, as well as the disease course and response to therapy of anti-PM/Scl patients.

**Methods:** All Johns Hopkins Myositis Center patients positive for anti-PM/Scl autoantibodies from 2002 to 2016 were included in the study and compared with other autoantibody-positive patients of the cohort. We studied the presence and rate of development of clinical features, the intensity of muscle and lung involvement, and the serologic and biopsy characteristics of these patients.

**Results:** 41 anti-PM/Scl patients were compared with 445 patients positive for other myositis autoantibodies. Muscle weakness was responsive to first-line immunosuppressants, similar in severity to that of patients with antisynthetase syndrome (AS) and dermatomyositis (DM) autoantibodies, and milder than in patients with immune-mediated necrotizing myopathy autoantibodies. Distal and deltoid weakness was more common in anti-PM/Scl patients than in other myositis subgroups. Muscle biopsies showed marked perivascular inflammation (79%) with scarce perifascicular atrophy (26%). ILD was detected in 61% of anti-PM/Scl patients, more frequently than in DM (13%) and less than in AS (80%), but was milder compared to AS. Extramuscular involvement was common and heterogeneous, with marked skin involvement. No major differences were detected between patients positive for both anti-PM/Scl-75 and anti-PM/Scl-100 and those positive for just one. The nucleolar ANA pattern was effective as a screening technique (sensitivity=94%, specificity=92%) to detect anti-PM/Scl autoantibodies in myositis patients. No increased cancer or mortality rates were detected in these patients.

**Conclusion:** Anti-PM/Scl myositis is characterized by a particular pattern of weakness, mild lung and muscle involvement, and marked extramuscular features.

## Angiogenesis and VEGF-Expressing Cells Are Identified Predominantly in the Fascia Rather Than the Muscle in the Early Phase of Dermatomyositis

Ken Yoshida<sup>1,2</sup>, Haruyasu Ito<sup>1</sup>, Kazuhiro Furuya<sup>1</sup>, Taro Ukichi<sup>1</sup>, Kentaro Noda<sup>1</sup> and Daitaro Kurosaka<sup>1</sup>, <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan, <sup>2</sup>Internal Medicine, Jikei University School of Medicine, Tokyo, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We previously showed that fasciitis is a frequent manifestation of the disease in dermatomyositis (DM) but not in polymyositis (PM) and that DM-associated fasciitis is detected, as the result of the increased vascularity in the fascia, by power Doppler ultrasonography. We examined whether angiogenesis and vascular endothelial growth factor (VEGF)-expressing cells in the fascia are histologically identified in the early phase of DM, and whether inflammation is involved in angiogenesis and an increased number of VEGF-expressing cells.

**Methods:** We prospectively evaluated en bloc biopsy specimens obtained from 22 patients with DM and 11 patients with PM before treatment. Immunohistochemical staining for CD31, VEGF, and TNF- $\alpha$  were performed. The total vascular inflammation score (TVIS) was defined as the total number of aggregates of  $\geq 50$  perivascular inflammatory cells per 4-mm<sup>2</sup> area in the 3 fields with the most remarkable infiltration of perivascular inflammatory cells to quantify the degree of inflammation. The angiogenesis score (AS) was defined as the total number of CD31-positive blood vessels in 3 high-power fields (200 $\times$ ) that showed the most remarkable proliferation of the vessels. The numbers of VEGF- and TNF- $\alpha$ -expressing cells were counted in the 3 high-power fields (400 $\times$ ) that showed the largest accumulation of these cells. The TVIS, AS, and numbers of VEGF- and TNF- $\alpha$ -expressing cells were statistically analyzed in the fascia and muscle tissues.

**Results:** The AS, the number of VEGF-expressing cells, and the TVIS in the fascia of patients with DM were significantly higher compared with those of patients with PM; no significant difference was found in the muscle of patients with DM and PM. The number of VEGF-expressing cells in the fascia was correlated with the AS of patients with DM. In the early phase (the period from the onset of muscle symptoms until the biopsy <2 months) of DM, the AS, the number of VEGF-expressing cells, and the TVIS in the fascia were significantly greater compared with the muscle. However, no significant differences were observed between the muscle and fascia in the late phase (the period  $\geq 2$ ) of DM. In patients with DM, the TVIS was correlated with the AS in the fascia, while the number of TNF- $\alpha$ -expressing cells was correlated with the TVIS and the number of VEGF-expressing cells in the fascia.

**Conclusion:** Angiogenesis, the number of VEGF-expressing cells, and the TVIS were higher in the fascia of patients with DM in comparison to patients with PM, and were increased predominantly in the fascia rather than the muscle in early-phase DM. Our data suggest that the angiogenesis induced by VEGF may progress from the fascia into the muscle in patients with DM. The degree of inflammation was correlated with that of angiogenesis in the fascia of patients with DM. These data suggest that the fascia can be a primary site of inflammation and angiogenesis in the pathogenesis of DM.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with polymyositis (PM) and dermatomyositis (DM) often experience relapse–remitting courses and recurrent myositis. However, only a few studies focused on this issue, and most of them were reported more than 10 years ago. We aimed to study the characteristics of PM/DM patients with recurrent myositis and to identify its risk factors.

**Methods:** We retrospectively reviewed the medical records of patients who were diagnosed as PM/DM between 1993 and 2016. All patients satisfied Bohan and Peter classification criteria for PM/DM. Patients with clinically amyopathic DM were excluded. Recurrent myositis was defined as a sustained elevation in serum creatine kinase (CK) levels, which required intensification of immunosuppressive treatment. Myositis-specific autoantibodies were thoroughly evaluated by immunoprecipitation and enzyme-linked immunosorbent assays. The baseline clinical characteristics were compared between patients with and without recurrent myositis. Univariate and multivariate logistic regression analyses were performed to identify the risk factors for recurrent myositis in patients with PM/DM.

**Results:** Of the 120 patients included in the present study, 56, 42, and 22 patients were PM, DM, and PM/DM associated with another connective tissue disease, respectively. Initially, glucocorticoids were administered to all the patients, and other immunosuppressants were concomitantly used in 76 patients, which led to the normalization of CK level in all the patients. Myositis recurred in 35 patients (29%) during the observational periods (median 2.4 years). Among these, 29 (83%) were treated with glucocorticoids alone at the time of the recurrence: median dosage was 10 mg/day as prednisolone. Table 1 shows the baseline characteristics of the patients with and without recurrent myositis. Baseline CK levels in patients with recurrent myositis were significantly higher than those without ( $p < 0.01$ ), and the ROC curve analysis determined the cutoff value for baseline CK level as  $\geq 2477$  U/l. By univariate analyses, baseline CK level  $\geq 2477$  U/l, positive anti-signal recognition particle (anti-SRP) antibody, and initial treatment without calcineurin inhibitor, namely tacrolimus and cyclosporine were associated with myositis recurrence ( $p < 0.01$ ). Multivariate analysis identified anti-SRP antibody (odds ratio [OR], 7.7; 95% confidence interval [CI], 1.6 to 38) as a positive risk factor, whereas initial treatment with calcineurin inhibitor (OR, 0.2; 95% CI, 0.1 to 0.7) as a negative risk factor for myositis recurrence.

**Conclusion:** The present study suggested that anti-SRP antibody is a risk for myositis recurrence and that initial treatment with calcineurin inhibitor is protective against myositis recurrence in patients with PM/DM. In addition, most of the patients with recurrent myositis were treated with glucocorticoids alone at the time of the recurrence.

**Table 1** Baseline characteristics of patients with and without myositis recurrence

	Patients with myositis recurrence ( $n = 35$ )	Patients w/o myositis recurrence ( $n = 85$ )	$p^{\dagger}$
Age, years	48 (28 to 76)	47 (19 to 80)	0.53
Woman, $n$ (%)	30 (86%)	64 (75%)	0.23
PM/DM/Overlap myositis, $n$	19/10/6	37/32/16	0.56
Interstitial lung disease, $n$ (%)	28 (80%)	58 (68%)	0.27
CK level, U/l	2986 (576 to 13380)	1266 (105 to 12917)	$< 0.01$
CK level $\geq 2477$ U/l, $n$ (%)	21 (60%)	25 (29%)	$< 0.01$
Myositis-specific autoantibodies			
Anti-ARS antibody <sup>‡</sup> , $n$ (%)	12 (34%)	39 (46%)	0.31
Anti-Jo-1 antibody, $n$ (%)	7 (20%)	21 (25%)	0.64
Anti-SRP antibody, $n$ (%)	9 (30%)	3 (4%)	$< 0.01$
Anti-Mi-2 antibody, $n$ (%)	1 (3%)	3 (4%)	1.00
Anti-NXP-2 antibody, $n$ (%)	1 (3%)	3 (4%)	1.00
Anti-TIF1- $\gamma$ antibody, $n$ (%)	0 (0%)	4 (5%)	0.32
Anti-MDA5 antibody, $n$ (%)	0 (0%)	5 (6%)	0.32
Initial treatment			
Prednisolone dosage, mg/day	50 (25 to 100)	51 (20 to 60)	0.81
Steroid pulse therapy, $n$ (%)	6 (20%)	16 (19%)	0.80
Methotrexate, $n$ (%)	4 (10%)	10 (12%)	1.00
Calcineurin inhibitor, $n$ (%)	4 (10%)	34 (40%)	0.02
Intravenous cyclophosphamide, $n$ (%)	9 (30%)	21 (25%)	1.00

<sup>†</sup>Unless otherwise noted, data are described as median (range).

<sup>‡</sup> $p$  values were determined by Fisher's exact test or Mann-Whitney  $U$  test.

<sup>‡</sup> Anti-Jo-1 antibody was included.

Polymyositis = PM; dermatomyositis = DM; CK = creatine kinase; ARS = aminoacyl-tRNA synthetase;

SRP = signal recognition particle; NXP-2 = nuclear matrix protein 2; TIF1- $\gamma$  = transcriptional intermediary factor 1- $\gamma$ ; MDA5 = melanoma differentiation-associated gene 5

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Paraneoplastic myositis provide an exceptional opportunity for cancer triggered autoimmunity. Myositis specific antibodies (MSAs) show great clinical utility in IIM diagnosis and classification. However, cancer-associated MSAs has not been systematically identified, which may help for targeted cancer screening and provide clues to study cancer-immune system interactions. The objective of the study was to systematically evaluate the association between MSAs and cancer-associated myositis (CAM).

**Methods:** Sera from 627 idiopathic inflammatory myopathies (IIMs) patients were tested for MSAs. The cancer risk with different MSAs was estimated by standardized incidence ratio (SIR). The temporal relationship between myositis onset and cancer diagnoses, as well as the correlation between the clinical course of myositis and cancer in patients with IIM were evaluated.

**Results:** Compared with the general Chinese population, IIM patients with anti-TIF1- $\gamma$  antibodies (SIR=17.28, 95% CI: 11.94 to 24.14); anti-NXP2 antibodies (SIR=8.14, 95% CI: 1.63 to 23.86); or anti-SAE1 antibodies (SIR=12.92, 95% CI: 3.23 to 32.94), or who were MSAs-negative (SIR=3.99, 95% CI: 1.96 to 7.14) faced an increased risk for cancer (Table 1). There was no association between specific MSAs subtypes and certain types of cancer. A close temporal relationship between the onset of myositis and cancer diagnoses was identified in the patients carrying anti-TIF1- $\gamma$ , as well as other MSAs. In addition, a parallel between clinical course of myositis and cancer was observed in patients from various MSAs, such as anti-Jo-1 and anti-PL-12. There were no prognostic differences among the CAM patients from different MSA subgroups. However, patients with cancer developing within 1.5 year of myositis onset had a shorter survival time than those suffered from cancer beyond 1.5 year of myositis (17.0 vs. 45.0 months,  $p=0.004$ ).

**Conclusion:** Our study demonstrates, in what is to our knowledge the largest population examined to date, that multiple myositis specific autoantibodies (anti-TIF1- $\gamma$ , anti-NXP2, and anti-SAE1) are associated with cancer in IIM patients. Moreover, our data suggest that in some cases, anti-Jo-1 and anti-PL-12 antibody production might also be driven by malignancy. This can aid in the etiologic research of paraneoplastic myositis and clinical management.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A disintegrin and metalloprotease (ADAM) family is protease that is thought to have an important role in tissue destruction and inflammatory reaction. ADAMs are also involved in the amputation from the cell surface of inflammatory cytokines. ADAM-17 is one of the ADAM family, and is first described as the protease responsible for tumor necrosis factor (TNF)- $\alpha$  shedding. However, the function of ADAM-17 in myositis is unclear. Here, we have shown the expression of ADAM-17 in inflammatory myopathy and demonstrated the role of inflammation in interstitial lung diseases (ILD).

**Methods:** The serum were collected from the patients who were diagnosed with inflammatory myopathy in Showa University Hospital from 2003 to 2015. Twenty-six patients were diagnosed with polymyositis (PM), 34 patients were diagnosed with dermatomyositis (DM), and 10 patients were diagnosed clinically amyopathic dermatomyositis (CADM). Clinical manifestations and clinical data were also collected. The levels of ADAM-17 in the serum samples were measured using enzyme-linked immunosorbent assay (ELISA). ADAM-17 expression was determined in muscle tissues from DM using immunohistological staining. To determine that the role of lung fibrosis in inflammatory myopathy with ILD, we used human lung fibroblasts (HLF). ADAM-17 expression on HLF was also demonstrated by immunohistological staining.

**Results:** ADAM-17 in inflammatory myopathy was significantly higher than in healthy control (n=19) (mean  $\pm$  SEM;  $1048 \pm 312$  pg/ml and  $36 \pm 18$  pg/ml, respectively,  $p < 0.05$ ). ADAM-17 in corticosteroid and/or immunosuppressant treatment patient serum was also significantly decreased compared with in pre treatment patient serum ( $1465 \pm 562$  pg/ml and  $1059 \pm 503$  pg/ml, respectively,  $p < 0.01$ ). ADAM-17 was significantly positive correlated with fractalkine/CX3CL1 in serum ( $r = 0.27$ ,  $p < 0.05$ ). In addition, ADAM-17 in inflammatory myopathy with ILD patients (n=46) was significantly higher than in non-ILD patients (n=24) ( $1379 \pm 454$  pg/ml and  $413 \pm 226$  pg/ml, respectively,  $p < 0.05$ ). Finally, we found the expression of ADAM-17 in muscle biopsy tissue. Hence, ADAM-17 on HLF was expressed by immunohistochemistry. ADAM-17 in IL-6 and IL-6R stimulated HLF was significantly higher compared with non-stimulated HLF ( $48 \pm 6$  pg/ml and  $0 \pm 0$  pg/ml, respectively,  $p < 0.05$ ).

**Conclusion:** ADAM-17 is expressed in inflammatory myopathies especially with ILD and expressed on HLF, suggesting that ADAM-17 may play the role in lung fibrosis. ADAM-17 may be a potential target in inflammatory myopathies with ILD.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Interstitial lung disease (ILD) is a frequent complication and a major contributor to mortality and morbidity in polymyositis and dermatomyositis (PM/DM). Prior studies have linked the presence of anti-synthetase autoantibodies (ASA) and part of the HLA 8.1 ancestral haplotype (AH8.1) to ILD in PM/DM patients. This study aimed to evaluate the contribution of HLA-DQA1\*05 to the presence of ILD in Caucasian PM/DM independent of ASA.

### **Methods:**

A total of 82 Caucasian patients with adult-onset PM/DM per Bohan and Peter criteria and with HLA class I (A, B and C) and class II (DRB1 and DQA1) evaluated by sequence-specific oligonucleotide probe hybridization and priming techniques or sequencing methods were included. ILD status was determined by retrospective chart review based on imaging results, lung biopsy, and/or pulmonary function tests. ASA were determined by standard immunoprecipitation methods. AH8.1 was defined as the presence of HLA-A\*01, B\*08, C\*07, DRB1\*0301, and DQA1\*05. Pearson chi-square (or Fischer exact when appropriate), multiple logistic regression tests and forward stepwise logistic methods were applied.  $P < 0.05$  was considered statistically significant.

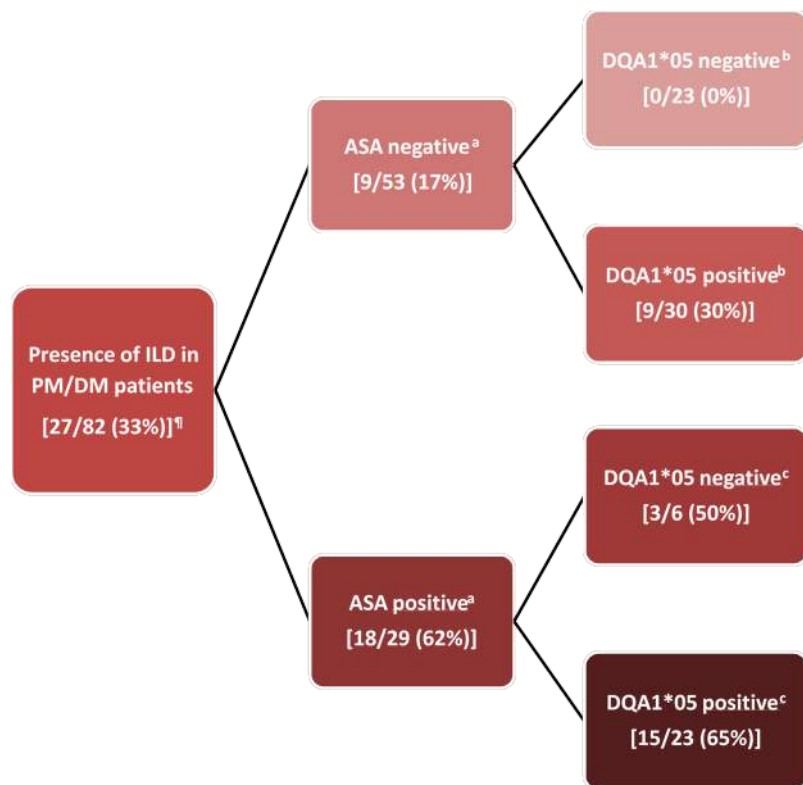

### **Results:**

Overall, 27 (33%) had ILD, 29 (35%) were positive for ASA and 29 (35%) carried the AH8.1. ILD was associated with ASA (OR=8.0, 95%CI: 2.83-22.58,  $P < 0.001$ ) and with the AH8.1 (OR=3.66, 95%CI: 1.38-9.67,  $P = 0.009$ ) as expected. Of the five AH8.1 alleles, HLA-DQA1\*05 was the only locus significantly associated with ILD after adjusting for the presence of ASA (OR=5.95, 95%CI: 1.47-24.05,  $P = 0.012$ ). This association remained significant after adjusting for the presence of the other alleles of the AH8.1 and ASA status (OR=12.31, 95% CI: 1.81-83.81,  $P = 0.010$ ). Chi squared tables, categorizing the cohort based on the presence or absence of each AH 8.1 allele, were used to assess the independent effect of HLA-DQA1\*05 on risk of ILD conditioned on ASA status and the frequency of ILD was higher in DQA1\*05 carriers, however, due to limited power, not all comparisons met statistical significance. Additionally, forward stepwise logistic analysis, while keeping ASA in the model regardless of step, showed that DQA1\*05 was the only HLA allele that remained in the best fit model for risk of ILD (OR=5.95, 95% CI: 1.47-24.05,  $P = 0.012$ ). Figure 1 shows the risk of ILD in Caucasian PM and DM patients based on the ASA and DQA1\*05 status.

### **Conclusion:**

HLA-DQA1\*05 is associated with an increased risk of ILD in Caucasian PM and DM patients, independent of ASA and other AH8.1 alleles, implying that HLA-DQA1\*05 impacts the risk of ILD independently from ASA in Caucasian PM/DM. Thus, HLA-DQA1\*05 may be a useful screening test for evaluating the risk of ILD in ASA negative PM/DM patients and may have diagnostic, prognostic and pathogenic implications for myositis-associated ILD that should be further assessed in additional cohorts.

Figure 1. Risk of ILD in Caucasian PM and DM patients based on ASA and HLA DQA1\*05 allele status

<sup>a</sup> Numbers in the brackets represent those positive for the presence of ILD over the total number in that study group. Percentages are shown in parenthesis

<sup>a</sup> Comparison between these groups has yielded an odds ratio of 8 (95% Confidence Interval 2.83-22.58),  $P < 0.001$

<sup>b</sup> Comparison between these groups has yielded an odds ratio of 20.77,  $P = 0.003$  (OR is calculated using Woolf-Haldane Correction method)

<sup>c</sup> Comparison between these groups has yielded an odds ratio of 1.87 (95% Confidence Interval 0.30 – 11.52),  $P = 0.50$

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic inflammatory myopathies (JIIM) are rare, autoimmune chronic muscle diseases of childhood with significant potential long-term morbidity. In this study we investigate associations of clinical and demographic factors with long-term outcomes in a referral population of patients with JIIM who are currently adults.

**Methods:** Adults with JIIM were assessed at two referral centers between 1994 and 2016. Bivariate analysis was used to test for associations of 94 clinical, demographic, and laboratory factors with two long-term outcomes: a higher Myositis Damage Index (MDI) and the presence of calcinosis on last evaluation. A multivariable regression model for MDI used backwards selection on factors with statistically significant associations ( $p < .15$ ) in bivariate analysis.

**Results:** Forty-nine patients with probable or definite JIIM (37 dermatomyositis, 5 polymyositis, 7 overlapping myositis) had a median age of 24 years [IQR 19, 28], and median follow-up period of 12 years after diagnosis [IQR 5, 20]; 59% were Caucasian and 82% were female; 63% had a chronic, 31% a polycyclic, and 6% a monocyclic illness course. Damage was present in 96%, with a median MDI score of 6 [IQR 3, 9]. Cutaneous (80%) and muscle (78%) damage were most frequent and most severe (median score 2 [IQR 1, 3] for both) among the MDI organ systems. Calcinosis was present in 55% of patients. Of the 94 potential predictors, 17 were significantly ( $p < 0.15$ ) associated with total MDI score and 11 were significantly ( $p < 0.05$ ) associated with the presence of calcinosis (Table). All selected variables in the multivariable model were independently associated with a higher MDI score: erythroderma, shawl sign, disease duration, worst ACR functional class, and heliotrope rash. Several factors were strongly associated with calcinosis in bivariate analysis including disease duration, younger age at diagnosis, falling episodes, Gottron's papules, clinical subgroup JDM, constipation, periungual capillary changes, lipodystrophy, and contractures (Table). The multivariable logistic regression model for calcinosis did not converge due to the small sample size.

**Conclusion:** This is one of the largest cohorts of patients with JIIM evaluated for long-term outcomes into adulthood. We were able to identify multiple clinical factors associated with long-term damage and calcinosis when JIIM patients become of adult age, which included specific cutaneous and musculoskeletal features.

**Table 1: Top factors associated with Myositis Damage Index (MDI) score and calcinosis at last evaluation (N = 49).**

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Polymyositis (PM), dermatomyositis (DM), and clinically amyopathic DM (CADM) are systemic inflammatory diseases that affect skeletal muscle, skin, and other organs, such as lungs, heart, and joints. Several complications, such as interstitial lung disease (ILD), cardiomyopathy, and malignancy, are associated with poor prognosis for patients with PM/DM/CADM. Previous studies have highlighted the mortality and prognostic factors in PM/DM. Recently, myositis-specific autoantibodies (MSAs) have been used to predict clinical features, treatment response, and prognosis in patients with PM/DM/CADM. However, disease status after the treatment of adult patients with PM/DM/CADM, such as persistent existing disease activity or sustained remission, remains unclear in daily practice. Therefore, we investigated the disease status after treatment and clarified the predictive factors for sustained remission in adult patients with PM/DM/CADM using clinical data, including MSAs.

**Methods:** A total of 161 adult patients with PM/DM/CADM who visited our hospital from January 2001 to January 2017 were enrolled in this study. We retrospectively compiled clinical data, including age, gender, disease duration, organ involvement, MSAs, treatment history, and disease activity after treatment. Sustained remission was defined as following: any of active skin rash, such as Gottron's papules/sign, heliotrope rash, and erythema, myositis, and ILD requiring treatment intensification were not revealed continuously for more than six months after one year since initiation of induction therapy for PM/DM/CADM.

**Results:** The number of patients with PM, DM, and CADM was 47, 85, and 29, respectively. The median duration of follow-up was 4 years. MSAs were identified in 102 patients. The prevalence of MSAs was as follows: anti-ARS antibody (Ab) in 40 (39%), anti-MDA5 Ab in 15 (15%), anti-TIF1- $\gamma$  Ab in 12 (12%), anti-SRP Ab in 4 (4%), anti-NXP2 Ab in 4 (4%), and anti-SAE Ab in 2 (2%) patients. MSAs were negative in 25 (24%) patients. The total sustained remission rate was 58%. In patients with anti-ARS, anti-MDA-5, anti-TIF1- $\gamma$ , or anti-SRP Abs, the sustained remission rate was 50%, whereas in those without any of these 4 MSAs, the sustained remission rate was 87%. Multivariate analysis revealed that the achievement of sustained remission was associated with absence of anti-ARS, anti-MDA5, anti-TIF1- $\gamma$ , or anti-SRP Abs (Odds ratio = 6.7, 95% confidence interval (CI) = 1.7–33.0,  $P = 0.0045$ ) and no complication of severe muscle weakness requiring assistance at the time of diagnosis (Odds ratio = 23.6, 95% CI = 2.6–618.2,  $P = 0.003$ ).

**Conclusion:** The absence of anti-ARS, anti-MDA5, anti-TIF1- $\gamma$ , and anti-SRP Abs and no complication of severe muscle weakness before initiation of treatment predict achieving sustained remission after treatment in adult patients with PM/DM/CADM.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** PM and DM are inflammatory myopathies, sometimes complicated by interstitial lung disease (ILD), myocarditis, arthritis, and malignancies. The intensity of immunosuppressive therapies depends on the severity of muscle weakness and organ complications associated with PM/DM in individual patients. Corticosteroids remain the mainstay of treatment for PM/DM, although immunosuppressive agents have also been administered to better control disease activity and taper the dose of prednisolone (PSL) as much as possible. Long-term usage of PSL could cause a wide range of complications such as steroid myopathy, infection, osteoporosis, and diabetes mellitus. However, in daily clinical practice, it is difficult for some patients with PM/DM to taper PSL dose because of disease activity or repetitive recurrence despite combination therapy with immunosuppressants. Therefore, we clarified the required dose of PSL as maintenance therapy and investigated factors associated with the maintenance PSL dose in patients with PM/DM.

**Methods:** A total of 133 patients with PM/DM, who visited our hospital from January 2001 to January 2017 and had been treated for more than one year after initiation of therapies for PM/DM, were enrolled in this study. We retrospectively compiled clinical data, including age, gender, muscle strength, organ complications, laboratory data, including myositis-specific autoantibodies (MSAs), and treatment content. We investigated factors associated with the requirement of >5 mg/day of PSL, using multiple logistic regression analysis.

**Results:** The number of patients with PM, DM, and clinically amyopathic DM was 41, 69, and 23, respectively. The median follow-up duration was 4 years. ILD was observed in 76 (57%), dysphagia in 23 (17%), and malignancies in 29 (22%) patients. The median initial PSL dose was 50 mg/day. Methyl-PSL pulse therapy was performed in 45 (34%) patients. Immunosuppressants, including MTX, AZA, cyclophosphamide, and calcineurin inhibitors, and IVIG were administered in 94 (71%) and 19 (14%) patients, respectively. The median maintenance PSL dose was 5 mg/day (interquartile range: 2–8 mg/day). The requirement of >5 mg/day of PSL as maintenance therapy was found in 52 patients (39%). In multivariate analysis choosing age, gender, disease duration, myositis type, MSAs, treatment content, and follow-up period as explanatory variables, the presence of anti-ARS antibody (Ab) was a significant factor associated with the requirement of >5 mg/day of PSL (Odds ratio = 6.3, 95% confidence interval = 1.5–33.1,  $P = 0.01$ ). There were no other statistically significant factors. The requirement of >5 mg/day of PSL was found in 23 (59%) patients with anti-ARS Ab, but only in 13 (24%) patients without anti-ARS Ab ( $P < 0.001$ ).

**Conclusion:** In most patients without anti-ARS Ab, it is possible to decrease the maintenance PSL dose to  $\leq 5$  mg/day. The presence of anti-ARS Ab is associated with difficulty of tapering PSL dose to 5 mg/day despite combination therapy with PSL and immunosuppressants.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Myositis is a rare systemic autoimmune disease with suspected environmental and genetic risk factors, but little is known about specific infections and medications that might be triggers.

**Methods:** Myositis patients (362 dermatomyositis [DM], 250 polymyositis [PM], 256 inclusion body myositis [IBM]) enrolled in MYOVISION, diagnosed after January 1, 2002, and who met Bohan and Peter or Griggs criteria were included. Infections and medications received within the 12 months prior to diagnosis were queried. Significant univariable results were examined in multivariable logistic regression. Odds ratio point estimates with 95% confidence intervals and p-values were reported for each subtype pairwise comparison, after adjusting for age, gender, race, and year of diagnosis. Interactions of the effects between any infection and any medication, antibiotics, or NSAIDs were tested, after adjusting for age gender, race, and year of diagnosis.

**Results:** Overall, infections in the 12 months prior to diagnosis were reported more frequently in DM (OR 1.86: 95% CI 1.19-2.92,  $p \leq 0.01$ ) and PM (OR 1.61: 95% CI 1.01-2.55,  $p \leq 0.05$ ) than in IBM. Similar relationships were seen for gastroenteritis (OR 3.45: 1.44-8.25 DM vs. IBM, OR 3.39: 1.40-8.20 PM vs. IBM,  $p \leq 0.01$ ), respiratory infections, including upper respiratory infections (OR 1.76: 1.07-2.89 DM vs. IBM, OR 1.82: 1.10-3.02 PM vs. IBM,  $p \leq 0.05$ ), and febrile illnesses (OR 3.18: 1.26-8.05 DM vs. IBM, OR 3.49: 1.37-8.90, PM vs. IBM,  $p \leq 0.05$ ). The same infections were increased in the year prior to diagnosis in patients with an anti-synthetase phenotype with lung disease and arthritis or fever compared to those without. In addition, pneumonia (OR 5.31: 95% CI 2.67-10.6,  $p \leq 0.0001$ ) was increased only in patients with an anti-synthetase phenotype. Hepatitis, urinary tract and skin infections were reported in  $\leq 10\%$  of patients in each subgroup and did not differ among subgroups. Among medications, statins were used more frequently in DM and PM than IBM (OR 2.22: 95%CI 1.33-3.70 DM vs. IBM, OR 2.13: 1.26-3.58 PM vs. IBM,  $p \leq 0.005$ ) in the year prior to diagnosis. Diabetes medications (OR 3.35: 95%CI 1.36-8.23,  $p = 0.008$ ) and levothyroxine (OR 2.20: 1.03-4.71,  $p = 0.042$ ) were also used more frequently in PM than IBM. Antibiotics (OR 1.76: 95% CI 1.18-2.63,  $p \leq 0.01$ ) and NSAIDs (OR 1.73: 1.17-2.57,  $p \leq 0.01$ ) were used more frequently in patients with the anti-synthetase phenotype. Use of blood pressure medicines, other lipid lowering agents, and oral contraceptives did not differ by subgroup. In examining the interaction of any infection with antibiotics, no interaction was detected by clinical subgroups ( $p = 0.14 - 0.84$ ), or within the anti-synthetase phenotype ( $p = 0.45$ ).

**Conclusion:** Variations among myositis subgroups in reported infections and medications received within the 12 months prior to diagnosis suggest possible risk factors for myositis phenotypes. Certain infections, particularly gastrointestinal and respiratory, are increased in DM and PM patients relative to IBM. A history of pneumonia and antibiotic usage are increased in patients with lung disease. Controlled studies examining these factors may be helpful in elucidating their role in disease development.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

To assess microvascular structure and function in patients with adult dermatomyositis (DM) and juvenile dermatomyositis (JDM), we have designed and built a mobile, high-resolution Nailfold Video Capillaroscopy (NFVC) installation for clinical use, and correlated the results with both laboratory and clinical measures in patients.

## Methods:

We quantified nailfold capillary features in patients with DM (n=28) and JDM (n=17) with median age of 16.1 yrs (IQR 10.5 – 42.8) and median disease duration of 2.95 yrs (IQR 1.1 - 10.2) (74% females and 59% Caucasian) and healthy control subjects (n=18) with similar demographics. Capillary structural markers, including capillary density, tortuosity, interlimb distance, and functional markers, including local blood velocity in arterial (BVA) and venous (BVV) segments of capillaries, were measured. Left ring finger imaging of the nailfold area was performed with a motorized stereomicroscope (Leica M205C) equipped with a video camera (Hamamatsu ORCA-Flash4.0) at 25x overall magnification, providing 1  $\mu$ m resolution and up to 100 Hz acquisition rate. Spearman rank correlation coefficients and p-values were calculated to determine correlations between NFVC markers and clinical data.

## Results:

Capillary density ( $p < 0.01$ ), BVA ( $p < 0.05$ ), and BVV ( $p < 0.05$ ) are significantly lower in patients with DM and JDM than healthy subjects. Interlimb distance and capillary tortuosity were higher in DM or JDM than healthy controls ( $p < 0.01$ ). Capillary density and capillary interlimb distance ( $r = -0.65$ ,  $p < 0.001$ ) correlated inversely, and BVA and BVV strongly correlated ( $r = 0.95$ ,  $p < 0.001$ ). There were no significant differences in any of these NFVC parameters between DM and JDM. NFVC markers correlated with myositis activity and damage measures and laboratory data from the combined DM/JDM group. Skin disease activity scores (DAS skin) negatively correlated with capillary density ( $r = -0.46$ ,  $p < 0.01$ ) and positively with capillary interlimb distance ( $r = 0.48$ ,  $p < 0.01$ ). Extramuscular Myositis Disease Activity Assessment Tool (MDAAT) correlated with capillary tortuosity ( $r = 0.35$ ,  $p < 0.05$ ). Gastrointestinal (GI) MDAAT scores correlated negatively with BVA and BVV ( $r = -0.62$  -  $-0.58$ ,  $p < 0.01$ ), whereas manual muscle testing correlated with BVA and BVV ( $r = 0.50$ - $0.53$ ,  $p < 0.05$ ). Among laboratory measures, ESR correlated with interlimb distances ( $r = 0.41$ ,  $p < 0.05$ ) and negatively correlated with BVA and BVV ( $r = -0.47$  -  $-0.48$ ,  $p < 0.05$ ), and white blood cell count correlated with capillary tortuosity ( $r = 0.55$ ,  $p < 0.001$ ). Muscle enzymes and von Willebrand factor related antigen levels did not correlate with NFVC parameters. Among damage measures, MD global damage and muscular and skeletal damage in the Myositis Damage Index (MDI) correlated with capillary tortuosity ( $r = 0.36$  -  $0.37$ ,  $p < 0.05$ ), and GI MDI scores correlated negatively with BVA and BVV ( $r = -0.57$  -  $-0.63$ ,  $p < 0.05$ ).

## Conclusion:

Structural and functional NFVC markers correlate with disease activity and damage measures in muscle and extramuscular organs in children and adults with DM. Functional parameters of NFVC, including tortuosity and blood velocity, reveal new dimensions of the utility of NFVC in myositis assessment.

National Institutes of Health, Bethesda, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster  
**Session Type:** ACR Poster Session C  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoantibodies recognizing cytosolic 5'-nucleotidase 1A (NT5C1A) are present in the sera of adults with myositis and other autoimmune diseases. They are especially prevalent in adults with inclusion body myositis (IBM), where they are associated with more severe weakness. This study was undertaken to define the prevalence and clinical features associated with anti-NT5C1A autoantibodies in juvenile myositis.

**Methods:** We screened sera from 380 juvenile myositis patients, 30 patients with juvenile idiopathic arthritis (JIA), and 92 healthy control children for anti-NT5C1A. Clinical characteristics were compared between myositis patients with and without anti-NT5C1A.

**Results:** Anti-NT5C1A autoantibodies were present in the sera of 102 of 380 (27%) patients with juvenile myositis, 11 of 92 (12%) healthy control children ( $p=0.002$ ) and 27% of children with JIA ( $p=0.05$  vs. controls). Eighty-three of 307 (27%) juvenile dermatomyositis and 16 of 46 (35%) juvenile overlap myositis patients' sera were anti-NT5C1A positive ( $p<0.01$  vs. controls for each). Only 3 of 27 (11%) juvenile polymyositis patients were anti-NT5C1A positive. Juvenile myositis patients with and without anti-NT5C1A autoantibodies had similar phenotypes. However, anti-NT5C1A positive myositis patients had more frequent hospitalizations ( $p=0.007$ ), required more medications ( $p<0.001$ ), and had higher early total, skin and lung symptom scores ( $p\leq 0.05$ ) (Table 1). The HLA alleles DRB1\*07 (21% vs. 9%,  $p=0.04$ ) and DQA1\*0201 (22% vs. 6%,  $p=0.005$ ) were more frequent in anti-NT5C1A negative patients.

**Conclusion:** Anti-NT5C1A autoantibodies are present in 27% of children with myositis, as is the case for JIA. As in adults with IBM, juvenile myositis patients with anti-NT5C1A autoantibodies have more severe disease.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The idiopathic inflammatory myopathies (IIM) are systemic autoimmune diseases with chronic muscle inflammation and microvasculopathy of muscle and skin capillaries. Circulating endothelial cells (CECs), von Willebrand Factor antigen (vWF), P-selectin, and thrombomodulin are released from damaged endothelium. Loss of function of endothelial progenitor cells (EPCs) has been associated with poor vascular outcomes in other autoimmune diseases. These endothelial markers may be part of the pathogenic changes of IIM and we hypothesized they may be indicators of disease activity.

**Methods:** We assessed endothelial biomarkers in 24 probable or definite IIM patients (20 juvenile dermatomyositis (DM), 2 adult DM, 1 each with juvenile and adult polymyositis) with a median age of 12.6 yrs [IQR 9.8-16.4] and 67% female, and in 29 healthy controls with similar ages and genders. CECs and EPCs in peripheral blood were quantitated by flow cytometry. EPC markers included CD34+/133+, KDR+/133+, and CXCR4+/133+. Plasma vWF antigen (Ag) was measured in an immunoassay, vWF activity in a Ristocetin cofactor assay, and Factor VIII (FVIII) in a one-stage clotting assay based on activated partial thromboplastin time. Thrombomodulin and P-selectin were measured by ELISA. IMACS and PRINTO myositis disease activity and damage measures were assessed and periungual nailfold capillary (NFC) morphology and density were quantified using digital photographs in IIM patients. Group differences were evaluated by Wilcoxon-rank sum test, and Spearman's rank correlations assessed relationships between variables.

**Results:** Among endothelial markers, CECs (median 0.89 vs. 0.20 cells/uL,  $p < 0.001$ ), vWF Ag (median 159 vs. 94 IU/mL,  $p < 0.001$ ), vWF activity (median 150 vs. 118 IU/dL,  $p = 0.018$ ), FVIII (median 187 vs. 141 IU/dL,  $p = 0.004$ ), and thrombomodulin (median 7.68 vs. 2.08 ng/mL,  $p = 0.020$ ), but not EPC subsets or P-selectin, were elevated in IIM patients vs. healthy controls. vWF measures correlated with each other and FVIII ( $r_s$  0.74-0.83,  $p < 0.001$ ). CECs correlated with pulmonary and extramuscular activity, and Disease Activity Scores (DAS) ( $r_s$  0.47-0.65,  $p \leq 0.022$ ), and inversely with NFC density ( $r_s$  -0.43,  $p = 0.052$ ). vWF Ag correlated with physician global activity, extramuscular activity, and the extent of NFC avascularity ( $r_s$  0.44-0.51,  $p \leq 0.034$ ). KDR+/133+ EPC cells negatively correlated with constitutional and extramuscular activity, total and muscle DAS scores, [C]HAQ, and LDH ( $r_s$  -0.50 – -0.67,  $p \leq 0.043$ ) and positively correlated with CMAS, NFC density and tortuosity ( $r_s$  0.50 – 0.80,  $p \leq 0.039$ ). Thrombomodulin only correlated with gastrointestinal activity ( $r_s$  0.48,  $p = 0.049$ ). None of the markers correlated with brachial artery flow-mediated dilation, Myositis Damage Index or physician global damage.

**Conclusion:** Markers of endothelial damage, including CECs, vWF and thrombomodulin, were increased in IIM patients, and correlate with some extramuscular measures of myositis activity, suggesting they may be good biomarkers for myositis phenotypes. EPCs, in contrast, correlate inversely with myositis activity measures, suggesting blood vessel regeneration may be diminished during active disease.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Polymyositis (PM)/dermatomyositis (DM) is a chronic inflammatory disorders involved in skeletal muscles. Interstitial lung disease (ILD) complicated with PM/DM patients is often developed as rapidly progressive ILD (RPILD), which can be treatment resistant and life threatening. However, serum biomarkers of PM/DM with RPILD still remain to be obscure. This study was aimed to identify the specific biomarkers to assess PM/DM complicated with RPILD.

**Methods:** Forty-six patients with PM/DM-ILD, in either RPILD (n = 20) or chronic ILD (n = 26), were enrolled from Nagasaki University Hospital and related institutions. They gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. Using medical records, we analyzed the patients' demographics and clinical characteristics. Serum levels of 42 cytokines/chemokines were measured by multi-suspension cytokine array. Serum levels of anti-melanoma differentiation-associated gene 5 (MDA5) antibody, ferritin and interferon-alpha (IFN- $\alpha$ ) were measured by enzyme linked immunosorbent assay. These serum variables were ranked by their importance by a multivariate classification algorithm termed

random forest analysis. We performed a logistic regression analysis to determine a set of specific biomarkers for distinguishing patients with RPILD from patients with chronic ILD.

**Results:** Patients with RPILD had significantly higher age, mortality, the frequency of clinically amyopathic DM (CADM), the prevalence of mediastinal emphysema, periungual erythema and mechanic's hand than patients with chronic ILD. Twenty-four out of 42 cytokines/chemokines, anti-MDA5 antibody, ferritin and IFN- $\alpha$  were available for further analyses. Patients with RPILD had significantly higher serum levels of 5 cytokines (IL-15, IL-6, CCL7, CXCL10 and VCAM-1), anti-MDA5 antibody and ferritin than patients with chronic ILD patients whereas CCL-22 was significantly low in RPILD patients. We found that IL15 was most significant cytokine to distinguish patients with RPILD from patients with chronic ILD using random forest analysis (Fig. 1). Additionally, we found that anti-MDA5 antibody, IL-15, TNF- $\alpha$ , CXCL-8, CCL-22 and IL-1RA were the best combination to distinguish patients with RPILD from patients with chronic ILD (sensitivity: 95%, specificity: 88.5%, accuracy: 91.3%).

**Conclusion:** Our data for the first time identify the combinational serum biomarkers to predict PM/DM patients complicated with RPILD.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CXCR3 is a chemokine receptor that plays an important role in T cell chemotaxis in human autoimmune diseases. CXCR3, which is activated by ligand interferon gamma-inducible protein 10 (CXCL10, IP-10), was reported to be increased in muscle tissue in polymyositis. We investigated the effect of CXCR3 blockade in C protein-induced myositis (CIM) animal model.

**Methods:** CIM was induced with human skeletal C protein in 7 week old female C57BL/6 mice. Mice were treated with anti-CXCR3 antibody or control IgG at day 8 and day 15 after induction with C protein. Mouse muscle tissue was evaluated on day 21. H&E stain of muscle was performed to evaluate infiltrated inflammatory cells. CXCR3 expressing cells from mouse splenocytes and lymph node cells were analyzed by flow cytometry.

**Results:** Flow cytometric analysis demonstrated decreased CXCR3<sup>+</sup>CD8<sup>+</sup> memory T cells and CXCR3<sup>+</sup>pDC cells in lymph nodes of the anti-CXCR3 antibody treated group compared to that of the control IgG treated group ( $36.583 \pm 9.39\%$  vs  $31.266 \pm 7.78\%$ ;  $p = 0.06$ ,  $40.6 \pm 5.622\%$  vs  $56.1 \pm 5.72\%$ ;  $p = 0.012$ , respectively). In addition, CD8<sup>+</sup>IFN- $\gamma$ <sup>+</sup>CXCR3<sup>+</sup> cells in lymph nodes significantly decreased in the anti-CXCR3 antibody group compared to that of the vehicle group ( $9.725 \pm 0.67\%$  vs  $17.05 \pm 4.69\%$ ;  $p < 0.01$ ). Anti-CXCR3 antibody group showed lower inflammation score in muscle compared to that of the vehicle group ( $p = 0.032$ ).

**Conclusion:** CXCR3 blockade suppressed inflammation in muscle and CXCR3 expression in lymph node cells in CIM model. These results suggest a therapeutic effect of anti-CXCR3 antibody in inflammatory myopathy.

**Conflicts of Interest (COI) declaration:** Anti-CXCR3 antibody and control IgG antibody were provided by Pfizer through collaboration with Charles MacKay and Remy Robert at Monash University, Melbourne, Australia.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The clinical and mechanistic relevance of peripheral CD4<sup>+</sup>CXCR4<sup>+</sup> T cells in idiopathic inflammatory myopathy (IIM)-associated interstitial lung disease (IIM-ILD) is not known.

### Methods:

Patients with IIM-ILD (n=36), disease-related controls (n=30), and healthy persons (n=13) were recruited. CD4<sup>+</sup>CXCR4<sup>+</sup> T cell percentages, stromal cell-derived factor-1 (SDF-1), Krebs von den Lungen-6 (KL-6), autoantibodies, lung function, HR-CT scores, and

individual disease progress were analyzed. Cytokine expression of isolated CD4<sup>+</sup>CXCR4<sup>+</sup> T cell and co-cultured fibroblast proliferation was measured.

**Results:**

The percentages of peripheral CD4<sup>+</sup>CXCR4<sup>+</sup> T cells are significantly elevated in IIM-ILD patients compared to controls (p<0.01 Figure 1), correlate with HRCT scores (r=0.5820) and pulmonary function impairments (FVC, DLCO/VA). They are associated with anti-MDA5 autoantibodies and the amyopathic dermatomyositis (ADM) phenotype. In IIM-ILD, percentages of CD4<sup>+</sup>CXCR4<sup>+</sup> T cells ≥ 45% revealed a 6-month mortality over 50% (Figure 2). CD4<sup>+</sup>CXCR4<sup>+</sup> T cells from ADM-ILD patients express high levels of IL-21. In vitro blockade of IL-21 signaling by neutralization of IL-21 or JAK inhibitor could abolish the fibroblast proliferation (Figure 3).

**Conclusion:**

CD4<sup>+</sup>CXCR4<sup>+</sup> T cells appear to be a potentially valuable novel biomarker associated with the severity and prognosis of IIM-ILD. They promote pulmonary fibroblast proliferation via IL-21, which may herald future targeted treatments for this severe disease.

Figure 1. Percentages of peripheral CD4<sup>+</sup>CXCR4<sup>+</sup> T cells are significantly elevated in IIM-ILD patients compared to disease and healthy controls.

Figure 2. In IIM-ILD patients, the percentages of CD4<sup>+</sup>CXCR4<sup>+</sup> T cells strongly correlate with the extent of ILD structural changes as identified by HRCT score (r=0.5820). High percentages of CD4<sup>+</sup>CXCR4<sup>+</sup> T cells ≥ 45% revealed a 6-month mortality over 50%.

Figure 3. ADM-ILD derived CD4<sup>+</sup>CXCR4<sup>+</sup> T cells promote pulmonary fibroblast proliferation via an IL-21 dependent manner. Neutralization of IL-21 with a monoclonal antibody or blockade of IL-21 signaling by a JAK inhibitor could abolish the pro-fibrotic effect of these CD4<sup>+</sup>CXCR4<sup>+</sup> T cells with an additive suppressive effect.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

The prevalence of dysphagia in patients with inflammatory myopathies has been reported to be as high as 60% (1). Aspiration pneumonia is one of the main causes of mortality in patients affected by immune mediated myositis, especially in those with chronic deterioration(2). The goal of this study was to characterize the pathophysiologic changes in swallowing of myositis patients by examining videofluoroscopic swallow studies (VFSS) for kinematic, temporal, and functional measures of swallowing.

## **Methods:**

VFSS of 23 myositis patients (IBM= 7, Necrotizing= 2, DM= 13, PM =1, age range= 21-81) complaining of dysphagia were collected, and frame by frame analysis of temporal and kinematic measures were performed. The swallows of each subjects were rated by MBSImP<sup>®</sup> and Penetration-Aspiration Scale. Swallowing measures from patients were compared to those from 64 healthy subjects (ages range= 18-90) by Wilcoxon rank-sum tests.

## **Results:**

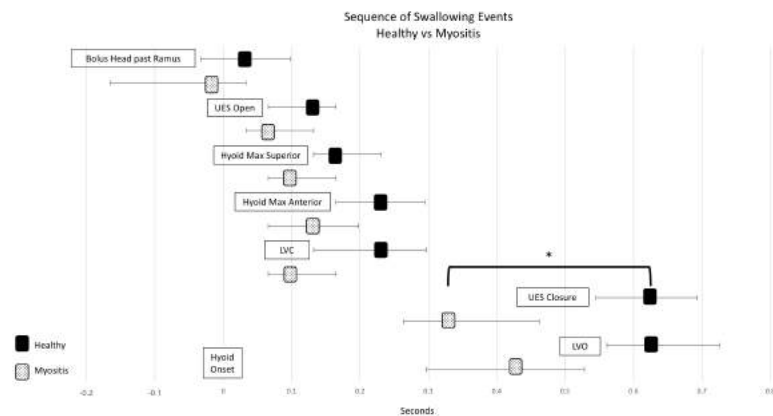

In patients with myositis, food entered the pharynx earlier relative to the initiation of swallowing than in healthy participants ( $p<0.0001$ ). Myositis patients had a significantly shorter duration of upper esophageal sphincter (UES) opening and laryngeal vestibule closure than healthy subjects ( $p<0.0001$ ). There were no statistically significant differences in AP diameter of the UES between healthy subjects and myositis patients ( $p=0.9$ ). In myositis patients, several MBSImP<sup>®</sup> component scores indicated impairment, particularly those related to residue after swallowing, base of tongue movement, and posterior pharyngeal wall movement. Aspiration was observed in 26% of the patients.

## **Conclusion:**

Swallowing pathophysiology in myositis appears to be related to reduced muscle strength and endurance. Tongue weakness resulted in premature entrance of bolus into the pharynx prior to airway closure. Diminished pharyngeal stripping wave and tongue retraction contributes to poor bolus clearance. Decreased duration of UES opening with preserved extent of anteroposterior diameter suggest conserved ability to open the UES but reduced endurance in the submental musculature to sustain opening. Strength and endurance exercises of the tongue and submental muscles are potential therapeutic targets for preservation of swallowing function in myositis patients.

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Injury to the vascular endothelium is implicated in the pathogenesis of dermatomyositis (DM). Normal high density lipoprotein (HDL) protects the vascular endothelium from damage due to oxidized phospholipids, which accumulate under conditions of oxidative stress

and are metabolized by the HDL-associated enzyme, paraoxonase 1 (PON1). The current work evaluates the relationship of the PON1Q192R genetic polymorphism and PON1 activity to disease activity and damage in DM pts.

### **Methods:**

In a cross-sectional cohort of 118 DM pts, the relationships between PON1 activity, PON1 genotype (for the functional polymorphism at position 192), and myositis disease activity and damage were assessed using physician global 5 point Likert and 100 mm visual analogue scales (VAS), CPK levels, and pulmonary function tests (PFTs) in pts with myositis-associated interstitial lung disease (ILD). Plasma PON1 activity was measured using paraoxon as the substrate and the PON1 Q192R genotype was determined as described previously (*A&R* 2013,65(11) 2765). Lipoprotein cholesterol levels were assessed by standard assays and traditional CV risk factors and myositis disease characteristics were assessed by questionnaire and chart review.

### **Results:**

PON1 activity was highest in DM patients with the RR genotype, intermediate for the QR genotype, and lowest for the QQ genotype (Table). Pts with the QQ genotype had trends for lower levels of systemic inflammation, higher HDL cholesterol (HDL-C), and significantly lower global disease activity/damage scales compared to QR or RR genotypes (Table). In patients with ILD who had available PFTs (n=30), the % predicted DLCO was significantly higher in the QQ group compared to the QR group; this relationship remained in multivariate (MV) analysis controlling for age and sex. A significant association of the QQ genotype with lower global disease activity (VAS) also remained in MV analysis controlling for demographic characteristics, medication use, disease duration, and HDL-C levels. Higher HDL-C levels were significantly associated with lower disease activity in this analysis.

### **Conclusion:**

In a large cross-sectional cohort of DM pts, the PON1Q192R QQ genotype was associated with a more favorable disease activity profile including lower global disease activity assessments and higher DLCO in patients with myositis-associated ILD. Because DM is a systemic vascular disease and the PON1Q192R polymorphism has previously been associated with vascular outcomes, further investigation and validation of these findings is warranted.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients(pts) with idiopathic inflammatory myopathies (IIM) have an increased risk of cardiovascular (CV) disease. Statins reduce CV risk but have been associated with myalgias, myositis, and rhabdomyolysis. We describe the use of statins in a longitudinal cohort of pts with IIM.

**Methods:** A retrospective review was conducted of 189 IIM pts (127 DM, 51 PM, 13 IBM, 3 HMGCR+ IMNM) enrolled in a longitudinal IIM cohort. All pts on statins were identified. Physician global myositis disease activity(DA) and damage(DD) assessments (100 mm visual analogue scales(VAS) and 5 point Likert scales) were performed at 3 visits: 1) visit prior to statin initiation, 2) visit immediately after statin initiation, and 3) most recent follow-up. For pts without visits prior to statin initiation, the initial study visit and two longitudinal visits were evaluated. All assessments were performed by the same myositis physician who was blinded to the statin use/non-use at the visits. Laboratory data and adverse events were gathered by chart review.

**Results:** 22 pts taking a statin were identified including 6 pts who were not on a statin at time of study enrollment and were started during the follow-up period. The 3 HMGCR ab+ IMNM pts in the cohort were historically on a statin but discontinued by the time of study enrollment and so not included in this analysis. Mean (SD) age was 53 (34) years and most were female (n=14, 64%). Thirteen pts had myositis antibody testing available: Ro (n=5), MDA5 (n=2), Jo1 (n=1), U1RNP(n=1), Ku(n=1) and MJ (n=1). Types of statins used included atorvastatin 10-40mg (n=12), rosuvastatin 5-20mg (n=7), simvastatin 40-80mg (n=2), pravastatin 20mg (n=2) and lovastatin 40mg (n=1). Mean (range) duration of observed statin use was 34 (0-90) months.

Among pts that were on a statin at study enrollment, 19/22 remained on a statin during the follow-up period. Of the remaining 3/22 pts: Pt #1 had a history of statin intolerance before onset of DM and remained intolerant to statins after DM diagnosis despite multiple agents tried; Pt #2 presented with rapidly progressive MDA5 + ILD, which was fatal within 1 month; Pt #3 had the statin discontinued by her primary care provider for unclear reasons (disease activity score remained low before (VAS DA=12) and after statin discontinuation (VAS DA=8) without note of intolerance). For the 6 pts started on statins during the study period, there was no worsening in disease activity measures between visit 1 (pre-statin) and visit 2 (post statin) (Table). Mean (SD) follow-up between visits 1 and 2 = 2.2(0.9) months. 3/6 IIM pts were started on a statin in the setting of active disease including cardiac muscle involvement (mean(SD) VAS DA= 49(9) n=3).

**Conclusion:** Statins were well tolerated in a relatively large longitudinal cohort of IIM patients. Use may be considered in IIM patients without HMGCR ab when clinically indicated for CV risk reduction.

	Visit prior to statin initiation	Visit after statin initiation

## Serum Microrna-1 Can be a Predictive Marker for Disease Activity of Polymyositis/Dermatomyositis-Associated Interstitial Lung Disease

**Yumiko Sugiyama**, Ryusuke Yoshimi, Yosuke Kunishita, Daiga Kishimoto, Yohei Kirino and Hideaki Nakajima, Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although intensive immunosuppressive treatment are necessary for the severe cases with polymyositis (PM)/dermatomyositis (DM), the prognostic factors or disease activity indices for PM/DM have not established yet. On the other hand, microRNAs are small non-coding RNAs, some of which have a certain function such as a transcriptional regulation. MicroRNA-1 (miR-1) has been shown to be associated with myocyte differentiation, decreased in muscle biopsy sample from patients with inflammatory myopathies, and induced by type I interferon. Here we investigated the association between serum miR-1 level and clinical course of PM/DM patients.

**Methods:** We retrospectively analyzed clinical features, and laboratory data at baseline in patients with PM/DM patients who had received initial treatment at Yokohama City University Hospital from 2008 to 2017. We also investigated initial therapeutic regimens, clinical outcomes, and episodes of serious infection. The serum samples from PM/DM were collected before and after starting treatment and those from healthy controls were recruited from the biobank institution in the hospital. The serum miR-1 levels were measured by quantitative real-time PCR.

**Results:** Twenty-two patients (PM 4, DM 11, clinically amyopathic DM (CADM) 7) were recruited. The mean age was  $63.5 \pm 8.5$  years, 13 (59%) were female, and 14 patients (64%) had interstitial lung disease. Among the patients, 3 patients died and 9 had infections which needed antibiotic therapy within 6 months from diagnosis. The serum miR-1 level was significantly elevated in PM/DM patients as compared to healthy control ( $p = 0.008$ ; Figure 1). In PM/DM patients, the serum miR-1 level was significantly decreased by treatment ( $p = 0.03$ ). There was a correlation between serum CK and miR-1 levels in PM/DM patients ( $p = 0.005$ ,  $r = 0.58$ ), although there was no correlation between the improvement rate of serum CK and miR-1 levels in PM/DM patients. We identified the cutoff value of serum miR-1 level from the two standard deviations in healthy controls, and divided all the PM/DM patients or PM/DM patients with interstitial lung disease (PM/DM-ILD) into two groups by the serum miR-1 level at baseline,

respectively. There were no significant differences in clinical data, outcomes, and treatment regimens in PM/DM patients. However, in the PM/DM-ILD patients, although there was no significant differences in clinical data at baseline and the initial dose of prednisolone (PSL), the higher miR-1 group needed longer time to be tapered to the half of initial PSL dose ( $p = 0.021$ ) as compared to lower miR-1 group. The higher miR-1 group also tended to be complicated by infection within 6 months from starting treatment more frequently ( $p = 0.008$ ).

**Conclusion:** This is the first report showing the elevated serum miR-1 level in PM/DM patients. miR-1 can be a predictive marker for response to immunosuppressive therapy for PM/DM-ILD.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although concomitant infectious diseases are the predominant causes of death in patients with polymyositis (PM)/dermatomyositis (DM)-associated interstitial lung disease (ILD), intensive immunosuppressive treatment are necessary for severe cases. We have already reported that high initial dose of glucocorticoid for induction therapy, high serum LDH and KL-6 levels at the baseline were independent risk factors for infection. Here we investigated the predictive risk factors for opportunistic infection during treatment for PM/DM-ILD by assessing cytomegalovirus (CMV) antigen test as a barometer for immunocompromised status.

**Methods:** We retrospectively analyzed clinical features, laboratory data and high-resolution computed tomography (HRCT) findings at baseline in the patients with PM/DM-ILD who had received initial treatment at six hospitals affiliated to Yokohama City University from 2003 to 2016. We also investigated initial therapeutic regimens and clinical outcomes including CMV antigenemia as a complication. We conducted univariate and multivariate analyses to extract risk factors for CMV antigenemia.

**Results:** One hundred sixteen patients (PM 22, DM 51, and clinically amyopathic DM (CADM) 43) were recruited. The mean age was 56 ± 15 years and 83 (71.6%) were female. As initial therapies, oral prednisolone (PSL) was prescribed in all patients. Methylprednisolone (mPSL) pulse, intravenous cyclophosphamide (IVCY), and oral calcineurin inhibitor therapies were performed in 78 (67%), 48 (41%) and 81 (70%), respectively. Forty patients (34%) received combination therapy with IVCY and a calcineurin inhibitor. Forty-two patients (36%) had CMV antigenemia within 6 months from initiation of immunosuppressants. Low serum albumin and PaCO<sub>2</sub> levels ( $p = 0.001$  and  $p = 0.004$ , respectively), high serum ferritin levels ( $p = 0.007$ ), ILD region existing in the upper lung field ( $p = 0.008$ ), high initial PSL dose ( $p = 0.006$ ), mPSL pulse ( $p = 0.001$ ), IVCY ( $p < 0.001$ ), and combination therapy ( $p < 0.001$ ) were extracted as risk factors for CMV antigenemia by univariate analyses (Table 1). There were no association between the cumulative PSL dose and CMV antigenemia. A multivariate logistic regression analyses revealed that low PaCO<sub>2</sub> ( $p = 0.044$ , OR 4.96), above 0.6 mg/kg/day of initial PSL dose ( $p = 0.027$ , OR 3.56) and the treatment with oral calcineurin inhibitor ( $p = 0.007$ , OR 21.23) were independent risk factors for CMV antigenemia. Of 27 patients who died during the observation period 13 (48%) had CMV antigenemia.

**Conclusion:** Although rapid and intensive therapies are required for PM/DM-ILD, appropriate monitoring, prophylaxis and early treatment for opportunistic infection are important, especially in patients who receive high initial dose of glucocorticoid or calcineurin inhibitor and who show low PaCO<sub>2</sub> level.

## Mycophenolate Mofetil Treatment with or without a Calcineurin Inhibitor in Resistant Inflammatory Myopathy

Hironari Hanaoka, Harunobu Iida, Tomofumi Kiyokawa, Yukiko Takakuwa and Kimito Kawahata, Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

First publication: September 18, 2017

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Muscle Biology, Myositis and Myopathies Poster

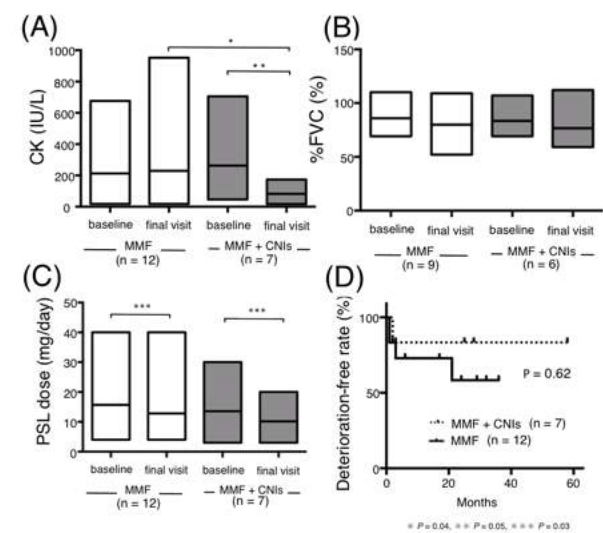

**Background/Purpose :** Patients with polymyositis (PM) and dermatomyositis (DM) refractory to glucocorticoid therapy have been treated with a variety of immunosuppressants including mycophenolate mofetil (MMF) and calcineurin inhibitors (CNIs). Although therapeutic effect of the each agent has been partially evaluated, its combination therapy has been poorly investigated. In this study, we evaluated the efficacy and tolerability of MMF with or without CNIs in patients with inflammatory myopathy taking prednisolone (PSL), but refractory to conventional immunosuppressive therapy.

**Methods:** The records of patients with inflammatory myopathy who had previously failed treatment with at least one immunosuppressant were retrospectively evaluated. We selected patients treated with MMF and divided them into two groups depending on whether or not there was concomitant use of CNIs. We investigated the efficacy by changes in creatine kinase (CK) levels, forced vital capacity (%FVC), and PSL dose. Deterioration was defined as death or drug change due to treatment failure.

**Results:** We identified 19 patients (14 for DM and 5 for PM) on MMF treatment. There were seven (36.8%) patients on MMF and CNIs, including five on cyclosporine and two on tacrolimus. Average observational periods were 18.6 (SD: 20.5) months in those with the MMF and CNIs and 14.3 (SD: 13.7) months in patients with MMF ( $P = 0.29$ ). At baseline no significant difference in clinical features including the prevalence of interstitial lung disease (ILD) was seen in between patients taking or not taking CNIs (Table 1). Improvement in CK was seen in patients treated with CNIs ( $P = 0.04$ ) but not in those without ( $P = 0.39$ ). No significant improvement in %FVC was found in patients with ILD in either group, and patients with CNIs had a slightly better result than those without in deterioration rate but no differences was seen ( $P = 0.62$ ) (Figure 1).

**Conclusion:** The combination of CNIs and MMF might be more effective for decreasing CK levels than MMF alone. Neither treatment arm had a beneficial effect on ILD or deterioration rate over a short-term observation.

Figure 1

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Idiopathic inflammatory myopathies (IIM) are characterized by inflammation and atrophy of skeletal muscles, pulmonary and articular involvement, which limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition. The aim of our study was to assess body composition and physical activity of IIM patients and healthy controls (HC).

**Methods:** 54 patients with IIM (45 females/9 males; mean age 57.3; disease duration 5.8 years; polymyositis (PM,22)/dermatomyositis (DM,25)/necrotizing myopathy (IMNM,7)) and 30 age-/sex-matched HC (25 females/5 males, mean age 54.9) without rheumatic/tumor diseases or manifest cardiovascular event were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. Anthropometric parameters and body composition were assessed (by densitometry-iDXA Lunar, and by bioelectric impedance-BIA2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Muscle involvement was evaluated by manual muscle test (MMT-8). Data are presented as mean±SD.

**Results:** Compared to HC, patients with IIM had significantly increased body fat % as assessed by iDXA (BF%: 38.7±6.7 vs. 42.5±7.1%, p=0.015), but decreased lean body mass as assessed both by iDXA (LBM: 45.7±6.6 vs. 40.3±7.0 kg, p=0.0005) and BIA (LBM: 53.2±8.5 vs. 48.7±9.0 kg, p=0.0295), and increased extracellular mass/body cell mass (ECM/BCM) ratio (1.00±0.12 vs. 1.43±0.42, p<0.0001), which reflects worse muscle predispositions for physical exercise, aerobic fitness/performance, and also increases with deteriorating nutritional status. Compared to HC, IIM patients had significantly lower bone mineral density (BMD: 1.16±0.10 vs. 1.05±0.11 g/cm<sup>2</sup>, p=0.0010), and were currently able to perform less energetically demanding physical activities according to HAP score (86.3±5.9 vs. 49.0±20.2, p<0.0001). Disease duration negatively correlated with BMD (r=-0.392, p=0.004) and LBM-BIA (r=-0.272, p=0.047). CRP was positively associated with BF% assessed both by DEXA (r=0.276, p=0.035) and BIA (r=0.306, p=0.025). MMT-8 score negatively correlated with ECM/BCM ratio (r=-0.385, p=0.006), and physical activity (HAP) negatively correlated with BF%-DEXA (r=-0.292, p=0.032).

**Conclusion:** Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease duration, inflammatory status, skeletal muscle involvement, and physical activity, and could reflect their impaired nutritional status and predispositions for physical exercise, aerobic fitness and performance.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Involvement of musculoskeletal system (inflammation, atrophy and permanent damage to the muscle) in idiopathic inflammatory myopathies (IIM) leads to impaired function, reduced muscle strength, endurance and aerobic capacity, decreasing quality of life. Data on efficacy of non-pharmacologic care in IIM is very limited due to variety in studied interventions/outcomes. The aim of our study was to address the limitations of existing studies, and evaluate the effect of a controlled, long-term (24-week intervention, 24-week follow-up), intensive (1h physiotherapy twice weekly, and home-exercise for 1h 5x weekly), tailored physiotherapy program to improve muscle strength, endurance and deep stabilizer system, and quality of life/disability in cohorts with a substantial number of IIM patients.

**Methods:** All patients fulfilled the Bohan and Peter 1975 diagnostic criteria for dermatomyositis (DM) or polymyositis (PM), had skeletal muscle involvement, and were consecutively recruited from 2014 to 2016 at the Institute of Rheumatology in Prague. Both groups received educational materials and instructions for home exercise at baseline, however, only intervention group underwent the intensive physiotherapy programme. At months 0,3,6,12 all patients were assessed by a physician (physical examination, MITAX, MYOACT, and MDI), and a physiotherapist blinded to intervention (standardized tests evaluating the level of muscle strength MMT-8), and endurance (FI-2), patients filled out patient reported outcomes (PRO)/questionnaires [HAQ, SF-36, Beck's depression inventory-II (BDI-II), PROs assessing nutrition and fatigue], body composition was analyzed using densitometry (iDXA Lunar) and bioelectric impedance (BIA2000-M), and patients provided blood for routine laboratory analysis and biobanking. Normality of data was tested and inter-group analysis performed with 2-way ANOVA and intra-group analysis by Friedman's test with Dunn's post hoc test.

**Results:** 27 IIM patients (22 female / 5 male, 10 DM / 12 PM / 5 IMNM (immune mediated necrotizing myopathy), median of age 58.0 and disease duration 7.0 years) were recruited into the intervention group (IG) and 27 patients into the control group (CG) (24 female / 3 male, 13 DM / 12 PM / 2 IMNM, median of age 56.5 and disease duration 4.7 years). Compared to observed statistically significant deterioration in CG over the period of months 0-6, we found statistically significant improvement in FI-2, MMT8, HAQ, BDI-II (Table 1). Only numerical improvement in IG compared to numerical deterioration in CG, which has not reached statistical significance, was observed in SF-36 and fatigue PROs.

**Conclusion:** Our intensive 24-week physiotherapy programme led to a significant improvement in muscle strength, endurance, function and depression, which was clinically meaningful in a substantial proportion of patients.

## **Myositis As a Complication of Checkpoint Blockade at a Comprehensive Cancer Center**

**Mohsin Shah**<sup>1</sup>, Jean Tayar<sup>1</sup>, Noha Abdel-Wahab<sup>1,2</sup> and Maria Suarez-Almazor<sup>1</sup>, <sup>1</sup>Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX, <sup>2</sup>Rheumatology and Rehabilitation Department, Assiut University Hospitals, Assiut, Egypt, Assiut, Egypt

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Immune checkpoint inhibitor therapy (ICI) has surfaced as a successful and robust treatment option in the fight to end cancer. As we gain more insight, immunotoxicity and autoimmunity as a result of ICI exposure have shown to affect every organ system of the human body in the form of immune related adverse events. In this novel case series, we report nine patients on ICI therapy that presented with either de novo myositis or with pre-existing dermatomyositis.

**Methods:** Patients with myositis in context of ICI therapy were identified from all institutional databases using ICD 9 & 10 diagnostic codes for myositis from January 2004 until September 2016. We included cases with de novo myositis occurring within 3 months of last treatment with one or more diagnostic codes that could not be present within a 6-month window before treatment. We defined de novo myositis in those cases including initial creatinine kinase levels at least three times the normal limit along with persistent elevation at the end of the following 7 days, a rheumatologist or neurologist diagnosing myositis, as well as muscle pains and weakness after starting ICI. Pre-existing dermatomyositis cases were defined as those that had a rheumatologist note diagnosing them prior to initiation of ICI. Clinical data was extracted retrospectively from time prior to starting checkpoint inhibitor therapy until 3 months.

**Results:** Nine patients with myositis were identified. Six patients developed de novo myositis as a result of ICI while 3 had pre-existing dermatomyositis out of which 1 flared post treatment. Mean age was 67.1 years (standard deviation=10.2) and 66.6% were males. Cancer types included melanoma, bladder cancer, and squamous cell carcinoma of the lung, acute myeloid leukemia, prostate cancer, and renal cell carcinoma. ICI regimens included nivolumab (n=2), ipilimumab (n=1), pembrolizumab (n=3; one patient received nivolumab followed by pembrolizumab 18 months later), and atezolizumab (n=1) as monotherapy or as a combination of nivolumab and ipilimumab (n=3). Other immune related adverse events included: pneumonitis, migratory joint pain, rash, and increase in transaminases as well as hypo and hyperthyroidism and severe rhabdomyolysis. Patients were treated with corticosteroids ranging from 1 to 2mg/kg with variable response rates, except for one patient who received non-steroidal anti-inflammatory drugs to manage his myalgias. Two out of 6 patients died with de novo myositis whereas 2 out of 3 died with pre-existing dermatomyositis. All patients with de novo myositis had elevated levels of creatinine kinase ranging from 514 to 13,010 U/L. Median time to development of de novo myositis from first infusion was 1.25 months (range=0.5-4.0).

**Conclusion:** We found evidence of de novo myositis in addition to patients with pre-existing dermatomyositis who flared following ICI therapy. This preliminary data warrants further investigation into determining the risk of developing myositis in the cancer patient population undergoing ICI which may help understand and treat the underlying etiology and prevent occurrence.

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017  
**Session Title:** Muscle Biology, Myositis and Myopathies Poster  
**Session Type:** ACR Poster Session C  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are limited treatment options and no published double-blind randomized placebo-controlled trials for the treatment of skin manifestations of dermatomyositis (DM). There is no information about patients enrolled in trials to study efficacy of treatments of skin involvement in DM. Anabasum is a non-immunosuppressive, synthetic, preferential CB2 agonist that resolves inflammation in animal and human models of innate immune responses and reduces cytokine production by isolated mononuclear cells from DM patients.

**Methods:** A double-blind randomized placebo-controlled Phase 2 trial (JBT101-DM-001) with NIH as a collaborator was designed to test efficacy and safety of anabasum in adults with DM and refractory skin involvement. The trial is done at a clinic specializing in skin involvement in DM which allows comparison of trial subjects to the general DM population at the same clinic.

**Results:** Selection criteria included Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity score of  $\geq 14$ , minimal active muscle involvement, failure or intolerance to hydroxychloroquine, and stable DM medications including immunosuppressive drugs. Trial subjects (N = 22) and the general clinic population (N = 221) were predominantly middle-aged white, non-Hispanic women (Table 1). Trial subjects had high skin disease activity compared to the clinic population and widespread use of immunosuppressive drugs (86%), including second-line immunosuppressive drugs (64%), with the mostly commonly used immunosuppressive drugs being antimalarial drugs (45%), mycophenolate (32%), methotrexate (23%), and systemic corticosteroids (23%).

Table 1. Comparison of demographics and disease characteristics between trial and overall DM population

Characteristic	JBT101-DM-001 N = 22	General DM Clinic N = 221
Age, median (range)	53 (36-69)	57 (23-88)
Sex, % female	95%	85%
Race, % white	95%	90%
Ethnicity, % not Hispanic or Latino	86%	97%
DM subset	41%	38%
· Classic	59%	62%
· Clinically amyopathic		
CDASI activity score, final visit, median (range)	33 (22-57)	13 (0-71)
CDASI damage score, final visit, median (range)	2 (0-13)	2 (0-14)
Physician Global Assessment, median, range	4.7 (2.6 – 8.3)	1 (0-9.4)
Patient Global Assessment, median, range	5.4 (0.4 – 9.7)	4 (0-10)
Skindex-29, median (range)	48.6 (17-77)	35.7 (0-96.4)
· Symptoms	37.8 (4-78)	30.0 (0-100)
· Emotions	24.2 (0-67)	12.5 (0-100)
· Functioning	40 (0-80)	50 (0-100)
· Photosensitivity		
≥ 1 immunosuppressive drug including antimalarials	86%	40%
≥ 1 immunosuppressive drug excluding antimalarials	64%	19%
IVIg	0%	10%

**Conclusion:** This is the first report of subject demographics and disease characteristics in a clinical trial focused on safety and efficacy in skin-predominant dermatomyositis. Trial subjects had similar demographics to the overall DM clinic population. However, skin disease activity and patient-reported skin symptoms were greater in the trial subjects than in the overall DM clinic population, despite much higher use of second-line immunosuppressive medications. Disease activity in trial subjects was much higher than required by inclusion criteria. Combined, these data show that subjects enrolled in trials of treatment of skin involvement in DM may have disease that is more active and more difficult to control than the general population of patients, reminiscent of early efficacy trials in other systemic autoimmune diseases.

## Factors Associated with Clinical Remission of Skin Disease in Dermatomyositis

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Quantitative estimates of the duration and severity of cutaneous disease are lacking for adult dermatomyositis (DM) patients. The Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) is a validated instrument that quantifies cutaneous disease activity (CDASI-a), and allows for objective assessments of disease severity. Our aims were to estimate the percentage of DM patients with clinically significant skin inflammation who achieve clinical remission (CR) of skin disease during a 3-year follow-up period and to examine the relationship between skin disease course and selected clinical variables.

## Methods:

Adult DM patients (age >18 years) seen at our outpatient clinic between May 15, 2007 and October 28, 2016 were considered for this study. DM was diagnosed using Bohan/Peter criteria, or, for clinically amyopathic patients, Sontheimer criteria. Patients were included if their initial CDASI-a score was greater than or equal to 12, and they had a minimum of 2 scores recorded 3 or more months apart. CR was defined as a CDASI-a less than or equal to 5 with no individual erythema score >1 and no ulcerations. Univariable and multivariable logistic regression analysis was performed using age, race, gender, amyopathic status, DM-associated malignancy, baseline CDASI-a, disease duration at baseline, time until first systemic therapy, autoantibody phenotype (Mi-2, TIF-1gamma, SAE1, MDA5, NXP2 or Ro52), and medication exposure as covariates. For selected variables, Kaplan-Meier plots were created and log-rank analysis used to compare curves.

## Results:

In total 74 patients met our inclusion criteria. The median duration of follow-up was 17.5 (11-28) months, with a median of 4 (3-6) months between CDASI scores. Overall, 36% of patients were treated with mycophenolate mofetil (MMF), 38% with antimalarials, 39% with methotrexate and 24% with IVIG. Twenty-eight patients (38%) entered CR within 3 years, and the overall probability of CR was 0.43 after 36 months (Figure 1A). The probability of CR was significantly higher for patients without anti-MDA5 antibodies (Figure 1B) as 0/10 anti-MDA5 patients entered CR. Increased age (OR 1.07, 95% CI 1.02-1.12;  $P=0.01$ ), DM-associated malignancy (OR 14.46, 95% CI 2.18-96.07;  $P=0.006$ ) and MMF (OR 6.00, 95% CI 1.66-21.78;  $P=0.0064$ ) were significantly associated with CR in multivariable regression analysis.

## Conclusion:

CR was relatively uncommon in our population, and even less common among anti-MDA5 patients, despite the use of aggressive systemic therapy. The positive association between MMF and CR suggests that MMF should be considered a first line agent for DM skin disease, while our overall results highlight the need for new therapies to more effectively treat skin disease in DM. Increased age and DM-associated malignancy were both associated with positive cutaneous outcomes, which has important prognostic significance.

**Figure 1.** Kaplan-Meier Analysis for Clinical Remission. (A) Overall probability of achieving CR; (B) Probability of anti-MDA5+ patients achieving CR

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Dermatomyositis (DM) is characterized by inflammation of the skin and skeletal muscle, and is occasionally complicated by interstitial lung disease or concomitant malignancy. It has been recognized that myositis-specific autoantibodies (MSAs) are correlated with unique sets of clinical manifestations. The mechanisms underlying production of MSAs still remain uncertain, but genetic factors, such as human leukocyte antigen (HLA) class II genes, are reported to play some roles. Anti-Jo-1 and anti-melanoma differentiation-associated gene 5 (MDA5) antibodies are associated with *HLA-DRB1*\*04:05 in Japanese population, but there is no information on the *HLA-DRB1* association with anti-transcriptional intermediary factor 1- $\gamma$  (TIF1- $\gamma$ ) antibody.

**Methods:** We enrolled 36 DM patients with anti-TIF1- $\gamma$  antibody, 24 DM patients without anti-TIF1- $\gamma$  antibody, and 161 ethnicity-matched healthy controls, who were recruited from 7 medical centers across Japan. Eighteen patients with anti-TIF1- $\gamma$  antibody had concomitant malignancy which was defined by the diagnosis within 2 years before or after DM diagnosis. HLA typing was performed by next-generation sequencing method. Strength of associations was estimated by odds ratios (OR) and 95% confidence intervals (CI) and frequencies were compared using the Fisher's exact test. *P* values were corrected by multiplying the number of alleles detected in Japanese.

**Results:** Although there is no statistically significant difference in distribution of *HLA-DRB1* alleles among 3 groups, we found a trend toward increased frequencies of *DRB1*\*04:03 and *DRB1*\*04:06 in DM patients with anti-TIF1- $\gamma$ , in comparison with DM patients without anti-TIF1- $\gamma$  or healthy controls (19% versus 4% or 7%, 19% versus 0% or 8%, respectively). Interestingly, *DRB1*\*04:03 and *DRB1*\*04:06 alleles are evolutionally close and commonly have unique amino acid sequence (LLEQRRAE at positions 67-74) in the third hypervariable region of the HLA-DRB1. The frequency of having either *DRB1*\*04:03 or *DRB1*\*04:06 in DM patients with anti-TIF1- $\gamma$  was significantly higher than the frequency in DM patients without anti-TIF1- $\gamma$  (39% versus 4%; OR = 14.6, 95%CI 1.8-121, corrected *P* = 0.04) and tended to be higher than the frequency in healthy controls (39% versus 16%; OR = 3.3, 95%CI 1.5-7.3, corrected *P* = 0.09). No significant difference was observed in the frequency of *DRB1* alleles between anti-TIF1- $\gamma$ -positive patients with and without concomitant malignancy.

**Conclusion:** In Japanese population, anti-TIF1- $\gamma$  antibody is associated with rare *HLA-DRB1*\*04:03/\*04:06 alleles, which are distinct from the *DRB1* allele associated with other MSAs, including anti-Jo-1 and anti-MDA5 antibodies.

## Dermatomyositis Acute Onset/Flares Following Ingestion of IsaLean® Herbal Supplement: Clinical and Immunostimulatory Findings

Majid Zeidi<sup>1,2</sup>, Peter B Chansky<sup>1,2</sup> and Victoria P Werth<sup>3,4</sup>, <sup>1</sup>Department of Dermatology, Corporal Michael J. Crescenz VAMC, PHILADELPHIA, PA, <sup>2</sup>Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, <sup>3</sup>University of Pennsylvania and the VA Medical Center, Philadelphia, PA, <sup>4</sup>Department of Dermatology, Corporal Michael J. Crescenz VAMC, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** The use of complementary and alternative medicine (CAM) has gained popularity in the United States over the last few decades. Herbal supplements have adverse medical effects. We observed two patients with acute onset/flare of their classic dermatomyositis after the ingestion of IsaLean®, an herb-based weight-loss product. The purpose of this study was to investigate and characterize the immunostimulatory properties of the herbal and dietary supplement IsaLean® underlying the acute onset/flare of dermatomyositis in two patients.

**Methods :** Peripheral blood mononuclear cells were isolated from 5 dermatomyositis patients and 5 control patients stimulated with increasing concentrations of IsaLean®: 0, 0.05, 0.5, and 5 µg/ml to evaluate the cellular production of tumor necrosis factor alpha (TNFα), interferon alpha (IFN-α), and interferon beta (IFN-β), key pathogenic cytokines in dermatomyositis. The cells were also incubated with IsaLean® and lipopolysaccharide (LPS), and the effect of neutralizing anti-TLR4, quinacrine (QC), and hydroxychloroquine (HCQ) on the cellular production of TNFα was examined. Cytokine production was measured by enzyme-linked immunosorbent assay. The One-way analysis of variance (ANOVA) with Dunnett's multiple comparison test was used to compare the level of TNF-α, IFN-α, and IFN-β after stimulation with IsaLean and treatment with Anti-TLR4, QC, and HCQ.

**Results :** The IsaLean® stimulated cells secreted mean (standard error) TNFα levels of 1.78 (0.38), 339.5 (39), 1188 (125.5) and 2224 (488.7) pg/ml at 0, 0.05, 0.5, and 5 µg/ml concentrations of IsaLean®, respectively. IsaLean® increased cellular secretion of TNFα at 0.5 µg/ml (p<0.01) and 5 µg/ml (p<0.001) (Figure 1). Anti-TLR4 suppressed cellular secretion of TNFα from IsaLean® (p<0.001) and LPS-stimulated cells (p<0.01) (Figure 2). QC significantly reduced the production of TNFα from IsaLean® (p<0.001) and LPS-stimulated (p<0.05) compared to HCQ (Figure 3).

**Conclusion :** IsaLean®, an herb-based weight-loss product, induced secretion of TNFα, IFN-α, and IFN-β from immune cells of dermatomyositis patients *in vitro*. These cytokines are thought to be key immunostimulatory cytokines causing cutaneous dermatomyositis. These studies demonstrate that the pro-stimulatory effects of IsaLean® are mediated through TLR4.

## Clinical Significance of Anti-Aminoacyl tRNA Synthetase Antibodies Which Are Positive By ELISA but Not By Immunoprecipitation – the Variations of Antigen Recognition and the Association with Interstitial Lung Diseases but Not Myositis –

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-aminoacyl tRNA synthetase (ARS) antibodies are associated with common clinical characters, which are fever, polyarthritis, interstitial lung disease (ILD), Raynaud's phenomenon, mechanic's hand and myositis, and the constellation of these symptoms in patients with anti-ARS antibody is called anti-synthetase syndromes (ASS). So far, anti-ARS antibodies have been screened by RNA/ protein immunoprecipitation (IP) or line blot. Recently, an enzyme-linked immunosorbent assay (ELISA), in which the mixture of 5 ARS antigens are coated on the plate, has been established, and growing number of blood samples has been examined in daily clinical practices. However, we often encounter such patients that are positive for anti-ARS antibody by ELISA but negative by IP. Thus, we analyzed the discrepancy between the ELISA and IP precisely to elucidate the underlying mechanism and the clinical meaning of the discrepant results.

**Methods:** We screened anti-ARS antibodies both by RNA-IP using HeLa cells and ELISA (MESACUP™ anti-ARS test, MBL CO., LTD., Nagoya, Japan) for sera obtained from patients who visited to our department with suspicion of rheumatic diseases from January 2014 to March 2017. The sera which showed discrepant results between two methods were further analyzed by individual antigen-specific ELISA, immunoblotting, and protein-IP. Obtained results were compared to see the discordance among different methods. The clinical features of the patients were also characterized.

**Results:** Eleven patients (6 females and 5 males with mean age of 67.3±12.4 years-old) were found to be positive for anti-ARS by the ELISA but negative by RNA-IP. The clinical diagnoses were 2 RA, 2 SSc, 1 SS, 1 DLE, 1 PM with SS, 1 DM and 3 unclassified ILD. Within these 11 patients, anti-Jo-1 antibody was detected by specific ELISA in 9 patients, but only in 5 and 1 by protein-IP and immunoblot, respectively. On the other hand, anti-EJ antibody was detected in 5 patients by immunoblot, and some of these sera were considered to cross-react to Jo-1 antigen by absorption ELISA using each antigen. Ten (91%) patients presented ILD, which responded to glucocorticoids without recurrence, while, numbers of patients presented other ASS symptoms were as follows; 3 (27%) mild myositis, 4 (36%) polyarthritis, 5 (45%) Raynaud's phenomenon, 1 (9%) mechanic's hand, and 0 (0%) fever.

**Conclusion:** Positivity of anti-ARS antibodies sometimes shows discrepancy between ELISA and IP, and it may be due to the recognition of denatured or cryptic ARS epitopes by the antibodies. In such cases, anti-ARS antibodies can be associated more strongly with ILD than with myositis. However, we need to further follow up these patients to investigate whether epitope spreading may occur, which leads to the onset of established myositis with positive anti-ARS antibodies not only by ELISA but also by IP.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Prior studies have shown that increased age at diagnosis and non-Caucasian race are associated with lower survival in polymyositis and dermatomyositis (PM/DM). However, it's unclear whether race is associated with differences in disease characteristics and response to treatment in PM/DM.

**Methods:** This was a retrospective, observational cross-sectional study of 96 patients (62 African American (AA) and 34 Caucasian) with PM/DM seen in an academic rheumatology clinic from 1994 - 2016. Clinical characteristics were compared, and they included demographics, clinical and laboratory data at initial presentation to the clinic, and development of interstitial lung disease (ILD) (Table 1). Treatment medications (immunosuppressives (IS) and steroids), mean creatine kinase values (CK) in the last year of follow-up, and frequency of achieving stable disease state on or off medications (IS and steroids) in the last year of follow-up were compared between the groups to study treatment response (Table 2). Multivariate linear and logistic regression analysis was performed to determine factors that were associated with initial CK, presence of ILD and achievement of stable disease state during follow-up.

**Results:** Median CK was higher and rash was seen more frequently in AA patients at presentation than in Caucasians. The disease duration prior to the initial presentation was longer in AA patients. The AA and Caucasian patients did not differ in terms of frequency of dysphagia, autoantibodies at presentation, presence of ILD or age at diagnosis (Table 1). In a multivariable model, age at diagnosis was associated with initial CK ( $P = 0.0142$ ) but other parameters including race did not correlate. During follow-up, the two groups were similar in terms of the number of IS used, and frequency of achieving stable disease state on or off medications in the last year of follow-up (Table 2). In a multivariable analysis, anti-Jo1 (OR 8.90,  $P = 0.00104$ ) and SSA antibodies (OR 5.60,  $P = 0.00795$ ) were associated with development of ILD. Presence of rash (OR 0.25,  $P = 0.00996$ ), ILD (OR 0.24,  $P = 0.00738$ ) and the number of IS used (OR 0.40,  $p=0.01199$ ) were negatively associated with achieving stable disease state on or off medications in the last year of follow-up. Race was not a significant factor in either model.

**Conclusion:** The AA and Caucasian patients did not differ in terms of development of ILD or achieving stable disease state. Other parameters including presence of autoantibodies, rash and ILD and higher number of immunosuppressants used were associated with worse outcome. To our knowledge, this study included one of the largest AA PM/DM patient cohort to date.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

In systemic sclerosis, a *scleroderma pattern* on nailfold videocapillaroscopy (NVC) (SSc) is well recognized. In idiopathic inflammatory myopathies (IIM), a *scleroderma-like pattern*, including giant-ramified capillaries, has been proposed. The aim of our study was to describe nailfold capillary abnormalities in IIM subsetted using newly proposed integrative criteria [1,2].

### Methods:

We studied IIM subjects in the Canadian Inflammatory Myopathy Study (CIMS), a cohort of subjects with early onset disease followed prospectively. NVC images were acquired using the DS MEDICA Videocap (X200 magnification). The nailfolds of the second, third, fourth and fifth fingers of both hands were photographed and scored by an experienced rheumatologist. Microhemorrhages, giant capillaries, ectasias and ramified capillaries were scored using a standardized semi-quantitative scale (0 = no, 1 =  $\leq 33\%$ , 2 = 33–66%, and 3 =  $\geq 66\%$  abnormalities per linear millimeter). Capillary density was scored both semi-quantitatively (0 if  $\geq 7$ , 1 if 4–6, or 2 if  $\leq 3$  capillaries/mm) and quantitatively (mean number of capillaries/mm). Each NVC parameter, as well as disorganization and giant-ramified capillaries, were also scored as present or absent. Finally, the proportion of subjects with *scleroderma-like*, *scleroderma* (SSc), non-specific, and normal patterns were compared.

### Results:

38 IIM subjects were included: 18 with DM (of which 9 had myositis specific antibodies and 9 were seronegative) and 20 with OM (of which 8 had anti-synthetase syndrome). Baseline characteristics of the subjects and NVC features and patterns are presented in Tables 1–3. Capillary density was lower than normal in both DM (mean 5.5/mm) and OM (mean 6.1/mm). Giant-ramified capillaries were present in 22.2 % of DM and 25% of OM subjects. SSc-like pattern was more common in DM (50%) than OM (25%), whereas active- or late-SSc pattern was more common in OM than DM (25% vs 5.6%).

### Conclusion:

This is the first study of NVC using integrative criteria for IIM. We found differences in NVC features and patterns between DM and OM subsets. NVC may be an additional diagnostic tool in IIM. A larger study is ongoing to confirm these findings.

George<sup>1</sup>, <sup>1</sup>Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Department of Dermatology, University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Myositis autoantibody testing is now widely commercially available, with an evolving role in routine clinical care. However, the use and performance of commercial "myositis panels" in usual practice have been poorly studied. We examined commercial myositis autoantibody panel ordering patterns and testing results in a large tertiary-care health system.

### Methods:

We conducted a retrospective observational study of all adult patients with a commercial myositis autoantibody panel ordered at all outpatient and two inpatient locations of the University of Pennsylvania between January 2011 and March 2016. We abstracted information about patient demographics, myositis panel orders [specialty of the ordering provider, symptoms/signs which prompted the order (indication), performing commercial vendor, autoantibodies tested], and relevant clinical, laboratory, radiographic, and histopathologic data. For each subject, clinical diagnosis was assigned considering all available information except autoantibody profile. Bohan and Peter's and Sontheimer's criteria were used for PM/DM and clinically amyopathic dermatomyositis (CADM), with positive skin biopsy required for definite CADM. Equivocal cases were resolved by consensus among all investigators.

### Results:

378 patients were included (66% women, mean age  $55 \pm 15$  years). Myositis panels were ordered most often by rheumatology (39%), pulmonology (23%), dermatology (18%), and inpatient medicine (12%). ARUP Laboratories performed 72% of testing. The number of myositis panels ordered markedly increased over the study period for all indications (Figure) and departments. 10.3% of subjects had positive myositis specific autoantibodies (MSA); 19.6% had positive myositis associated autoantibodies (MAA). The rate of positive MSA was similar for all indications [ $p=0.47$ ]. Only 11 of 76 (14.5%) of patients with probable/definite PM, DM, or CADM had positive MSA (Table). A comparable rate of positive MSA occurred in patients with ILD without myositis [10/102 (9.8%);  $p=0.34$ ]. Patterns for MAA followed similar trends.

### Conclusion:

Commercial myositis autoantibody panel testing has dramatically increased for expanding clinical indications by rheumatologists and non-rheumatologists alike. Clinicians must be aware that negative MSA testing with these assays was common, even in patients with clinically affirmed disease. MSA were found at a similar rate in patients with isolated ILD, and may provide important information for this population. Continued study of the performance of commercial myositis autoantibody testing is required as the role of these assays further develops.

**Figure:** Number of commercial myositis autoantibody panels sent at the study institution by calendar year, subdivided by reason the panel was ordered (indication).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-aminoacyl-tRNA synthetase antibodies (Abs), which mainly consists of anti-Jo1, PL-7, PL-12, EJ, OJ and KS, are the most common myositis-specific autoantibodies (MSAs). It has been recognized that anti-synthetase Abs are associated with characteristic clinical phenotype, chronic disease course, good response to initial glucocorticoid therapy and relatively good prognosis. However, we sometimes encounter such patients that are resistant to immunosuppressive therapies and have poor prognosis. Therefore, we retrospectively analyzed prognostic factors in polymyositis(PM)/ dermatomyositis (DM) patients with anti-synthetase Abs.

**Methods:** We retrospectively examined medical records of 121 PM/DM patients with anti-synthetase Abs who had been treated in our hospital from April 2001 to December 2016 (32 with Jo-1, 26 with PL-7, 25 with EJ, 21 with PL-12, 11 with OJ, 4 with KS, 1 with PL7 and PL12, 1 with Jo-1 and PL12). Anti-ARS Abs were examined with RNA immunoprecipitation using Hela cells. We analyzed the prognostic factors with univariate cox proportional hazards regression analysis. Next, we analyzed each of them with multivariate analysis. Comparison of survival time among each anti-synthetase Abs, we used Kaplan-Meier method.

**Results:** The 10-year survival of whole anti-synthetase Abs-positive PM/DM patients was 74.7%. 21 patients died of interstitial pneumonia (n=8), infection (n=2), malignancy (n=4), thrombotic thrombocytopenic purpura (TTP) (n=1), alveolar hemorrhage (n=2), subarachnoid hemorrhage (n=1), unknown cause (n=3). In univariate analysis, old age at onset, male, anti-PL-7, high values of lactate dehydrogenase, high dose of maintenance glucocorticoid, no use of immunosuppressant were found to be significant poor prognostic factors. Multivariate analysis revealed 5 significant poor prognostic factor, anti-PL-7 Ab, old age at onset, male, high dose of maintenance glucocorticoid, no use of immunosuppressant. In Kaplan-Meier analysis, it was suggested that anti-EJ-positive patients may have poor prognosis after more than 15 years follow-up as well as anti-PL-7-positive patients.

**Conclusion:** The poor prognostic factors in anti-ARS-positive patients were anti-PL-7 Ab, old age at onset, male, high dose of maintenance glucocorticoid, no use of immunosuppressant. Moreover, anti-EJ have poorest survival after more than 15 years follow-up as well as anti-PL-7.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Myositis autoantibodies have diagnostic, therapeutic and prognostic implications, but their utility in clinical practice is unclear. We aimed to describe our institution's ordering practices and positivity rate in an undiagnosed population of patients to improve utilization.

### Methods:

We included all Duke University Health System patients who had a myositis autoantibody panel (including anti-Jo-1, PL-7, PL-12, EJ, OJ, Mi-2, SRP, PM/Scl, Ku and U2-snRNP) ordered between October 2014 and December 2015. We recorded autoantibody positivity, demographics, past medical history, family history, review of systems items (ROS) and physical examination (PE) findings. Fisher's exact and t-tests were performed for statistical significance.

### Results:

Of 373 ordered tests, there were 75 (20%) positive autoantibodies. Significant demographic factors were older age and African American race or Hispanic ethnicity (Table 1). Positivity rates among African Americans (30%) and Hispanic/Latinos (50%) were

higher than in Caucasians (15%; 71% of the tested population). A recorded past medical history of RA, SLE or connective tissue disease were associated with positive autoantibodies, while use of statins, antibiotics or chronic steroids had a negative association. The only statistically significant ROS factor was photosensitivity. Important ROS elements were infrequently documented prior to testing in this cohort. Specifically, <50% of tested patients were asked about myalgias, 20% about photosensitivity, 13% about voice changes and 3% about nasal regurgitation. Of recorded PE findings symmetric muscle weakness, sclerodermoid skin changes and arthritis were significantly associated with a positive antibody test.

### Conclusion:

Myositis autoantibodies were positive in more than 30% of African American and Hispanic individuals tested. History of an autoimmune disease, photosensitivity and expected IIM PE findings were associated with a positive panel. While many easily obtainable factors may be associated with positive myositis autoantibodies, these history, PE and ROS elements are incompletely recorded. In our large academic multispecialty practice, the myositis autoantibody panel appears to be largely used as a screening test. Future efforts will include cohort characterization and provider education to guide testing.

Table 1. Significant variables based on antibody positivity within cohort					
Variable	Total Tested (%)	Positive Antibody (%)	Negative Antibody (%)	Positivity Rate	p-value

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Despite the absence of specific guidelines or trials on intravenous immunoglobulins (IvIg) in patients with idiopathic inflammatory myopathies (IIM), the treatment is considered effective in refractory IIMs. The aim of our study is to evaluate the efficacy of IvIg in patients with IIM followed in 3 third level centers and to identify predictive factors correlated to their efficacy.

### **Methods:**

retrospective study of IIM pts classified according to Bohan and Peter criteria treated with IvIg (2gr/kg/month). At baseline and after treatment the following data were collected: muscle necrosis enzymes, myositis specific autoantibodies; muscle strength (manual muscle test-MMT), clinical symptoms (skin lesions, dysphagia severity according to patient's VAS, dyspnea, loss of strength) and clinical response according to physician judgment. We analyzed indications to treatment, major organ involvement, previous therapies.

### **Results:**

92 pts were included (30 M, 62 F), 34 affected by PM, 48 DM, 3 IBM and 7 IIM overlap (3 Sjögren syndrome, 4 SSc); 12 were affected by cancer associated MII. Mean age at the start of IVIG therapy was 57.4±15 years, mean disease duration was 39±88 months.

Main indications to the treatment were: loss of strength (74), dysphagia (42), lung involvement (6), DM rash (27), arthritis (3).

IvIg were started in all pts for refractory disease to treatment with corticosteroids (CS). CS were used alone (22 pts) or associated with immunosuppressive drugs (70 pts). In 19/22 pts treated with cs alone, immunosuppressive drugs were contraindicated for neoplasia (9), recurrent infections (9), pregnancy (1).

The treatment was suspended after an average duration of 14 months; at the treatment suspension, muscle necrosis enzyme CK, LDH, GOT and GPT decreased significantly ( $p<0.001$ ) and the mean MMT value increased ( $102.3\pm24.37$  vs  $125.0\pm23.16$   $p<0.001$ ); mean dysphagia VAS decreased from  $40.5\pm36.8$  to  $11.7\pm21.7$  ( $p<0.001$ ). The mean weekly corticosteroid dose decreased from  $152.5\pm126.3$  mg to  $71.2\pm63.3$   $p<0.001$ .

According to physician judgment, 71 pts were classified as responder to IVIG (77.1%); 41 pts responded after six months of treatment and 30 pts after more than 6 months of treatment (mean  $26.3\pm29.3$  months).

Responders had a shorter disease duration ( $p<0.001$ ), higher CK levels at baseline ( $2038\pm2479$  vs  $626\pm736$   $p<0.001$ ), higher prevalence of dysphagia ( $p=0.012$ ) and lower prevalence of Raynaud phenomenon ( $p=0.031$ ) compared to non responders.

### **Conclusion:**

Despite their high cost, IvIg confirmed their efficacy in refractory IIM pts, particularly in muscular and oesophageal manifestations. A shorter disease duration, higher CK levels and specific clinical features are associated to a better response.

## **Efficacy and Safety of Rituximab in Anti-Synthetase Positive and Negative Patients with Idiopathic Inflammatory Myopathy– a Registry-Based Study**

Valérie Leclair, Maryam Dastmalchi, Angeles Shunashy Galindo-Feria and Ingrid E. Lundberg, Department of Medicine, Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rituximab (RTX) in idiopathic inflammatory myopathies (IIM) failed to show efficacy in the placebo-controlled Rituximab in Myositis (RIM) trial. However, post hoc analyses indicated that patients with specific auto-antibodies may benefit from RTX treatment. The aim of this study was to evaluate the efficacy and safety of RTX in IIM subjects in relation to their auto-antibody profile.

### **Methods:**

Adult IIM subjects registered in the Swedish Quality Registry (SRQ) who received  $\geq 1$  dose of RTX were enrolled. Clinical data were extracted from SRQ or medical records including myositis autoantibodies status (anti-aminoacyl-tRNA synthetase (ARS), anti-MDA5, anti-Mi2, anti-NXP2, anti-SAE, anti-SRP, and anti-TIF1-gamma antibodies). Efficacy was based on measures endorsed by the International Myositis Assessment and Clinical Studies group taken at baseline, after first and last RTX cycle. Safety assessment included serious infections, infusion reactions and death during study period. Comparisons between groups based on anti-ARS status were done using the Student's t-test or Mann-Whitney U test for continuous variables, and Chi square or Fisher exact test for categorical variables.

### **Results:**

Sixty-five subjects were included and 68% had a follow-up visit within 6 to 10 months (Table 1). At baseline, efficacy measures were similar except for higher HAQ score in the anti-ARS negative subjects (1.69 vs 0.75,  $p=0.003$ ) (Table 2). After one cycle, the anti-ARS positive group had significantly lower patient global assessment (33.8 vs 51.4,  $p=0.042$ ) and extra-muscular activity (9.9 vs 21.3,  $p=0.009$ ) on visual analog scales (0-100) compared to the anti-ARS negative group. A steroid-sparing effect was only seen in the anti-ARS positive group (median steroid dosage 20 to 10mg,  $p<0.001$ ). After several cycles, anti-ARS positive ( $n=19$ ) compared to anti-ARS negative subjects ( $n=10$ ) showed a faster decrease in disease activity, moreover, they had lower HAQ (0.5 vs 1.75,  $p=0.003$ ), patient global assessment (mean 30.1 vs 57.8,  $p=0.011$ ) and steroid doses (4.37 vs. 10mg,  $p=0.04$ ). In the anti-ARS positive group, 3 deaths, 2 infusion reactions and 3 severe infections were recorded compared to 1 death, 1 infusion reaction and 2 severe infections in the negative group.

### **Conclusion:**

In this observational study, we confirmed the benefit of RTX in anti-ARS positive patients who showed a significant decrease in several disease activity measures including patient-reported measure (ex: HAQ), in addition to a significant steroid-sparing effect. The effect was less dramatic in the anti-ARS negative group. These findings support the role of B cell in IIM pathogenesis.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Interstitial lung disease in patients with polymyositis (PM) and dermatomyositis (DM) is characterized by decrease in both lung compliance and pulmonary vascularity, leading to decreased forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO). However, since DLCO is also influenced by the pulmonary circulation, additional pulmonary vascular disease would disproportionately decrease DLCO. This study was aimed to investigate the changes in FVC and DLCO over time in patients with DM and PM and to identify factors associated with disproportional decline in DLCO.

### **Methods:**

A total of 89 DM and 14 PM patients who had been cared at the Rheumatology Clinic of Seoul National University Hospital, a tertiary referral center, from January 2004 to June 2016, with 2 or more pulmonary function tests (PFTs) during follow-up duration, were retrospectively evaluated. FVC and DLCO were expressed as the percentage of values predicted on the basis of patient age, sex, height and weight. Regression was calculated using mixed model with random effect.

### **Results:**

Total of 103 patients with DM and PM were included. The study population was predominantly female (72.8%), with the mean age at diagnosis of  $49.9 \pm 12.9$  years. The mean duration of follow-up was  $4.4 \pm 3.2$  years. There was a strong correlation between FVC and DLCO at baseline ( $r = 0.618$ ,  $p < 0.001$ ). In 85 (82.5%) of 103 patients, DLCO was lower than FVC by  $9.8 \pm 14.2\%$  at baseline. There was disproportional change in DLCO relative to FVC over time. Patients with worse decline of DLCO than the change of FVC over time had a higher frequency of Raynaud's phenomenon (35.1% vs 9.7%,  $p = 0.021$ ) and positive antinuclear antibody (ANA) (78.4% vs. 48.4%,  $p = 0.012$ ) compared to the patients with better improvement of DLCO relative to FVC over time. There was no significant difference in other clinical and laboratory parameters according to disproportional decline in DLCO relative to FVC. Patients with Raynaud's phenomenon had significantly higher decline of DLCO from the baseline than those without Raynaud's phenomenon ( $-5.6 \pm 16$  vs  $4.4 \pm 18.4$ ,  $p = 0.016$ ) and the observed changes of DLCO per year ( $-9.0 \pm 28.3$  vs  $4.9 \pm 29.4$   $p = 0.040$ ).

### **Conclusion:**

In patients with DM and PM, Raynaud's phenomenon and positive ANA are associated with disproportional decline in DLCO relative FVC. Further prospective studies are needed to determine whether improving pulmonary circulation adds any therapeutic benefit in those idiopathic inflammatory myopathy patients with disproportional decline in DLCO.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Recent studies have suggested the possible benefit of the anti-CD20 agent Rituximab (RTX) in autoimmune myositis (AIM). As AIM is a rare and heterogeneous condition, no randomized controlled trial results are available to validate these findings. We present a two-center experience with the use of RTX in AIM.

### Methods:

Adult patients (pts) with AIM treated with RTX between years 2005-2016 were identified by electronic medical record inquiry from two large urban multispecialty care systems in the Twin Cities, Minnesota. Charts were reviewed by two trained rheumatologists to confirm the correct diagnosis and treatment. 28 cases were identified, of them 16 pts were classified as primary idiopathic myositis (PIM) by accepted diagnostic criteria and 12 pts were classified as overlap myositis (OM) by criteria for their respective connective tissue disease (CTD) and clinically demonstrated inflammatory myositis. RTX was used for disease refractory to initial treatment, severe initial onset, and the presence of interstitial lung disease (ILD). Outcomes data for up to the first 3 RTX courses were obtained from clinical records, up to 4 months prior to each RTX and 4-6 months post RTX, and included prednisone dose, serum creatinine kinase (CK), serum C-reactive protein (CRP), forced vital capacity (FVC), and hip flexion strength (HFS). Paired sample T-tests were used for analysis.

### Results:

For pts with PIM, mean age was  $43 \pm 16$  y, 8 were female (50%), and mean disease duration was  $33 \pm 48$  mo, with subgroups of 7 with dermatomyositis, 6 with polymyositis, and 3 with necrotizing autoimmune myopathy. For pts with OM, mean age was  $53 \pm 13$  y, 11 were female (92%), and mean disease duration was  $47 \pm 54$  mo, with subgroups of 7 with systemic lupus erythematosus, 2 with systemic sclerosis, 2 with Sjogren's syndrome, and 1 with mixed CTD. The average number of non-corticosteroid medications used prior to the first RTX for pts with PIM was  $2.2 \pm 1.6$  and for OM was  $3.5 \pm 1.7$ .

After one RTX course, pts with PIM but not OM had a significant reduction in prednisone dose from  $44.38 \pm 23.58$  mg/day to  $14.34 \pm 15.27$  mg/day ( $p=0.0002$ ). After one RTX course, pts with PIM but not OM had a significant reduction in CRP from  $25.57 \pm 22.56$  mg/dL to  $9.61 \pm 6.31$  mg/dL ( $p=0.029$ ). Among AIM pts with concomitant ILD, there was also a statistically significant improvement in % predicted FVC after one RTX course by  $9.2 \pm 8.69$  % ( $p=0.045$ ). There was no observed statistically significant change in CK or HFS.

### Conclusion:

In 28 AIM pts treated with RTX, we observed a significant improvement in prednisone dose and serum CRP levels following the first treatment cycle for pts with PIM but not OM. There was also a modest improvement in % predicted FVC among patients with concomitant ILD, but no significant change in CK levels or HFS.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The presence of anti-MDA5 antibody is associated with amyopathic dermatomyositis and/or rapidly progressive interstitial lung disease that can be fatal. In the latter case, it is mandatory to confirm the diagnosis as soon as possible in order to initiate aggressive treatments and the presence of anti-MDA5 autoantibodies is an important part of the differential diagnosis. The immunoassay using photonic microrings is a new sensitive technology that enables rapid results in less than 15 minutes. The aim of our study was to evaluate this technology for the detection of anti-MDA5 antibodies in sera with known positivity.

**Methods:** The system is based on immobilizing the antigenic target, MDA5, above the photonic rings in a silicon chip. We analyzed a total of 72 sera drawn from 40 patients known to be positive for anti-MDA5 antibody in our laboratory using immunoblotting assays and 4 negative controls. For some patients, several samples drawn during the follow-up could be analyzed.

**Results:** Using the photonic ring immunoassay, we could confirm the presence of anti-MDA5 antibody in all samples known as positive for anti-MDA5 antibody by other techniques. No false positive or false negative results were found. Moreover, high levels of MDA-5 antibodies measured at diagnosis are associated with interstitial lung disease with respiratory functional impairment at presentation. Interestingly, we observed a decrease in anti-MDA5 antibodies titers in followed-up patients.

**Conclusion:** The photonic ring immunoassay is a fast and reliable technology for the detection of anti-MDA5 antibodies.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Background/Purpose:** Myositis leads to significant morbidity and loss of function. Currently, simple objective measures of patient functional outcomes are lacking. Our aims were to a) test functional measures (sit to stand [STS], timed up and go [TUG], and 6-minute walk distance [6MWD]) in myositis patients against established myositis core set measures, and b) evaluate reliability of the same measures self-performed by patients at home.

**Methods:** We collected data on the 6 validated myositis core measures (manual muscle testing [MMT], physician global disease activity, patient global disease activity, extra-muscular global disease activity, HAQ and muscle enzymes) as well as performed 3 functional measures in clinic (STS, TUG, and 6MWD) on patients with DM, PM and necrotizing myopathy at baseline, 3 and 6 months. STS is number of times a patient can stand from a seated position and sit back down, as many times in 30 seconds. TUG is the time needed to rise from a chair, walk 3 meters, return to the chair and sit down. 6MWD is the maximum distance patient can walk in 6 minutes. We instructed patients on conducting these functional measures at home, and they reported performance results at home within a week of clinic evaluation. To assess validity we compared functional measures against all core set measures at baseline and MMT longitudinally. We examined test-retest reliability of home assessments with in clinic assessments. We use Spearman correlations with  $\rho > 0.5$  considered strong, 0.35-0.5 moderate, and 0.2-0.35 weak.

**Results:** Data from 31 patients [58% females, 90% Caucasians, mean age 48 ( $\pm 16$ )] from an ongoing observational study were included in this analysis. As shown in table 1, at baseline, STS correlated strongly with -MMT, patient/physician global assessment, and muscle enzymes, and had moderate correlation with HAQ, and no correlation with extra-muscular global. Similarly, at baseline, TUG showed moderate correlation with physician/patient global and muscle enzymes, but only weak association with MMT, HAQ and extra-muscular global. The 6MWD showed strong correlation with MMT, moderate with patient global and HAQ, and weak with physician global and muscle enzymes. Longitudinally, 6MWD showed strong association with MMT, where as STS and TUG showed moderate and weak associations with MMT respectively. Home assessments of STS ( $\rho$ : 0.91), TUG ( $\rho$ : 0.94) and 6MWD ( $\rho$ : 0.86) showed high test-retest reliability compared to clinic assessment ( $P < 0.01$  for all 3).

**Conclusion:** Preliminary data suggests strong cross sectional correlation of STS and 6MWD with MMT and moderate to strong correlation with MMT longitudinally. All tests were reliable when self-performed by patients at home. This suggests these simple measures may provide objective functional assessment of patient-centric outcomes in myositis in clinic as well as- at home.

# Clinical Significance of Serum Levels of Anti-Transcriptional Intermediary Factor 1- $\gamma$ Antibody in Patients with Dermatomyositis

**Nobuaki Ikeda**, Yukie Yamaguchi, Miwa Kanaoka, Yasushi Ototake, Eriko Takebayashi and Michiko Aihara, Department of Environmental Immuno-Dermatology, Yokohama City University Graduate School of Medicine, Yokohama, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Dermatomyositis (DM) is an autoimmune inflammatory disease characterized by skin eruptions and myositis, which is occasionally complicated by interstitial lung disease (ILD) or concomitant malignancy. It has been recognized that myositis-specific autoantibodies (MSAs) are correlated with unique sets of clinical manifestations. Anti-transcriptional intermediary factor 1- $\gamma$  (TIF1- $\gamma$ ) antibody is one of the most frequently detected MSAs both in juvenile and adult DM, and adult DM positive for anti-TIF1- $\gamma$  have a markedly higher rate of malignancy. In Japan, an individual measurement of anti-TIF1- $\gamma$  by enzyme-linked immunosorbent assay (ELISA) is now covered by insurance. However, little is known about clinical utility of quantitative ELISA index of anti-TIF1- $\gamma$  in association with disease activity.

**Methods:** We studied 26 Japanese adult DM patients positive for anti-TIF1- $\gamma$  antibody detected by ELISA, who had been under treatment in our department. All patients were confirmed negative for anti-Mi-2 antibody concomitantly measured by ELISA. Seventeen patients with anti-TIF1- $\gamma$  antibody (65.4%) had concomitant malignancy which was defined by the diagnosis within 2 years before or after DM diagnosis. Sequential serum samples were obtained in 16 patients. Clinical utility of quantitative anti-TIF1- $\gamma$  index was analyzed in association with patient's characteristics and disease severity.

**Results:** Anti-TIF1- $\gamma$ -positive patients frequently had facial erythema (84.6%) including heliotrope rash (73.0%), Gottron's papules (69.2%), erythema of the trunk (61.5%), and dysphagia (46.2%). Three patients were classified as clinically amyopathic DM (11.1%) and 5 patients had ILD (18.5%). Although maximum levels of serum creatine kinase (CK) was significantly higher in patients with malignancy compared to those without (mean  $\pm$  SD IU/L,  $2494.1 \pm 5326.9$ ,  $392.3 \pm 423.3$ , respectively,  $P < 0.05$ ), there was no significant difference on anti-TIF1- $\gamma$  index between patients with and without malignancy ( $105.4 \pm 38.0$ ,  $113.0 \pm 39.2$ , respectively,  $P = 0.32$ ). No positive correlation was found between levels of serum CK and anti-TIF1- $\gamma$  ( $r = 0.32$ ,  $P = 0.17$ ). In sequential analysis ( $n=16$ ), anti-TIF1- $\gamma$  level in patients without malignancy was decreased by more than 30% or turned negative after treatment for DM. However, antibody titer tended to be sustained in patients with malignancy at stage IV. Interestingly, re-increase of antibody titer was observed at a recurrence of malignancy ( $n=1$ ) or increase of DM activity ( $n=3$ ). Two patients had completely succeeded treatments for their malignancy, then anti-TIF1- $\gamma$  level turned negative as loss of DM activity.

**Conclusion:** Higher index of anti-TIF1- $\gamma$  may not directly indicate the presence of malignancy or higher activity of DM. However, longitudinal change of anti-TIF1- $\gamma$  index in individual patients may partially reflect activities both of DM and malignancy. Close monitoring may be suggested if patients have sustained antibody titer despite no malignancy and loss of DM activity.

## Characteristics Unique to MDA5 and Anti-Ro/SSA-52 Kda Dual Antibody Positive Patients with Inflammatory Myopathies

**Juan J Maya**, Olga Pinkston, Florentina Berianu, Benjamin Wang and Andy Abril, Rheumatology, Mayo Clinic Florida, Jacksonville, FL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The anti-melanoma differentiation-associated gene 5 antibody (MDA5) was recently classified as a myositis-specific antibody (MSA), and has been associated with rapidly progressive interstitial lung disease (ILD), amyopathic dermatomyositis (aDM), mechanic's hands, ulcerations, inflammatory arthritis, and increased mortality. This study sought to distinguish the clinical characteristics of MDA5-positive patients with and without additional MSAs.

**Methods:** We retrospectively identified all MDA5 positive patients who were evaluated at our center from 2015 to 2017 with suspected myositis and had myositis-associated autoantibodies tested using a commercial panel (Myomarker Panel 3, RDL Reference Laboratories). For all patients who were positive for MDA5, we collected clinical information on the presence of myopathy, skin involvement and ILD, data on the autoantibody profile, PFTs and high resolution CT pattern.

**Results:** In our sampling period, 62 patients were positive for 1 or more MSA, of which 13 were positive for MDA5 (20.9%). Two MDA5 positive patients had incomplete clinical data and were not included in the analysis. Of the remaining 11 patients, 7 were females and 4 were males, with mean age 56.6 years (SD 10.9). Six MDA5 positive patients also had high titers of anti-Ro/SSA-52 kDa (46.1%) (mean Ab level by ELISA 120.5, SD 52). Five of the dual-positive patients had ILD (83.3%), versus 2 of MDA5-only patients (40%) ( $p=0.39$ ). Of the dual-positive patients with ILD all had nonspecific interstitial pneumonitis (NSIP), 3 of which also had organizing pneumonia (67%), while in the MDA5-only group, one had fatal acute interstitial pneumonitis (20%) and the other one had UIP (20%). All of the dual-positive patients demonstrated improvement with immunosuppressive treatment as determined by CT, PFTs and clinical evaluation (100%), while only 2 patients from the MDA5-only group did (40%) ( $p=0.12$ ). Three of the 6 dual-positive patients had EMG and/or MRI evidence of myopathy (50%) compared to 2 of 5 of the MDA5-only patients (40%). Two patients in the dual-antibody group had mechanic hands while only one in the MDA-only group had it.

**Conclusion:** Anti-Ro/SSA-52 kDa was frequently encountered in patients with MDA5-positive myopathic disease. In these dual-positive patients, ILD and NSIP were more common compared to patients that were positive for MDA5-only. A definite trend for response to immunosuppressive treatment was seen in the dual-positive group than in the MDA5-only group. As it has been reported previously, there was a high incidence of mechanic's hands and aDM in patients positive for MDA5. This preliminary study indicates that certain autoantibody profiles in myositis are related to pulmonary and cutaneous manifestations, and may be predictive of response to treatment. These data highlight the importance of screening for these markers. Further study is ongoing to further elucidate the association of MSA and the clinical manifestations and response to treatment response of patients with inflammatory myopathies.

## Investigating Exercise- and Crossfit-Induced Rhabdomyolysis: Data from a Community Healthcare System

Sneha Sundaram<sup>1</sup>, Michelle Meyer<sup>2</sup>, Richard Shaw<sup>3</sup> and Ingeborg Schafhalter-Zoppoth<sup>1</sup>, <sup>1</sup>Internal Medicine, California Pacific Medical Center, San Francisco, CA, <sup>2</sup>Pediatrics, UCSF Benioff Children's Hospital Oakland, Oakland, CA, <sup>3</sup>California Pacific Medical Center, San Francisco, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The work-up of elevated muscle enzymes is a common reason for rheumatology consults. The differential diagnosis of rhabdomyolysis includes trauma, exertion, hereditary myopathies, drugs, toxins and infections. Especially exertional rhabdomyolysis can be underdiagnosed as its prevalence in civilians is unclear and its clinical course is mostly described by case reports. We studied the

prevalence, nature, and consequences of exertional rhabdomyolysis in patients younger than 55 years. We especially focused on CrossFit- induced rhabdomyolysis as data of its involvement in rhabdomyolysis are controversial. CrossFit is a conditioning program involving high-intensity exercises performed in rapid repetition with minimal recovery time.

**Methods:** We conducted a retrospective chart review of all encounters with a diagnosis of rhabdomyolysis within all acute and ambulatory Sutter locations in Northern California between January 2004 and February 2016. Patients older than 55 years or with Medicare insurance were excluded. We reviewed the records and identified cases of rhabdomyolysis caused by exercise. Extracted data included age, gender, BMI, types of exercises performed, symptoms, sites of injury, location of presentation, creatinine and CPK levels at initial presentation and at follow-up, treatment administered, and hospitalization or discharge. Statistical analyses included Chi-square, Fisher's exact tests, t-tests, and linear regression.

**Results:** We identified 1,277 patients with rhabdomyolysis. Exercise-induced rhabdomyolysis was diagnosed in 297 patients, with 42 of these cases caused by CrossFit. Mean age of all patients with exercise-induced rhabdomyolysis was 31 years (range: 12 to 53), with a gender composition of 70% males and 30% females. The majority of patients (51%) presented to the emergency department. Mean CPK at presentation was 36,120 U/L (range: 213 to 522,040), mean creatinine was 1.14 mg/dl (range: 0.37 to 29.00). Higher levels of CPK and creatinine were associated with hospitalization ( $p<0.0001$  and  $p=0.004$ , respectively) and with longer hospital stays ( $p=0.025$  and  $p<0.0001$ , respectively). Average hospital stay was 4 days (range 1-12 days). Patients with CrossFit related rhabdomyolysis had lower creatinine levels at presentation (0.82 vs 1.19 mg/dl,  $p=0.008$ ), were more likely to have IV fluids administered (86% vs 73%,  $p=0.048$ ), and a shorter hospital stay (3.5 vs 4.4 days,  $p=0.029$ ).

#### **Conclusion:**

This is the first large-scale study to investigate exercise- and CrossFit-induced rhabdomyolysis. The prevalence of exertional rhabdomyolysis is significant, with a notable proportion of these cases attributable to CrossFit. As patients with muscle pain and elevated muscle enzymes are referred to the rheumatologist it is important to know about this disease. There is often a delay in diagnosis and treatment, therefore education to physicians and athletes about exertional rhabdomyolysis for primary prevention and for early diagnosis is necessary.

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The idiopathic inflammatory myopathies (IIM) are often associated with interstitial lung diseases (ILD). Yet, pulmonary function testing (PFT) results can be confounded by patient effort, mixed obstructive/restrictive disease and pulmonary hypertension. Our purpose was to evaluate the correlation between measurements from quantitative thoracic high-resolution CT (HRCT) analysis with Computer-Aided Lung Informatics for Pathology Evaluation and Rating (CALIPER) software and PFTs in patients with IIM-associated ILD.

**Methods:** A cohort of patients with IIM-associated ILD seen at a single institution was identified from medical record review in 2003-2011. Retrospective analysis of HRCT data and PFTs at baseline and 1 year was performed. The abnormalities in HRCT were quantified using CALIPER software. Correlation between baseline CALIPER measurements and PFT measurements as well as correlation between changes of CALIPER measurements and PFT measurements at one year (compared with baseline) were assessed using Spearman correlation coefficients.

**Results:** A total of 110 patients were identified. At baseline, total interstitial abnormalities as measured by CALIPER, both by absolute volume and by percentage of total lung volume, had a significant negative correlation with diffusing capacity for carbon monoxide (DLCO), total lung capacity (TLC) and oxygen saturation (Table). Analysis by subtype of interstitial abnormality revealed significant negative correlations between ground glass opacities (GGO) and reticular density (RD) with DLCO ( $p < 0.001$ ) and TLC ( $p < 0.001$ ).

At one year, changes of total interstitial abnormalities compared with baseline had a significant negative correlation with changes of TLC and oxygen saturation ( $p = 0.015$ ;  $p < 0.01$ ). Figure 1 demonstrates a sample of CALIPER analysis of a lung affected by progressive nonspecific interstitial pneumonia, 2009-2012.

**Conclusion:** This study provides evidence of the utility of CALIPER software, as it is the first study to demonstrate the correlation between CALIPER measurements and functional measurements in patients with IIM-associated ILD.

**Table: Correlation between CALIPER measurements and PFT measurement at baseline**

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Muscle Biology, Myositis and Myopathies Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Clusterin (also known as apolipoprotein J) is a molecular chaperone that participates in a number of biological processes, such as inflammation and apoptosis. Recent data suggest its possible role in the development of chronic autoimmune diseases. The aim of this study was to analyse skeletal muscle expression and serum levels of clusterin in patients with idiopathic inflammatory myopathies (IIM) and in healthy individuals, and to investigate their potential association with clinical disease activity.

**Methods:** Protein expression of clusterin in muscle tissues was determined by immunohistochemistry in 5 patients with polymyositis (PM), 5 patients with dermatomyositis (DM) and in 5 control subjects. Clusterin mRNA expression in skeletal muscle samples was analysed in 10 patients with IIM and 10 healthy donors by qPCR. Clusterin serum levels were measured by commercial ELISA kit (BioVendor) in 65 IIM patients (28 PM, 27 DM, 10 immune-mediated necrotizing myopathy (IMNM)) and 65 age-/sex-matched healthy individuals. Patients with PM and DM fulfilled Bohan and Peter diagnostic criteria. IMNM was diagnosed according to ENMC 2003 criteria. Disease activity was assessed using myositis disease activity assessment visual analogue scales (MYOACT), myositis intention to treat index (MITAX), health assessment questionnaire (HAQ) and global disease assessment evaluated by patient and doctor. Data are presented as mean  $\pm$  SD.

**Results:** Clusterin mRNA expression in muscle tissues was significantly increased in patients with IIM compared to healthy donors ( $p=0.029$ ). Clusterin protein was found to be accumulated in the cytoplasm of regenerating muscle fibers in patients with PM/DM. Serum clusterin levels were significantly higher in all IIM patients than in healthy subjects ( $87.1 \pm 22.8$  vs  $66.9 \pm 11.9$ ,  $p<0.0001$ ) and also in individual subsets of patients in comparison to the control group (PM:  $86.1 \pm 23.2$ , DM:  $87.7 \pm 24.7$ , IMNM:  $88.15 \pm 18.0$ ,  $p<0.0001$  for all). Clusterin levels in all patients with IIM positively correlated with MYOACT ( $r=0.337$ ,  $p=0.008$ ), MITAX ( $r=0.357$ ,  $p=0.004$ ) and global disease assessment evaluated by a doctor ( $r=0.309$ ,  $p=0.015$ ). In patients with DM, positive correlations with MYOACT ( $r=0.499$ ,  $p=0.009$ ), MITAX ( $r=0.491$ ,  $p=0.009$ ), HAQ ( $r=0.470$ ,  $p=0.014$ ) and global disease assessment evaluated by a doctor ( $r=0.559$ ,  $p=0.004$ ) were found. No such associations were observed in PM or IMNM subsets.

**Conclusion:** We demonstrate increased local and systemic expression of clusterin in IIM patients compared to healthy individuals and its association with clinical disease activity, especially in patients with DM.

## The Medial Shift of the Tibial Articular Surface Is One Factor of Medial Osteoarthritis of the Knee

Ryuji Nagamine, Artificial joint and rheumatism, Fukuoka Tokushukai Medical Center, Kasuga, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Varus alignment is one factor of medial osteoarthritis (OA) of the knee. According to the concept of the constitutional varus, the bone growth disturbance at the medial proximal metaphysis of the tibia results in proximal tibia vara. In this situation, the tibia is bent at the proximal metaphysis. Therefore, the tibial articular surface (TAS) tilts in varus position and shifts medially. The medial shift of TAS may influence the value of the Hip-knee-ankle (HKA) angle because the ankle joint shifts laterally relative to the TAS. The purpose of this study was to assess the extent of the medial shift of TAS in knees with medial OA, and to assess the effect of this medial shift of TAS on the value of HKA angle, and to discuss the importance of the medial shift of TAS for the onset of medial OA of the knee.

**Methods:** This study consisted of 116 knees with medial OA. The mean age was 75.3 years old. The mean standing femorotibial angle (FTA: lateral angle between femoral and tibial anatomical axes) was  $183.6^\circ$ . On the anteroposterior view radiograph of the tibia, an anatomical axis (AA), a mechanical axis (MA) and a tibial plateau tangent were drawn. AA was the central line of the tibial shaft. MA is the line between the center of the tibial spines notch and the center of the tibial plafond (ankle joint). Two angle parameters and two distance parameters were measured. Those were angle between AA and MA (Angle A-M) (the value was positive when MA located medial to AA), angle between the tibial plateau tangent and the line perpendicular to AA (Angle plateau), distance from AA to MA on the tibial plateau (Distance A-M) (the value was positive when MA located medial to AA), and the length of MA.

**Results:** The mean ( $\pm$ SD) Angle A-M and Angle plateau was  $1.0^\circ \pm 0.6^\circ$  (range,  $-0.1^\circ$  to  $3.0^\circ$ ) and  $8.2^\circ \pm 2.9^\circ$  ( $1.0^\circ$  to  $17.0^\circ$ ), respectively. The mean Distance A-M and length of MA was  $5.6\text{mm} \pm 3.4\text{mm}$  ( $-1.4\text{mm}$  to  $16.1\text{mm}$ ) and  $347.3\text{mm} \pm 3.4\text{mm}$  ( $300.7\text{mm}$  to  $408.2\text{mm}$ ), respectively. The correlation coefficient between Angle Plateau and Distance A-M was 0.62. The more proximal tibia had varus deformity, the more TAS shifted medially. The maximum Distance A-M was 16.1mm. In this case, HKA angle underestimated varus deformity up to  $3^\circ$ . The coronal alignment of the lower extremity is expressed in the two-dimensional coordinate system. HKA angle is constructed by three points (hip, knee and ankle) in the system on condition that AA and MA match on the tibia. The difference between MA and AA cannot be assessed by HKA angle. The medial shift of the TAS would increase the mechanical loading in the medial side of the knee.

**Conclusion:** The knees with proximal tibia vara have medial shift of the tibial articular surface. HKA angle under-estimates varus deformity in such knees. The medial shift of the tibial articular surface should be taken into account for one factor of the medial OA of the knee, and for the treatment of the medial OA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Metabolic changes or low-grade inflammation related to cardiovascular disease (CVD) and diabetes have been hypothesized to contribute to the development of OA. Prior studies have demonstrated an association between diabetes and OA, and recognized OA as a risk factor for incident CVD. However, it remains unclear whether these associations are truly causal as they have not been confirmed in longitudinal cohort studies and may be explained by shared risk factors. The aim of the current study was therefore to examine the associations of pre-existing CVD and diabetes with incident knee OA.

**Methods:** The study sample consisted of Multicenter Osteoarthritis (MOST) Study participants. We used a self-administered modified Charlson comorbidity questionnaire to assess pre-existing CVD (heart attack, stroke, transient ischemic attack, heart or leg bypass surgery, treatment for heart failure) and diabetes in the participants at baseline. We assessed radiographic (ROA) and symptomatic (SxOA) knee OA at baseline and at 60-months follow-up. We defined ROA as Kellgren-Lawrence grade  $\geq 2$  on the knee radiograph, and SxOA as ROA and frequent knee pain in the same knee. While we primarily aimed to evaluate the effect of CVD and diabetes on development of knee OA, we recognize that such comorbidities are often chronic and their effects on OA may have already occurred in these older study subjects prior to their study entry. This could result in depletion of susceptibles in a study of their effects on incident knee OA. Therefore, we evaluated both the cross-sectional and longitudinal relation of CVD and diabetes to prevalent and incident ROA and SxOA using logistic regression. We adjusted the models for age, sex, race, body mass index (BMI), history of knee injury/surgery, physical activity, and correlation between knees within each participant.

**Results:** We included 5929 knees of 3014 participants in the baseline cross-sectional analyses (mean $\pm$ SD age 62.5 $\pm$ 8.1, mean BMI 30.8 $\pm$ 6.0, 60% Caucasian) and 2317 knees of 1181 participants free of knee OA at baseline in the longitudinal analyses (mean $\pm$ SD age 60.7 $\pm$ 7.7, mean $\pm$ SD BMI 29.1 $\pm$ 4.7, 59% Caucasian). In cross-sectional analyses, CVD and diabetes were not associated with ROA and SxOA (Table). In longitudinal analyses, we also found no association of CVD or diabetes with incident ROA or SxOA (Table).

**Conclusion:** Self-reported CVD and diabetes were not associated with prevalent or incident knee ROA or SxOA after adjustment for potential confounders. Although some of our analyses had limited precision, our results suggest that these common comorbidities do not appear to contribute to development of knee OA. Specific factors that may contribute to a metabolic OA phenotype require

further evaluation.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** High variability in patient-reported outcome scores presents a major challenge in the design and interpretation of clinical studies in osteoarthritis (OA). We present a novel successive prediction algorithm that forecasts individual WOMAC scores based on known clinical parameters and identifies risk factors for deviations between observed and predicted scores.

**Methods:** Participants from the Osteoarthritis Initiative progression cohort with a baseline Kellgren-Lawrence grade  $\geq 2$  for either knee were selected for analysis (N = 1,122). Demographic data, history of pain and depression, BMI, and physical activity parameters at baseline and eight subsequent annual observation times were processed to maximize the number of complete records. WOMAC scores were predicted for study years four through eight, using a mixed effects regression model applied to data up to, but not including, each study year. The predictive model adjusted for continuous time trends for individual subjects as well as the overall cohort, yielding an expected WOMAC score for each participant. To identify subgroups with excessive residual WOMAC scores, subject-specific residuals were analyzed by a separate multivariable regression at each time point.

**Results:** We were able to accurately model WOMAC scores and to use the fitted models to predict individual scores for each successive year. The predictive model for each visit showed significant overall fit ( $p < 0.0001$  at all targeted study years). The succession of fitted models adapted to new information gained over time, and adjusted predictions to minimize residuals (Figure 1). Factors associated with lower than expected WOMAC scores on more than one successive visit were long-standing history of knee pain and history of hip pain, with mean residual WOMAC (95% confidence interval) ranging from  $-3.3$  ( $-5.5, -1.7$ ) to  $-7.7$  ( $-13.2, -2.3$ ). The factor associated with higher than expected WOMAC scores was high performance on the 20-meter walk test, with mean residual WOMAC ranging from  $+3.3$  ( $+0.5, +6.0$ ) to  $+4.5$  ( $+1.7, +7.2$ ).

**Conclusion:** A successive prediction model closely predicted WOMAC scores based on traditional OA risk factors and prior clinical assessments. Subjects with long-standing histories of knee pain and associated hip pain, as well as subjects with good physical performance displayed unexpected WOMAC scores over time.

Figure 1. Observed and Predicted WOMAC Total Scores for a Single Subject Through Study Year 6.

Plot of observed values of WOMAC total score (pain + stiffness + functional limitations), which can range from 0 to 96, shown as solid circles from Baseline through Study Year 5, and as an open circle for Study Year 6, the desired year of prediction. The prediction curve is based on a mixed effects model, and is illustrated as a solid line in segments through successive years. The expected WOMAC total score for Study Year 6 is at the right tip of the prediction (solid) curve. Subtracting the value from that observed at Year 6 yields the WOMAC Residual for this Subject, highlighted by the dashed red arrow in the plot. At Year 6, this Subject reported a WOMAC total score that was 19.5 points lower than expected. All WOMAC scores were transformed by a scaled logistic function for modeling; the y-axis is annotated with original WOMAC values.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Obesity and metabolic syndrome (MetS) are the strongest modifiable risk factors of knee OA, and frequently affect the same individual. The reported associations in hip OA are less consistent. Weight reduction alone has not been shown to prevent the progression of hip OA, which led us to consider the metabolic effects of obesity. This study tests the interaction between obesity and MetS on hip OA in older men and women, to determine whether odds of hip OA were higher among individuals with both MetS and obesity as compared to those with only one or neither of these conditions.

**Methods:** Cross-sectional analysis was performed on two groups: 4871 women from the Study of Osteoporotic Fractures (SOF) and 3567 men from the Osteoporotic Fractures in Men Study (MrOS) cohorts. Participants were included if they had available hip

radiographs, documented hip exam, and measurements of body mass index (BMI), systolic blood pressure, triglycerides, high density lipoprotein, and fasting glucose. Clinical hip OA was defined as a modified Croft Score <sup>32</sup> or THR by radiographic review, and either hip pain or limited hip range of motion. The odds ratio for hip OA in obese (BMI<sup>30</sup>) as compared to non-obese and in MetS as compared to non-MetS participants was estimated using multivariable logistic regression, adjusting for covariates (Table). An interaction term was then included to determine whether MetS modified associations between obesity and hip OA. In SOF, serum measurements required to evaluate MetS were only available for 401 participants. Compared to the 4871 SOF participants, these 401 women were 0.6 years older, less educated, had 2.6% more DM; and were similar in prevalent hip OA and anthropometry.

**Results:** The prevalence of obesity was 21.4% in men and 19.3% in women. Fifty percent of women and 60.2% of men met the definition for MetS. In men, there was a 70% higher odds of hip OA in obese as compared to non-obese individuals in fully adjusted analysis (95% CI: 1.03-2.84). Among women, no significant association between obesity and hip OA was found in fully adjusted analysis (Table 1). There was no significant association between MetS and hip OA (Table 1) or interactive effect (data not shown) between MetS and obesity on hip OA in either women (p=0.996) or men (p=0.394).

**Conclusion:** Obesity, but not MetS, conferred a higher odds of hip OA in a population of community-dwelling older men, suggesting that mechanical load has a more significant role in hip OA pathogenesis than the metabolic effects of increased adiposity. Neither obesity nor MetS were associated with hip OA in the women studied. Given the small sample size, future studies are needed to evaluate MetS and hip OA in women.

Table 1. Odds ratios (and 95% Confidence Intervals) for associations of obesity (BMI<sup>30</sup> kg/m<sup>2</sup>) and metabolic syndrome (2 of 4 NCEP-ATPIII criteria, excluding waist circumference) with clinical hip osteoarthritis in SOF and MrOS.

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Joint pain in hand osteoarthritis (OA) is associated with synovitis in cross-sectional studies. Therefore we hypothesized that synovitis could be a target for treatment. Our aim was to investigate the longitudinal associations between inflammatory features on MRI and joint tenderness in patients with primary hand OA over a two-year period.

**Methods:** Eighty-five consecutively included patients (81.2% women, median age 58.7 years) with primary hand OA (89.4% fulfilling ACR classification criteria) from a rheumatology outpatient clinic, who received contrast-enhanced MRI and physical examination of the right hand at baseline and at follow-up two years later, were studied. Fat suppressed T2-turbo spin weighted and pre- and post-gadolinium injection T1-weighted sequences were performed in axial and coronal planes on a 1.5 Tesla extremity MR unit. Baseline and follow-up images were scored paired in unknown time order, blinded for clinical data, by one reader according to the Hand OA MRI scoring system (HOAMRIS). Joint tenderness was assessed by trained research nurses. Odds ratios were calculated on joint level (n=680; 8 interphalangeal joints of right digits 2-5 per patient), using generalized estimating equations to account for the within patient effects. Additional adjustments were made for gender, baseline status of MRI-defined osteophytes, synovitis and BML, and change in MRI-defined osteophytes, synovitis/BML and erosions, when appropriate.

**Results:** Out of 116 joints with baseline tenderness, 73 had loss of tenderness at follow-up. Decrease in synovitis was seen in 21 joints, and decrease in BMLs only in 13. Loss of tenderness was associated in adjusted analyses with a decrease in synovitis, but not in BMLs (Table 1). However, when stratifying for change in synovitis, a decrease in BMLs showed an additive effect (Table 2). Out of 564 joints without baseline tenderness, 103 had incident tenderness at follow-up. Incident tenderness was associated with an increase in synovitis and, to a lesser extent, BMLs. After adjusting for each other it became apparent that synovitis was the main effect modifier and BMLs only had an additive effect (data not shown).

**Conclusion:** A decrease in inflammatory MRI features is associated with loss of joint tenderness, supporting targeting MRI-defined synovitis in hand OA.

**Table 1** The associations between decrease of MRI features and loss of joint tenderness (in joints with tenderness at baseline)

	Joints with loss of tenderness (yes/no)	Adjusted analyses <sup>a</sup> OR (95% CI)
<i>Associations between decreasing MRI features and loss of joint tenderness</i>		
Synovitis		
No change/increase	54/37	1.0 (reference)
Decrease	16/5	4.94 (1.29 to 18.93)
Bone marrow lesions		
No change/increase	63/35	1.0 (reference)
Decrease (≥0.5)	6/7	0.63 (0.19 to 2.12)
Decrease (≥1)	5/6	0.90 (0.30 to 2.68)

OR=Odds ratio; CI=confidence interval; <sup>a</sup>Adjusted for patient effect, gender, baseline status of MRI-defined osteophytes, synovitis and BML, and change in MRI-defined osteophytes, synovitis/BML and erosions, when appropriate.

**Table 2** The odds ratios for loss of joint tenderness (in joints with tenderness at baseline) when stratified for change in both synovitis and bone marrow lesions.

		Synovitis	
		No change/increase	Decrease
Bone marrow lesions	No change/increase	1.0 (reference)	3.13 (0.80 to 12.32)
	Decrease ( $\geq 0.5$ )	0.43 (0.08 to 2.44)	4.38 (0.94 to 20.40)

Odds ratios (95% confidence interval), adjusted for gender, baseline status of MRI-defined osteophytes, synovitis and BML, and change in MRI-defined osteophytes and erosions.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** DISH has been reported to be associated with constitutional and metabolic derangement. In particular, patients with DISH were reported to bear a higher cardiovascular risk. The outcome of these CV risks has never been evaluated. The aim of the study was to explore if patients with DISH develop, over time, a significant cardio-vascular morbidity in a real life scenario.

**Methods:** This is a follow-up study on a group of patients without cardiovascular diseases. The patients' characteristics and their CV risk factors, their prevalence of MS and their Framingham risk score has been already described. The medical records were reviewed, and the data about their current diagnoses, medical treatments, hospitalizations and mortality were re-collected. The statistical analysis compared the data with the historical data of the same groups (DISH vs non-DISH) as well as changes within the same group (DISH or non-DISH).

**Results:** There were 49 patients in the DISH group and 48 in the NDISH group. In this cohort, patients with DISH were significantly more often affected by type 2 diabetes, obesity, insulin resistance. They also had a significant higher risk for the development of cardiovascular events. The mean follow-up time was approximately 10 years for both groups. No differences for gender, age, age at diagnosis were observed. Patients with DISH were more often admitted to the department of medicine, the difference though did not reach statistical significance ( $p=0.07$ ). More DISH patients developed acute MI (12 vs 2  $p=0.0044$ ), and were affected by hypertension and DM (60% vs 86%  $p=0.0049$ ; 17% vs 54%  $p=0.0001$  respectively). The crude odds ratios for DISH patients to develop myocardial infarction during the follow-up and after adjustment for diabetes, hypertension and obesity were 7.46 (95%CI 1.57-35.44) and 5.65 (95%CI 1.08-29.43) respectively. The Framingham CV risk score underestimated the occurrence of cardiac events in particular in the DISH group. No differences were detected between the groups in the prevalence of TIA's, CVA's or PVD. The mortality rate between the groups was nearly equal (8.33 vs 10%). Significantly more patients in the DISH group developed de novo DM, and were prescribed ACE inhibitors, compared with the NDISH group. Increased hypertension prevalence, between the first assessment and at 10 years, was similar between the groups.

**Conclusion:** The incidence of MI is significantly higher in patients with DISH compared with age and sex matched NDISH patients. The increased CV risk attributed to patients with DISH is evidenced at ten years with a significant increase in myocardial infarction events during that period of time. The Framingham score underestimated the risk in patients with DISH. On the other hand, the prevalence of vascular morbidities such as TIA's, CVA's or PVD's was similar between the groups. More studies are needed to determine if these findings depend only on the association of DISH with traditional CV risk factors, or, if there is a contribution of the musculoskeletal condition per se.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Randomized controlled trials (RCTs) of interventions for knee OA (KOA) may include a patient-reported outcome (PRO) measure as a primary endpoint. Several measures of KOA symptoms are potential candidates, although their comparative performance is unclear. The objectives of this study were to 1) estimate clinically important differences in 2-year changes in symptoms by anchoring change scores to a clinically important outcome, that is, future knee replacement (KR), and 2) compare 2-year changes in symptom scores with respect to their ability to discriminate knees that underwent KR over 7 years of follow-up.

**Methods:** OA Initiative knees were selected for analysis, based on eligibility criteria typical of a disease-modifying osteoarthritis drug (DMOAD) RCT for KOA, including Kellgren-Lawrence grade of 2 or 3, medial minimum joint space width  $\geq 2.5$  mm, knee pain at worst in the past 30 days from 4 to 9 on a 10-point numerical rating scale (NRS) or 0 to 3 if pain medication was taken for joint pain, excluding those with malalignment of  $>5^\circ$ . KOA symptoms were assessed over 2 years, including knee pain severity over the past 30 days on a NRS, and over the past 7 days on a NRS, as well as WOMAC subscales, Knee injury and OA Outcome Score (KOOS) subscales, and the 12-item short-form health survey (SF-12). Scores were scaled 0–100, with 100 as the worst possible score. To characterize clinically relevant change, 2-year change in symptom scores was anchored to KR up to 7 years of follow-up and difference in mean change was estimated. To evaluate the ability of 2-year change in symptom scores to discriminate knees that went on to future KR, area under the receiver operating characteristic curve (AUC) was estimated and compared.

**Results:** The sample included 1,181 knees, with median follow-up of 5.8 years after the initial 2-year assessment, and 131 underwent KR. Two-year changes in WOMAC total, KOOS NRS 7 days, KOOS symptoms score, and NRS 30 days had similar discrimination for future KR (Table 1). When compared directly, the AUC for NRS 30 days was significantly better than other measures such as NRS 7 days (AUC difference = 0.05, CI = 0.01–0.10), total WOMAC (AUC difference = 0.06, CI = 0.01–0.11), and KOOS symptoms (AUC difference = 0.06, CI = 0.002–0.12).

**Conclusion:** Among knees that met typical eligibility criteria for a DMOAD RCT, 2-year change in WOMAC total, KOOS symptoms score, KOOS pain frequency, and KOOS pain severity NRS 7 days performed similarly, although the NRS 30 days was marginally better at discriminating future KR up to 7 years of follow-up. Investigators conducting RCTs of KOA interventions may consider each of these PRO measures as potential primary endpoints. Overall performance was modest, and additional work is needed to develop more responsive measures.

Table 1. Two-year change in symptoms and future knee replacement

Symptom score	KR, Yes (n=131) Mean (SD)	KR, No (n=1050) Mean (SD)	Difference in means (95% CI)	AUC estimate (95% CI)
Knee pain at worst, NRS past 30 days	4.20 (32.77)	-11.33 (29.62)	-15.53 (-21.46, -9.59)	0.65 (0.60, 0.70)
WOMAC total score	1.04 (17.56)	-3.04 (14.58)	-4.08 (-7.24, -0.92)	0.59 (0.54, 0.65)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** For some individuals with knee osteoarthritis (OA), the failure of conservative management can often lead to knee replacement (KR). Identifying who will progress to KR may allow efficient dedication of resources towards this group with interventions that may delay or prevent the need for surgery. To date, self-reported pain severity and function has not provided sufficient prediction of KR. The speed of a person's gait is a powerful predictor of significant health events in older adults. Gait speed may encapsulate a range of functional limitations and impairments that could precipitate the need for KR and may therefore be an appropriate measure that predicts the need for KR in patients with knee OA. At the same time, because KRs occur in older individuals, observational studies need to properly account for competing risk of death and study withdrawal to obtain valid estimates of risk of KR. The aim of this study was to investigate the relation of gait speed to incident KR in older individuals with or at risk for knee OA.

**Methods:** The MOST Study is a NIH-funded cohort of persons with or at risk of knee OA. MOST participants completed baseline, 30-, 60-, and 84-month clinic visits. Gait speed at the baseline clinic visit was calculated from the time taken to complete the 20-meter walk test (meters(m)/second(s)). Date of first KR was confirmed. Participants without a KR were censored at their last attended clinic visit. We examined the relation of gait speed to KR using a Cox proportional hazards model accounting for competing events. Participants without a KR were censored at their 84-month visit, and death and early withdrawals were considered competing events. In separate models, we dichotomized gait speed at values related to functional limitation and community walking speed (1.0 and 1.2 m/s, respectively), and also into tertiles. Analyses were adjusted for age, sex, BMI, clinic site, baseline knee pain severity (visual analog scale 0-100 in the most painful knee) and baseline Kellgren-Lawrence (KL) score (maximum of right and left).

**Results:** 2774 participants were included: mean±SD age, BMI, and gait speed were 62.3±8.0, 30.6±6.0, and 1.20±0.2, respectively; 60% were female. 47% and 15% of participants walked at 1.0 and 1.2 m/s at baseline, respectively. While lower gait speeds were associated with higher risk of KR in the crude model, once we accounted for the confounding effects of pain severity and the competing risk of death and study withdrawal, lower gait speeds were no longer associated with incident KR (Table). Compared with the highest gait speed tertile, those in the lowest had 1.2 (0.9, 1.6) times the risk of KR.

**Conclusion:** Gait speed was not a strong predictor of KR once we accounted for the confounding effects of pain and competing risk of death and study withdrawal.

	Hazard Ratio (95% CI) for KR (n=2774)	
	Crude	Adjusted for age, sex, BMI, clinic site, KL score, and knee pain severity
20-m walk <1.0 m/s	2.1 (1.7, 2.5)	1.0 (0.8, 1.3)
20-m walk <1.2 m/s	2.2 (1.8, 2.7)	1.1 (0.8, 1.4)
20-m walk (range)		
Lowest Tertile (0.2-1.13)	3.0 (2.3-3.8)	1.2 (0.9-1.6)
Middle Tertile (1.14-1.29)	1.7 (1.3-2.2)	1.2 (0.9-1.5)
Highest Tertile (1.3-1.9)	1.0 (ref)	1.0 (ref)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The knee adduction moment (KAM) estimates medial knee load during gait, with high KAM fueling worsening OA. Understanding how foot mechanics contribute to KAM would inform the development of more effective footwear and insoles to prevent worsening knee OA. During the initial and early stance phases, a neutrally aligned foot with adequate pronation could dissipate impact loads, reduce varus thrust, and minimize KAM as it rises to an initial peak. Yet, excessive pronation in late stance redistributes load medially, possibly increasing KAM as it reaches a second peak. In persons with medial knee OA, we assessed: 1) the relation of foot pronation during the initial and early stance phases to 1<sup>st</sup> peak KAM; and 2) the relation of foot pronation during late stance to 2<sup>nd</sup> peak KAM. Given possible effects of both diminished and excessive pronation, we assessed both linear and u-shaped trends.

**Methods:** The Effectiveness of Shoes and Insoles on Loading at the Knee (SILK) Study included adults aged 45-70 yrs with medial knee OA. Plantar pressure profiles of the index limb were acquired during 5 trials of self-paced barefoot walking using an Emed-X platform. From these, we measured foot pronation during the initial, early, and late stance phases using the Pronation-Supination Index (PSI) as described by Motooka et al., where lower PSI values indicate greater pronation (retest ICC 0.46-0.90). Concurrently, a Qualisys motion capture system with AMTI force plates measured 1<sup>st</sup> and 2<sup>nd</sup> peak KAM in Newton-meters per kg of body weight (retest ICC= 0.86). In tertiles of increasing pronation (decreasing PSI), generalized linear models estimated mean 1<sup>st</sup> and 2<sup>nd</sup> peak KAM while adjusting for age, sex, body mass, and walking velocity. Tests for linear and u-shaped trend identified dose-response relationships.

**Results:** In 70 SILK participants (mean age 60.3 ± 9.6 yrs, body mass 87.3 ± 18.5 kg, walking velocity 1.12 ± 0.23 m/sec, 61.4% female), mean 1<sup>st</sup> and 2<sup>nd</sup> peak KAM was 0.36 and 0.32 Nm/kg, respectively. At initial contact, feet with diminished (PSI ≥ 58.14) or increased (PSI ≤ 55.09) pronation in comparison to the middle PSI tertile (PSI 55.10, 58.13) had increased 1<sup>st</sup> peak KAM (mean difference = 0.07 and 0.10 Nm/kg, respectively), resulting in a significant u-shaped trend (p for trend = 0.02). During early stance, 1<sup>st</sup> peak KAM was greatest among feet with the least pronation and declined linearly across tertiles of increasing pronation (p for trend = 0.06). There was no association between foot pronation in late stance and 2<sup>nd</sup> peak KAM (see table).

**Conclusion:** In adults with medial knee OA, feet with diminished or excessive pronation at initial contact, and feet with reduced pronation during the early stance phase of walking, experience increased peak medial knee loads. These findings could inform efforts to refine more effective footwear or insole interventions to minimize loads for persons with medial knee OA.

**Table.** Medial knee load, as measured by 1<sup>st</sup> or 2<sup>nd</sup> peak knee adduction moment (KAM), in tertiles of increasing foot pronation (PSI) during the initial, early, and late stance phases of walking.

		Foot Pronation				
		PSI (high)	increasing	PSI (low)		
Initial Contact					p linear	p u-shaped
PSI range	66.62, 58.14	58.13, 55.10	55.09, 46.26			
Mean* 1 <sup>st</sup> peak KAM	0.38	0.31	0.41	0.44	0.02	
95% CI	0.31, 0.44	0.25, 0.37	0.35, 0.47			
Early Stance					p linear	p u-shaped
PSI range	65.19, 57.07	57.06, 53.69	53.68, 47.55			
Mean* 1 <sup>st</sup> peak KAM	0.40	0.38	0.32	0.06	0.70	
95% CI	0.34, 0.47	0.31, 0.44	0.26, 0.38			
Late Stance					p linear	p u-shaped

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pain is the main symptom in hip osteoarthritis (OA) and many patients experience recurrent pain exacerbations. The purpose of this study is to evaluate the association between hip injury and hip pain exacerbations in persons with symptomatic hip OA.

**Methods:** We conducted an internet-based case-crossover study to assess potential risk factors, including hip injury, for hip pain exacerbation. Eligible participants with symptomatic hip OA were followed for 90 days and asked to complete online questionnaires at 10-day intervals (control periods). They also logged on to the study website to complete questionnaires in the episode of a hip pain exacerbation (case periods) defined as an increase of 2 points in pain intensity compared with baseline on numeric rating scale (0-10). Participants were asked whether they had hip injury that limited usual activities (such as falls, sports injuries, etc.) during the last 7 days and whether they experienced any episodes of hip "giving way" in the last 2 days at both control and case periods. The relationship of hip injury and "giving way" to the risk of pain exacerbation was examined using conditional logistic regression.

**Results:** Of 249 patients recruited 133 (53%) and 132 (53%) with both control periods and case periods were included in the analysis of injury and "giving way" respectively. Hip injury during the last 7 days increased the risk of pain exacerbations (odds ratio [OR] 2.74, 95% CI 1.62, 4.62) compared with no injury to the hip. Hip "giving way" during the last 2 days was also associated with an increased risk of hip pain exacerbation (OR 2.50, 95% CI 1.68, 3.73), and showed a significant dose-response relationship between the number of hip "giving way" events and risk of hip pain exacerbations during the last 2 days ( $\geq 6$  vs. 0 episodes; OR 7.86, 95% CI 2.74, 22.55).

**Conclusion:** The findings of this study indicate that hip injury and episodes of hip "giving way" are significantly related to pain exacerbation in persons with symptomatic hip OA. Reducing and avoiding such episodes may decrease the risk of hip pain exacerbations and improve the pain situation in persons with hip OA.

## Tables

Table 1. Association of hip injury and hip pain exacerbation (132 subjects)

Hip injury	Case periods (n=304)	Control periods (n=807)	OR (95% CI)	P-value
No	253 (83%)	760 (94%)	-	-
Yes	51 (17%)	47 (6%)	2.74 (1.62, 4.62)	<0.001

Table 2. Association of hip "giving way" and hip pain exacerbation (133 subjects)

Hip "giving way"	Case periods (n=347)	Control periods (n=905)	OR (95% CI)	P-value
No	288 (83%)	843 (93%)	-	-
Yes	59 (17%)	62 (7%)	2.50 (1.68, 3.73)	<0.001

Table 3. Association of the number of hip "giving way" events and hip pain exacerbations

Number of hip “giving way” events in the past 2 days	Case periods (n=347)	Control periods (n=905)	OR (95% CI)	P-value
0	215 (62%)	718 (79%)	-	<0.001
1	43 (12%)	87 (10%)	1.86 (1.14, 3.04)	
2-5	64 (18%)	92 (10%)	4.53 (2.00, 5.75)	
≥6	25 (7%)	8 (1%)	7.86 (2.74, 22.55)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACRC Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Sensitive and specific blood biomarkers to detect the initial stages of osteoarthritis (OA) and to predict the future development of the disease are not available in clinical routine. Consequently, there is a considerable interest in the identification of new markers. The small non-coding microRNAs (miRs) are endogenous regulators of gene expression by binding to complementary sequence on target messenger RNA transcripts that results in translational repression or target degradation. The remarkable miR stability in biofluids has suggested their utility as non-invasive disease biomarkers. Thus the levels of 19 circulating miRs has been assessed in subjects with and without OA in the OFELY cohort.

### Methods:

The study group for the measurement of serum miR expression included French postmenopausal women belonging to the population-based cohort OFELY (Os des Femmes de LYon, n= 610). Firstly, we randomly selected 43 women with a prevalent knee OA (Kellgren & Lawrence score of 2 and 3; early and intermediate knee OA) with or without OA at others sites (lumbar spine, hip, hand) (age: 68.3 ± 6.6 years, body mass index (BMI): 26.6 ± 4.4 kg/m<sup>2</sup>) and 43 healthy women without OA at any site matched for age and BMI.

Secondly, we randomly selected 23 women with incident knee OA over the next 4 years (age: 68.4 ± 8 years, BMI: 25.2 ± 4 kg/m<sup>2</sup>) and 25 healthy subjects without incident OA matched for age and BMI. We have selected 19 candidate miRs (let-7e-5p; 16-5p; 29a-3p, 29b-3p; 29c-3p; 93-5p; 126-3p; 132-3p; 139-5p; 146a-5p; 184; 186-5p; 195-5p; 199a-3p; 200a-3p; 345-5p; 375; 885-5p; 1299) for real-time PCR analysis on the basis of our previous Next Generation Sequencing study measuring all circulating miRs and on literature data. Total RNA was extracted from 200 µl of serum (RNA isolation biofluids, EXIQON). MiRs were reverse-transcribed and PCR was performed with custom TaqMan array microRNA cards on a QuantStudio 7 flex (Applied Biosystems). The expression levels were

quantified after data normalization using miR-191-5p; 222-3p; 361-5p as endogenous controls and cel-miR-39-3p as qPCR quality control.

## Results:

When considered as a continuous variable, miR-146a-5p was significantly increased in the group of prevalent OA compared with healthy subjects (RQ: relative quantification; median [IQR]: 1.12 [0.73; 1.46] RQ vs 0.85 [0.62; 1.03] RQ,  $p=0.015$  respectively). Using logistic regression analysis, the risk of OA prevalence was significantly increased (odds-ratio [95% CI]: 1.83 [1.21-2.77],  $p=0.004$ ) for each quartile increase in serum miR-146a-5p. Moreover, there was a significant association between baseline miR-186 levels and the risk of incident knee OA for each quartile increase (odds-ratio [95% CI]: 1.71 [1.00-2.95],  $p=0.049$ ).

## Conclusion:

We have shown that miR-146a-5p is increased in women suffering from mild to moderate OA compared to healthy women. Importantly, miR-186 is also increased in those women who will develop radiographic knee OA over the next 4 years, therefore with the potential to detect preclinical knee OA.

# Risk of Disability in Underweight Persons with or at Increased Risk of Knee Osteoarthritis

Nilasha Ghosh, Joan S. Chmiel, Orit Almagor, Karen W. Hayes, Kirsten C. Moisio, Alison H. Chang, Julie Szymaszek and Leena Sharma, Northwestern University, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** US studies have revealed a U-shaped relationship between BMI and poor outcomes (function, mortality); both underweight and overweight/obese persons have greater risk. In knee OA, effects of overweight/obesity have been studied, but the impact of being underweight is unknown. We hypothesized that, in persons with or at higher risk for knee OA, underweight persons are at higher risk for incident and worsening disability.

**Methods:** A cohort study of persons 45-79 yrs with or at higher risk of knee OA, the OAI began ADL/IADL collection at 48m (analysis baseline). 48m BMI was stratified as underweight ( $<20 \text{ kg/m}^2$ ), healthy weight ( $\geq 20$  to  $<25$ ), overweight ( $\geq 25$  to  $<30$ ), or obese ( $\geq 30$ ), and disability levels were: none (no ADL/IADL limitation), mild (only IADL), moderate (1-2 basic ADL), or severe ( $\geq 3$  basic ADL). Incident disability was defined as 96m IADL or basic ADL disability in persons without 48m disability, and worsening disability as 48m-96m level worsening. Logistic regression was used to assess associations between BMI group (vs. healthy weight) and outcomes. Multivariable models included BMI and variables with univariate  $p \leq 0.20$ ; backward selection (removing variables with adjusted  $p > 0.20$ ) was used for final models.

**Results:** Of 2795 persons eligible (57% female, mean age 64.7, BMI 28.5), 754 (27%) developed incident disability. Of 3054 persons (57% female, age 64.8, BMI 28.6), 360 (12%) had worsening disability. Each BMI group had increased odds for both outcomes, not statistically significant for underweight, vs. healthy (Table, Fig). In final models, age, comorbidity, depressive symptoms, knee symptoms, hip pain, ankle pain, and physical activity were associated with both outcomes; sex, with incident disability only; and injury, confidence, and falls with worsening disability only.

**Conclusion:** In persons with or at increased risk for knee OA, being underweight may result in an increased risk for incident and worsening disability. The lack of significance may be due to the small number (60) of underweight persons in the OAI, which was enriched for higher BMI. These findings suggest the importance of targeting a healthy BMI range and identify a subgroup who may be at risk for poor outcome.

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

## Background/Purpose:

The contribution of metabolic factors in the development of OA has not been fully elucidated. The aim of this work is to analyze the influence of metabolic syndrome (MetS) in the rate of radiographic progression of knee osteoarthritis, as well as in the prevalence of radiographic hand OA.

## Methods:

For this work we used data from the Spanish cohort PROCOAC (PROspective Cohort of OsteoArthritis A Coruña). This cohort consists of subjects that visited the Rheumatology consultations at different time points and comprises 984 subjects at baseline including radiographic knee and hip KL grade, radiographic hand OA status (129 of them with an erosive phenotype), demographic and clinical data as well as the necessary information to assess the MetS at baseline, that is, abdominal circumference (in cm) in addition to at least two of the following parameters: triglycerides above 200mg/dL, low HDL (<35 mg/dL), hypertension and glucose blood levels (>110 mg/dL). To assess the severity of the disease, the number of affected joints was coded as 0-1 and 2-3, according to the radiographic information of hands, knees and hips. Appropriate statistical analyses including regression models adjusting for the confounder variables of gender, age and BM, and chi-square contingency tables, were performed with SPSS v24.

## Results:

MetS appeared as a significant risk factor ( $HR=2,651; 95CI:1,224-5,744; p\text{-value}=0.0013$ ) in those OA patients that experienced radiographic knee OA progression over time (any KL increase from  $KL \geq 2$  at baseline) (Figure 1).

MetS is also a risk factor for OA occurrence if BMI is not taken into account ( $HR=1,716; 95CI:1,069-2,754; p\text{-value}=0.025$ ); however, when BMI is considered, the effect of MetS in OA is lost.

MetS was not associated with radiographic hand OA presence ( $HR=1,063; 95CI:0,573-1,976; p\text{-value}=0,847$ ). In relation to each of the components of MetS, only hypertension was borderline statistically significantly associated with radiographic hand OA ( $HR=1,584; 95CI:0,986-2,546; p\text{-value}=0,057$ ). When considered the subgroup of patients with the erosive phenotype, MetS significantly associates with an increased risk ( $HR=1,821; 95CI:1,023-3,241; p\text{-value}=0,042$ )

In terms of severity, MetS associates with an increased number of affected joints ( $OR=1,735; 95\%CI=1,102-2,731; p=0.016$ ).

## Conclusion:

MetS condition the progression of knee osteoarthritis and is also a risk factor for erosive hand OA; however, its impact in the occurrence of the knee OA is dependent of BMI. The possible role played by hypertension in radiographic hand OA requires further investigation

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Veterans have increased predilection for multiple health conditions. We undertook this study to investigate the possible association of participation in active military duty in veterans with osteoarthritis.

Since the year 2000, the United States has been involved in two major military conflicts in Afghanistan and Iraq (Operation Enduring Freedom and Operation Iraqi Freedom). The number of troops that have taken part in these interventions is around 2.5 million. There has also been an increase in deployment for female veterans since 2000, with women comprising of over eleven percent of troops deployed. Veterans have a higher predisposition for several health conditions including arthritis. There are however limited data regarding active military duty and its effects on the risk for developing arthritis.

**Methods:** We analyzed Center for Disease Control and Prevention (CDC) Behavioral Risk Factor Surveillance System (BRFSS) survey data for the years 2000 and 2015 to understand the changes in arthritis prevalence in the veteran population following the two major military conflicts. We compared the prevalence odds ratio for arthritis in the year 2000 versus 2015 amongst male and female veterans as compared to the general population in United States. The data was stratified by sex (Male and Female) and age (18-29, 30-49, 50-69 and over 70) and a weighted analysis was done using Statistical Analysis System (SAS) software.

### Results:

We found that the odds ratio for arthritis in

female veterans for age 18-29 were significantly higher in the year 2015 as compared to the year 2000 (difference in OR=1.54, p=0.008,

95% CI= 2.69 to 0.39). The 2015 odds ratio was also higher in 18-29 male veterans compared to the 2000 odds ratio (difference in OR=0.96, p=0.012, 95% CI= 1.72 to 0.2). The odds ratio for male veterans age 50-69 was also marginally higher as compared to the general population in 2015 (difference in OR=0.4, p= less than 0.001, 95% CI= 0.57 to 0.26). The odds ratios for other age groups for both male and female veterans as compared to the general population between 2000 and 2015 were not significantly different.

**Conclusion:** The prevalence odds ratio for male and female veterans in age 18-29 years have increased significantly from 2000 to 2015 following the two major military interventions.

## **Widespread Regulation of Gene Expression By Glucocorticoids in Chondrocytes from OA Patients As Determined By NGS-Based Genome Wide Expression Analysis**

**Antti Pemmari**, Erja-Leena Paukkeri, Mari Hämäläinen, Tiina Leppänen and Eeva Moilanen, The Immunopharmacology Research Group, Faculty of Medicine and Life Sciences, University of Tampere and Tampere University Hospital, Tampere, Finland, Tampere, Finland

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In osteoarthritis (OA), chondrocytes display marked changes in their gene expression profile. Some of these are thought to be protective [e.g. increased synthesis of extracellular matrix (ECM) components] and some harmful (e.g. secretion of proteolytic enzymes and proinflammatory factors). Glucocorticoids (GCs) can counteract many of those harmful changes. Accordingly, intra-articular GC injections are widely used as a symptomatic treatment for OA. However, there are also concerns about their potentially harmful effects, and their comprehensive effect on chondrocyte phenotype remains poorly understood. We studied the effects of GCs on gene expression in OA chondrocytes with genome wide expression analysis based on next generation sequencing (NGS).

**Methods:** Chondrocytes were isolated from cartilage obtained from ten OA patients undergoing knee replacement surgery. The cells were cultured with or without the GC dexamethasone for 24 h. Total mRNA was isolated and sequenced with Illumina HiSeq2500 at the Institute for Molecular Medicine Finland. Functional analysis was performed against the GO (Gene Ontology) database. We also separately investigated the 54 genes linked to OA in recent genome-wide association (GWAS) studies (Loughlin 2015, Wang et al. 2016), as well as those 19 genes previously found to be differentially expressed in OA affected vs. preserved cartilage in a genome wide expression analysis (the RAAK study, Ramos et al. 2014).

**Results:** In dexamethasone-treated chondrocytes, 896 genes were down- and 685 upregulated in a statistically significant manner with a fold change of more than 2.0. Several genes associated with lipid and glucose metabolism as well as those involved in inflammation were among the most strongly affected genes. In the GO analysis, genes involved in ECM organization, cell proliferation and adhesion, and both collagen catabolism and anabolism were enriched among the significantly affected genes. Of note was the downregulation of several matrix degrading enzymes (e.g. MMP1, MMP13 and ADAMTS1) and pro-inflammatory factors (e.g. COX-2, MCP-1 and TNFSF15) but also cartilage-specific collagens (including COL2A1, COL9A1 and COL11A1). Conversely, several anti-inflammatory (e.g. DUSP1, DUSP4) and antioxidative (e.g. KLF9, FOXO3) genes were upregulated. Notably, 11 (COL11A1, FILIP1L, VEGFA, DIO2, COX-2, IGFBP3, VDR, ADAM12, ASPN, GDF5 and IL16) of the 54 genes linked to OA in GWAS studies were significantly affected by dexamethasone. Of these, IL16 was up- and all others downregulated. Also, two (NGF and COL9A1) of the 19 genes identified to be upregulated in OA vs. normal cartilage in the RAAK study were downregulated by dexamethasone.

**Conclusion:** The results indicate that GCs regulate the expression of a wide range of genes in OA chondrocytes. In addition to clear anti-inflammatory and anticatabolic effects, GCs affect lipid and glucose metabolism in chondrocytes, an observation that might be particularly important in the metabolic phenotype of OA. Further studies are needed to confirm the long-term net effects of these wide-range changes in chondrocyte pathophysiology, as they are induced by a widely used pharmacological treatment.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bone marrow lesions (BMLs) have been consistently associated with the development of osteoarthritis (OA); however the extent to which they are genetically driven by mitochondrial genetic background is unknown. Since specific mtDNA haplogroups have been associated with decreased risk of incident knee OA, the aim of this work was to examine the associations between mtDNA haplogroups and MRI-detected BMLs

**Methods:** Knees that did not develop either incident OA or radiographic progression during 48 months follow-up were identified from 1030 Osteoarthritis Initiative (OAI) subjects. The most common Caucasian mtDNA haplogroups (H, Uk, J, T and Others) were assigned to all participants using the single base extension (SBE) assay. BML measurements from MR images acquired using IW-TSE sequence with sagittal slices in different knee regions were obtained annually between baseline and 24 months using an automated system, and were expressed as % of the bone region. Logistic regression with generalized estimating equations and multinomial logistic regression models were used to evaluate the association between mtDNA haplogroups and i) large BMLs, present at any point between baseline and 24 months and defined as  $\geq 33\%$  of the subregional bone volume, as well as ii) the progression of BMLs at 24 months according to an increase of  $\pm 1\%$  volume between baseline and final visit. Both models were adjusted by confounder variables of gender, age and BMI. Participants with haplogroup H served as the reference group

**Results:** Participants included in this study had a mean age of 62,43 (sd 9,2), with a percentage of females of 54,1%. Haplogroups for the 1030 participants included H (n=419, 40,7%), J (n=88, 8,5%), T (109, 10,6%), Uk (n=236, 22,9%) and the less common haplogroups “others” (n=178, 17,3%).

Knees of participants with haplogroup J had significantly lower risk of large BMLs in lateral femur (OR=0,545;95%CI:0,299–0,996;p=0,048); in contrast, participants with haplogroup T had significantly increased risk of large BMLs in global tibia (OR=1,500;95%CI:1,020–2,206;p=0,039) and lateral plateau (OR=1,525;95%CI:1,003–2,320;p=0,048). No evidence of a protective or risk effect of any other haplogroup in the odds of large BMLs was detected in the rest of the knee compartments.

In terms of BMLs progression, participants with haplogroup J showed a lower risk of BML progression over time and an increased rate of no change in global femur compartment (OR=0,549;95%CI:0,309–0,977;p=0,041); participants with haplogroup T showed an increased rate of BML regression over time in global knee (OR=2,534;95%CI:1,236–5,195;p=0,011) as well as in medial plateau (OR=1,987;95%CI: 1,006–3,925;p=0,048). No other haplogroup was associated with the risk of BML progression for either knee region

**Conclusion:** mtDNA haplogroup J appeared to be OA protective, as it is associated with lower risk of large BMLs in lateral femur as well as a lower rate of BML progression over time in global femur. Interestingly, haplogroup T, despite its association with an increased risk of large BMLs, was significantly associated with BML regression rates in the whole knee. Both haplogroups J and T slow down the progression of BMLs

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The benefits of physical activity in the general population and among persons with knee osteoarthritis (OA) are well-established. However, it remains unclear if inactivity or heavy activity accelerate structural progression of knee OA disease. We tested the hypothesis that objectively measured physical activity is associated with greater risk of radiographic worsening of knee OA.

**Methods:** In Osteoarthritis Initiative (OAI) participants with or at higher risk for knee OA enrolled in an accelerometer substudy at 48m (analysis baseline), physical activity was measured by a uniaxial accelerometer (ActiGraph GT1M). Radiographic progression was defined primarily as any 48m-96m KL grade worsening. All analyses were knee-level; we used multivariable logistic regression with GEE, adjusting for key covariates.

**Results:** 1206 persons [mean age 64 yrs (SD 9), 631 (52%) women, BMI 28 (5), sedentary activity 602 minutes (86), light activity 284 minutes (75), moderate-vigorous activity 20 minutes (20)] contributed 1978 knees (at 48m, 57% KL0, 28% KL1, 10% KL2, 5% KL3) to the analysis sample, of which 267 (14%) had KL worsening. As shown in the Table, average daily accelerometer counts were not associated with worsening, nor was any type of physical activity examined in separate models. When sedentary, light, and moderate-vigorous activity were included in the same model, age, sex, BMI, and pain, but no type of activity, were associated with worsening: sedentary, adjusted OR 1.00, 95% CI 0.98, 1.02; light, adjusted OR 1.01, 95% CI 0.99, 1.04; moderate-vigorous, adjusted OR 1.01, 95% CI 0.93, 1.10. In analyses of the sample with full-limb alignment data, findings were similar and further adjustment for alignment had minimal impact. Inclusion of a quadratic term in these models did not reveal any evidence of a U-shaped relationship.

**Conclusion:** In persons with or at higher risk for knee OA, age, sex, BMI, and pain – but not average daily accelerometer counts or minutes of sedentary, light, or moderate-vigorous activity – were associated with subsequent worsening of KL grade. In this sample, most knees had no or only mild radiographic OA, and time spent in moderate-vigorous activity was relatively low. Whether findings differ in persons with more severe knee OA and/or engaged more frequently in moderate-vigorous activity should be examined in future studies.

## The Relationship between the Number of Prescription Medications and Physical Activity Amongst Patients with or at High Risk for Knee Osteoarthritis

Nivaas Thanoo<sup>1</sup>, Abigail Gilbert<sup>2</sup>, Jing Song<sup>3</sup>, Dorothy D. Dunlop<sup>4</sup> and Rowland W. Chang<sup>5</sup>, <sup>1</sup>Feinberg School of Medicine, Chicago, IL, <sup>2</sup>Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>3</sup>Center for Healthcare Studies, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>4</sup>Inst Hlthcare Studies, Northwestern Univ/ Feinberg, Chicago, IL, <sup>5</sup>Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Physical activity amongst individuals with knee osteoarthritis (KOA) has been linked to improved pain, functional status, and less disability. It is important to understand possible barriers to physical activity within this population in order to minimize less favorable health outcomes associated with low levels of physical activity. One possible risk factor for lower physical activity is taking a large number of prescription medications, the side effects of which may reduce physical activity. This study evaluated the relationship between the number of prescription medications taken and moderate-vigorous physical activity.

**Methods:** Adults with or at high risk for KOA from an Osteoarthritis Initiative (OAI) substudy had physical activity assessed by accelerometer monitoring. We used a hierarchical median quantile regression analysis to determine the relationship between the number of prescription medications taken in the 30-days prior to the visit and the median daily minutes of moderate-vigorous (MV) physical activity. Model 1 of the analysis controlled for demographic factors known to affect physical activity (age, gender, race, BMI), model 2 controlled for model 1 variables and disease confounders (Kellgren and Lawrence grade, WOMAC pain), and model 3 additionally controlled for comorbidity confounders (Charlson comorbidity index and high depressive symptoms defined as Center for Epidemiological Studies Depression Scale <sup>3</sup>16).

**Results:** Valid physical activity data and prescription medication data at the 4-year visit were available for 1889 men and women; mean age 65, 55.5% female, 83.9% white, non-Hispanic. A total of 278 (14.7%) participants reported not taking any prescription medications in the 30 days prior to the visit, 1265 (67%) reported 1-5 prescription medications, and 346 (18.3%) reported 6 or more prescription medications. Controlling for demographic factors, we found a decrease of 0.58 minutes in the median daily moderate-vigorous physical activity per additional prescription medication (95% CI -.87, -.29; p<0.001). This decrease persisted when additionally controlling for disease confounders (0.53 minutes/prescription medication, 95% CI -.83, -.23; p=0.001) and comorbidity confounders (0.52 minutes/prescription medication, 95% CI -.85, -.19; p=0.002).

**Conclusion:** Participants taking more prescription medications had lower levels of moderate-vigorous physical activity independent of OA severity and comorbidities. These results show that polypharmacy might be a risk factor for lower physical activity. Future research should explore the relationship between certain medication classes common to KOA patients (e.g. narcotic analgesics, psychotropics, beta-blockers, statins, antihistamines) and physical activity.

**Session Time:** 9:00AM-11:00AM

**Title:** The Relationship between Self-reported Restless Sleep and Objectively Measured Physical Activity

**Background/Purpose:** Despite many health benefits of physical activity, inactivity is endemic among adults, especially those with knee osteoarthritis (KOA). Attempts to sustain long-term increases in physical activity in adults with KOA show limited success. Poor sleep is a potentially powerful modifiable risk factor but is under-investigated as a determinant of physical activity. Sleep may be a novel target to improve physical activity. However the relationship between sleep and physical activity in individuals with KOA remains unknown. We evaluated if participants with greater self-reported restless sleep were more likely to have decreased physical activity.

**Methods:** The Osteoarthritis Initiative (OAI) enrolled adults with or at high risk for radiographic KOA. Clinical data and physical activity data by accelerometer monitoring were collected at the 4 year follow-up visit. We evaluated weekly minutes of moderate-vigorous activity stratified by responses to the Center for Epidemiological Studies-Depression (CES-D) question on frequency of restless sleep in the past week. Due to skewed distribution, weekly moderate-vigorous physical activity was log-transformed. We repeated the analysis adjusting for potential confounders including age, gender, BMI, KOA severity, Charlson comorbidity score and depressive symptoms (CES-D>16).

**Results:** Complete data were available for 1900 OAI participants. A total of 169 (9%) reported they experienced restless sleep much of the time (3-4 days in the past week), and 132 (7%) reported restless sleep most or all of the time (5-7 days in the past week). Participants who reported 3-4 days and 5-7 days of restless sleep had 11.1% and 23.8% less weekly minutes of moderate-vigorous activity, respectively, compared to participants reporting restless sleep rarely or none of the time. These results were similar when adjusted for potential confounders with 8.4% and 19.1% less moderate-vigorous activity for restless sleep reported 3-4 days and 5-7 days, respectively, compared to those who rarely reported restless sleep (p for trend 0.0330).

**Conclusion:** Participants who reported restless sleep much or most of the time performed less moderate-vigorous physical activity than those who rarely reported restless sleep. Some of this effect might be mediated by depression. Future research could focus on characterizing the mechanisms of how poor sleep might result in less physical activity and the possibility of a bidirectional relationship.

Table. Difference<sup>a</sup> in weekly moderate-vigorous physical activity minutes compared to restless sleep rarely or none of the time

	Rarely/none of the time (<1 day in the past week)	Some of the time (1-2 days in the past week)	Much of the time (3-4 days in the past week)	Most/all of the time (5-7 days in the past week)	p for trend
Average weekly activity minutes	130.2	128.1	122.5	96.6	
Unadjusted model	Reference	-1.4% (-14.7, 11.9)	-11.1% (-34.3, 10.8)	-23.8% (-52.2, -2.2)	0.022
Adjusted <sup>b</sup> model	Reference	2.3% (-8.6, 13.3)	-8.4% (-27.8, 10.2)	-19.1% (-42.9, 0.5)	0.033

<sup>a</sup> Percent difference for each restless sleep category compared to rarely or none of the time.

<sup>b</sup> Adjusted for age, gender, body mass index, Kellgren-Lawrence grade, Charlson comorbidity index, and high depressive symptoms (Center for Epidemiological Studies Depression Scale greater than 16)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many people with knee OA have bone marrow lesions (BMLs). BMLs are related with structural pathology and pain. Some investigators have found an association between strenuous physical activity and increased BML volume, leading to a potential increase in pain. Because of the health benefits of exercise, it is important to determine if physical activity could affect pain

levels in patients who have knee OA. The purpose of this study was to determine if physical activity influences the existing relationship between BMLs and pain.

**Methods:** To determine if exercise has an effect on the relationship between BMLs and pain, we performed an exploratory analysis on a sample of 85 knees with BMLs from the Osteoarthritis Initiative (OAI). To determine the presence of a BML, one reader (AC), used customized software to segment the BML volume (patella, tibiofemoral; intraclass correlation coefficient  $\geq 0.96$ ) on paired baseline and 24-month MRIs. All MRI scans and measurements were assessed for quality with another reader (JD). To measure physical activity, we used the Physical Activity Scale for the Elderly (PASE). The questions on walking, light sport/recreation, moderate sport/recreation, and strenuous sport/recreation of the Physical Activity Scale for the Elderly (PASE) were used to calculate exercise hours per week. To get a more accurate picture of typical physical activity in our sample, we took the average of 0, 12-, and 24-month exercise hours. To measure pain, we used the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale (range 0-20). A change of 2 points was considered clinically meaningful. We assessed two exercise categories: any vs. none. Spearman correlations were calculated. Ordinal logistic regression was used to assess the relationship between change in WOMAC pain (improved, no change, worsened) and exercise category. We adjusted for age, sex, and BMI.

**Results:** The study population was mostly white (81%), female (58%), and had KL grades 2 (38%) or 3 (53%) at baseline. 63 participants (74%) exercised. Of those who exercised, 96.5% walked, 27.1% participated in light recreation, 38.8% participated in moderate recreation, and 49.4% participated in strenuous recreation for at least one time point. There was no significant difference in the change in WOMAC pain between those who did or did not exercise ( $p=0.59$ ) (Table 1). In the group that exercised, there was a weak positive correlation ( $r= 0.27$ ,  $p=0.037$ ) between total BML at baseline and change in WOMAC pain scores. In the group that did not exercise, there was a weak negative correlation ( $r= -0.19$ ,  $p=0.44$ ) between total BML at baseline and change in WOMAC pain score.

**Conclusion:** When adjusted, BMLs are associated with pain, but only among those who exercise. As our population was relatively sedentary, this study may not be generalizable to a population that regularly participates in vigorous exercise.

Table 1. Frequencies and Odds Ratios between Change in WOMAC Pain Score and Exercise Category				
Patient Group^	WOMAC Pain Score Improved by 2 points (%)	No Change in WOMAC pain score (%)	WOMAC Pain Score Worsened by 2 points (%)	Adjusted OR* (CL)
Exercise (n=63)	24	37	40	1.2 (0.8, 1.9)
No Exercise (n=22)	36	32	32	(reference group)
^ All participants had the presence of a BML

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Knee osteoarthritis (OA) is a leading cause of functional limitation and disability in older adults. But why some knee OA patients develop functional limitation but not others, is unclear. Systemic inflammation is a strong risk factor for aging-related muscle impairment which can contribute to functional limitation. Modest elevations in measures of systemic inflammation are present in persons with knee OA. We hypothesized that this inflammation might play a role in contributing to OA-related function limitation. We examined the relation of serum TNF- $\alpha$  level (marker of systemic inflammation) with 20 meter walk time and timed chair stands (measures of physical function) in community-dwelling older adults, with and without knee OA.

**Methods:** We included a subset of participants from the Multicenter Osteoarthritis (MOST) study, a NIH-funded longitudinal cohort of persons with or at risk of knee OA who had assessments of serum TNF- $\alpha$ , knee radiographs, 20m walk time (time to walk 20 meters) and timed chair stands (time to perform chair stands X 5) assessed at baseline visit. Persons with whole knee radiographic OA (ROA, yes/no) were defined by the presence of tibiofemoral (KL grade  $\geq 2$ ) or patellofemoral (osteophytes  $\geq 2$  or joint space narrowing score (JSN)  $\geq 1$  or JSN plus any osteophyte) OA in either or both knees. Persons with symptomatic knee OA (SOA, yes/no) were defined by presence of pain plus ROA in the same knee. To examine the association of serum TNF- $\alpha$  with 20 m walk time and timed chair stands (separate analyses), we performed linear regression, adjusting for age, sex, BMI, physical activity score (PASE) and site, stratified by ROA and SOA status.

**Results:** Among 953 subjects (55% women, mean  $\pm$  SD age  $62 \pm 7.7$ , mean  $\pm$  SD BMI  $30 \pm 5.4$ ), 494 subjects had ROA (52%) and 276 (30%) had SOA at baseline. We found higher serum TNF- $\alpha$  levels were significantly associated with slower 20 m walk time (Std.  $\beta$   $0.15 \pm 0.04$ ) and slower chair stands (Std.  $\beta$   $0.08 \pm 0.04$ ), among those with ROA but not in persons without ROA (walk time Std.  $\beta$   $0.02 \pm 0.05$ ; chair stands Std.  $\beta$   $0.01 \pm 0.05$ ) (**Table**). Similar significant association between higher serum TNF- $\alpha$  level and slower walk time was found in those with SOA but not those without SOA (**Table**). Serum TNF- $\alpha$  was not associated with timed chair stands, irrespective of SOA status (**Table**).

**Conclusion:** In this large cross-sectional study of community-dwelling older adults, a systemic inflammatory marker was significantly associated with measures of physical function in those with knee OA but not in those without knee OA. Future longitudinal studies are warranted to evaluate whether presence of systemic inflammation leads to development of functional limitation in knee OA.

**Table: Cross-sectional association of serum TNF- $\alpha$  with 20 m walk time and timed chair stands by radiographic and symptomatic knee OA status**

	20m Walk Time			5 Chair Stands Time		
	N	Std. $\beta$ $\pm$ SE*	p-value	N	Std. $\beta$ $\pm$ SE*	p-value
<b>Radiographic OA</b>						
Yes	494	$0.15 \pm 0.04$	$<.0001$	471	$0.08 \pm 0.04$	0.05
No	459	$0.02 \pm 0.05$	0.69	459	$0.01 \pm 0.05$	0.77
<b>Symptomatic OA</b>

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inflammation contributes to OA disease pathogenesis. Subsets of knee OA patients with peripheral blood leukocyte (PBL) detected inflammatory gene expression profiles exhibit more rapid radiographic joint space narrowing (JSN). Bone marrow lesions (BMLs) on baseline knee MRI also predict JSN. We investigated whether the combination of the PBL inflammatory transcriptome(s) together with medial BML enhanced the ability of either alone to predict radiographic knee OA progression.

**Methods:** PBL inflammatory gene expression (IL-1, TNF $\alpha$ , COX-2) and 3T knee MRI were assessed in 111 patients with symptomatic medial knee OA and BMI<33. At baseline and 24 months, subjects underwent standardized fixed-flexion knee radiographs, scored for joint space width (JSW) by a musculoskeletal radiologist blinded to subject data; a separate, also blinded radiologist scored MRIs for BMLs using the whole-organ MRI scoring method scoring system. JSN was determined as medial JSW change over the study period. Radiographic progressors were defined by various cut-points of JSN (JSN>0.0mm, >0.2mm, and >0.5mm) and were compared to nonprogressors (JSN  $\leq$ 0.0 mm). Logistic regression model was fit with 10-fold cross validation and repeated 100 times. Models were evaluated by area under the receiver operating characteristic curve (AUC) on test data. P values were obtained from DeLong test comparing models' AUC to 0.5.

**Results:** Progressors by any JSN cut-point had significantly higher baseline medial BML scores (1.42 $\pm$ 2.11, 1.45 $\pm$ 2.13 and 1.78 $\pm$ 2.23 for JSN>0.0mm, >0.2mm, and >0.5mm, respectively; p=0.025, 0.021, and 0.003) than nonprogressors (0.59 $\pm$ 1.14). Baseline medial BML scores distinguished progressors by any level of JSN, from non-progressors in multivariate analyses (Table1; AUC 0.61, p=0.025; AUC 0.61, p=0.023, AUC 0.66, p=0.004, for JSN>0.0mm, >0.2mm, and >0.5mm, respectively). Elevated baseline PBL inflammatory gene expression also predicted JSN at all levels of progression, with COX-2 being the strongest predictor (Table 1). The combination of baseline medial BML scores with PBL inflammatory transcriptome markers, especially that of BML and PBL COX-2 expression (AUC 0.78, p<0.001 for JSN >0.5mm), yielded improved predictive power than any of the individual biomarkers alone (Table 1).

**Conclusion:** The combination of PBL-based inflammatory transcriptome and MRI-based medial BML biomarkers improves the prognostic utility to predict knee OA radiographic progression.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Much of osteoarthritis (OA) research has focused on identifying treatments for late stage disease. However, interventions in early disease may be most effective. Capitalizing on the heritability of knee OA, we assessed the feasibility of using the phenotype of a proband to study risk factors in their offspring. The objectives of this study were: 1) to establish feasibility of deploying such an offspring study within the Osteoarthritis Initiative (OAI) where the proband phenotype is well-characterized, 2) to assess whether this offspring design can detect known risk factors of medial compartment knee OA, and 3) to evaluate exploratory risk factors.

**Methods:** We selected two groups of proband OAI participants from the University of Pittsburgh site: medial tibiofemoral OA group and no OA group. To preferentially include those more likely to have a heritable etiology of their phenotype, we recruited probands with the same OA phenotype in both knees. The case probands had bilateral medial tibiofemoral OA; control probands had no radiographic evidence of OA in either knee. We only included biological offspring who were  $\geq 18$  years old. We approached current OAI participants from the Pittsburgh site who met our eligibility criteria. We developed a privacy-sensitive method of contacting the proband's offspring to invite them to participate. Willing offspring completed an online survey that assessed OA symptoms and diagnoses as well as known and exploratory risk factors. We calculated the percentage of probands with OA in each strata of the risk factors. To see if OA risk factors in offspring are associated with proband OA status, we used logistic regression models conducted with generalized estimating equations to account for the correlation among offspring related to a given proband.

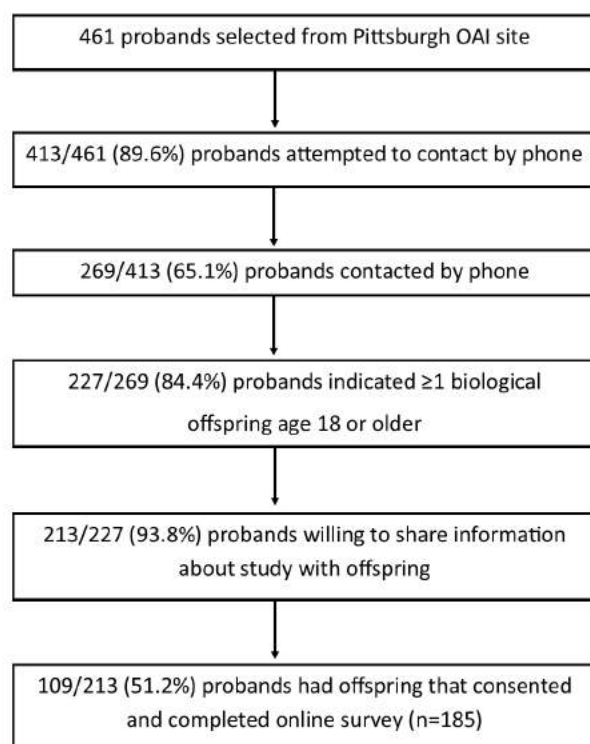

**Results:** We established contact with 269/413 (65.1%) potential probands. Most (227/269, 84.4%) had  $\geq 1$  eligible biological offspring, with 213/227 (93.8%) willing to share information about the study with their offspring. Our online survey was completed by 185 offspring from 109 probands. Offspring age ranged from 21 – 67 years old (mean=42.9), with 64.9% female, 84.3% White/Caucasian, and mean BMI=23.7 kg/m<sup>2</sup>. Median time to complete survey =14.1 minutes.

Table. Associations of risk factors between offspring and proband OA status.

<b>Known OA Risk Factors in the Offspring</b>	<b>% of Probands with OA</b>	<b>p-values</b>
Heberden's Nodes Present	13/15 (87%)	0.03
Heberden's Nodes Absent	92/170 (54%)	
Overweight	19/61 (69%)	0.07
Not Overweight	63/124 (51%)	
Obese	20/28 (72%)	0.1
Not Obese	85/157 (54%)	
Knee Injury	31/51 (61%)	0.5
No Knee Injury	74/134 (55%)	
<b>Exploratory OA Risk Factors in the Offspring</b>		
Regular Cigarette Smoker	24/37 (65%)	0.6
Never Regular Cigarette Smoker	77/141 (55%)	
Diabetes Present	4/7 (57%)	1.0
Diabetes Absent	99/176 (56%)	
Hypertension Present	20/25 (80%)	0.03
Hypertension Absent	84/158 (53%)	
Hyperlipidemia Present	16/27 (59%)	0.8
Hyperlipidemia Absent	88/157 (56%)	

**Conclusion:** Our pilot study establishes feasibility of deploying an offspring study within the OAI using an online survey. Using this design, we detected significant associations between offspring presence of Heberden's nodes and hypertension, and presence of parental OA. Our findings show good proof of concept for performing an offspring study based out of the OAI.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Walking is recommended for those with knee OA (KOA). However, few studies have explored the association between walking and symptomatic OA, and conflicting data exists whether walking is beneficial or harmful to knee structure. Walking is a weight-bearing exercise and chronic mechanical overloading could physically damage knee structures. Alternatively, people who walk are likely to have a lower body mass index (BMI), which is protective of KOA. Therefore, we evaluated the relationship of history of walking with symptomatic KOA in the Osteoarthritis Initiative (OAI).

**Methods:**

This is a cross-sectional study of OAI participants with knee x-rays, symptom assessments, and lifetime physical activity. At the 96-month visit, a modified version of the Lifetime Physical Activity Questionnaire (LPAQ) asked participants about the number of times they walked for exercise from ages 12 – 18, 19 – 34, 35 – 49 and >50 years old. This information was used to create biologically meaningful groups based on walking history. The lowest group were people who did not walk for exercise. The highest group included the top one or two levels of walking. We pooled the number of times people walked from all time periods. PA semi-flexed knee radiographs were obtained at OAI 48-month visit and scored for Kellgren-Lawrence (KL) grade (0-4). Radiographic OA (ROA) was defined as  $KL \geq 2$ . Frequent knee pain within a person required at least one knee have frequent knee pain at the OAI 48-month visit. Symptomatic radiographic OA (SOA) required that at least one knee had both ROA and frequent knee pain. Anyone with a total knee replacement was classified as having SOA. We performed logistic regression with the predictor of groups based walking history over a lifetime and in the specific age ranges. The outcomes were ROA, frequent knee pain, and SOA; adjusted analyses included covariates age, sex, and BMI at the 48-month visit and injury up to the 48-month visit.

**Results:**

2637 participants were included, 44% were male, mean age was 64.3 (8.9) years and BMI was 28.4 (4.9)  $\text{kg/m}^2$  at the 48 month visit. Walking for exercise increased with increasing age. The percentage of obesity by lifetime walker group (never walker to high level walker) was: 41%, 39%, 33%, and 30% respectively. Findings for frequent knee pain and ROA were similar for SOA.

<b>*Adjusted for age, sex, BMI, and prior knee injury.</b>			

## Conclusion:

Our findings suggest walking for exercise at any time in life is not associated with a higher odds of prevalent ROA, knee pain, and SOA later in life. Walking for exercise may be beneficial but this may be obscured due to confounding by indication. Because people self-select whether they walk, they may stop the activity because of knee symptoms. Walking for exercise was more common with increasing age and was inversely associated with obesity. Walking for exercise does not appear detrimental, and may be protective of SOA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Relative local knee periarticular bone mineral density (paBMD) as measured by dual x-ray absorptiometry (DXA) has been associated with static alignment cross-sectionally, but not longitudinally; we postulated that there would be an association. We evaluated the association of paBMD with femur-tibial angle (FTA) within the Osteoarthritis Initiative (OAI).

## Methods:

We performed a longitudinal study of a subgroup of the incidence subcohort of the OAI who had right knee DXA scans from both the 72-month and 96-month visits, generating knee medial:lateral paBMD ratios focused on the tibial plateau. Also, participants had to have radiographs read for FTA at the 72- and 96- month visits (negative value = greater varus) and 48-month readings of Kellgren and Lawrence (KL) grade, where grade  $\geq 2$  was considered as having ROA. Stratified by ROA status, we performed Spearman's correlations of: 72- month paBMD ratio and FTA, as well as the 72- to 96- month change in paBMD ratio and FTA.

**Results:** 400 participants, 54% female, were included with a mean age of 65.0 (8.2) years and BMI of 28.3 (4.9) kg/m<sup>2</sup>.

Among those with no ROA based on the 48 month radiographs, n = 168, mean 72- month paBMD ratio was 1.09 (0.09) and FTA was -5.26 (1.66) (varus). Mean change from 72- to 96- month paBMD ratio was 0.00 (0.05) and FTA was -0.04 (0.83) (varus). Spearman correlations are presented in table 1.

Among those with ROA based on the 48 month radiographs, n = 232, mean 72- month paBMD ratio was 1.12 (0.13) and FTA was -5.43 (2.77) (varus). Mean change from 72- to 96- month paBMD ratio was 0.00 (0.06) and FTA was -0.04 (0.80) (varus). Spearman correlations are presented in table 2.

**Table. Spearman's Correlations of paBMD and Static Alignment**

No ROA				
	paBMD Ratio	FTA	paBMD Ratio Difference	FTA Difference
paBMD Ratio	1.00	-0.22 0.004	-0.016 0.8	0.25 0.001
FTA		1.00	0.08 0.3	0.01 0.9
paBMD Ratio Difference			1.00	-0.05 0.5
FTA Difference				1.00
ROA				
paBMD Ratio	1.00	-0.60 <.0001	-0.11 0.1	0.23 0.0004
FTA		1.00	0.10 0.1	-0.10 0.13
paBMD Ratio Difference			1.00	-0.06 0.4
FTA Difference				1.00
For each cell correlation coefficients are provided with the p-values below.				

**Conclusion:** Baseline paBMD was associated with change in static alignment in those without and with OA. However, baseline static alignment was not associated with change in paBMD and change in paBMD was not associated with change in static alignment. Perhaps this is evidence that change in paBMD precedes altered static alignment in the natural history of OA. These findings support the idea that paBMD changes occur early in the natural history of OA and holds the promise of being a good marker for early disease.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Osteoarthritis (OA) is the most common form of arthritis, caused by a combination of systemic and local factors. Its multi-factorial etiology includes oxidative stress and the overproduction of reactive oxygen species (ROS). Previous researchers tried to investigate the role of ROS pathway to reveal the pathogenesis of OA. Oxidative balance score (OBS), which is based on the summed intake of various pro-oxidants and anti-oxidants, is well known to reflect oxidative stress in an individual. Recent studies have investigated the

associations between OBS and several chronic diseases, including prostate cancer, colorectal cancer, and the risk of cardiovascular disease and end-stage renal diseases. However, the association between OBS and OA has not been studied. This study aimed to investigate the association between OBS and OA and between OBS and quality of life in patients with OA.

### Methods:

Using the Korea National Health and Nutrition Examination Survey (KNHANES) VI (2014–2015) program, OBS was calculated by combining 10 pro- (polyunsaturated fatty acid, omega-6, smoking, alcohol, BMI) and anti-oxidant (carotene, retinol, vitamin C, omega-3, physical activity) factors through baseline nutritional and lifestyle assessment. OBS was divided into quartiles (Q1–Q4), considering the lowest quartile, Q1 (predominance of pro-oxidants), as a reference. Multivariable logistic regression was used to estimate adjusted odds ratios (ORs) for OA and EuroQol five dimensions questionnaire (EQ-5D) in patients with OA after adjusting for demographic factors and comorbidities.

### Results:

Among the 14,930 participants, 296 patients with OA and 1,309 controls were included in the analysis. Patients with OA had lower OBS than that of controls ( $17.04 \pm 0.22$  and  $17.08 \pm 0.12$ , respectively), although there was no statistically significant difference between the groups. Especially, patients with OA had significantly lower anti-oxidant OBS than that of controls ( $p < 0.01$ ). The OR of dietary anti-oxidant OBS was 0.92 (95% confidence interval 0.87–0.97) and that of non-dietary lifestyle anti-oxidant (physical activity) OBS was 0.82 (0.71–0.94). In a logistic regression model to assess the association of OBS with OA, the adjusted OR for OA was 0.95 (0.91–1.00). Moreover, the adjusted OR for higher EQ5D was 1.17 (1.06–1.30) in patients with OA.

### Conclusion:

Higher OBS was associated with a lower risk of OA. Among the OBS items, lower physical activity had the greatest contribution to the risk of OA. In addition, higher OBS was associated with better quality of life in patients with OA.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Hip osteoarthritis (OA) is a major public health concern. It is associated with hip pain, functional decline and possibly increased cardiovascular mortality. The determinants of hip OA, however, are not as well understood as those of other OA sites, such as the knee. Therefore, we sought whether hip geometry, bone mineral density and microarchitecture were associated with hip OA.

### Methods:

We have studied 1537 post-menopausal women from the QUALYOR prospective cohort. At baseline, we measured areal BMD by DXA at the lumbar spine and the hip, volumetric BMD and geometry by hip quantitative computerized tomography (QCT) scan using the Bone Investigational Toolkit (BIT) software, and microarchitecture at the distal radius and tibia by high resolution peripheral quantitative tomography (HRpQCT). We built a hip OA score (CT OA score) with images from the hip CT, based on the depiction of the

four major signs of osteoarthritis: increased density of the subchondral bone, joint space narrowing, osteophytes and subchondral cysts. The severity of each of these four signs was graded as absent, light, moderate or severe (semi-quantitative score ranging from 0 to 3 for each sign thus 0 to 12 in total). Women with and without hip OA were compared by way of analysis of variance and multivariable modeling.

## Results:

The mean age was 65.9 and the mean body mass index was 24.6. Among these 1537 women, 670 had a OA score of 0, 710 between 1 and 4 (mild OA) and 157 greater than 4 (severe OA). Women with severe osteoarthritis had significantly higher areal BMD at the lumbar spine (0.866 vs 0.875,  $p < 0.05$ ) and the femoral neck (0.656 vs 0.671,  $p < 0.005$ ); significantly higher area (30.74 vs 31.95,  $p < 0.001$ ) and volume (85.58 vs 89.90,  $p < 0.001$ ) of the hip and lower trabecular hip BMD (128.1 vs 123,  $p < 0.001$ ). Cortical hip BMD did not differ between women with and without hip OA (964.5 vs 969,  $p = 0.45$ ). The BIT analysis showed higher parameters of bone resistance (CSA with 8.36 vs 8.91, CSMI with 5.68 vs 6.51 and Z polar with 7.66 vs 8.4,  $p < 0.001$ ) at the OA femoral neck, more important trochanter, femoral and global width and hip axis length, and a significantly lower cortical thickness. In multivariable analysis, parameters most strongly related to severe OA were the trabecular and cortical volumes of the femoral neck, in the dominant and non-dominant hip. No difference was observed in peripheral bone microarchitecture between hip OA patients and non OA individuals.

## Conclusion:

Women with hip OA have a bigger femoral neck, suggesting a sizeable role of bone geometry in the pathophysiology of hip OA.

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Neuropathic pain (NP) was accused for increased pain and reduced functional capacity in knee osteoarthritis (KO). Here we aimed to find out the prevalence of neuropathic pain and it's relationship with gender, age, body mass index (BMI), pain, symptom duration and functional status in patients with KO.

### Methods:

713 patients with KO were included in the study from the multicenter national cohort conducted by the Turkish League Against Rheumatism-Osteoarthritis Study Group. Sociodemographic variables, BMI, and duration of symptoms were recorded. Pain severity was measured by visual analog scale (VAS), neuropathic pain was assessed by PainDETECT questionnaire and Western Ontario and McMaster Universities Arthritis Index (WOMAC) questionnaire and timed up and go test were used for functional evaluation, and somatosensorial dysfunction and characteristics of pain (night pain, relief of pain on rest, pain on motion, aggravation of symptoms with cold) were also questioned.

### Results:

The mean age of the patients with KO were  $63.29 \pm 9.53$  and 83.9 % were female, 16.1% were male, mean duration of symptoms was  $80.73 \pm 86.59$  months (1-720 months), and BMI was  $31.5 \pm 5.4$ . NP was found in 20.9 % of the patients and 19.2% of the patients were in the unclear range according to PainDETECT. The age, gender and symptom duration of patients were comparable in patients with or without NP. BMI ( $31.2 \pm 5.4$  vs  $32.0 \pm 5.4$ ,  $p=0.016$ ), pain severity ( $6.35 \pm 0.12$  vs  $6.77 \pm 0.29$ ,  $p=0.004$ ), WOMAC function [31 (3-80) vs 43 (5-106),  $p=0.036$ ] and WOMAC stiffness [3 (0-16) vs 4 (0-8),  $p=0.014$ ] scores, night pain (68.4% vs 31.5%,  $p=0.001$ ) and aggravation of symptoms by cold (70.4% vs 29.5%,  $p=0.032$ ) were higher in KO patients with NP. There was no difference between the WOMAC total, WOMAC pain and timed up and go test scores, somatosensorial dysfunction, relief of pain on rest and pain on motion of the patients with or without NP.

### Conclusion:

BMI and pain severity were higher in KO patients with NP and may probably provoke neuropathic pain which in turn decreases functional capacity. Night pain and aggravation of symptoms with cold may also be related to neuropathic pain.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Knee osteoarthritis (OA) is more common in women than men; however, the biological mechanisms for sex difference in knee OA are not well understood. Bone shape is a strong risk factor for hip OA, and studies have found a relation with knee OA. The purpose of the present study was to describe knee bone shape changes over time and to examine whether sex is associated with change of bone shape.

**Methods:** We used data collected from the NIH-funded Osteoarthritis Initiative (OAI), a cohort of persons aged 45-79 at baseline who either had symptomatic knee OA or were at high risk of it. We selected a random sample of 473 knees with radiographs present at baseline, 2 years and 4 years at follow-up visits regardless of OA status. We outlined distal femur and proximal tibia shape on radiographs at all three time points using Statistical Shape Modeling. Group-based trajectory modeling was employed to identify distinctive patterns of bone shape change for each mode. We examined the association between sex and radiographic OA at baseline with trajectories of each bone shape mode using multivariable polytomous regression model while adjusting for age, BMI, race, and results for the first modes for femur and tibia are presented here.

**Results:** The mean age was 59.9 years ( $\pm 9.3$  SD) for the subjects; the proportion of women was 53.8%. Thirteen modes were derived for proximal tibial shape and for distal femoral shape, accounting for 95.5% of the total variance. In all modes, three distinct trajectory groups were derived with the mean posterior probabilities ranging from 84.3% to 98.8%, indicating excellent model fitting. For the majority of both femoral and tibial modes, the slopes of change were mostly similar within each mode but the intercepts for the 3 trajectory subgroups were different. For femur mode 1, which explained the greatest amount of variance of shape, subgroup mode values decreased slightly over time (see figure); compared with group 1, trajectory subgroup 3 was more likely to include a knee from a woman (OR=28.8, 95% CI: 12.4, 67.1) as was subgroup 2 (OR=4.6, 95% CI: 2.7, 7.9); subgroup 3 was less likely to include knees with OA (OR=0.66; 95% CI 0.56, 0.80), as was subgroup 2 (OR=0.8; 95% CI: 0.7, 0.9). For mode 1 in the tibia, subgroup mode values remained constant over time; compared with group 1, trajectory subgroup 3 was less likely to include women's knees (OR=0.6; 95% CI 0.3, 1.1; NS), as was subgroup 2 (OR=0.5; 95% CI 0.3, 0.9); knees with OA were more likely in group 3 (OR=1.3; 95% CI: 1.3, 1.6), but no difference was observed in trajectory membership between groups 2 and 1 for knees with OA.

**Conclusion:** The shapes of the distal femur and proximal tibia change little over time but do divide into separate trajectory groups largely due to baseline differences that propagate across the years. The trajectory subgroups are associated with both sex and knee OA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In clinical trials, weight loss was associated with improvement in knee osteoarthritis (OA) pain and function up to 18 months of follow up. However, clinical trials are performed under highly controlled conditions, and may not be representative of long-term effects in community settings. The aim of this study was to investigate the effects of healthy weight loss on knee pain and function over long-term follow up in a pragmatic cohort setting.

**Methods:** Participants from the Osteoarthritis Initiative progression cohort with a baseline Kellgren-Lawrence grade  $\geq 2$  in either knee, and baseline BMI  $\geq 25$  were selected. Weight and WOMAC scores were followed for up to 8 years, along with demographic data, depression scores, physical activity indicators, pain medication use, and pain in other joints. Weight loss modality was reported retrospectively at 8 years by participants who lost weight during the study period; subjects who reported unhealthy weight loss were excluded. Linear mixed effects models were used for analyses.

**Results:** Nine hundred and fifty six patients were enrolled. Over 8 years, weight was stable (within 5% margin) in 60% of subjects, 17% of subjects lost  $\geq 5\%$  of weight, and 24% of subjects gained  $\geq 5\%$  of weight. Weight change trends were gradual and linear for both weight loss and gain. Those who lost  $\geq 5\%$  of their weight had improved WOMAC scores over 8 years compared with the weight stable group: -4.2 points in an unadjusted model ( $p=0.006$ ), and -3.9 in a fully adjusted model (adjusted for age, gender, race, depression score, baseline BMI, pain medication use, PASE, and pain in other joints,  $p=0.01$ ). Within the weight loss group, there was no statistically significant difference in WOMAC in  $\geq 10\%$  weight loss vs 5-10% weight loss: -4.8 points in unadjusted model ( $p=0.2$ ) and -4.4 ( $p=0.24$ ) in fully adjusted model.

**Conclusion:** In overweight community adults, healthy, gradual weight loss of  $\geq 5\%$  was associated with improved knee pain and function over 8 years. There was no added benefit for losing  $\geq 10\%$  of weight.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Excessive cartilage degradation is a known characteristic of osteoarthritis (OA), and several methods of quantification of cartilage degradation exist. Biomarkers such as urinary C-telopeptide fragments resulting from inflammatory destruction of collagen type II (uCTX-II) have been shown to be associated with disease severity and pain in OA, yet the tissue-origin of uCTX-II has been disputed.

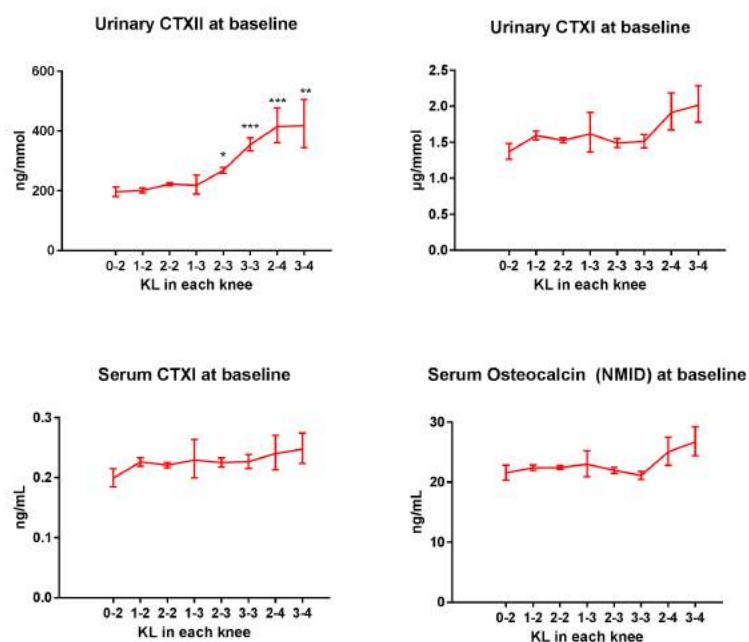

The purpose of this analysis was to investigate the potential association between OA in single and multiple joints at different radiographic stages on circulating levels of uCTX-II and biomarkers of bone resorption and bone formation; serum and urine C-telopeptide of collagen type I, CTX-I, and serum osteocalcin, respectively.

**Methods:** Pooled, pre-treatment baseline data of two phase III randomized clinical trials (NCT00486434 and NCT00704847) in patients with radiographic OA of at least one knee joint were analyzed post-hoc. Key inclusion criteria were knee OA with a Kellgren and Lawrence (KL) score of 2 or 3, and pain of at least 150 mm out of 500 mm using the WOMAC pain subscore, of at least one knee. A subgroup with available urine samples (N=1200) was analyzed for this report. Baseline levels of serum and urine CTX-I, urine CTX-II and serum osteocalcin were analysed using validated enzyme-linked immunosorbent assays and analyzed for associations with combined KL-scores for both knees, and cumulative KL-scores to assess the individual biomarker contribution of joints at different disease stages using multiple pairwise comparisons. KL score of 0 was defined as absence of OA, while all knees with KL scores of  $\geq 1$  were defined as OA joints.

**Results:** Unilateral knee OA was present in 4.1 % of patients in the study. 63.1 % of patients had bilateral, early OA, 10.1 % had bilateral late OA, and 22.0 % had bilateral OA of mixed stages. No patients had unilateral OA with late stage disease. Patients with bilateral, late-stage OA had significantly higher levels of uCTX-II compared to patients with earlier OA. The presence of at least one KL-4 joint appeared to markedly increase the level of CTX-II regardless of the KL-score of the contralateral knee joint. Levels of CTX-I and osteocalcin were not significantly different between KL-grades.

**Conclusion:** These results confirm that levels of uCTX-II are associated with radiographic severity of OA, while biomarkers of bone turnover was not. Multiple joints appear to contribute to uCTX-II levels in an incremental manner according to radiographic severity of individual joints.

Figure 1

Association between geometric mean concentration of uCTX-II, sCTX-I and osteocalcin and Kellgren-Lawrence radiographic stage in the knees of 1200 OA patients. Asterisks indicate statistically significant ( $p < 0.05$ ) difference to the group of subjects with the lowest cumulative KL-score, i.e. a KL-grade of 0 in one knee and 2 in the other ("0-2").

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis (OA) in the thumb base joints (first carpometacarpal [CMC1] and scaphotrapeziotrapezoid [STT]) is highly prevalent and disabling, however much is still unknown about its pathophysiology, and focussed studies on thumb base OA are rarely performed. We took advantage of the newly developed OMERACT thumb base OA MRI scoring system (TOMS)<sup>1</sup> to investigate the prevalence of MRI synovitis and bone marrow lesions (BMLs) in the thumb base, and their association with pain, in addition to radiographic features.

**Methods:** Two readers scored MRIs of the right thumb base for synovitis and BMLs in CMC1 and STT (grade 0-3) in consecutive patients diagnosed by their treating rheumatologist with primary hand OA from the Hand OSTeoArthritis in Secondary care (HOSTAS) study. BMLs were evaluated in proximal and distal joint parts separately, resulting in 0-6 and 0-9 sum scores for CMC1 and STT, respectively. Synovitis and BML scores were both aggregated into dichotomous thumb base scores (0-1 in both joints versus  $\geq 2$  in at least one joint). Trained nurses assessed thumb base tenderness on palpation. Osteophyte presence (according to OARSI atlas) in CMC1 and STT was assessed on radiographs. Associations between MRI synovitis or BMLs and thumb base tenderness were analysed using logistic regression, stratified for absence/presence of osteophytes.

**Results:** 85 of 202 hand OA patients (84% women, mean age 60.1 years, 90% fulfilling ACR criteria) reported thumb base tenderness on palpation. Synovitis was seen in both thumb base joints (CMC1 42%, STT 37%), although prevalence of grade 2-3 synovitis was low in both the CMC1 (16%) and STT (14%). BMLs were present in CMC1 and STT in 54 and 53%, respectively, with 18 and 21% having a sum score of 2-3, and 16 and 7% a sum score  $\geq 4$ . In absence of radiographic osteophytes, presence of synovitis or BMLs in either thumb base joint was not statistically significantly associated with thumb base tenderness (odds ratio (OR) 1.9 [95% confidence interval 0.6-6.4] and 1.5 [0.5-4.3]). However, in absence of severe synovitis or BMLs, radiographic osteophytes and pain were associated, with increasing ORs when synovitis or BMLs were additionally present (Table). Similar results were found for self-reported thumb base pain (not shown).

**Conclusion:** Synovitis and BMLs are present in thumb base OA, although severe synovitis or BMLs were uncommon. Osteophytes seemed more important in predicting thumb base tenderness than synovitis or BMLs alone. Combined presence of osteophytes and synovitis or BMLs had a small additive effect. These findings differ from interphalangeal OA studies, supporting thumb base OA as a distinct subset. It might also explain why trials investigating intra-articular corticosteroids in thumb base OA produced equivocal results.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Associations between obesity and osteoarthritis (OA) in non-weight bearing joints suggest that systemic influences also contribute to OA. Systemically active substances secreted by adipose tissue, including adipokines, are hypothesized to

play a role in OA. We examined whether two adipokines, leptin and adiponectin, mediate the association between body mass index (BMI) and hand and knee OA.

**Methods:** Participants of a cross-sectional population-based study completed questionnaires and underwent standardized physical examination of hands and knees to define OA according to clinical ACR criteria. Fasting serum leptin and adiponectin were measured with immunoassays. Potential mediation was investigated using the Baron and Kenny framework. Four assumptions were investigated: associations between (1) BMI and OA (pathway *C*), (2) BMI and adipokines (pathway *A*), (3) adipokines and OA (pathway *B*), and (4) attenuation of the association between BMI and OA after including adipokines (pathway *C'*). No exposure-mediator interaction and mediator-outcome confounding was assumed. Assumptions were investigated using logistic and linear regression analyses as appropriate. Odds Ratios (ORs) were calculated per standard deviation (SD) in BMI, and per 10 and 5 units in leptin and adiponectin. Percentage mediation with 95% confidence intervals (CIs) was estimated when all four assumptions were fulfilled, using causal mediation analyses in Stata (*medeff*). Models were adjusted for age, ethnicity and education, and stratified by sex.

**Results:** In 6462 participants (56% women, median age 56 years (range 45-65), mean BMI 26.3 kg/m<sup>2</sup>), prevalence of hand OA, knee OA and combined hand and knee OA were 8%, 10% and 4%, respectively. Median leptin and adiponectin concentrations were 7.1 ug/L (range 0.9-60.9) and 6.0 mg/L (0.5-23.7) in men, and 19.1 ug/L (0.5-262.0) and 10.5 mg/L (0.5-98.6) in women. BMI was positively associated with OA presence and serum leptin in both men and women (Table). A negative association was observed between BMI and serum adiponectin (-0.73 mg/L per SD BMI, 95% CI -0.55;-0.91). Leptin was positively associated with most OA types, except knee OA in men. Leptin partially mediated the association of BMI with hand OA in men (9% mediation, 95% CI 5;17) and women (30%, 13;198), and the association of BMI with knee OA in women (15%, 12;21). Similar analyses for adiponectin revealed a negative association of adiponectin with hand OA in men and partial mediation of the association of BMI with hand OA in men (19%, 12;37), whereas mediation was absent in other subgroups.

**Conclusion:** Leptin partially mediated the association of BMI and hand OA in both men and women, as did adiponectin in men. Moreover, mediation by leptin for the association of BMI and knee OA was demonstrated in women. These findings suggest that systemic mediators contribute to hand OA, and to a lesser extent to knee OA.

<b>Table.</b> Associations of BMI with leptin and different types of OA (OR, 95% CI)

Kloppenburg<sup>1,4</sup>, <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Rheumatology, Uludag University Medical Faculty, Bursa, Turkey, <sup>3</sup>Radiology, Leiden University Medical Center, Leiden, Netherlands, <sup>4</sup>Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis (OA) in the first carpometacarpal (CMC1) joint in the thumb base is frequent and has a large contribution in hand pain and disability. Previous ultrasonography (US) studies of hand OA have focussed on interphalangeal joints, showing inflammatory features that associate with clinical signs and symptoms. Until now, US studies specifically addressing the CMC1 joint have not been performed. We investigated the associations between inflammatory features, structural damage and pain in CMC1 OA.

**Methods:** Cross-sectional data of 87 hand OA patients according to ACR criteria who participated in the EChography in Hand OA (n=63) and the Etanercept in Hand OA (n=24) study at the Leiden University Medical Center were used in this analysis. Both CMC1 joints were assessed with US for synovial thickening, effusion and power Doppler signal (PDS) on a 0-3 scale by experienced ultrasonographers. Presence of pain upon palpation of the thumb base was assessed by trained research nurses on the same day as the US. Hand radiographs were scored blinded for clinical and US features, according to the Osteoarthritis Research Society International atlas for osteophytes (0-3), joint space narrowing (JSN, 0-3), sclerosis (0-1) and malalignment (0-1) in the CMC1 joint. Risk ratios (RRs) with 95% confidence intervals (CIs) were calculated using generalized estimating equations to investigate associations between US or radiographic features and thumb base pain on joint level.

**Results:** Of 87 patients (mean age 60.3 years, 82% women, mean BMI 27.2 kg/m<sup>2</sup>) 174 CMC1 joints were assessed, of which 54 (31%) were painful. The US features synovial thickening, effusion and PDS were found in 26%, 33% and 25% of the joints, respectively. Radiographic features were present in 55% (osteophytes), 79% (JSN), 20% (sclerosis) and 12% (malalignment) of the joints. No associations were seen between inflammatory US features and pain upon palpation of the thumb base (Table). However, osteophytes and sclerosis were associated with more pain (RR 2.5 [95% CI 1.4 to 4.6] for osteophytes grade 3 versus no osteophytes, and RR 2.0 [95% CI 1.3 to 3.2] for presence of sclerosis). Other radiographic features (JSN, malalignment) showed a trend for increased risk of pain on palpation, and for osteophytes and JSN a dose-response relation was apparent.

**Conclusion:** Radiographic features, especially osteophytes and JSN, were prevalent and more frequently present than US inflammatory features in the CMC1 joints of hand OA patients. In contrast to what is known from studies in interphalangeal joints, the presence of inflammatory US features was not associated with pain in the thumb base, but structural damage was. These results suggest differences in aetiology of pain in thumb base compared to interphalangeal OA, with a larger role for structural damage in thumb base OA.

## Investigation of Self-Reported Painful Joint Count As an Outcome Measure in Hand Osteoarthritis

F.P.B. Kroon<sup>1</sup>, J.L. van der Plas<sup>1</sup>, S. van Beest<sup>1</sup>, W. Damman<sup>1</sup> and M. Kloppenburg<sup>1,2</sup>, <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hand osteoarthritis (OA) research is in need of disease-specific validated instruments to measure patient-reported outcomes. Self-reported painful joint count (PJC) could be useful to assess pain, including information about the distribution of tender joints, while being less time-consuming than assessor-reported PJC. We investigated metric properties of self-reported PJC compared to assessor-reported PJC to measure pain.

**Methods:** Symptomatic hand OA patients from the Hand OSTeoArthritis in Secondary care (HOSTAS) study marked which joints were painful on standardized hand diagrams. Pain upon palpation was scored on similar diagrams by trained nurses, who were unaware of patients' scores. Self- and assessor-reported PJCs were calculated as the sum of painful joints of both hands (range 0-30). Patients also rated pain on visual analogue scale and completed Australian/Canadian Hand Osteoarthritis index pain subscale, Short Form-36 Mental/Physical Component Summary scales, and Hospital Anxiety and Depression Scale. Radiographs were scored according to Kellgren-Lawrence. MRIs of the right distal and proximal interphalangeal joints (DIPs/PIPs) were evaluated for bone marrow lesions and synovitis. Validity was investigated by assessing correlations between self- and assessor-reported PJC, and of both PJCs with other outcome measures. Absolute agreement between PJCs on joint level, and patient level intra-class correlation coefficients (ICCs) were calculated.

**Results:** Of 524 hand OA patients (86% women, mean age 61, 90% fulfilling ACR criteria), 506 (96.9%) reported <sup>3</sup>1 painful joint (median PJC 8 [interquartile range (IQR) 4-13]), while nurses reported <sup>3</sup>1 painful joint in 426 (81.3%) patients (PJC 3 [1-7]). Patients and assessors both reported pain most often in DIP 2-3, PIP 2-3 and the thumb base, and least often in metacarpophalangeal joints (MCPs) 2-5. Correlation between self- and assessor-reported PJC was 0.38. Correlations of both PJCs with other measures were comparable, ranging from 0.11 to 0.37 (Table). Absolute agreement was highest in MCPs 2-5 and lowest for thumb base, DIP 2-3 and PIP 2-3 (range 61%-89%). ICC between PJCs was 0.28 (95% confidence interval 0.08-0.14).

**Conclusion:** Hand OA patients reported more painful joints than assessors. Self-reported PJC correlated weakly with assessor-reported PJC, and other instruments measuring pain and physical health. Divergent correlations with mental health and imaging scores were even lower. Agreement between patients and assessors was highest in joints with low prevalence of pain, but overall agreement was low. Despite apparent advantages, these results suggest that self-reported and assessor-reported PJCs cannot be used interchangeably, and further study of PJC as an outcome measure in hand OA is warranted.

**Table.** Correlation coefficients for painful joint counts (PJC) and selected clinical and imaging outcomes.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are two major needs in clinical DMOAD development: Identifying a population with an active and progressive disease to demonstrate significant improvements by an efficacious intervention; Phenotyping patients and linking them to a corresponding treatment mode-of-action (e.g. anti-inflammatory). CRPM is a metabolite of CRP. It is released from the inflamed tissue when CRP is degraded by proteases such as MMPs. The purpose of this study was to translate the use of the blood-based marker CRPM to OA, from rheumatoid arthritis (RA), where it has been extensively tested. Furthermore, to test whether it is predictive of radiographic progression in OA.

**Methods:** The placebo arms of two phase III OA trial (NCT00486434/NCT00704847), a phase III RA study (the LITHE study, N=490), which included patients with active, moderate-severe RA (NCT00106535), and in an early RA cohort (N=92) were used.

Subjects with symptomatic and radiographic knee OA: WOMAC pain  $\geq 150$ mm and/or WOMAC function  $\geq 510$ mm, and KL grade 2 or 3. KLG were scored for both knees at baseline and year 2 (Y2). Serum CRPM and CRP were measured at baseline. The association between serum CRPM levels and disease activity score (DAS28) and CRP was investigated by Spearman's correlations. Quartile ranges of CRPM in the early RA cohort were used to define the cut-off between inflammatory OA and non-inflammatory OA. OA knees were divided into cases and controls based on a terminology proposed by the FNIH-OAI consortium; knees with KLG $\geq 2$  at BL were excluded, and incidence OA at Y2 was defined KLG $\geq 2$ . Logistic regression was used to compare cases and controls.

**Results:** There was a significant correlation between disease activity measures and CRPM in both RA studies. Seventy-five percent of the LITHE patients had high or very high levels of CRPM at BL, which was changed to a pattern similar to early RA after treatment (table). Mean CRPM levels were significantly lower in OA (8.5 [8.3-8.8]) compared to the RA patients (15.6 [9.5-21.6]); however, a significant subset of OA patients (41%-31% in SMC2301/02) had CRPM levels  $\geq 9$ ng/mL, as 75% of patients with early RA. Patients with BL or Y2 CRPM levels  $\geq 9$ ng/mL were more likely to develop knee OA than patients with low level of CRPM. Overall, moderate to very high levels of CRPM at BL and Y2 were predictive of incidence OA with odds ratio of 4.6 [1.2-17] and 2.5 [1.2-4.8].

**Conclusion:** CRPM is associated with disease activity and modulated in response to anti-inflammatory treatment in RA. A subset of OA patients, up to 41%, appear to have tissue inflammation comparable to that of RA, reflected by the level of CRPM. Furthermore, high CRPM levels was prognostic of incident knee OA.

## “Generalized Osteoarthritis”: Update to a Systematic Review

Terese R. Gullo<sup>1,2</sup> and Amanda Nelson<sup>3</sup>, <sup>1</sup>Thurston Arthritis Research Center, Chapel Hill, NC, <sup>2</sup>Ohio State University College of Medicine, Columbus, OH, <sup>3</sup>Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To perform a systematic review of the definitions of *generalized osteoarthritis* (GOA). An initial systematic review of the literature for GOA was published in 2014 (PMID 24461078); this review is an update to the definitions analyzed in the original work.

**Methods:** We performed a systematic review in Medline using the terms osteoarthritis, generalized, polyarticular, multiple joint, multi-joint, and others to obtain articles related to GOA, following PRISMA guidelines. The search was performed 4/18/17 by a professional librarian. The initial searches produced 216 articles for title and abstract review (performed by AEN and TRG), after which 75 underwent full text review (AEN and TRG). Of these, 39, along with 3 identified through bibliographic review, were included for data extraction (TRG) based on pre-specified criteria including the requirement for a clearly stated definition of OA (clinical, radiographic, or symptomatic) assessed at more than one body site.

**Results:** In the 42 included articles, 29 large cohorts (n~56,000) were represented along with 7 clinical series (n~28,000), 1 systematic review (n=79 studies) and 2 meta-analyses (n~980,000) across 14 countries and 5 years (2012-2017). The sites assessed, and OA definitions at each site, varied but most often included the hands, knees and hips. Five of the 42 studies explicitly stated a definition for

GOA, and 1 gave an implicit definition. No two of these definitions were the same, however all required a minimal number of joints affected without regard to body region (Table). No definitions contained a supporting rationale. Estimates of the prevalence of GOA in these studies ranged from 7-13%.

Although the remaining 36 articles did not provide a definition for GOA, 11 studies did collect data for OA disease characteristics in multiple joints within the individual. For instance, one study tallied the number of painful joint regions to assess the extent of disabling OA at the *person level* (as opposed to the regional level). Another study listed *Clinical OA- number of sites* as a categorical variable. Finally, in at least 7 articles the authors used alternate terms to denote multiple joint involvement—among these *polyarticular OA* and *multijoint OA*.

**Conclusion:** As in 2014, when the initial systematic review was conducted, GOA remains a commonly used term in the literature despite its lack of a clear or widely agreed upon definition. Most studies that discuss GOA do not define it, and for those that do, still no consensus has been reached. Alternate terms have been used, such as multijoint OA, to describe symptoms and/or radiographic features manifested in more than 1 joint in the individual. However, the use of these terms has yet to improve precision in the definition of GOA. It remains appropriate for individual studies to clearly define any terms used to designate OA of multiple joints or joint groups.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster II: Observational and Epidemiological Studies

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Currently there are a large number of postulated predictors for OA progression, proposed on the basis of relatively small studies (100’s), and measurement approaches involving large error margins. Supervised machine learning techniques, allows the study of key pathologies without prior assumptions, and accurate quantified segmentation. Our aim was to evaluate predictors of cartilage loss in the entire OAI dataset.

## Methods:

Automated cartilage segmentation was assessed for repeatability and accuracy and then applied to all knees from the OAI with baseline, 1 and 2-year images. Shape models were used to measure cartilage thickness in a consistent anatomical region of the medial tibiofemoral joint.

Multilevel modelling was used to consider the effects of previous postulated covariates at knee-level and subject-level at baseline and in longitudinal change. Gender, KL grade, race, knee alignment, height and weight, age, pain, physical activity, NSAID use, previous surgery, smoking and systolic blood pressure were used as covariates.

## Results:

The segmentation method showed excellent accuracy; miss-n-out validation in a training set of 287 knees with varying radiographic OA, showed a mean point-to-surface accuracy of 0.12 mm, mean 95% error of 0.37mm (less than one voxel edge). 9,254 knees were included; mean age was 61.2 (SD 9.2); 58.5% were female. 24.8% used NSAIDs, 47.2% were smokers, 22.7% had previous surgery.

Gender and KL grade explained almost all the variability in cartilage thickness at baseline; for example, the adjusted pseudo- $r^2$  of femur and tibia models using only gender and KL grade were 38% and 40%, the full models were 40% and 43%, coefficients are provided in Table 1. A similar pattern was found in longitudinal analysis (Table 2); gender and KL grade accounted for almost all the variability in change in thickness.

## Conclusion:

This is the first study to characterise the relationship of cartilage thickness, and its change, using a very large dataset. Two covariates explained almost all the variance in thickness: gender and radiographic disease, previously described factors such as weight and alignment (nor NSAIDs and smoking) had surprisingly little effect. This changes our concept of osteoarthritis progression, and potential interventions.

## Effect of Single 6 MI Intraarticular Injection of Hylan G-F 20 in Patients with Knee Osteoarthritis: Results of a Single Centre Study

SUNIL KUMAR PANDEY<sup>1</sup> and SAT PAL SINGH<sup>2</sup>, <sup>1</sup>ORTHOPEDIC DEPARTMENT, SAFDARJUNG HOSPITAL, VMMC, NEW DELHI, NEW DELHI, India, <sup>2</sup>DEPARTMENT OF MEDICINE, SAFDARJUNG HOSPITAL, VMMC, NEW DELHI, NEW DELHI, India

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Osteoarthritis – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the effect of single 6ml intraarticular injection of hylan G-F 20 in patients with knee osteoarthritis.

**Author:** Dr. Pandey Sunil Kumar\*, Dr. Singh Sat Pal\*

\*Safdarjung hospital, New Delhi

**Objective:** To evaluate efficacy and effect on analgesic requirement of 6 ml single injection of hylan G-F 20 in patients with primary knee osteoarthritis

**Methods:** In this prospective study, adult patients with primary knee osteoarthritis (grade II to IV) were treated with 6 ml single intra-articular injection of hylan G-F 20. Patients were followed at 6 and 12 months. Difference in WOMAC score from baseline to 6 and 12 months was evaluated by paired “t” test. Numbers and percentages of patients requiring analgesics on daily basis were recorded at all visits.

**Results:** A total of 352 patients [male 113 (32.10%); female 239 ((67.90%)] [grade II 197(55.97%), grade III 119 (33.81%) and grade IV 36 (10.23%)] with mean age of 59.10 (4.39) years and mean body mass index 27.20 (3.81) kg/m<sup>2</sup> were included in the study. Mean weight and height of the study participants was 68.11 (7.40) kg and 159 (10) cm respectively. One hundred patients (28.41%) patients had varus deformity. Twenty five (7.10%) and 14 (3.98%) patients had effusion in the right and left knee respectively. The WOMAC score from reduced from 64.44(16.89) at baseline to 34.00(10.31) at 6 month and 36 (11.65) at 12 months respectively. The difference in the WOMAC score from baseline to 6 months and 12 months was statistically significant (P<0.001 for both). Number of patients requiring analgesics daily reduced from 28(7.95%)at baseline to 2(0.57%) at 6 months and 3(0.85%) at 12 months.

**Conclusion:** Single 6 ml injection of hylan G-F was effective and well tolerated in patients with knee osteoarthritis. Hylan G-F 20 also reduced the requirement of analgesics.

**Key words:** Efficacy, hylan G-F 20, knee osteoarthritis

## **Are Adults with Arthritis Advised to Exercise By Their Health Care Providers? National Health Interview Survey, 2002 and 2014**

**Jennifer M. Hootman**<sup>1</sup>, Louise Murphy<sup>2</sup>, Michael Boring<sup>3</sup> and Teresa J. Brady<sup>3</sup>, <sup>1</sup>Centers for Disease Control and Prevention, Kennesaw, GA, <sup>2</sup>Division of Population Health, Centers for Disease Control and Prevention, Atlanta, GA, <sup>3</sup>Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Osteoarthritis – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Most published clinical practice guidelines for the management of osteoarthritis recommend exercise as a primary self-management strategy. Despite this, less than one-third of primary care physicians provide exercise advice during office visits. This study's purpose was, for 2002 and 2014, to: 1) estimate percentage of US adults with arthritis whose health care provider (HCP) advised them to exercise to manage their arthritis, and 2) describe sociodemographic and health-related subgroups with low prevalence of HCP exercise advice.

### **Methods:**

The National Health Interview Survey (NHIS), is an ongoing survey of the civilian, non-institutionalized population and gathers data on a variety of health topics. We analyzed 2002 and 2014 data (sample sizes = 31,044 and 36,697, respectively). Doctor-diagnosed arthritis was defined as a ‘yes’ to: “Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus or fibromyalgia?” HCP advice for exercise was defined as a ‘yes’ to “Has a doctor or other health professional EVER suggested physical activity or exercise to help your arthritis or joint symptoms?” Age-standardized prevalence (%) and 95% confidence intervals (CI) of HCP advice for exercise was calculated overall and by sociodemographic characteristics (age, sex, race/ethnicity, and education) and health-related characteristics (arthritis-related activity limitation (AAAL), self-rated health (excellent/very good, good, fair/poor), body mass index (BMI, <25.0, 25.0-<30 and 30.0+), smoking status (current, former, never), physical activity level (inactive, insufficient, meets recommendations) and having a primary care provider (yes, no). All analyses

accounted for NHIS' complex survey design. Prevalence of HCP advice for exercise was considered low if <50% in 2002 and <60% in 2014.

## Results:

In 2002 and 2014, age-standardized prevalence of HCP advice for exercise among adults with arthritis was 51.9% (CI 49.9-53.8%) and 61.0% (CI 58.6-63.4%), respectively (a 17.5% increase). In 2002, groups with low age-standardized prevalence of HCP advice for exercise were: men; Non-Hispanic Others; those with less than a high school or high school/GED education; no AAAL; Excellent/very good health; those who were overweight or obese; current smokers; physically inactive; and had no primary care provider. In 2014, groups with low age-standardized prevalence of HCP advice for exercise were the same as in 2002 with the addition of those age 18-44 year old age. In 2002 and 2014, the prevalence of HCP for exercise among adults with arthritis who were physically inactive was 47.2% (CI 44.0-50.4%) and 56.7% (CI 52.3-61.0%), respectively (a 20% increase).

## Conclusion:

While prevalence rates of HCP advice for exercise have increased over more than a decade, there are still groups with high need that have persistently low prevalence. Incorporating prompts into electronic medical records and written exercise prescriptions are potential strategies that may lead to increased prevalence of HCP advice for exercise.

# Combined Impacts of Lifestyle Factors on Knee Osteoarthritis in the Osteoarthritis Initiative

**Zhaoli (Joy) Dai**<sup>1</sup>, Carrie Brown<sup>2</sup>, Yuqing Zhang<sup>3</sup> and David T. Felson<sup>4</sup>, <sup>1</sup>Boston University School of Medicine, Boston, MA, <sup>2</sup>Boston University School of Public Health, Boston, MA, <sup>3</sup>School Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>4</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Osteoarthritis – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Body mass index (BMI), healthy diet or components, physical activity, and tobacco smoking have been examined independently with risk of knee osteoarthritis (OA). Sleep quality has been shown to be related to chronic pain but its relation to knee OA is unclear. In this study, we evaluated the combined effects of lifestyle factors with or without BMI on risk of knee OA.

**Methods:** We used data from the Osteoarthritis Initiative (OAI), a prospective, multicenter study of 4,796 U.S. men (41.5%) and women [mean (SD) age: 61.2 (9.2) y and BMI: 28.6 (4.8) kg/m<sup>2</sup>] with or at risk of knee OA. Lifestyle factors assessed at baseline of the study including overall diet (assessed by Dietary Approaches to Stop Hypertension, DASH), physical activity (Physical Activity Scale for the Elderly, PASE), tobacco smoking (never, former and current smokers), and sleep quality (frequency of restless sleep in the Center for Epidemiologic Studies Depression Scale, CESD), and BMI (kg/m<sup>2</sup>) were examined separately for their relationship with risk of incident symptomatic (SxOA) and radiographic (ROA) knee OA. Because physical activity did not show a consistent relationship with knee OA, each participant was scored on all factors except PASE from least healthy (0 point) to healthiest (1 point) for each factor with a total score of 0 (least healthy) to 3 (healthiest) excluding BMI in the composite or a total score of 0 (least healthy) to 4 (healthiest) including BMI (see Table 1). Incident ROA was defined as a new onset of Kellgren and Lawrence grade  $\geq 2$  and incident SxOA was defined as new cases of both ROA and a painful knee on most days in past month. We applied Generalized Estimating Equations to account for correlations of both knees in each person in multivariable regression models to assess the association between the lifestyle composite and risk of knee OA using 0 (least healthy) as the referent group.

**Results:** Up to 96 months in OAI, we identified 1340 knees with incident SxOA among 7662 knees and 625 knees with incident ROA among 5861 knees after excluding knees with missing values of OA status or knees with prevalent OA. When BMI was excluded in the composite, a higher score was associated with a lower risk of SxOA (p-trend<0.0001), but no association was found with ROA. When BMI was included in the composite, there was a significant inverse relationship with risks of SxOA and ROA (p-trend<0.0001) (see Table 2).

**Conclusion:** Data from the OAI suggested that persons who lived a healthy lifestyle independent of BMI and physical activity had a lower risk of symptomatic knee OA, but the combined impacts of diet, sleep and tobacco smoking was not related to risk of radiographic knee OA.

Table 1. Lifestyle factors at baseline and their score criteria in the Osteoarthritis Initiative			
Lifestyle factor	Score	Interpretation of score	Percentage (%)
Sleep	0	Restless sleep at least 1 day/week in CESD	58.7
	1	Restless sleep <1 day/week in CESD	
Smoking tobacco	0	Former or current smokers	21.0
	1	Never smokers	
Diet quality-DASH	0	Lower 75%	75.0
	1	Upper 25%	
BMI	0	$\geq 25$ (kg/m <sup>2</sup> )	76.2
	1	<25 and $\geq 18.5$ (kg/m <sup>2</sup> )

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Osteoarthritis – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Quadriceps weakness is associated with functional limitations and a target in the treatment of knee osteoarthritis (OA). There are limited data on the effect of modest strengthening on improvements in function. Our objective was to evaluate concurrent changes in quadriceps strength and physical function over 5 years.

**Methods:** We examined subjects in the Multicenter Osteoarthritis (MOST) study who had knee extensor strength measured using an isokinetic dynamometer at 60°/sec at baseline and 60-month visits. We excluded those with knee replacement after baseline, and those whose values at baseline, at 60 months or in change from baseline were in the most extreme 1%.

Based on studies using 15% change in a person's strength as a clinically important cutoff (ArchPMR 88:626, 2007), we created a 3-category variable defined by whether, at 60 months, strength increased  $\geq 15\%$ , decreased  $\geq 15\%$ , or remained within 15% of baseline. Sensitivity analyses assessed 20% and 30% change in strength.

Physical function was measured with the Five-Times Sit-to-Stand-Test, 20-Meter Walk Test, and WOMAC physical function score. Generalized linear models were used to evaluate if a 15% change in strength was associated with a change in physical function over 60 months. Analyses were stratified by sex and adjusted for baseline age and weight. Based on cross-sectional analyses in MOST which suggested a threshold of strength for function in women, we stratified analyses at 56Nm at baseline to determine whether associations differed in weaker vs. stronger women.

**Results:** Of 1534 study participants (60.6% women; mean age 62 years, mean BMI 30) 44% of women and 43% of men had Kellgren-Lawrence grades  $\geq 2$ . 89% had a walking speed of  $\geq 1$  m/s. Mean quadriceps strength in women (68 $\pm$ 23Nm) was lower than in men (124 $\pm$ 38Nm). 22% of men and 30% of women increased strength at least 15% at 60 months; 31% of men and 23% of women decreased strength at least 15%. Decreases of  $\geq 15\%$  strength were associated with slower walking and chair stand times and worse WOMAC scores.

Compared with women whose strength did not change by at least 15%, among weaker women ( $<56$  Nm) at baseline (see table), a 15% increase in strength was associated with 1.0 second faster chair stands time, but there was no effect on 20-meter walking time or WOMAC scores. In stronger women ( $>56$  Nm), a 15% increase in strength was associated with faster chair stands time of 0.6 seconds ( $p=0.06$ ), but little improvement in walk time or WOMAC scores. A 15% increase in strength had no effect in men.

Sensitivity analyses of 20% and 30% change in strength showed similar results.

**Conclusion:** An increase in measured strength was associated with improved chair stand performance in women, but not improved walk time or self-reported functional limitations. Increase in strength was not associated with change in physical function in men. Modest improvements in strength may not affect physical function.

Table 1. Change in 20-meter walk time, chair-stands time, and WOMAC Scores, stratified by strength, in women											
Women		Analysis Of Maximum Likelihood Parameter Estimates									
Weaker (n=295) Baseline strength <= 56Nm		Mean Change in 20-meter walk time (seconds)		Mean Change in chair-stands time (seconds)		Mean Change in WOMAC Score "going up stairs"		Mean Change in WOMAC Score "rising from chair"		Mean Change in WOMAC Score "getting on or off toilet"	
Parameter	Estimate Wald 95% CI	p-value	Estimate Wald 95% CI	p-value	Estimate Wald 95% CI n=231	p-value	Estimate Wald 95% CI n=228	p-value	Estimate Wald 95% CI n=179	p-value	
Change in strength Decrease<=15%	1.2(0.1-2.3)	0.03	0.8(-0.6-2.2)	0.28	0.3(-0.1-0.7)	0.18	0.5(0.1-0.9)	0.03	0.3(-0.2-0.7)	0.24	
Increase>=15%	0.1(-0.6-0.9)	0.73	-1.0(-2.0-0.0)	0.04	0.0(-0.3-0.4)	0.83	-0.1(-0.4-0.2)	0.66	-0.2(-0.5-0.1)	0.23	
No change (<15% change)	0	.	0	.	0	.	0	.	0	.	
Stronger (n=630) Baseline strength > 56Nm						n=383		n=365		n=250	
Change in strength Decrease<=15%	0.9(0.4-1.4)	<0.01	0.9(0.4-1.5)	0.01	0.3(0.1-0.6)	0.01	0.3(0.1-0.5)	<0.01	0.5(0.3-0.7)	<0.01	
Increase>=15%	-0.5(-1.1-0.1)	0.10	-0.6(-1.3-0.0)	0.06	-0.2(-0.5-0.1)	0.21	-0.2(-0.4-0.1)	0.18	0.0(-0.3-0.3)	0.95	
No change (<15% change)	0	.	0	.	0	.	0	.	0	.	
All analyses stratified by sex and adjusted for age and weight at baseline. Maximum likelihood parameter estimates are mean change over 60 months for each outcome by categories of change in strength (over 60 months): change in 20-meter walk time in seconds; change in execution time for 5 chair-stands in seconds; change in WOMAC physical function scores. E.g. An estimated mean change in "chair stands time" of -1.0 for an increase in strength of >=15%, indicates those participants were on average 1-second faster at the 60-month visit than at baseline.

Bradley<sup>3</sup>, Baojin Zhu<sup>3</sup>, Carol L Gaich<sup>3</sup>, Zhihong Cai<sup>4</sup>, Amanda Quebe<sup>3</sup>, Anabela Cardoso<sup>3</sup>, Yun-Fei Chen<sup>3</sup> and Roy Fleischmann<sup>5</sup>, <sup>1</sup>Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, <sup>2</sup>Leeds Musculoskeletal Biomedical Research Unit, LTHT Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds, United Kingdom, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>Eli Lilly Japan K.K., Kobe, Japan, <sup>5</sup>University of Texas Southwestern Medical Center, Dallas, TX

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patient (pt)-reported pain is common in rheumatoid arthritis (RA), even in pts with good disease control<sup>1</sup>. This analysis evaluated pain control achieved by methotrexate (MTX), baricitinib (BARI), or combination of baricitinib+MTX (BARI+MTX) in DMARD-naïve RA pts from a Phase 3 study, RA-BEGIN<sup>2</sup>.

### Methods:

Pts were randomized and treated with MTX (N=210), BARI (4 mg QD, N=159), or BARI+MTX (N=215). Pain intensity was assessed on a 0-100 mm visual-analog scale (VAS). Percentage of pts reporting improvement in pain of ≥30%, ≥50%, and ≥70% was evaluated, and time to achieve these improvements was assessed with the cumulative incidence estimate<sup>3</sup>. Between-group comparisons of pain improvement (≥30%, ≥50%, and ≥70%) and percentage achieving low disease activity (LDA) and remission were made using logistic models. Pain improvement among pts achieving remission (CDAI ≤2.8) or LDA (CDAI ≤10) was assessed relative to thresholds for 'remaining' pain (pain VAS ≤10 mm, ≤20 mm, or ≤40 mm) at Week 24.

### Results:

The mean (SD) baseline pain VAS for MTX, BARI, and BARI+MTX were 65.2 (24.1), 64.1 (21.6), and 62.6 (22.6), which improved to 35.2 (26.2), 24.2 (22.2), and 23.8 (23.0) at Week 24, respectively. BARI and BARI+MTX resulted in more pain improvement (-40.8

and -41.2, respectively,  $p<0.001$ ) than MTX (-30.0). The percentage of pts reaching  $\geq 70\%$  pain improvement by Week 24 was 32.7% for MTX, 50.0% for BARI ( $p\leq 0.001$  vs. MTX), and 50.5% for BARI+MTX ( $p\leq 0.001$  vs. MTX). The time when 50% of pts achieved 70% pain improvement was 20 weeks for MTX, 12 weeks for BARI and 8 weeks for BARI+MTX, respectively. The cumulative incidence for achieving 70% improvement is shown (Fig). BARI and BARI+MTX demonstrated similar pain improvement responses. The percentage of pts achieving remission at Week 24 was higher for BARI (21%) and BARI+MTX (22%) compared to MTX (11%)<sup>2</sup>. Similarly, the percentage of pts achieving LDA was higher for BARI (60%) and BARI+MTX (59%) compared to MTX (39%).<sup>2</sup> Mean pain VAS at Week 24 was 6.9 and 16.8, respectively, for pooled patients in remission and LDA. Across treatment groups, the percentage of pts achieving  $\leq 10$ ,  $\leq 20$  or  $\leq 40$  mm remaining pain by remission and LDA are presented in the Table.

### Conclusion:

More pts treated with BARI or BARI+MTX had greater levels of pain improvement more rapidly compared to MTX. Pts treated with BARI or BARI+MTX were more likely to achieve remission and LDA. Patients achieving remission had less remaining pain than those in LDA.

## Neuropathic-like Pain Affects the Tender Joint Count and Health-Related Quality of Life in Patients with Rheumatoid Arthritis

Kentaro Noda<sup>1</sup>, Miku Tajima<sup>2</sup>, Yosuke Oto<sup>3</sup>, Kazuhiro Otani<sup>3</sup>, Yoshiga Masayuki<sup>3</sup>, Haruyasu Ito<sup>1</sup>, Ken Yoshida<sup>1</sup> and Daitaro Kurosaka<sup>1</sup>, <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan, <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan, <sup>3</sup>Internal Medicine, Jikei University School of Medicine, Tokyo, Japan

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pain in rheumatoid arthritis (RA) has been thought to be due to nociceptive pain, but it was reported recently to include a mechanism associated with neuropathic pain as well. We therefore examined the frequency and clinical characteristics of RA patients with neuropathic-like pain.

**Methods:** Neuropathic-like pain in 145 outpatients (37 males, 108 females) with RA was evaluated from December 2015 to July 2016 using the PainDETECT Questionnaire (PDQ), a screening tool for evaluating neuropathic pain. The disease activity was evaluated using the disease activity score of 28 joint (DAS28), clinical disease activity index (CDAI), and simplified disease activity index (SDAI). The following parameters were evaluated: swollen joint count on 28 joints (SJC), tender joint count on 28 joints (TJC), patient global assessment (PGA), estimator global assessment (EGA), pain visual analogue scale (PainVAS), serum C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). The physical function was evaluated using the mHAQ-DI. The quality of pain was evaluated using the short form of the McGill Pain Questionnaire (SF-MPQ). The health-related quality of life was evaluated using the short-form 36-item health survey (SF-36). We compared the clinical parameters between the patients with (PDQ $\geq$ 13) and without (PDQ $\leq$ 12) neuropathic-like pain.

**Results:** Thirty (20.7%) of the 145 patients with RA had neuropathic-like pain according to the PDQ. In patients with neuropathic-like pain, the sex, PGA, EGA, PainVAS, TJC, DAS28, CDAI, SDAI, SF-MPQ sensory and affective scores, HAQ-DI, mental component summary scores (MCS), and role-social component summary scores (RCS) in SF-36 were significantly higher than in those without neuropathic-like pain. There were no significant differences in the RA patients with and without neuropathic-like pain in SJC, CRP, or ESR. In a multinomial logistic regression analysis, significant differences were found in the TJC (p=0.015, OR 1.54), physical component summary (PCS) scores (p=0.041, OR 0.959), MCS scores (p=0.024, OR 0.940), and RCS scores (p=0.021, OR 0.959) in SF-36.

**Conclusion:** Neuropathic-like pain in RA patients was associated with subjective indicators, including TJC and the health-related quality of life, rather than objective indicators of the disease activity, including SJC, CRP, and ESR. Proper treatment of neuropathic-like pain in RA patients may improve the health-related quality of life.

## Eradication of Hepatitis C Among US Veterans: Examination of Changes in Pain Severity and Prescription Opioid Use Following Treatment

**Anand Kumthekar**<sup>1</sup>, Sarah Shull<sup>2</sup>, Benjamin Morasco<sup>3,4</sup>, Travis Lovejoy<sup>3,4</sup>, Michael Chang<sup>2</sup> and Jennifer Barton<sup>3</sup>, <sup>1</sup>Rheumatology, Oregon Health & Science University, Portland, OR, <sup>2</sup>Gastroenterology, VA Portland Health Care System, Portland, OR, <sup>3</sup>VA Portland Health Care System, Portland, OR, <sup>4</sup>Oregon Health & Science University, Portland, OR

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Hepatitis C virus (HCV) is associated with chronic wide spread pain, fatigue, myalgia, arthritis, sicca symptoms and vasculitis. Data regarding prior interferon-based treatment of HCV on pain is conflicting and the impact of direct acting antivirals (DAA) on extrahepatic manifestations is unknown. The study objective is to assess the impact of DAA treatment on pain and opioid use among patients treated at a single VA medical center.

## **Methods:**

Data was obtained from the VA electronic health record through retrospective administrative data abstraction and manual chart review. Inclusion criteria: Veterans with positive HCV antibody or HCV RNA or HCV genotype test or an ICD 9/ICD 10 code for HCV, seen in the rheumatology clinic at least once during the study period and treated with DAA without interferon between January 1, 2010 and December 31<sup>st</sup> 2016; exclusion criteria: deceased during study period. In addition to demographics, HCV status and HCV treatment, data abstracted included (1) numeric rating scale pain scores (0=“no pain” to 10=“Worst pain imaginable”) obtained with other vital signs during outpatient visits and (2) opioid dose for patients prescribed opioid therapy. Pain scores were averaged over two 6-month periods: 6 months leading up to HCV treatment and 6 months following completion of treatment. Opioid dose was converted to a morphine equivalent daily dose (MEDD) and averaged across the same two 6-month intervals. Generalized estimating equations were used to model the change in average pain and MEDD from pre- to post-HCV treatment.

## **Results:**

A total of 126 patients completed HCV treatment with DAA, of which 121 (96%) achieved a sustained virologic response (SVR) and were included in the analysis. A majority (93%) were male, with a mean age of 59 ( $\pm$  5.6) years. Average pre-treatment pain was 4.4 (SD 2.4). Among the 67 patients prescribed opioid therapy, average pre-treatment MEDD was 52.40mg. Both pain and MEDD decreased following SVR. The effect of time was associated with an average reduction in pain of 0.54 points ( $p=0.02$ , Cohen's  $d=0.16$ ). Of the 67 patients prescribed opioids in the pre-treatment period, average MEDD decreased by 8mg during the post-treatment period ( $p<0.01$ , Cohen's  $d=0.24$ ), and 67% of patients experienced an opioid dose reduction, with 12 patients discontinuing opioids entirely.

## **Conclusion:**

Among US Veterans with HCV seen in a rheumatology clinic at a single center, subjective pain scores were reduced post-treatment. In addition, among those prescribed opioids pre-treatment, a majority had a reduction in opioid dose post-treatment. Further evaluation of change in musculoskeletal manifestations of HCV and utilization of rheumatology care with the advent of highly effective HCV treatment is warranted.

## Comparative Risk of Respiratory Depression in Patients Treated with Opioids for Non-Malignant Pain

**Meghna Jani**, Kamilla Kopec-Harding, Mark Lunt and William G Dixon, Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Opioid use for non-cancer pain has increased considerably over the last 30 years. The U.S. Food and Drug Administration announced several boxed warnings in 2016 to highlight serious opioid related risks in an effort to reduce fatal overdoses, 80% of which are unintentional. The most serious opioid related adverse event is respiratory depression (RD), which is potentially fatal. Few data exist on the incidence of RD in opioids users for non-malignant pain with no comparative data between drugs. The aim of this study was to assess the comparative risk of RD in new users of opioids for non-malignant pain using routinely collected electronic patient records (EPR).

### Methods:

Opioid users from Salford hospital EPR were identified (26/9/14-31/5/16). Patients with prior malignancy were excluded using ICD-10 codes. Those with prior history of opioid use were excluded using keyword searches within the medicines reconciliation document. Administered medication was categorised as opioid monotherapy by drug or combination of opioids. Electronic National Early Warning Scores (regularly monitor vital signs during inpatient stays) were used to classify RD. An RD event was defined as any one of the following: respiratory rate (RR)  $\leq 8/\text{min}$ , RR  $\leq 10/\text{min}$  and oxygen saturations  $< 94\%$ , RR  $\leq 10/\text{min}$  and altered consciousness, or dispensed naloxone use. The primary analysis attributed RD to opioids during a risk window of 'on drug + 1 day', unless the patient switched to

another opioid. Patients contributed follow up time for a particular drug from dispensed drug start date until day after discontinuation, first RD event, death or end of last hospital admission. Crude rates/1000 person years of follow up were calculated and Cox proportional hazards models were used to examine the comparative risk of administered opioids and RD, adjusted using propensity scores (PS) derived using inverse-probability of treatment weights.

Results:

7702 opioid users were included in the study, 3,839 female (50%) and a mean age (SD) of 52(21) years. There were 261 RD events observed on treatment, 130 with severe respiratory depression (RR<8/min), 135 requiring naloxone and 3 respiratory arrests. Patients on fentanyl, morphine, oxycodone and combination treatment had the highest crude rates (table). Patients on oxycodone had the highest proportion of comorbidities. In the propensity adjusted Cox-model, using codeine as the referent, patients on fentanyl, morphine, and combination opioids had the highest risk of RD (table). Compared to morphine, codeine had an adjusted HR of 0.64 (95% CI: 0.43, 0.95).

Conclusion:

Fentanyl and morphine monotherapy have a significantly higher risk of RD than codeine. Following PS adjustment the risk of RD on oxycodone no longer remained significant. The strengths of this study include real time physiological parameters to define RD and administered medication use (rather than prescribed) to define exposure.

Opioid (no. of patients)	Codeine (n=4,312)	Fentanyl (n=505)	Morphine (n=3,662)	Oxycodone (n=1,609)	Tramadol (n=364)	Alfentanil (n=364)	Buprenorphine (n=90)	Combination (n=3,030)

SESSION INFORMATION

Session Date: Tuesday, November 7, 2017  
Session Title: Pain – Basic and Clinical Aspects Poster  
Session Type: ACR Poster Session C  
Session Time: 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis (OA) is a common cause of pain and is associated with depression in older adults. Pain and depression are major burdens to people suffering from OA. Being physically active has broad health benefits for people with OA, including reduced pain and depressive symptoms. Increasing physical activity within a fixed 24-hour day requires trading time with other behaviors. Applying isotemporal substitution methods to observational data, we modeled the potential benefits in relation to pain and high depressive symptoms from trading time in one type of activity for another (e.g. replacing sedentary time with moderate physical activity).

**Methods:** This cross-sectional study examined data from the Accelerometer Sleep Substudy of Osteoarthritis Initiative. Participants wore two ActiGraph GT3X triaxial accelerometers for 24 hours over 7 days: one on non-dominant wrist to monitor sleep and one on waist to monitor physical activity (PA). Outcomes were the presence of WOMAC knee pain, report of pain interference with work, and presence of high depressive symptoms identified by Center for Epidemiologic Studies Depression scale  $\geq 16$ . Odds ratio (OR) and 95% confidence interval (CI) from logistic regression were presented for the isotemporal substitution of the same amount of time in one type of activity (sleep, sedentary behavior, light PA, moderate PA) for another in relation to the outcomes holding time in other activities constant. Isotemporal substitution models controlled for socioeconomic (age, sex, race, income) and health factors (knee OA, obesity, comorbidity).

**Results:** These 187 men and women had mean age 67 (SD 8.5), 50% were female, 41% obese and 60% had radiographic knee OA. On a daily basis, these adults on average spent 7 hours in sleep, 10 hours in sedentary behavior, 6 hours in light PA, and 27 minutes in moderate PA. Isotemporal analyses on WOMAC pain indicated substituting 10 minutes/day of moderate PA for either sleep (OR=0.82) or light PA (OR=0.83) was significantly ( $P \leq 0.05$ ) associated with less frequent reports of knee pain. Similarly, substituting 10 minutes/day of moderate PA for sleep (OR=0.60), sedentary behavior (OR=0.62) or light PA (OR=0.62) was significantly associated with less frequent pain interference. Isotemporal analyses on high depressive symptoms indicated substituting 10 minutes/day of light PA for either sleep (OR=0.78) or sedentary behavior (OR=0.79) was significantly associated with less frequent report of high depressive symptoms.

**Conclusion:** Interventions promoting moderate activities may be beneficial to address pain while substituting light activity for sedentary behavior or sleep may be beneficial to address depressive symptoms.

# Analgesic Potential of NEO6860, a Modality Selective TRPV1 Antagonist, in Osteoarthritis Knee Pain: Results of a Randomized, Controlled, Proof-of-Concept Trial

Pierre Arsenault<sup>1</sup>, **Richard Leff**<sup>2</sup>, Nathaniel Katz<sup>3</sup>, Philippe Walker<sup>4</sup> and Dan Chiche<sup>4</sup>, <sup>1</sup>Diex Recherche Sherbrooke, Sherbrooke, QC, Canada, <sup>2</sup>Richard L Leff LLC, Chadds Ford, PA, <sup>3</sup>Analgesic Solutions, Natick, MA, <sup>4</sup>NEOMED Institute, Montreal, QC, Canada  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Current treatments of osteoarthritis (OA) of the knee, such as NSAIDs, have significant limitations in both efficacy and safety. NEO6860 is a modality selective antagonist (shows full antagonism when activated by capsaicin, but little or no antagonism when activated by heat or low pH) at the cloned human transient receptor potential vanilloid subtype 1 (TRPV1) receptor. In a phase I study<sup>1</sup>, NEO6860 showed good bioavailability and demonstration of pharmacodynamic effect as well as a target engagement.

**Methods:** This proof-of-concept, randomized, double blinded, placebo controlled, 3-period crossover, phase II study compared alternately 1 day (2 doses): NEO6860 (500 mg bid), placebo, and naproxen (500 mg bid) in a random sequence in 54 patients with OA (mean age: 61; mean BMI 29 kg/m<sup>2</sup>; 35% with hypertension, 14% with dyslipidemia and 10% with diabetes).

## Results:

Pharmacokinetics (PK) data revealed that the exposure was approximately 1.6 times higher when compared with phase I at the same dose ( $C_{max}$  = 4337 ng/mL and 2770 ng/mL, respectively). An analgesic effect of NEO6860 was shown using Numerical Rating Scale (NRS) post-exercise at 3 and 24h, using a mixed ANCOVA Model, controlling for Period, Sequence and Treatment as fixed effects and baseline by period as covariate:

Least-squares-means  
(95% CI)

	NEO6860 (N=52)	Naproxen (N=52)	Placebo (N=50)
Change in NRS from baseline to			
3 hours post-dose, Mean (95%CI)	-0.56 (-0.94 ; -0.19)	-0.7 (-1.09 ; -0.34)	-0.38 (-0.75 ; -0.00)
8 hours post-dose, Mean (95%CI)*	-0.57 (-0.95 ; -0.20)	-0.65 (-1.02 ; -0.27)	-0.83 (-1.20 ; -0.46)
24 hours post-dose, Mean (95%CI)	-0.67 (-1.09 ; -0.26)	-0.97**(-1.39 ; -0.55)	-0.29**(-0.71 ; 0.13)

\*: 8 h post dose was the primary endpoint; \*\*:  $p < 0.05$  comparing naproxen to placebo.

This pattern was confirmed on NRS pre-exercise, Patient's Global Impression of Change (PGIC) and, to a lesser extent, the WOMAC; however, the observed effect was below the hypothesis used for power estimate, explaining in part the  $P$  values  $\geq 0.05$ . The safety profile was comparable to that in the prior phase I study, taking into consideration the unexpectedly higher level of exposure, and the two severe adverse events (AEs) reported (feeling hot and headache, each reported by one patient) were resolved within one day. Importantly, no hyperthermia and no change in heat pain perception were reported.

## Conclusion:

In patients with OA pain, an analgesic effect was observed with NEO6860 while not showing the two AEs previously observed with TRPV1 antagonist, consistent with its modality selective mode of action. Future investigations should emphasize on: 1- reducing the NEO6860 dose, which may maintain the analgesic effect with multiple dosing, and 2- testing NEO6860 in combination with NSAIDs to improve analgesia and potentially alleviate safety concerns of current treatments of OA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Morton's neuroma (MN) is a painful condition of the third intermetatarsal space caused by distal common digital nerve compression. CNTX-4975, a highly purified, synthetic *trans*-capsaicin, targets the transient receptor potential vanilloid 1, producing analgesia via reversible desensitization of end terminals of primary afferent pain fibers. A prior double-blind randomized trial demonstrated efficacy of CNTX-4975 100 µg injected into the area surrounding the neuroma.\* This phase 1b, open-label trial further evaluated dosing, safety (including sensory and motor examination), tolerability, efficacy, and duration of pain relief following injection of CNTX-4975.

**Methods:** Subjects with painful MN indicated their level of pain at baseline and up to 6 months following a single injection of CNTX-4975 200 µg or 600 µg using the Numeric Pain Rating Scale (NPRS; 0 [none]–10 [severe]). Clinically meaningful pain reduction was defined as ≥30% pain decrease versus baseline.

**Results:** Eleven subjects were enrolled (200 µg, n=5; 600 µg, n=6). The mean (SD) baseline pain score with walking was 5.7 (1.3). A substantial reduction in pain with walking was evident as early as 1 week in both dose groups (−3.0, 200 µg; −2.9, 600 µg). The mean (SD) change in pain with walking score at 8 weeks was −3.0 (3.8) in the 200-µg group and −4.3 (2.4) in the 600-µg group. At 6 months (only the 600-µg group was followed), the change in pain score was −3.8 (3.1). None of the subjects had a decrease in sensory or motor function compared with baseline. All 11 subjects reported procedure pain as tolerable.

**Conclusion:** A single injection of CNTX-4975 200 µg and 600 µg for MN provided a rapid and prolonged duration of clinically meaningful pain reduction with acceptable tolerability and safety. This study provides a basis for further randomized trials at these dose levels. \*Campbell, et al, *Pain*, 2016.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Morton's neuroma (MN) is a painful condition of the third intermetatarsal space caused by distal common digital nerve compression. CNTX-4975 is a highly purified, synthetic, *trans*-capsaicin that targets the transient receptor potential vanilloid 1, producing analgesia via reversible desensitization of end terminals of primary afferent pain fibers. Prior trial data support the use of injectable CNTX-4975 to treat MN in subjects who fail conservative measures.\*

**Methods:** The primary efficacy endpoint in this phase 2, 12-week randomized, double-blind, placebo-controlled trial was change from baseline to week 4 in the average diary scores for neuroma foot pain with walking using the Numeric Pain Rating Scale. Clinically meaningful pain reduction was defined as  $\geq 30\%$  pain reduction versus baseline. Safety and tolerability assessments included treatment-emergent adverse events (TEAEs) and sensory function examination.

**Results:** Subjects received a single, ultrasound-guided injection of placebo (n=39), CNTX-4975 200  $\mu\text{g}$  (n=38), or CNTX-4975 600  $\mu\text{g}$  (n=39) following ankle-block anesthesia. Although the primary endpoint did not reach statistical significance, both doses were numerically superior to placebo, with greater clinically meaningful reductions from baseline at weeks 4 and 12. One study site, identified as an outlier site before database lock, had a high placebo rate; in a post-hoc analysis excluding this site, results either achieved (weeks 5 and 12;  $P < 0.05$ ) or neared statistical significance despite a 34% decrease in the number of subjects. The cumulative responder analysis at week 12 showed  $>90\%$  pain reduction versus baseline for 2% of the placebo group and 40% of the CNTX-4975 200- $\mu\text{g}$  group. In total, 63% of subjects reported  $\geq 1$  TEAE (56%, placebo; 74%, CNTX-4975 200  $\mu\text{g}$ ; 56%, CNTX-4975 600  $\mu\text{g}$ ). No decline was observed in tactile sensibility following injection.

**Conclusion:** A single injection of CNTX-4975 200  $\mu\text{g}$  or 600  $\mu\text{g}$  for MN provided rapid and prolonged clinically meaningful pain reduction with good tolerability. \*Campbell, et al., *Pain*, 2016.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Synovitis-associated pain is an important aspect of arthritis pathology. Several inflammatory mediators released by the synovium have been implicated in the regulation of pain, including S100A8 and S100A9 which may regulate pain either via direct stimulation of TLR4 on the nerve endings in the synovium or via stimulation of the dorsal root ganglia (DRG), thereby enabling an increased phagocyte infiltration. To investigate the role of S100A9 in the pain response after induction of an acute synovitis using streptococcal cell walls (SCW) as a trigger, comparing S100A9<sup>-/-</sup> mice and their WT controls.

### Methods:

Acute synovitis was induced by a single i.a. injection of SCW in the knee joint of C57Bl6 (WT) mice and S100A9<sup>-/-</sup> mice, control mice received an i.a. saline injection. Serum S100A8/A9 levels were investigated by ELISA and expression of S100A8 and S100A9 in synovium and DRG by immunohistochemistry. Joint swelling and cell influx was assessed by <sup>99m</sup>Tc accumulation and histology, respectively. Pain response were investigated Incapacitance Tester (weight bearing), Catwalk (gait analysis) and von Frey's filaments (mechanical allodynia). Gene expression of inflammatory mediators and neuron activation markers in DRG were determined by q-PCR.

## Results:

A single i.a. injection of SCW resulted in increased synovial expression of S100A8 and S100A9 and subsequent increased serum S100A8/A9 levels (2.6-fold,  $P < 0.001$ ) 1 day p.i., which returned to basal levels at 7 days p.i. The increased expression of S100A9 did not contribute to the development of inflammation since joint swelling and cell influx were similar in WT and S100A9<sup>-/-</sup> mice 1 day p.i. Using the Incapacitance Tester, WT mice showed a marked and significant decrease in percentage of weight bearing on the SCW injected hindpaw (28%) compared to saline injection (47%,  $P < 0.001$ ) 1 day p.i., whereas S100A9<sup>-/-</sup> mice did not. In addition, gait analysis showed that the stand-phase of the unaffected paws were significantly increased in WT mice 1 day p.i., which will reduce the load on the inflamed paw, while in S100A9<sup>-/-</sup> mice these parameters were not altered. No difference in mechanical allodynia was observed, both mouse strains showed a similar reduction of paw withdrawal threshold (4.2 and 4.5 fold decrease respectively). Analysis of DRG showed no increased phagocyte infiltration after SCW injection as determined by S100A8 and S100A9 immunohistochemistry and no change in gene expression of MCP-1, KC, IL-1 $\beta$  or TNF was measured. However, expression of neuron activation markers NAV1.7, ATF3 and GAP43 were significantly increased at 1 day after SCW injection in WT mice as compared to saline injected mice ( $P = 0.022$ ,  $0.004$  and  $0.030$ , respectively) while SCW injection in S100A9<sup>-/-</sup> mice did not show increased expression, which is in line with the reduced pain response observed earlier in S100A9<sup>-/-</sup> mice.

## Conclusion:

These findings show that S100A9, which is released from the synovium upon inflammation, is an important mediator of inflammatory pain response in the knee, and that during the acute phase of inflammation is likely regulated via direct activation of TLR4 on nerve endings in the synovium and not via increased infiltration of phagocytes in the DRG.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid Arthritis (RA) is an autoimmune disease very commonly associated with chronic pain which is often resistant to current analgesics. Targeting Nerve Growth Factor (NGF), a neurotrophic factor, is already considered a very promising treatment of RA. However, it could lead to serious adverse effects. Our aim is to better understand the involvement of the specific intracellular signaling pathways activated by NGF through the tyrosine kinase type A (TrkA) receptor, in the pathophysiology of RA especially those involved in associated chronic pain.

## Methods:

We performed a multimodal study in TrkA/C knock-in mice expressing a chimeric receptor formed by the native extracellular part of TrkA and the functional transmembrane and intracellular part of the tyrosine kinase type C receptor (TrkC) which binds neurotrophin 3 (NT3). We investigated nociceptive behavior such as mechanical allodynia and thermal hyperalgesia using von Frey and paw immersion test in CFA induced-arthritis model. *In vivo* cartilage and bone remodeling were assessed by scintigraphic imaging using  $^{99m}\text{Tc}$ -NTP 15-5 and  $^{99m}\text{Tc}$ -HMDP radiotracers, respectively. CD68 positive cell infiltration and CGRP positive nerve fibers sprouting were assessed in the joint as well as TrkA and ASIC3 expression in DRG cells bodies using an immunohistochemical approach. We are currently investigating the intracellular pathway potentially involved at the DRG level.

**Results:** Our results showed a specific lack of mechanical allodynia development while thermal hyperalgesia was unaffected in TrkA/C monoarthritic mice compared to WT littermates. This change in pain behavior was associated with a specific decrease of  $^{99m}\text{Tc}$ -HMDP in TrkA/C monoarthritic mice, suggesting a unique change in bone remodeling. Indeed, cartilage remodeling was similar between both genotypes. We also observed a decrease of CD68-positive cell infiltration as well as CGRP expression in the inflamed joint in TrkA/C mice compared to WT mice while the expression of TrkA and ASIC3 in the DRGs was unaffected between both genotypes following monoarthritis.

#### Conclusion:

The present study demonstrates a specific involvement of NGF/TrkA signaling in pain, especially mechanical hypersensitivity and also bone remodeling in inflammatory arthritis. We are now investigating the specific intracellular pathway involved.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Substance P (SP) release and binding to NK-1 produces pain transmission. Neurotoxins (NT) that prevent release of SP, such as onabotulinum toxin (BoNT/A), and those that deplete SP, such as vanilloids (VAN), produce analgesia in chronic murine arthritis. This study evaluated the relationship of dorsal root ganglion (DRG) SP expression to pain and analgesia in murine arthritis treated with these NTs.

**Methods:** C57Bl6 male mice received intra-articular (IA) carrageenan, Complete Freund's Adjuvant (CFA) or Collagenase (COL) to produce acute inflammatory, chronic inflammatory or chronic noninflammatory arthritis respectively. IA therapies were given at appropriate intervals before examination. Twelve-week-old mice were examined after arthritis induction. Evoked and spontaneous pain was quantitated. DRGs were harvested for immunohistochemistry (IHC) after pain assessment. SP expression was measured as % DRG neurons expressing SP.

**Results:** Evoked pain in arthritic and naïve mice correlated with SP expression ( $R^2=0.906$ ,  $\beta=1.343$ ). IA vanilloid agonists and antagonist reduced SP expression in a dose dependent manner in chronic inflammatory arthritis (CFA). IA BoNT/A reduced SP expression in CFA arthritis but significantly increased SP expression in COL arthritis at 4 weeks after induction but not at 6 weeks. None of the neurotoxins altered SP expression in non-arthritic mice.

**Conclusion:** Both SP depletion and release inhibition are analgesic in chronic murine arthritis. SP expression varied with NT mechanism of action in COL arthritis at 4 weeks. BoNT/A had different effects on SP expression in 4 week COL and CFA arthritis but SP expression in 6 week COL treated with BoNT/A was similar to that seen in BoNT/A treated CFA. The effect of NT on SP expression may depend on pathophysiology of pain production and chronicity. Understanding the effect of NT treatment on NK-1 expression will be important.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Opioid prescribing in the U.S. has increased at an alarming rate amid uncertainty over effectiveness and rising concerns over safety of this practice. Patients with systemic inflammatory diseases (SID) often suffer from chronic pain, and may be more likely to be prescribed opioids compared to those without SID. We investigated the rates of opioid prescribing in SID patients compared to age, sex and index date-matched patients with hypertension (HTN) but no SID.

**Methods:** We conducted a cohort study using insurance claims data from Truven MarketScan (2003-2014). We identified individuals aged >18 years with prevalent SID [i.e., rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), ankylosing spondylitis (AS), and psoriatic arthritis (PsA)] based on a combination of ≥2 diagnosis codes and ≥1 dispensing for disease-specific drug dispensing and defined the dispensing date of the disease-specific prescription as the index date. We matched each SID patient 1:1 by age, sex and index date to a HTN patients, identified using >2 diagnosis codes for HTN and >1 dispensing for antihypertensive medication. We excluded patients with any malignancy. All patients were required to have ≥1 year of continuous enrollment before and after the index date. We assessed prescription opioid use during the 1-year follow-up from the index date in the SID group compared to HTN group.

**Results:** We identified 181,922 RA (77% female, mean age 55), 45,879 SLE (91% female, mean age 47), 30,346 PsA (51% female, mean age 50) and 7,704 AS (39% female, mean age 45) patients, matched to HTN patients. At baseline, depression and fibromyalgia were more prevalent in SID cohort compared to matched HTN patients, while diabetes and cardiovascular disease were more common in HTN patients. Back pain was most prevalent among AS cohort (16%) compared to 4% in the matched HTN cohort (p<0.001). During

1 year follow-up, >1 opioid prescription was dispensed among 46% RA (vs. 32% HTN,  $p<0.001$ ), 46% SLE (vs. 33% HTN,  $p<0.001$ ), 41% PsA (vs. 31% HTN,  $p<0.001$ ), and 50% AS (vs. 30% HTN,  $p<0.001$ ) patients. Long-term opioid use (>90 days), and extended-acting opioid prescriptions also showed similar trends, with higher rates seen in SID cohorts compared to HTN, and highest use seen among AS patients (Table).

**Conclusion:** Nearly half of SID patients and approximately 30 % of HTN patients used prescription opioids during a 1-year period. The highest percentage of opioid dispensing were seen among patients with AS. Compared to HTN patients, SID patients had more frequent use of any opioids, multiple types or long-acting opioids. Long-term use was also more common in SID patients.

Table. Patient characteristics at baseline and their prescription opioid use patterns during 1-year followup

# MCC22, a Novel Compound That Targets Both CCR5 and Mu Opioid Receptors, Is Highly Effective in Treating Inflammatory Arthritis Pain

**Raini Dutta**<sup>1</sup>, Mary Lunzer<sup>2</sup>, Jennifer L. Auger<sup>3</sup>, Eyup Akgün<sup>2</sup>, Philip Porthoghese<sup>2</sup> and Bryce A. Binstadt<sup>3</sup>, <sup>1</sup>Pediatrics, University of Minnesota, Minneapolis, MN, <sup>2</sup>Department of Medicinal Chemistry, University of Minnesota, Minneapolis, MN, <sup>3</sup>Center for Immunology and Department of Pediatrics, University of Minnesota, Minneapolis, MN

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The pain that accompanies rheumatoid arthritis and other chronic inflammatory conditions is difficult to manage. Although opioids provide potent analgesia, chronic opioid use is associated with tolerance and addiction. Recent studies have demonstrated functional interactions between chemokines and opioids in pain signaling pathways. Reported crosstalk and even heterodimerization between chemokine and opioid receptors led our group to develop bivalent compounds that can bind both types of receptors, with the goal of targeting opioids to sites of inflammation. MCC22 is novel bivalent compound comprising a CCR5 antagonist and a mu opioid receptor agonist, connected by a 22-atom linker. We evaluated the efficacy of MCC22 in the K/B.g7 T cell receptor transgenic mouse model of inflammatory arthritis.

**Methods:** MCC22 or morphine was administered intraperitoneally at varying doses to arthritic K/B.g7 mice or non-arthritic control mice. Mechanical pain hypersensitivity was measured each day before (baseline) and after drug administration, using the electronic von Frey test. The potency of MCC22 relative to morphine was calculated. Functional readouts of pain included grip strength and nesting behavior. A separate dosing regimen was used to determine whether the drugs induced pharmacologic tolerance.

**Results:** MCC22 provided ~3000-fold more potent analgesia than morphine in this model of inflammatory arthritis. Daily treatment with MCC22 also led to a cumulative analgesic effect, reducing the daily baseline pain level. MCC22 produced no observable analgesic effect in non-arthritic control mice. Importantly, repeated administration of MCC22 did not induce pharmacologic tolerance, whereas a similar regimen of morphine did. Both grip strength and nesting behaviors improved among arthritic mice treated with MCC22. Ankle thickness and arthritis scores were not affected by MCC22 administration. The analgesic effect of MCC22 was abolished in K/B.g7 mice genetically lacking CCR5, demonstrating the receptor specificity of the pharmacophore.

**Conclusion:** MCC22 is a novel bivalent compound that relies on a CCR5 antagonist to deliver an opioid agonist to sites of inflammatory pain. Our findings demonstrate that MCC22 provides highly potent analgesia and improved functional outcomes in a model of inflammatory arthritis, without inducing typical opioid tolerance. These findings suggest that MCC22 or similar compounds could be used to treat the pain associated with inflammatory arthritis and related conditions, while minimizing the risks typically associated with chronic opioid use.

## A Role for CCR2 in Chronic Behavioral and Neuroimmune Changes in the DMM Model of Osteoarthritis

Phuong Tran<sup>1</sup>, Shingo Ishihara<sup>2</sup>, Rachel E. Miller<sup>3</sup>, Richard J. Miller<sup>4</sup> and **Anne-Marie Malfait**<sup>1</sup>, <sup>1</sup>Rheumatology, Rush University Medical Center, Chicago, IL, <sup>2</sup>Internal Medicine, Rush University Medical Center, Chicago, IL, <sup>3</sup>Biochemistry, Rush University Medical Center, Chicago, IL, <sup>4</sup>Pharmacology/Medical Humanities and Bioethics, Northwestern University, Chicago, IL

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pain – Basic and Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The aim of this study was to explore pain-related behaviors and associated cellular changes in the pain pathway in experimental osteoarthritis (OA) induced by destabilization of the medial meniscus (DMM). In wild-type (WT) mice, DMM results in slowly progressive knee OA, associated with pain behaviors, including mechanical allodynia and decreased locomotion. We have previously reported that CCR2 signaling is a key mediator for persistence of pain after DMM. Specifically, 8 weeks after DMM, L3-L5 dorsal root ganglia (DRG) neurons show increased expression of CCR2 gene and protein. *Ccr2* null mice develop initial mechanical allodynia following DMM, but the allodynia is not maintained (unlike in WT mice). WT and *Ccr2* null mice develop the same extent of joint damage after DMM.

**Methods:** DMM or sham surgery was performed in the right knees of 10-week old male WT or *Ccr2* null C57BL/6 mice. The elevated plus maze was employed as a method for assessing anxiety-related responses (time spent grooming; time spent immobile) over a period of 5 minutes. To assess cellular changes in the peripheral and central nervous system, we quantified (1) macrophages in the L4 DRG, by immunostaining for F4/80 and (2) activated microglia in the L4 dorsal horn of the spinal cord, based on the morphology of Iba1-immunoreactive microglia, using established methods.

**Results:** Eight weeks after sham or DMM surgery, WT mice showed no behavioral changes in the elevated maze plus test. However, by 16 weeks after surgery, DMM (but not sham) operated mice showed behaviors indicative of anxiety, including increased periods of immobility ( $p=0.002$ ,  $n=5-13$ ) and increased time spent grooming ( $p=0.0073$ ,  $n=6-15$ ). These behaviors did not develop in *Ccr2* null mice ( $p>0.9$ ,  $n=8-14$ ).

In WT mice, L4 DRG were strongly infiltrated with F4/80 expressing macrophages, 8 and 16 weeks after DMM. In contrast, in *Ccr2* null mice, L4 DRG showed some macrophage infiltration at 8 weeks, but to a lesser extent than in WT mice. Furthermore, in *Ccr2* null mice, F4/80 levels returned to baseline by week 16. The L4 dorsal horn in WT mice showed a clearly increased number of activated microglia 8 and 16 weeks after DMM but not sham surgery (wk 8:  $p=0.015$ ; wk 16:  $p=0.039$ ,  $n=3-6$ /group/time point). In *Ccr2* null mice, activated microglia were increased 8 wks after DMM compared to baseline ( $p<0.05$ ,  $n=3-9$ /group/time point), but this returned to baseline by week 16.

**Conclusion:** We describe a novel behavior that specifically develops during the chronic stage of the DMM model: increased grooming, which is considered an indicator of anxiety. Increased grooming may be indicative of pain-related anxiety, since it coincides with the chronic pain phase of the disease. *Ccr2* null mice did not develop this grooming behavior, confirming our previous findings that these mice do not develop chronic pain after DMM. Overall, these data support our previous work suggesting that CCR2 activation is important in the maintenance of chronic OA pain, perhaps by mediating neuro-immune interactions in both the DRG and the spinal cord. The fact that *Ccr2* null mice developed initial macrophage infiltration and microgliosis that subsequently resolved suggests that these pathways may be targetable.

## The Role of Life Purpose in Disability and Depression in Patients with Acute Low Back Pain

**Background/Purpose:** *Life purpose* (also termed *purpose in life* or *meaning in life*) has been defined as “believing one’s actions have a set place in the larger order of things and that one’s behavior fits naturally into the course of a larger, more important social whole.” Although there is a dearth of published research on the role of life purpose in patients with acute low back pain, research in chronic pain suggests that those with chronic pain who have increased life purpose had less depression among other important health outcomes.

**Methods:** We used linear regression models to describe the relationship of life purpose (*Scale of Psychological Well-Being- Life Purpose* subscale; range=14-84) with disability (total score, *Roland Morris Disability Scale*, range=0-24) and depression (total score, *Center for Epidemiologic Studies Depression Scale*, range=20-80) in persons with acute low back pain (healthcare provider diagnosed low back pain present for less than 3 months;  $N=37$ ) participating in a randomized clinical trial to prevent transition to chronic low-back pain.

**Results:** In our predominantly female sample (81.8%) with a mean age of 53 years (standard deviation =11.6 years), 52% worked full-time. Controlling for current work status (working full-time versus not), the overall model was significant for disability ( $R^2=.16$ ,  $F[2,36]=3.17$ ;  $p=.05$ ), with an adjusted  $R^2$  of 0.11. Predicted disability was lower by .38 points per 1-point higher score on life purpose ( $p=.02$ ). Controlling for gender (rates of depression are higher in females), the overall model was significant for depression ( $R^2=.26$ ,  $F[2,36]=6.07$ ;  $p=.006$ ), with an adjusted  $R^2$  of 0.22. Predicted depression score was lower by 0.52 points per 1-point higher score on life purpose ( $p=.002$ ).

**Conclusion:** Findings from this study suggest that life purpose has a significant association with disability (controlling for work status) and depression (controlling for gender) in this sample of persons with acute low back pain which is previously undescribed in the identified published literature. A further understanding of the relationship between life purpose and depression and disability could improve these important health factors in this population.

**Session Time:** 9:00AM-11:00AM

### Disability in Acute Low Back Pain: The Role of Pain Severity, Pain Catastrophizing, Depression, and Exercise

**Background/Purpose:** The effectiveness of cognitive treatments for low back pain, a prevalent and costly condition, are commonly based on the principles of the Vlaeyen Fear of Movement/(Re) Injury Model. In this model, persons with a painful injury/experience who also engage in pain catastrophizing are most likely to avoid activity leading to disability. The validation of this model in patients suffering from acute low back is limited. The purpose of this project is to describe whether level of disability is associated with variables identified in the Fear of Movement/(Re) Injury Model, including pain, pain catastrophizing, depression, and exercise in persons with acute low back pain.

**Methods:** Linear regression was used to assess the association of disability (total score, *Roland Morris Disability Scale*, range=0-24) with exercise (Yes/No), pain catastrophizing (total score, *Pain Catastrophizing Scale*, range=0-52), depression (total score, *Center for Epidemiologic Studies Depression*, range=20-80), and pain intensity (*Brief Pain Inventory* intensity score, range=0-40) at baseline among subjects with acute low-back pain ( $N=39$ ) participating in a randomized clinical trial to prevent transition to chronic low-back pain.

**Results:** Over half (52%) of our predominantly female (82%) sample worked full-time and their average age was 53 years (standard deviation=11.6). Controlling for age, gender, and work status (working full-time or not), the overall model was significant for disability ( $R^2=.73$ ,  $F[7,39] = 12.06$ ;  $p<.0001$ ), with an adjusted  $R^2$  of 0.73. Predicted disability was higher by .46 points per 1-point higher score on pain catastrophizing ( $p=.002$ ) and higher by .51 points per 1-point higher score on pain severity ( $p<.0001$ ). Exercise and depression were not significant predictors of disability.

**Conclusion:** Findings from this study suggest that pain catastrophizing and pain were significant correlates of disability in this sample of persons with acute low back pain. These findings suggest that the application of the Fear of Movement/(Re) Injury Model to this population is appropriate and that there is likely clinical utility to the use cognitive therapy. In turn, effectively treating patients during the acute phase of this condition might prevent the transition to a chronic low back pain state.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Pain – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The use of prescription opioids has been under increasing scrutiny due to concerns about the potential for misuse, dependency and increased adverse events. The objectives of our study were to examine the rates of prescription opioid use among pre-surgical knee, hip and spine osteoarthritis (OA) patients as well as the association between use and a range of socio-demographic and health status characteristics.

**Methods:** Study participants were 1204 patients with knee ( $N=577$ ), hip ( $N=459$ ) and spine ( $N=168$ ) OA scheduled for surgery at a tertiary care hospital in Toronto, Canada. In pre-surgery questionnaires, data were collected on current usage (never, sometimes, daily) of opioid pain medications, as well as other prescription (NSAIDs, anti-depressants, neuroleptics) and over-the-counter pain medications for arthritis/joint pain. Additional questionnaire variables included: socio-demographics (age, sex, education), body mass index, comorbidity, depressive symptoms (Hospital Anxiety and Depression Scale) and pain level (0-10 numeric rating scale for average pain in the past week). Rates of opioid use were calculated by sex, age (<65 and 65+) and surgical site. Multivariable logistic regression was used to examine the associations between current reported opioid use (outcome: sometimes/daily vs. never) and other study variables.

**Results:** Participants were of mean age 65.6 years; 55.5% were women. Overall, 15% of patients reported 'sometimes' using opioid and an additional 15% reported 'daily' use. Any reported use of opioid was highest among spine OA patients (40%) and similar among knee and hip patients (28% and 30%). Younger women (<65 years) reported the greatest use of opioid overall, and particularly among spine patients (61%). From multivariable logistic regression, greater likelihood of opioid use was significantly associated with spine OA (vs. knee OA;  $p=0.03$ ), younger age ( $p=0.02$ ), obesity (vs. underweight/normal;  $p<0.01$ ), fibromyalgia (present vs. absent;  $p=0.02$ ), greater depressive symptoms ( $p=0.01$ ), greater pain ( $p<0.001$ ) and current use of other prescription pain medication ( $p<0.001$ ).

**Conclusion:** Nearly a third of pre-surgical knee, hip and spine OA patients reported using prescription opioid medication for their OA pain. The higher use among younger individuals and those with greater depressive symptoms may warrant attention given growing

concerns around adverse outcomes related to opioid use. While increased use of opioids among those with higher levels of current pain may be expected, this additionally raises questions as to whether these individuals are deriving intended clinical benefits. Further, available research suggests that opioid use in the surgical OA population may negatively impact outcomes. Consideration of pre-surgical opioid use screening, including potential dependency, may be warranted for patients undergoing surgery for OA.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Pain – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is increasing support in the literature for a neuropathic component to OA pain. Our primary objective was to determine whether pain at rest and pain on activity are differentially associated with neuropathic pain scores in individuals with end-stage hip and knee OA. In addition, we examined the associations of neuropathic pain scores with psychological factors, health status and sociodemographic characteristics. As there is evidence of sex specific effects on pain, we analysed men and women separately.

**Methods:** Study participants were 843 patients with hip or knee OA scheduled for total joint arthroplasty (TJA) in Toronto, Canada. In pre-surgery questionnaires, data were collected using the painDETECT scale for neuropathic pain, the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale (items split into pain at rest (sitting, night pain) and pain on activity (standing, up/down stairs, walking on flat ground) and summed), the Hospital Anxiety and Depression Scale (HADS; depression only) and the Pain Catastrophizing Scale (PCS). Data on socio-demographics, health status (body mass index (BMI), comorbidity count, possible neuropathic comorbidities, symptomatic joint count) and medication use were also collected. Multivariable linear regression models were estimated for men and women to examine associations with neuropathic pain scores (higher indicates greater likelihood of neuropathic pain) by entering variables in predetermined blocks.

**Results:** Participants were of mean age 65.1 years; 57.1% were women. 55.3% of men and 57.6% of women were scheduled for knee TJA. Mean painDETECT scores were significantly higher ( $p=0.0001$ ) for women ( $11.2\pm6.6$  out of 38) than men ( $9.3\pm7.0$ ), with 35.6% of women and 27.7% of men meeting established cut-offs for possible (painDETECT scores: 13-18) or likely (painDETECT scores: 19+) neuropathic pain. In regression modeling, pain at rest explained the most variance in neuropathic pain scores (men: 23.4%; women: 13.9%). In the final regression model for women, surgical joint (knee>hip;  $p=0.04$ ), joint count, pain at rest, pain on activity, depression and pain catastrophizing were significantly associated with neuropathic pain score. In the final model for men, pain at rest, depression, pain catastrophizing and use of narcotics were significantly associated with neuropathic pain score. For women, the coefficient for pain at rest was 1.6 times greater than that for pain on activity. For men, pain on activity was not significantly associated ( $p=0.47$ ) with neuropathic pain score.

**Conclusion:** Findings support that likely neuropathic pain is experienced by a notable proportion of patients with end-stage hip and knee OA. A greater neuropathic pain score was more strongly associated with pain at rest than pain on activity, particularly in men. Clinically, the presentation of pain at rest may suggest that a more thorough evaluation for potential neuropathic pain is warranted and may have implications for appropriate pain management. Findings also suggest that use of the WOMAC pain subscale as a single measure of pain burden (i.e. combined pain at rest and pain on activity) may need to be revisited.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To describe the work productivity and activity impairment in adult patients diagnosed with primary Sjögren's Syndrome (pSS). To evaluate the association between activity impairment and clinical manifestations, depression and anxiety. To compare the activity impairment according to educational level and site of care (public or private centers) as surrogates of socio-economic status.

**Methods:** We included patients with diagnosis of pSS according to the American-European criteria (2002) treated in 11 private and public Argentine rheumatologic centers between November 2013 and December 2016. All patients with another autoimmune rheumatic or chronic disease were excluded. The WPAI questionnaire was used. Design: observational, analytic, cross-sectional study. For the descriptive analysis, continuous variables were informed as mean and SD. Categorical variables were reported in percentage. A multiple linear regression model was performed, taking impaired activity due to health as the dependent variable, adjusted by potential confounders. The performance of the model was evaluated (assumptions, atypical observations, multicollinearity). If linearity and/or homoscedasticity was not fulfilled, transformation of variables or robust regression was performed, as appropriate.

**Results:** 252 patients were included, 98.38% were female, mean age of 52.64 years (+/-14.84). The mean percentage of working time lost due to health was 15.74% (+/-30.12.CI95%:9.58- 21.90); disability work due to health was 27.18% (+/-30.19. CI95%:21.25-33.11), the total disability percentage due to health was 33.70% (+/-35.76.CI95%: 26.39-41.01) and impaired activity due to health was 34.17% (+/-30.94.CI95%:30.35-37.99). The following variables showed significantly and independent association in the multivariable analysis of robust regression: xerostomy ( $\beta$  coefficient: 0.25. CI 95%: 0.13-0.37), arthritis ( $\beta$  coefficient: 11.15.CI 95%:0.55-21.74), mild depression ( $\beta$  coefficient: 8.77. CI 95%: 1.43-16.12), moderate depression ( $\beta$  coefficient: 25.47. CI 95%: 13.84-37.10), moderately severe depression ( $\beta$  coefficient: 36.92. CI 95%: 26.91-46.93), severe depression ( $\beta$  coefficient: 32.12. CI 95%: 16.31- 48.10). The mean impaired activity due to health was 38.24% (+/- 30.67) in patients treated in public centers vs 28.04% (+/-30.61) on private centers, being this difference statistically significant. No statistically significant differences were found between patients with full or higher secondary education ((32.96% (+/- 31.03)) vs patients with lower educational level ((35.73% (+/-31.08)).

**Conclusion:** We found a decrease in the score of all WPAI scales. Arthritis, xerostomy and depression were significantly and independently associated with impaired activity due to health. The patients treated in public centers presented a greater impaired activity. This could be an expression of the impact of the socio-economic status in these aspects.

## **Mapping Paindetect, a Neuropathic Pain Screening Tool, to Patient-Reported Outcomes Measurement Information System (PROMIS) 29 in Patients with Rheumatoid Arthritis: Developing a Neuropathic Pain Scale As a Measure of Treatment Outcome**

Yong Gil Hwang<sup>1</sup>, Lei Zhu<sup>2</sup>, Ajay Wasan<sup>3</sup> and Larry W. Moreland<sup>1</sup>, <sup>1</sup>Rheumatology & Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Departments of Anesthesiology and Psychiatry, University of Pittsburgh, Pittsburgh, PA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate relationships between painDETECT (PDQ), neuropathic pain screening tool, and patient-reported outcomes measurement information system (PROMIS) 29 in patients with rheumatoid arthritis (RA).

**Methods:** For rheumatoid arthritis (RA) subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER), a cross-sectional analysis was performed for all RACER patients who completed PDQ and PROMIS29 short form. Association between PDQ and PROMIS29 was evaluated by Spearman's correlation coefficient. Multiple regression models were conducted for PROMIS29 domain scores, adjusting for age, gender, race, RA disease activity measured by clinical disease activity index (CDAI). Analysis of variance and pairwise comparisons for adjusted scores were performed among PDQ classifications and standardized mean differences were calculated to assess the magnitude of effect.

**Results:** For the 302 subjects analyzed, age was 63.8 +/- 12.4 (mean +/- SD) years with disease duration of 18.4 +/- 11.9 years. PDQ score was moderately correlated with pain severity (current, average pain for the past week, and past month, rho = 0.52, 0.60, 0.56, p < 0.001, respectively). PROMIS29 scores showed poorer physical function, participation in social role and higher depression, anxiety, fatigue, and sleep disturbance across PDQ classifications from nociceptive (N=225, 74.7%) to transitional (45, 14.9%) to neuropathic pain group (N=31, 10.3%) (Figure 1 and 2). Pairwise comparisons of PDQ classifications for adjusted PROMIS29 domain scores showed significantly worse health status for neuropathic pain group relative to both nociceptive and transitional group (Table).

**Conclusion:** Mapping the relationships between PDQ and PROMIS29 domains showed classifications by PDQ of nociceptive, transitional and neuropathic pain are characterized by overall decremental health status measured by PROMIS29. These data support the PDQ score as a possible treatment outcome measure and its use in RA management.

Table. Pairwise comparison of PROMIS29 domain scores across painDETECT classifications (Noci: Nociceptive, Tr: Transitional, NeP: Neuropathic, SMD: standardized mean difference, PFA: physical function, ANX: anxiety, DEP: depression, FTG: fatigue, SLP: sleep disturbance, SRP: Abilities to participate in social role, PIN: pain interference)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ultrasound (US) is able to show subclinical synovitis in patients (pts) with rheumatoid arthritis (RA) who are in clinical remission (CR); this has been proposed as a predictive factor for both clinical flares and progression of the structural damage in CR pts. The aim of this work was to investigate the US characteristics of RA pts presenting either CR or low disease activity (LDA).

**Methods:** in 2015 and 2016 an educational event focus on the added value of US in RA pts was held in 22 rheumatology centers in Italy. After a brief presentation on the evidence of the added value of US for the clinician given by expert sonographers (rheumatologists with a special interest in US who were performing US as their usual activity since many years), in every center, the local rheumatologists provided RA pts to be examined by US. All of the US machine were identical both for type (Logiq E R7, General Electrics, with a 4.2-13 MHz linear probe) and settings (both for grey-scale and power Doppler (PD)). Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). The US examination was performed bilaterally on wrists, MCP and MTP joints, looking for synovitis (effusion, synovial proliferation and PD) and erosions. The positive findings were scored according to a 0-3 score for synovitis components and presence/absence for erosions; the number and dimensions of the largest erosion were also registered.

**Results:** demographic and descriptive data of the 1466 pts examined are reported in Table I. Pts were divided on the basis of the DAS28 result. A statistically significant difference in age was registered between the group in CR and the group with DAS28>3.2 (p=0.003), while no differences were found for HAQ or MTX use. Higher prevalence of findings (regardless the score) was present in LDA group with respect to the CR one for effusion, synovial proliferation, PD and erosions, with significant differences for effusion (global, wrist, MCP and MTP joints; p=0.001, 0.024, 0.001 and 0.000 respectively), synovial proliferation effusion (global, wrist and MTP joints; p=0.019, 0.005, and 0.029 respectively), PD positivity (global, wrist, MCP and MTP joints; p=0.000, 0.000, 0.001, and 0.000 respectively) and erosions (global and MCP joints; p=0.009 and 0.000 respectively).

**Table I: demographic data**

	DAS28 <2.6	DAS28 2.6-3.2	DAS28>3.2
N (M:F)	271 (69:202)	323 (70:253)	139 (26:113)
Age (mean±SD; yy)	56.6±13.9	59.2±11.7	61.0±11.1
Disease duration (mean±SD; dd)	2619.08±2686.78	2850.47±2509.29	2046.39±1951.16

**Conclusion:** in this large group of RA pts, US showed frequent abnormalities both in the CR and in the LDA group. Our results are in line with previous studies and confirm that US is a useful imaging tool for the detection of subclinical joint abnormalities in RA.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient engagement in research has become a key requirement of many research funding organizations in Western countries. The principle of justice is central to patient engagement, indicating an ethical imperative for people who may be affected by health research to have the right, if they choose, to say in what and how research is undertaken. There is, however, little empirical evidence to better understand ethical issues encountered in the everyday practice of patient engagement, particularly from the perspectives of patients. Our objective is to explore benefits and risks within patient-researcher relationships from the perspectives of arthritis patients with experience engaging in the research process.

**Methods:** The project is jointly designed and conducted by researchers and patient partners. Participants were invited to take part in a one-hour in-depth interview, in-person or by phone. Eligible participants were current or past members of an arthritis patient advisory board in a research centre. A semi-structured topic guide was used with prompts and probes to elicit detail about relationships with researchers. An iterative thematic analysis was conducted using constant comparison methods. A lens of relational ethics was found to highlight benefits and risks originating in emergent themes. Key elements of an ethical relationship, according to a relational ethics framework, include mutuality (encompassing deep understanding of each other's values), choice and consideration of context.

**Results:** In 2015-16, 22 participants (aged between 26 and 68 years old) were recruited. Twenty-one (95%) were female, and 14 (64%) had at least one university degree. Of the 21 participants who reported, 12 (55%) had inflammatory arthritis, 5 (23%) had osteoarthritis, and 4 (18%) had both. Time spent as a patient partner ranged from 1 month to 10 years. Benefits and risks in patient-researcher relationships emerged across 2 distinct but related themes: 1) "*Being Heard*": Participants described being heard as a mutual benefit in respectful patient-researcher relationships. Being heard involved having patient and researcher perspectives taken seriously and acted upon in the research process, which required patients and researchers to value different ways of knowing (e.g., lived experience, objective fact); 2) "*Being with Supportive People*": Participants valued researchers who actively supported them to manage (actual and potential) negative physical and emotional impacts (e.g., fatigue, stress, uncertainty) of engaging in research in the context of their daily lives.

**Conclusion:** Findings make visible important values and behaviours for developing and maintaining ethical patient-researcher relationships, from the perspectives of patients with varying experiences of engaging in arthritis research. These values and behaviours can serve as a guide for researchers and patients who have chronic illness to anticipate and address benefits and risks that may arise in their engagement with each other. Our findings are a critical step to fostering everyday ethical practices of patient engagement in research that are anchored in patients' perspectives.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** This study is to evaluate pattern shifts and outcome trends of treat-to-target (T2T) under standard of care in ankylosing spondylitis (AS) patients with interactive Smart System of Disease Management (SSDM).

**Methods:** Ankylosing Spondylitis Disease Activity Score (ASDAS) was adopted to evaluate the degree of disease activity and the inflammatory response in AS patients. ASDAS score  $\leq 1.3$  represents inactive disease (ID) status and achievement of T2T.

SSDM is a set of disease management tool based on mobile internet. The patient's terminal system includes self-evaluation (ASDAS, HAQ), lab test results and medication management. After data entry, patients can synchronize data to the mobile terminal of their authorized rheumatologist. Under the guidance of health professionals, patients downloaded SSDM and registered, then self-evaluated ASDAS and was required for repeated evaluation after leaving the hospital. Data were analyzed and processed by IBM SPSS 22.0. The one-way ANOVA was used to analyze the influential factors. The chi square test was adopted to compare rates between groups, with  $P < 0.05$  as the criterion for the significant differences.

**Results:** From January 2015 to June 2017, 4,668 AS patients from 251 hospitals registered on SSDM, with mean age of  $33.63 \pm 11.47$  years and median disease duration of 20.47 (0.73 - 66.73) months. Among them, 3,311 patients performed ASDAS evaluation at least once, totally 5,433 times; 989 patients carried out repeated evaluation for 2,122 times (male 690, female 299) through  $>5$  month follow-up.

Among patients repeated assess ASDAS, baseline rate of T2T was 23% (228/989), and the final rate of T2T was significantly increased to 34% (334/989) ( $\chi^2 = 392.114$ ,  $p < 0.001$ ) after median evaluation of 3 (2-16) times per patient. The mean score of ASDAS decreased from  $2.13 \pm 1.07$  to  $1.81 \pm 1.07$  (mean improvement  $-0.32 \pm 0.58$ ,  $p < 0.001$ ). Analysis of influential factors showed that: among T2T patients in baseline (228, 23%), 151/228 (66%) remained T2T and 77/228 (34%) relapsed at the end of follow-up, there was no difference in age, sex distribution and disease duration between maintaining T2T achiever and the relapser but the mean interval of ASDAS evaluation in maintaining T2T achiever was significantly shorter than that of the relapser (26 days vs. 40 days,  $p < 0.05$ ). Among patients failed to reach target in baseline (761/989, 77%), 183/761 (24%) patients achieved T2T and 578/761 (76%) patients remain failure of T2T. There were no significant difference in age, sex distribution and disease duration between T2T achievers and patients remaining failure of T2T, but the mean evaluation interval of the achievers was significantly shorter than that of the latter (30 days vs. 40 days,  $p < 0.05$ ).

**Conclusion:** T2T rate of AS in daily care is low in China. Significant improvement is observed under applying SSDM through empowering patients. Regularly performing self-management with SSDM associates with the achievements of maintaining T2T pattern and converting the patterns from failure of T2T to T2T. SSDM warrant a further evaluation and clinical application.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treat-to-Target (T2T), achieving a DAS28 lower than 2.6 (remission) or below 3.2 (low disease activity), is the main management strategy. The Smart System of Disease Management (SSDM) is an interactive mobile disease management tool, including the doctors' and patients' application system. The patients can perform self-evaluation, including DAS28, morning stiffness time (MST) and HAQ, and enter medical records (including medication and laboratory test results) through the mobile application. The data synchronizes to the mobiles of authorized rheumatologists through cloud data base and advices could be delivered. The purpose of this study is to evaluate the patterns of T2T and related influential factors among RA patients after applying SSDM in real world.

**Methods:** Patients were registered through downloading the SSDM application, then were trained to master SSDM by health professionals in clinics. The first assessment for DAS28 were performed as baseline. The patients were required to perform repeated assessments once a month after leaving hospital.

**Results:** From June 2014 to June 2017, 1,232 RA patients from 145 hospitals across China were followed up for more than 6 months through SSDM, and the results at baseline and in final follow up were shown in table 1. The rate of T2T achievers were 40% (491/1,232) at baseline, and improved significantly to 64% (793/1,232) after 6 month follow up. Among T2T achievers at baseline, 75% (369/491) maintained T2T, 25% (122/491) relapsed. Compared with relapsers, T2T maintainers performed more self-evaluation (5.78 vs 4.73, P=0.017), took medications at higher ratio on DEMARDs (69% vs 59%), lower ratio on NSAIDs (4% vs 13%, p<0.01) or glucocorticoid (3% vs 8%, p<0.01). Among patients failed to reach T2T at baseline, 57% (424/741) achieved T2T after 6 months. Comparing with 6 month failure (317/741), new T2T achievers got shorter the MST (16.77±27.12 vs 27.03±33.76, p£¼0.001), lower HAQ score (2.17 ± 3.36 vs 3.36 ± 4.05, p£¼0.001) at baseline, performed more times of self-evaluation (6.56 vs 5.35, P=0.007).

However, even in patients of 6 month failure, the MST and HAQ score improved significantly in final follow up comparing with those at baseline (16.59;À28.76 vs 27.03;À33.76, p£¼0.001; 2.77;À3.52 vs 3.36;À4.05, p£¼0.001, respectively).

**Conclusion:** After interactive disease management via SSDM for more than 6 months, the rate of T2T in RA patients increased significantly. More NSAIDs and glucocorticoid but less DMARDs were associated with higher probability of relapse. The patients perform more self-evaluations through SSDM had lower probability of relapse and higher T2T maintaining and achievement. SSDM is a valuable tool for long term RA follow-up through empowering patients. Future RCT of improvingT2T outcome through intervention of above influential factors with SSDM is warranted.

Table1. Results at baseline and in the final follow up from 1232 patients with RA

	Baseline Total (1232)	Achiever of T2T (491, 40%)		Failure of T2T (741, 60%)	
	Final follow up (>6 month)	Maintainer of T2T 306 (75%)	Relapse 122 (25%)	Maintaining failure of T2T 424 (57%)	Achiever of T2T 317 (43%)
Age (years): mean ± SD		49.29 ± 12.83	47.89 ± 12.3	50.38 ± 13.59	48.36 ± 12.64
Disease duration (months): mean ± SD		69.04 ± 110.18	59.49 ± 89.23	76.95 ± 114.57	56.13 ± 93.46
Times of patient self-evaluation and data entry: mean ± SD		5.78 ± 4.35	4.73 ± 3.75*	5.35 ± 5.75	6.56 ± 6.34**
Medication	DMARDs (%)	69%	59%	62%	62%
	NSAIDs (%)	4%	13%	10%	10%
	Glucocorticoids	3%	8%	4%	3%
	Medication quantity	2.99 ± 1.77	3.48 ± 1.71	3.50 ± 1.99	3.44 ± 1.64
DAS28: mean ± SD	Baseline	2.29 ± 0.61	2.41 ± 0.39	4.94 ± 1.15	4.37 ± 1
	Final follow up	2.15 ± 0.63	4 ± 0.65	4.45 ± 1	2.38 ± 0.57

## Youtube Videos on Rheumatoid Arthritis: A Qualitative Analysis of Views and Content

Mosaab Mohameden<sup>1</sup>, Baker Alkhairi<sup>2</sup>, Seba Issa<sup>3</sup>, Asmaa Mohameden<sup>4</sup> and Candice Yuvienco<sup>5</sup>, <sup>1</sup>Internal Medicine, University of California San Francisco - Fresno Medical Education Program, Fresno, CA, <sup>2</sup>Internal Medicine, Blake Medical Center, Bradenton, FL, <sup>3</sup>Pediatrics, American University of Beirut, Beirut, Lebanon, <sup>4</sup>Internal Medicine, School of Medicine, Almaarefa Colleges for Science and Technology, Ad Diriyah, Saudi Arabia, <sup>5</sup>Internal Medicine, Division of Rheumatology Director, University of California San Francisco, Fresno Medical Education Program, Fresno, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis is a chronic potentially disabling disease affecting about 1.3 million people in the U.S. and as much as 1% of the worldwide population. Patient education plays a paramount role in rheumatoid arthritis management. Patients use the internet, and particularly social media, to learn about their medical condition. Youtube is the second largest search engine after Google and the most visited social media site with more than two billion views every day. In our study, we aim to evaluate the quality of material available for rheumatoid arthritis patients on Youtube.

**Methods:** Youtube.com main page was queried for the search term “Rheumatoid Arthritis.” The resulting videos were evaluated for content, duration, source, and audience interaction: number of views, likes, and dislikes. Content was classified as useful, misleading or patient’s views/experience. Useful videos were further analyzed for content using the published DISCERN instrument with 16 questions each consists of 5-point scale for assessing the quality of health information.

**Results:** The search term “rheumatoid arthritis” retrieved about 160.000 videos sorted by default filter of “relevance.” The top 20 videos were analyzed as these are the videos that patients were likely to view by visitor statistics. On average, videos had 15:52 minute duration, 76005 views, 639 likes, and 23 dislikes. 40% of videos were from non-professional educational groups, 30% from individuals/patients, 20% from health care professionals, 5% from news agencies, and 5% from health care organizations. 50% of the videos were classified as useful, 30% were patient views/experience, and 20% were misleading. Useful videos scored an average of 3.1 out of 5 on the DISCERN scale indicating fair quality. 60% of the useful videos were from non-professional educational groups with average DISCERN score of 3.5 out of 5. 20% were from health care professionals with average score of 2.5 out of 5. 10% were from individual/patient experience with a score of 2 out of 5. 10 % were from news agency reports with a score of 3 out of 5.

**Conclusion:** Despite being the most visited social media site and the second largest search engine, Youtube lacks high quality education materials for patients with rheumatoid arthritis. Majority of videos were from non-professional educational groups with fair quality. Healthcare organizations and professionals contributed to only 20% of Youtube videos on rheumatoid arthritis. Rheumatologists and professional healthcare organizations are encouraged to engage in patient education using Youtube given the high utilization frequency of this site by patients, but the quality of education must be stringently overseen, and misleading views have to be corrected.

## **Can Achieving Remission Improve Work Ability and Quality of Life in Early Rheumatoid Arthritis (RA) Patients? a Prospective Cohort Study**

**Ho Man Lam**<sup>1</sup>, Tsz Ho CHENG<sup>2</sup> and Lai-Shan Tam<sup>1</sup>, <sup>1</sup>Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, <sup>2</sup>Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** RA patients often suffer from impaired work ability and reduced health related quality of life (HRQoL). Whether achieving remission through tight-control treatment strategy using conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) can improve work ability and HRQoL remains unclear. The aim of this study was to ascertain whether achieving remission can improve work ability and quality of life in early RA patients.

**Methods:** Early RA patients with symptom onset <2 years were recruited. All patients satisfied the 2010 ACR-EULAR classification criteria for RA (>=6 points). Remission status was measured by Disease Activity Score 28 (DAS28) and Simple Disease Activity Index (SDAI) every 3 months. Work ability was evaluated by working ability index (WAI) compared to life time best (score from 0-10, with 10 as best). HRQoL was assessed by 36-Item Short Form Survey (SF-36), Health Assessment Questionnaire Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy (FACIT) and EuroQol five dimensions questionnaire (EQ-5D).

**Results:** A total of 199 (51; 13 years old, 158[79.4%] female, 146[73.4%] employed) patients completed one year follow up. At baseline, unemployed patients have a higher physician global assessment score, more swollen joints, lower WAI, lower EQ-5D and higher HAQ-DI (Table1). Using multivariate linear regression, achieving DAS28 and SDAI remission at ≥ 2 visits are independent predictors for better WAI, HRQoL, HAQ, FACIT and EQ5D at one year after adjustment for other covariates (Table2). Achieving remission only once in the first year was not associated with improvement in WAI.

**Conclusion:** Achieving at least two time remissions is important in improving patientsf work ability and HRQoL.

## The Effects of Structural Damage on Functional Disability in Psoriatic Arthritis

Andreas Kerschbaumer<sup>1</sup>, Gabriela Supp<sup>1</sup>, Josef S. Smolen<sup>1,2</sup> and Daniel Aletaha<sup>1</sup>, <sup>1</sup>Medical University Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria, <sup>2</sup>2nd Department of Medicine, Hietzing Hospital, Vienna, Austria  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017  
**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III  
**Session Type:** ACR Poster Session C  
**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Functional outcomes are central in patients with chronic inflammatory musculoskeletal diseases. In a secondary data analysis of the GO-REVEAL trial we investigated if structural damage is linked to functional impairment in patients with psoriatic arthritis (PsA).

## Methods:

We analyzed data of patients enrolled in the GO-REVEAL trial including modified Sharp-van-der-Heijde X-ray -scores for PsA (mSVDHS) performed at weeks 0, 24, 52 and 104 (n=363). In longitudinal data analyses, all patients and patients in Disease Activity index for PSoriatic Arthritis (DAPSA) remission (n=117), utilising all remission visits (REM; DAPSA <4), we used the HAQ as dependent variable and total mSVDHS, joint space narrowing (JSN) and erosion (ERO) scores, respectively, as independent variables. To analyse effects of structural damage on the potential to improve physical function, we identified a subgroup of patients who had major functional limitations at baseline (HAQ $\geq$ 1) and showed a major DAPSA-response. In this model we assessed the effect of mSVDHS on changes in HAQ (n=67). As validation cohort, we analyzed routine PsA patients from our clinic with complete cDAPSA (DAPSA without CRP) and mSVDHS (n=160).

## Results:

As visualised in figure 1, mSVDHS (panel A) JSN and ERO (panel B+C) had significant effects on HAQ in all patients (ALL) and patients in REM.

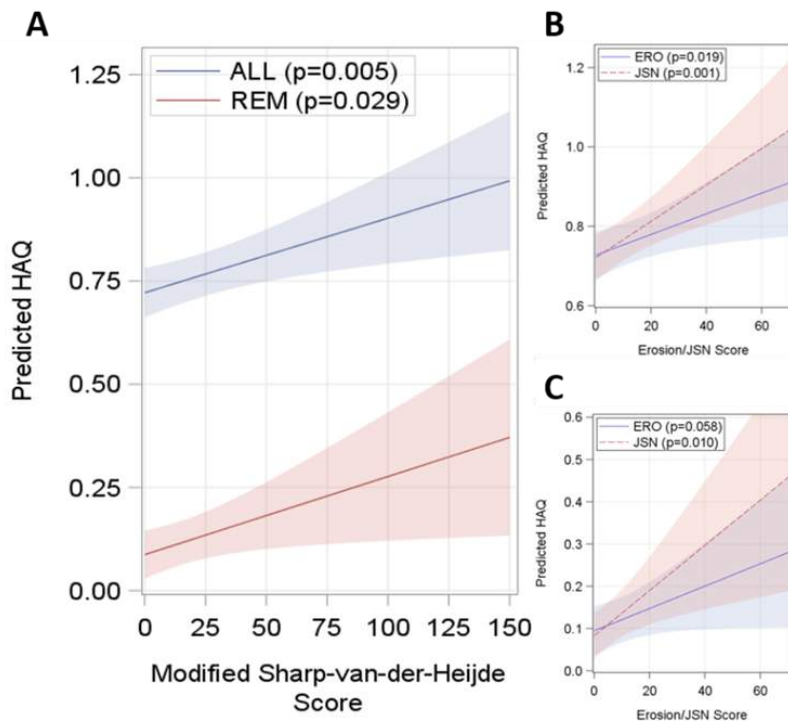

In the second analysis (figure 2), in patients achieving DAPSA major response, results were significant for the association of mSVDHS and JSN with relative (REL) and absolute (ABS) HAQ changes (panel A). Additionally, higher estimates of JSN, compared with erosion scores could be observed, with absolute (B) and relative (C) HAQ change as outcome parameter.

These results could be confirmed in the validation cohort and in analyses using the SF-36 Physical Component Score instead of the HAQ as outcome variable in GO-REVEAL patients.

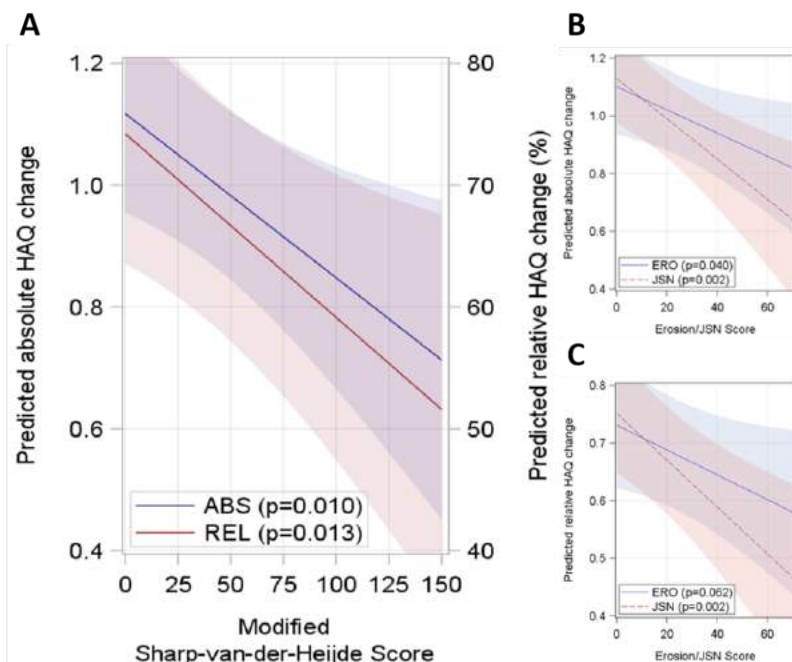

## Conclusion:

Our results reveal that responsiveness of functional impairment decreases with increasing joint damage. They further suggest that JSN is functionally more important than erosions. Both, achievable HAQ levels and HAQ responses are negatively impacted by a high degree of structural damage. Consideration of these components is clinically and therapeutically relevant, as the HAQ component related to inflammation is expected to be reversible, while that related to damage is not.

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) raises cardiovascular disease (CVD) risk, yet RA patients underestimate their personal risk. The principle of self-management posits patients will be self-motivated stewards of their health if they have the knowledge, resources, and support to influence their care. We assess how an education handout aimed at improving RA patients' self-management of CVD risk changes their knowledge, attitudes, and behaviors. We hypothesize it will improve knowledge with little effect on attitudes and behaviors.

**Methods:** We prospectively recruited RA patients from an outpatient general rheumatology clinic to read a patient education handout and answer three surveys at time of enrollment (week 0), week 1, and week 8. We distributed education handouts after completion of the week 0 survey. Surveys at weeks 0 and 8 contained questions about behavioral risk factors from the Centers for Disease Control's Behavioral Risk Factor Surveillance System, novel Likert scales ranking patients' attitudes about CVD risk, and the Heart Disease Fact Questionnaire-Rheumatoid Arthritis (HDFQ-RA), a validated measurement of RA patients' knowledge of general CVD and RA-specific CVD risk. The survey at week 1 was the HDFQ-RA. Wilcoxon signed-rank test ( $\alpha=0.05$ ) analyzed changes in HDFQ-RA scores and Likert rankings, while McNemar's test ( $\alpha=0.05$ ) analyzed changes in behaviors.

**Results:** A total of 38 participants completed all surveys and read the handout. Most patients were female (89%), aged 61.5 ( $\pm 11.9$ ) years old with a mean RA duration of 15.3 ( $\pm 13.3$ ) years. Based on total HDFQ-RA scores, both general and RA-specific CVD knowledge significantly improved at week 1 and was sustained at week 8 (table 1).

Table 1:

Survey	Mean Change	P-Value
<b>Total Heart Disease Fact Questionnaire-Rheumatoid Arthritis (HDFQ-RA) Score (13 questions)</b>		
Week 0 vs Week 1	1.342	<0.001
Week 0 vs Week 8	1.421	<0.001
Week 1 vs Week 8	0.079	0.549
<b>General Cardiovascular Disease (CVD) Risk Knowledge from HDFQ-RA Score (9 questions)</b>		
Week 0 vs Week 1	0.895	<0.001
Week 0 vs Week 8	0.816	<0.001
Week 1 vs Week 8	-0.079	0.407
<b>Rheumatoid Arthritis-Specific CVD Risk Knowledge from HDFQ-RA Score (4 questions)</b>		
Week 0 vs Week 1	0.447	0.015
Week 0 vs Week 8	0.605	<0.001
Week 1 vs Week 8	0.158	0.041

Based on Likert scales, only attitudes regarding the influence of RA disease activity on CVD risk changed ( $p=0.012$ ). A total of 23 of the 38 participants (73.7%) stated the handout motivated them to make lifestyle changes, and a significant change was noted in exercise at week 8 ( $p=0.016$ ), but not in smoking cessation or diet ( $p>0.99$ ).

**Conclusion:** A patient education handout improved RA patients' self-management of CVD risk, not only enhancing knowledge but also improving lifestyle self-management, as patients increased their exercise habits over an 8-week period. Patients also believed that RA management is more important in mitigating their CVD risk after reading the handout. This data suggests a patient handout can effectively change patients' understanding of CV risks and influence certain lifestyle factors, such as exercise. Further study is needed to review self-management strategies that may further augment knowledge, attitudes, and behaviors of CVD in RA patients and potentially improve CV risk factors.

## Secondary Fibromyalgia Is Not Associated with Higher Likelihood of Patient-Physician Discordance in Global Assessment in Patients with Osteoarthritis and Rheumatoid Arthritis

**Isabel Castrejón**, Shakeel M. Jamal and Najia Shakoor, Division of Rheumatology, Rush University Medical Center, Chicago, IL  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pain is the strongest driver of patient-physician discordance in global assessment in patients with rheumatoid arthritis (RA) and osteoarthritis (OA). Having secondary fibromyalgia (FM), a disorder with vague and nonspecific symptoms (e.g.,

widespread body pain or fatigue) may increase the likelihood of discordance. We aim to analyze if patients with RA and OA presenting with secondary FM have higher likelihood of discordance.

**Methods:** All patients complete a multidimensional health assessment questionnaire (MDHAQ) as part of their routine care which includes scores for physical function, pain, PATGL, fatigue, and demographic data. Rheumatologists complete a RheuMetric including 4 visual analogue scales: a physician global assessment (DOCGL) and three subscales for inflammation, damage, and distress/FM. A mean difference PATGL-DOCGL  $\geq 2$ cm was considered a relevant discordance. Patients with a clinical diagnoses of OA or RA were classified into 3 categories: PATGL  $\geq$  DOCGL by 2/10 units, PATGL = DOCGL, and DOCGL  $\geq$  PATGL by 2 units. Secondary FM was evaluated using two criteria: 1) clinical diagnosis by the treating rheumatologist. 2) A score  $\geq 6$  in the VAS for distress/FM. The percentage of patients in each group was compared using chi-square.

**Results:** 243 OA and 216 RA patients were included. Patients with OA were older and showed higher scores for PATGL, pain, and fatigue (data not showed) and higher level of discordance (PATGL>DOCGL) in comparison with RA (34% vs 18%,  $p<0.001$ ). A higher percentage of patients with OA showed secondary FM (15% versus 3%,  $p<0.001$ ) and a VAS for distress  $\geq 6$  (12% versus 5%,  $p=0.01$ ) in comparison with patients with RA. Patients with OA and secondary FM have **higher** level of concordance (PATGL=DOCGL) in comparison with patients with OA without secondary FM (Table). There were no significant differences in the RA patients group when comparing patients with and without secondary FM (Table).

<b>Table.</b> Level of discordance/concordance in patients with or without secondary FM with OA or RA						
	<b>OSTEOARTHRITIS</b>			<b>RHEUMATOID ARTHRITIS</b>		
<b>Discordance groups, no. (%)</b>	<b>No Secondary FM</b>	<b>Secondary FM</b>	<b>p</b>	<b>No Secondary FM</b>	<b>Secondary FM</b>	<b>p</b>
	<b>207 (85%)</b>	<b>36 (15%)</b>		<b>210 (97%)</b>	<b>6 (3%)</b>	
PATGL>DOCGL	72 (35%)	10 (28%)	0.03	37 (18%)	2 (33%)	0.58
PATGL=DOCGL	<b>110 (53%)</b>	<b>26 (72%)</b>		141 (67%)	3 (50%)	
PATGL<DOCGL	25 (12%)	0 (0%)		32 (15%)	1 (17%)	
	<b>Distress VAS&lt;6</b>	<b>Distress VAS<math>\geq</math>6</b>	<b>p</b>	<b>Distress VAS&lt;6</b>	<b>Distress VAS<math>\geq</math>6</b>	<b>p</b>
	<b>184 (88%)</b>	<b>24 (12%)</b>		<b>188 (95%)</b>	<b>9 (5%)</b>	
PATGL>DOCGL	65 (35%)	5 (21%)	0.24	31 (16%)	0 (0%)	0.40
PATGL=DOCGL	97 (53%)	17 (71%)		127 (68%)	7 (78%)	
PATGL<DOCGL	22 (12%)	2 (8%)		30 (16%)	2 (22%)	

**Conclusion:** Patient-physician discordance is more prevalent in patients with OA versus RA. FM is also more prevalent in OA versus RA but the presence of FM does not account for the higher discordance rate. In fact, those with OA and FM appear to have more concordant scores with their physicians. The dual diagnoses of FM may make the physicians more sensitive to the pain of their patients.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The patient global assessment (PGA) is widely used in disease activity scores for RA, including the CDAI, SDAI, and DAS28. While pain has been shown to be a major component of this score, other specific contributors of the patient experience to this score remain less clear. We examined the contribution of multiple domains of health-related quality of life measured by Patient-Reported Outcomes Measurement Information System (PROMIS) computer adapted testing. These measures by nature have heavily correlated structures which may lead to erroneous results from regression. Here, a factor analysis was used to identify latent variables. Using these latent variables along with clinical characteristics, we developed a multivariable model to explain the relative contributions of these measures to the PGA.

**Methods:** We conducted a cross sectional analysis of a cohort of 196 patients with RA receiving guideline-based care in an academic rheumatology clinic. PROMIS computer-adapted tests, including domains of physical function, pain interference, social participation, fatigue, sleep disturbance, depression, and anxiety were used. Factor analysis was used to identify factor structures. A multivariable linear regression model was then developed to identify an optimal model including these factors and other clinical characteristics.

**Results:** Among 196 patients (mean age 54.8 +/- 13.4 years, 81% female, mean RA duration of 11 +/- 9.6 years, mean PGA 29). Most (69%) were well-controlled, in remission or low disease activity. Factor analysis revealed three major factors. The first, referred to as "function", had highest loading of physical function, followed by pain interference, fatigue, and social participation. The second, referred to as "emotional distress", had equal loading of depression and anxiety. A third had loading only on sleep disturbance. "Function" alone, in univariable analysis, explained 52% of the variance in PGA. A multiple linear regression including "function", sleep disturbance, swollen joint count, sex, BMI, and an interaction term of each of the three factors with one another explained 59% of the variance in PGA.

**Conclusion:** A single factor including fatigue, pain interference, physical function, and social participation explained most of the variance in the PGA in univariable regression. Emotional distress was not associated with the PGA when other factors were adjusted for. These data suggest that the PGA was primarily related to one latent variable related to "function", and was influenced by "emotional distress" only insofar as it modified other symptoms.

	Univariable			Multivariable – Adj R <sup>2</sup> = 0.59	
	β	p-value	R-squared	β	p-value
"Function"	20.8	<0.0001	0.52	18.0	<0.0001

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The discordance between patient global assessment (PGA) and physician global assessment (PhGA) of rheumatoid arthritis (RA) disease activity may be problematic in clinical practice. The aim of this study was to identify determinants of this discordance using a nationwide RA database in Japan (*NinJa*) with special attention to large joint involvement.

**Methods:** We investigated 12,043 adults with RA and used a discordance cutoff of 3 cm. Large joint involvement was investigated using novel joint indices ( $x$ ,  $y$ ,  $z$ ) and the large joint index (Nishiyama S et al. *Rheumatol Int.* 2012;32:2569), in which  $x$  and  $y$  were the indices for upper and lower joints, respectively, and  $z$  was for large joint predominance. Predictors of PGA-PhGA discordance and determinants of PGA and PhGA were analyzed by multivariate logistic and linear regression models, respectively. In logistic regression analysis, the odds ratio (OR) for positive discordance ( $\text{PGA} \geq \text{PhGA}$  by 3 cm) was computed using a concordance (no discordance) group as reference.

**Results:** Multivariate logistic regression identified age (OR: 1.01 [95% confidence interval: 1.01–1.02]), pain (2.15 [2.08–2.22]) and modified Health Assessment Questionnaire score (1.56 [1.39–1.75]) as significant predictors of positive discordance. On the other hand, TJC (0.93 [0.91–0.94]), SJC (0.92 [0.90–0.94]), CRP (0.88 [0.83–0.93]), class 3-4 (0.63 [0.53–0.76]),  $Z$  (0.72 [0.59–0.88]), and the large joint index (0.59 [0.47–0.74]) predicted significantly against positive discordance. Linear regression analysis demonstrated that PGA was mainly determined by pain, whereas PhGA was determined by various factors, including the large joint index (Figure 1) and  $Z$ .

**Conclusion:** RA care providers should focus on pain, functional disability and the size of affected joints to decrease PGA-PhGA discordance and to share with patients a common recognition of disease activity.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time: 9:00AM-11:00AM**

**Background/Purpose:** Non-adherence to gout medication is high. This may be due in part to patients' belief that gout is primarily caused by overindulgence in certain foods and beverages and that it can therefore be alleviated by diet change alone. We sought to identify whether an incongruence existed between professional web-based content created for gout patients and patient's online discussions.

**Methods:** Using word frequency analysis and NLP, we examined linguistic differences in a convenience sample of professional webpages and online patient discussions for gout, comparing content from three types of media: 1) consumer literature for patients posted on websites by health organizations (e.g. Gout and Uric Acid Education Society, WebMD, Mayo Clinic) and pharmaceutical companies (n=205 webpages with average of 330 words/page); 2) patient blogs (e.g. gout blogs on patient.com) (n=337 blogs average 641 words/post); and 3) social media (e.g. gout subreddit, a forum on the website Reddit where people can post thoughts or questions for comment) (n=687 original posts average 157 words/post and n=5274 comments average 70 words/comment), excluding posts or comments <20 words. Each unique page on a website relevant to gout was collected and saved into separate text files. After processing and cleaning, consumer sites, blogs, original and reply posts on Reddit were analyzed separately. Differences in psychological processes were identified using LIWC2015 (Pennebaker, Boyd, Jordan, & Blackburn, 2015), a text analysis program measuring a number of psychological dimensions.

**Results:** LIWC analysis yielded two main findings: 1) consumer sites had greater health focus, shown by use of words like *doctor*, *pain*, *disease* ( $d=1.34$ ), while blogs/social media, had slightly greater focus on ingestion (i.e. food/drinks) indicated by words such as *eat*, *sweet*, *feed* ( $d=0.18$ ); and 2) professional and health sites used more risk-oriented language ( $d=0.57$ ) concerned with prevention and losses (e.g. words like *lose*, *lack*, *worse*), while blogs/social media were somewhat more reward-oriented ( $d=0.43$ ) focused on potential benefits and gains of treatment and prevention (e.g. words like *optimistic*, *success*, and *good*). All differences between the two groups were significant ( $p<0.01$ ) and showed comparable patterns across all three types of media. One commonality between sites is frequent discussion of symptoms (e.g. attacks and flares). Word clouds (Figure 1) showed the 30 most common words in each type of site based on basic frequency analysis methods.

**Conclusion:** People living with gout focus more on food and diet, whereas medical professionals emphasize medical causes and preventions/treatments. More research is needed to determine the most effective ways to encourage patients to seek treatment beyond diet and lifestyle changes.

**Figure 1. Most common words by site type**

Preferences For Physical Activity: A Discrete Choice Experiment In People With Chronic Knee Pain

**Background/Purpose:** Understanding preferences for physical activity (PA) can help guide patient consultations. The purpose of this study is to discover the relative importance of attributes associated with the decision to engage in PA for adults with knee pain and to identify whether clusters of adults with shared preferences exist.

**Methods:** A discrete choice experiment was conducted using the PAPRIKA method to determine the relative importance of six attributes: health benefit, enjoyment, convenience, financial cost, effort, and time cost. All participants completed health history questionnaires, patient reported outcomes, and standing knee radiographs. Cluster analysis was performed to identify clusters (subgroups) of adults who place similar importance on attributes. Differences in sample characteristics between clusters were assessed using chi-square for categorical variables and ANOVA with Bonferroni correction for continuous variables.

**Results:** The study sample included 150 adults; 47% were 65 years or older, 72% female, 47% white, non-Hispanic, and 41% black, non-Hispanic. The six attributes in decreasing order of importance (mean weights) were: health benefit (0.26), enjoyment (0.24), convenience (0.16), financial cost (0.13), effort (0.11) and time cost (0.10) (see Figure 1). Table 1 reports on socio-demographic and health outcomes of the full sample and by preference cluster. Three clusters are found in Table 1: Cluster 1 (n=33), for whom enjoyment (0.35) is twice as important as health benefit; Cluster 2 (n=63), health benefit (0.38) is most important; Cluster 3, all attributes are equally important. Cluster 1 was healthiest (e.g., best self-reported health, lowest BMI), Cluster 2 had greatest exercise self-efficacy, and Cluster 3 had greatest number of participants with <sup>3</sup>1 comorbidity.

**Conclusion:** In the full sample, health benefit and enjoyment are the most important attributes associated with the decision to engage in PA, whereas financial cost, effort and time are much less important. Distinct subgroups place different relative importance on the attributes. These findings may help to better target interventions to increase PA engagement.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Juvenile myositis (JM) can worsen quality of life (QoL) via proximal weakness, rashes, and treatments side effects. QoL legacy instruments may be limited by floor effects, unresponsiveness, and cost, justifying the need for new approaches. We present cross-sectional data for initial validation of Patient-Reported Outcomes Measurement Information System (PROMIS) in JM.

### Methods:

Children (5-17 yo) with JM and parents enrolled at routine clinic visits. Demographic/clinical data were recorded, e.g. Physician Global Assessment of Disease Activity (PGA); Disease Activity Score (DAS-Total, -Muscle, -Skin); Childhood Myositis Assessment Scale (CMAS); muscle enzymes; nailfold capillary end row loops (NFC-ERL); neopterin; absolute NK cell count; C4 level. Children (8-17 yo) and parents (of all patients 5-17yo) completed patient/parent-proxy versions of PedsQL-generic core scales and rheumatology module (PedsQL-GC, -RM) and PROMIS Pain Interference, Physical Function (Mobility, Upper Extremity), Fatigue, and Emotional Distress (Depressive Symptoms, Anxiety) fixed short forms. Interrater (i.e. patient-parent) reliability was assessed via intraclass correlation coefficients (ICCs). Concurrent and construct validity were assessed via Spearman's correlation coefficients between PROMIS and PedsQL scales and between PROMIS domains and clinical/lab data respectively.

### Results:

Table 1 lists descriptive data. Patient-Parent ICCs were highest for PedsQL-GC (>0.6 for all except Social domain [=0.48]) compared with PedsQL-RM and PROMIS (>0.4 for all but PedsQL-RM Worry/Communication domains). Patient/parent PROMIS domains demonstrated concurrent validity (Spearman's  $\rho$  >0.4) with related PedsQL-GC/-RM domains (Table 2). Pediatric PROMIS and PedsQL-GC/-RM did not correlate with clinical/lab data; parent-proxy PROMIS fatigue, physical function (mobility, upper extremity), and multiple PedsQL-GC/-RM domains correlated with DAS-muscle and CMAS (Table 3).

Conclusion:

PROMIS pediatric fixed short forms demonstrate similar evidence for reliability and validity compared with PedsQL-GC/-RM in children with JM. Patient and parent-proxy reports differ sufficiently to suggest both should be collected. PROMIS can be considered for clinical/research use in JM.

Table 1: Patient Demographic, Clinical, and Patient-Reported Outcome (PRO) Descriptives

Diagnosis	n (%) / median (IQR)	Patient-Reported Outcomes*	median (IQR)	PROMIS (parent-proxy report)	median (IQR)

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The management of patients with rheumatic diseases is partly guided by the medical history at each clinic visit. Patients however often find it difficult to accurately remember the course of their symptoms between appointments. Regular App-based patients' self-monitoring of disease between clinic visits might provide an innovative and feasible improvement. The COMPASS I study [1] demonstrated that RA patients' self-assessments of disease activity via App correlate strongly with clinicians' assessments.

The main aims of COMPASS II are to assess if continuous self-monitoring of the disease optimises disease management in rheumatic diseases, and to assess the fluctuation of disease activity between clinic visits. This abstract describes the set-up and recruitment of the COMPASS II study in the first 16 months.

### Methods:

The COMPASS II App questionnaire consists of the RAPID3 score, a validated, commonly used PRO to self-assess disease activity. Additionally, patients are asked about their therapy compliance and cortisone dose. COMPASS II is embedded in the SCQM (Swiss Clinical Quality Management for Rheumatic Diseases) registry and hence allows the linkage of data obtained via the WebApp from the patients with routine clinical data collected in the SCQM. Interested SCQM patients with RA, axSpA or PsA are electronically randomized into 3 study arms (Figure). In arm 1 patients and rheumatologists are displayed the self-assessed disease activity over time, the patient directly via the App and the rheumatologists via SCQM. In arm 2 only patients are displayed their chart and in study arm 3 neither sees the recorded data. Patients are encouraged to fill in the App weekly.

### Results:

The COMPASS II App went online in 02/2016. In the first 16 months, 329 patients were enrolled. 65% of patients used the App, 78% of those filled in the questionnaires for longer than a month; currently, the longest follow-up is 16 months. On average patients use the App every 2 weeks.

Patients using the App for longer than 6 months rated the user-friendliness/usability of the WebApp as very positive in terms of the ease of use (mean of 82 on the system usability scale, a score of 68 is considered average [2]) and indicated that they felt a benefit in terms of patient physician communication with a mean score of 58 on the 100-mm VAS.

## Conclusion:

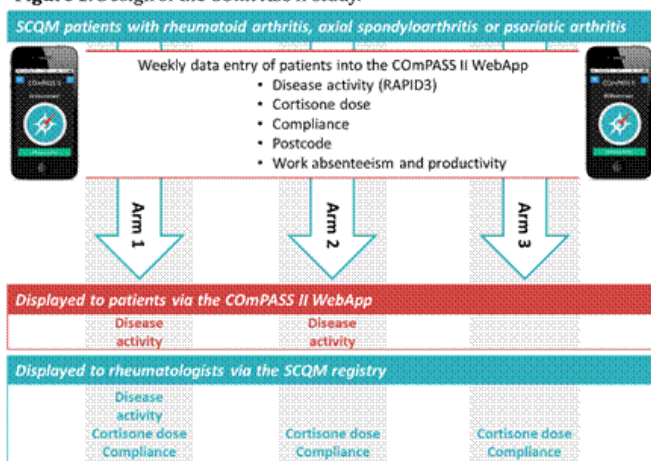

Patients are highly adherent in the App use, rate it as very user-friendly and feel a benefit in patient physician communication. The COMPASS II study will validate the utility of app-based patients' self-assessments in enhancing disease control.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disabilities in daily living and quality of life are key endpoints to evaluate the outcome of treatment for rheumatoid arthritis (RA). Among factors that may contribute to good outcome are adherence and health literacy.

**Methods:** The survey included a representative, nationwide sample of German physicians specialized in RA and patients with RA. The physician questionnaire included the disease activity score (DAS28) and medical prescriptions. The patient questionnaire included fatigue (EORTC QLQ-FA13), health assessment questionnaire (HAQ), quality of life (SF-12), health education literacy (HELP), and patients' listings of their medications.

Adherence was operationalized in various ways: patient-reported (CQR5), behavioral (correspondence between physicians and patients listings of medications), physician-assessed (five-point rating scale ranging from 1=very adherent to 5=not at all adherent) and a combined measure of physician rating (1= very adherent, 0 = less adherent) and the match between physicians' prescriptions and patients' accounts of their medications (1 = perfect match, 0 = no perfect match), leading to three categories of adherence: high, medium and low. Linear regressions were calculated using HAQ and SF-12 (physical and psychological) as dependent variables and adherence, health literacy and the set of demographic and clinical variables as predictor variables.

**Results:** A total of 708 pairs of patient and physician questionnaires were analyzed. The mean age of the patients, of whom 73% were women, was 60 years (SD=12). All results are shown in the multiple regression analyses.

**Conclusion:** This study showed that HAQ and SF-12 were related to adherence and health literacy. This finding highlights the importance of patient education and counseling in order to increase both, medical understanding and adherence to therapy.

## Using PROs to Guide Patient-Centered Conversations and Care in Inflammatory Arthritis: The Patient Perspective

**Clifton O. Bingham III**<sup>1</sup>, Katherine Clegg Smith<sup>2</sup>, Elaine de Leon<sup>2</sup>, Michelle Jones<sup>3</sup>, Anna Kristina Gutierrez<sup>4</sup>, Allie Butanis<sup>5</sup> and Susan J. Bartlett<sup>4</sup>, <sup>1</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, <sup>3</sup>Johns Hopkins University School of Medicine, Baltimore, MD, <sup>4</sup>Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>5</sup>Rheumatology, Johns Hopkins School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although optimal care is patient-centered and grounded in shared decision-making (SDM) between patients and providers, rheumatologists often have little insight into the day-to-day experiences of their patients with inflammatory arthritis. We hypothesized that the use of validated patient-reported outcomes (PROs) querying RA symptoms and impact would provide insight into patient priorities, values, and preferences and facilitate SDM around treatment choices.

**Methods:** Participants in an observational study at an academic arthritis center completed PROMIS fatigue, pain, physical function, sleep, and participation on a tablet in the waiting room. Reports of results in numerical and graphical formats were available during the visit for review and discussion with the rheumatologist. Within 48 hours of the clinic visit, patients completed surveys about the relevancy and impact on the clinical visit. In-depth interviews were conducted with a subset.

**Results:** Survey data are from 68 patients who were mostly white (85%), female (81% with a mean age of 54 (13) and RA duration of 10 (9) years. Interviews with 15 participants provided additional support to themes identified in the survey. Almost all (94%) reported the PRO question addressed important aspects of their health:

- *Addresses a wide range of issues, which is great*
- *It shows the impact my arthritis has on me, not just the pain*
- *Helps give a better overall picture of what's going on*

Most (82%) reported the discussion of results during the visit improved communication and made it easier to raise issues:

- *I love seeing data and graphs -- it really helps me*
- *It focuses...discussion with your physician so you can address the most pressing, sort of prioritize, the issues you want to address*
- *Doctor referred to my answers during discussion*

A few (3%) were unclear if PRO results had been reviewed, or whether care was impacted:

- *I think my doctor [already] treats me well*

**Conclusion:** Patients place high value on PRO information which gives insight into day-to-day life and unmet needs. Expanded PRO assessment with real time review of results provides an opportunity for more patient-centered RA care and SDM by guiding conversations and improving communication about disease-related symptoms and impacts that matter to patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** High-consequence, albeit rare, adverse side effects of osteoporosis medication raise patients' risk perceptions and contribute to non-adherence. In the past decade, fears of osteonecrosis of the jaw (ONJ) and atypical femoral fractures (AFF) have been increasingly reported as barriers to both the initiation of and adherence to osteoporosis medications. We examined the temporal prevalence of self-reported concern about ONJ and AFF as reason for discontinuation of osteoporosis medication.

**Methods:** Activating Patients at Risk for Osteoporosis (APROPOS) enrolled US women from the Global Longitudinal Study of Osteoporosis (GLOW) with previous self-reported fractures and no current use of osteoporosis medication. Using mailed surveys in 2010 (T1), 2012 (T2) and 2013 (T3), women were asked whether they discontinued osteoporosis medication in the prior year because of concerns about ONJ at three time points (T1, T2, T3) and AFF at two time points (T2, T3). We calculated the proportion of women reporting fears of ONJ and AFF among those who discontinued osteoporosis medication, and compared the proportions using chi-square tests.

**Results:** A total of 833 women discontinued osteoporosis treatment at three time points, T1 (N = 255), T2 (N = 471), and T3 (N = 107), respectively. There were no differences in the demographic characteristics between groups. The proportion of women reporting concerns of ONJ was 18.4% (T1), 26.7% (T2) and 64.5% (T3), while 23.5% (T2) and 60.7% (T3) reported fear of AFF as reason to discontinue osteoporosis treatment. These differences were statistically significant ( $p < 0.0001$ ) for all comparisons.

**Conclusion:** The proportion of women reporting concerns of ONJ and AFF increased over time among those women who discontinue osteoporosis medications. Strategies are needed to help patients balance risks and benefits given a significant and temporally growing concern of rare bisphosphonate side effects.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite considerable advancements in pharmacotherapy treatments, millions of people still suffer with Rheumatoid Arthritis (RA). This puts management in the hands of the patients, requiring lifestyle changes to improve symptoms associated with RA. This study of patients with RA examined the efficacy of behavior modification in reducing RA-inducing stressors (1,2) and increasing healthy behaviors proven to reduce symptoms, healthy eating (3,4) and exercise (5). We hypothesized that the program would increase healthy habits and decrease the negative effects of RA.

**Methods:** RA patients (n=127) were enrolled in a 12 week behavior modification program. Each patient was paired with a non-clinical health coach. The patients were contacted once a week by telephone and surveyed about their behaviors and condition. Information about mental and physical health were collected through PROMIS Global Health-10. The Patient Activity Scale-II (PAS-II) was used to determine symptom severity and disease activity.

**Results:** Results indicate significant improvements in BMI (decrease 0.54 kg/m<sup>2</sup>), weekly physical activity (increase of 73%), hours of sleep per night (increase of .4 hrs), and alcohol and tobacco consumption (decrease of 15% and 25%, respectively). The effect of behavior change was shown by significant increases in physical (PROMIS physical health domain, 24%) and mental health (PROMIS mental health domain, 17%) as well as higher motivation (6%). In addition, flare frequency dropped by 48% suggesting that improvement of healthy behaviors and the reduction of stressors were associated.

**Conclusion:** The results of the study indicate that behavior modification would improve healthy behaviors and decrease RA symptoms. Future studies should examine the impact of coaching in various segments of RA patients such as underserved, those with multiple comorbidities and those newly diagnosed versus patients living with RA for multiple years.

# Real-World Evidence Linking Health-Related Quality of Life to Work Outcomes in Patients with Rheumatoid Arthritis

Vibeke Strand<sup>1</sup>, Mark Kosinski<sup>2</sup>, Regina Rendas-Baum<sup>2</sup>, David Brooks<sup>3</sup> and **Rita Ganguly**<sup>4</sup>, <sup>1</sup>Division of Immunology/Rheumatology, Stanford University, Stanford, CA, <sup>2</sup>Optum, Inc, Eden Prairie, MN, <sup>3</sup>GlaxoSmithKline, Philadelphia, PA, <sup>4</sup>GlaxoSmithKline, Collegeville, PA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Evaluating health-related quality of life (HRQoL) scores is a key component of the management of rheumatoid arthritis (RA) and evaluation of treatment efficacy. There is a need to further understand how observed differences in these scores translate into impact on work-related outcomes. The objective of these analyses was to establish a quantitative link between reported HRQoL and work outcomes of RA patients.

**Methods:** Patient data was obtained from 2 independent databases: QualityMetric's 2009 PRO Norming Survey (QMPRONS) and the Medical Expenditure Panel Survey (MEPS). Physical and Mental Component Summary (PCS and MCS) scores of Short Form-12v2 Health Survey (SF-12v2; captured in MEPS) and Short Form-36v2 Health Survey (SF-36v2; captured in QMPRONs) assessed HRQoL. Work outcomes were evaluated using the following endpoints: inability to work due to disability, lost days of work/housework, self-rated job performance, and presence of serious cognitive difficulties. Logistic regression models analyzed binary outcomes (inability to work, self-rated job performance [low vs medium/high], and presence of cognitive difficulties). A zero-inflated Poisson model was used to analyze the relationship between HRQoL and lost days of work/housework. A 5-point difference was used to illustrate the impact of lower HRQoL on work outcomes.

**Results:** Lower PCS and MCS scores were significantly associated with inability to work due to health (lower PCS: odds ratio [OR], 2.42; 95% confidence interval [CI], 2.14-2.74; lower MCS: OR, 1.40; 95% CI, 1.28-1.52; both  $P < 0.0001$ ). Furthermore, lower SF-12v2 summary scores were significantly associated with increased numbers of missed days of work/housework (lower PCS: 4.4 vs 1.3 missed days for scores of 40 vs 45, respectively;  $P < 0.0001$ ; lower MCS: 3.6 vs 1.6 missed days for scores of 40 vs 45, respectively;  $P = 0.0002$ ). For SF-36v2 MCS, a lower score was associated with greater odds of low job performance among employed patients (OR, 1.58; 95% CI, 1.34-1.85;  $P < 0.0001$ ), although a lower PCS score did not significantly increase odds of reporting low job performance. Lower SF-12v2 scores were significantly associated with increased risks for serious cognitive difficulties in both employed and all patients (all  $P < 0.0001$ ; **Figure**).

**Conclusion:** Low physical and mental health is associated with an increased inability to work and increased number of missed days of work. These analyses demonstrate that lower scores significantly impact work outcomes and underscore the importance of both summary measures in terms of measuring the impact of RA.

**Figure.** Increase in the odds of presence of cognitive difficulties associated with a 5-point lower SF-12v2 score.

SF-12v2, Short Form-12v2 Health Survey; PCS, physical component summary; MCS, mental component summary; CI, confidence interval.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile dermatomyositis (JDM) is the most common clinical pediatric idiopathic inflammatory myopathy and it may severely compromise the quality of life of affected patients. Early adequate immunosuppressive treatment can improve the quality of life in JDM as in other rheumatic diseases like juvenile idiopathic arthritis (JIA).<sup>1</sup>

**Objective:** To evaluate the HRQoL change over time in children with new-onset JDM patients enrolled in the PRINTO trial<sup>2</sup>.

**Methods:** In the PRINTO JDM trial, children aged 18 years old or younger with newly diagnosed and untreated probable or definite JDM were enrolled. All patients received three daily pulses of intravenous methylprednisolone at onset, and then they were randomized to one of the following three different treatment groups: prednisone (PDN), prednisone plus ciclosporin (PDN+CSA) and prednisone plus methotrexate (PDN+MTX).

In our study, we considered patients who had a complete HRQoL assessment at onset through the Child Health Questionnaire (CHQ). We compared quality of life among the responders (PRINTO20-50-70) belonging to the three treatment groups, and between responder and not responder patients. Moreover we compared the affected patients to healthy children.

**Results:** Out of a total of 139 patients enrolled in the PRINTO JDM trial, 129 (92.8%) were retained for the analysis (41.9% males and 58.1% females; median age 7.4 years). At baseline, patients with JDM showed poorer scores in quality of life (PhS = 15.6 and PsS=40.0) than healthy children. In particular, “Physical Summary score” (PhS) turned out to be significantly lower than 2 standard deviations with respect to the mean value of the healthy children with no difference among the 3 treatment groups (PDN, PDN+MTX, PDN+CSA). Less compromised scores were observed for the PsychoSocial summary Scale, with values between 1 and 2 standard deviations below the mean values of healthy children. We found similar values between «responder 20» and «not responders». A statistically significant improvement was observed after 6 months of treatment both in the PhS and in the PsS subscales ( $P<0.0001$ ) irrespective of the treatment group, and in all items of the CHQ with the exception of the GBE (Global behavior parameter). A significant improvement over time was observed regardless of the treatment group and the level of response (PRINTO 20, 50, 70). “Responder” patients showed PhS values significantly higher than “not responder”; on the contrary, PsS values did not reveal a significant difference between “responders” and “not responders”, despite an improvement over time.

**Conclusion:** Children with new-onset JDM, treated with PDN alone or in combination with other therapies, showed a significant improvement in quality of life during a two-year follow-up. According to the “PRINTO 20-50-70” criteria, “responder” patients showed a statistically significant improvement in the PhS score compared to the “not responders”.

Taylor<sup>5</sup>, Henrik Gudberg<sup>1</sup> and Lars Erik Kristensen<sup>1</sup>, <sup>1</sup>The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen F, Denmark, <sup>2</sup>NATiON, Copenhagen, Denmark, <sup>3</sup>Communication IKH, Roskilde University, Roskilde, Denmark, <sup>4</sup>University of Southern Denmark, Odense, Denmark, <sup>5</sup>University of Oxford Botnar Research Centre, Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Introducing a non-medical switch from originator to a biosimilar product in the management of chronic arthritis, i.e. switching patients in remission or low disease activity, may generate economic advantages, but on the other hand jeopardize patient engagement and empowerment. To explore impact of performing a non-medical switch from etanercept originator to a biosimilar in Danish patients with a chronic arthritis, and to explore the economic impact.

## Methods:

The Parker model, a 3-step qualitative research approach, was used to study the impact of switching from etanercept originator to a biosimilar in patients with remission or low disease activity. Concept mapping (CM), a structured group process focused on patient-relevant themes, was used to identify treatment-related issues and concerns. Subsequently, the retrieved information was utilized in a series of iterative participatory design (PD) sessions. Finally, these two methods were complemented by stakeholder evaluations (SE) based on semi-structured group and solo-interviews with a series of disease-management stakeholders.

## Results:

The study included 10 rheumatoid arthritis (RA) patients, 5 spondyloarthritis patients (SpA), 1 ankylosing spondylitis (AS) patient, 2 doctors, 2 nurses, 1 medical secretary, and 4 key public stakeholders involved in the disease-management of the selected rheumatic diseases. Saturation was reached after 3 CM workshops, including patients switching from etanercept originator to a biosimilar, generating 122 statements, out of which 7 concepts were generated; information from doctors/nurses, concerns/side effects, effect of medication, etanercept biosimilar, economy, own perception of switch, and discomfort. In addition, 1 extra workshop was conducted including 5 RA patients switching from etanercept biosimilar back to originator or to a third biologic agent, generating 45 statements, from which 4 concepts were generated; patient experiences/concerns, information, meeting with healthcare professionals/therapists, and etanercept biosimilar. These data were used in the iterative PD sessions, resulting in 5 newly proposed personalized communication strategies. Finally, SE demonstrated that implementing a non-medical biological switch involves both dialogue and clear communication in relation to logistic and background information. Communication needs to be well prepared, allowing sufficient time for providing all involved with an opportunity to discuss relevant educational materials. Health economic analyses estimated that the annual savings are between approx. DKK 8,900 and DKK 64,600 per patient depending on type of administration.

## Conclusion:

Patient participation in the 3-step qualitative Parker Model identified important aspects regarding communication strategies to consider when introducing a biosimilar to the market for the treatment and management of RA and SpA. The importance of systematic education and communication with all directly involved stakeholders was highlighted. The cost of implementing switching is very limited and savings incurred by the significantly lower prices of biosimilar compared to originator makes the switch instantly economically viable.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with RA and SLE are at higher risk for premature cardiovascular disease (CVD) than peers. Smoking is a leading modifiable risk factor for CVD and exacerbates rheumatic disease symptoms. Despite this, our prior work showed that only 10% of rheumatology visits with patients who smoke document cessation counseling. To address this gap, we previously implemented a new rheumatology staff protocol that increased referrals to the tobacco quit line 20-fold. The objective of the current study was to engage RA and SLE patients who smoke in focus groups to 1) examine barriers and facilitators of smoking cessation to further inform the protocol, and 2) identify meaningful outcomes that are signs of progress towards smoking cessation.

**Methods:** Using targeted letters, we recruited 19 patients (12 RA and 7 SLE) from two health systems to participate in one of three focus groups about smoking cessation support. 89% of participants were female, 47% white, 42% black, and 11% unknown race/Hispanic ethnicity. Ages ranged from 33-72. Two expert facilitators led each one-hour focus group using a semi-structured interview guide. Focus groups were recorded and transcribed verbatim. We used directed content analysis to classify barriers, facilitators, and valued outcomes regarding smoking cessation support. Two trained coders reviewed and coded all data using NVivo software.

**Results:** Participants discussed common barriers to quitting, including viewing smoking as “a crutch,” “a comfort,” and “the one thing I still have control over” while dealing with the burden of rheumatic disease, socioeconomic and other stressors, or trauma (Table 1). The new protocol was well received. Participants endorsed flexible terms like “cutting down” as opposed to strictly “quitting,” and preferred to receive counseling from staff who had personal experience with smoking or quitting. The outcomes that participants said they would value most fell primarily within two categories: knowing *why* to quit and knowing *how* to quit. Few were aware of the physiological impact smoking has on rheumatic disease, and none had heard that smoking can reduce the efficacy of rheumatic disease medication. Participants reported that knowing more about the effects of smoking on rheumatic disease and treatment would be a key motivator to quit smoking. Many requested that rheumatology staff help them identify tangible, day-to-day strategies to overcome cravings and connect them with resources they can use to quit smoking.

**Conclusion:** Focus group findings identified two key facilitators of smoking cessation for those with RA and SLE: understanding the specific health risks of smoking in rheumatic disease and knowing tangible steps to take towards quitting. Emphasizing the *why* and the *how* of smoking cessation is essential when designing and evaluating outcomes of rheumatology smoking cessation interventions.

Table 1. Barriers & Facilitators of Smoking Cessation in RA & SLE	
Barriers	
Maintaining Autonomy	"There's so much stuff I don't have control over, [smoking] is the one thing I still have control over."
Coping with Burden of Disease	"Every day, when you get up in pain, and you go to work, you have to put this persona on: [...] you're not sick. And then that cigarette is the break that allows you to get through it."
Navigating the System	"I requested from my primary doctor and my rheumatologist to put me on [cessation drug X], and they said that my healthcare doesn't cover that."
Facilitators	
Knowing <i>Why</i>	"I didn't have any idea that [smoking] changed how the [RA] medications work. Because the medications are super expensive, and there's always days when you wish it was working better, so if I'm inhibiting that [by smoking], then I need to take that into consideration."
Knowing <i>How</i>	"Everybody just says 'quit, quit, quit...' I think it would be helpful if they suggested other things you could do."

## Knowledge, Beliefs and Concerns about Osteoporosis – a Qualitative Synthesis

Jude des Bordes<sup>1</sup>, Seema Prasad<sup>2</sup>, Gregory Pratt<sup>3</sup>, Maria Suarez-Almazor<sup>1</sup> and **Maria A. Lopez-Olivo<sup>1</sup>**, <sup>1</sup>Section of Rheumatology and Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX, <sup>2</sup>Gastroenterology Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX, <sup>3</sup>Research Medical Library, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, Houston, TX

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Educating patients with osteoporosis about bone health could increase their knowledge and self-efficacy. These can help them adopt healthy lifestyles to prevent osteoporosis-associated fractures. To undertake an effective bone health education for these patients, it is necessary to determine what the gaps in knowledge are. This study synthesized the evidence on perceptions about osteoporosis.

**Methods:** A comprehensive search of the literature was done in an electronic database (Ovid – Medline) from 1946 to 2016, to identify qualitative studies exploring knowledge, beliefs and concerns of patients about osteoporosis and related terms. We included any study reporting detail data on literacy, understanding, perceptions and/or learning needs about bone health, low bone density, and osteoporosis. Major themes were identified and organized by categories.

**Results:** Ninety-three records were identified. Eight studies comprising 5 qualitative and 3 mixed-methods studies were included and underwent analysis. Population included 1,475 participants (including men and women), 18-90 years, 21% with confirmed osteoporosis. Major areas of knowledge deficits included: i) risk factors, ii) causes, iii) treatment, and iv) prevention. Two major categories were identified when patients were asked their *beliefs* about osteoporosis: i) osteoporosis is a disease of the old, frail with collapsed back and associated with weak bones and fractures; and ii) some thought it was very painful and could be caused by circumstances beyond one's control and stressful life situations. Patients also reported that osteoporosis was not perceived as a serious illness such as stroke or cancer and that long term medication safety or efficacy was limited. There were four categories identified as *concerns*: i) diagnosis and treatment could be a source of worry (especially in the absence of symptoms); ii) patients may be "labeled" with the condition; iii) side effects and costs of osteoporosis medications, and iv) living with fractures.

**Conclusion:** Areas of knowledge deficit were risk factors, causes, treatment and prevention. The most common themes regarding patients' beliefs across studies were that osteoporosis is a condition associated with weak bones and is painful. Medication side effects were of most concern to patients. This information can be used to tailor education, communication, and service initiatives to increase bone health knowledge and self-efficacy in osteoporosis patients and decrease fracture risk.

## **Obesity Independently Associates with Worse Patient Reported Outcomes in Women with Systemic Lupus Erythematosus**

**Sarah L. Patterson**<sup>1</sup>, Gabriela Schmajuk<sup>2</sup>, Kashif Jafri<sup>3</sup>, Katherine D. Wysham<sup>3</sup> and Patricia P. Katz<sup>4</sup>, <sup>1</sup>Division of Rheumatology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>San Francisco VA Medical Center, University of California San Francisco, San Francisco, CA, <sup>3</sup>University of California, San Francisco, San Francisco, CA, <sup>4</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Obesity has been shown to exacerbate systemic inflammation in the general population and contributes to worse disease-related outcomes in rheumatoid arthritis. The impact of excess adiposity in systemic lupus erythematosus (SLE) has not been established despite obesity being a common comorbidity in SLE. We aimed to determine whether excess adiposity in women with SLE independently associates with worse patient reported outcomes (PROs).

**Methods:** Participants in this sample, drawn from the Arthritis Body Composition and Disability (ABCD) study, were at least 18 years old, female, and carried a diagnosis of SLE verified by medical record review. Body mass index (BMI) was calculated as weight (kg) divided by height ( $m^2$ ), and fat mass index (FMI), a measure of total fat mass adjusted for height, was assessed using whole dual x-ray absorptiometry (DXA). Two established definitions for obesity were used:  $FMI \geq 13 \text{ kg}/m^2$  and  $BMI \geq 30 \text{ kg}/m^2$ . Dependent variables included 4 validated PROs: disease activity via Systemic Lupus Activity Questionnaire (SLAQ), depressive symptoms via Center for Epidemiologic Studies Depression Scale (CES-D), pain via Short Form 36 Health Survey (SF-36) Pain Subscale, and fatigue via SF-36 Vitality Subscale. We used multivariable linear regression to evaluate the associations of obesity with PROs while controlling for potential confounders (age, race, education, income, smoking, disease duration, disease damage, and prednisone use). We then calculated adjusted means for each outcome based on the multivariable regression.

**Results:** The sample ( $n=148$ ) was 65% white, 14% Asian, and 13% African American; mean age  $48 (\pm 12.3)$  years; 17% with poverty-level income; 86% with education beyond high school; mean disease duration  $16 (\pm 9)$  years; and 45% taking glucocorticoids. 32% and 30% of participants met criteria for obesity by the FMI and BMI definitions, respectively. In the multivariate regression model, obesity defined by FMI associated with worse scores on each PRO: greater disease activity, higher levels of depressive symptoms, more pain, and more fatigue (Table). The same relationship between obesity and each of the reported PROs was observed after repeating the analyses using the traditional  $BMI \geq 30 \text{ kg}/m^2$  cut-off.

**Conclusion:** In a representative sample of women with SLE, obesity (by FMI and BMI) independently associated with worse patient reported outcomes, including disease activity, depressive symptoms, and symptoms of pain and fatigue. Obesity may represent a modifiable target for improving outcomes in this patient population.

**Table. Adjusted Means for Patient Reported Outcomes by Obesity Status**

Patient Reported Outcomes	Adjusted Mean <sup>a</sup> (95% CI)		
	Obese <sup>b</sup>	Not Obese	P-value
Disease Activity (SLAQ)	14.8 (12.7-16.9)	11.5 (10.1-12.9)	0.010
Depression (CES-D)	19.8 (16.1-23.4)	13.1 (10.6-15.6)	0.004
Pain (SF-36 Pain) <sup>c</sup>	38.7 (35.7-41.7)	44.2 (42.2-46.3)	0.004
Fatigue (SF-36 Vitality) <sup>c</sup>	39.6 (36.2-43.0)	45.2 (42.9-47.6)	0.010

<sup>a</sup> Adjusted means calculated based on multivariate linear regression adjusted for age, race, education, income, smoking, disease duration, disease damage (Brief Index of Lupus Damage score), and prednisone use.

<sup>b</sup> Obesity defined by fat mass index  $\geq 13 \text{ kg/m}^2$

<sup>c</sup> Higher scores reflect better status (less pain/fatigue)

SLAQ – Systemic Lupus Activity Questionnaire

CES-D – Center for Epidemiologic Studies Depression Scale

SF-36 – Short Form 36 Health Survey

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Background/Purpose:** Low educational attainment is associated with higher prevalence, morbidity, and mortality of many diseases, including rheumatoid arthritis<sup>1</sup> (RA) and osteoarthritis<sup>2</sup> (OA). These associations often are attributed to limited access of disadvantaged people to medical services. We studied clinical status of patients with RA or OA, all of whom had access to rheumatology care, at their initial visit.

**Methods:** All patients seen at an academic rheumatology clinic complete a multidimensional health assessment questionnaire (MDHAQ) at each visit. MDHAQ is a patient self-report questionnaire that includes 3 0-10 scales for physical function (FN), pain (PN), and global assessment (PATGL), compiled into a 0-30 routine assessment of patient index data (RAPID3). We identified 132 new patients with a diagnosis of either RA (n=66) or OA (n=66) seen for an initial visit between May, 2011 and February, 2017, and for whom all data were available. Patient-reported FN, PN, PATGL and RAPID3 were compared in 3 groups according to completed years of schooling, < 12 years, 12 years, and > 12 years, using analysis of variance (ANOVA).

**Results:** Mean MDHAQ scores were remarkably similar in OA vs RA, and varied similarly according to education level (Table). Mean RAPID3 scores were 15.4 in OA vs and 15.3 in RA patients, 18.2 and 19.8 in OA vs RA patients with <12 years, 15.9 and 16.0 in OA and RA patients with 12 years, and 14.0 and 13.7 in OA vs RA patients with >12 years of education (p=0.11 for OA, p=0.04 for RA) (Table). FN scores were 2.9 for all patients in both OA and RA, 3.9 in both groups for <12, 3.3 in both groups for 12, and 2.3 and 2.4 in OA vs RA patients, respectively, for those with >12 years of education (comparisons by education level p=0.02 for OA, p=0.08 for RA). PN scores were 6.9 and 6.4 in all OA vs RA patients, 7.3 and 8.5 for OA vs RA patients with <12 years, 7.1 and 6.2 for OA vs RA patients with 12 years, and 6.7 and 5.9 for OA vs RA patients with >12 years of education (p=0.69 for OA, p=0.02 for RA). PATGL was 5.6 and 6.0 for all OA vs RA patients, 7.0 and 7.4 for OA vs RA patients with <12 years, 5.5 and 6.5 for OA vs RA patients with 12 years, and 5.1 and 5.4 in OA vs RA patients, with >12 years of education (p=0.14 for OA, p=0.12 for RA).

Table:

Mean & standard deviation (SD) scores for physical function, pain, patient global assessment and RAPID3 of patients with RA or OA at first visit, by formal education level. \*p value for differences between education groups by ANOVA

OA	Total N=66	Groups by level of Education (years)			
		<12 (n=12)	12 (n=21)	>12 (n=33)	p*
MDHAQ-Function	2.9 (2.0)	3.9 (1.5)	3.3 (2.3)	2.3 (1.7)	0.02
MDHAQ-Pain	6.9 (2.3)	7.3 (1.7)	7.1 (2.4)	6.7 (2.5)	0.69
MDHAQ-PATGL	5.6 (2.9)	7.0 (2.1)	5.5 (3.1)	5.1 (2.9)	0.14
RAPID3	15.4 (6.0)	18.2 (3.9)	15.9 (6.8)	14.0 (5.9)	0.11
RA	Total N=66	Groups by level of Education (years)			
		<12 (n=12)	12 (n=21)	>12 (n=33)	p*
MDHAQ-Function	2.9 (2.2)	3.9 (3.0)	3.3 (2.1)	2.4 (1.8)	0.08
MDHAQ-Pain	6.4 (2.9)	8.5 (1.5)	6.2 (3.4)	5.9 (2.7)	0.02
MDHAQ-PATGL	6.0 (3.0)	7.4 (3.1)	6.5 (3.3)	5.4 (2.8)	0.12
RAPID3	15.3 (7.2)	19.8 (6.3)	16.0 (8.1)	13.7 (6.5)	0.04

**Conclusion:** Low education was associated with RAPID3 and all measures both in RA and OA. Differences according to formal education level differed far more than differences by diagnosis, which were negligible. These variations do not appear attributable to differences in access to medical service.

## **Survey on Gout-Related Knowledge and Perception in Inpatient Setting on Hospitalized Patients with Gout**

**Roshanak Habibi**<sup>1</sup>, David T Liss<sup>2</sup>, Sreelakshmi Panginikkod<sup>1</sup>, Alvaro Altamirano Ufion<sup>3</sup>, Ehsan Rajabirostami<sup>1</sup> and Manish Jain<sup>4</sup>, <sup>1</sup>Internal Medicine, Presence Saint Francis Hospital, Evanston, IL, <sup>2</sup>Northwestern University, Chicago, IL, <sup>3</sup>Internal Medicine, Advocate Illinois Masonic Medical Center, Chicago, IL, <sup>4</sup>Rheumatology, Presence Saint Francis Hospital, Evanston, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The increasing global burden of gout disease and its impact on the patient's quality of life calls for new strategies in management. Even though gout is one of the most effectively treated of all rheumatic diseases, it is among the worst-managed diseases due in part to barriers in patient knowledge and perception about the disease. Our aim was to assess the disease-related knowledge and attitude among gout patients in inpatient setting and to identify the barriers to optimal management.

### **Methods:**

A cross section survey of patients admitted to a community hospital for various reasons including acute gout flare from March 2016 through March 2017 was conducted using a 10-item gout related survey, previously used in the literature. Patients were identified for survey if they carried a diagnosis for gout based on American college of rheumatology classification criteria. Patient medication and demographic information was also collected. Patients were considered to have "good" knowledge if they answered 70% of the questions correctly. Gout survey performance was compared to demographic and medication data. In bivariate analysis, we examined differences in mean survey performance using 1-way analysis of variance (ANOVA). We obtained adjusted relative risks (RRs) of good knowledge by estimating a multivariable Poisson regression model with robust variance estimates, adjusted for covariates. Analyses were conducted using Stata, version 14.2.

### **Results:**

Fifty-eight patients surveys were conducted. Most were aged 65 and older (60%) with equal number of males and females. Only 29% of respondents completed college or above and 24% were currently employed. Mean duration of gout in years was 11.8 years. Thirty-nine (81%) patients had at least one visit to the treating physician and thirty-five patients had at least 1 flare (60%) in last year. Most of the patients were taking allopurinol (69%). Good knowledge was demonstrated by 60% of the respondents. Knowledge strengths in terms of percentage of patients having correct answers included the majority of patients identifying that gout was related to elevated uric acid levels (86%); that pain with swelling in the joint as being a sign of acute flare (82%); and that hypertension was associated with gout (89%). Knowledge gaps included: uric acid goals (19%), treatment of acute flare (29%), prophylaxis of flare (37%), duration of ULT (42%), and life style modification (14%). In multivariable regression analysis, gout related knowledge was found to be higher among females (RR-1.5; P=0.03; 95% CI,1.04 to 2.28); patients with higher level of education (RR-3.4; P=0.04;95% CI,1.08 to 10.9) and in those patients using allopurinol (RR-1.9; P=0.05; 95% CI,0.97 to 4.00).

### **Conclusion:**

We conclude that a large disease related knowledge gap is identified in our survey of gout patients in inpatient setting. Our data informed the areas of major knowledge gaps. We also identified certain demographic and medication factors influencing gout knowledge. To our knowledge this is the first patient education study in gout focusing on a hospitalized patient population, and we believe the inpatient setting may be a focus of opportunity for gout education.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While there are multiple biologic options for ankylosing spondylitis (AS), few attempts have been made to examine patients' knowledge and understanding of these therapies outside of traditional surveys. Social media is a new data source which presents a rich opportunity to learn from patients outside of controlled environments

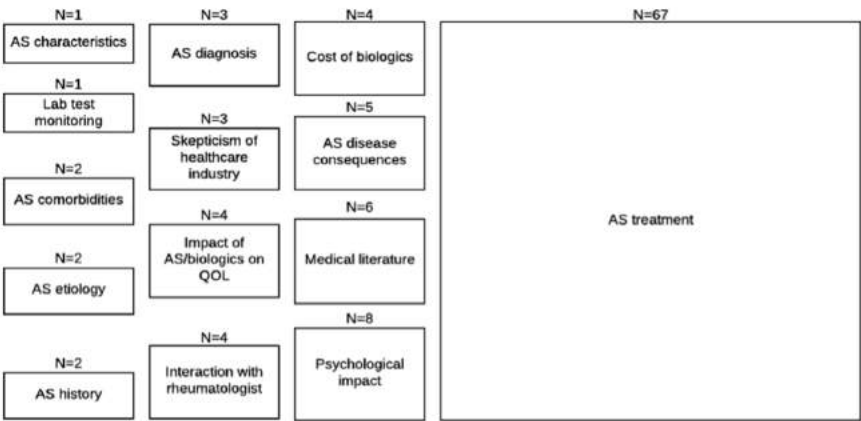

such as in clinical trials and clinic visits. In this study, we used social media data to examine AS patients’ knowledge, attitudes, and beliefs regarding biologic therapies.

**Methods:** We collected posts from 601 social media sites made between 1/1/06-4/26/17. Each post mentioned both an AS keyword and a biologic. To explore themes within the collection in an unsupervised manner, a latent Dirichlet allocation (LDA) topic model was fit to the dataset. Under LDA, each discovered topic is represented as a discrete distribution over the words in the collection, which may be thought of as a word cloud (i.e. words with more probability are larger in the cloud). The topics were manually reviewed to identify themes, which were then confirmed by reviewing relevant posts within each candidate topic.

**Results:** We examined 27,416 social media posts that focused on AS and biologics and found 112 themes. The majority of themes (60%, 67/112) focused on discussions surrounding AS treatment. Other themes including psychological impact of AS, reporting of medical literature, and AS disease consequences accounted for the remaining 40% (45/112) of topics (**Figure 1**). Within AS treatment discussions (**Figure 2**), most topics (61%) involved discussions about pharmacologic treatment (biologic and non-biologic options). The majority of biologic subthemes (78%) centered on side-effects related to its use (e.g. fatigue, allergic reactions), biologic attributes (e.g. dosing, frequency), and concerns with its use (e.g. increased cancer risk, reproductive concerns).

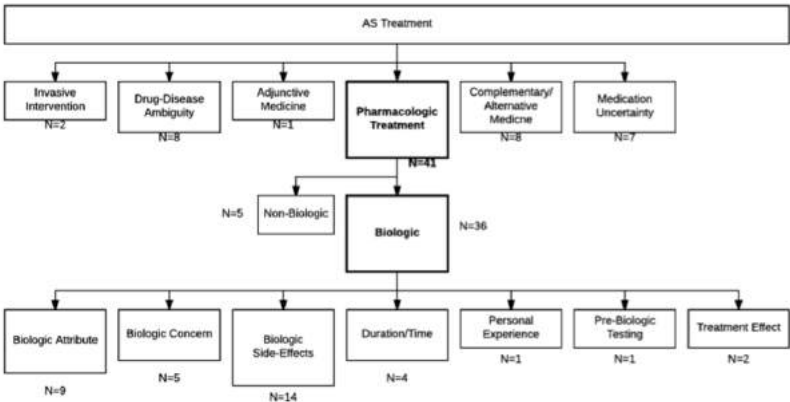

**Conclusion:** Social media reveals a dynamic range of themes governing AS patients’ experience and choice with biologics. The complexity of selecting among biologics and navigating their risk-benefit profiles suggests merit in creating online tailored decision-tools to support patients’ decision-making with AS biologic therapies.

## **Health Related Quality of Life in Lupus: Self-Management- a Modifiable Predictor**

Kenneth Johnsen<sup>1</sup>, Meenakshi Jolly<sup>2</sup> and Narender Annapureddy<sup>3</sup>, <sup>1</sup>Division of Rheumatology, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Rush, Chicago, IL, <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster III

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

Health Related Quality of Life in Lupus: Self-Management- a Modifiable Predictor.

**Background/Purpose:** Health related quality of life (HRQOL) is significantly effected in patients with Lupus. While mortality in Lupus patients has improved in the past few decades, these patients continue to have significant impairment in their health related quality of life. There are multiple complex factors which can influence health related quality of life in these patients

**Methods:** A cross sectional study was done in 50 Patients in the Vanderbilt Lupus Center meeting the 1997 ACR classification criteria for SLE. LupusPRO, a disease-specific patient reported outcomes tool, was used to assess HRQOL and non HRQOL. Disease activity was assessed using the SLEDAI-2K. Data on following were collected: coping (BRIEF-COPE questionnaire), social support (ENRICH Social Support Instrument (ESSI)), quality of patient-health care provider communication (Patient-Health Care Provider Communication Scale (PHCPCS)), self-management (Perceived Medical Condition Self-Management Scale (PMCSMS)), and patient-reported medication adherence (Medication Adherence Self-report Inventory (MASRI)). Correlational and multivariate linear regression analyses with HRQOL as the dependent variable were conducted. A p-value of <0.05 was considered significant on 2-sided t-test.

**Results:** Mean (SD) age was 40.3 (12.9) years; 94% of patients were women (Table 1). Mean (SD) HRQOL score was 68.0 (21.5). HRQOL correlated positively with PMCSMS (0.704, p <0.001), BRIEF-COPE (0.643, p<0.001), ESSI (0.299, p 0.041), PHCPCS (0.464, p 0.001), and SLEDAI (-0.320, p 0.027). On multivariate linear analysis regression, PMCSMS (beta- 2.079, 0.001) and BRIEF-COPE (1.969, p 0.036) were independent predictors of HRQOL (Table 2). Domains for coping, social support and satisfaction with care on the LupusPRO correlated with BRIEF-COPE, ESSI and PHCPCS respectively.

**Conclusion:** Self-management skills and coping mechanism, are both modifiable predictors of HRQOL in our lupus patients. Besides controlling for disease activity, strategies to intervene on self-management and coping need to be integrated into routine care of Lupus patients.

Table 1: Characteristics of the sample, n=50		
	Mean ± SD	% (n)
Age (Years)	40.3 + 12.9	
Female	94 (47)	
Duration of disease	13.5 + 8.1	
Age at diagnosis (Years)	26.9 +11.7	
SLEDAI 2K	2.0, 5.0 (median, IQR)	

Table 2: Correlation of HRQOL as assessed by LupusPRO	
Univariate analysis	Multivariate analysis
PMCMS 0.70 (<0.001)	PMCSMS 2.08 (0.001)
BRIEF-COPE 0.64 (<0.001)	BRIEF-COPE 1.97 (0.036)
ESSI 0.30 (0.041)

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Patient Outcomes, Attitudes, and Preferences Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In rheumatoid arthritis (RA), up to 80% of patients were found to be non-adherent to prescribed medication and non-pharmacological interventions. These patients do not reach optimal clinical outcomes. In the present study, we therefore explored predictors that may lead to non-adherence from the perspective of patients.

**Methods:** In a mixed-methods study, retrospective, observational data from patients with RA diagnosed according to the EULAR/ACR criteria with at least one DMARD therapy who failed to attend to the follow-up visits for at least 9 months (and were thus considered to be potentially non-adherent to recommended interventions) were selected from the databases of two rheumatology centers. Subsequently, we invited all these patients to take part in a qualitative semi-structured interview study with a meaning condensation data analysis. Based on the interviews, patients were assigned to the sub-groups ‘adherent’ (e.g. having regular rheumatology visits in another clinic) or ‘non-adherent’ (e.g. having stopped taking the prescribed medication and interventions). Possible predictors derived from the qualitative analysis and clinical variables obtained from the patient databases of the centers were tested in a logistic regression model.

**Results:** In total, data of 459 eligible patients (346 [75.4%] females; total mean age 63.0 [SD 14.8]) were identified. One hundred thirty one of these (109 [83.2%] females; total mean age 64.8 [SD 14.1]) agreed to participate in the qualitative interviews. In addition to already known themes, new issues important to patients emerged from the qualitative analysis (table 1): (i) the so-called “patient’s dogma” inhibited adherent behavior, in that patients felt that pain was an important part of life and attributed this to having had a high manual workload during life of which patients were proud; (ii) patients trusted physicians who were seeking support from other physicians less, because they appeared to be “young or unexperienced”; (iii) some patients did not feel properly understood if physicians only prescribed medication without offering advice on non-pharmacological aspects of treatment. Two clinical variables were also found to be predictors for non-adherent behavior: higher number of swollen joints (OR 0.9; CI 95% 0.8-1.0) are associated with a higher likelihood of non-adherence, whereas older patients (OR per decade 1.3; CI 95% 1.0-1.7) were more likely adherent.

**Conclusion:** The predictors for non-adherence may be used to improve patients’ counseling and to enhance patient adherence and improve clinical outcome in pharmacological and non-pharmacological interventions.

### Table 1. Qualitative results.

Main Topics	Description/Examples
So-called “patient’s dogma”	“Patient’s dogma” which is defined as preconceived opinions of the patient trigger non-adherent behaviour. For example, some patients believed that rheumatologists’ decisions are influenced by the pharmaceutical industry and therefore they just prescribe medications instead of letting “natural” processes of inflammation occur (Participant No. 2, female, age 40).
Perceived “trustworthiness” of physicians/health professionals	Patients search for the best and most trustworthy physician/health professional. For Example, if two physicians disagree and have different opinions regarding recommendations (Participant No. 28, female, age 43), patients were likely not to adhere to the prescriptions.
Comprehensive medical advice including non-pharmacological methods	Patients were seeking comprehensive medical advice. If advice on non-pharmacological aspects of treatment e.g. strategies for daily routines, sports, limited evidence of diet and alternative medications, are not covered (Participant No. 182, female, age 34), patients were less likely to adhere.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Patient Outcomes, Attitudes, and Preferences Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient engagement in research is promoted to improve the relevance and quality of health research, but has little conceptualization derived from empirical data. To address this issue, we sought to develop an empirically based conceptual framework for *meaningful* patient engagement in research founded on a patient perspective.

**Methods:**

We conducted a qualitative analysis of transcripts from one-on-one in-depth interviews with 18 patient research partners who are living with arthritis. The data analysis involved three phases: identifying the themes, developing a framework, and confirming the framework. Specifically, we coded and organized the data, and abstracted, illustrated, described, and explored the emergent themes using thematic analysis. Directed content analysis was conducted to derive concepts from 18 publications related to patient engagement in research to supplement, confirm or refute, and extend the emergent conceptual framework. The framework was critically reviewed by our entire research team, including four patient research partners with arthritis.

**Results:** The experiences the participants had when they worked with researchers were generally positive. Eight themes emerged: *Procedural Requirements, Convenience, Contributions, Support, Team Interactions, Research Environment, Feel Valued, and Benefits*. These themes were interconnected and formed a conceptual framework to explain the phenomenon of meaningful patient engagement in research from a patient perspective. For example, the contributions of patient research partners could be facilitated when researchers maintain certain procedural requirements, offer opportunities to engage in ways that patient research partners find convenient, and provide appropriate support, such that patient research partners feel valued and identify benefits from engaging with a research team.

**Conclusion:** The Meaningful Patient Engagement in Research (PEIR) Framework provides guidance regarding key aspects of meaningful patient engagement in research that could be operationalized by research teams. It could be particularly useful when patient-researcher partnerships are led by researchers with little experience of engaging patients in research.

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The efficacy and safety of intravenous (IV) tocilizumab (TCZ), an interleukin-6 receptor-alpha inhibitor, have been demonstrated in patients with polyarticular-course juvenile idiopathic arthritis (pcJIA) (Brunner HI et al. *Ann Rheum Dis.* 2014;74:1110-7). This study investigated appropriate dosing regimens of subcutaneous (SC) TCZ in a similar population.

**Methods:** We enrolled patients aged 1-17 years with pcJIA who had inadequate response/intolerance to methotrexate and were TCZ naive or received TCZ IV with adequate disease control. TCZ SC was administered open label according to a body weight (BW)-based dosing regimen based on pharmacokinetic (PK) simulations aimed at obtaining TCZ trough exposures at or above those achieved by approved IV dosing in pcJIA patients. pcJIA patients weighing <30 kg received TCZ 162 mg every 3 weeks (Q3W) while those weighing ≥30 kg received TCZ 162 mg Q2W for 52 weeks. Adequacy of TCZ dosing was assessed by comparing model-estimated PK parameters ( $C_{trough}$ ,  $C_{max}$ , area under the concentration-time curve) with the IV exposure data; safety and efficacy (exploratory; JADAS71) were also measured.

**Results:** Among the 52 patients (69% female) enrolled, 27 patients had <30 kg BW and 25 patients ≥30 kg BW. Median baseline age was 6.0 years for the <30 kg BW group and 15.0 years for the ≥30 kg BW group. In the <30 kg BW group 85% were TCZ naive, and in the ≥30 kg BW group 56% were TCZ naive. Given similarities in steady state PK of the naive vs non-naive patients, pooled data analyses are presented. Median  $C_{trough}$  was similar between BW groups and higher than with TCZ IV in both BW categories, confirming adequate exposure from SC doses.  $C_{max}$  and  $AUC_{12weeks}$  were higher in the <30 kg BW than the ≥30 kg BW TCZ SC group. Consistent with SC vs IV administration, median  $C_{max}$  from SC dosing was lower than with IV dosing in both BW groups. Changes in PD parameters for TCZ-naive patients were consistent with those previously observed for TCZ IV, suggesting adequate reduction of inflammation. JIA activity (JADAS-71) improved in both BW groups (Table), with trends consistent with those observed for TCZ IV. Infections were the most frequent adverse event (AE). Four serious AEs occurred in 3 patients (croup and varicella [same patient], anorexia, and arthralgia). Injection site reactions were more common in the ≥30 kg BW group (Table). No serious hypersensitivity, AE leading to withdrawal, opportunistic infection, serious hepatic AE, or death occurred. The overall rate of AEs was 7.9/100 patient-years, consistent with that for TCZ IV in pcJIA.

**Conclusion:** The BW-based TCZ SC dosing regimens for pcJIA provided adequate exposure to support efficacy comparable to that of TCZ IV, with an acceptable benefit-risk profile.

Table. Results		
	TCZ 162 mg SC Q3W BW <30 kg (n = 27)	TCZ 162 mg SC Q2W BW ≥30 kg (n = 25)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** JIA is the most common chronic inflammatory rheumatic disease of childhood. Due to their known safety and efficacy, TNF inhibitors are used for long-term control of pJIA disease. The purpose of this analysis was to evaluate the 7 year (y) safety of Adalimumab treatment with or without methotrexate (ADA±MTX) when used in current clinical practice for treatment of patients (pts) with active pJIA.

**Methods:** This is a 7 y interim analysis of an ongoing, multicenter, non-interventional, observational registry of pts with pJIA with up to 10 y safety follow-up. Included pts were treated with either ADA±MTX or MTX alone as comparison arm according to routine clinical care in US, EU, and Australia. MedDRA observational adverse events (AEs) were recorded from 1<sup>st</sup> day in the registry through last contact, irrespective of the duration of registry treatment.

**Results:** In January 2014, enrollment was complete. As of June 1, 2016 cut-off date, 838 pts (301- MTX arm and 537 - ADA±MTX arm) were treated in the registry. There were 39 pts who rolled over from MTX to the ADA±MTX arm. At registry entry mean pJIA disease duration was 1.3 y and 3.7 y and mean AJC71 was 5.8 and 5.2 for MTX and ADA±MTX arms, respectively. CHAQ disability index was 0.6 for both arms. The mean duration of study drug exposure in registry was 2.0 y (range: 0.0 – 7.1) and 2.5 y (range: 0.0 – 7.9) for MTX and ADA±MTX arms, respectively. The mean duration of observation in registry was 3.9 y (range: 0.0 – 7.2) and 3.5 y (range: 0.0 – 7.9) for MTX and ADA±MTX arms, respectively. Overall, 213 pts (70.8%) in MTX and 225 pts (41.9%) in ADA±MTX arms discontinued registry drug through 7 y. The main reasons for registry drug discontinuation for MTX arm: pts required additional therapy (32.6%), other (13.3%), lack of efficacy (11.6%), AEs (9.3%), or pts achieved JIA remission (8.6%), and for ADA±MTX arm: lack of efficacy (17.9%), other (7.3%), lost to follow-up (5.6%), AEs (5.4%), or pts achieved JIA remission (5.0%). Frequencies and rates of treatment-emergent AEs (from 1<sup>st</sup> dose date of registry drug in registry up to last dose + 70 days in registry, excluding AEs occurring during treatment interruption) were similar to those reported for observational AEs (from 1<sup>st</sup> day in registry up to last contact irrespective of drug treatment duration) (**Table**). The rate of serious infections was similar between MTX and ADA±MTX arms. One pt (0.2%) reported an event of opportunistic infection (fungal oesophagitis) in ADA±MTX arm. No reports of deaths, malignancies, active tuberculosis, oral candidiasis, demyelination, or congestive heart failure.

**Conclusion:** Overall, ADA±MTX was well-tolerated in these pts with pJIA with no new safety signals. The retention rate for registry drug was higher in ADA±MTX arm compared to MTX arm.

<b>Table. Overview of the Observational Adverse events</b>

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Abatacept is an FDA- and EMA-approved biologic that is widely used in children with juvenile idiopathic arthritis (JIA). The purpose of this long-term ongoing registry is to describe the longitudinal effectiveness and safety of SC and IV abatacept in JIA patients (pts). **Methods:** Using a standardized protocol, clinical sites in the Pediatric Rheumatology Collaborative Study Group (PRCSG) and Paediatric Rheumatology International Trial Organization (PRINTO) enrolled pts with JIA currently on or starting abatacept in this longitudinal registry. Planned duration of follow-up is 10 years (yrs) and data shown are those collected through March 31, 2017 (up to 4 yrs' follow-

up). **Results:** Overall, 354 pts with JIA were enrolled since January 2013, resulting in a total abatacept exposure of 364.5 pt-yrs (mean/median duration of abatacept treatment was 12.4/6.5 months), and 76 (22%) pts were new starters on abatacept ( $\leq 1$  month of treatment), 76 (22%) had received abatacept for  $>1$ – $\leq 6$  months, 73 (20%) for  $>6$ – $\leq 12$  months and 129 (36%) for  $>12$  months. SC abatacept was used in 80 (23%) pts and IV in 274 (77%); 4% of the pts were aged 2–5 yrs at enrollment. *Baseline:* Of the 354 pts, 281 (79%) were female, mean/median age at enrollment was 13.0/13.6 yrs, and 15 (4%) were aged 2–5 yrs. JIA subtypes were: systemic (2%), oligoarticular (21%), polyarticular RF– (58%), polyarticular RF+ (9%), psoriatic (3%), enthesitis-related (3%) and undifferentiated (4%). At baseline, JIA duration was 5.4/4.4 yrs, mean/median active joint count was 2.9/0, a history of uveitis was recorded in 47 (13%) pts and 14 (4%) had active uveitis. Concomitant JIA medications were used by 81% of pts (58% MTX, 48% NSAIDs, 8% systemic steroids, 3% leflunomide, 4% hydroxychloroquine,  $<1\%$  cyclosporine, 1% sulfasalazine). *Follow-up outcomes & safety.* Clinical, functional and HRQoL scores are based on observed results for up to 4 yrs' time in the registry (Table). In total, 23 serious AEs were reported (all single occurrences) in 23 pts (6% of study population), resulting in an overall serious AE rate per 100 pt-yrs on treatment of 6.3 (95% CI 4.1, 9.3). There were three events of special interest (ESI): acute uveitis, MRSA wound infection, infusion reaction; the ESI rate was 0.82/100 pt-yrs on treatment (95% CI 0.2, 2.2). No new autoimmune diseases, malignancies or tuberculosis cases were reported. There was one death due to pre-existent cardiopulmonary disease considered unrelated to abatacept.

**Conclusion:** Abatacept was well tolerated and no new safety signals were observed. In this JIA cohort, abatacept demonstrated persistent effectiveness with low MD Global disease activity, low number of active joints and  $>30\%$  of pts had clinical inactive disease.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A Phase 3b, open-label (OL), multicenter study (CLIPPER) has shown the safety of etanercept (ETN) in pediatric patients (pts) with extended oligoarticular (eo) juvenile idiopathic arthritis (JIA), enthesitis-related arthritis (ERA), and psoriatic arthritis (PsA). CLIPPER2 is an ongoing OL extension study assessing long-term safety and clinical benefits of ETN in this population. The objective of the current study was to describe the safety of 6 years (y) of ETN treatment in the CLIPPER (2-y) and CLIPPER2 (4-y) studies.

**Methods:** 127 pts with eoJIA (2-17 y), ERA, or PsA (each 12-17 y) who received  $\geq 1$  ETN dose (0.8 mg/kg QW [max, 50 mg]) in CLIPPER were eligible to enter CLIPPER2. Long-term safety of ETN treatment was assessed as the total incidence of events from CLIPPER baseline (BL) to month (m) 72, frequency of events per 100 patient-years (EP100PY), and frequency of events in each study year.

**Results:** 109/127 (86%) pts entered CLIPPER2. At m72, 39/127 (31%) were actively taking ETN, 6 (5%) had withdrawn from treatment due to low/inactive disease, 7 (6%) had re-started ETN following an earlier withdrawal from treatment, 36 (28%) had stopped ETN (but remained in the study under observation), and 37 (29%) had permanently discontinued from the CLIPPER studies. The safety of ETN treatment from BL to m72, including incidence of treatment-emergent adverse events (TEAEs) and infections, and patient withdrawals owing to these, is shown in Table 1. From BL to m72, the most frequently reported TEAEs were (N [EP100PY]), headache (28 [5.34]), arthralgia (24 [4.58]), pyrexia (20 [3.81]), diarrhea, and leukopenia (both 12 [2.29]). All 32 serious TEAEs occurred at a rate of  $\leq 3$  events each. In this study, only 1 case of malignancy (Hodgkin's lymphoma) was reported (1 patient with eoJIA in y3 of the study). There were no cases of active tuberculosis or demyelinating disorders, and no deaths. The number and frequency (N [EP100PY]) of TEAEs (excluding infections/ISRs) decreased over the 6-y study period from 193

[173.81] in y1 to 37 [61.34] in y6 (Table 2). The number and frequency of TE infections and serious TE infections also decreased over the 6-y study period. The incidence of serious TEAEs, however, varied from a high of 10 [9.61] in y2 to a low of 0 in y4 with no clear trend of decrease with time.

**Conclusion:** OL ETN treatment to m72 was well tolerated. Frequency of TEAEs and TE infections decreased over time. **Trial Registration:** NCT00962741/NCT01421069

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate changes in the risk for adverse events of special interest in juvenile idiopathic arthritis (JIA) patients treated with Etanercept documented in the German BIKER registry.

**Methods:** This prospective cohort study included German JIA patients who began treatment with Etanercept 2000 to 2016 (n = 2,776, 11,772 patient years [PY]). Documentation began at the time of initiation visit and was continued irrespective of the withdrawal of medication. Adverse events (AE) were requested at every visit. AE of special interest included serious infections, uveitis events, diagnosis of chronic inflammatory bowel disease (CED) and malignancies. AE were attributed to Etanercept therapy if they occurred upon treatment or before 90 days of discontinuation. Malignancies were counted as ever exposed.

**Results:** In total there were 151 serious adverse events (0.054/pt.), 50 serious infections (0.018/pt.), 63 uveitis events (0.023/pat), 16 cases with CED (0.006/pt.) and 8 malignancies (0.003/pt.). The crude incidence rate ratios were 1.3/100 pt-years for all serious events, 0.4/100 pt-years for serious infections, 0.5/100 pt-years for uveitis events, 0.14/100 pt-years for CED and 0.06/100 pt-years for malignancies. The incidence of total serious events in the first year of 2.5/100 pt-years markedly decreased upon continuous treatment as well as the incidence of serious infections (first year 0.81/100PY), uveitis events (first year 1.09/100 PY) while no trend was observed with the rate of CED events (first year 0.20/100 patient years) or the rate for malignancies (0.08/100 patient years). Upon observation for more than 10 years, the yearly incidence markedly decreased for serious infections and uveitis events upon continuous treatment and remained stable for CED and malignancies (figure).

**Conclusion :** These results indicate significant decrease of the risk for several adverse events of special interest with continuous etanercept treatment over time; this may be explained by an evidence-based risk management for JIA patients given etanercept including the renouncement of steroids in the case of serious infections. Susceptible patients may be recognized early during the course of treatment. No increase of any of the risks was observed upon continuous treatment for up to 16 years.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Stopping medications is a priority for many patients with well-controlled JIA, but few factors predict favorable outcomes after discontinuation. We examined factors associated with sustained discontinuation off disease-modifying drugs in a large pediatric registry.

**Methods:** We conducted a case-control study using the Childhood Arthritis & Rheumatology Research Alliance Registry of clinical data from >55 pediatric rheumatology clinics in the United States and Canada. The study included children with JIA who started at least 1 conventional or biologic DMARD and had at least 2 years of available subsequent data. Reasons for drug discontinuation were obtained from the medication log. Sustained discontinuers had at least 1 year of drug-free follow-up after discontinuation for well-controlled disease. Comparators included children who did not discontinue all DMARDs for well-controlled disease (never discontinuers) and those who stopped DMARDs for at least 30 days and restarted within 1 year (unsustained discontinuers). Children in each group may have stopped DMARDs for reasons besides well-controlled JIA. We compared characteristics of sustained discontinuers and comparators using descriptive statistics, excluding children with <1 year of follow-up off medicines without restarting DMARDs.

**Results:** There were 1194 children with JIA who started DMARDs, of whom 479 (40%) stopped all drugs due to well-controlled disease for at least 30 days after median 1.9 years of DMARD use (interquartile range [IQR] 1.1, 3.4). There were 175 sustained discontinuers (15%, group 1). Comparators included 268 unsustained discontinuers (22%, group 2) and 681 never discontinuers (57%, group 3) (Table). Only 24 children in group 2 subsequently stopped all DMARDs for at least 1 year. Compared with all children who started a DMARD (unsustained and never discontinuers), sustained discontinuers were younger at diagnosis and DMARD initiation, less likely to have polyarthritis, and less likely to have used a biologic DMARD. Compared with unsustained discontinuers, sustained discontinuers were less likely to have used biologics. No other factors were associated with sustained discontinuation among those who stopped DMARDs, including time to discontinuation and JIA category. A history of uveitis and radiographic joint damage were not associated with sustained discontinuation in either comparison.

**Conclusion:** In a large multicenter cohort of children with JIA who started DMARDs, only 1 in 6 children stopped DMARDs for well-controlled disease for at least 1 year. Younger age at DMARD initiation, oligoarticular disease course, and exclusive use of conventional DMARDs were independently associated with sustained discontinuation. The prognostic value of these factors should be considered when making decisions about stopping medicines for well-controlled JIA.

**Table. Characteristics of study subjects with JIA who started at least 1 DMARD**

## Etanercept (Enbrel®) Treatment Retention in the Sub-Population of Pediatric Patients from a Retrospective Cohort Study Using Canadian Claims-Level Data

**Majed M M Khraishi**<sup>1</sup>, Brad Millson<sup>2</sup>, John Woolcott<sup>3</sup>, Heather Jones<sup>4</sup> and Lisa Marshall<sup>4</sup>, <sup>1</sup>Faculty of Medicine, Memorial University of Newfoundland, St John's, NF, Canada, <sup>2</sup>Health Access and Outcomes, QuintilesIMS, Kanata, ON, Canada, <sup>3</sup>Inflammation & Immunology Global Outcomes & Evidence, Pfizer, Inflammation & Immunology Global Outcomes & Evidence, Collegeville, PA, <sup>4</sup>Inflammation & Immunology Global Medical Affairs, Pfizer, Collegeville, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Etanercept (ETN) was the first biologic approved for use in the treatment of patients with polyarticular-course juvenile idiopathic arthritis (JIA),<sup>1</sup> and is now indicated in other JIA subcategories.<sup>2</sup> Evidence from registry studies and real-world data suggest ETN is favored as a first-line biologic therapy in clinical practice in patients

with JIA;<sup>3,4</sup> however, the factors associated with long-term retention of ETN in this population have been little explored. **Objectives:** To evaluate retention rates up to 6 years in ETN-treated pediatric patients in Canada.

**Methods:** A retrospective cohort study was conducted using longitudinal prescription drug claims data from QuintilesIMS Private Drug Plan database (PDP), Ontario Public Drug Plan database (OPDP), and Quebec Public Drug Plan database. Between 07/2003 and 01/2011, biologic-naïve patients (ie, patients with no biologic treatment in the preceding 12 months) who initiated ETN, were identified and followed for 72 months. Disease indications were inferred through patient drug history. 12-month retention rates were evaluated in 1-year increments for all patients retained on therapy, and compared with the first-year retention rate. Exact 95% confidence intervals (CI) were calculated. McNemar's test was used to assess the difference between two correlated proportions, where these were based on the same sample of subjects, with reference to year-1 retention. This analysis assessed pediatric patients (ie, age 2-16 years at time of first prescription).

**Results:** The study identified 172 ETN-treated pediatric patients across Canada, who initiated therapy during the selection period. 67% were female; 94% were diagnosed with JIA. Private claims accounted for 69% of ETN-treated pediatric patients, and 49% of the patient population were from Ontario. Of the 152 patients covered by PDP and OPDP, 45% and 55% were aged 2-11 years and 12-16 years at initiation, respectively. 12-month ETN retention rates increased following their first year on therapy. 78% of patients were retained at year 1; 12-month retention rates through years 2-6 are shown in the Table. Retention rates for the corresponding periods in the adult population (>18 years) were: 66%, 79%, 82%, 84%, 83%, and 79%. 38% of pediatric patients remained on ETN treatment for the entire 72-months' study. 66 patients switched treatments after discontinuing ETN, with 44% doing so more than once during the 6-year period.

**Conclusion:** Pediatric patients treated with ETN demonstrated significantly higher retention rates after the first year, with a considerable proportion of patients continuing for 6 years; many who discontinued ETN and subsequently switched treatment did not remain on their first-choice treatment. Further analysis of the reasons for ETN treatment discontinuation may assist in identifying measures to support patients in maintaining treatment to achieve sustained clinical benefit<sup>5</sup> and quality of life.<sup>6</sup>

Table. ETN treatment retention in pediatric patients (age 2-16 years of age)

Year	Tracked Patients, n	Retained Patients, n	Yearly Retention Rate, % (95% CI)	Cumulative Retention Rate, % (95% CI)	P-Value (Retention Rate Reference to Year 1)
1	172	135	78 (72, 84)	78 (72, 84)	
2	135	118	87 (81, 92)	69 (61, 75)	<0.0001
3	118	101	86 (78, 91)	59 (51, 66)	<0.0001
4	101	90	89 (81, 94)	52 (45, 60)	<0.0001
5	90	81	90 (82, 95)	47 (39, 55)	<0.0001
6	81	65	80 (70, 88)	38 (31, 45)	<0.0001

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. The treatment of JIA has been revolutionized by the use of biologic agents. Since studies on biologic therapy in young adults include relatively low numbers of patients and short trial durations, more evidence regarding safety issues is needed. Our aim is to evaluate the safety of biological therapy in JIA.

**Methods:** Multicenter prospective study. Information was obtained from BIOBADASER, a study based on routine clinical practice. All patients diagnosed before age 16 in our database between 2000 and 2015 were included in the analysis. JIA is classified into 7 subgroups: systemic, persistent or extended oligoarthritis, RF positive polyarthritis, RF negative polyarthritis, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis. Due to the design of the registry, it was not possible to identify each of the JIA subgroups; thus, we classified them into systemic/oligo/polyarticular JIA, JIA related to enthesitis, and psoriatic JIA. Adverse events were coded using version 13.0 MedDRA (Medical Dictionary for Regulatory Activities).

Proportions, means and standard deviations (SD) were used to describe our population. Incidence rates and 95% confidence intervals were calculated to assess adverse events.

**Results:** A total of 469 patients were classified as systemic/oligo/polyarticular JIA (70.6%), JIA related to enthesitis (25%) and psoriatic JIA (4.5%). 46.1% of patients were women. Age at diagnosis was 9.4 (SD = 5.3) and years of disease evolution 24.1 (SD = 14.1). The age at biological treatment initiation was 23.9 years (SD= 13.9). Biologicals were used as monotherapy in the 42.4% of the treatments, while methotrexate was used in combination in 44.0% of the treatments. Table 1 shows incidence rates for adverse events. Serious adverse events had an incidence of 41.4 (35.2-48.7). Only in one case was a fatal adverse event (mycoplasma pneumonia during treatment with anakinra) recorded.

**Conclusion:** The most common incident adverse events were: infections, gastrointestinal disorders, skin and subcutaneous tissue disorders. There seemed to be little difference between the results for patients with JIA and those diagnosed with rheumatoid arthritis in BIOBADASER. Although this project allowed us to examine long-term drug safety in JIA, large registries that focus on such patients are needed to better understand rare adverse events.

Table 1. Incidence of adverse events recorded in patients with JIA by line of treatment.

<b>Incidence (CI95%) x 1,000 persons/year</b>	<b>First-line biologic</b>	<b>Second-line Biologic</b>	<b>Total</b>
Total adverse events	367.2 (342.8-393.3)	383.2 (351.3-417.9)	373.2 (353.6-393.8)
Severe adverse events	36.6 (29.4-45.5)	49.5 (38.9-63.0)	41.4 (35.2-48.7)
Fatal adverse events	-	0.7 (0.1-5.3)	0.3 (0.0-2.0)
<b>By system / organ class</b>			
Infections and infestations	171.2 (154.8-189.3)	151.5 (131.9-173.9)	163.8 (151-177.6)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Biologic medications have allowed a significant proportion of JIA patients to achieve inactive disease. However, some patients will have ongoing moderate to high disease activity or will not tolerate the medication. Current treatment recommendations suggest changing biologic medications when inactive or low disease activity is not attained, but the switching patterns and reasons for switching in clinical practice in North America are not currently known.

**Methods:** We used the Childhood Arthritis & Rheumatology Research Alliance (CARRA) Registry of clinical data from >55 pediatric rheumatology clinics in the United States and Canada. Individuals with JIA and no prior biologic medication use were included if they newly started a biologic medication on or after enrollment in the registry and had a minimum of 6 months of observable time following medication start. Individuals with systemic JIA were excluded. Subjects were labelled switchers if they had subsequent use of any other biologic medication during the 6 month follow up time and labelled non-switchers if they did not. We compared characteristics of switchers and non-switchers using descriptive statistics and reported patterns of and reasons for switching.

**Results:** There were 134 biologic-naïve children with JIA who started a biologic medication after enrollment, of whom 14 (10%) switched to a different biologic medication within 6 months (Table). The median time before switching was 107.5 days (interquartile range (IQR) 75 - 133). The majority of patients had started on etanercept (102, 76%) and switched to adalimumab (9), abatacept (1), infliximab (1), and rituximab (1). One patient switched from adalimumab to etanercept, and 1 switched from infliximab to tocilizumab. Ineffectiveness was the most common reason for switch (6, 43%), 2 patients switched for intolerance of administration, 2 switched for adverse effects, and 1 each switched for financial cost, parental discretion, and not starting the first biologic. None of the individuals with persistent

oligoarticular disease switched. There was no difference in methotrexate use or presence of uveitis between those who did and did not switch.

**Conclusion:** In a multicenter cohort of children with JIA who started a biologic, only 10% of children switched biologic medication in the 6 months after initiation of the first biologic. Etanercept was the most common first biologic medication and most patients who switched started another TNF inhibitor. Additional studies are needed to evaluate the clinical predictors of switching, the outcomes following biologic switching, to identify the optimal timing of switching and the preferred second-line agent.

Table. Characteristics at time of biologic initiation among those who do and do not switch within 6 months (values are n (%) unless otherwise noted)

	All biologic initiators n = 134	Non switchers n=120	Switchers n=14

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The effectiveness of target use of biological medications depends on how personalized they are to fit patient's individual parameters with juvenile idiopathic arthritis (JIA). The proper selection of biologicals allows one to reach maximum effectiveness and reduce the dosage of concomitant therapy. Both the steroid- and NSAID-sparing effects of biological drugs are the key aspects of the dynamics of patient's condition. Purpose: To study the dynamics of concomitant treatment with NSAIDs and corticosteroids during etanercept treatment in patients with JIA.

### Methods:

This analysis was performed on 197 etanercept-naïve JIA patients (69.5% females) with median age of 7.25 years (IQR, 4–12 years). For each time point, as well as for the past medical history, the data on concomitant therapy were collected: the status of NSAID use, the fact of administration and dosage of oral glucocorticoids (orGC) and methotrexate (MTX). The effectiveness of primary therapy and the dynamics of concomitant therapy were analyzed after 3 months and every 6 months during the long-term follow-up (up to 4.5 years).

### Results:

At the baseline, 162 (82.2%) patients received concomitant MTX; 10 (5.0%) patients, orGC; and 121 (61.4%) patients, NSAIDs. All patients with concomitant orGC received both ETA and MTX. No patients received intra-articular GK for the entire study period.

Within 1 year treatment with ETA, NSAIDs were discontinued in 114 (94.2%) patients, orGC were discontinued completely in 4 children (40%), and the dose of orGC was reduced in 1 patient (10%).

By the end of follow-up period, NSAIDs were withdrawn in 115 patients (95%), orGC were withdrawn in 4 (40%) patients, and were reduced in 4 (40%). Only one patient during the observation required an increase in dosage of orGC. During the entire period of observation, the appointment of NSAIDs or orGC was not required for any patient who had not previously received these drugs. There were no significant differences in the dynamics of withdrawal of NSAIDs in

patients who received and did not receive MTX background therapy: the total withdrawal was 91 out of 96 (94.8%) patients in the MTX+ETA group vs 24 of 25 (96%) in the ETA group ( $p = 0.804$ ). By the end of the follow-up period 36 (19.3%) of 187 patients who had any background therapy, could switch to ETA monotherapy.

## Conclusion:

Our results demonstrate that long-term therapy with ETA makes it possible to reduce the dosage or completely discontinue most concomitant therapy agents (orGK, NSAIDs, MTX) in a significant percentage of patients. This reduces the risk of development of NSAID- and GC-associated pathological conditions, while the effectiveness of therapy of the underlying condition remains high.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The range of biological drugs currently used in JIA therapy includes not only anti-TNF but also other varieties. However, despite the high effectiveness and good tolerability of biological agents, the first-line biological medication is discontinued in a certain cohort of children. The questions regarding effectiveness of switching to second-line and further biologics depending on the reasons for discontinuation of prior therapy and the acceptable number of drug switches still need to be solved. Purpose: To compare the effectiveness of adalimumab (ADA) therapy as the first-, second-, and third-line biological drug in children and adolescents with JIA.

**Methods:** A total of 214 juvenile patients were enrolled in this study: 120 ADA-naïve patients, 83 and 11 patients with a history of one and two drug switches, respectively. Response to therapy was assessed using the ACRPedi 30/50/70/90

criteria and the Wallace criteria. The treatment schedule and the reasons for discontinuation of prior biological medications were collected.

## Results:

Eight patients received abatacept as the prior biological drug; 16 patients, etanercept; 64 patients, infliximab; 4 patients, rituximab; and 2 patients, tocilizumab. The predominant reasons for discontinuation of prior biological therapy were lack of primary effectiveness (16 (17%) patients) and partial ineffectiveness (39 (41.5%) patients); 14 patients (15%) had uveitis flare. In 8 patients (8.5%), therapy was discontinued because of adverse events; in 2 patients (2%), because of administrative reasons; and in 15 (16%) patients, because of stable remission. ADA therapy proved to be effective regardless of the number of prior biological drugs used. ACR90 was achieved by 75 (62.5%) ADA-naïve patients and by 60 patients (63.8%) in the switching groups ( $p=0.841$ ) within 1 year of treatment. Stable remission was achieved by 51 (42.5%) and 43 (45.7%) patients, respectively ( $p=0.635$ ). However, the negative reasons for discontinuation of prior biological therapy are the risk factors for poor prognosis for response to therapy with different drugs. Among 57 children who discontinued the prior biological medication because of poor effectiveness, ADA was discontinued within the first year because of the same reason in 6 (10.5%) patients. Within this group, only 10 patients (17.5%) reached remission during the first year of ADA therapy and 32 patients (56.1%) reached ACR90.

## Conclusion:

Adalimumab is highly effective as the first-, second-, and third-line biological drug in children with JIA. Discontinuation of prior drug because of poor effectiveness reduces the chances for reaching stable remission and improvement in ACR90 during the first year of ADA therapy.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry began enrolling children with juvenile idiopathic arthritis (JIA) in July 2015. The large number of children with prevalent JIA in the Registry and inclusion of medication logs which document medication use prior to enrollment provide a unique opportunity to describe patterns of medication use among children with JIA.

**Methods:** Participants were enrolled at >55 centers in the US and Canada. Children with polyarthritis, including the ILAR categories of extended oligoarticular JIA and polyarticular JIA (RF positive and negative), were included in these analyses if they had >12 months of data available since diagnosis. Data were obtained from Registry medication logs that contained the patient's medication use history, including start and stop dates. Patient date of diagnosis and medication start and stop dates were imputed if month or day were missing. Longitudinal treatment maps were developed to visualize patient's individual treatment courses and identify common usage patterns among them. To generate the treatment maps, each patient's disease duration was divided into 60-day intervals over the first two years since diagnosis. Medication use for each interval was classified by the predominant medication usage pattern during that interval, including non-biologic and/or biologic DMARDs, or no treatment. Patients were sorted by initial and subsequent medication use to determine the most common patterns of medication use.

**Results:** 853 patients were included, the majority of whom had RF negative polyarticular JIA (71%; Table). 50% of children with RF negative polyarthritis 66% of children with RF positive polyarthritis received a biologic DMARD, most commonly a tumor necrosis factor alpha inhibitor (TNFi). Among children with extended oligoarticular JIA, 35% of children did not receive non-biologic or biologic DMARD treatment. The most common pattern of medication use in this group was methotrexate monotherapy (oral or subcutaneous). Among children with polyarticular JIA (RF positive or negative), the most common sequence was methotrexate monotherapy with addition of biologic DMARD, most commonly TNFi. Less common patterns were biologic DMARD monotherapy and initial therapy with biologic and non-biologic DMARDs. Use of a second or third TNFi and non-TNFi biologics was rare during the first 2 years of treatment.

**Conclusion:** Although there is variability in treatment approaches to non-systemic polyarthritis in children, patterns of early medication use can be identified by longitudinal mapping of individual patients' medication data. These data may be used to assess how treatment approaches change over time as new therapies become available.

Table. Patient Characteristics and Medication Use During the First 24 Months After JIA Diagnosis

	Extended Oligoarticular JIA  (n=118)	Polyarticular JIA,  RF positive  (n=127)	Polyarticular JIA,  RF negative  (n=608)

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite the many available new and effective treatments for polyarticular JIA (P-JIA), there is significant variation in the timing of when biologic medications are started. Three consensus treatment plans (CTPs) reflecting the currently most commonly-used strategies for starting biologic treatment were developed by the Childhood Arthritis and Rheumatology Research Alliance (CARRA) using consensus methodology. The CARRA Start Time Optimization of Biologic Therapy in Polyarticular JIA (STOP-JIA) study aims to compare the effectiveness of the 3 CARRA P-JIA CTPs using a prospective, observational study design. This abstract describes interim baseline characteristics and CTP choices for the patients enrolled in STOP-JIA.

**Methods:** Untreated P-JIA patients were enrolled into the CARRA Registry. Providers and patients together chose one of the CTPs to follow: 1) Step-Up treatment (initial therapy with DMARD and biologic added after 3 months if needed); 2) Early Combination (initial therapy with both DMARD and biologic); and 3) Biologic First (initial treatment with biologic monotherapy). Providers had the option of prescribing glucocorticoids at baseline per their usual practice and were provided with tapering options. There is no randomization or blinding in this observational study.

**Results:** One hundred and eighty two patients were enrolled at 37 sites in the US and Canada between 1 Nov 15 and 31 May 17. Patient characteristics are summarized in Table 1. The most commonly chosen CTP was Step-Up (n=116; 64%). Early Combination CTP was the next most common choice (n=44; 24%). Forty eight (26%) of patients received oral steroids at baseline. To date, 491 follow up visits have been entered and 30 patients have completed their 12 month visit. Of the patients who have completed their 3 month visit, 10 patients were reported to have changed CTP. There

were 9 Serious Adverse Events (SAE) or Important Medical Events (IME): 1 each of septic shock (CTCAE Grade 3), influenza A (Grade 2), new onset uveitis (Grade 2), shingles (Grade 2), seizure (Grade 1), hepatitis (Grade 1), and 3 infections treated with IV antibiotics (Grades 1, 2, and 3).

**Conclusion:** To date, patients have been enrolled into all 3 CTP choices, with the Step-Up CTP being the most common. Ongoing, prospective data collection from these patients will allow for a comparison of the effectiveness of the strategies.

Table 1. Baseline Patient Characteristics

	Total Cohort (n=182)	Step up (n=116)	Early Combination (n=44)	Biologic First (n=22)
Female N (%)	134 (74%)	85 (76%)	31 (71%)	15 (68%)

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Up to 37% of patients prescribed adalimumab (AD) report significant injection-site pain (Registered Prescribing Information, 2016). For AD to be a stable pre-filled product, the pH is 5.2, which contributes to injection-site discomfort. Injection site pain is a major factor in patient willingness to initiate/continue AD. Literature reports less injection-site pain with older age, smaller volume, and use of autoinjectors. In 2008, we also reported that addition of lidocaine (LID) decreased discomfort by 80% and improved acceptance of AD. Incompatibility is not reported between AD and LID. AD and LID were combined at room temperature; no precipitation occurred. In our practice, when initiating AD, patients are offered the option of adding 0.2 ml of LID to AD.

To better understand the impact of LID added to AD, we evaluated two groups of JIA patients: those who used AD with LID, compared to those who did not. Our aim was to understand characteristics of the groups and to identify patients who might benefit by adding LID. We also sought to assess differences in disease control and adverse events that might occur when adding LID

**Methods:** Chart review of AD-treated JIA patients was performed. Age when instituting AD, sex, diagnoses, ESR, joint counts, and adverse events were reviewed. **Results** were compared between LID users (LID+) and non-users (LID-). Chi Square, T-Test and Z-score statistics assessed differences between groups.

**Results:** 98 JIA patients treated with AD from 2008 to May 2017 were included; 71 patients added LID, whereas 27 did not. JIA subtypes were: 28 ERA, 17 poly, 26 oligo, 23 psoriatic, 1 undifferentiated, 3 systemic; uveitis was present in 19 patients. No differences in LID use by diagnosis were found. Fewer males than females added LID (56% versus 78%) (p = 0.036). Mean age when AD was instituted and duration of use was similar: 12.2 years of age in LID+ group and 12.7 years in LID- group; AD taken for 16.2 mos ±14.2 in the LID- group and taken for 20.9 ± 20.6 mos in the LID+ group (both age and duration NS). JIA patients ≤ 10 yo did not add LID more often than those ≥ 11 yo. Further analysis by age showed that 91% of early adolescents aged 10-14 years added LID, compared to 59% children aged 1-9 years and 50% teens ≥15 years (p=0.002). In the LID+ group, joint counts and ESR improved significantly after taking AD (p =0.002 and p< 0.00001, respectively), but no improvement was seen in either metric in the LID- group. 11% of the total population reported mild adverse events. One patient in LID- group discontinued AD due to injection site pain.

**Conclusion:** In our cohort, adding LID to AD was preferred more by female and early adolescent patients. Adding LID produced no increased adverse events and did not impede response to AD, as shown by improved joint count/ESR in the LID+ group after starting AD. Interestingly, the LID- group demonstrated no such improvement. This may reflect non-adherence to AD in the latter group possibly due to painful injections and will need further study. Our previous work showed AD plus LID produced less injection-site pain; hence patients continued this treatment. We conclude that it is safe to add LID to AD and certain JIA patients prefer this addition, possibly with improved adherence and better disease control.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. The advent of new biological drugs has changed the prognosis and therapeutic approach to these patients. Our aim was to evaluate the use of biological therapy in JIA.

### Methods:

Multicenter prospective study. Information was obtained from BIOBADASER. All patients diagnosed before age 16 in our database between 2000 and 2015 were included in the analysis. JIA is classified into 7 subgroups: systemic, persistent or extended oligoarthritis, RF positive polyarthritis, RF negative polyarthritis, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis. Due to the design of the registry, it was not possible to identify each of the JIA subgroups; thus, we classified them into systemic/oligo/polyarticular JIA, JIA related to enthesitis, and psoriatic JIA.

Proportions, means and standard deviations (SD) were used to describe our population and the utilization of treatments. Survival rates were calculated until termination of treatment for any reason.

**Results:** A total of 469 patients were classified as systemic/oligo/polyarticular JIA (70.6%), JIA related to enthesitis (25%) and psoriatic JIA (4.5%). 46.1% of patients were women (n= 216). Age at diagnosis was 9.4 (SD= 5.3) and years of disease evolution 24.1 (SD= 14.1). The age at biological treatment initiation was 23.9 years (SD= 13.9). 42.4% of the biologicals were used as monotherapy. Methotrexate was used in combination in 44.0% of the biological treatments. 12.4% of the patients received more than 3 biologicals (December 2015). The most commonly used drug was Etanercept (34.7%), followed by Infliximab (21.6%). Table 1 shows the biologic therapies used in our sample. 42.4% of

the treatments with Etanercept were in monotherapy. The median survival rate with the drug was over three years (Table 2).

**Conclusion:** TNFi were the most commonly used biologic therapies in JIA. Ineffectiveness was the main reason for discontinuation. Survival rates can be a crucial endpoint in JIA, with age at initiation of biological treatment of particular concern.

Table 1. Biological and concomitant drugs used in patients with JIA.

<b>Biologic drug</b>	<b>First-line Biologic n (%)</b>	<b>Second-line Biologic n (%)</b>	<b>All n (%)</b>
Etanercept	204 (43.5)	119 (25.8)	323 (34.7)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To analyze the efficacy and safety of biologic agents in adult patients with juvenile idiopathic arthritis (JIA).

### **Methods:**

ATTRA is a Czech national registry of patients with different forms of chronic arthritis who are treated with biologics. We have used this registry to evaluate treatment with TNF antagonists and other biologics in adult patients with juvenile idiopathic arthritis. Patients were treated with doses recommended for rheumatoid arthritis patients. Those patients, who failed to improve in DAS28 by at least 1.2 after 3 months at 2 consecutive visits, who lost the response during the treatment, or who had to be discontinued due to adverse event, were switched to alternative TNF inhibitor or other biologic drug. Clinical efficacy was assessed by the improvement in DAS28 and by assessment of quality of life using standard questionnaires (HAQ, SF36). Survival on therapy with biologic agent was calculated. Safety assessments were done for all patients during the whole follow-up period in 3 months intervals.

### **Results:**

There are 419 adult patients with JIA followed in the ATTRA registry. Seventy-four started the treatment with biologic before 16 year of age; the remaining 345 commenced biologics in adult age. Valid and complete data for analysis are available in 275 patients, who have begun treatment in adulthood.

At the start of the treatment with biologics the mean age was 27±9 years, duration of disease 16±10 years and 73.8% were females. Mean age at the diagnosis was 11±6 years.

Patients were of the following subtypes of JIA: JIA RF negative 28.3%, JIA RF+ 22.8%, enthesitis related arthritis 18.9%, extended oligoarthritis 12.2%, psoriatic arthritis 7.2%, systemic onset 6.1% and persistent oligoarthritis 4.4%.

The first biologic was either infliximab (37.1%), or etanercept (26.2%), adalimumab 27.6%), golimumab (4.4%), certolizumab (2.5%), tocilizumab (1.5%), abatacept (0.4%) and rituximab (0.4%).

#### **Efficacy of the first biologic (DAS28):**

<i>DAS28</i>	<i>Before treatment</i>	<i>3 months</i>	<i>1 year</i>	<i>5 years</i>	<i>10 years</i>
<i>Mean±SD</i>	5.7±1.0	3.1±1.1	2.8±1.2	2.4±1.1	2.5±1.4
<i>Median</i>	5.7	3.0	2.7	2.2	2.1
<i>5.; 95.perc</i>	(4.0; 7.2)	(1.4; 5.2)	(1.2; 4.9)	(1.1; 4.5)	(1.2; 6.0)
<i>Remission</i>	2 (0.7%)	82 (34.2%)	91 (47.6%)	61 (64.2%)	23 (69.7%)
<i>LDA</i>	4 (1.5%)	56 (23.3%)	36 (18.8%)	15 (15.8%)	3 (9.1%)
<i>Number of patients</i>	275	240	191	95	33

#### **Efficacy of long term treatment including switches (DAS28):**

<i>DAS28</i>	<i>Before treatment</i>	<i>3 month</i>	<i>1 year</i>	<i>5 years</i>	<i>10 years</i>
<i>Mean±SD</i>	5.7±1.0	3.1±1.2	2.9±1.3	2.7±1.3	2.8±1.4
<i>Median</i>	5.7	3.1	2.8	2.5	2.4
<i>5.; 95.perc</i>	(4.0; 7.2)	(1.4; 5.2)	(1.2; 5.3)	(1.2; 5.4)	(1.2; 6.0)
<i>Remission</i>	2 (0.7%)	83 (33.5%)	96 (45.1%)	86 (51.8%)	40 (53.3%)
<i>LDA</i>	4 (1.5%)	56 (22.6%)	42 (19.7%)	25 (15.1%)	13 (17.3%)
<i>Number of patients</i>	275	248	213	166	75

#### **Conclusion:**

A significant number of adult JIA patients benefit from long-term treatment with biological agents. DAS28 showed excellent and persistent improvement for patients maintaining first biologic up to 10 years. Treatment effect to second and other biologic agents was only slightly smaller and contributed to a very good persistence on the treatment. The effect on activity was mirrored also in the functional improvements assessed by HAQ.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with juvenile spondyloarthritis (JSpA) have lower clinical remission rates, report higher pain scores, worse functioning and lower quality of life compared to other juvenile arthritis subtypes. JSpA patients present with different clinical features, including enthesitis, lower back pain, and sacroiliitis. Biologics, such as anti-tumor necrosis factor drug (TNFi), are increasingly being used for the treatment of pediatric inflammatory arthritis. In JSpA, TNFi are typically a second or third line treatment. We sought to evaluate the reasons for TNFi initiation in JSpA, identify specific measures of disease activity and disease progression associated with the TNFi start, and assess the effect of TNFi on JSpA disease activity.

**Methods:** A retrospective cohort study of JSpA patients with first-time use of a TNFi followed by the Pediatric Rheumatology Department at Stanford Children's Health from January 1, 2007, to December 31, 2014, was conducted. Patients were identified using Stanford STRIDE, a clinical data review tool. Reasons for TNFi initiation and change in JSpA disease activity index (JSpADA) components were assessed. JSpADA components changes were compared at diagnosis, TNFi initiation, 6 months post-TNFi initiation and 12 months post-TNFi initiation, as well as by disease duration at TNFi start.

**Results:** A total of 86 patients with clinical documentation at the time of JSpA diagnosis, TNFi initiation, and 6 months post-TNFi initiation were included in the analysis. The median age at JSpA diagnosis was 13.4y (IQR 9.9-15.5y) and the median time from JSpA diagnosis to TNFi initiation was 0.5y (IQR 0.2-2.4y). The most common reason for the physician to initiate a TNFi was for physical exam findings consistent with active disease (61%). Pain was included as a reason for initiation in 24% of patients, but never as the only reason. After six months of TNFi therapy, patients on average had three fewer active joints and one fewer active enthesitis point. Patient-reported pain also improved from moderate/severe to mild pain. At 12 months post-TNFi initiation, 54% of TNFi initiators were still considered to have active disease. Comparisons with the total JSpADA scores were unable to be performed due to missing data.

**Conclusion:** This study provides insight into the relationship between TNFi initiation and clinical disease activity in the JSpA population. Physical exam findings of active disease were enough to escalate therapy with a TNFi for most JSpA patients. TNFi initiation for pain alone without any definitive signs of active disease was not found to be a reason for escalation. Six months after initiating a TNFi, there was an improvement in active joint and enthesitis counts as well as patient-reported pain. However, more than half of the patients still had active disease one year after TNFi initiation. The physician's reason for starting a TNFi and the timing of TNFi initiation did not influence the clinical disease status after one year of TNFi therapy.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite their increasing use in adults, there is little to no data available on the use of biosimilar drugs in children with JIA, despite anecdotal evidence of their use in clinical practice. This analysis aims to describe the characteristics of children and young people (CYP) with JIA starting biosimilars in the UK over the first 2 years following their approval in the United Kingdom (UK) for adults with musculoskeletal diseases.

**Methods:** The Biologics for Children with Rheumatic diseases (BCRD) study, launched in 2010, is an ongoing prospective UK study of children with JIA starting biologic therapies other than etanercept (followed in a separate parallel study). Baseline information is collected via questionnaires completed by the treating physician or affiliated clinical research nurse. Follow-up data including disease activity measures and changes in drug therapy are collected at 6 months, 1 year and annually thereafter. Since 30/09/2015, data has been captured on 3 biosimilars available in the UK: infliximab (Inflectra and Remsima) and etanercept (Benepali).

**Results:** To 10/05/2017, 26 patients were identified in the BCRD study starting a biosimilar: 21 (81%) Remsima, 3 (12%) Inflectra and 2 (8%) Benepali). Of these, 9 (35%) started a biosimilar as their first biologic therapy. Only 1 patient starting Remsima switched directly from the originator product, Remicade. Sixteen (62%) switched from an alternative non-originator biologic (table). Reasons for switching from these alternative biologics were efficacy reasons (n=8, 50%), safety reason (n=5, 31%), efficacy and safety issues combined (n=2, 13%) and needle phobia (n=1, 6%). Six-month and 1 year follow-up data were available in 3 and 1 CYP respectively. No serious adverse events have been reported to date and all 4 CYP continue on their biosimilar drug.

**Conclusion:** This preliminary study gives a first overview of initial biosimilar use in CYP with JIA in the UK. It has shown that these drugs are used as both first-line and subsequent-line biologic therapy despite a lack of license for this indication. Unlike evidence from Rheumatoid Arthritis, where a majority of patients receiving biosimilars to date have switched from the originator, this initial experience in JIA suggests that biosimilars are being considered as front line therapeutic option instead of the originator, presumably as a cost-saving measure. Further follow-up of these children will assess the effectiveness and safety of these products in paediatric use.

Table

	Biological naive	Subsequent line biologic
<b>Number</b>	9	17
<b>Biosimilar, n (%)</b>

## Successful Treatment of Methotrexate Intolerance in Juvenile Idiopathic Arthritis Using Eye Movement Desensitization and Reprocessing (EMDR)

Lea Höfel, Bruno Eppler, Elisabeth Schnöbel-Müller, Johannes Peter Haas and **Boris Hügler**, German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is commonly used in the treatment of children with juvenile idiopathic arthritis (JIA). It frequently has to be discontinued due to intolerance with anticipatory and associative gastrointestinal

symptoms. Eye Movement Desensitization and Reprocessing (EMDR) is a therapy where non-processed and dysfunctional experiences and memories are reprocessed by intensive recall combined with eye movements. This leads to selective processing of the negative affect.

The objective of this study was to investigate effectiveness of EMDR in the treatment of MTX intolerance in JIA patients, with the underlying hypothesis that intolerance occurs due to dysfunctional memories and expectations.

**Methods:** An open prospective study on consecutive JIA patients with MTX intolerance was performed. Intolerance was determined using the Methotrexate Intolerance Severity Score (MISS) questionnaire, and health-related quality of life was determined using the PedsQL, at 3 time points: directly before and after treatment (after treatment: MISS only), as well as 4 months after treatment. Patients were treated using a standardized EMDR protocol with 8 sessions over a time period of 2 weeks. Changes in MISS and PedsQL were compared using descriptive and non-parametric methods.

**Results:** 14 patients with MTX intolerance (median MISS at inclusion: 13.5, range: 6-26) were included. Directly after treatment, all patients reported marked improvement of MTX intolerance symptoms (median MISS: 0.5, range: 0-3,  $p=0.001$ ). After 4 months, lasting reduction of MTX intolerance symptoms was observed ( $n=5$ , median MISS: 5, range: 0-10,  $p=0.068$ ). However, 2/5 patients (40%) showed renewed signs of MTX intolerance with MISS  $>6$ . The health-related quality of life showed a trend towards improvement 4 months after treatment ( $n=5$ , median pedsQL prior to treatment 84.4%, 4 months after treatment 92.4%,  $p=0.46$ ).

**Conclusion:** MTX intolerance in children with JIA can effectively be treated using an EMDR protocol, with lasting improvement over a period of 4 months. This intervention could potentially increase quality of life in affected patients and enable continued treatment with MTX as an effective, economic and well-tolerated medication.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Research in Arthritis in Canadian Children emphasizing Outcomes cohort (ReACCh-Out) showed a 45% chance of attaining inactive disease within a year of diagnosis with conventional JIA treatments. Children who do not attain inactive disease may miss a window of opportunity to start aggressive treatment. Here, we used ReACCh-Out data to develop models to assign probability of **early remission on medication (ERM)** for each child with JIA at diagnosis.

**Methods:** ReACCh-Out recruited 1497 patients newly diagnosed with JIA in 2005-2010 and followed them for five years or until May 2012. Children were included in this study if they 1) were enrolled within 90 days of diagnosis, 2) received conventional treatment (no biologics or triple DMARD within 6 months of diagnosis) and 3) had enough follow-up to determine the outcome. Outcome (ERM): at least six months of inactive disease with the first inactive disease visit occurring within one year of diagnosis. Documentation of any of the following within that period meant ERM was not attained: an active joint, enthesitis, a physician global assessment of 1 or more in a 10cm scale, systemic JIA manifestations, active uveitis, corticosteroid eye drops, morning stiffness >15 min, ESR >20 mm/h, CRP >5 mg/L. Patients who discontinued treatment during that period and remained inactive were still counted as having attained ERM. Eligible subjects were randomly split into a *training* set to develop candidate models (75% of subjects) and a *test* set to determine their accuracy (25% of subjects). Missing data on predictors were imputed using multiple imputation (20 datasets). Data splitting and model fitting were repeated 10 times for each imputed dataset to assess model stability.

**Results:** We included 916 children enrolled a median of 2 days after JIA diagnosis, of whom 409 (44.7%) attained ERM. Among 50-plus assessed variables, 17 were positively or negatively associated with ERM (Table). A logistic regression model combining these variables had a c-index of 0.62 (95% CI 0.59, 0.66). Although predicted and observed frequencies of ERM paralleled each other (Figure), the model's c-index was similar to using JIA category alone (c-index of 0.59; 95% CI 0.56, 0.63). C-index values >0.70 are considered helpful prediction.

**Conclusion:** In this cohort, many variables easily available at diagnosis were associated with ERM in children with JIA. However, a prediction model combining the variables was only marginally better than using JIA category alone. Novel biomarkers and modelling methods may be needed to improve prediction accuracy.

## Comparing Effectiveness of Early Initiation of Biologic Treatment for Newly Diagnosed Juvenile Idiopathic Arthritis Using a Novel Statistics Causal Inference Method Applied to Observational Data

Bin Huang<sup>1</sup>, **Esi Morgan**<sup>2</sup>, Chen Chen<sup>2</sup>, Jinzhong Liu<sup>2</sup>, Michelle Adams<sup>2</sup>, Timothy Beukelman<sup>3</sup>, Hermine I. Brunner<sup>4</sup> and Daniel J Lovell<sup>5</sup>, <sup>1</sup>Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>2</sup>Cincinnati Children's Hospital, Cincinnati, OH, <sup>3</sup>Pediatric Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>4</sup>Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>5</sup>PRCSG, Cincinnati, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We compare the effectiveness of two approaches to treat Juvenile idiopathic arthritis (JIA): early combination of biologic and non-biologic disease modifying anti rheumatic drugs (b+nbDMARDs) vs. non-biologic DMARDs (nbDMARDs) alone using a novel statistics causal inference method applied to an existing observational study. Other commonly used causal inference methods are also applied and the results are compared.

**Methods:** A study of health related quality of life (HRQoL) study enrolled 193 children age 2-16 with newly diagnosed (< 6 month) JIA treated at a large pediatric rheumatology clinic in United States between October 2008 and August 2012, and prospectively followed the participants at 6 and 12 months after enrollment. The current study retrospectively extracted medication prescriptions to the HRQoL participants from the date of diagnosis to the 12 month follow up visit. Patient with polyarticular forms of JIA (pJIA) and on DMARDs at the study baseline were eligible for the current study. The study endpoint was Juvenile Arthritis Disease Activity Score (JADAS) at the 6 months of follow up visit. Different statistics causal inference methods are considered, including propensity score sub-classification, inverse treatment probability weighting (IPTW), regression adjustment, and a newly proposed Bayesian Gaussian Process (GP) causal inference method that is designed to model outcome and while matched on pre-treatment factor simultaneously.

**Results:** At the baseline visit, 111 children were treated with DMARDs: 32 (29%) with b+nbDMARDs, 66 (59%) nbDMARD and 13 (12%) bDMARDs only. Table 1 provides the baseline characteristics of patients by treatment group. Patients on b+nbDMARDs had higher JADAS scores at the baseline, with mean±SD of 18.66±11.69 vs. 11.46±8.54 (Student P value <.02), and higher rate of RF positive (28.1% vs. 10.6%, Chisq P<.05). Controlled for treatment selection bias, Bayesian GP method find children treated with b+nbDMARDs show 3.83 points improvement (95% confidence interval of 0.14-7.53) in JADAS than those treated with nbDMARDs at 6 month. Other causal inference methods suggested similar effectiveness but with more uncertainty.

**Conclusion:** The early initiation of b+nbDMARDs approach improves clinical outcomes at 6 months more effectively than the nbDMARDs alone strategy in children with newly onset of pJIA.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

The BeSt treatment strategy for children with juvenile idiopathic arthritis (JIA) has not been determined. The aim of the BeSt for Kids study was to investigate, which of three treatment strategies is most effective and safe, by direct comparison. The target was inactive disease in all arms was inactive disease by rapid reduction of disease activity and repeated monitoring and revision of therapy in case of insufficient response. We hypothesized that early treatment with etanercept and methotrexate (arm 3), compared to initial monotherapy (arm 1) or initial combination therapy with methotrexate and prednisone (arm 2), would lead to significantly earlier clinical inactive disease.

## **Methods:**

We conducted a randomized, single blinded, multicenter, treatment strategy study with 24 months of follow up. Disease modifying anti rheumatic drug (DMARD)-naïve JIA patients were randomized to 1. sequential DMARD-monotherapy (sulfasalazine (SSZ) or methotrexate (MTX), 2. combination therapy: MTX and prednisolone-bridging, 3. Combination-therapy MTX with etanercept. For all arms, the treatment protocol described a number of subsequent treatment steps in case medication failed. Missing data were imputed. Primary outcome was time to inactive disease and time to flare after tapering and stopping DMARD therapy calculated using Kaplan Meier plot with log rank test. Secondary outcomes are adjusted ACRpedi 30/50/70/90 scores and toxicity. Generalised Estimates Equations were used for longitudinal data analyses.

## **Results:**

Ninety-four patients were randomised, 32 in arm 1, 32 in arm 2 and 30 in arm 3. Two patients received a different diagnosis during follow-up and were left out of all analysis. Two patient were lost to follow up but were analysed due to intention to treat principle. Overall baseline median (InterQuartileRange IQR) age was 9.1 (4.6-12.9) years. 37% were ANA positive, 11 patients had oligo-articular disease, 66 patients polyarticular JIA and 15 patients juvenile psoriatic (polyarticular) arthritis. Baseline median (IQR) ACRpedi-scores: VAS physician 50 (39-58) mm, VAS patient 54 (37-70) mm, ESR 6(2-14) mm/hr, active joint count 8 (5-12), limited joint count 2.5 (1-5), CHAQ score 0.9 (0.6-1.5). Inactive disease occurred overall after mean 9.8 months (8.5-11.1). Time to inactive disease was not significantly different in all three arms (log rank test  $p=0.23$ ). Outcome measures after 24 months are summarised in the table.

	Arm 1 n=31	Arm 2 n=32	Arm 3 n=29	3 vs 1 p OR (CI)	2 vs 1 p OR (CI)	3 vs 2 p OR (CI)
aACRPedi30(%) (CI)	92.2 (82.1-102.4)	84.4 (71.2-97.5)	96.6 (89.8-103.3)	0.14 1.7 (0.8-3.4)	0.8 0.9(0.5-1.7)	0.09 1.8 (0.9-3.7)
aACRPedi50 (%) (CI)	85.5 (72.4-98.6)	83.8 (70.1-97.4)	93.1 (83.7-102.4)	0.3 1.4(0.7-2.8)	0.9 1.1(0.6-2.0)	0.4 1.3(0.7-2.7)
aACRPedi70 (%) (CI)	69.0 (52.1-85.9)	68.8 (51.6-85.9)	82.8 (68.8-96.8)	0.07 1.8(1.0-3.3)	0.7 0.9(0.4-1.7)	0.03 2.1(1.1-4.0)
aACRPedi90(%) (CI)	58.4 (40.6-76.1)	55.3 (37.3-73.3)	69.0 (51.8-86.1)	0.34 1.4 (0.7-2.6)	0.38 0.7(0.4-1.5)	0.06 1.9 (1.0-3.5)
Inactive disease (%) (CI)	61.0 (39.7-82.3)	63.1 (43.6-82.7)	61 (40.9-81.2)	0.9 1.0(0.7-1.7)	0.1 0.7(0.4-1.1)	0.09 1.5(0.9-2.5)
JADAS-10 (CI)	2.6(1.4-3.8)	4.0(2.2-5.8)	3.0(1.6-4.4)	0.6 0.6(0.1-3.5)	0.2 3.1(0.5-20.3)	0.09 0.2(0.03-1.3)

## Conclusion:

Although our study did not meet its primary end point, treat-to-target treatment in this cohort of children with recent onset JIA resulted in high frequencies of clinical inactive disease and adjusted ACRpedi30/50/70 scores in all three arms. In clinical trials inactive disease seems a feasible goal in juvenile idiopathic arthritis patients. Tight control seems to be more important than the agent(s) inducing it.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

The efficacy of medications in randomized trials may differ substantially from their effectiveness (degree of beneficial effect under “real world” clinical settings). Reliable estimates of actual observed effectiveness of medications in usual medical practice will help parents and physicians make better-informed treatment decisions. Therefore we sought to estimate the effectiveness of common treatment strategies observed in usual practice in JIA patients followed in a large prospective inception cohort.

## **Methods:**

Data from the Research in Arthritis in Canadian Children emphasizing Outcomes (ReACCh-Out) cohort were used to describe the observed success rate of common JIA treatment strategies. Treatment changes in each child were conceptualized as a series of n-of-1 treatment trials and systematically analyzed. A treatment trial starts with a change in treatment and concludes with the next change in treatment. The start could also be the initial treatment. Success was defined as attainment of inactive disease, or as maintenance of inactive disease when tapering treatment. Inactive disease was defined as no active joints, no extra-articular manifestation and PGA <10mm according to criteria by Wallace et al. Success rates and 95% confidence intervals (CI) were calculated for trials observed in at least 25 patients.

## **Results:**

2962 treatment trials were observed in 1275 children; 2151 (72.6%) were step-up trials. NSAID monotherapy (usually naproxen) was trialed in 606 children, mostly as first line treatment for oligoarthritis, at a mean of 1.1 years after disease onset and had a success rate of 62%. NSAID plus joint injection (JI) had a success rate of 74% (see Table). Adding a DMARD to NSAID ±JI was trialed in 445 children. Methotrexate plus NSAID was trialed in 385 children, many with polyarticular involvement, at a mean of 1.2 years since onset and had a success rate of 67%. In logistic regression analyses, the odds of success for NSAID ±JI were reduced by each additional active joint at the start of a trial (odds ratio OR 0.90, 95%CI 0.87-0.94) and by each additional year since onset (OR 0.90, 0.81-0.99). RF negative polyarthritis, ERA and undifferentiated JIA had decrease chances of DMARD success relative to oligoarticular JIA. After adjustment for time since disease onset, number of active joints and JIA category, ankle or wrist involvement were associated with a reduced NSAID success rate (OR for ankle 0.53, 0.38-0.74; for wrist 0.66, 0.42-1.0). Similar trends were observed for response to adding a DMARD to NSAID ±JI.

## **Conclusion:**

These estimates of effectiveness of medications in usual medical practice from a prospective nation-wide cohort can help answer parents' questions regarding how effective NSAID monotherapy or combinations of DMARD and NSAID may be for their child and help inform treatment decisions.

Table: Success rate of various treatment strategies:

Treatment	Subgroup	Number of patients/trials	Success rate (95% CI)
NSAID Monotherapy	All	606	62(58-66)
	Naproxen	514	62(58-66)
	Indomethacin	66	56(42-66)
	Ibuprofen	21	--*
	<5 active joints	501	67(63-71)
	5 or more	105	36(26-46)
NSAID+JI	All	298	74(69-79)
	Naproxen+JI	260	76(71-82)
	Indomethacin+JI	21	--*
	Ibuprofen+JI	16	--*
	<5 active joints	271	75(70-80)
	5 or more	27	66(47-86)
Adding DMARD to NSAID ±JI	Methotrexate	385	67(62-72)
	<5 active joints	182	75(69-82)
	5 or more	203	60(53-66)
	Sulfasalazine	60	62(49-74)

\*not estimated as number was <25.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Identifying predictors for clinically inactive disease (CID) and sustained remission would allow rapid escalation of therapies for children less likely to achieve these states. This analysis assessed predictors of achievement of CID and sustained remission states over the first five years following diagnosis in children with JIA.

**Methods:** Children and young people enrolled in the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort, before January 2011, were selected if diagnosed with oligoarticular, RF-negative or RF-positive polyarticular JIA.

Components for CID and sustained remission according to i) Wallace's preliminary criteria and ii) cJADAS10 were collected at annual follow-ups to five years according to CAPS protocol. Sustained remission was defined as two consecutive follow-ups in CID. Individual baseline core outcome variables (active joint count, limited joint count, physician's global, parental global, functional ability (Childhood Health Assessment Questionnaire (CHAQ)) and ESR) were tested for predictive ability for i) CID at one year and ii) ever sustained remission within five years. Associations were tested in multivariable logistic regressions including all COVs, age and symptom duration at initial presentation, gender, ILAR subtype and recruiting centre. Multiple imputation accounted for missing predictor and outcome data.

**Results:** Of 832 children, 70% were female and the majority had oligoarticular JIA (68%). At one year, 31% had achieved CID according to Wallace's preliminary criteria and 44% according to the cJADAS10 (26% CID on both). Within five years, 60% had ever achieved sustained remission on Wallace's preliminary criteria and 66% on the cJADAS10 (52% sustained remission on both).

In multivariable analyses, an increase in 0.125 points (1 unit) on the CHAQ at baseline independently predicted 4% lower odds of CID on the cJADAS10 (95% CI 0.92, 0.99). No baseline COVs predicted CID on Wallace's preliminary criteria. An increased year of age at initial presentation to paediatric rheumatology independently predicted 12% higher odds of sustained remission on Wallace's preliminary criteria (95% CI 1.07, 1.17). In addition, one increased unit in CHAQ at baseline independently predicted 6% lower odds of sustained remission on both outcome measures (95% CI: Wallace: 0.91, 0.99; cJADAS10: 0.90, 0.98). Compared with oligoarticular JIA, children with RF-negative polyarticular and RF-positive polyarticular JIA had at least 49% and 68% lower odds of both sustained remission states, respectively. Gender and symptom duration to initial presentation were not independently associated with either outcome.

**Conclusion:** There were different predictors for CID on the cJADAS10 vs. Wallace's preliminary criteria although similar predictors for sustained remission using either definition were identified. Children with poor functional ability, polyarticular JIA and younger age at initial presentation could be targeted with more aggressive treatment strategies than currently in practice to better control their disease.

## **Utilizing the Pediatric Rheumatology Care and Outcomes Improvement Network to Assess Practice Pattern Variation in Juvenile Idiopathic Arthritis**

**Emily A. Smitherman**<sup>1</sup>, Janalee Taylor<sup>2</sup>, Esi M. Morgan<sup>1</sup> and C. April Bingham<sup>3</sup>, <sup>1</sup>Pediatric Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>2</sup>Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>3</sup>Pediatrics, Penn State College of Medicine, Hershey, PA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Despite modern treatment options for patients with juvenile idiopathic arthritis (JIA), rates of clinical inactive disease (CID) remain low. The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) includes 18 centers that serve as a representative sample for current practice. **Results** from the PR-COIN registry have demonstrated marked center-to-center variability in the rate of CID. The objective of this study was to survey PR-COIN centers to assess JIA practice patterns that may account for CID variation.

**Methods:** A survey was distributed to PR-COIN centers in October 2016 that consisted of 23 Likert items with a 7-point scale ranging from “totally disagree” = 1 to “totally agree” = 7. Practice patterns were defined as “standard methods of how care is conducted” within the local rheumatology clinic or division. The items represented evidence and consensus-based factors both specific to JIA management and adapted from chronic illness models. All items were constructed using declarative statements in the positive direction. For the analysis, the 23 items were grouped into 7 domains, including prepared proactive team, self-management, multidisciplinary team, decision support, patient access and follow-up, medication management, and quality improvement (QI) engagement. Statistical analyses included descriptive statistics for the results across individual items and summarized within domains.

**Results:** A total of 10 PR-COIN centers completed the practice pattern survey with a single set of responses per center. The median and range of each item and domain were calculated (Table I). A diverging stacked bar chart was constructed to illustrate the frequency of Likert responses within each item (Figure 1). Overall, the results demonstrate substantial variation in responses both across items and within items. Two items demonstrated total agreement and 5 additional items demonstrated all positive responses. However, the remaining 16 items demonstrated a wide range of responses and 12 items included at least one center that answered “totally disagree”.

**Conclusion:** We identified wide variation in JIA practice patterns among centers that participate in the PR-COIN network. These initial results are critical for targeting future quality improvement interventions across the network as well as launching additional investigations into the specific practices that are associated with higher rates of CID. Next steps will include semi-structured interviews with the PR-COIN centers to better characterize modifiable factors and develop a best-practice JIA bundle.

Table 1. PR-COIN Practice Pattern Survey Responses		
Question	Median	Range
<b>Care Coordination</b>		
1. My site performs some form of pre-visit planning (PVP) at least 80% of the time.	6	5-7
2. We regularly use a population management tool to review patients with active disease.	2	1-7
3. We consistently review as a team patients who have ongoing active disease.	2.5	1-7
Summary	5.5	1-7
<b>Self-Management</b>		
4. We regularly use self-management tools with patients and families (e.g., self-management assessment tool, barriers checklist, or action plans).	4	1-7
5. Team members (including prescribing providers, nurses) at my site have received training in self-management principles and behavior change counseling techniques.	4	1-7
Summary	4	1-7
<b>Multidisciplinary Team</b>		
6. Our patients and families have easy access to OT/PT appointments.	6	1-7
7. We have an OT/PT dedicated to pediatric rheumatology at our site.	2	1-7
8. Our patients and families have easy access to SW, if needed.	6	1-7
9. A social worker meets with all newly diagnosed JIA patients at our site.	2.5	1-7
10. Child life specialist is available for patients, if needed.	7	4-7
11. Nurses with pediatric rheumatology expertise are available in all clinics all the time.	7	3-7
Summary	6	1-7
<b>Decision Support</b>		
12. We use and regularly act upon functional assessment tool results.	5	1-7
13. We use algorithms/standardized treatment approaches for patients with active disease.	5	1-7
14. We use a decision support mechanism at our site to help with implementation of algorithms/treatment guidelines.	3	1-7
Summary	5	1-7
<b>Patient Access and Follow-Up</b>		
15. Our patients get a call back for a medical concern within 1 day by a nurse or physician.	7	7-7
16. Appointment slots are available when needed.	6.5	3-7
17. We have a system in place to keep track of patients who do not come back for follow up as recommended.	3	1-7
18. Patients with a disease flare are seen within one week.	6	5-7
Summary	6	1-7
<b>Medication Management</b>		
19. Joint injections are performed within 2 weeks of recognized need for all patients.	6	3-7
20. Most prescribing providers at my site generally initiate DMARDs within 2 months after diagnosing polyarticular or systemic JIA.	7	7-7
21. Most prescribing providers at my site escalate treatment within 3-4 months for patients whose JIA remains active/is not responding to treatment.	7	6-7
Summary	7	3-7
<b>QI Engagement</b>		
22. All prescribing providers at my site enroll patients into PR-COIN.	7	5-7
23. All prescribing providers at my site participate in PDAs/PR-COIN improvement activities for JIA patients.	6	5-7
Summary	5	5-7

Figure 1. Diverging stacked bar chart showing responses across PR-COIN centers to JIA practice pattern survey with 7-point Likert scale.

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is the most used immunomodulatory drug in Juvenile Idiopathic Arthritis-associated uveitis (JIA-U) although its efficacy has been shown only in retrospective studies with limited number of subjects, short follow up and sometimes questionable methodology. The timing of MTX start in JIA-U as well as of switch from first and second-line therapy are still controversial. Aim of the present study was to evaluate the efficacy of MTX as first-line therapy in a monocentric inception cohort of patients with JIA-U.

**Methods:** Patients with JIA-U refractory to local eye drops treatment were managed by a standard protocol including MTX, at a standard dose of 10-15 mg/m<sup>2</sup>/week, as first line systemic treatment. Data, recorded every 3 months, included ocular flares and complications, drug-related adverse events (AE) and treatment change. The diagnosis of JIA was based upon the ILAR criteria<sup>1</sup> and the diagnosis of uveitis was made according to the SUN Criteria<sup>2</sup>. Uveitis flare was defined as an increase of cells in the anterior chamber of 2+ or more as compared to the baseline. Clinical remission was defined as the absence of flares for more than 6 months on treatment, without or with minimal topical treatment (corticosteroid and/or mydriatic-cycloplegic eye drops ≤ 1/day). Data of patients treated for at least 1 year were analyzed using descriptive statistics.

**Results:** 84 consecutive JIA patients (71 F, 13 M), 82 oligoarticular, 2 polyarticular, treated with MTX for JIA-U and at least one year f/u entered the study. Mean age at MTX start was 5.7 years (1.8–21.6); mean f/u since MTX start 8.9 y (1–20 y). 68 patients started MTX primarily to treat uveitis (group A) (JIA duration 1.8 y), 16 patients introduced MTX for arthritis (group B) (JIA duration 0.54 y). The mean interval time between arthritis and uveitis onset was 0.8 y in group A and 2.1 y in group B (p<0.01). After treatment start, 25% relapsed with uveitis flare by 5 months, 50% by 9.7 mo and 75% by 36 mo. At the last evaluation, 40 pts (47.6%), 28 in group A and 12 in group B, needed anti-TNF therapy to control uveitis flares; 35 (41.7%) were in remission on medication and only 9 (10.7%) (all in group A) reached a complete remission at a mean f/u of 39.4 mo.

**Conclusion:** MTX loses its efficacy quite rapidly overtime and ensures clinical remission only in a minority of patients. When started before uveitis, MTX delays the uveitis onset but does not prevent its severe course.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Infliximab (IFX) effectiveness is impacted in part by immunogenicity and the development of drug neutralizing anti-drug antibodies, thus methotrexate is commonly co-administered to minimize the immune response to IFX. However the mechanism by which MTX impacts IFX concentrations and anti-drug antibody formation is unknown. In adults with Rheumatoid Arthritis, higher concentrations of MTX polyglutamates (MTXGlu<sub>3</sub>) were associated with lower drug antibody formation, suggesting that MTXGlu may impact IFX pharmacokinetics (1), however, little is known in children.

**Methods:** This is a cross-sectional study of patients receiving IFX at Children's Mercy Kansas City (n=97) and included patients with Inflammatory Bowel Disease (IBD n= 73), Juvenile Idiopathic Arthritis (JIA n=16), and childhood uveitis (CU n=8). 35 patients were on concomitant MTX therapy (26% IBD, 75% JIA, 75% CU). Serum trough samples were analyzed for IFX and anti-IFX antibodies using a NF- $\kappa$ B luciferase gene-reporter assay (ARUP Laboratories), and for erythrocyte MTXGlu<sub>n</sub> levels by HPLC-MS/MS. Clinical data were collected by chart review. Statistical testing was conducted by Wilcoxon-rank sum or Spearman's rank correlation analysis, and data were log transformed for regression analyses.

**Results:** Despite wide variations in dose, frequency, and trough IFX concentrations between groups, when normalized for variation in dose and frequency (NormIFX), troughs were not statistically different (median (IQR) in IBD: 3.5 (1.8, 5.2), JIA: 4.1 (2.3, 5.6), and CU: 4.4 (3.4, 5.6)). Only 3 IBD patients had anti-IFX Ab detected, and they had significantly lower median NormIFX concentrations (3.9 (2.2, 5.3) vs. 0 (0, 0) p<0.01), but no difference in MTXGlu concentrations, although only 1 patient was receiving MTX concurrently. When the JIA and CU patients were evaluated separately, there was a *negative* association between long chain MTXGlu<sub>3-6</sub> formation and NormIFX levels for JIA ( $\rho$  -0.81 p=0.005) and CU ( $\rho$  -0.94 p=0.005). This remained significant despite controlling for MTX dose and route in a linear regression model (JIA p=0.04, CU p= 0.04). In JIA patients, higher NormIFX levels were associated with lower cJADAS ( $\rho$  -0.72 p=0.009).

**Conclusion:** Anti-IFX Ab were rarely observed in this cohort of patients, and only seen in children whose trough IFX levels were undetectable. Once normalized for dose and frequency, trough IFX concentrations were not statistically significantly different between disease groups, although JIA and CU troughs were higher. In JIA and CU, but not IBD, MTXGlu<sub>n</sub> accumulation negatively impacted NormIFX trough levels, suggesting mechanisms by which MTX enhances infliximab effectiveness may be independent of MTXGlu<sub>n</sub> formation and may also be disease specific.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Uveitis is a severe manifestation of Juvenil Idiopathic Arthritis (JIA). Systemic treatment is based on conventional immunosuppresants. Anti-TNFa are used in refractory cases, mainly adalimumab (ADA) or infliximab (IFX) (Levy-Clarke et al. Ophthalmology 2014). However, sometimes they are ineffective, contraindicated or non tolerated. The next

therapeutic step is not defined. The main objective of this study was to compare Golimumab (GLM) vs Tocilizumab (TCZ) in uveitis related to JIA and refractory to conventional immunosuppressive drugs and anti-TNF $\alpha$  drugs.

## Methods:

National multicenter study of 33 patients diagnosed with uveitis associated to JIA. The patients were refractory to conventional treatment with high dose of corticosteroids and at least **a)** 1 conventional immunosuppressive systemic treatment and **b)** 1 anti-TNF $\alpha$ . For this reason it was decided to initiate treatment with TCZ or GLM. TCZ was used in 25 patients: 8 mg/kg/4 w/iv (n=21), 8 mg/kg/2 w/iv (n=2); 8 mg/kg/8 w/iv (n=1) and 2.9 mg/kg sc/w (n=1). GLM was used in 8 patients (50 mg/sc/month). The main parameters assessed were the visual acuity (VA), degree of intraocular inflammation, vitreous inflammation and macular thickening (by OCT). Quantitative variables were expressed with mean $\pm$ SD or median [IQR], according to its distribution. They were compared with the Student t or the Mann-Whitney U test, respectively. Dichotomous variables were expressed as percentages and compared by the chi-square test.

## Results:

We studied 33 patients/61 affected eyes. There were no significant differences between both groups at baseline (TCZ vs GLM) in sex ( $\text{♂}/\text{♀}$ ; 4/21 vs 3/5; p=0,19), mean age (18.5 $\pm$ 8.3 vs 19.9 $\pm$ 8,7; p=0.55), positive ANA (95% vs 100%; p=0.7), uveitis duration before TCZ o GLM onset (116,4 $\pm$ 93,6 vs 142,3 $\pm$ 74,7 p=0,46), number of previous biological treatments (1.9 $\pm$ 1.1 vs 2 $\pm$ 1.4; p=0.84), VA (0.57 $\pm$ 0.35 vs 0.5 $\pm$ 0.37; p=0.42), combined immunosuppressive therapy (88% vs 75%; p=0.37), presence of cells in the anterior chamber (median [IQR] 1 [0-1] vs 1 [0.25-1.5]%; p=0,6), vitritis (0 [0-0] vs 0 [0-1]; p=0,7), macular thickening (358.7 $\pm$ 92.2 vs 313.6 $\pm$ 77.1; p=0.32).

Once the treatment was initiated there were no significant differences in the ocular parameters TABLE.

After a mean follow-up of 20.48 $\pm$ 11.7 months with TCZ and 24.25 $\pm$ 17 months with GLM the following side effects were observed; with TCZ: viral conjunctivitis + bullous impetigo (n=1), severe thrombocytopenia and pneumonia. This last patient showed hemolytic anemia, thrombocytopenia and splenomegaly, for this reason treatment with TCZ was discontinued. With GLM cutaneous reaction was observed in 2 patients.

## Conclusion:

This study shows that both, TCZ and GLM, appear to be equally effective and safe for the treatment of uveitis associated to JIA refractory to conventional treatment and anti-TNF $\alpha$ . Further studies should be performed.

## TABLE

	TCZ (n=25)	GLM (n=8)	p

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) is a chronic arthritis with onset before 16 years of age, that persists for at least 6 weeks, and has an unknown etiology.<sup>1</sup> Uveitis is a serious and common extra-articular manifestation of JIA, affecting 12-30% of patients (most commonly female patients with the antinuclear antibody-positive oligoarthritis subtype of JIA).<sup>2,3</sup> First-line treatment for JIA-associated uveitis is usually topical corticosteroids and/or conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), such as methotrexate (MTX). Biologic DMARDs (bDMARDs), such as the TNF inhibitors etanercept (ETN) and adalimumab (ADA), are used after failure of first-line treatments.<sup>2</sup> However, it has been reported that ETN use is associated with uveitis flares or new-onset uveitis<sup>4</sup> while a recent observational study reported similar uveitis flare rates for both ADA and ETN.<sup>5</sup> The objective of this study was to analyze the occurrence of uveitis in patients with JIA treated with ETN, ADA, or MTX (as monotherapy and as part of combination therapy).

**Methods:** International Statistical Classification of Diseases (ICD)-9 diagnosis codes in a Truven MarketScan claims database were used to identify JIA patients diagnosed with uveitis over a 5-year interval. The analysis assessed the proportion of JIA patients (aged 0-19 years) treated with ETN, ADA, or MTX, as monotherapy or in combination. The percentage of patients diagnosed with uveitis and the time interval for uveitis diagnosis in JIA patients were determined.

**Results:** A total of 22,789 patients with JIA were included in this analysis. Mean age was 11.4 years, 69% of patients were female, and mean JIA disease duration was 3 years. This patient population included 19,814 patients with chronic, or not otherwise specified, polyarticular JIA. A total of 2581 (11.3%) patients (mean age 10.2 years, 73% female) were diagnosed with uveitis. There was no apparent difference in the percentage of JIA patients receiving ETN, ADA, or MTX who were diagnosed with uveitis. A total of 2.7-5.9% of patients receiving monotherapy were diagnosed with uveitis compared with 3.2-3.6% of patients receiving combination therapy (Figure). The vast majority of patients (2123 of 2581, 82.3%) with uveitis were diagnosed within a year of their JIA diagnosis.

**Conclusion:** In this patient database, a similar proportion of patients with JIA who were treated with ETN or ADA (either as monotherapy or in combination with MTX) received a subsequent diagnosis of uveitis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Background/Purpose:** Several reports examined ethnic differences of Juvenile Idiopathic Arthritis -associated uveitis (JIA-U), however, there were no information from Japan. Therefore, PRAJ underwent multi-center surveillance in Japan to clarify the clinical and epidemiologic characteristics of JIA-U.

**Methods:** Questionnaires were sent to pediatric rheumatologists in Japan to investigate clinical characteristics of JIA patients.

**Results:** Of 726 patients involved in this study, 44 (6.1%) had JIA-U during the whole disease course. Overall 682 non-uveitis JIA patients were compared with 44 JIA-U patients. Female ratio in non-uveitis vs JIA-U was 67.6% vs 70.5% ( $P=0.7425$ ). Age at JIA diagnosis was 7.3 (4.5) vs 4.9 (4.0) (mean (SD)) years old ( $P<0.0001$ ). The subtype of arthritis was shown in Table. There were no patients with uveitis in poly-RF positive and systemic type. Positivity for ANA was 57.5%, for RF was 2.5% and ACPA was 0% in JIA-U patients and that of ANA was significantly higher than non-uveitis JIA patients ( $P<0.0001$ ). There were no family histories of uveitis and episodes of infection before onset of uveitis. The mean age at diagnosis of uveitis was 5.5 (2.7) (mean(SD)) years old and the age under 8 years old were 82.5%. Uveitis occurred before the onset of arthritis in 5.0%, within the first 7 years after onset of arthritis in 97.5%. On the other hand, uveitis occurred during arthritis treatment in 35% and after off therapy in 20%. It occurred bilateral in 55.3% and 82.1% was anterior. 64.9% had no eye symptom, 36.8% had ocular complications (cataracts, posterior synechia of the iris, etc.), and 58% had active arthritis at the first diagnosis of uveitis. 39.5% had uveitis without arthritis at the last visit. There were no blindness, but eyes of 56.9% were not improved visual acuity at the last visit.

**Conclusion:** This is the first report of characteristics of JIA-U in Japan. Prevalence of JIA-U in Japan is lower than that of other country that were reported before. The reason may be because ratio of oligo-type JIA patients is lower in Japan than that of other country, though the risk factor of JIA-U of Japanese patients (oligo-type arthritis, ANA positive, early onset arthritis, RF negative) is similar that of reports from other country.

Table. Ratio of JIA subtype in non-uveitis vs JIA-U

JIA subtype	overall (N=726)	without uveitis (N=682)	with uveitis (N=44)	P-value
Oligo persistent	184 (25.3%)	155 (22.7%)	29 (65.9%)	<0.001
Oligo extended	40 (5.5%)	33 (4.8%)	7 (15.9%)	0.0076
Poly RF(-)	95 (13.1%)	90 (13.2%)	5 (11.4%)	1.000
Poly RF(+)	152 (20.9%)	152 (22.3%)	0	<0.001
Systemic	204 (28.1%)	204 (29.9%)	0	<0.001
Psoriatic	4 (0.6%)	4 (0.6%)	0	1.000
Enthesitis related	37 (5.1%)	35 (5.1%)	2 (4.6%)	1.000
Undifferentiated	10 (1.4%)	9 (1.3%)	1 (2.3%)	0.467

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

MRI studies on RA revealed that subclinical synovitis is common in patients in clinical remission and it is responsible for structural damage progression. MRI-detected synovitis in JIA patients with clinically inactive disease was also reported. Due to the lack of longitudinal studies in JIA, it is unclear whether this phenomenon entails an higher risk of joint damage progression and should affect treatment decisions.

**Objectives:** to assess the prevalence of MRI-detected synovitis in a cohort of JIA patients in clinical remission and to evaluate its association with disease flare and damage progression.

## Methods:

all JIA patients who met the Wallace criteria for clinical remission and underwent contrast-enhanced MRI at the Study Unit between 2007 and 2015 were included. MRIs were scored by two independent readers according to the Outcome Measure in Arthritis Clinical Trials (OMERACT) Rheumatoid Arthritis Scoring System (RAMRIS). Joint damage progression was assessed by conventional radiography (CR) according to the adapted versions of the Sharp/van der Heijde score and to the Childhood Arthritis Radiographic Score of the Hip. The concordance between the readers was assessed using kappa statistics. Categorical data were analyzed using chi-squared test and Fisher's exact test. Comparison of quantitative variables was performed by the non-parametric Mann-Whitney U-test. A logistic regression model was applied to perform multivariate analysis of the radiographic damage risk factors.

**Results:** a total of 90 patients (75 F; mean age 13.8 years; mean disease duration 8.5 years; mean follow-up duration 2.9 years) were included. Fourteen out of 90 patients (15.6%) were in remission off medication, while 76/90 patients (84.4%) were in remission on medication. Forty-five patients were assessed by MRI in the wrist, 30 in the hips, 13 in the ankle and 2 in the knee. Fifty-seven patients (63.3%) had evidence of synovitis on MRI. The inter-observer agreement for presence/absence of synovitis was good ( $k=0.74$ ; 95% CI: 0.5-0.9). Forty-three out of 57 patients (75.4%) with synovitis experienced a disease flare versus 11 out of 33 patients (33.3%) who hadn't any synovial inflammation ( $P<0.0001$ ). Radiographic progression was assessed in 54/90 patients for whom follow-up CRs were available and was detected in 19/54 patients (35.2%). A significant association between systemic JIA subtype and deterioration of joint damage was found ( $P=0.027$ ). MRI-detected bone marrow oedema (BMO) and the baseline radiographic damage scores were also related to structural progression ( $P=0.002$ ). The multivariable logistic regression analysis showed that only BMO score  $\geq 3$  independently contributed to explain radiographic damage progression (OR 4.82; 95% CI: 1.0-23.2;  $P=0.035$ ).

## Conclusion:

A sizeable proportion of patients in clinical remission has MRI evidence of persistent joint inflammation. Subclinical synovitis was significantly associated with disease flare, while BMO showed remarkable promise in predicting joint destruction. These findings support the utility of MRI for the assessment of JIA patients in clinical remission and may have important clinical implications for their management.

## Assessing the Utility and Impact of Musculoskeletal Ultrasound in a Large Pediatric Rheumatology Clinic

**Onengiya Harry**<sup>1</sup>, Jennifer L. Huggins<sup>2</sup>, Janalee Taylor<sup>3</sup>, Michael J. Holland<sup>4</sup> and Tracy Ting<sup>5</sup>, <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>2</sup>Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>3</sup>Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>4</sup>Pediatric Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>5</sup>Rheumatology/MLC 4010, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Musculoskeletal ultrasound (MSUS) use in the care of pediatric rheumatology patients is increasing. Yet, despite the growing availability of MSUS, it remains unclear how best to utilize ultrasound within a busy pediatric rheumatology clinic - and how its results might affect patient care. A questionnaire was developed to assess the following: reasons for referral, correlation with clinical assessment, changes to management, and the patient/parent experience. The aim of this study is to evaluate physicians' responses on the utility and impact of MSUS.

**Methods:** Beginning September 2016, pediatric rheumatology providers from a large tertiary care center with an established MSUS clinic were given a short questionnaire after the completion of a patient MSUS session. The questionnaire included 4 main outcome variables: normal or abnormal MSUS findings, consistency of MSUS results with clinical exam, family's response to MSUS, and impact on management decisions. Secondary outcomes were: reasons for referral, how MSUS findings correlate to clinical exam (better, worse, or same), aid in family's understanding of diagnosis, and influence on clinical management - (no change, maximize dose of medication, perform joint injection, or other). Descriptive analysis was performed on collected responses with frequency distribution reported for each variable.

**Results:** Survey responses were collected on 86 patients. The majority of referrals were placed to evaluate the extent of disease activity. Other reasons included the identification of active joint/tendon(s) for possible joint injection and in instances of discordance between clinical exam and patient symptoms. 80% of the MSUS results were abnormal; and 51% of the time, providers did not anticipate the results. While 51% of MSUS findings were consistent with clinical

exam, 41% identified more active joint/tendon(s). 66.3% of the time MSUS result had an impact on management decision. Of the 57 cases where MSUS influenced clinical management: 46% had medications maximized and 44% underwent joint injection. Providers reported that 97% of families found MSUS helpful in general; while 81% found it useful in their understanding of their child's disease.

**Conclusion:** MSUS is a valuable tool to complement clinical examination in the care of children with rheumatologic disease. For a majority of referred patients, MSUS helped to assess disease activity and shape clinical management. MSUS can be an important screening tool in identifying worsening, or improving, disease than may be clinically apparent. This ongoing study suggests that there may be a role for MSUS in educating parents/children about their disease. A survey of families is needed to better clarify the impact of MSUS on their understanding of their disease.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Information regarding longer-term outcomes in JIA largely pre-date the introduction of biologic therapies and have been cross-sectional. The aim of this analysis was to assess physician and parent-reported outcomes over the first 5 years following initial presentation to paediatric rheumatology in young people diagnosed with JIA since 2001.

**Methods:** Young people with JIA of any disease subtype were selected if enrolled in the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort, between October 2001 and January 2011. The following outcomes were assessed annually to five years and included in this analysis: Active joint count, limited joint count, physician's global assessment (10cm visual analogue score (VAS)), parental global evaluation (10cm VAS), pain (10cm VAS), functional ability (Childhood Health Assessment Questionnaire (CHAQ) and psychosocial health (psychosocial scale on the Child Health Questionnaire (CHQ)).

Outcomes were assessed descriptively over time and differences between subtypes were assessed by applying multilevel (patient-level) zero-inflated negative binomial (CHAQ) and linear (all other outcomes) regression analyses, adjusting for age and disease duration at presentation, gender and hospital.

**Results:** Of 1087 young people, 67% were female and median age at initial presentation to paediatric rheumatology was 8 years (IQR 3, 12). The most common disease subtype was oligoarthritis (52%) and least common RF-positive polyarticular JIA (4%). Eighty four percent had ever been treated with NSAIDs, 74% corticosteroids, 55% with DMARDs and 21% with biologics within follow-up.

In the entire cohort, all outcomes were mild to moderate at baseline (median 2 active joints, 1 limited joint, physician's global 2.9cm, patient global 2.2cm, pain 3.1cm, CHAQ 0.8 and CHQ psychosocial 50). Overall improvements were evident in all outcomes over the first year then remained stable with no further improvements at the cohort level to five years.

Compared with those with oligoarticular JIA, patients with both polyarthritis and systemic subtypes experienced significantly poorer outcomes across all variables. The most extreme point estimates were experienced in RF-positive polyarticular JIA, having 3 more active and limited joints (both 95% CI 2, 4), 1cm higher physician's (95% CI 0.4, 1.2), parental (95% CI 0.5, 1.9) and pain (95% CI 0.3, 1.8) scores and 50% higher CHAQ scores (95% CI 1.2, 1.7). Young people with enthesitis-related, psoriatic and undifferentiated JIA experienced largely similar outcomes to those with oligoarthritis over follow-up.

**Conclusion:** On average, the largest improvement in physician and patient-reported outcomes occur in the first year following diagnosis, perhaps confirming the importance of early treat-to-target strategies. Patients with systemic and both polyarticular JIA subtypes have poorer parent and physician-reported outcomes than those with enthesitis-related, psoriatic, undifferentiated or oligoarthritis.

## **Six Minute Walk Test in Children with Juvenile Idiopathic Arthritis: Normative Values, Prediction Equation, and Comparison to Healthy Children**

**Dax G. Rumsey**<sup>1,2</sup>, Michelle Roy<sup>1</sup>, Cara Kaup<sup>1</sup>, Lyne Bourassa<sup>3</sup>, Elham Khodayari Moez<sup>4</sup>, Olaf Verschuren<sup>5</sup> and Lesley Pritchard-Wiart<sup>1,3</sup>, <sup>1</sup>Glenrose Rehabilitation Hospital Edmonton, Edmonton, AB, Canada, <sup>2</sup>Paediatrics, University of Alberta, Edmonton, AB, Canada, <sup>3</sup>Physical Therapy, University of Alberta, Edmonton, AB, Canada, <sup>4</sup>School of Public Health, University of Alberta, Edmonton, AB, Canada, <sup>5</sup>Brain Center Rudolf Magnus and Center of Excellence for Rehabilitation Medicine, University Medical Centre Utrecht, Utrecht, Netherlands

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The 6-minute walk test (6MWT) is a widely used measure of functional exercise capacity. It has not, however, been routinely used in pediatric rheumatology practice to date. There is little known about normative values for children with

rheumatic disease, including juvenile idiopathic arthritis (JIA). The objectives of this study were to: 1) describe normative values for patients with JIA; 2) investigate which characteristics best predict 6-minute walk distance (6MWD) in this population and establish a prediction equation; and 3) compare 6MWD in patients with JIA to published values for healthy children.

## Methods:

At the Glenrose Rehabilitation Hospital in Edmonton, Canada, we have been administering the 6MWT to our JIA patients every 6 months since June 2013. We performed a retrospective chart review of 116 unique patients with a total of 272 6MWTs. Each 6 MWT was administered on a 25 m track by a therapy assistant. Sex, weight, height, date of birth, testing date, JIA subtype, and lower limb involvement (active and chronic) were recorded. A mixed effects model was used to analyze the data. Univariate modelling of outcome (6MWD) vs. potential predictors was conducted. Variables with  $p \leq 0.2$  were selected for inclusion in the final model (cross-sectional age, longitudinal age, height and weight). To address objective 3, predicted 6MWT distances were calculated according to established prediction equations for healthy children developed by Geiger et al. (2007) and Ben Saad et al. (2009). Percentage of predicted values were calculated using actual 6MWDs.

## Results:

Normative values for children with JIA are presented in Table 1. The final prediction model for our population was  $6MWD = 161.45 + \text{cross-sectional age(years)} * 2.33 + \text{longitudinal age} * 15.86 + \text{height (m)} * 2.954 - \text{weight (kg)} * 1.79$ ;  $r^2 = 0.62$ ). All other factors, including sex, lower limb involvement, and JIA subtype were not significant and therefore were excluded from the model. The 6MWDs of children with JIA were lower than reported for typically developing children (Geiger = 84%, range 59%-109% of predicted; Ben Saad = 78%, range 53% -107% of predicted).

## Conclusion:

This study provides normative values and a prediction equation for the 6MWT for children with JIA. Reference values are clinically relevant as they provide a user-friendly method for the interpretation and prediction of functional exercise capacity. The characterization of functional exercise capacity in children with JIA could provide the basis for an outcome measurement in this population. The difference in 6MWD between children who are typically developing and the children with JIA shows that children with JIA have impaired functional exercise capacity.

**Table 1: 6 MWT Results by Age**

Age (years) (n)	Height, cm (mean,SD)	Weight, kg (mean,SD)	Mean 6MWD, m (mean,SD)
6 (15)	120 (3)	24 (4)	478 (61)
7 (18)	126 (6)	28 (8)	494 (56)

## Joint Injection Practices in Pediatric Rheumatology – Preliminary Data from an Ongoing Web Based Survey

Anita Dhanrajani<sup>1</sup> and Raju Khubchandani<sup>2</sup>, <sup>1</sup>Rheumatology, Vasculitis Research Fellow - HSC, Toronto, ON, Canada, <sup>2</sup>Department of Paediatrics, Jaslok Hospital and Research Center, Mumbai, India

First publication: September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Corticosteroid joint injections are a routine procedure in pediatric rheumatology. The dearth of existing literature on current practices led the authors to conduct an online survey targeting pediatric rheumatologists in Europe and North America.

**Methods:** An electronic survey with 22 questions related to pre-procedural sedation, choice of anesthetic agent, dose and type of therapeutic agent, number of joints injected, use of ultrasound, and post procedure complications was designed with a web based survey engine – Survey Monkey. The survey was distributed via email to physicians registered in the PRINTO and CARRA/PRCSG networks.

**Results:** 187/213 respondents (Table 1) performed joint injections as a routine clinical practice, of which 110 (57.6%) had received formal training in the procedure. 51.1% procedures were performed as an outpatient, either in a procedure room, day care or minor operation room. 152/180 respondents (85.5%) injected multiple joints in one sitting. Less than half physicians (45%) resort to ultrasound guidance, most often for the hip joint. Ignoring availability, triamcinolone hexacetonide (TH) was the most preferred agent by 79.6% of respondents. Other agents were Triamcinolone acetate, Methylprednisolone acetate, hydrocortisone acetate and betamethasone acetate, in order of frequency. Only 51.5% physicians said that TH was consistently available in their country. There was some consensus about the dose of steroid (TH equivalent) as 1 mg/kg for large joints (62.9%), but wide variation in the dose for smaller joints. 65.9% physicians resorted to local anesthesia, including EMLA cream, subcutaneous Lidocaine, Lidocaine spray, ethyl chloride spray or a combination. Intravenous sedation was used by more than half physicians (51.2%), oral sedation by 15.7%, long anesthesia by 2.4% and other methods by 30.7%

Most respondents experienced some procedural complications in their clinical experience, commonest being subcutaneous atrophy (Table 2). Most physicians recommended home ambulation for 24-48 hours after procedure, however some variations such as complete bed rest, splinting, immobilization, and rest for longer than 48 hours were observed. 48.2% respondents follow significantly different practices in 0-5 year age group, for either choice of anesthesia, setting of procedure, use of ultrasound guidance or number of joints injected.

**Conclusion:** Practices related to pediatric joint injection procedures are not uniform and methods to develop standardization of this extremely common procedure is the need of the hour.

Table 1:

Geographical Location of training	Percentage (n)
Europe	34.5(38)

## Efficacy of Function-Based Exercise Program on Functional Ability, Pain and Quality of Life in Children with Juvenile Idiopathic Arthritis

Ela Tarakci<sup>1</sup>, Saime Nilay Baydogan<sup>1</sup>, Sezgin Sahin<sup>2</sup>, Amra Adrovic<sup>2</sup>, Kenan Barut<sup>2</sup> and **Ozgur Kasapcopur<sup>2</sup>**,

<sup>1</sup>Istanbul University, Faculty of Health Science, Division of Physiotherapy and Rehabilitation, Istanbul, Turkey,

<sup>2</sup>Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Department of Pediatric Rheumatology, Istanbul, Turkey

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

## **Background/Purpose:**

Juvenile idiopathic arthritis (JIA) is one of the most common rheumatic diseases in childhood, affecting at least 1 in 1000 children. Children with JIA, experience joint inflammation and swelling, pain and tenderness, morning stiffness, limited mobility. Children with JIA complain pain and have lower functional ability and decreased quality of life compared with their peers. The objective of this study was to investigate the effects of a function-based exercise program on pain, functional ability and quality of life in children with JIA.

## **Methods:**

32 children with JIA (19 female and 13 male), age range 5- 16 years, participated in this study. Patient population consisted of 21 children with polyarticular, 9 children with oligoarticular, 1 children with systemic arthritis, and 1 children with psoriatic arthritis. All children and their parents were informed of about the study and the informed consent was obtained. The study was approved by Ethics Committee of Istanbul University.

Functional ability, pain, and quality of life were assessed with a Childhood Health Assessment Questionnaire (CHAQ), 11-point Numeric Analogue Scale (NRS) and the Pediatric Quality of Life Inventory (PedsQL), respectively. The children completed a 12-week individually planned function-based exercise program for thrice a week at the hospital in the supervised by the physical therapist. Function-based exercise program contained weight bearing to affected joint, squat, walking stair climbing and various activities for the upper limb (variable according to the needs of each patient).

## **Results:**

The mean age and disease duration were  $10.13 \pm 3.50$  and  $5.57 \pm 3.20$  years, respectively. The mean of number of affected joint was  $3.31 \pm 1.20$ . Baseline scores were NRS  $30.31 \pm 24.81$ , CHAQ  $0.73 \pm 0.68$  and PedsQL  $62.61 \pm 25.15$ . After the function-based exercise program, scores of NRS, CHAQ and PedsQL were  $20.47 \pm 20.13$ ,  $0.23 \pm 0.38$  and  $84.46 \pm 13.67$ , respectively. Statistically significant improvements were found in all the outcome measures after the function-based exercise program ( $p < 0.001$ ). Also, it was found clinically relevant changes of CHAQ scores in a total of %74.4 of the children with JIA after the treatment.

## **Conclusion:**

The study demonstrated that a 12-week individually planned function-based exercise program could result in improved pain, independence of functional, quality of life in children with JIA. So, we suggest that an exercise program should be planned individually and focus function in children with JIA. Further research is needed to clarify the long-term effect of exercise in children with JIA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Higher disease activity has been described in Hispanic patients with Juvenile Idiopathic Arthritis (JIA) living in the United States (US) vs non-Hispanics. There is no data available comparing JIA disease activity among Hispanics living in the US vs Latin America, or between Hispanic subgroups. We aim to describe the clinical characteristics of Hispanic children with JIA at several centers in the United States and in Latin America.

**Methods:** We analyzed preliminary data of 95 subjects from 4 centers (US: 2, Latin America:2) with a confirmed diagnosis of JIA based on the revised ILAR criteria with age of disease onset  $\leq 16$  years old. Subjects were grouped based on self-reported ethnicity and residency, with 52 Hispanics residing in Latin America (Colombia and Puerto Rico). In the US, 20 Hispanics and 23 non-Hispanic subjects were surveyed. Data collection is ongoing; we anticipate 240 subjects by completion of the study. We compared clinical characteristics, physician assessment of disease activity, parent/subject assessment of disease activity and pain, CHAQ score and presence/absence of imaging evidence of joint damage among the three groups.

**Results:** There was a significant difference in distribution of JIA subtypes between groups. Oligoarticular JIA was the most common among non-Hispanic US patients (27%) and polyarticular RF negative was the most common subtype in both Hispanic groups (35%). RF positive polyarticular JIA was more common in US Hispanics (25%) vs US non-Hispanics (13%), but lower in Hispanics residing in Latin America (12%). HLA B27 positivity was more frequent in US non-Hispanics (18% vs 5% in Hispanics in US and 15% in Hispanics in Latin America). Radiographic damage was significant more frequent among Latin American Hispanics (42%), compared to US Hispanics (35%) and US non-Hispanics (22%). Systemic steroid use was more frequent among Latin American Hispanics. Treatment with biologics was highest in US Hispanics (80%) vs US Non-Hispanics (70%); 54% of subjects in Latin America reported receiving biologics. Non-biologic DMARD use was similarly prevalent in the three groups: 90% in Latin American patients, 86% in US non-Hispanics, and 85% in US Hispanics. CHAQ scores were slightly higher in non-Hispanics; however physician global disease assessment was worse in Hispanics, particularly those residing in US.

**Conclusion:** Radiographic changes were significantly higher in all Hispanics which may reflect more aggressive disease as well as decreased use of biologic medications in Latin America. Systemic steroids are used more commonly among Latin American patients which likely reflects decreased availability of other medications, particularly biologics. In addition to treatment variation, genetics and environmental factors may contribute to the variable phenotypic expression of JIA found among Hispanic groups in this preliminary study. An improved understanding of the characteristics of JIA among Hispanic children is essential to guide disease management and better meet the needs of this population.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease that often persists into adulthood. In addition to disability and poorer quality of life, JIA is associated with increased long-term morbidity and mortality. The long-term risk of comorbidities is uncertain and guidance on risk assessment is not currently available. The objective of this study was to determine the frequency of comorbid conditions in JIA patients.

**Methods:** Patients with JIA transferred from the biologic registry BIKER to the follow-up (FU) registry JuMBO were included in this analysis. All comorbidities, except for serious infections, prospectively recorded by physicians to BiKeR or JuMBO were considered. Comorbidity rates among the various JIA categories were assessed. The Medical Dictionary for Regulatory Activities (MedDRA) was used for disorder coding. Differences in the occurrence of comorbidities between JIA categories were analyzed by multinomial logistic regression.

**Results:** A total of 1,022 young adults (67% female) with JIA and a mean FU of 7.8 (SD=3.5) years (ys) were included in this analysis. The patients' mean age was 23.1 ys (SD=3.7), and disease duration was 12.8 ys (SD=5.9) at last FU. The majority were classified as polyarticular-course JIA (53%) at BiKeR enrollment. Patients had received a mean of

2.9 (SD=1.3) DMARDs, 77% were ever treated with biologics. Comorbidities were reported for more than half of the patients (54%), 24.5% of the conditions were stated for the first time in adult age. Eye disorders were the most common comorbid condition group (16.9%), followed by Immune system disorders (12.3%), and psychiatric disorders (10.1%). The most frequently reported single diseases were uveitis in 15.9%, depression in 9.1%, hypertension in 8.5%, chronic secondary pain syndrome in 4.4%, and psoriasis in 3.3%. Females had significantly more often depression (11.8% versus 3.4%), pain syndromes (5.8% versus 1.6%), and autoimmune thyroiditis (3.3% vs. 0.9%) than males, whereas men had more often inflammatory bowel diseases than women (4.0% vs. 1.9%). The rate of comorbid conditions significantly differed across the various JIA categories, with the highest rates in patients with extended oligoarthritis, psoriatic arthritis and systemic arthritis. While extraarticular manifestations of JIA were the most common comorbid conditions in extended oligoarthritis and psoriatic arthritis, disease- or treatment-related complications were relevant comorbidities in systemic arthritis.

**Conclusion:** Young adults with JIA have a high rate of comorbidity overall, with extraarticular JIA manifestations being the most frequent comorbid conditions. Comorbidity rates vary among the various JIA categories. Patients with systemic JIA have the highest rate of cardiovascular risk factors and osteoporosis, while patients with extended OA have the highest rate of uveitis. An underreporting or unawareness of comorbidities by rheumatologists is possible, guidance on risk assessment in adults with JIA is needed.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Adult-onset psoriasis (PsO) and psoriatic arthritis (PsA) have been associated with increased rates of diabetes, obesity, and hypertension. We sought to evaluate the prevalence of these comorbidities in children with PsO and juvenile PsA (JPsA) in the United States.

## Methods:

Utilizing a secure cloud-based platform, Explorys, we conducted a retrospective cross-sectional study of males and females  $\leq 19$  years of age from the United States with PsO and JPsA using pooled de-identified data from multiple United States healthcare systems, collected from 1999 to 2017. PsO subjects carried this diagnosis and also met exclusion criteria for any inflammatory arthritis or inflammatory bowel disease (IBD). Patients with both IBD and JPsA were included and analyzed separately. Comorbidities of interest included diabetes, hypertension, and obesity. Hypertension and diabetes was determined by the presence of their respective Systematized Nomenclature for Medicine-Clinical Terms (SNOMED-CT), as the Explorys database is ontology based. Subjects were considered obese if body mass index (BMI) was equal to or greater than the 95<sup>th</sup> percentile, based on CDC 2010 recommendations. Chi-squared test and odds ratio were calculated using Stata 10.0 software, Austin, Texas.

## Results:

Of those  $\leq 19$  years of age, 6180 subjects with PsO were identified and 930 were identified with JPsA, 50 of those were also diagnosed with IBD. Of the PsO subjects, 54% were male versus 34% of total JPsA. Both cohorts were mostly Caucasian, with over three-fourths representation. Among children with PsO, 42% were obese compared to 52% of JPsA children. In this cohort, those with JPsA and IBD did not have concomitant diabetes or hypertension. JPsA patients were significantly more likely to have diabetes, hypertension, and obese than patients with purely skin disease. Having JPsA was associated with diabetes (OR 0.33, 0.23-0.48), hypertension (OR 0.41, 0.30-0.51), and obesity (OR 0.75, 0.65-0.86) compared to PsO. Table 1 summarizes the findings of each patient population at the time of data collection.

## Conclusion:

Metabolic comorbidities are more prevalent in children with JPsA than PsO. Hypertension and diabetes diagnosed in childhood is more common in those with JPsA compared to those with skin disease only. Those diagnosed with PsO and JPsA in childhood have high rates of obesity, when determined by BMI percentile.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Relatively little is known about the epidemiology of juvenile psoriatic arthritis (PsA), including risk factors for development of PsA among children with psoriasis. It is also unknown whether children with PsA are at increased risk of cardiovascular and metabolic disease, similar to adults.

**Methods:** We conducted a retrospective cohort study of children with incident psoriasis and PsA using the Clinformatics TM DataMart (OptumInsight, Eden Prairie, MD), a de-identified administrative claims database. All incident psoriasis patients had  $\geq 1$  ICD-9 code for psoriasis and PsA patients had  $\geq 1$  ICD-9 code for PsA or psoriasis and arthritis. The index date was the date of the first ICD-9 code for the diagnosis of psoriasis or PsA. Patients were required to be continuously enrolled for 6 months before and 12 months after the index date. Controls were matched on age, sex, and date of psoriasis or arthritis diagnosis at a 10:1 ratio. Cox proportional hazard regression was performed to assess the risk of developing arthritis in children with psoriasis over time. Incidence rate ratios were used to compare the relative frequency of cardiovascular and metabolic co-morbid diagnoses.

**Results:** We identified 1,012 children with PsA, 14,610 with psoriasis, and 203,907 controls. The median time of continuous enrollment was 3.0 years (IQR 1.9-4.9). Median ages at the first diagnoses of PsA and psoriasis were 12 and 10 years, respectively. 56% and 53% of children with PsA and psoriasis were female. Amongst those children who had both psoriasis and arthritis, approximately 37% developed psoriasis first. Median time to development of arthritis after psoriasis diagnosis was 1.8 years (IQR 0.4-2.8). Older age was associated with a significantly increased risk of developing arthritis in children with psoriasis (Table 1). There was a trend towards increased risk of arthritis in psoriasis patients with ulcerative colitis and uveitis, albeit statistically insignificant. Children with psoriatic arthritis had a significantly increased incidence of hypertension, hyperlipidemia, and cerebrovascular disease compared to healthy controls (Table 2).

**Conclusion:** Older age was a risk factor for PsA among children with psoriasis. Similar to adults, PsA was associated with a higher risk of developing metabolic and cerebrovascular disease in children.

Table 1: Risk Factors in the Development of Psoriatic Arthritis				
	Univariate Analysis		Multivariate Analysis	
	Hazard Ratio (95% CI)	p-value	Hazard Ratio (95% CI)	p-value

## Increased Risk of Extreme Obesity in Adults with History of Childhood Arthritis

**Sangeeta Sule**<sup>1</sup> and Kevin Fontaine<sup>2</sup>, <sup>1</sup>Pediatrics, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Dept. of Health Behavior, Univ. of Alabama at Birmingham, Birmingham, AL

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Over one-third of U.S. adults are obese, leading to major health conditions and increased costs. Identified risk factors that contribute to obesity include lifestyle, genetics and childhood diseases. Using data from the National Health and Nutrition Examination Survey (NHANES), we investigated whether the risk of obesity in adults associates with juvenile arthritis.

### **Methods:**

We linked NHANES 2007-2014 datasets to assess the obesity status of respondents reporting any type of arthritis diagnosed prior to 18 years of age and compared them to a group of respondents with asthma diagnosed prior to 18 years of age (participants with both diseases were excluded from the analyses).

Body mass index (BMI), calculated as weight in kilograms divided by height in meters squared, and was used to characterize obesity status. Using federal BMI-defined obesity categories (normal weight (18.5-24.9 kg/m<sup>2</sup>), overweight (25-29.9 kg/m<sup>2</sup>), obese ( $\geq 30$  kg/m<sup>2</sup>) and extreme obesity ( $\geq 40$  kg/m<sup>2</sup>), we conducted logistic regression analyses controlling for age, gender and race, was used to estimate the odds ratio (OR) of obesity or extreme obesity, incorporating sample weight to account for the complex sampling design.

### **Results:**

There were 294 respondents who reported being diagnosed with juvenile arthritis (JA) and 4232 who reported a diagnosis of childhood asthma. Participants with JA were older (45.9 vs. 37.2 years,  $p < 0.01$ ), female (59% vs. 45%,  $p < 0.01$ ), and Caucasian (74% vs. 53%,  $p < 0.01$ ) compared to those with childhood asthma. Adults with history of JA were shorter (168.4 vs. 170.5 cm,  $p = 0.02$ ) and had higher body weight (86.2 vs. 84.1 kg,  $p = 0.04$ ). There was also a trend towards higher BMI in the JA group (30.3 vs. 28.9 kg/m<sup>2</sup>,  $p = 0.07$ ). Unadjusted OR of obesity in the JA group were 1.2 (95% Confidence Interval (CI): 0.7-2.1) and adjusted OR was 0.9 (95% CI: 0.5-1.7). The odds of extreme obesity in the JA group compared to asthma group was almost double with unadjusted OR of 2.4 (95% CI: 1.2-4.8,  $p = 0.02$ ) and adjusted OR of 2.2 (95% CI: 0.9-5.7,  $p = 0.09$ ).

### **Conclusion:**

A diagnosis of childhood arthritis independently associated with an increased risk of extreme obesity in adulthood. Our results may have been influenced by recall bias (i.e., misreporting age of diagnosed arthritis or asthma diagnosis). We were also unable to assess whether JA was still active in the adults. Nonetheless, our results suggest that factors related to having JA (e.g., inflammation, decreased physical activity, medical treatment) might contribute to developing extreme obesity in adulthood.

## **Prospective Validation of the Juvenile Spondyloarthritis Disease Activity Index and Its Comparison with Adult Spondyloarthritis Disease Activity Scores**

**Abhishek Zanwar**, Sanat Phatak and Amita Aggarwal, Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Among JIA children with Enthesitis related arthritis (ERA) category have more pain, poorer health status and are less likely to achieve or maintain sustained remission. There has been paucity of instruments to measure disease activity in ERA and recently the Juvenile Spondyloarthritis Disease Activity Index (JSpDA) was developed. We planned to prospectively validate JSpDA and compare its performance with other disease activity scores used in children and adults.

### **Methods:**

Children with ERA (ILAR criteria) less than 18 years of age were enrolled. Baseline characteristics and different disease activity measures (JSpDA, BASDAI, ASDAS-ESR, JADAS-10) and C-HAQ were recorded at baseline and on follow up after at least 3 months of follow up. At both visits physician global assessment and patient global assessment was recorded on the scale of 0-10. Construct validity was tested using JADAS-10, physician global assessment, patient global assessment and C-HAQ. Correlation of JSpDA and different disease activity scores was done. Internal consistency was evaluated using peripheral arthritis score. Discriminative validity was evaluated using the physician global assessment.

### **Results:**

The mean age of 125 children (114 boys) was 14.2±2.23 years. The mean disease duration was 34.8±28.04 months. Eighty nine children had persistent disease while 31 had episodic disease and 5 children had less than 3 months of disease. Eighty eight of 102 (86%) children were HLA-B27 positive. Seventy seven (61.6%) children had inflammatory back pain ever and 43% had radiographic sacroiliitis. 113 had peripheral arthritis ever (90.4%) and eighty two (65%) at the time of recruitment.

Among 125 patients 91 were taking NSAIDs and 28 were taking synthetic DMARDs (Methotrexate=19, sulfasalazine=8, Leflunomide=1). Mean disease activity score were, JSpDA: 3.07±1.84, JADAS10: 12.43±8.58, BASDAI:3.06±2.3 ASDAS ESR: 3.01±1.24. Mean C-HAQ was 0.75 ±0.65.

JSpDA showed high correlation with JADAS-10 ( $r=0.874$ ) and PGA ( $r=0.875$ ) and moderate to high correlation with C-HAQ ( $r=0.733$ ). Hence demonstrated good construct validity. Correlation between peripheral disease component and total score was 0.96, showing good internal consistency. The mean JSpDA scores for children with a physician global assessment (PGA) on visual analog scale score of 0 ( $n=19$ ) &  $>0$  ( $n=105$ ) were 0.31 and 3.6 respectively ( $p<0.001$ ) hence showing good discriminative validity.

37 children had a follow up visit at least 3 months later, disease activity increased in 21, decreased in 13 & did not change in 3. Mean change in JSpDA was significantly different among those who improved [ $+2.29\pm0.57$ ] when compared to who worsened [ $-1.67\pm0.48$ ; ( $p<0.001$ )], showing good sensitivity to change.

JSpDA also showed highly correlation with other scores like JADAS10 ( $r=0.87$ ) and BASDAI( $r=0.83$ ), ASDAS ESR( $r=0.85$ ). Adult score showed moderate to high correlation with PGA [ASDAS ESR( $r=0.87$ ), BASDAI ( $r=0.77$ )] and moderate with C-HAQ [ASDAS ESR( $r=0.77$ ), BASDAI ( $r=0.68$ )]

**Conclusion:** JSpDA is a valid score for measuring disease activity in ERA.

## Prevalence of Serum 14-3-3 $\eta$ (eta) in Juvenile Idiopathic Arthritis

**Iris Reyhan**<sup>1</sup>, Olga S. Zhukov<sup>2</sup>, Robert J. Lagier<sup>3</sup>, Robert Bridgforth<sup>4</sup>, Gary J Williams<sup>5</sup>, Joanna M. Popov<sup>2</sup>, Stanley J. Nades<sup>2</sup> and Andreas Reiff<sup>6</sup>, <sup>1</sup>Rheumatology, Children's Hospital of Los Angeles, Los Angeles, CA, <sup>2</sup>Immunology, Quest Diagnostics Nichols Institute, San Juan Capistrano, CA, <sup>3</sup>Research Support, Alameda, Quest Diagnostics Alameda, Alameda, CA, <sup>4</sup>Quest Diagnostics Nichols Institute, Alameda, CA, <sup>5</sup>Quest Diagnostics Nichols Institute, San Juan Capistrano, CA, <sup>6</sup>Children's Hospital of Los Angeles, Los Angeles, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) is the most common pediatric rheumatic disease. Currently, diagnosis is based on clinical assessment defined by the International League of Associations for Rheumatology criteria. Disease specific laboratory biomarkers are limited to rheumatoid factor (RF) and cyclic citrullinated peptide (CCP) antibodies, which are associated with a poor JIA prognosis. Elevated serum levels of 14-3-3 $\eta$  (eta) biomarker have improved the diagnostic sensitivity of RF and CCP in adult RA and elevated 14-3-3 $\eta$  is associated with a more severe RA phenotype [1,2]. The objective of this study was to evaluate the prevalence and clinical significance of serum 14-3-3 $\eta$  in children with JIA.

**Methods:** One hundred fifty two patients from the Pediatric Rheumatology Core at Children's Hospital of Los Angeles were divided into five groups: 39 with polyarticular JIA RF+ (PJIA RF+), 39 PJIA RF-, 36 oligoarticular JIA (OJIA), 20 with psoriatic arthritis (PsA) and 18 with enthesitis-related arthritis (ERA). OJIA patients served as a control group. RF, CCP, and 14-3-3 $\eta$  were measured via immunoturbidimetry, immunoassay, and ELISA, respectively. Based on adult onset RA, a 14-3-3 $\eta$  serum level of >0.2ng/mL was considered positive. Association of JIA with 14-3-3 $\eta$  positivity was performed by Fisher's exact test. Disease activity was assessed by Juvenile Arthritis Disease Activity Score-10/71 (JADAS-10/71).

**Results:** RF, CCP, and 14-3-3 $\eta$  data are summarized in Table 1. Thirty five (23%) patients had a positive 14-3-3 $\eta$ . Twelve (8%) were single positive for 14-3-3 $\eta$ , 23 (15%) were positive for 14-3-3 $\eta$  and RF and/or CCP, and 17 (11%) were positive for all 3 markers. There was a positive correlation between 14-3-3 $\eta$  and PJIA RF+ vs. OJIA (p-value = 0.029) and PJIA RF+ vs. PsA (p-value = 0.012) and, but there was no correlation between presence and titer of 14-3-3 $\eta$  compared to JADAS-10/71.

**Conclusion:** All patient groups tested had levels of 14-3-3 $\eta$  above baseline. PJIA RF+ patients had the highest prevalence of 14-3-3 $\eta$  compared to all other groups. Of note, 14-3-3 $\eta$  was positive in other forms of JIA, especially OJIA where 22% of patients were positive. There was a positive correlation between 14-3-3 $\eta$  and positive RF and CCP, but none with disease activity. 14-3-3 $\eta$  might be a useful biomarker in the diagnosis, prognosis and in monitoring therapeutic response of children with PJIA RF+. However its role in other forms of JIA remains to be determined.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with juvenile idiopathic arthritis (JIA) often present with signs and symptoms suggestive of infection. However, it is a diagnostic challenge to differentiate infectious from non-infectious presentation in routine clinical care. Procalcitonin (PCT) is a serum biomarker elevated in the setting of bacterial infection, but whether it can reliably differentiate infection from disease flare in patients with JIA is unknown.[\[1\]](#) We conducted a prospective cohort study to test the hypothesis that PCT levels will differ between active JIA, quiescent JIA, bacteremic patients and healthy controls.

**Methods:** From 10/16-4/17, consecutive children 6 months - 18 years with a) active untreated JIA ( $\geq 4$  inflamed joints) b) quiescent JIA and c) healthy elective pre-surgical candidates were recruited from clinics at a musculoskeletal specialty hospital. JIA was defined according to ILAR criteria. Patients with active JIA despite treatment were excluded, to avoid confounding by treatment. Consecutive bacteremic patients were identified from an associated pediatric intensive care unit over the same period. No matching was performed. PCT as well as other common measures of inflammation were compared. Descriptive statistics and univariate logistic analyses were performed as appropriate. The study was IRB approved.

**Results:** Patient characteristics are summarized in Table 1. Bacteremic patients were younger (mean age 1.1 vs. 14.1 years) and had *Staphylococcus aureus* (80%) and *Kingella kingae* (20%) infections. PCT was elevated in bacteremic patients, and was undetectable in all other subjects (p-value  $<0.001$ ; Table 2). There were trends towards higher ESR and CRP in bacteremic patients, but these were not statistically significant.

**Conclusion:** Serum PCT levels appear to be a reliable biomarker to distinguish infection vs. active JIA at presentation, and can aid in directing therapy. However, PCT does not appear to be a useful biomarker to assess disease activity in JIA. Further studies are needed to assess utility of serum PCT measurement in differentiating JIA flares from less severe infections.

### Table 1. Patient characteristics

	All patients (N = 48)	Active Untreated JIA (N = 12)	Quiescent JIA (N = 15)	Healthy Controls (N = 16)	Bacteremic Patients (N = 5)	p-value

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Oligoarticular Juvenile Idiopathic Arthritis (oligoJIA) is the most common JIA subtype.

According with the most recent classification criteria<sup>1</sup>, monoarticular JIA (monoJIA) is included in the oligoarticular subgroup. We investigated whether patients with persistent monoJIA have different clinical features and outcome as compared to those with oligoarticular disease.

**Methods:** We evaluated patients with oligoJIA followed at our Pediatric Rheumatology tertiary Center and at least one year of disease duration. MonoJIA we selected on the basis of the exclusive involvement of one single joint during the overall disease course. Each patients was followed with check visits, including ophthalmologic evaluation, every 3-4 months. For each patient, the following parameters were considered: sex, age at onset, presence of joint hypermobility (JH) according to Beighton's criteria<sup>2</sup>, family history positive for JH, ANA (titer > 1/80 on Hep2 cells), presence and localization of active arthritis, presence of uveitis, treatment during the overall course of the disease and outcome. Treatment was grouped in four categories: intra-articular corticosteroid injection (IACs), non-steroidal anti-inflammatory drugs and/or oral corticosteroids (AIDs), MTX and other disease-modifying anti-rheumatic drugs (DMARDs), and biological agents (BAs). Outcome was defined according to Wallace criteria<sup>3</sup> as: clinical remission (CR), clinical remission on medication (CRM) and active disease (A).

**Results:** 356 patients with oligoJIA, as defined by the ILAR criteria, entered the study. Among these, 23 were excluded for lack of complete data and 12 for follow-up shorter than 1 year. Among the remaining 321, followed for mean 7,6 years (1-21.7), 227 (70.7%) presented oligoJIA and 94 (29.3%) monoJIA. MonoJIA resulted significantly different from oligoJIA for the higher frequency of JH, positive family history for JH, lesser frequency of ANA+ and uveitis and for the less aggressive treatment and better long-term outcome. **(Table 1)**

**Conclusion:** MonoJIA seems to be a separate nosological entity from oligoJIA with less incidence of ANA, less uveitis and better long-term outcome. A different treatment approach should be therefore foreseen.

## Symptoms of Depression and Anxiety in Children with JIA: Relation to Other Domains of Health Related Quality of Life

**Michael Miller**<sup>1</sup>, Yufan Yan<sup>2</sup> and George Lales<sup>3</sup>, <sup>1</sup>Pediatrics, Feinberg School of Medicine, Northwestern University, Chicago, IL, <sup>2</sup>Feinberg School of Medicine, Northwestern University, Chicago, IL, <sup>3</sup>Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile Idiopathic Arthritis (JIA) is associated with symptoms of anxiety and depression. We studied these symptoms and other health related quality of life (HRQOL) domains in JIA patients over a 3 year period, because associations between these domains have not been completely determined.

**Methods:** At each visit, all JIA patients meeting ACR classification criteria seen by M.L.M. receive Patient Reported Outcome Measurement Information System Short Form questionnaires v.1.0 (PROMIS) as part of routine care. Scores were calculated for mobility, anxiety, depressive symptoms, fatigue, peer relationships, pain interference domains. Data

extracted by optical mark recognition software was merged with EMR data, using Extract/Transform/Load software, for all visits March 2014 – February 2017, including active joint counts, visit age, ANA, RF, and B27 status.

**Results:** Data from 148 patients (114 females for 435 visits; 34 males for 118 visits; median 14.35 yrs, IQR 4.65) were analyzed, 70 oligo-JIA, 9 extended oligo-JIA, 19 ERA, 21 poly-RF- JIA, 5 poly-RF+ JIA, 11 undifferentiated arthritis, 3 psoriatic, 10 systemic arthritis. For all patients, by forward stepwise regression, depression scores were predicted by anxiety, pain interference, and peer relationship domains ( $p < 0.001$ ), but not other domains. Topological data modeling showed that patients endorsing depressive symptoms often reported anxiety and, less often, problems with peer relationships (figure). 31 patients (21%: 28 females, 3 males) had depression scores 60% or greater, with no predilection for subtype. However, per centile depression scores were comparable to normal reference scores (40.6, IQR 14.4); females had higher scores (43.5 IQR 14.4) than males (37.7 IQR 5.8)\*. Anxiety scores, which correlated with depression scores ( $r = 0.814$ ), also were lower than norm scores for all patients (42.6 IQR 20.9), but higher for females (42.6 IQR 10.5 v. 39.5 IQR 13.7)\* (\* $p < 0.001$  Mann-Whitney Rank Sum Test). There were no gender differences for other domains. No specific differences were distinguished by disease activity, JIA subset, laboratory results, or medications taken.

**Conclusion:** We found depressive symptoms related to anxiety, pain interference and peer relationship in JIA patients. While anxiety and depressive symptom scores were comparable to reference scores, PROMIS was effective in quickly identifying individual patients in need of additional support. PROMIS is effective in identifying the nature of HRQOL problems in JIA patients.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Few studies in children with chronic illnesses/disability have reported challenges faced by patients at school. Therefore, the objective of this study is to identify barriers and their associated impact in Juvenile Idiopathic Arthritis (JIA).

**Methods:** A cross-sectional observational study of children aged 8 to 17 diagnosed with JIA followed at the Rheumatology Clinic/Alberta Children's Hospital was performed between July and December 2016. Demographics, diagnosis and disease course were obtained from health records. A survey was administered to the child/caregiver to assess the barriers experienced by JIA patients at school. The survey collected information about school attendance/performance, impact of JIA symptoms (e.g. pain, fatigue), challenges and accommodations, communication, participation/peers, and school support. Descriptive statistics were used to analyze the data.

**Results:** A total of 80 children were recruited into the study. The median age of participants was 13 (range 8-17). The most common subtypes were rheumatoid factor negative polyarticular JIA (36%) and oligoarticular persistent JIA (33.7%) with a median disease duration of 5 years (range 0-15). The treatment included DMARDs (68.9%), NSAIDs (37.8%), biologics (36.7%), steroids (3.3%) and no medication (10%). Appointments, illness and JIA symptoms had a minor impact on school attendance and performance. However, physical challenges (e.g. gym, writing, sitting for long periods of time) at school were a barrier for 42.9% (sometimes 31.2%, often 9.1 %, almost always 2.6%). 25% recorded using accommodations (e.g. modified gym, accommodation letter, computer access). Patients were unable to participate in activities in class/outside with their peers (36.8%; sometimes 32.9%, almost always 3.9%) and in gym (41.4%; sometimes 35.7%, often 5.7%). Patients told their teachers/gym teacher about their disease (81%) but most patients did not continue to update their teachers. 9.5% of participants reported that their teachers did not understand their illness compared to 19.1% of gym teachers. 81.7% of participants told their friends about their illness and 41.9% told their classmates. Social concerns included being treated differently, being told they were faking their illness, and looking like they weren't trying. The majority reported that the school was supportive of their illness (86%). Barriers tend to be reported more often by patients with active disease.

### **Conclusion:**

JIA had a minor impact on school attendance and performance. However, many patients experienced some impacting physical challenges. Additional barriers included teacher understanding, participation and social anxiety.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster III: Juvenile Arthritis

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Research in Canadian Children with Childhood Arthritis Emphasizing Outcomes (ReACCh-Out) cohort (2005-2010) has characterized outcomes for Canadian children with Juvenile Idiopathic Arthritis (JIA). However, little is known about the uptake of this information, or JIA research findings in general, into clinical care. The aim of this study is to identify barriers and facilitators that influence the uptake and use of these findings by parents of children with JIA.

**Methods:** This descriptive exploratory study was conducted at 4 Canadian Centres (Halifax, Ottawa, Hamilton, Vancouver). Purposeful samples of parents were assembled based on duration and severity of JIA. Semi-structured focus group (FG) interviews were developed, focusing on perceptions about JIA research, how information from research was obtained/used, and what information was of greatest interest. Analysis comprised an open coding and general inductive approach.

**Results:** FG interviews were completed at the 4 sites (individual interviews supplemented low turnout at 2 sites). FG numbers ranged from 3-8 [22 parents (16 mothers); mean age 46 (32-59)]. None of the parents were aware of receiving information from the ReACCh-Out study as part of their child's care, but subjects uniformly agreed on the importance of Canadian JIA research. They indicated a preference to receive information from their child's health care providers and clinician endorsed organizations. Respondents conveyed a desire to have information at the time of diagnosis and when making decisions. Parents expressed a desire to have their interests taken into account when research questions are formulated. Sample quotes are shown in Table 1. Online or printed information was preferred.

**Conclusion:** Parents of children with JIA want up-to-date information from research translated and incorporated into clinical care and place trust in the health care team to deliver this information. Parents, however, were generally unaware of specific research findings on JIA. Critical time points when parents feel they need the most up-to-date information have been identified, however many barriers currently exist for parents who wish to access and use this information. Future work will incorporate findings from the other stakeholders in this study and will be directed at developing KT interventions that optimize delivery and utilization of research findings to improve the care of children with JIA.

Table 1: Barriers and Facilitators with Sample Quotes

Identified Barriers	Sample Quote
Lack of awareness of JIA research	"I don't know a lot about the individual studies going on, but I would trust that the practitioners and physicians here are the top notch and are doing the research that is needed."
Parent's don't want new information when their child's disease is stable	"Once things were stabilized, we were a bit saturated with all the information and once we were stabilized, we said, well we're functioning."
Parents are overwhelmed by the large volume of complex information	"I read the 30 pages of information on juvenile arthritis and it made me scared, I didn't know how to interpret it, it was too much."
Research questions misalign with parents' interests	"I wish there were more information, more studies on whether or not these adjunct therapies would help [if] integrated into the treatment."
Identified Facilitators	
New diagnosis of JIA	"When your child is diagnosed, you research and you try and find everything you can."
Medication change	"...unless you go on new medication or there's a reason for something specific, you don't look for new research actively."

## Measurement of Serum Infliximab and Antibody Levels As an Adjunct to Clinical Decision Making Regarding Infliximab Therapy

Eileen Pagano<sup>1</sup>, Myriam Kline<sup>2</sup> and B. Anne Eberhard<sup>3</sup>, <sup>1</sup>Pediatric Rheumatology, Cohen Children's Medical Center of New York, New Hyde Park, NY, <sup>2</sup>Biostatistics Unit, Feinstein Institute for Medical Research, Northwell Health, Manhasset, NY, <sup>3</sup>Pediatric Rheumatology, Cohen Children's Medical Center of New York, Lake Success, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Pediatric Rheumatology – Clinical Aspects Poster

**Background/Purpose:**

Infliximab (IFX) is a chimeric monoclonal antibody against tumor necrosis factor alpha (TNF- $\alpha$ ). It is known to be effective and often used in the treatment of juvenile idiopathic arthritis (JIA) and /or chronic iritis. It is known that children on IFX therapy may develop serum antibodies to IFX. The presence of serum IFX antibodies may potentially decrease effectiveness of IFX therapy and may be associated with severe systemic allergic reactions. The purpose of our study was to determine whether the regular monitoring of IFX serum and antibody levels may be a useful clinical tool in the management of JIA and iritis patients receiving IFX.

**Methods:**

The study was a single center retrospective chart review of 28 JIA and/or chronic iritis patients who received intravenous IFX from 3/15-5/17. Data was recorded prior to each infusion, which varied from one to a maximum of 17 infusions per patient, regarding diagnosis, age, IFX dose and frequency, IFX serum and antibody levels, methotrexate and/or leflunomide dose and route, active arthritis joint count, chronic iritis and/or worsening iritis, antinuclear antibody, rheumatoid factor, cyclic citrullinated peptide antibody, erythrocyte sedimentation rate, and c-reactive protein (CRP). A generalized linear mixed model for longitudinal binary data was used to predict the outcome variables.

**Results:**

A total of 19 female and 9 male patients were included in our sample, mean (SD) age was 15 (4.5). See **Table I** for characteristics of study patients. While patients with arthritis develop antibodies, it appears that the clinical effects of the antibodies are only seen in the iritis patients. Anti-IFX antibodies significantly predict active iritis ( $p=0.05$ ) and worsening iritis ( $p=0.0079$ ); with each one hundred unit increase in anti-infliximab antibodies, the odds of active iritis increase by 16% and the odds of worsening iritis increase by 29%. Increased CRP significantly predicted active iritis ( $p=0.03$ ) and worsening iritis ( $p=0.014$ ); with each increase in 0.5mg of CRP/L, the odds of active iritis and worsening iritis are increased by 36% and 48%, respectively. Advancing age significantly predicted decreased incidence of active iritis ( $p=0.0005$ ) and worsening iritis ( $p=0.0028$ ); with each one year increase in age, the odds of active iritis and worsening iritis are decreased by 15% and 19%, respectively.

**Conclusion:**

Monitoring anti-IFX antibodies during IFX therapy appears to be useful in the management of IFX therapy in pediatric patients with iritis. Our results indicate that younger age and rising CRP are associated with increased incidence of active iritis and may be a useful alert in managing patients with iritis. Future research with a larger sample and prospective design will be needed to confirm the relationships among the variables found herein.

**Table I – Characteristics of Study Group – N = 28**

Diagnoses	RRR Reason for Infliximab Therapy		
	Arthritis Only	Iritis Only	Arthritis & Iritis
Oligo Persistent JIA – N = 6 (21.4%)	2	3	1
Oligo Extended JIA – N = 5 (17.9%)	3	1	1
Polyarticular JIA, RF-Pos, - N = 1 (3.6%)	1	0	0
Polyarticular JIA, RF-Neg, - N = 8 (28.6%)	5	1	2
Psoriatic Arthritis – N = 3 (10.7%)	3	0	0
Systemic Onset JIA – N = 2 (7.1%)	2	0	0
Idiopathic Iritis – N = 1 (3.6%)	0	1	0
Granulomatous Iritis – N = 1 (3.6%)	0	1	0
Pars Planitis – N = 1 (3.6%)	0	1	0

## Bradycardia after High-Dose Solu-Medrol

Deirdre De Ranieri<sup>1</sup> and Umesh Dyamenahalli<sup>2</sup>, <sup>1</sup>Pediatric Rheumatology, The University of Chicago Medicine, Chicago, IL, <sup>2</sup>Pediatric Cardiology, University of Chicago, Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Pediatric Rheumatology – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methylprednisolone (MP) in both high dose (2mg/kg or higher) and pulse dose (30mg/kg up to 1000mg) is often used to treat patients with connective tissue diseases, as these doses are more effective in controlling exacerbations than lower doses. We present 6 patients with SLE who experienced bradycardia after pulse-dose MP. Three of these patients had EKGs which revealed sinus bradycardia, with heart rates decreasing below 60 beats per minute, and occasionally as much as 40%-50% below baseline. There is scarce literature explaining this occurrence, so those who are unfamiliar with steroid induced bradycardia might order redundant lab tests and imaging to further evaluate this phenomenon.

**Methods:** Review of patient medical records and the literature on this topic.

**Results:** The mechanism for this dysrhythmia remains unclear. It could be multifactorial, however one theory is that steroids, through their effect on the potassium and sodium balance in the body, may cause acute electrolyte shifts across the myocardial cell membranes, and another theory suggests that a subsequent increase in intravascular volume may trigger a reflex bradycardia. In adults, there are reports of steroid-induced bradycardia in patients with a number of

different autoimmune conditions. In children, there is little literature on this topic. Herein, we report 6 children with SLE who experienced bradycardia subsequent to high dose or pulse MP infusions. However, contrary to what has been found before, in our review of the patients, the bradycardia occurred within 4 to 24 hours of receiving MP and resolved within 24 hours of discontinuation. During this time, the patients were not symptomatic, and EKG revealed sinus bradycardia.

**Conclusion:** It is reasonable to obtain a baseline EKG and electrolytes in patients being treated for connective tissue diseases who experience bradycardia as a side effect of treatment, as these diseases can affect the myocardium independent of medications. However, if patients are asymptomatic, their electrolytes are normal, they have no prior history of cardiac disease, and the EKG reveals only sinus bradycardia, these patients require only monitoring of rhythm and hemodynamics and might not require additional tests to identify the cause of bradycardia. Because of the lack of knowledge regarding this phenomenon in pediatrics, the bradycardia in this setting leads to major concerns among the treatment team, resulting in multiple studies. Despite most patients being asymptomatic, there are reports of symptomatic steroid induced bradycardia. It would be prudent in patients with or without known underlying cardiac problems to have cardiac monitoring during high dose/pulse steroid therapy. Risk factors for steroid induced bradycardia have not been evaluated to date.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Pediatric Rheumatology – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The goals of this report are to describe various therapeutic protocols, volume of intravenous (IV) infusions, and associated adverse events at the University of Alabama at Birmingham (UAB) Pediatric Rheumatology Infusion Center from 2012 through 2015.

### **Methods:**

This was an institutional review board (IRB) approved retrospective chart review of 7,585 IV infusions given to 398 patients from 2012-2015. Infusion medications included abatacept, belimumab, cyclophosphamide, immune globulin (IVIG), infliximab, methylprednisolone, N-acetylcysteine, pamidronate disodium, rituximab, and tocilizumab. For calendar year 2015, all adverse reactions were recorded along with management strategies and outcomes. Rates of adverse events were calculated per infusion medication.

## Results:

During calendar year 2015, 234 patients received 2,181 infusions. Newer biologics (other than IVIG) represented 59% of the total IV infusions given. Of the 234 patients, 37 experienced 45 infusion reactions. The total adverse event rate for all infusions was 2%. Medications with infusion reactions were abatacept, infliximab, immune globulin, methylprednisolone, rituximab, and tocilizumab. Rituximab had the highest rate of adverse drug reactions with 11 patients experiencing reactions during 107 infusions (10%), mainly allergic in nature, while infliximab had the lowest rate of those with reactions with 7 adverse events occurring from 818 infusions (0.8%). All reactions were mild and resolved on slowing the infusion rate and treatment with antihistamines, corticosteroids, analgesics, anti-emetics, or epinephrine as needed.

## Conclusion:

In recent years, the UAB Pediatric Rheumatology Infusion Center has treated a wide variety of diagnoses and given thousands of IV infusion. Adverse reactions were few and mostly mild and transient. The use of standardized infusion protocols, the experience of managing physicians and nurses, along with the safety of the medications themselves, allow for safe IV infusions for pediatric rheumatology patients, and provide examples for similar and future infusion centers. Of note, this study does not explore potential later events, such as cancer or tuberculosis, for example.

# Current Practices and New Directions in Occupational and Physical Therapy for Children with Rheumatic Diseases in the Biologic Era

**Jill R. Blitz**<sup>1</sup> and Talitha Cox<sup>2</sup>, <sup>1</sup>Rehabilitation Services, Children's Hospital Los Angeles, Los Angeles, CA, <sup>2</sup>MS 56, Children's Hospital Los Angeles, Los Angeles, CA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP Pediatric Rheumatology – Clinical Aspects Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The development of targeted biologic therapy for rheumatic diseases, has led to improved patient outcomes and a change in the role of physical (PT) and occupational therapy (OT).. The purpose of this study was to assess the current role of PTs and OTs nationally and internationally in the pediatric rheumatology population.

**Methods:** An internet survey was sent to pediatric PTs and OTs through 3 listservs: American Physical Therapy Association pediatric section listerv, rehab directors listserv, and pediatric rheumatology bulletin board list serve. Email links were also sent directly to colleagues working in the field. Demographic information was collected. The survey identified the presence of therapies in rheumatology clinics, diagnoses seen, treatments used, and changing PT and OT patient needs and clinical practice with the advent of biologic therapy.

**Results:** Eighty-five therapists (58 PT/ 27 OT) from more than 40 hospitals and 2 outpatient clinics completed the survey. The majority of respondents were from the US, with others from Canada, Australia and Germany. Sixty percent of respondents had over 10 years of experience. Thirty-eight percent had PT and OT presence in the rheumatology clinic. Thirty-eight percent saw children with rheumatic diagnoses 1-2x/month and 18% saw them >2x/week. Treatment sessions were evenly distributed between stretching (20%), active ROM (21%), strengthening (21%) and building endurance (19%). Twelve percent provided casting or splinting for contractures. Forty-eight percent noted a decreased need for PT and OT services since the advent of biologics. Facilitating patient involvement in community activities was specifically identified by 48% of respondents.

**Discussion:** While the advent of biologics has resulted in less need for traditional PT and OT services, there continues to be an important role in providing these therapies. In addition, PT and OT clinical practice may require an increased focus on getting children with rheumatic diseases involved in community sports and activities. PT and OT are in a unique position to identify underlying issues that may present as barriers to full participation in sports or other community activities, as well as provide guidance for safe participation in these activities.

**Conclusion:** Since the introduction of biologics, the role of PTs and OTs in the pediatric rheumatologic population has evolved to not only include traditional therapies but also the facilitation of wellness and participation in sports and community activities.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Children with chronic non-infectious uveitis are at high risk for sight-threatening complications and vision loss. No biomarker predicts uveitis development or treatment response. Aqueous humor has been studied but is not feasible to collect in children with JIA without eye disease. Tear proteomics is increasingly used for biomarker discovery in ocular and non-ocular diseases. Advantages of tear collection are easy accessibility, non-invasiveness and tolerance. We examined the tear profile of children with uveitis to identify potential markers for activity vs dormancy.

**Methods:** Tear samples were collected from children with chronic non-infectious uveitis (Table 1). A Schirmer strip was placed 6mm from the lateral canthus of the anesthetized eye for 2-5 minutes. Then, 50 ug of proteins were extracted for Tandem Mass Tag (TMT) labeling. The TMT pool was loaded onto an offline electrostatic repulsion interaction chromatography (ERLIC) fractionation HPLC system and 20 fractions were collected. LC-MS/MS analysis was done on all 20 fractions. Proteome Discoverer 2.1 (ThermoFisher Scientific, San Jose, CA) was used to search all the MS/MS spectra against a Uniprot human reference protein database (retrieved April 20, 2015; 90,411 target sequences) and TMT reporter quantitation was performed.

We compared children with 1) active vs inactive uveitis of all locations and 2) active vs. inactive anterior uveitis only (JIA-associated and idiopathic). Active uveitis was defined as anterior chamber cell grade of 0.5+ (1-5 cells/hpf) and greater. Inactive uveitis was grade 0.

**Results:** There were 19 children (29 eyes) examined. We quantified 1426 unique protein groups and found 34 and 39 statistically significant proteins, respectively for all uveitis and anterior uveitis only comparisons. Gene ontology showed pathways related to extracellular exosomes (adjusted  $p=10.6e-13$  for all uveitis locations and  $p=1.23e-14$  for anterior uveitis only). In children with anterior uveitis only, there were pathways related to intracellular RNP complex ( $p=7.47e-04$ ), poly (A) RNA binding ( $p=0.002$ ), and cadherin binding involved in cell-cell adhesion ( $p=0.012$ ). These results suggest the homeostatic balance of translational and signaling machinery is disrupted during disease activity.

**Conclusion:** We identified potential biomarkers that may differentiate active ocular inflammation in children with uveitis. This may improve our understanding of the underlying mechanisms associated with ocular inflammation in children with JIA. Discovery of biomarkers in combination with clinical outcome measures may lead to better prediction of uveitis development and response to therapy.

## **Exploring HLA-DRB1 Risk Alleles in Non-Hispanic African American Children with Juvenile Idiopathic Arthritis and Chronic Anterior Uveitis**

### **Background/Purpose:**

HLA-DRB1\*08, 11 and 13 are risk alleles associated with juvenile idiopathic arthritis (JIA). Carriage of DRB1\*11 and \*13 may increase the risk for uveitis in Non-Hispanic White children with oligoarticular and polyarticular rheumatoid factor (RF) negative JIA. HLA-B8, in linkage disequilibrium with DRB1\*03, was reported in African American children with uveitis. Few studies investigate the role of HLA-DRB1 alleles in Non-Hispanic African American (NH AA) children with JIA or uveitis because they are rare conditions. Our aim is to explore the association of HLA-DRB1 alleles in NH AA children with JIA and chronic anterior uveitis (CAU).

### **Methods:**

High-resolution HLA-DRB1 genotyping was performed to determine the frequency of HLA-DRB1\*03, 08, 11 and 13 alleles in our cohort of NH AA children with JIA and/or uveitis. Frequencies were compared among JIA and CAU (JIA-associated uveitis and idiopathic chronic anterior uveitis) groups using Chi-square tests and Exact tests. In addition, we compared the frequency of these alleles in our cohorts to 3734 AA healthy controls from the National Marrow Donor Program (NMDP) using two-sided Z-tests for proportions.

### **Results:**

There were 58 NH AA children (43 JIA, 6 JIA-associated uveitis, and 9 idiopathic chronic anterior uveitis) who were mainly female (66%). Of those with JIA, 22 (45%) had extended or persistent oligoarticular JIA, and 27 (55%) had polyarticular RF negative JIA. Antinuclear antibody was positive in 17 (40%) JIA children and 3 (50%) JIA-associated uveitis (JIA-U) children.

Comparing children with JIA and CAU, there was a borderline significant difference in DRB1\*03 (30.2% vs. 6.7%,  $p = 0.087$ ) (Table 1).

Compared to AA controls, NH AA children with JIA alone had increased DRB1\*03 (30.2% vs. 13.6%,  $p = 0.001$ ), DRB1\*08 (18.6% vs. 3.3%), and DRB1\*11 (32.6% vs. 13.4%,  $p < 0.001$ ). NH AA children with CAU (JIA-U and idiopathic chronic anterior uveitis) also had increased DRB1\*08 (13.3% vs. 3.3%,  $p = 0.029$ ) and DRB1\*11 (46.7% vs. 13.4%,  $p < 0.001$ ), which may be associated with the JIA diagnosis (Table 2).

### **Conclusion:**

Carriage of HLA-DRB1\*08 and 11 may increase the risk for JIA and uveitis in NH AA children. Carriage of DRB1\*03 may also increase the risk for JIA in this cohort. Further studies including larger sample sizes of NH AA children should be conducted to investigate the role of HLA-DRB1 in children with JIA and uveitis.

**Table 1. HLA-DRB1 alleles in Non-Hispanic African American Children with Polyarticular Rheumatoid Factor Negative or Oligoarticular JIA and Chronic Anterior Uveitis**

HLA configuration	JIA <sup>a</sup> N = 43	CAU <sup>b</sup> N = 15	P-value

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Macrophage activation syndrome (MAS) is a life-threatening complication of systemic juvenile idiopathic arthritis (SJIA), characterized by activation and expansion of cytolytic lymphocytes and macrophages with hemophagocytic properties. Recent work has shown that emergence of MAS is associated with a surge in IFN $\gamma$  and IFN-induced chemokines; however, previous gene expression studies failed to demonstrate this IFN-induced signature in peripheral blood cells. However, these studies were limited by a failure to examine key myeloid effector cells, specifically activated macrophages which traffic to tissue including bone marrow during MAS.

**Objective:** Utilize single-cell RNA-sequencing to identify specific gene expression signatures of bone marrow macrophage populations in SJIA and MAS.

**Methods:** Macrophage single cell suspensions were obtained from unused portions of bone marrow aspirates using cell sorting for populations expressing the monocyte and macrophage surface markers CD14 and CD163 while excluding cells expression the granulocyte/monocyte marker CD15, prior to loading onto the Fluidigm C1 Single-Cell Auto Prep System. Extracted RNA was converted into cDNA and sequenced as a pooled library, and aligned to the human Ensembl transcriptome using Kallisto through AltAnalyze version 2.1.1.

**Results:** Three control samples yielded 180 single cells, and while there was substantial inter-individual variability, a core set of genes were identified that contributed to the heterogeneity of normal bone marrow macrophage population. Control macrophages formed at least three primary cellular clusters, which were distinguished based on expression of genes associated with proinflammatory receptors, GM-CSF signaling, and aurora B signaling. 61 single bone marrow macrophages were captured from a patient with newly diagnosed SJIA with active systemic features, arthritis, marked anemia, relative thrombocytopenia, but lacking other overt signs of MAS, but did have mild hemophagocytosis on diagnostic bone marrow aspiration. Expression profiles were broadly similar to control macrophages, and all macrophage clusters were represented. However, a distinct subpopulation of bone marrow macrophages from the SJIA patient was identified that exhibited markedly altered transcriptional profiles. Compared to other control and patient macrophages, this SJIA macrophage population showed alterations in gene pathways including cellular response to interferon gamma ( $p=1.35e-14$ ), endocytic vesicle membranes ( $p=8.44E-14$ ), phagosome ( $p=2.98e-9$ ) and vesicle-mediated transport ( $p=1.05E-07$ ). These cells showed a proinflammatory gene expression signature, including enrichment for genes regulated by NF- $\kappa$ B and STAT1.

**Conclusion:** We identify a distinct subpopulation of bone marrow macrophages in an SJIA patient with features associated with emergence of MAS, including interferon response, phagocytosis and vesicular transport. This validates a single-cell approach, and demonstrates the importance of studying these effector cells at the sites of inflammation, and suggests that tissue macrophages may be a key source of IFN-induced products during MAS.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The pathogenesis of Macrophage activation syndrome (MAS) complicating systemic juvenile idiopathic arthritis (s-JIA) is still unknown, but overproduction of proinflammatory cytokines from activated T lymphocytes and macrophages plays an important role to develop MAS. To understand the pathogenesis of MAS and to identify serum biomarker for the diagnosis of MAS, we employed an antibody array that simultaneously detects 174 serum cytokines.

### **Methods:**

Twenty five patients with s-JIA and 4 healthy controls (HCs) were analyzed. Among 25 s-JIA patients, 15 patients including 5 patients receiving tocilizumab (TCZ) were complicated with MAS. Serum cytokine levels were quantified by Raybio Human Cytokine Antibody Array. Serum CXCL9 levels were quantified by enzyme-linked immunosorbent assay. The results were compared with the clinical features of MAS.

### **Results:**

We identified fourteen cytokines whose levels increased in MAS compared to those in active phase of s-JIA. Of which, CXCL9, an interferon- $\gamma$  induced chemokine, increased most significantly with the development of MAS. The cytokine profile during active phase of s-JIA was quite different between those in s-JIA patients with MAS and without MAS. Eighteen cytokines and 72 cytokines were lower in patients receiving TCZ compared to those in patients not receiving TCZ in active phase of s-JIA and in MAS, respectively. Serum CXCL9 levels were significantly elevated in MAS compared to those in the acute phase of s-JIA. Serum CXCL9 levels profoundly and rapidly increased as MAS developed and correlated positively with disease activity. Serum CXCL9 levels were significantly lower in patients receiving TCZ but those reflected disease activity.

### **Conclusion:**

The elevated levels of CXCL9 and their correlation with disease activity of MAS indicate a pivotal role of IFN- $\gamma$  in MAS. Monitoring of serum CXCL9 is useful for the evaluation of disease activity in s-JIA and MAS. The expression of many inflammatory cytokines decreased in patients receiving TCZ, suggesting suppress of many cytokines other than IL-6 by TCZ is closely related to masking of clinical symptoms of MAS and s-JIA during TCZ therapy.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have previously shown that neutrophils in children with polyarticular juvenile idiopathic arthritis (JIA) display abnormal transcriptional patterns linked to fundamental metabolic derangements. These transcriptional abnormalities include complex re-ordering of miRNA-RNA expression networks. In the current study, we sought to determine the effects of therapy of the reorganization of miRNA-RNA networks in polyarticular JIA.

**Methods:** In this cross-sectional analysis, we studied children with untreated, active JIA (ADU-n=35), 26 children with active disease on therapy with methotrexate + etanercept (ADT), and 14 children with inactive disease also on therapy (ID). We used Affymetrix exon and miRNA microarrays to identify expressed transcripts and compared results to findings from 35 healthy control (HC) children.

**Results:** Computational modeling demonstrated substantial re-ordering of miRNA-RNA networks after the initiation of therapy. Each of the 3 disease states, i.e., ADU, ADT, and ID, was associated with its own distinct transcriptional profile that showed only modest overlaps with the other 2. Gene ontology analysis corroborated this finding, as the genes showing differential expression between each of the disease states and HC were associated with different biological functions. Among the networks, the ADT state differed the most from HC while ID more strongly resembled HC. Computational modeling demonstrated complex interactions between transcription factors and miRNA that determine the gene expression signatures of each disease state.

**Conclusion:** Therapy for JIA induces substantial re-organization of neutrophil transcriptomes. It is interesting to note that each of the different treatment stages, which we derived from clinical observations (Wallace criteria), appear to be biologically distinct. These findings affirm the value of using the Wallace criteria for staging treatment response in JIA. Furthermore, these findings demonstrate that treatment response is not a linear process that results in gradual “normalization” of transcriptomes. Rather, treatment response occurs in distinct phases each with its own specific pattern of gene expression.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** 14-3-3 proteins are chaperonins found in all eukaryotic cells. There are multiple isoforms which are thought to be involved in intracellular signaling and transcription regulation. Recent work has implicated the  $\eta$  (eta) isoform as having diagnostic potential in inflammatory arthritides. Its utility in JIA has not been established. Our preliminary prior investigation indicated positivity in some JIA patients. In this study, we investigated a much larger cohort of patients with JIA and disease and healthy controls.

**Methods:** Measurement of 14-3-3 $\eta$  protein was evaluated in 29 rheumatoid factor (RF) positive (pos) polyarticular (poly) JIA patients, 29 RF negative (neg) poly patients, 34 oligoarticular (oligo) patients, 12 systemic-onset (SO) patients, 19 adult rheumatoid arthritis (RA) patients, 60 patients with systemic lupus (SLE), and 20 healthy controls by the assay established at Quest Diagnostics. Comparisons were made to CBC, ESR, CRP, RF and anti-CCP isotypes, and ANA positivity.

**Results:** 14-3-3 $\eta$  at 0.2 ng/ml or higher was considered positive; values of 0.5 ng/mL or greater have been considered prognostic of poor outcome in adults. Ten of 29 (34%) RF pos polys were positive for the 14-3-3 $\eta$  protein; 8 (28%) had values > 0.5 ng/mL. Nine of 29 (31%) RF neg polys were positive; 8/29 (28%) had values >0.5 ng/mL. Only 6/34 (18%) oligos were positive; 5/34 (15%) >0.5 ng/mL. Only 2/12 (16%) SO were positive; 1/12 (8%) >0.5 ng/mL. In the disease controls, 14/60 (23%) SLE were positive, but only 7/60 (12%) >0.5 ng/mL. 7/19 (37%) RA patients were positive, 4/19 (21%) >0.5 ng/mL. In the healthy controls, only 3/20 (15%) were positive, 1/20 (5%) > 0.5 ng/mL. The RF pos and RF neg polys positivity, especially at values >0.5 ng/mL compared favorably with the adult RA patient and were notable compared to disease and healthy controls. A weak correlation was noted between 14-3-3 $\eta$  positivity and CRP. Five of the 8 RF neg polys at original diagnosis that were 14-3-3 $\eta$  positive at >0.5 ng/mL have subsequently developed a positive RF and an anti-CCP antibody isotype. Also, the one SO positive for 14-3-3 $\eta$  >0.5 ng/mL also developed a positive RF.

**Conclusion:** Significant levels of 14-3-3 $\eta$  protein can be found in about 30% of RF pos and RF neg poly JIA patients. It may represent a new biomarker for RF neg poly JIA patients and a marker indicating the possibility of these patients becoming RF/anti-CCP antibody positive in the future. Further longitudinal studies are required to confirm these findings.

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) is often accompanied by inflammation of the joints. The mechanisms involved in the inflammation in JIA are incompletely understood. Several cells and soluble mediators, including lipid mediators regulate the course of inflammation. Lipid mediators such as prostaglandins and leukotrienes, derived from arachidonic acid have mostly pro-inflammatory properties, while specialized pro-resolving lipid mediators (SPM) derived from docosahexaenoic and eicosapentaenoic acid have anti-inflammatory/pro-resolving actions. Both types of lipid mediators are generated by cyclooxygenases and lipoxygenases. It is currently unknown which lipid pathways are present in synovial fluid (SF) of JIA.

The aim of this pilot study is to identify the lipid mediators present in the SF of JIA to gain a better understanding of the inflammatory process in the JIA joint.

## Methods:

Ten anonymized JIA SF were obtained as leftover material from arthrocentesis from patients visiting the outpatient unit of the Pediatrics department in the LUMC. Clinical data such as diagnosis, age, gender and BMI were provided. Different immune cell populations in the SF were identified using flow cytometry. The presence of 60 different lipid mediators was determined in SF using liquid chromatography-mass spectrometry (LC-MS/MS) after hyaluronidase treatment, protein precipitation using methanol followed by enrichment for polar lipids by solid-phase extraction.

## Results:

Major immune cell populations identified in SF were monocytes, neutrophils, T cells and B cells. In general, the abundance of these populations was comparable in all JIA samples, except for neutrophils, which were more prevalent in patients that showed enthesitis.

Using LC-MS/MS, we detected arachidonic acid and several of its derivatives in SF. Pro-inflammatory lipid mediators and their precursors derived from arachidonic acid and generated by cyclooxygenases (thromboxane B2, prostaglandin E2) and 5-lipoxygenase (5-HETE and leukotriene B4) were detected in most of the samples. Interestingly, precursors of arachidonic acid-derived anti-inflammatory lipids generated by 15-lipoxygenase (15-HETE) and 12-lipoxygenase (12-HETE) were also detected. However, despite the high levels of docosahexaenoic acid (a precursor of SPM) present in all SF, we did not detect any of its anti-inflammatory lipoxygenase derivatives or SPM. Moreover, only low levels of eicosapentaenoic acid (a precursor of SPM) were detected, but none of its derivatives.

## Conclusion:

Our data suggests that the enzymatic pathways involved in both pro-inflammatory and anti-inflammatory lipid mediator production are active in JIA. However, they appear to preferentially handle arachidonic acid above docosahexaenoic and eicosapentaenoic acid to generate downstream metabolites.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** HLA B27 and gut bacteria are postulated to play a role in pathogenesis of Enthesitis Related Arthritis. Gut microbes can activate monocytes/macrophages by TLR pathway. However the mechanism of perpetuation of inflammation is not clear. Levels of endogenous ligands of TLR4 like myeloid Related Protein (MRP) 8/14 and Tenascin-C (TNC) are increased in patients with ERA. Thus we studied if monocytes from patients with ERA produce more pro-inflammatory cytokines in response to stimulation with TLR4 endogenous ligands (TNC and MRP8/14) as compared to healthy controls.

**Methods:** ERA patients satisfying ILAR criteria were enrolled. Whole blood was stimulated with TNC protein, MRP8/14 protein fragment, LPS or Proteoglycan for 24 hours and the culture supernatant was analyzed for IL-6 and TNF-alpha. Cytokine production was also measured by flow, cytometry after 6 hours culture and staining with antibodies against CD14, TNF- $\alpha$  and IL-6.

**Results:** 38 ERA patients ( $14.5 \pm 3.6$  years) with JSpADA score of ( $3.8 \pm 1.15$ ) and 23 healthy controls were enrolled. ERA patients showed significantly higher TNF-a production at baseline ( $18.4 \pm 14.2$  ng/ml for HC,  $57.9 \pm 53.21$  ng/ml for ERA;  $p < 0.05$ ) as well as after stimulation by MRP8/14 (ERA- $135.56 \pm 165.51$  ng/ml;  $p < 0.05$ ), Tenascin C (ERA- $89.03 \pm 81.8$  ng/ml), LPS (ERA- $583.38 \pm 212.59$  ng/ml) and PG (ERA- $1104.43 \pm 272.94$  ng/ml) as compared to healthy subjects ( $p < 0.05$ ).

IL-6 production levels though not increased at baseline showed a significant increase after LPS (HC-  $26.11 \pm 7.62$  pg/ml, ERA-  $33.24 \pm 6.49$  pg/ml), PG (HC-  $30.41 \pm 10.63$  pg/ml, ERA-  $42.23 \pm 6.35$  pg/ml) and TNC (HC-  $8.78 \pm 7.39$  pg/ml, ERA-  $21.47 \pm 9.43$  pg/ml) stimulation (all  $p < 0.01$ ) as compared to healthy controls.

On flow cytometry also the ERA patients had higher frequency of TNF alpha producing monocytes as compared to healthy control ( $ERA-23.70 \pm 12.0$ ,  $p<0.01$ ) at baseline. Stimulation with the endogenous ligands viz., MRP8 ( $HC-33.9 \pm 6.9$ ,  $ERA-50.78 \pm 15.74$ ), TNC ( $HC-22.4 \pm 10.2$ ,  $ERA-32.1 \pm 15.16$ ) and exogenous ligands viz., LPS ( $HC-69.6 \pm 12.2$ ,  $ERA-85.75 \pm 14.64$ ) and PG ( $HC-70.2 \pm 12.1$ ,  $ERA-89.27 \pm 11.15$ ) led to a significant increase in the frequency of TNF- $\alpha$  producing monocyte frequency in ERA patients compared to healthy controls ( $p<0.01$ ). Similar trend was seen in frequency of IL-6 producing cells.

**Conclusion:** : Patients with ERA have pre-activated monocytes in their peripheral blood. TLR4 endogenous ligands may be contributing to immune-inflammation by activating monocytes and leading to production of high levels of pro-inflammatory cytokines

## **Evidence for Alternatively Activated (M2) Macrophage Activation in Patients with Enthesitis Related Arthritis Category of Juvenile Idiopathic Arthritis**

Amita Aggarwal<sup>1</sup>, Priyanka Gaur<sup>2</sup> and Akhilesh Yadav<sup>3</sup>, <sup>1</sup>Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, <sup>2</sup>Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, <sup>3</sup>Department of Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Among juvenile idiopathic arthritis (JIA), enthesitis related arthritis (ERA) category includes most children with juvenile onset spondyloarthritis (SpA). Synovial fluid from patients with SpA causes more M2 polarization of peripheral blood monocytes than SF from patients with RA. Recently an increase in CD163+ macrophages was seen in ileal biopsies from patients with AS. A 6.5 fold higher expression of CD163 has been reported in SFMC gene expression as compared to PBMC of children with ERA. Thus we studied levels of sCD163 as a marker of activation of M2 macrophages in serum and synovial fluid of children with ERA.

### **Methods:**

Serum samples from patients with ERA and healthy young adults were assayed for sCD163 using ELISA (R&D systems). In addition SF from children with ERA was also analyzed where available.

### **Results:**

Sera from 85 patients and synovial fluid from 32 patients with ERA and serum from 46 young adults were analyzed. The average age of patients at inclusion was 16+3.24 years and age at onset was 11.2+2.79 years. 79 of them were boys

and HLA B27 was positive in 64/80 patients (data not available in 5)

The mean serum sCD163 levels were higher in patients as compared to healthy controls (1433.61 +1256.11 versus 907.35+726.56ng/ml;  $p<0.001$ ). The synovial fluid levels were much higher than serum levels (4307.38+3363.92 ng/ml;  $p<0.003$ ). Data on disease activity was available in 56 patients. The mean TJC was 3+2.7, SJC was 2.3+2.2, ESR was 74+34 mm and CRP was 6.98+5.4 mg/dl. The serum levels of sCD163 did not have any correlation with disease activity parameters.

#### Conclusion:

A higher levels of sCD163 in serum of patients with ERA and even higher levels in paired SF suggest that there is activation of alternatively activated macrophages in ERA. Lack of correlation with activity may suggest that they have immune regulatory role in patients with ERA.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Macrophage activation syndrome (MAS) is a severe complication of rheumatic disease, particularly of systemic JIA (sJIA). It is currently classified among the secondary forms of HLH (sHLH). Primary HLH (pHLH) is caused by mutation of genes that code for proteins that are involved in cytotoxic functions. Mice carrying heterozygous mutations in more than 1 pHLH gene carry a higher risk to develop HLH following viral infection, suggesting that accumulation of partial genetic defects may be relevant in HLH.

**Methods:** Genes involved in pHLH were analysed, with next generation sequencing (NGS), in MAS in the context of different rheumatic diseases and in sHLH. A Targeted resequencing were performed on all patients using a panel including the 7 principal HLH-related genes (*PRF1*, *UNC13d*, *STX11*, *STXBP2*, *RAB27a*, *XIAP*, *SH2D1A*). Sequencing analysis were performed on the MiSeq® and NextSeq550® platforms (Illumina, San Diego, CA); all variants identified were confirmed by Sanger. The possible functional impact of variants was studied by *in silico* analysis using SIFT and PolyPhen softwares. We took into account only variants with allelic frequency in the global population up to 1%, in

the dbSNP and Ensembl databases, with the exception of A91V variant in *PRF1* gene, because of its conflicting interpretation of pathogenicity.

**Results:** Fifty patients, 29 MAS (23 developed this complication in the context of sJIA, and 6 developed MAS respectively in the context of systemic vasculitis, Crohn's disease, systemic lupus erythematosus, anti-phospholipid syndrome, chronic recurrent multifocal osteomyelitis and Kawasaki disease) and 21 patients with HLH secondary to infections or without any demonstrable trigger, were analysed. At least 1 heterozygous variant was identified in one of the pHLH-associated genes in 24 patients (12/29 MAS, 12/21 sHLH) with a detection rate of 48%. Seventeen patients (34%) showed only 1 variant, while more than 1 variant were found in 7 patients (14%). Seven (24%) patients with MAS showed the A91V variant in *PRF1* in an heterozygous state, and 5 (17%) patients showed an heterozygous variant in *UNC13d* gene. Four of the 29 MAS patients had mutations in two different genes: one of them had recurrent episodes of MAS with a severe disease and a prolonged ICU admission. Two MAS patients carried 2 heterozygous variants in the same gene. Three (14%) patients with sHLH showed a heterozygous mutation in *RAB27a*, 3 in *UNC13d* and 4 in *PRF1* gene. Two patients carried more than a single heterozygous variant: one had variants in two different genes, while one patient showed 3 different variants in the same gene (*PRF1*). For two of these patients with variants in two different genes, one of them presented three episodes of HLH reactivation and the other one presented a severe disease with exitus.

**Conclusion:** Mutations of *PRF1* and *UNC13d* genes were frequently observed in patients with MAS or secondary HLH; *RAB27a* variants seems to be more frequent in patients with sHLH. Re-occurrence and severity of disease tend to be more frequent and more severe in sHLH patients who carry mutations in two genes. The contribution of these variants to the risk of MAS or sHLH remains to be established in the context of a polygenic model of sHLH and MAS.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Background/Purpose:** We have recently reported high levels of IFN $\gamma$  and of the IFN $\gamma$ -related chemokines, (CXCL9 and CXCL10) in patients with MAS (1).

**Methods:** Circulating levels of IFN $\gamma$ , CXCL9, CXCL10, IL-18, neopterin and sCD25 IFN $\gamma$ , CXCL9, CXCL10, IL-18, neopterin and sCD25 were measured by Luminex assay in 57 samples obtained from 24 patients with active sJIA and in 37 samples from 20 MAS patients with variable degrees of disease severity and under different treatments at time of sampling. We evaluated if blood levels of these biomarkers may help to identify sJIA patients with the predisposition to develop MAS, and additionally if they may help clinicians to distinguish MAS from active sJIA.

**Results:** Levels of IFN $\gamma$ , CXCL9, CXCL10, IL-18, neopterin and sCD25 were significantly elevated in MAS compared to active sJIA without MAS at sampling (p-values <0.0001, except for IL-18 p=0.012) and were significantly correlated with laboratory parameters of disease severity, except for IL-18, whose levels were available only for a portion of the samples. During active sJIA without MAS at sampling, levels of the IFN $\gamma$ -induced chemokines (CXCL9 and CXCL10) were significantly higher in patients with a history of MAS as compared to those of patients without a history of MAS (Table 1). In order to verify if measurement of these biomarkers could help in distinguishing MAS from active sJIA, we analyzed sensitivity and specificity and the area under the curve (AUC) for each parameter. The highest AUC (=0.95) was found for neopterin levels >14.62 nmol/L (Sensitivity 85.3% Specificity 84.6%). AUC for IFN $\gamma$  (>8.5 pg/ml), CXCL9 (>2677 pg/ml), CXCL10 (>725.5 pg/ml), IL-18 (>4309 pg/ml) and sCD25 (>211.65 pg/ml) were 0.77, 0.82, 0.82, 0.82 and 0.86, respectively.

**Table 1.** Cytokine levels in sJIA patients with active disease with or without history of MAS

	sJIA with history of MAS (N=17)	sJIA without history of MAS (N=40)	P
IFN $\gamma$ (pg/ml)	5.6 (3.2-14.4)	5.3 (3.2-10)	0.74
CXCL9 (pg/ml)	3889 (965-7142)	519 (385-1168)	0.0015
CXCL10 (pg/ml)	764 (323-1259)	215 (152-470)	0.0003
IL-18 (pg/ml)	4405 (582-7122)	439 (312-824)	0.067
neopterin (nmol/L)	8.2 (6.5-13.9)	8.1 (6.6-8.8)	0.94
sCD25 (pg/ml)	80 (80-229)	80 (80-193)	1
Values are expressed as median (IQR)			

**Conclusion:** Elevation of neopterin and CXCL9, both reflecting IFN $\gamma$  production, and their correlation with laboratory parameters, supports the pathogenic role of IFN $\gamma$  in MAS. Circulating levels of CXCL9 and CXCL10 (to a lesser extent of IL-18, though, not reaching statistical significance) are higher in patients with a history of MAS compared to patients without a history of MAS, suggesting subclinical activation of this pathway even in the absence of overt MAS and that CXCL9 and CXCL10 may identify patients at high risk for MAS; larger studies are needed. Regarding distinguishing MAS from active sJIA, levels of neopterin, IFN $\gamma$ , CXCL9, CXCL10, sCD25, and IL-18 may be used and the possibility to integrate the currently available classification criteria with one or more of these biomarkers investigated in larger studies.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pharmachild is a pharmacovigilance registry on children with JIA treated mainly with biologics ± methotrexate (MTX). Little evidence exists in literature about the role of JIA or its immunosuppressive therapy in determining infections, especially caused by opportunistic pathogens.

### **Methods:**

To provide an update on opportunistic infections (OI) revised by an independent Safety Adjudication Committee (SAC) (3 pediatric rheumatologists and 2 pediatric infectious disease specialists).

**Methods:** The participating centres were asked to report all infections encountered by their JIA patients. PRINTO and the medical monitor (MM) classified events based on MedDRA dictionary. Moderate/serious/severe/very severe infections were then revised blindly by the SAC, who were asked to answer 6 questions. The events with consensus of at least 3/5 experts on the first 3 questions ('Is this an infection?', 'Is it common?', 'Is it opportunistic?') were retained for the analysis. With referral to the recommendations by Withrop *et al.*<sup>1</sup>, for the first time a list of opportunistic infections in children with JIA on immunosuppressive therapy was elaborated and approved by consensus, through three Delphi steps.

**Results:** A total of 772 safety events related to 634 patients were submitted to the Safety Adjudication Committee. 689 (89.2%) events received consensus among the experts on the 3 questions and, of these, 682 (99.0%) were considered as infections, corresponding to 53 High Level Term (HLT) including 153 different Preferred Terms (PT), according to

MedDRA dictionary. Among the 682 infections, 603 (88.4%) were defined by the experts as common and 119 (17.4%) as opportunistic. For 92 (60%) of the 153 PT, the MM and SAC used the same PT, while the remaining 40% was adjudicated by a third examiner, who analyzed again the case reports and assigned the PT which was the most appropriate taking into account the experts' opinion. A final number of 52 HLT emerged and, among them, herpes viral infections, tract respiratory infections and EBV were the most frequent (Table1). Analyzing the infections by PT, 151 different PT resulted. Of them, the experts adjudicated: 22 as OI, 117 as not OI, 8 discordant and 4 not evaluable. Comparing the experts' adjudication with the approved list of OI by PT, there was full agreement for the 22 PT classified as OI, while 26/117 (22.2%) PT resulted in the list, but were not classified as OI by the experts.

**Conclusion:** Our preliminary analysis showed a significant number of opportunistic infections in JIA patients on immunosuppressive therapy, which was mostly confirmed in the list of opportunistic infections approved by the experts. Further analysis on the correlation with medications is ongoing.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Juvenile spondyloarthritis (jSpA) is a complex disease with both genetic and environmental factors contributing to the etiology. Recently obtained gene signatures in jSpA patients revealed TLR4 and CXCR4 gene had increased, while NLRP3 and PTPN12 had decreased expression, though the mechanism(s) responsible for those alterations remained unknown. To elucidate the possible role of epigenetic modifications in the regulation of those genes, DNA methylation analysis was performed.

### **Methods:**

DNA was isolated from PBMCs of 19 patients diagnosed with jSpA according to ILAR classification criteria for enthesitis related arthritis (ErA) and seven matched healthy children. None of the jSpA participant had symptoms for more than six months and all were untreated. Methylated DNA Immunoprecipitation (MeDIP) was performed in promotor region of differentially expressed genes (TLR4, CXCR4, NLRP3, PTPN12) using the Magmedip kit. Enrichment in MeDIP fraction was determined by quantitative RT-PCR using the AriaMx. MeDIP results were expressed as fold enrichment of immunoprecipitated DNA for each site.

## Results:

Statistical analysis revealed significant hypermethylation of promoter sites in NLRP3 gene ( $p=0,0220$ ). No significant alterations in methylation status were observed in promoter regions of other genes (Table 1).

## Conclusion:

Our study indicates the hypermethylation of NLRP3 gene promotor is probably responsible for expression alterations in jSpA patients in the initial phase of the disease. The NLRP3 gene has a crucial role in assembly of NLRP3 inflammasome, innate immune sensor that regulates “danger” response upon various signals. While increased expression of this gene has been found in many autoinflammatory diseases, decreased expression has been associated with IBD in which the microbiota is believed to contribute to the intestinal inflammation. Therefore, it is not entirely surprising decreased expression has also been observed in jSpA, the disease that has clinical and genetic similarities with IBD and is often characterized by subclinical gut inflammation. The growing number of evidence shows any modification of gut microbiota can lead to dysbiosis with long-term consequences for the whole organism. Specifically, in jSpA this could result in increased influx of TLR4 ligands and increased expression of TLR4 gene, as well as in reduction of commensal bacteria with anti-inflammatory properties, namely bacteria *Faecalibacterium prausnitzii* that inhibits NF- $\kappa$ B signaling, leading to TNF- $\alpha$  abundancy characteristic for jSpA. Since inflammasomes have been shown to shape the microbiota, it is reasonable to assume these processes can at least partially be explained by reduced NLRP3 expression due to hypermethylation. Therefore, our findings could have important implications in understanding of the disease mechanisms and possible therapeutic options.

**Table 1.** Results of DNA promoter methylation and previously performed gene expression analysis in juvenile spondyloarthritis patients<sup>1</sup>.

GENES	Fold Enrichment of Immunoprecipitated DNA			Fold Change of Expression <sup>1</sup>	
	Patients	Controls	<i>p</i>	Fold Change	<i>p</i>
TLR4	0,213	0,153	0,5759	+3,91	<0,01
NLRP3	11,24	5,412	<b>0,0220</b>	-5,00	<0,01
CXCR4	0,372	0,182	0,182	+1,87	<0,01

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile dermatomyositis (JDM) is a systemic disorder of childhood characterized by muscle inflammation and vasculopathy. The mechanisms of the blood vessel injury in JDM remain to be fully solved. Anti-endothelial cell antibodies (AECA) are detected in infectious, inflammatory diseases and autoimmune diseases such as vasculitis, and we have hypothesized that such antibodies may target the endothelium in JDM. In this study, we aimed to comprehensively detect endothelial target antigens in JDM using a proteomics approach. **Methods:** We extracted proteins from human aortic endothelial cells (HAEC), which were used as antigen sources. To comprehensively detect target antigens for AECA, we separated proteins extracted from HAEC by two-dimensional electrophoresis (2DE) and then transferred them onto membranes. Using standard western blotting techniques, membranes were probed with sera from children with JDM or healthy controls. Autoantigens that were positive only in sera from children with JDM but not healthy controls were then identified by mass spectrometry (MS). Enzyme-linked immunosorbent assay (ELISA) was then used to confirm presence of specific antibodies. **Results:** Five candidate protein spots as JDM-specific proteins were detected in 2DE-WB. From these spots, we successfully identified 34 proteins. 22 of the 34 identified antigens represented membrane proteins. Using Ingenuity Pathway Analysis, 27 of the 34 candidate target antigens for AECA in JDM were predicted to interact with chaperone proteins involved in antigen processing and presentation. Among the 8 chaperone or co-chaperone proteins were heat shock cognate 71 kDa protein (HSC70), heat shock protein HSP 90-beta (HS90B) and stress-induced-phosphoprotein 1 (STIP1), a protein that mediates the association of HSC70 and HSP90. By ELISA, IgG autoantibodies to HSC70 were detected in 23% of the patients with JDM (n=39). However, 50% of the untreated JDM patients with active disease (n=10) had anti-HSC70 antibodies, in contrast to 7% (p<0.05) of the patients with juvenile idiopathic arthritis (JIA) (n=15) and 5% (p<0.01) of control children (n=20). 13% of the treated JDM patients with active disease (n=15) and 14% of the inactive patients with JDM (n=14) had anti-HSC70 antibodies. IgG autoantibodies to HS90B were detected in 6% of the patients with JDM (n=31) and in 5% of control children, in contrast to 20% of the patients with JIA. Similarly, IgG autoantibodies to STIP1 were not detected patients with JDM, but were present in 5% of control children and 20% of the patients with JIA. **Conclusion:** IgG antibodies to chaperone proteins in the proteome of HAEC are present in the sera of children with JDM. The presence of AECA in JDM could implicate these antibodies in the disorders of immune system in JDM.

## Expression of Myxovirus-Resistance Protein a: A Possible Marker of Muscular Disease Activity in Juvenile Dermatomyositis

Sirisucha Soponkanaporn<sup>1</sup>, Claire Deakin<sup>2</sup>, Lucy Marshall<sup>2</sup>, Cerise Johnson<sup>2</sup>, Peter Schutz<sup>1</sup> and Lucy R Wedderburn<sup>2</sup>, <sup>1</sup>Infection Inflammation and Rheumatology Section, UCL Great Ormond Street Institute of Child Health, University College London, United Kingdom, London, United Kingdom, <sup>2</sup>Infection, Immunity and Inflammation Programme, UCL Great Ormond Street Institute of Child Health, University College London, United Kingdom, London, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Juvenile dermatomyositis (JDM) is a chronic autoimmune myopathy characterized by proximal muscle weakness and typical skin rashes. Type I interferon (IFN) gene expression in blood has been shown to correlate with muscle involvement in adult and juvenile dermatomyositis. Myxovirus-resistance protein A (MxA), a type I IFN-induced protein, is specifically regulated by type I IFN pathway. Since muscle is the major target of inflammation, the presence of MxA protein in muscles could be of greater relevance to direct mechanisms of tissue injury. This study aims to examine whether MxA protein expression in muscles correlates with disease activity in JDM.

### Methods:

103 patients enrolled in the Juvenile Dermatomyositis Cohort and Biomarker Study (JDCBS) had muscle biopsies available, which were stained for MxA by immunohistochemistry. The expression of MxA in muscle fibres was scored semi-quantitatively. Scores range from 0 to 3 (0 = no MxA staining; 1 = weak; 2 = moderate; 3 = strong). Clinical and laboratory data at initial presentation including Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing of Eight Muscles (MMT8), physician's global assessment (PGA) and muscle enzymes were collected. Kruskal-Wallis ANOVA with Bonferroni's correction were tested to examine differences of MxA scoring data in muscle disease activity. Multiple linear regression analysis was performed to estimate the association between MxA expression on muscle fibres and muscle disease activity. The strength of the association was described by the standardised coefficient ( $\beta$ ).

### Results:

The median age at disease onset was 6.3 years and median duration from disease onset to muscle biopsy was 3.8 months. About 9% of patients had received corticosteroids at the time of biopsy. MxA expression was identified in 63 of 103 patients, with 57% of those showing strong MxA expression on myofibres. The distribution of MxA expression was observed in both perifascicular (46%) and scattered (53%) patterns. Comparing patients with varying MxA scores, there were no significant differences in age at onset, gender, and clinical features at first presentation, such as, the presence of calcinosis, nail fold capillary changes and PGA. There were statistical differences in duration from disease onset to muscle biopsy ( $p = 0.046$ ), CMAS ( $p = 0.002$ ) and MMT8 ( $p = 0.026$ ). CMAS and MMT8 were significantly lower in the group of patients with strong MxA expression. From post hoc analysis, there were significant differences in CMAS between patients with scores of 0 and 2 ( $p = 0.044$ ), and scores of 0 and 3 ( $p = 0.001$ ). Also, MMT8 in patients with scores of 0 and 3 were statistically significantly different ( $p = 0.013$ ). Regression analysis confirmed that expression of MxA was significantly associated with CMAS ( $\beta = -0.433$ ) and MMT8 ( $\beta = -0.368$ ) at disease onset, after adjustment for time to biopsy.

### Conclusion:

This study reveals an association between level of MxA expression on muscle fibres and clinical measures of muscular disease activity in JDM patients, CMAS and MMT8. This shows how immunohistochemical staining of MxA on muscle tissues has the potential of providing more insight into pathogenesis of JDM and may help develop more targeted therapies for JDM patients.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile dermatomyositis (JDM) is a complex heterogeneous autoimmune disease. Myositis-specific autoantibodies (MSAs), present in up to 80% of JDM patients, help define distinct phenotypes within JDM and may indicate distinct pathogeneses. To define biomarkers and better understand JDM pathogenesis, aptamer-based proteomic technology was used to mine the serum proteome in a well-characterized JDM cohort.

**Methods:** Sera from 41 JDM patients (prevalent cases on variable treatment) were selected for relatively high disease activity (physician global activity or PGA median 4.0 (IQR 3.0-5.0)) with anti-TIF1 (n=21), NXP-2 (n=10), and MDA5 MSAs (n=10), and compared with 28 age- and gender-matched healthy controls (HC). Broad proteomic analysis of 1306 targets with a slow off-rate modified aptamer-based assay (SomaLogic, CO) generated simultaneous quantitative serum levels. Internal discovery/validation was done with 2 independently-analyzed groups each with JDM and HC sera, stratified to evenly distribute PGA, MSA, gender, oral steroid dose (median oral prednisone dose 0.40 mg/kg/day, IQR 0.17-0.73) and age. From proteins with Mann Whitney U FDR corrected p values of <0.10 (JDM vs. HC) common to both groups with expression ratio of >1.3, we performed Ingenuity Pathway Analysis (Qiagen, CA), as well as exploratory Spearman correlation of protein levels versus PGA, also among MSA groups, and protein levels vs. oral steroid dose (mg/kg/day).

**Results:** 166 proteins met significance criteria in both analysis groups of JDM versus HC sera, with 80 proteins upregulated and 86 downregulated (see Table). Pathway analysis revealed granulocyte/agranulocyte adhesion/diapedesis, interferon, remodeling/damage, Th1, and adipokines as top dysregulated pathway clusters in JDM, even after excluding 4 proteins that correlated with steroid dosage. We identified 13 proteins with serum levels positively correlated with PGA for JDM overall ( $r_s = 0.31-0.41$ ), 13 proteins in NXP2 Ab group ( $r_s = 0.65-0.89$ ), 4 proteins in TIF1 Ab group ( $r_s = 0.45-0.54$ ); none in MDA5 Ab group. Individual proteins within MSA groups had stronger correlation with PGA than in JDM overall, and some proteins were only identified in MSA groups (e.g. IFNB in NXP2 Ab group).

**Conclusion:** Broad quantitative proteomic analysis identified key differentiating pathway clusters in JDM versus HC, including some novel proteins. Several protein levels correlated with PGA, with stronger correlation within MSA groups and notable IFN-related proteins upregulated in the NXP2 MSA group. These proteins identified through a high-throughput screen bring to light pathways that may be important in JDM and potentially MSA-group specific pathogenesis.

This research was supported by the Cure JM Foundation and the Intramural Research Program of the NIH, NIEHS, NHLBI, NIAID, NIAMS and the CC.

**Table 1: Top Dysregulated Proteins in JDM versus HC**

	Target Full Name	Target	JDM/HC expression ratio
Upregulated	Leukotriene A-4 hydrolase	LKHA4	5.98
	Stromelysin-1	MMP-3	5.77
	Ubiquitin-like protein ISG15	UCRP	5.39
	C-X-C motif chemokine 1B	IP-10	5.16
	Complement C3b	C3b	4.20
Downregulated	6-Phosphogluconate dehydrogenase, decarboxylating	6-Phosphogluconate dehydrogenase	0.42
	Creatine kinase M-type:Creatine kinase B-type heterodimer	CK-MB	0.46
	Mast/stem cell growth factor receptor Kit	SCF sR	0.47
	Growth/differentiation factor 11/B	GDF-11/B	0.48
	Proto-oncogene tyrosine-protein kinase receptor Ret	RET	0.51

## Plasma Exosomes from Children with Juvenile Dermatomyositis Are Taken up By Human Aortic Endothelial Cells and Are Associated with Altered Gene Expression in Those Cells

Kaiyu Jiang<sup>1</sup>, Zihua Hu<sup>2</sup>, Rie Karasawa<sup>3</sup>, Yanmin Chen<sup>1</sup> and James Jarvis<sup>4</sup>, <sup>1</sup>Pediatrics, University at Buffalo, Buffalo, NY, <sup>2</sup>Center for Computational Research, University at Buffalo, Buffalo, NY, <sup>3</sup>Institute of Medical Science, St. Marianna University School of Medicine, Japan, Kawasaki, Japan, <sup>4</sup>Department of Genetics, Genomics & Bioinformatics, University at Buffalo, Buffalo, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The pathology of juvenile dermatomyositis (JDM) is characterized by prominent vessel wall and perivascular inflammation. This feature of the disease has remained unexplained and under-investigated. We have hypothesized that plasma exosomes, which play an important role in inter-cellular communication, may play a role in the vascular injury associated with JDM.

**Methods:** We purified exosomes from plasma samples of children with active, untreated JDM (n= 10) and healthy controls (n= 10) using the ExoQuick Precipitation method. We characterized the small RNA cargoes in JDM and control exosomes by RNA sequencing using the Illumina HiSeq 2500 platform. We incubated isolated exosomes from healthy controls and JDM patients with cultured human aortic endothelial cells (HAEC) for 24 hours. Fluorescence microscopy was used to confirm that both control and JDM exosomes were taken up by HAEC. RNA was then purified from HAEC that had been incubated with either control or JDM exosomes and sequenced on the Illumina platform. Differential expression of mRNAs from HAEC incubated with control or JDM exosomes was ascertained using standard computational methods. Finally, we assessed the degree to which differential gene expression in HAEC could

be attributed to the different small RNA cargoes in JDM vs control exosomes using conventional and novel analytic methods.

**Results:** We identified 10 small RNA molecules that showed differential abundance when we compared JDM and healthy control exosomes. Fluorescence microscopy of labeled exosomes confirmed that both JDM and control exosomes were taken up by HAEC. Differential gene expression analysis revealed 193 genes that showed differential expression between HAEC incubated with JDM exosomes vs HAEC incubated with exosomes from controls. Gene ontology analysis revealed that many of these differentially expressed genes (e.g., CXCL8/IL8) are associated with leukocyte migration and adherence. Analysis of the differentially expressed genes, however, failed to provide a strong link between the miRNA cargoes in the exosomes and patterns of gene expression

**Conclusion:** Plasma exosomes from children with active, untreated JDM are taken up by HAEC and are associated with alterations in gene expression in those cells. However, we were unable to establish a strong link between transcriptional changes and the small RNA cargoes of JDM exosomes. This suggests that other exosome components are more likely to be involved.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

There is growing evidence for an involvement of interferons (IFNs) in the chronic inflammation that characterizes juvenile dermatomyositis (JDM). The aim of this study was to investigate muscle expression of type I (IFN $\alpha/\beta$ ) and type II (IFN $\gamma$ ) IFN inducible genes in muscle biopsies of JDM patients and their correlations with clinical and histological aspects of the disease.

**Methods:** In a retrospective cohort of patients diagnosed with JDM (n=35), expression of the six genes part of the so called type I IFN score (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1), as well as of IFN $\gamma$  and of CXCL9, CXCL10, CXCL11, CIITA, were analyzed by real-time PCR on snap-frozen muscle biopsies and compared with biopsies from Duchenne muscular dystrophy (DMD) patients (n=24) and 4 healthy controls (HC). Expression levels of CXCL9, CIITA (genes specifically induced by IFN $\gamma$ ) and IFN $\gamma$  itself were used to generate a type II IFN score. We also analyzed mRNA expression of the pro-inflammatory cytokines interleukin-1 $\beta$  (IL-1 $\beta$ ), tumor necrosis factor- $\alpha$  (TNF $\alpha$ ) and interleukin-6 (IL-6). Patient charts were reviewed to record clinical features at diagnosis and long term outcomes: physician's global assessment of disease activity, serum levels of muscle enzymes, erythrocyte sedimentation rate, C-reactive protein level, antinuclear antibodies status, time to inactive disease and time to prednisone (or equivalent) dose 0.2 mg/kg/daily, and relapses. We furthermore evaluated typical histological aspects of JDM (inflammatory infiltrate, necrosis, perifascicular atrophy and fibrosis) on tissue sections of the muscle biopsies.

**Results:** JDM patients treated (n=12) with systemic glucocorticoids before biopsy were excluded from analysis, because expression levels of the studied genes were markedly reduced compared to untreated patients. The type I IFN score and type II IFN score were significantly higher in the muscle of untreated JDM patients (n=23) compared with controls (p<0.0001, p<0.001 respectively). Expression of TNF $\alpha$ , but not of IL-1 $\beta$  and IL-6, was significantly (p<0.05) higher in untreated JDM muscle biopsies compared with those of controls. Type I IFN score correlated with inflammatory infiltrate and necrosis, while the type II IFN score correlated with inflammatory infiltrate, perifascicular atrophy and fibrosis. Type I IFN score, type II IFN score and TNF $\alpha$  expression significantly correlated with physician's global assessment at diagnosis (r=0.38, r=0.42, r=0.62, respectively). When analyzing correlations with long term outcomes, we found that patients with elevated type II IFN score reached clinically inactive disease significantly later than patients with low type II IFN score (log-rank chi square value=10.1, p<0.01).

**Conclusion:** IFN type I and type II scores in muscle biopsies of JDM patients correlate with clinical and histological features suggesting a pathogenic role of IFNs in muscle damage and inflammation in JDM. Noteworthy the type II score correlated with time to clinically inactive disease, suggesting a correlation with disease severity.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Interferons (IFNs) seem to be important contributors in the pathogenesis of juvenile dermatomyositis (JDM). Our group previously reported that expression of both type I and type II IFNs is increased in muscle biopsies of JDM patients and correlates with histological and clinical aspects of the disease, and other authors described up-regulation of interferon regulated genes (IRGs) in blood samples of JDM patients. The aim of this study was to investigate expression of IRGs (measured as type I IFN score) and serum levels of two type II IFN (IFN $\gamma$ ) induced chemokines (CXCL9, CXCL10) in peripheral blood of JDM patients. Furthermore, we wanted to evaluate possible correlations of type I IFN score, as well as of CXCL9 and CXCL10, with clinical and laboratory findings during disease course.

**Methods:** We collected 79 blood samples from 26 JDM patients at different times during the disease course. We measured expression of IRGs (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1) by real-time PCR and calculated a type I IFN score; serum levels of CXCL9 and CXCL10 were analyzed by ELISA. The first blood sample was collected at the same time the patient underwent muscle biopsy in six patients. At each visit, the following clinical data were recorded: physician's global assessment of disease activity VAS (Visual Analogue Scale), cutaneous VAS, Cutaneous Assessment Tool (CAT) activity and damage score, Childhood Myositis Assessment Score (CMAS), serum levels of creatine phosphokinase (CK, IU/l), prednisone (or equivalent) dose (mg/kg/daily), ongoing immunosuppressive medications.

**Results:** Blood expression levels of IRGs were up-regulated in untreated JDM patients at diagnosis compared to healthy controls. Type I IFN score progressively reduced after start of glucocorticoid and immunosuppressive therapy. CXCL9 and CXCL10 serum levels had a similar trend. These patients also showed an increased expression of IRGs, CXCL9 and CXCL10 in muscle biopsies obtained at diagnosis. We found that the type I IFN score correlates with cutaneous disease activity assessed by the CAT activity score ( $p = 0.027$ ), whereas there was no significant correlation with cutaneous VAS ( $p = 0.09$ ) or CAT damage score ( $p = 0.88$ ). Serum levels of CXCL10 showed correlation with serum CK levels ( $p = 0.042$ ) and muscular function assessed by CMAS ( $p = 0.021$ ). None of the evaluated clinical features showed correlation with serum levels of CXCL9.

**Conclusion:** Our findings indicate that in addition to CXCL10, already suggested as potential biomarker in JDM, expression of IRGs measured as type I IFN score reflects disease activity in JDM.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Juvenile dermatomyositis (JDM) is a rare, severe autoimmune disease characterized by muscle weakness and rash. Clinical features of JDM are heterogeneous, and can include serious complications such as calcinosis, ulceration, treatment-resistant rash and involvement of major organs, including gut, lungs and brain. While JDM and adult-onset dermatomyositis (DM) share similar clinical and biological features, there are differences in prevalence of clinical features. Cancer development is a major complication of DM, but not JDM. Conversely, calcinosis is a major cause of morbidity in JDM, but has a low occurrence in DM. The prevalence of myositis-specific autoantibodies (MSA), which are linked to different clinical features of disease, also differs between the adult and juvenile forms of the disease. These differences in the distribution of MSA and clinical features suggest an influential role for age of disease onset on the pathogenesis of disease.

## Methods:

Caucasian JDM cases from the UK (n=312) were genotyped using the Illumina HumanCoreExome chip. Caucasian control data (n=2808) were obtained from the Wellcome Trust Case Control Consortium. Following quality control, classical human leukocyte antigen (HLA) alleles and HLA amino acids were imputed using SNP2HLA. Logistic, linear and Cox regression were performed using PLINK and R package GenABEL, with adjustment for the first two principal components. Genome-wide significant association was set at  $P < 5.0 \times 10^{-8}$  and suggestive association at  $P < 1.0 \times 10^{-5}$ . We subsequently built an international consortium to create a replication cohort of Caucasian cases from North America (n=475).

## Results:

Case-control analyses confirmed involvement of HLA including multiple loci within *HLA-C* ( $p = 1.35 \times 10^{-8}$ , OR = 2.49, 95% CI = 1.82 - 3.42) and *HLA-DRB1* ( $p = 2.73 \times 10^{-8}$ , OR = 0.56, 95% CI = 0.46-0.69) at genome-wide levels of statistical significance. Outside the HLA region there was suggestive evidence of association at *ZNF337* ( $p = 7.49 \times 10^{-6}$ , OR = 1.81, 95% CI = 1.40-2.34), a zinc finger protein of unknown function. Analyses of association with age of disease onset did not implicate HLA involvement, suggesting the associations between HLA and JDM/DM are not influenced by age. Analysis of age of onset as a quantitative trait revealed suggestive associations at *PDE1A* ( $p = 1.56 \times 10^{-6}$ ,  $\beta = -1.61$ , 95% CI = -2.26- -0.97) and *AGPAT3* ( $p = 2.26 \times 10^{-6}$ ,  $\beta = 1.63$ , 95% CI = 0.97-2.30), genes involved in regulating intracellular cyclic nucleic acid concentrations and phospholipid biosynthesis/ Golgi-to-endoplasmic reticulum

retrograde transport, respectively. In addition, we now have a replication cohort via our international consortium to validate these findings.

## Conclusion:

This study has confirmed findings from previously published GWAS and Immunochip studies of JDM and DM concerning HLA involvement. Additionally, analyses of associations with age of JDM onset identified novel loci, *PDE1A* and *AGPAT3*, which if validated could suggest novel processes involved in pathogenesis. These findings will be confirmed in an independent replication cohort. Together with these validation samples, this study will be the largest GWAS of JDM to date.

## Transcriptomic Analysis Reveals Mitochondrial and Monocyte Dysfunctions Are Linked to the Interferonopathy of Juvenile Dermatomyositis

Claire Deakin<sup>1</sup>, Elizabeth Rosser<sup>1</sup>, Lucy Marshall<sup>1</sup>, Meredyth Wilkinson<sup>2</sup>, Aziza Khabbush<sup>3</sup>, Stefania Simou<sup>1</sup>, Georg Otto<sup>3</sup>, Stefanie Dowle<sup>3</sup>, Daniel Kelberman<sup>3</sup>, Simon Yona<sup>2</sup>, Simon Eaton<sup>3</sup> and Lucy R Wedderburn<sup>1</sup>, <sup>1</sup>Infection, Immunity and Inflammation Programme, UCL Great Ormond Street Institute of Child Health, University College London, United Kingdom, London, United Kingdom, <sup>2</sup>Division of Medicine, University College London, London, United Kingdom, <sup>3</sup>Genetics and Genomic Medicine Programme, UCL Great Ormond Street Institute of Child Health, University College London, United Kingdom, London, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Although type I interferon (IFN1) and endoplasmic reticulum (ER) stress have been implicated in pathogenesis of juvenile dermatomyositis (JDM), little else is known about additional biological processes that may be involved and perhaps upstream of these pathways, or about processes that remain abnormal even when inflammation is controlled. To identify novel pathways dysregulated in JDM, we performed RNASeq on sorted immune subtypes from JDM patients and healthy controls.

## Methods:

Peripheral blood samples were obtained from patients enrolled in the Juvenile Dermatomyositis Cohort and Biomarker Study (JDCBS) at pre-treatment (n=13) and 11.8 [11.3-13.2] months follow-up, (n=13) including n=10 matched

samples, and age/sex-matched healthy controls (n=8). CD4<sup>+</sup>, CD8<sup>+</sup>, CD14<sup>+</sup> and CD19<sup>+</sup> cells were flow-sorted from PBMCs by flow cytometry and RNA was extracted and sequenced. Gene set enrichment analysis (GSEA) and gene ontology (GO) term enrichment analysis were performed.

## Results:

A strong IFN1 signature was identified: “IFN $\alpha$  signaling” was the most strongly enriched gene set identified by GSEA in all cell types (normalized enrichment scores of 2.39 (p<0.001), 2.84 (p<0.001), 2.88 (p<0.001) and 3.41 (p<0.001) for CD4, CD8, CD19 and CD14 cells, respectively). Overall, a higher proportion of differentially expressed (DE) genes were identified in CD14<sup>+</sup> monocytes compared to other cell subtypes. Interestingly, 1,594 genes were DE in on-treatment monocytes compared to controls when IFN1 was no longer abnormal, suggesting on-going abnormal function even after a year of treatment. GO analysis of these genes identified over-representation of GO terms involved in mitochondrial function. A mitochondrial score (comprising all 13 protein-coding mitochondrial genes) correlates negatively with an IFN1 score (15 representative IFN-stimulated genes) in baseline monocytes (R=-0.87, p=0.003), indicating reduced expression of mitochondrially-encoded genes is associated with increased IFN1 signature. Analysis of the 343 genes annotated by the “Mitochondrion” Gene Ontology term GO:0005739 showed 54 were DE in baseline monocytes compared to follow-up, 51 were DE in baseline monocytes compared to controls, and 59 were DE in follow-up monocytes compared to controls. Notably, a set of genes involved in mitochondrial function were abnormally expressed in both baseline and follow-up monocytes compared to controls, indicating that mitochondrial dysfunction is not fully corrected by current treatment. Functional studies to characterise dysfunctions of monocytes and mitochondria are ongoing.

## Conclusion:

This transcriptomic study has identified abnormal gene expression in the monocyte compartment in particular, and a striking dysregulation of genes involved in mitochondrial function. Ongoing functional work to characterize these dysfunctions will explore the potential of mitochondrial dysfunction as a novel treatment target.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Immunoglobulin-A (IgA) vasculitis, also known as Henoch-Schönlein purpura (HSP), is the most common type of primary small-sized blood vessel leukocytoclastic vasculitis in children, although it may also develop in adults [1]. IgA vasculitis has a multifactorial etiology in which both environmental and genetic factors seem to contribute to the predisposition and clinical phenotype of the disease [1,2]. However, the genetic component of this type of vasculitis remains poorly understood, as only a few candidate gene studies have been performed to date [3,4]. Taking these considerations into account, and to increase the current knowledge on the genetic component of this vasculitis, we performed the first genome-wide association study (GWAS) on this condition using the largest series of IgAV patients of European ancestry ever assessed for a genetic study.

**Methods:** 308 IgA vasculitis patients and 1,018 healthy controls from Spain were genotyped by Illumina HumanCore BeadChips. Imputation of GWAS data was performed using the 1000 Genomes Project Phase III dataset as reference panel [5]. After quality control filters and GWAS imputation, 285 patients and 1,006 controls remained in the datasets and were included in further analysis. Additionally, the human leukocyte antigen (HLA) region was comprehensively studied by imputing classical alleles and polymorphic amino acid positions [6].

**Results:** A linkage disequilibrium block of polymorphisms located in the HLA class II region surpassed the genome-wide level of significance (odds ratio = 0.56, 95% confidence intervals = 0.46-0.68). Although no polymorphic amino acid positions were associated at the genome-wide level of significance, P-values of potential relevance were observed for the positions 13 and 11 of HLA-DRB1 (P = 6.67E-05, P = 1.88E-05, respectively). Outside the HLA, potential associations were detected, but none of them were close to the statistical significance.

**Conclusion:** Our study suggests that IgA vasculitis is an archetypal HLA class II disease.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Cell-bound complement activation products, CB-CAPs (C4d deposition on erythrocytes [EC4d], B lymphocytes [BC4d], reticulocytes [RC4d], platelets [PC4d], and C3d deposition on reticulocytes [RC3d]) are sensitive and specific markers for the diagnosis and evaluation of lupus. Cell-specific CB-CAPs may have a role as biomarkers of organ/systems involvement in SLE, such as the association of PC4d with cardiovascular events/presence of antiphospholipid antibodies, and EC4d with proteinuria. The current study investigated the role of CB-CAPs as markers of SLE flares, as well as their possible association with muco-cutaneous involvement.

### **Methods:**

This was a longitudinal study of 33 patients with childhood onset SLE (cSLE, diagnosed at or before age 19) who fulfilled ACR SLE classification criteria and had up to 6 months of follow-up. Venous blood was collected every 3 months for CB-CAPs and results were reported as net mean fluorescence intensity index (MFI). Additionally, anti-dsDNA, complement levels (C3 and C4) and laboratory work needed for SLE Disease Activity Index (SLEDAI) scoring were also evaluated. Disease activity was assessed at each visit using SLEDAI. Lupus flares were identified using the Safety of Estrogens in Lupus Erythematosus: National Assessment (SELENA) SLEDAI flare index (SFI).

### **Results:**

The study included 33 patients (19±4 years old, 79% female, 45% Hispanic, 33% African American). Patients met on average 5±1 ACR-SLE classification criteria; 97% had positive ANA titers, 88% had elevated dsDNA titers, and 21% tested positive for the antiphospholipid antibodies. Abnormal EC4d (>14 net MFI) levels were observed in 19, BC4d (>75 net MFI) in 20, and PC4d levels (> 20 net MFI) in 12 patients. All patients were treated with hydroxychloroquine, 55% with corticosteroids and 70% with immune-suppressants.

Twelve visits with SLE flares were identified, 7 of which were mild/moderate and 5 severe. Of these 12 flares, 5 patients had rashes, 4 arthritis, 4 nephritis (proteinuria) and 1 vasculitis.

SLE patients with flares (SLEDAI =  $9 \pm 3$ ), as compared to SLE patients with stable disease (SLEDAI =  $4 \pm 3$ ), had significantly higher PC4d values (18 [IQ 7-70] vs. 8 [IQ 3-15] net MFI;  $p=0.045$ ). Among these patients with flares, two patients had normal complement levels and another one had stable/normal dsDNA levels but elevated PC4d. EC4d levels were numerically higher in patients with flares, 17 [IQ 14-29] vs 10 [IQ 6-26] net MFI,  $p=0.07$ . BC4d was not significantly different between the two groups, 81 [IQ 32-180] vs 77 [IQ 36-135] net MFI,  $p=0.91$ . In addition, within the cohort of 33 patients, 14 with rash had elevated RC3d and a trend toward elevated PC4d levels, with a median level of 4 [IQ 1-7] vs. 1 net MFI [IQ 1-4] ( $p=0.04$ ) and 10 [IQ 5-36] vs. 8 [IQ 3-15] net MFI ( $p=0.09$ ) respectively.

### Conclusion:

These pilot findings suggest CB-CAPs as a potential biomarker to identify disease flares more consistently than low complement or high levels of anti-dsDNA in cSLE. The relatively shorter lifespan of platelets might allow for closer tracking of changes in disease activity associated with flare. Our data also suggest that reticulocyte bound CB-CAPs may play a role as a biomarker to predict muco-cutaneous involvement in cSLE patients.

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Deficiency of adenosine deaminase 2 (DADA2) is a recently recognized, autosomal recessive genetic disease. Patients present with various, early-onset systemic vascular and inflammatory manifestations, and often recurrent strokes. The clinical features and histological findings of DADA2 overlap with those of early childhood onset polyarteritis nodosa (PAN), a primary “idiopathic” systemic vasculitis, characterized by necrotizing inflammatory lesions of small and medium-sized vessels. Despite similar clinical presentation, individuals with PAN and DADA2 may benefit from

different therapy. While treatment of primary chronic vasculitis is usually with toxic immunosuppressive drugs, there has been clinical indication that DADA2 patients respond better to less toxic IL-6 receptor antagonists and anti-TNF $\alpha$  therapy. We aimed to screen patients with PAN, cutaneous PAN, unclassifiable phenotype, or chronic vasculitis of any type with onset-age less than 5 years for variants in adenosine deaminase 2 (*ADA2*).

#### **Methods:**

Of the 493 pediatric patients included in our international, multi-ethnic cohort, ARChive (A Registry of Childhood Vasculitis), there were 99 patients who provided DNA samples, and 41 of these fulfilled screening criteria. We sequenced the coding exons of *ADA2* in these 41 patients. Identified variants in *ADA2* were characterized by quantifying their effect on *ADA2* expression, secretion, and enzymatic activity by qPCR, standard ELISA, and kinetic colorimetric assays, respectively. RNA sequencing of whole blood was done to enable transcriptomic profiling of patients with DADA2 versus PAN and other types of chronic vasculitis.

#### **Results:**

We have identified variants in *ADA2* with known and novel association with DADA2; four patients were found to be homozygous or compound heterozygous for rare (MAF < 0.01), predicted pathogenic variants. An additional two patients were found to be heterozygous for rare, missense variants; further analysis of expression and enzymatic activity may guide the identification of additional pathogenic variants that could contribute to the observed phenotype.

#### **Conclusion:**

At present, the gold standard for direct diagnosis of vasculitis is histopathological examination of biopsy specimens from involved organs. Screening *ADA2* among patients with possible early-onset chronic vasculitis or PAN phenotype may identify and diagnose patients, perhaps without requirement for biopsy. Early diagnosis of DADA2 patients may spare them treatment with toxic systemic immunosuppressive drugs, and allow more effective intervention with targeted biologic and/or gene therapy.

## **Chemokine Ligand 9 (CXCL9) [Monokine Induced By Gamma Interferon (MIG)] As a Predictor of Active Disease Status in Localized Scleroderma**

Kathryn S. Torok<sup>1</sup>, Qi Mi<sup>2</sup>, Emily Mirizio<sup>3</sup>, Kaila Schollaert-Fitch<sup>1</sup>, Mark Fritzler<sup>4</sup> and Marvin J. Fritzler<sup>5</sup>, <sup>1</sup>Pediatric Rheumatology, University of Pittsburgh Med Ctr, Pittsburgh, PA, <sup>2</sup>Department of Sports Medicine and Nutrition, University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Pediatric Rheumatology, University of Pittsburgh Med Ctr, Pittsburgh, PA, <sup>4</sup>Eve Technologies, Calgary, AB, Canada, <sup>5</sup>Medicine, University of Calgary, Calgary, AB, Canada

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Background/Purpose:**

Localized scleroderma (LS) is a fibrotic autoimmune disease of the skin and underlying tissues which can lead to disfiguring sequelae, especially in childhood-onset. Untreated active disease is associated with long-term damage and disability; therefore accurate assessment of the active disease state is imperative, and a distinct activity biomarker would assist clinicians to intervene before disease progression. The purpose of this study was to investigate a wide variety of cyto/chemokines, specifically within disease transition from active to inactive phases in individual patients, which correlate to established clinical measures of disease activity in LS.

**Methods:**

Plasma from 70 juvenile LS (jLS) patients with clinical data and longitudinal samples (average of 6 years follow-up), including at least one active and one inactive specimen (272 samples total), were evaluated by microarray to study a 60-analyte cyto/chemokine panel. This included the study of  $T_H1$ ,  $T_H2$ , and  $T_H17$  associated cytokines with an additional IFN- $\gamma$  panel that emphasized CXCL9, CXCL11, and MIP-3 $\beta$  chemokines. Wilcoxon Signed-Ranks Test ( $p < 0.05$ ) was used to compare cyto/chemokines between active and inactive disease subsets. Next, to focus on clinically significant cytokines, additional analyses included spearman's correlation of analytes with the modified Localized Skin Severity Index (mLoSSI), a validated active disease variable, followed by multiple regression analyses of the significantly correlated cytokines using R language.

**Results:**

When dichotomizing the LS samples into active vs. inactive subjects, many reoccurring cytokines were significantly elevated (*Table 1 – left column*). Correlation of the 60 analyte panel resulted in moderate to strong correlation of IFN- $\gamma$  and  $T_H1$ -like associated cyto/chemokines with the mLoSSI, including CXCL9 (MIG), MIP-3 $\beta$ , and IL-10 (*Table 1 – right column*). Of those that correlated strongly with the mLoSSI, IL-10 and CXCL9 were statistically significant predictors in multiple linear regression analyses ( $p = 0.002$  and  $0.001$ , respectively), with an adjusted R-squared of 0.71; meaning the change of IL-10 and CXCL9 are related to the change in mLoSSI, signifying change in disease activity status.

**Conclusion:**

This is a unique examination of circulating cytokines in jLS and further correlates the biological activity to clinical disease activity measures used for disease monitoring, the mLoSSI. The correlated chemokines indicate a strong IFN- $\gamma$  associated environment. CXCL9 is a predominant IFN- $\gamma$  inducible chemokine and is part of the IFN- $\gamma$  family that contributes to the activation of the M1 phenotype and recruitment of  $T_H1$  cells, both of which induce further inflammatory cytokine response. Further analysis using the best-fit model is underway with the overall goal of finding the strongest core set of biomarkers that highly predicts the mLoSSI in LS patients, signifying degree of disease activity.

**Table 1: Analyses of 60 cyto/chemokines in LS with focus on disease activity**

*Active vs. Inactive LS peripheral blood cyto/chemokine*  
Cyto/chemokine

*Correlation of the mLoSSI with the peripheral blood cyto/chemokines*

Cyto/chemokine	<u>p-value</u>	Cyto/chemokine	<u>Spearman's correlation</u>	<u>p-value</u>

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many pediatric patients (pts.) with early-onset autoinflammatory disease (AID) phenotypes are mutation-negative for genetically known AIDs. Recent data suggest a role for Type-I interferon (IFN) dysregulation in causing AID phenotypes with clinical features that are distinct from those found in pts. with IL-1 mediated AIDs. We screened pts. for the presence of IFN-response gene signatures (IRS) to characterize their clinical phenotypes, IFN-related biomarkers and genetic causes.

**Methods:** We assessed IRS from 63 consecutively evaluated patients (pts.) who were negative for known AID-causing mutations. Gene expression of 28 selected interferon response genes (IRG) was determined by Nanostring and an IFN-score was calculated. Serum levels of 48 cytokines were measured by a multiplex immunoassay. Pts. underwent clinical assessments and genetic analyses were performed by whole exome/genome sequencing (WES/WGS).

**Results:** Of 63 pts. tested, 36 had elevated IRS. Pts. with high IRS had higher serum levels (all in pg/ml) of: most pronounced in IP-10 ( $11169 \pm 1849$  vs  $834 \pm 117$ ,  $p < 0.0001$ ), and MIG/CXCL9 ( $7133 \pm 2450$  vs  $706 \pm 61$ ), MIP1 $\alpha$  ( $195 \pm 23$  vs  $153 \pm 5.8$ ), GRO $\alpha$  ( $423 \pm 95$  vs  $165 \pm 14$ ), all  $p < 0.01$  and MIP1 $\beta$  ( $301 \pm 42$  vs  $220 \pm 13$ ), SCF ( $63 \pm 15$  vs  $28 \pm 4.8$ ), with  $p < 0.05$ , than those with negative IFN scores. Pts. with high IRS had significantly higher frequencies of panniculitis (58 vs 0%), basal ganglia calcifications (45 vs 0%), interstitial lung disease (ILD) (48 vs 4.8%), myositis (65 vs 15%), all with  $p < 0.01$  and skin vasculitis (29 vs 7.4%), and arterial hypertension (32 vs 3.7%),  $p < 0.05$ , and lower frequency of aseptic osteomyelitis (0 vs 22%,  $p < 0.01$ ) than pts. without an IRS. Furthermore, anemia (33 vs 7.4%), lymphopenia (26 vs 0%) and positive ANA (42 vs 11%), all  $p < 0.05$ , were more frequent in pts. with an IRS. Based on disease manifestations, patients could be assigned to 8 distinct groups. Pts. with ILD and macrophage activation syndrome (MAS) had very high IL-18 serum levels and a cytokine signature seen in other patients with MAS. Two pts. with lipodystrophy had novel *LRBA* mutations, 2 pts. with lymphohistiocytic panniculitis have a novel *NEMO* mutation, 5 patients with neutrophilic panniculitis, ILD, cytopenias and white matter disease have *de novo* truncating mutations in *SAMD9L*, and 2 with myositis and ILD had anti-MDA5 autoantibodies. One patient with “atypical CANDLE” had a novel *PSMB8* mutation, and one pt. each had mutations in a novel proteasome gene, *PSMG2*, and a *de novo* somatic mutation in *TREX1*. *IFI27* was the most upregulated gene in patients with SAVI, CANDLE and Aicardi-Goutières syndrome (AGS), but its expression in patients with *LRBA* and *NEMO* mediated disease was significantly lower.

**Conclusion:** The presence of an IFN signature is associated with distinct clinical and cytokine patterns, including pts. with ILD and high serum IL-18 and a predisposition to MAS. Our data suggest that IFN leads to a set of clinical features that combined with the assessment of an IFN response gene signature can identify patients and autoinflammatory interferonopathies and help define clinically distinct disease subsets. Whether IFN is the pathogenic cause of these diseases needs to be further investigated in treatment studies.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Next generation sequencing (NGS) represents a revolution in the field of molecular medicine, and offers a new approach to deciphering the pathogenesis of complex diseases. One hypothesized that patients with early-onset lupus may be carrying genetic mutation responsible for the autoimmune condition. We have in the past described a B cell-related Mendelian form of lupus due to a deficiency of PKC $\delta$ . Here, we identified and characterized a new B cell-related Mendelian lupus secondary to *IKZF1* mutation and compared this novel monogenic disease with PKC $\delta$  deficiency.

## Methods:

We designed a NGS panel comprising 200 genes including proven disease-associated as well as prospective candidate genes, and analyzed 131 patients.

We identified a family with three affected patients carrying a new mutation in *IKZF1*. We set up functional assays including oligonucleotide pulldown assay, B cell phosphorylation and deep B cell immunophenotyping by mass cytometry.

## Results:

We have identified a heterozygous missense mutation in *IKZF1* c.359A>T in three affected patients in a single family. *IKZF1* encodes IKAROS, a key transcriptional factor for B cell development. The patients did not display any recurrent infection and IgG level was normal. Functional assays showed that stability was not impaired, but DNA-binding was partially impacted for mutant IKAROS. We performed mass cytometry comparing SLE patients carrying *PRKCD* and *IKZF1* mutation. We identified B cell clusters and unsupervised analysis underlined the wide differences between two monogenic diseases leading to SLE.

## Conclusion:

Ikaros deficiency reveals that monogenic lupus occurs under various B cell anomalies underlining that lupus should be considered as a syndrome more than a single homogenous disease.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Several rheumatic diseases are characterized by overexpression of type I interferon (IFN)-inducible or viral response genes, termed the IFN signature. Recently this signature has been reported in a novel group of monogenic Type-I IFN mediated autoinflammatory diseases (AIDs) or autoinflammatory interferonopathies. We aimed to compare a set of clinical features previously associated with monogenic autoinflammatory AIDs and a blood IFN score with autoimmune (SLE, JDM) interferonopathies, and other disease controls.

### **Methods:**

We identified 12 patients with probable interferonopathy and selected clinical features of IFN mediated AIDs based on literature review/expert opinion (Table 1). We compared the clinical criteria with 23 controls (8 healthy children, 6 oligoarticular juvenile idiopathic arthritis [oJIA] patients, 4 systemic lupus erythematosus [SLE], 5 with DADA2). The expression of 28 IFN-related genes was quantified from RNA from whole blood using NanoString technology. Summary scores for IFN6/IFN28/ and a z-score for CXCL10 (IP10) were calculated.

### **Results:**

The mean clinical score was in the presumed IFNopathies (minimum-maximum) 5 (3-7). The median IFN6, IFN28, scores were significantly higher in the probable interferonopathy cases as compared to healthy controls and oJIAs and DADA2 patients but did not differ from SLE patients. Interestingly, CXCL10 (IP10) scores were higher (but not significant) in the probable interferonopathy group than the SLE and DADA2 groups.

### **Conclusion:**

We suggest a set of clinical criteria combined with the 6 gene or 28gene IFN score in developing criteria for IFN-mediated AIDs. Development and validation of an appropriate criteria is ongoing.

**Table 1.** Preliminary clinical score to differentiate interferon(IFN)-mediated autoinflammatory diseases (AIDs) from interleukin-1(IL-1)-mediated AIDs

<b>Clinical preliminary criteria</b>	<b>Presumed  IFN mediated AIDs  n=12</b>	<b>JIA  n=6</b>	<b>SLE  n=4</b>	<b>DADA2  n=5</b>

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Pathogenesis and Genetics Poster

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Oral and gut microbes have been implicated in the pathogenesis of rheumatoid arthritis, spondyloarthropathy, and juvenile enthesitis-related arthritis (ERA). Pro-inflammatory microbes in the bacteroides phyla appear to be over-represented, while commensals in the firmicutes phyla are under-represented in inflammatory disease. The role of dysbiosis in the microbiota is not well-studied in new-onset juvenile idiopathic arthritis (JIA); individual variation secondary to diet, age, and other environmental factors makes such an analysis challenging. Previous studies demonstrated that healthy children derive most of their microbes from their mothers, and thus share similar microbial communities. We hypothesized that if the gut microbiota contributes to systemic inflammation, then children with JIA will have an altered microbiota compared to their mothers.

### Methods:

Stool samples were collected from ten new-onset, treatment naive JIA patients aged 2-15 years (four oligoarticular, two polyarticular, three ERA, and one psoriatic), and their mothers in preservative-filled Omnigene-GUT cryovials designed to stabilize microbial communities. DNA was extracted from stool using the PowerSoil DNA Isolation Kit, and sequencing was performed on the Illumina HiSeq-2000 platform. Human DNA sequences, duplicate reads, sequence reads with ambiguous bases, and reads shorter than 80 bases were identified and removed from analysis. Taxonomic classification and relative species abundance of bacteria were obtained using MetaPhlAn2.

### Results:

Compared to their mothers, 60% of JIA patients had lower fecal firmicutes populations. In 50%, higher bacteroidetes phyla were identified. Four of ten patients had both low firmicutes and increased bacteroidetes. The mean firmicutes:bacteroides ratio in patients was 7.2 (IQR 2.8-7.8) compared to 17.5 (IQR 9.6-24.9) in their mothers. The lowest ratio was detected in oligo JIA (mean 5.1, range 2.1-7.2), followed by poly JIA (6.7, range 1.3-12) and ERA (10, range 2.8-21). Of all of the patients, the three with the lowest ratios (1.3-2.8) all carried antinuclear antibodies.

## Conclusion:

Consistent with previous results in adult RA and JIA, in new-onset JIA, fecal microbial communities were skewed toward bacteroides phyla, which can be pro-inflammatory. Whether this finding reflects a microbial trigger for JIA, or rather the coincident result of immune dysregulation, remains to be determined.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patients with rheumatoid arthritis (RA) are at increased risk for cardiovascular disease (CVD) with subsequent morbidity and mortality<sup>1</sup>. It is well known that prolonged sedentary behaviour (SB) and reduced physical activity (PA) are risk factors for CVD. The purpose of this study was to examine the independent relationships between SB, very light (VLPA), light (LPA), and moderate to vigorous (MVPA) and 10-year CVD risk in a subsample of people with RA using the Framingham risk score (FRS), an accurate and widely used tool to assess 10 year CVD risk.<sup>2</sup>

### Methods:

A subsample of individuals diagnosed with RA was extracted from the 2003–2006 National Health and Nutrition Examination Survey (NHANES) database, a population-representative US sample. Actigraphy, a uniaxial accelerometer ActiGraph 7164, was used to derive SB and PA volume and pattern. Raw actigraphy data were categorized into SB, VLPA, LPA, and MVPA expressed as mean minutes per day. Pattern variables, including number of breaks in sedentary time, length of sedentary time, and active bouts were calculated. Functional limitation was assessed by self-reported questionnaire. The 10-year CVD risk was determined based on the FRS. Descriptive statistics and multiple linear regression models were used in the analysis using Stata software version 14.

### Results:

A total of 273 individuals with RA were included in the analysis. Mean age of participants was  $62.7 \pm 13$  years; 143 (52.4%) were women, and 167 (61.6%) had functional limitations. Participants spent an average of 9 hours/day in SB, 4 hours/day in VLPA, 1 hour/day in LPA, 23 minutes/day in MVPA.

Based on the FRS which considers age, sex, cholesterol (HDL-D and total), systolic blood pressure, diabetes and smoking, 35% of participants had higher than 20% 10 year CVD risk; 29% had 10-20% risk; and 36% had less than 10% risk.

Greater sedentary time ( $p=0.019$ ) and average length of sedentary bout ( $p<0.001$ ) were associated with higher 10-year of CVD risk in patients with RA. Greater daily VLPA ( $p<0.001$ ), LPA ( $p=0.001$ ), MVPA ( $p=0.021$ ), and total number of sedentary breaks ( $p<0.001$ ) were negatively associated with 10-year CVD risk. The association between average length of activity bouts and 10-year CVD risk was not significant ( $p=0.068$ ).

In the fully adjusted regression model (adjusted for wear time, body mass index, and waist circumference) the association between 10-year CVD risk and SB ( $R^2=0.26$ ,  $p<0.001$ ), VLPA ( $R^2=0.25$ ,  $p<0.001$ ), LPA ( $R^2=0.24$ ,  $p=0.003$ ), sedentary bout length ( $R^2=0.24$ ,  $p=0.002$ ), and breaks in sedentary time ( $R^2=0.23$ ,  $p=0.026$ ) remained significant.

While functional limitation was directly associated with higher 10-year CVD risk in the unadjusted model ( $p=0.006$ ), this relationship was attenuated in the fully adjusted model ( $p=0.045$ ).

### Conclusion:

Given the increased cardiovascular risk in people with RA, high sedentary behaviour and low physical activity is concerning. Interventions aimed at decreasing SB and promoting PA may help to reduce long-term CVD risk.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Baricitinib (BARI) is an oral selective inhibitor of Janus kinase (JAK)1 and JAK2 approved in the EU for the treatment of active RA. Patients (pts) with RA have increased cardiovascular risk, including for arterial and venous occlusive events.<sup>1-3</sup> This abstract examines the effects of BARI on cardiovascular events in RA.

**Methods:** Data were pooled from 8 completed studies (1 Phase 1b, 3 Phase 2, 4 Phase 3) and 1 ongoing long term extension study (LTE) with data up to Sept. 1, 2016. The All BARI RA (All Exposure) analysis set included all pts exposed to any BARI dose. Comparisons with placebo (PBO) were based on 6 studies with BARI 4 mg once daily (QD) and PBO. Dose response was assessed based on 4 studies with BARI 2 and 4 mg QD, including data from the LTE (Extended 2 vs 4 mg set). Two studies contained active comparators (MTX and adalimumab [ADA]). Major adverse cardiovascular events (MACE) (composite of myocardial infarction, stroke and cardiovascular death) were blindly adjudicated by an independent panel for phase 3 studies and the LTE. Study database terms of “deep vein thrombosis” (DVT) / “pulmonary embolism” (PE) were analyzed without adjudication. Incidence rates (IR) per 100 pt-years [PY] of exposure were used.

**Results:** 3492 pts were exposed to BARI (6637 PY), 2723 pts (78.0%) for >1 year and 1867 (53.5%) for >2 years. In the 6-study PBO-controlled set (0-24 weeks), 2 cases of MACE were reported in the PBO group and 3 cases in the BARI 4 mg group (Figure 1). DVT/PE were reported for 0 pts in the PBO group and 5 in the BARI 4 mg group (Figure 2); 2 were serious, all had multiple risk factors, 1 occurred after discontinuing study drug, and 4 pts either continued or restarted BARI without worsening or occurrence of another event. In the Extended 2 vs. 4 mg set, IR for MACE and DVT/PE were comparable between doses. In the All BARI RA set, event rates were stable over time (Figure 3), with overall IR of 0.51 per 100 PY for MACE and 0.46 for DVT/PE (published RA DVT/PE rates 0.29 to 0.79 per 100 PY).

**Conclusion:** For MACE, IR were similar across analysis sets and did not increase with prolonged exposure. For DVT/PE, events were reported for BARI 4 mg but not PBO; IR were similar between doses, consistent over time, and comparable to published rates in RA.<sup>1-3</sup>

# The Relationship between Disease Activity, VEGF and E-Selectin Levels with Arterial Stiffness in Rheumatic Patients Treated with Biological Agents

**Taskin Senturk**<sup>1</sup>, Huseyin Baygin<sup>1</sup>, Gokhan Sargin<sup>1</sup>, Hakan Akdam<sup>2</sup> and Mustafa Yilmaz<sup>3</sup>, <sup>1</sup>Rheumatology, Adnan Menderes University, Aydin, Turkey, <sup>2</sup>Nephrology, Adnan Menderes University, Aydin, Turkey, <sup>3</sup>Biochemistry, Adnan Menderes University, Aydin, Turkey

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatic diseases are chronic-inflammatory disease associated with endothelial damage, changes in vascular permeability and plaque formation. VEGF and E-selectin play an important role in chronic inflammation, therefore arterial stiffness is affected. Our aim was to evaluate association between disease activity, VEGF, E-selectin and arterial stiffness in patients with rheumatic diseases.

**Methods:** 41 patients with rheumatic disease (13 AS, 28 RA, 27 females and 14 males with mean age of 51,0±12,1 years) and 30 healthy controls (20 females and 10 males with mean age of 51,9±10,8 years) were enrolled to the study. Arterial stiffness, VEGF, E-selectin levels, BASDAI and DAS-28 scores were evaluated. VEGF and E-selectin were determined by ELISA, and arterial stiffness was measured by oscillometric method. Student's T Test, Mann-Whitney-U Test and Wilcoxon Test were performed as statistical analysis and p<0.05 was accepted as statistically significant.

**Results:** BASDAI, DAS-28, ESR and CRP levels were significantly decreased on the 3th month of treatment in all patients (p<0,001). Increased VEGF, E-selectin and decreased arterial stiffness parameters (PWV and Alx) was observed with treatment. These changes were not statistically significant. While the level of PWV was stable, Alx was decreased on the 3th months of non-TNF treatment in RA patients

**Conclusion:** Disease activity score, ESR and CRP were decreased in RA and AS patients with treatment *resulting in reduced inflammation*. Arterial stiffness and cardiovascular risk is expected to be reduced significantly ongoing treatment process. VEGF, E-selectin, arterial stiffness parameters (PWV and Alx) can be used as a marker of disease activity in RA and AS.

## Inflammatory Markers in Relation to Risk Factors for Cardiovascular Disease in the Pre-Symptomatic Phase of Rheumatoid Arthritis

**Heidi Kokkonen**<sup>1</sup>, Linda Johansson<sup>2</sup>, Hans Stenlund<sup>3</sup> and Solbritt Rantapaa-Dahlqvist<sup>4</sup>, <sup>1</sup>Public Health and Clinical Medicine/ Rheumatology, Umeå University, Umeå, Sweden, <sup>2</sup>Public Health and Clinical Medicine/Rheumatology, Umeå University, Umeå, Sweden, <sup>3</sup>Department of Public Health and Clinical Medicine, Epidemiology and Global

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Individuals who later developed rheumatoid arthritis (RA) have increased levels and frequencies of risk factors for cardiovascular disease (CVD), years before onset of RA.

The relationships between CVD risk factors and inflammatory markers, *i.e.*, cytokines and chemokines, were analysed in individuals prior to onset of symptoms and compared with controls.

## Methods:

A case-control study was based on population surveys from The Västerbotten Intervention Programme (VIP) and the WHO Multinational Monitoring of Trends and Determinants in Cardiovascular Disease (MONICA) with data collected on socioeconomic and lifestyle factors, BMI, waist, blood pressure, and blood samples by a nurse. The register of patients with RA (ARA criteria) was co-analysed with the registers from the Medical Biobank and 469 pre-symptomatic individuals (median age 50.2 years; 67.8% women, median predating time 5.0 (IQR; 2.0-8.0) years), and 234 controls (median age 50.3 years; 67.1% women) were identified. CVD risk factors were defined as: hypertension (treatment or systolic blood pressure  $\geq 140$  mmHg and/or diastolic blood pressure  $\geq 90$  mmHg), elevated ApoB/ApoA1 ratio (women  $\geq 0.7$ , men  $\geq 0.8$ , including lipid lowering treatment), BMI  $\geq 25$  kg/m<sup>2</sup>, diabetes, and ever being smoker. Concentrations of eotaxin, interferon gamma-induced protein (IP-10), monocyte chemoattractant protein 1 (MCP1), macrophage derived chemokine (MDC), interleukin (IL) 2, IL-4, IL-6, IL-8, and IL-10, were analysed in plasma using R&D systems' assays (Minneapolis, MN) according to the manufacturer's instructions.

**Results:** Pre-symptomatic individuals had significantly higher levels of IL-6 compared with controls, both in women and men. IL-10 was significantly higher in pre-symptomatic men compared with controls. Cytokines/chemokines were significantly associated with the CVD risk factors in the cases *e.g.* IL-6 with each of the risk factors, eotaxin with smoking, IP-10 with increased BMI, being diabetes or having hypertension, whilst MDC was associated significantly with smoking and BMI  $\geq 25$  kg/m<sup>2</sup>. After adjustments for sex and age only eotaxin concentrations were significantly associated with being ever smoker. In women, MDC was significantly associated with smoking, BMI  $\geq 25$  kg/m<sup>2</sup> and diabetes. Having the combination of several CVD risk factors was associated with significantly higher concentrations of MCP-1, MDC, and IL-6 in pre-symptomatic women. IL-6 increased further the relative risk in combinations with all CVD risk factors for the pre-symptomatic cases compared with controls.

## Conclusion:

Increased concentrations of cytokines/chemokines were associated with CVD risk factors to a higher extent among the pre-symptomatic RA cases compared with controls. The pattern of association varied between the risk factors and the sex of the cases.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) increases atherosclerotic cardiovascular disease risk. Wave reflection occurs at arterial branching points, which are particularly prone to atherosclerosis. We hypothesised that wave reflection as assessed in separation analysis, represents atherosclerosis in RA.

**Methods:** Confounder adjusted associations of SphygmoCor determined arterial stiffness (pulse wave velocity), wave reflection (augmentation index, reflected wave pressure and reflection magnitude) and pressure pulsatility (central systolic blood pressure, central pulse pressure, peripheral pulse pressure, pulse pressure amplification and forward wave pressure) with carotid plaque and intima-media thickness (c-IMT) on ultrasound were assessed in 163 RA patients (110 white, 31 Asian, 17 black and 5 of mixed ancestry) without cardiovascular disease. As age, sex, race, heart rate, body height, body weight and brachial mean blood pressure are established potential confounders in the present context, these characteristics were entered into each of the initial multivariable models (Table). Subsequently, other baseline characteristics that had bivariate associations with the arterial function variables were additionally entered as potential confounders in fully adjusted models on atherosclerosis (Table).

**Results:** One SD increase in reflected wave pressure (OR (95% CI) = 2.54 (1.41-4.44),  $p = 0.001$ ), reflection magnitude (OR (95% CI) = 1.84 (1.17-2.89),  $p = 0.008$ ), central pulse pressure (OR (95% CI) = 1.89 (1.12-3.22),  $p = 0.02$ ) and peripheral pulse pressure (OR (95% CI) = 2.09 (1.23-3.57),  $p = 0.007$ ) were independently associated with plaque (Table). The association of wave reflection with plaque was further independent of arterial stiffness and pressure pulsatility, and was present in both hypertensive and normotensive RA patients. In receiver operator characteristic curve analysis (Figure), the optimal cutoff value for reflected wave pressure in predicting plaque presence was 25 mm Hg with a sensitivity, specificity, positive predictive value and negative predictive value of 45.2%, 89.3%, 78.6% and 66.2%, respectively; a high reflected wave pressure increased the odds ratio for plaque 6.3 and 13.7 fold in univariate and adjusted analysis, respectively. Central systolic blood pressure (partial  $r = 0.161$ ,  $p = 0.05$ ) was independently related to c-IMT.

**Conclusion:** Increased wave reflection is associated with high risk atherosclerosis in RA. Consideration and therapeutic targeting of wave reflection may improve cardiovascular disease prevention in RA.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with (RA) experience impaired inflammation induced arterial and endothelial function. Apelin can improve arterial function by enhancing the expression of endothelial nitric oxide synthase but this effect is dependent on endothelial integrity. We examined the potential effects of apelin on arterial function in RA.

**Methods:** Associations of apelin concentrations with SphygmoCor determined arterial stiffness (pulse wave velocity), wave reflection (augmentation index, reflected wave pressure and reflection magnitude) and pressure pulsatility (central systolic blood pressure (CSBP), central pulse pressure (CPP), peripheral pulse pressure (PPP), pulse pressure amplification (PPA) and forward wave pressure (FWP)) were identified in comprehensively adjusted multivariate regression models among 170 RA patients (112 white; 32 Asian; 22 black and 4 of mixed ancestry) without cardiovascular disease. Left ventricular stroke volume and ejection fraction were determined by echocardiography.

**Results:** Apelin concentrations were not independently associated with arterial function measures ( $p \geq 0.15$ ) in all patients. Joint deformity counts impacted the apelin-CSBP, apelin-CPP, apelin-PPamp and apelin-FWP relations (interaction  $p = 0.004, 0.01, 0.01$  and  $< 0.01$ , respectively); the Disease Activity Score in 28 joints (DAS28) and erythrocyte sedimentation rate (ESR) influenced the apelin-CSBP association (interaction  $p = 0.04$  and  $0.05$ , respectively). In stratified analysis, apelin was associated with CSBP (partial  $r = -0.33$ ,  $p = 0.01$ ), CPP (partial  $r = -0.26$ ,  $p = 0.04$ ), PPamp (partial  $r = 0.27$ ,  $p = 0.03$ ) and FWP (partial  $r = -0.33$ ,  $p = 0.01$ ) in patients without but not with joint deformities; apelin was related to CSBP (partial  $r = -0.24$ ,  $p = 0.05$ ) in those with a DAS28 joint  $< 2.8$  (median value) (partial  $r = -0.24$ ,  $p = 0.05$ ) but not  $\geq 2.8$ , and to CSBP (partial  $r = -0.30$ ,  $p = 0.01$ ), CPP (partial  $r = -0.25$ ,  $p = 0.03$ ), PPamp (partial  $r = 0.26$ ,  $p = 0.02$ ) and FWP (partial  $r = -0.23$ ,  $p = 0.04$ ) in those with an erythrocyte sedimentation rate  $< 18$  mm/hr (median value) but not  $\geq 18$  mm/hr. Apelin concentrations were not related to left ventricular stroke volume and ejection fraction, and upon additional adjustment for systolic function, the relationships of apelin concentrations with pressure pulsatility were unaltered.

**Conclusion:** Apelin is associated with reduced pressure pulsatility in RA patients without but not with a high inflammatory burden. Apelin can additionally improve systolic function through enhancing myofilament sensitivity to intracellular calcium whereas pressure pulsatility is mediated by not only arterial properties but also the episodic nature of cardiac contractility. The apelin-pressure pulsatility relations were independent of systolic function in this study. A loss of apelin protective effects on arterial function may contribute to the link between heightened cardiovascular risk and RA severity.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Rheumatoid arthritis (RA) is associated with a chronic inflammatory state, accelerated atherosclerosis and excess cardiovascular risk. Quantification of morphological changes in the retinal microvasculature has emerged as a novel biomarker for cardiovascular health<sup>1</sup>. These include narrower retinal arterioles, wider venules and a decrease in their ratio (retinal arteriovenous ratio, AVR), which represents an important parameter as it is widely used, can be objectively measured, and adjusts for both arterioles and venules. The present study examines retinal AVR for the first time in patients with RA, particularly in regard with systemic inflammation and subclinical atherosclerosis.

## Methods:

Consecutive RA patients and age-, gender- and blood pressure-matched volunteers underwent nonmydriatic digital fundus photography with a NIDEK AFC-230/210 camera. Images were processed using a validated computerized semi-automated system, which measures vessel width in arterioles and venules, to obtain central retinal arteriolar equivalent (CRAE) and central retinal venular equivalent (CRVE), respectively, as well as their ratio (AVR)<sup>2</sup>. Carotid ultrasound (Aloka Prosound A7) was used to assess subclinical atherosclerosis by measurement of carotid intima-media thickness (cIMT) in each common carotid artery.

## Results:

A total of 129 individuals, 87 RA patients and 42 controls, with a mean age of 58.8±10.9 years, were studied. Patients exhibited narrower retinal arteriolar caliber (78.8±8.9 vs 93.9±8.0 µm, p<0.001), whereas retinal venular caliber did not differ compared to controls (115.0±14.8 vs 112.7±11.9 µm, p=0.381); accordingly, AVR was significantly decreased in RA patients (0.69±0.09 vs 0.84±0.09, p<0.001). Subclinical atherosclerosis was more pronounced in RA patients, who presented increased cIMT compared to controls [0.67 (0.60 – 0.77) vs 0.59 (0.55 – 0.67) mm, p=0.006]. In the univariate analysis, AVR inversely correlated with both C-reactive protein (CRP) (r=−0.449, p<0.001) and cIMT (r=−0.232, p=0.035) in the RA group. On the contrary, disease duration and activity appeared to have no effect on AVR in patients with RA. In the linear regression analysis accounting for age, sex, and hypertension, the association between AVR and cIMT was no longer significant (p=0.453), whereas CRP was identified as an independent prognostic factor of AVR (p=0.045).

## Conclusion:

Quantitative evaluation of the retinal vessel morphology in our study revealed that patients with RA exhibit lower AVR compared to controls, mainly as a result of narrower arterioles. The heightened inflammatory state in these patients appears to be the biological link for the observed association between AVR and subclinical atherosclerosis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Despite increased cardiovascular (CV) risk in rheumatoid arthritis (RA), chest pain and angina have received little attention among RA patients. We examined the frequency of chest pain and angina, and their ability to predict CV mortality in an RA cohort, compared to controls from the general population.

### Methods:

We recruited consecutive RA patients from public and private rheumatology practices. All patients underwent a comprehensive clinical and psychosocial assessment, and were followed prospectively over time until they died, or were lost to follow-up. Population-based controls were sampled from census tracks and recruited in their homes and followed prospectively as well. Patients and controls were interviewed by certified personnel for the presence of chest pain and angina pectoris using the Rose angina questionnaire, a standardized instrument designed for assessing the presence of angina pectoris in epidemiological studies. We ascertained deaths from family members, physician or hospital records, obituaries or public databases. We obtained certificates for all deaths. Deaths were attributed to CV causes using established criteria.

We used logistic regression to compare the baseline frequency of chest pain and angina between RA and controls, adjusting for age and sex. We used Cox proportional hazard models to examine the age- and sex-adjusted association of chest pain and angina with CV mortality in cases and controls.

## Results:

We studied 1211 RA patients, of whom 906 were women (75%) and 5158 controls, of whom 2937 were women (56%). The mean follow-up time was 8745 person-years for RA cohort and 73,403 person-years for the control group. During this time there were 278 deaths in RA cohort, for a mortality rate 1.3 per 100 person-years, and 547 in the controls, for a mortality rate of 0.3 per 100 person-years.

Chest pain was more frequent in RA than in controls, with an age-sex adjusted frequency of 47% vs 31%,  $p < 0.0001$ , as was angina, age- and sex-adjusted frequencies of 11.7% vs 4.2%,  $p < 0.001$ , (Figure). Chest pain was a significant predictor of CV mortality in the RA patients (age-sex adjusted) HR 1.65, (95% CI 1.13-2.39), but not in the controls, adjusted HR 1.09 (95% CI 0.85, 1.41). Angina predicted CV mortality in both cohorts, adjusted HR 1.84(95% CI 1.0, 3.36) for RA and adjusted HR 1.77 (95% CI 1.15-2.72) for controls.

## Conclusion:

These findings suggest that chest pain and angina are more frequent in RA than in controls, and that these symptoms are significant predictors of CV mortality. Clinicians should be aware that RA patients experiencing chest pain may be at high risk of death from CV causes.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis (RA) patients are at higher risk of developing stroke but whether their risks for severe strokes are unknown.

### **Methods:**

All patients with a diagnosis of RA who were registered in The National Health Insurance Research Database (NHIRD) of Taiwan from 1999 through 2005 were identified (N=23,820), and each patient was matched with one controls by age and gender. All those hospitalized for a first Ischemic stroke or hemorrhagic stroke were identified between the date of diagnosis of RA and December 31, 2015 or death. We used a claims-based stroke severity index (SSI) in patients with stroke to evaluate the risk in different severity (severe form: SSI > 12). Hazard ratios (HRs) and 95% confidence intervals (95% CI) were estimated using Cox proportional hazard regression models after adjusting for age, sex, Charlson comorbidity index (CCI) and co-medication.

### **Results:**

We observed 1179 (4.95%) ischemic strokes and 14 (3.42%) hemorrhagic strokes in RA patients, compared to 1166 (4.90%) and 659 (2.77%) in the matched controls. The crude incidence rates (95% CI) of ischemic strokes and hemorrhagic strokes per 100 person years among 23,820 RA patients were 6.0 (5.6-6.3) and 4.1(3.9-4.4), respectively, compared to 5.85 (5.53-6.20) and 3.25(3.01-3.50) in matched controls. Multivariate HR (95% CI) were 1.09 (0.98-1.22) for ischemic stroke and 1.38(1.21-1.58) for hemorrhagic stroke. The HR (95% CI) was 1.05(0.93-1.19) for mild Ischemic stroke, 1.21 (0.98-1.49) for severe ischemic stroke, 1.25 (1.04-1.50) for mild Hemorrhagic stroke and 1.53 (1.26-1.86) for severe hemorrhagic stroke.

### **Conclusion:**

RA patients have higher risks for severe strokes, particularly for hemorrhagic form.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The most common cause of mortality in RA patients is the cardiovascular disease (CVD), with almost twice the risk for CVD events. Nailfold videocapillaroscopy (NVC) has emerged as an important tool for predicting severe organic disease in several rheumatic diseases. Although a correlation between NVC findings and CVD stratification risk has been poorly explored, NVC may be used as an early predictor for CVD risk. Our objective in this study was to evaluate the correlation between Expanded Cardiovascular Risk Prediction Score for Rheumatoid Arthritis (ESR-RA) scale and NVC morphological data.

**Methods:** This was cross-sectional study conducted in a single center; patients with RA according to the 2010 ACR/EULAR classification criteria were recruited. NVC was performed according to a standard method with a videocapillaroscope equipped with image analysis software (DinoCapture2.0). The following parameters were obtained: 1) demographic characteristics, 2) degree of enlarged capillaries, giant capillaries, tortuous capillaries, capillary density, disorganization of vascular array, meandering capillaries, ecstastic capillaries and ramified capillaries assessed by a semi-quantitative method 3) ESR-RA scale using the 10 years ERS-RA Risk Score Calculator for CVD risk. Correlation among individual capillaroscopy parameters with ESR-RA and RA disease duration was performed by Spearman's rank correlation test.

**Results:** A total of 104 patients were analyzed (85.4% female; age  $49.8 \pm 11.83$  years). The mean disease duration was  $7.4 \pm 6.67$  years. Raynaud's phenomenon was observed in 14.6%. The median ESR-RA score was 7.99% (IQR 1-54). A highest ESR-RA score correlated significantly with meandering capillaries (Rho 0.2459;  $p=0.012$ ), disorganization of vascular array (Rho 0.276;  $p=0.004$ ) and tortuous capillaries (Rho 0.1914;  $p=0.05$ ). Significantly longer disease duration correlated with lower density (Rho -0.1961;  $p=0.047$ ), meandering capillaries (Rho 0.2844;  $p=0.0036$ ), ecstastic capillaries (Rho 0.2192;  $p=0.027$ ), disorganization of vascular array (Rho 0.3655;  $p<0.001$ ) and tortuous capillaries (Rho 0.1935;  $p=0.05$ ).

**Conclusion:** In this study, a correlation between the ESR-RA scale, longer disease duration and different capillaroscopic findings was demonstrated in patients with RA. Our findings suggest that capillaroscopy can be considered as a transcendent tool of the evaluation in patients with RA.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**-Background/Purpose:** Steroid pulses are widely used in treatment for multiple inflammatory pathologies. The prevalence of hyperglycemia is 55-98%, and hypertension 5-52.5%. (1-2); safety profile could be different according glucocorticoid used and doses. Information at this topic is limited, and the development factors unknown.

**-Methods:** This was a retrospective cohort study, single-hospital. Participants were patients treated with steroid pulse in the last 10 years due to autoimmune diseases. Data was obtained from medical records: demographic data, capillary glycaemia and blood pressure. Data analysis were performed with R Commander V2.3-1. A bivariate analysis was performed between patients with and without hyperglycemia or hypertension for categorical variables test X2/ exact Fisher, for continuous variables parametric/no parametric tests as corresponded. In multivariate logistic regression model to assess independent factors for uncontrolled hypertension or blood glucose, as well as mixed models.

**-Results:** We included 171 patients, 156 received methylprednisolone and 15 dexamethasone. Logistic Regression identified previous diabetes ( $p = 0.0001$ ) and use of fractional doses ( $p = 0.03$ ), were factors associated with hyperglycemia. In hypertension male patients were less likely to develop this event (OR 0.43, IC95% 0.2-0.89,  $p = 0.02$ ). Patients who received methylprednisolone were less likely to develop diastolic hypertension (OR 0.28, 95% 0.06-1,  $p = 0.03$ ).

**-Conclusion:** The prevalence of hyperglycemia and hypertension was 53 and 42% respectively. Single-dose pulse therapy and methylprednisolone were protective factors. Age, female, prior diabetes mellitus or hypertension and creatinine level were associated as risk factors.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular (CV) disease risk prediction models, that were originally developed for use in the general population, have been found to have suboptimal performance in patients with rheumatoid arthritis (RA) and to underestimate CV disease risk. The purpose of this study was to identify new protein biomarkers that could be added to the classic Framingham Risk Score model to improve capacity for coronary artery calcification (CAC) prediction. Our secondary aim was to quantify the improvement in the prediction of CAC with the assessment of these circulating biomarkers.

**Methods:** 561 patients with RA were included in this study. CAC by computed tomography was assessed using the Agatston method. 168 soluble protein-based potential candidate CV biomarkers were selected from literature screens and bioinformatics databases. 8 biomarkers were selected after algorithm training, 4 cytokines: Osteopontin, cartilage glycoprotein-39, cystatin C, chemokine (C-C motif) ligand 18; and 3 MRM (Spectroscopy Multiple Reaction Monitoring) biomarkers: SerD1\_NFGYTLR PON1\_IQNILTEEPK, Clusterin\_IDSLENDR. 6 models were designed: FRS (model 1); FRS + RA related factors (model 2); FRS + cytokines (model 3); FRS + RA related factors + cytokines (model 4), FRS + cytokines + MRM (model 5); FRS + RA related factors + cytokines + MRM (model 6). Increase in calibration between models was calculated through logistic regression using model 1 as the reference. Net reclassification index (NRI) and integrated discrimination improvement (IDI) and calibration of the models were calculated. Final reliability was performed using a 5-fold cross-validation of the final model.

**Results:** FRS score was statistically significantly associated with AUC values for both CAC >100 (0.784 [95% confidence interval -CI- 0.743-0.824]) and CAC >300 Agatston units (0.808 [95%CI 0.762-0.854]) categories. When FRS AUC was compared with the other 5 models, a statistically significant difference was found between model #3 vs. the FRS reference model (AUC 0.823 [95% CI 0.783-0.862] vs. 0.784 [95% CI 0.743-0.824], p=0.027) in the CAC >100 Agatston units subset. However, no differences were found between the other models or within the same model in the >300 Agatston units analysis. In the RA population with CAC higher than 300 Agatston units, model #3 (0.086 [95% CI 0.016-0.157], p=0.016), and model #4 (95% CI 0.093 [0.014-0.016], p=0.025), were found to have statistically significant NRIs. All models in the CAC > 100 Agatston units analysis disclosed a significantly higher integrated discrimination improvement (IDI) value when compared to the FRS reference model. Similarly, in the CAC > 300 Agatston units model, IDI was significantly higher in model #3, model #4 and model #5 when compared to the reference FRS model. Models calibrations were found to be optimal throughout the study. Internal cross-validation of model #4 through pseudo-R-squared was found to be optimal with a value of 0.237 and 0.218, respectively, for the prediction of CAC higher than 100 and higher than 300 Agatston units.

**Conclusion:** The addition of novel biomarkers related to RA and CV pathophysiological pathways to traditional CV risk scores might improve its prediction capacity.

# Does Galectin-3 Have Utility As a Biomarker of Subclinical Cardiovascular Disease in RA Patients Independently of RA Disease Activity?

Amanda Nussdorf<sup>1</sup>, Isabelle Amigues<sup>2</sup> and Joan Bathon<sup>3</sup>, <sup>1</sup>Columbia University Medical Center, New York, NY, <sup>2</sup>Division of Rheumatology, Columbia University Medical Center, New York, NY, <sup>3</sup>Division of Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Galectin-3 is a beta-galactoside-binding lectin and is a marker of cardiovascular disease (CVD) in the general population. However, galectin-3 level is also elevated in RA sera and synovia. Thus, its utility as a biomarker of subclinical cardiac pathology in RA patients is not established. We investigated the association between galectin-3 levels and measures of cardiac structure and function in a cohort of patients with RA and no known clinical CVD.

**Methods:** RA patients (n=114) without clinical CVD participated in a prospective cohort study and underwent 3D echocardiography and cardiac (18F-fluorodeoxyglucose [FDG]) positron emission-computed tomography. FDG uptake in aorta and in myocardium, measured as standardized uptake values (SUV), was available in 88 and 97 participants respectively. Linear regression models were used to explore the associations of galectin-3 levels with RA patient characteristics, left ventricular mass index (LVMI), and SUVs.

**Results:** A total of 114 RA patients [mean age 56 years; 80% female; 36% White, 15% non-Hispanic Black, 44% Hispanic; Median RA duration 6.9 years; 77% RF or anti-CCP positive; Median CDAI 15.8; 51% treated with only conventional DMARD, 29% treated with conventional DMARD and biologic, 10% treated with biologic only, 10% treated with no DMARD; 38% on prednisone] were analyzed. Median galectin-3 level was 8.26 ng/mL. In univariate analyses, galectin-3 levels were significantly and positively correlated with age, Hispanic ethnicity, RA duration, IL-6 level, treatment with biologic only, prednisone use, diabetes, and aortic SUVmean, but not with LVMI or myocardial SUV. In an adjusted multivariable model (Model 2a), age ( $\beta=0.0107$ ,  $p=0.002$ ) and treatment with biologic only ( $\beta=0.4790$ ,  $p=0.001$ ) remained significantly associated with galectin-3 level. In an additional model adding aortic SUVmean (n=88) (Model 2b), prednisone use ( $\beta=0.3073$ ,  $p=0.000$ ) and aortic SUVmean ( $\beta=0.2803$ ,  $p=0.0004$ ) were significantly associated with galectin-3 level.

**Conclusion:** Age, treatment with biologic only, prednisone use, and aortic inflammation were associated with higher galectin-3 levels in RA patients without clinical CVD disease, while LVMI and myocardial inflammation were not. Galectin-3 was not an independent marker of higher LV mass (a precursor of heart failure) in this RA cohort, but additional measures of LV structure and function will be examined.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Compared with the general population, patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease or events (CE): stroke, Myocardial Infarction (MI), Congestive Heart Failure (CHF) and Cardiovascular Mortality (CVM). Systemic inflammation is the cornerstone of both RA and atherosclerosis. Over the past fifteen years, new treatment strategies such as tight control, treat to target, methotrexate optimization, biologic DMARDs use has allowed a better control of this inflammation.

**Objective:** The aim of this systematic review was to assess the excess risk of presenting a CE in RA patients as compared to general population, for all studies and, before and after 2000.

**Methods:** We systematically searched literature (via Pubmed and Cochrane library) up to March 2016 for observational studies providing data about the occurrence of a CE (among stroke, MI, CHF, CVM) in patients with RA and in a control group. A meta-analysis of the relative risk (RR) concerning patients with RA in relation to the control group was performed for each cardiovascular event and for each period (before and after 2000).

## Results:

Out of 5714 screened references, 28 studies were included. There was a significant increased risk for all CEs among people with RA relative to the general population.

For studies realized before 2000, a significant increased risk of CEs was observed in RA patients:

- RR=1.32 [1.24; 1.41],  $p<0.00001$  for MI.
- RR=1.25 [1.14; 1.32],  $p<0.00001$  for CHF
- RR=1.21 [1.15; 1.26],  $p<0.00001$  for CVM
- RR=1.12, [95 % CI 1.04; 1.21],  $p<0.002$  for stroke

For all studies realized after the year 2000, the excess risk of MI was significantly reduced in comparison with the period before 2000: RR=1.18 [1.14; 1.23],  $p<0.00001$ ; the increased risk was not retrieved for CHF (RR= 1.17 [0.88; 1.56],  $p=0.27$ ) and CVM (RR=1.07 [0.74; 1.56],  $p=0.71$ ). The excess risk of stroke was stable: RR=1.23 [1.06; 1.43],  $p=0.006$ .

**Discussion:** This meta-analysis confirms an increased risk of CEs among people with RA relative to the general population. It also appears that this excess risk is less prevalent than prior to 2000s. This might have two explanations: a better management of the cardiovascular risk in patients with RA and a better control of chronic systemic inflammation thanks to new therapeutic strategies.

**Conclusion:** The cardiovascular excess risk of RA patients relative to the general population seems to be decreased since 2000, especially for MI and CVM. This suggests that the recent improvements in RA management may have a positive impact on cardiovascular comorbidities.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

In 2011, we started a cardiovascular (CV) risk management program for rheumatoid arthritis (RA) patients visiting Reade in the Netherlands. We previously reported the presence of under treatment of hypercholesterolemia and hypertension [1].

The aim of this study was to assess the effectiveness of our CV risk management program after one year.

## Methods:

CV risk screening was performed at baseline and we informed the general practitioner (GP) about the results, including advices regarding the initiation of cardio preventive drugs. In high risk patients (i.e. a 10-year CV risk score  $\geq 20\%$ ), antihypertensives were recommended when systolic blood pressure  $> 140$  mm/Hg and statins were recommended when low-density lipoprotein  $> 2.5$  mmol/l. The decision to start preventive medication was left to the GP. CV risk screening was repeated after one year. Patients completed a questionnaire about the actions that were taken following the results of the initial screening.

## Results:

Of the 266 patients 202 (76%) were female, the mean age was  $58 \pm 11$  years. After one year, 88 out of 134 patients who received inadequate or no treatment at baseline were still untreated or undertreated. Of the 188 (71%) patients who were at high CV risk and who did have an indication to start therapy, only 7.5% was contacted by their GP and another 6.8 % arranged an appointment themselves. While the 10-year CV risk did not decrease in the group as a whole, a risk reduction was found in the patients that started medication. Remarkably, 42% of patients reported lifestyle changes, including more exercise (20%), diet adaption (16%) and weight loss (9%).

**Table 1. Cardiovascular risk factors at baseline and after one year**

	Baseline	Follow-up
CV disease history	20 (7.5)	23 (8.6)

Antihypertensives	81 (30.5)	88 (33.1)
Statins	38 (14.3)	57 (21.4)**

CV=Cardiovascular, HDL=high-density lipoprotein, LDL=low-density lipoprotein, TC=total cholesterol, SBP= Systolic blood pressure. Results are presented as mean ± standard deviation or n, (%). \*p<0.05  
\*\*p<0.01

## Conclusion:

It is striking that one year after the introduction of our CV risk management program, only 14,3% patients with an indication for preventive treatment visited their GP and only 14% started with CV risk lowering drugs. This was mainly caused by the small percentage of high risk patients that contacted their GP. On the other hand, a high percentage reported the start of healthy lifestyle. These results underscore the need for a short-term follow-up, in close collaboration with primary care providers to ensure appropriate CV risk management. This is a future implementation project that will be initiated shortly.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular diseases (CVD). It is unclear whether an elevated serum uric acid (UA) further increases that risk. We study CVD and their risk factors in association with UA in RA patients.

**Methods:** Adult patients who satisfied the ACR classification criteria for RA from The Kuwait Registry for Rheumatic Diseases (KRRD) from four major hospitals were evaluated from February 2013 through May 2017. Patients with recorded UA were identified and CVD and their risk factors were studied in those patients. To optimize classifier number and prediction accuracy, hierarchical cluster analyses for multiple factors were performed, which indicated nine possible independent CVD risk factors. A binary logistic regression was conducted to examine their significant association with CVD and the independence of UA as a risk factor.

**Results:** A total of 564 RA patients with available UA were identified, 353(62.6%) females. Mean age was 50.8±11.5 years and disease duration 10.5±2.9 years.

Mean UA was 271±78µmol/L. Of those patients, 31 (5.5%) were reported to have CVD. UA was significantly correlated to the presence of CVD ( $\chi^2=6.49$ ,  $p=0.011$ ). Logistic regression model indicated a 10% increase of CVD with every 10 µmol/L increase in UA (table). A correlation matrix between UA and other risk factors showed a significant association between high uric acid and a younger age at RA diagnosis ( $r=-0.262$ ), hyperlipidemia ( $r=0.191$ ) and diabetes mellitus ( $r=0.244$ ).

	B	p-value	Odds Ratio	95% C.I.	
				Lower	Upper
Uric acid	0.011	<0.001*	1.011	1.006	1.016
Smoking	-0.535	0.280	0.586	0.222	1.546
Anti-cyclic citrullinated peptide antibodies	-1.017	0.115	0.362	0.102	1.280
Rheumatoid factor	-0.717	0.337	0.488	0.113	2.111
Age at RA diagnosis	-0.071**	<0.001*	0.931	0.896	0.968
Hyperlipidemia	2.220	0.001*	9.210	2.606	32.548
Hypertension	1.824	<0.001*	6.199	2.470	15.556
Male gender	-1.097**	0.020*	0.334	0.132	0.844
Diabetes mellitus	2.619	<0.001*	13.724	4.665	40.372

**Conclusion:** Our study suggests that UA may be an independent risk factor for CVD and is associated with the presence of other risk factors. UA should be measured and carefully approached in RA patients.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The role of glucocorticoids (GCs) in the treatment of rheumatoid arthritis (RA) is widely debated. GCs stimulate bone resorption and impair bone formation. Inflammatory cytokines also stimulate bone resorption, and patients with RA have a high risk of osteoporosis (OP) and fragility fractures. However, in patients with both RA and OP, impairment of bone formation by GCs may be counter-balanced by reduced systemic inflammation and increased physical activity.

This systematic review aims to assess the effect of oral prednisolone and prednisone on bone mineral density (BMD) in patients with RA analyzed in randomized, controlled trials (RCT).

## Methods:

We performed a systematic literature search and identified double-blinded RCTs. Prednisolone or prednisone was the intervention. BMD was measured by dual-energy absorptiometry at baseline and at least once thereafter. Two authors independently reviewed references, extracted data and assessed risk of bias. We used Cochrane's risk of bias tool and assessed overall quality of evidence using the GRADE methodology. Primary outcomes were mean change in BMD over time. Secondary endpoints included RA disease activity and radiographic progression.

## Results:

We identified 7 studies. Studies were comparable regarding study population and intervention. Risk of bias was considered low for BMD outcomes. Data completeness was low in some studies. Overall quality was rated high for BMD and disease activity outcomes and low for radiographic progression. Standard mean difference (SMD) in change in BMD from 0 to 24 months was -0.02 (95%CI -0.16, 0.12) at the lumbar spine and -0.11 (95% CI -0.25, 0.02) at the hip (Figures 1 and 2). Concomitant treatment of RA differed between studies, as did osteoporosis prophylaxis. However, sensitivity analyses excluding studies where anti-OP therapy was used yielded no difference in the estimate in the lumbar spine, but a small, not clinically relevant difference in the hip.

## Conclusion:

In this group of RCT studies we found no difference in change in BMD in patients with RA who received GCs compared to placebo. The interpretation of this is difficult as it challenges the well-established fact that GCs negatively impact BMD through low calcium uptake and altered sex hormones. However, our findings suggest that in a population where BMD is affected by systemic inflammation, the dampening of the inflammation as well as increased physical activity may outweigh the inherent negative effects on bone when GCs are administered.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Individuals with RA have a 1.5-2.0 fold higher risk of developing congestive heart failure (CHF) than the general population. It is important to understand more about subclinical left ventricular (LV) dysfunction, which can be a strong predictor of clinical CHF. There is an increasing interest in using noninvasive cardiac imaging biomarkers to diagnose subclinical myocardial dysfunction. Feature tracking cardiac magnetic resonance (CMR) imaging is a novel postprocessing technique increasingly being used to assess regional myocardial function. Especially, LV global longitudinal peak systolic strain (GLS) is a prognostic indicator of adverse cardiovascular outcomes in various patient populations, and global circumferential peak systolic strain (GCS) is a predictor of CHF in the general population. We previously reported that a high prevalence of myocardial abnormalities assessed by CMR were observed in patients with RA. Our current prospective study aimed to evaluate the association of regional function with myocardial abnormalities by using feature tracking CMR imaging in patients with RA without cardiac symptoms.

**Methods:** Patients with RA without cardiac symptoms were enrolled. Patients with RA and control subjects with no history and/or clinical findings of systemic and pulmonary hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia underwent contrast CMR imaging. Patients with RA received conventional synthetic DMARD (csDMARD) or biologic DMARD (bDMARD). All study subjects underwent evaluation of LV regional function, as measured by feature tracking CMR imaging. The GLS and GCS were calculated by the feature tracking of cine MRI in 6 segments of the mid-slice of the left ventricle. Late gadolinium enhancement (LGE) was obtained to assess myocardial fibrosis. Group comparisons were made using the Wilcoxon rank sum test, Fisher exact test, and Steel test, as appropriate. Multivariable linear regression analyses of the correlates were performed.

**Results:** We evaluated 70 patients with RA (88% women; mean age, 55.2±9.0 years); 30% of them had positive LGE. The GCS in the LGE positive group decreased more than that in the LGE negative group ( $p=0.001$ ). However, the GLS tended to decrease in the LGE positive group compared to the LGE negative group. The GCS was associated with the LGE positive group ( $p=0.05$ ). However, RA characteristics were not associated with the GCS. The GLS tended to be associated with the LGE positive group ( $p=0.07$ ). The GCS was decreased more in the csDMARD group than in the bDMARD group ( $p=0.04$ ). However, there were no differences in the GLS between the csDMARD and bDMARD groups. Results of multivariable analysis showed that the GCS was independently associated with positive LGE (area under the curve 0.75).

**Conclusion:** This is the first study to report an association between LV regional function and myocardial abnormalities in patients with RA. LV regional dysfunction may predict the myocardial abnormalities observed in patients with RA without cardiac symptoms. Longitudinal studies are required to determine whether the GCS predicts those who will develop clinical CHF.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a chronic and systemic inflammatory disease. The incidence of the cardiovascular (CV) disease is significantly increased in patients with RA compared with the general population, which is related to the fact that atherosclerosis has an inflammatory etiology. We previously have shown a synergistic interaction between inflammatory burden and conventional CV risk factors in the development of carotid atherosclerosis. In this study, we investigated the association between bone mineral density (BMD) and the formation of new carotid plaque in RA patients in a Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) cohort study.

**Methods:** After a baseline evaluation for KARRA cohort enrollment, RA patients were prospectively followed up for 5 years or until deaths. We analyzed the demographic findings, conventional CV risk factors, RA disease activity, and BMD. Carotid ultrasounds at baseline and year 5 were performed for evaluation of the intima-medial thickness (IMT) and presence and progression of carotid plaques. BMD was measured at the lumbar spine (L-spine, L1-L4), femur neck (femoral neck), and distal forearm (radius).

**Results:** A total of 417 RA patients were included in the baseline KARRA cohort, and 325 patients with RA were followed for the 5 year period. New carotid plaque formation was found in 90 of 212 (42.5%) patients at year 5. New development of carotid plaques at year 5 in RA patients was associated with total and LDL cholesterol, ATP risk factor number, DAS28-ESR, DAS28-CRP, ESR area under the curve (AUC) and CRP AUC at year 5. The BMD in the L-spine, femur, and radius was significantly lower in patients with new carotid plaques (n = 77), compared to patients without new plaques (n = 111) ( $1.07 \text{ g/cm}^2 \pm 0.16$  vs.  $1.01 \text{ g/cm}^2 \pm 0.19$ ,  $p = 0.012$  for L-spine;  $0.87 \text{ g/cm}^2 \pm 0.13$  vs.  $0.83 \text{ g/cm}^2 \pm 0.15$ ,  $p = 0.034$  for femur; and  $0.61 \text{ g/cm}^2 \pm 0.11$  vs.  $0.55 \text{ g/cm}^2 \pm 0.13$ ,  $p = 0.001$  for radius, respectively). Multivariate logistic regression analysis revealed that age (OR 1.12 [95% CI 1.06 - 1.18;  $p < 0.001$ ]),

LDL cholesterol (OR 1.02 [95% CI 1.00 - 1.03;  $p = 0.016$ ]), DAS28-ESR at year 5 (OR 1.31 [95% CI 1.09 - 1.61;  $p = 0.030$ ]), 5-year ESR AUC (OR 1.05 [95% CI 1.00 - 1.70;  $p = 0.036$ ]), and BMD at radius (OR 2.07 [95% CI 1.08 - 2.66,  $p = 0.042$ ]) were independent risk factors for new carotid plaque formation during the 5-year followed period. Correlation coefficients were calculated to analyze the relationship between 5-year ESR AUC and BMD. L-spine BMD (RR -0.206 [ $p < 0.001$ ]), femur BMD (RR -0.297 [ $p < 0.001$ ]), wrist BMD (RR -0.344 [ $p < 0.001$ ]), and 5-year ESR AUC all showed the good correlation.

**Conclusion:** This study implicates that carotid plaque formation measured by ultrasound is associated with BMD as well as the conventional CV risk factors and inflammatory burden in RA patients, which supports further investigation of the linking processes between juxta-articular bone health and carotid atherosclerosis.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) and hypertension (HT) are multifactorial polygenic diseases. The incidence of hypertension in patients with RA is higher than in the general population, ranging from 20 to 60%. The role of genetic polymorphisms in the development of this comorbidity is investigated, but there is little information on the subject. So, potentially promising is the study of the prognostic value of gene promoter polymorphism of endothelial nitric oxide synthase NOS3 T-786C (rs2070744) in patients with RA. Additionally NOS3 plays an important role in the regulation of vascular tone, angiogenesis, osteogenesis, inflammation. The aim of the study was to investigate the prevalence of NOS3 T-786C (rs2070744) gene promoter polymorphism in patients with RA and RA associated with hypertension.

**Methods:** The study involved 148 patients with RA (100% women) aged 47.0 [42.8; 52.0] years, disease duration 78 [48; 120] months, moderate and high disease activity (DAS28 > 3.2). The diagnosis of RA was established by ACR/EULAR (2010) criteria. Polymorphism of NOS3 T786C gene (rs2070744) was performed by PCR (Real-Time PCR, Bio-Rad iCycler IQ5) using a set of «SNP-express» (NPF "Lyteh", Russia). All studied polymorphism satisfied Hardy-Weinberg equilibrium ( $\chi^2$  test,  $p > 0.05$ ). The study was conducted in accordance with the Declaration of Helsinki of the World Medical Association "Ethical principles of medical research involving human subjects" (2000), the requirements of GCP, the applicable national legislation. Statistical analysis of the results was performed by methods of variation statistics in the application package SPSS22 (© SPSS Inc.).

**Results:** Among the patients with RA normotensive were 83 (56.1%) and 65 (43.9%) patients were hypertensive. In 44 (29.7%) patients with RA hypertension was registered after the onset of RA. In patients without hypertension ( $n = 83$ ),

the frequency of genotypes was as follows: T/T - 43.3% (36 pts) T/C - 44.6% (37 pts), C/C - 12% (10 pts). In RA patients with hypertension (n = 65), the frequency of genotype C/C was significantly higher – 30.8% (20 pts);  $\chi^2 = 8.44$ ,  $p < 0.01$ ), and the frequency of genotype TT was conversely lower - 29.8%, than in RA patients without hypertension. Analysis of the common and recessive inheritance patterns showed that patients with RA, carriers of CC genotype, have 3 times higher risk of developing hypertension (OR = 3.24; 95% CI 1.39-7.55) compared to T/T and T/C genotype carriers. Analysis of the dominant inheritance model showed that patients with RA, presence of T/T genotype was characterized by tendency ( $\chi^2 = 3.12$ ;  $p = 0.08$ ) to decrease the risk of hypertension compared to T/C and C/C genotype (OR = 0.54, 95% CI 0.27-1.07).

**Conclusion:** The association of T786C NOS3 (rs2070744) gene promoter polymorphism with the development of hypertension in patients with rheumatoid arthritis in the Ukrainian population was established. In RA patients the presence of genotype C/C increased risk of hypertension.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). This post-hoc analysis aims to explore the efficacy of tofacitinib in patients (pts) with RA based on their baseline (BL) body mass index (BMI).

**Methods:** Data were analyzed from Phase 3 studies for pts who were methotrexate-naïve (NCT01039688) or had an inadequate response to DMARDs (NCT00960440, NCT00847613, NCT00814307, NCT00856544, NCT00853385) who received  $\geq 1$  dose of tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO). Pts were stratified by BL BMI (<25, 25 to <30,  $\geq 30$ ). Efficacy endpoints (American College of Rheumatology [ACR]20/50/70 response rates at Month [M] 6; changes from baseline ( $\Delta$ ) in Health Assessment Questionnaire - Disability Index [HAQ-DI], Disease Activity Score in 28 joints by Erythrocyte Sedimentation Rate [DAS28-4(ESR)], and Clinical Disease Activity Index [CDAI] at M3 and M6) were assessed.

**Results:** Overall, 1589, 1611, and 681 pts received tofacitinib 5 and 10 mg BID and PBO, respectively, with 1690, 1173, and 1017 pts in the BMI <25, 25 to <30, and  $\geq 30$  categories, respectively. BL demographics were generally

similar between BMI categories with the exception of higher rates of diabetes (12.9–14.2 vs 3.5–9.8%), hypertension (53.2–58.9 vs 22.0–39.8%), and use of prior TNFi (23.7–46.8 vs 15.0–26.9%), and numerically higher tender (28.8–29.9 vs 23.5–26.9) and swollen joint counts (16.5–17.1 vs 14.5–16.3) and HAQ-DI scores (1.6 vs 1.4–1.5) in the BMI  $\geq 30$  group vs BMI  $< 25$  or 25 to  $< 30$ . In general, ACR response rates were significantly higher ( $p < 0.05$ ) in the tofacitinib vs PBO groups, regardless of BMI category (Figure 1). There appeared to be a trend towards lower ACR20/50/70 response rates with increasing BMI at M6 in tofacitinib- and PBO-treated pts; however, confidence intervals (CI) overlap. A trend for smaller  $\Delta$ HAQ-DI through M6 with increasing BMI was observed only in pts receiving tofacitinib 5 mg BID, with overlapping CI (Figure 2A). The  $\Delta$ DAS28-4(ESR) and  $\Delta$ CDAI scores were similar for tofacitinib- and PBO-treated pts regardless of BL BMI (Figure 2B–C). Generally similar trends were observed when stratified by weight.

**Conclusion:** Results of this post-hoc analysis suggest that tofacitinib is associated with improvements in RA outcomes compared with PBO regardless of BL BMI category. In both tofacitinib and PBO groups, similar trends in improvements were seen in most endpoints regardless of BMI category, implying that the effect of BL BMI is not specific to tofacitinib. Further investigation is needed to assess the degree of impact of BMI on tofacitinib efficacy.

## Obesity and the Impact on Treat to Target Goals and Functional Ability in RA. Results from Two Multi-Centre UK Inception Cohorts

Elena Nikiphorou<sup>1</sup>, Sam Norton<sup>2</sup>, Patrick Kiely<sup>3</sup> and Adam Young<sup>4</sup>, <sup>1</sup>Academic Rheumatology Department, King's College London, London, United Kingdom, <sup>2</sup>Academic Rheumatology, King's College London, London, United Kingdom, <sup>3</sup>St George's Hospital, London, United Kingdom, <sup>4</sup>University of Hertfordshire, Hertford, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The links between inflammation, obesity and joint dysfunction are well established. How these translate into clinical disease activity and functional disability in rheumatoid arthritis (RA) though, remains to be defined. This study explores associations between BMI and 1. The achievement of disease remission or low disease activity and 2. Functional ability, in RA.

**Methods:** Data from two consecutive UK multi-centre RA inception cohorts with similar design were used: the Early RA Study (ERAS) and Early RA Network (ERAN). Recruitment figures/median follow up for ERAS and ERAN were 1465/10 years (maximum 25 years), and 1236/6 years (maximum 10 years) respectively. Standard demographic and clinical variables were recorded at baseline and then annually until loss to follow-up or the end of study follow up. Multivariable logistic regression analysis was used with remission (R-DAS)/low disease activity status (L-DAS) and health assessment questionnaire (HAQ,  $<1$  vs  $\geq 1$ ) as dependent categorical variables in models adjusted for patient, disease-related clinical variables and recruitment year. BMI was examined in separate models as both a continuous and categorical predictor variable according to WHO definitions.

**Results:** Baseline BMI data from 2420 patients (90%) indicated that 37.2% were overweight, 21.3% obese. Mean BMI at baseline was 25.5 in ERAS and 27.6 in ERAN and this increased over 5 years (Figure). In multilevel logistic models (table) adjusting for age, sex and year of recruitment among other, higher BMI was associated with reduced odds of achieving R-DAS (OR 0.97;95%CI 0.95, 0.99) (table) and L-DAS, although the latter did not reach statistical significance (OR 0.98;95%CI 0.96, 1.00). Obesity was related to a significantly lower chance of R-DAS by 29% (OR 0.71;95%CI 0.55, 0.93) and L-DAS by 31% (OR 0.69;95%CI 0.55, 0.87). Higher BMI was predictive of higher disability (OR 1.04;95%CI 1.01, 1.06). More specifically, obesity increased the odds of higher disability by 63% (OR 1.63;95%CI 1.20, 2.23) and in the same models, higher DAS was also strongly predictive of higher disability (OR 3.67;95%CI 3.41, 3.95).

**Conclusion:** Higher BMI and in particular obesity was associated with lower remission and low disease activity states and higher disability. These findings argue strongly for the screening and management of obesity to become a central part of all treatment strategies in RA.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The association of body mass index (BMI) with the outcomes of rheumatoid arthritis (RA) has been inconsistent in the literature. It is postulated that high BMI or obesity may have a diverse influence on RA risk, clinical activity and treatment response. The aim of our study is to investigate the association of BMI with RA disease activity and severity in a multi-ethnic RA cohort in Singapore.

### Methods:

We reviewed data that was collected from November 2013 to March 2017 in a tertiary rheumatology centre. There were 288 patients (83.68% Chinese, 5.9% Malay, 9.72% Indian, 0.69% others; 87.85% female, 12.15% male). All patients fulfilled the ACR 1987 criteria for RA. Based on the World Health Organization classification, patients were categorized into 3 groups: low, normal and high BMI [ $<18.5\text{kg/m}^2$  (underweight),  $18.5\text{--}25\text{kg/m}^2$  (normal weight) and

>25kg/ m<sup>2</sup> (overweight) respectively]. Sociodemographic data, clinical features, disease activity (DAS28), laboratory variables (C-reactive protein, fasting lipid profile), functional status and co-morbidities were compared between the three BMI groups. Chi-square, T-test, Kruskal Wallis test and Wilcoxon rank sum test were used where appropriate. Statistical significance was defined as p-value < 0.05.

## Results:

The mean age of the cohort was 44.7±11.85 years, the median RA duration 197.5 months, with no statistical difference between the three groups. Patients with normal BMI were the most likely to attain remission (DAS28<2.6) among the three groups (58.14% vs 81.43% vs 76.24%, p=0.038). Patients with normal BMI had a significantly lower C-reactive protein (mg/L) compared with the two other groups (4.1 vs 3.2 vs 4.6, p=0.0214). The low BMI group had a higher physician's assessment of disease activity, but this did not reach statistical significance (12.47±18.13 vs 7.45±15.82 vs 9.18±18.51, p=0.236). The obese patients had significantly lower physical functioning scores in SF-36 (85 vs 75 vs 70, p=0.0198). Not unexpectedly, obese patients were more likely to have hypertension (p<0.0001), low HDL (p=0.004) and high TG (p=0.0001) levels, but there was no statistically significant difference for diabetes mellitus, ischemic heart disease, cardiovascular accident, liver and renal disease in the three groups. The three groups did not differ in gender, smoking status, prevalence of rheumatoid factor and anti-citrullinated peptide antibody, number of deformed joints, health assessment questionnaire (HAQ) scores and treatment.

## Conclusion:

In our multi-ethnic cohort, patients with normal BMI appear to have the best RA control. High BMI should be considered a modifiable risk factor for poor RA outcome. Future studies should be done to investigate the relation of BMI and adiposity, as well as influence of frailty and sarcopenia on RA disease activity.

## Obesity Impacts ESR and Not Other Measures of Rheumatoid Arthritis Disease Activity

**Ana Maheshwari**<sup>1</sup>, Oumoul Barry<sup>1</sup> and MJ Bergman<sup>2</sup>, <sup>1</sup>Internal Medicine, Mercy Catholic Medical Center, Darby, PA, <sup>2</sup>Medicine, Drexel University College of Medicine, Philadelphia, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disease activity measurement is a cornerstone to treat to target strategy. The impact of body mass index (BMI) on disease activity in rheumatoid arthritis (RA) is not clear. We studied the impact of body mass index on various patient and physician variables in RA patients.

**Methods:** A retrospective observational study was done in a community based rheumatology clinic. Random visits from 155 patients with a diagnosis of RA who had documented DAS28-(ESR) (Disease Activity Score) and BMIs were

studied. Baseline patient demographics, DAS28, RAPID3, CDAI, SDAI, tender count, swollen count, physician global, pain scale, patient global, function, ESR, CRP, and BMI were collected. Obese was defined as: BMI < 29.9 (NON-OBESE) and BMI ≥ 30.0 (OBESE). A multiple regression analysis was done using a random set of patients. We used BMI and Obese as independent variables to determine the impact of BMI or Obesity on RA disease activity.

**Results:** Study population consisted of 155 patients of which 46% of the patients were obese with a mean BMI of 30. Patients had a mean DAS28 of 2.40, RAPID3 of 9.08, CDAI of 11.26, SDAI of 11.94. After controlling for age, sex, and duration of disease, higher BMIs were found to have a significantly increased ESR; obese patients had elevated ESR and DAS28, without changes in any other patient or physician reported measure. Additional results show that for every 10-point increase in BMI, ESR increases by 4.3mm/hour which leads to an increase in 1.02 points in the DAS28.

**Table 1: Multiple regression for impact of Obesity on RA disease activity measures, controlling for age, sex, disease duration**

Variables	Coefficient	p-values
DAS28	0.3856	<b>0.029</b>
RAPID3	0.1168	0.918
CDAI	0.9643	0.474
SDAI	1.1216	0.425
Tender Count	-0.3653	0.362
Swollen Count	1.2703	0.062
Physician Global	0.3587	0.222
Pain Scale	0.0926	0.848
Patient Global	-0.3430	0.450
Function	0.3151	0.285
ESR	5.598	<b>0.046</b>
CRP	0.6957	0.713

**Conclusion:** In this cohort, BMI was shown to significantly affect ESR, but no other objective or subjective measures of RA disease activity, suggesting that obesity in itself may increase the levels of inflammatory markers rather than the actual disease process. Using ESR may erroneously elevate DAS28 leading to misclassification of RA. This could lead to potential overtreatment in obese patients with RA. Further studies comparing the treatment groups and using larger number of patients are required to substantiate the results of this study.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Obesity has been proposed as a risk factor to develop rheumatoid arthritis (RA) and it has been associated with a worse response to several disease modifying anti-rheumatic drugs (DMARDs). Objective: To study the differences in baseline characteristics according to the body mass index (BMI) of patients in the PEARL (Princesa Early Arthritis Register Longitudinal) cohort.

**Methods:** A total of 432 patients (69.1% female) of the PEARL cohort were included for this study. The register protocol comprises the collection of sociodemographic, disease-related and treatment data in five visits (baseline, 6, 12, 24 and 60 months). The local ethics and clinical research committee approved the register protocol and all patients sign an informed consent prior to their inclusion. For this study it was analyzed the data of the baseline visit from the 304 (70.37%) patients that met ACR 1987 criteria for RA after 2 years of follow-up, as well as those considered undifferentiated arthritis (UA) since other diagnoses were excluded. The WHO definition for low weight, normal weight, overweight and obesity (BMI <18.5, 18.5-25, 25-30 or  $\geq 30$  kg/m<sup>2</sup> respectively) was applied. ACPA were assessed by enzyme immunoassay (CCP2 Eurodiagnostica). HLA-DRB1 genotype was determined in 219 patients using specific HLADRB1 typing kits (Dynal RELI SSO). A multivariate logistic regression was performed to determine which factors may be related to ACPA positivity, including BMI, age, sex, smoking habit, number of SE alleles and study level as independent variables.

**Results:** Patients were 54.9 years old [44.2-67.5] (median [p25-p75]); disease duration was 5.3 months [3-8.4]. Differences in pain perception and disability were related to BMI. Table 1 shows the main variables significantly associated to BMI. It was observed an inverse relationship between the presence of ACPA and BMI as well as a lower frequency of SE in patients with a higher BMI. The multivariate analysis, performed with the data of the 219 patients in whom the genetic study was available, showed, as previously described, that being smoker (ever/or current) and carrying SE alleles is associated with the presence of ACPA. Moreover, adjusted by these variables, overweight and obesity were associated with a significantly lower probability of suffering an ACPA positive disease (OR 0.49, p = 0.027 and OR 0.39, p = 0.019 respectively).

Table 1 – Variables significantly different according to BMI

BMI	Age (years)	Sex (W/M)	Level of studies (N/P/Se/U; %)	HAQ	VAS pain	TJC28
Lowweight	52.3 [22.2-64]	7/0	0/14.3/42.9/42.9	1.25 [0.9-2.2]	50 [26-75]	7 [2-19]
Normalweight	50 [38.6-64]	145/24	1.2/21.4/35.1/42.3	0.87 [0.4-1.4]	41 [20-61]	3 [0-7]
Overweight	57.9 [47-69.6]	120/45	8.5/35.4/32.9/23.2	0.87 [0.5-1.6]	49 [20-62]	3 [0-9]
Obesity	59 [50.7-69.8]	68/23	12/38.5/26.5/22.9	1.3 [0.7-1.9]	50 [36-65]	5 [2-12]
	p $\leq$ 0.001	p=0.01	p $\leq$ 0.001	p=0.0018	p = 0.031	p=0.047

\*W: women; M: men; N: no studies; P: primary studies; Se: secondary studies; U: university studies.

**Conclusion:** In our early arthritis registry, patients with a higher BMI have predominantly ACPA negative disease, a more intense perception of pain and higher disability. These findings should be validated in other populations.

## **Weight Histories Expose the Systematic Underestimation of the Risks of Obesity on Mortality in Rheumatoid Arthritis**

**Joshua Baker**<sup>1</sup>, Bryant R. England<sup>2</sup>, Ted R. Mikuls<sup>3</sup> and Kaleb Michaud<sup>4</sup>, <sup>1</sup>Medicine/Rheumatology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Division of Rheumatology & Immunology, Department of Internal Medicine, Nebraska-Western IA VA Health Care System & University of Nebraska Medical Center, Omaha, NE, <sup>3</sup>Internal Medicine, Division of Rheumatology, University of Nebraska Medical Center, Omaha, NE, <sup>4</sup>University of Nebraska Medical Center, Omaha, NE

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Emerging evidence suggests that long-term weight loss is an important confounder that results in an underestimation of the risks of obesity in chronic illness. Methodologies that consider weight earlier in life may help address this epidemiologic challenge. This study evaluated weight histories of patients with RA and their relationship to mortality.

### **Methods:**

Patients with RA were active participants from 1999 to 2016 and of age >40 years in the National Data Bank for Rheumatic Diseases. Current and age-30 height and weight were self-reported at each semi-annual questionnaire. Body mass index (BMI) and percent weight change from age-30 were calculated and classified based on previously defined categories. Multivariable Cox proportional hazards models assessed the relationships between BMI at enrollment and age-30 with mortality. Estimates of risk were also assessed before and after adjusting for disability (HAQ) and comorbidity (Rheumatology Disease Comorbidity Index [RDCI])- factors hypothesized to be in the causal pathway.

### **Results:**

Among 12,679 participants (80% female), the mean (SD) age and disease duration were 59.9 (10.5) and 13.9 (12.4) years, respectively. There were 1,520 deaths in 80,502 person-years of follow-up. Relationships between BMI categories and mortality were distinct by time of assessment (Figure). For example, at enrollment, low BMI was associated with a greater risk of death (Table). In contrast, those with low age-30 BMI were not at greater risk. While obesity at enrollment was modestly associated with mortality [HR 1.25 (1.10, 1.42) p=0.001], an obese age-30 BMI was associated with a pronounced increase in risk [HR 1.75 (1.45, 2.11) p<0.001]. Weight loss since age-30 was a strong and dose-dependent predictor of mortality independent of enrollment BMI. Compared to normal BMI, an obese age-30 BMI was associated with greater disability and comorbidity scores and greater odds of diabetes, hypertension, and work disability at enrollment after adjusting for sex, race, and age at enrollment. Adjustment for disability and comorbidity resulted in even further potential underestimation of risks of obesity at enrollment [HR 0.92 (0.80, 1.06) p=0.24] (Figure).

## Conclusion:

Lifetime weight histories expose substantial underestimation of the risks of obesity on mortality in clinical studies in RA. Systematic underestimation of risk is due to the confounding effects of long-term unintentional weight loss often observed due to aging and chronic illness and to the over-adjustment for factors that are likely to be in the causal pathway.

Table: Cox proportional hazard models evaluating the independent associations between BMI at enrollment and weight loss since age 30.*				
<i>N</i> =12,272; <i>PY</i> =78,152	Enrollment BMI		Enrollment BMI + Weight Change Since Age 30

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Obese patients with rheumatoid arthritis (RA) have greater disability in cross-sectional studies. There are no long-term studies that assess trajectories of disability among individuals in different body mass index (BMI) categories. We evaluated associations between obesity, weight loss, and incident disability in two large longitudinal registries.

### Methods:

This study included patients with RA and available data from the National Data Bank of Rheumatic Diseases (NDB) (N=22,432) and the Veterans Affairs RA (VARA) registry study (N=1580). Incident disability was defined as an increase of >0.2 on the Health Assessment Questionnaire (HAQ or MD-HAQ) (based on the MCID). Disability scores and BMI were recorded at routine clinical visits (VARA) or by questionnaire every 6 months (NDB). Patients from NDB were asked to estimate their weight at age 30. Multivariable Cox proportional hazards models evaluated associations between BMI and weight change and the risk of incident disability.

## **Results:**

Disability was greater at enrollment in severely obese (BMI >35 kg/m<sup>2</sup>) patients compared to normal weight (BMI 18.5-25 kg/m<sup>2</sup>) after adjustment for demographics in NDB [B: 0.31 (0.28,0.34) p<0.001] and VARA [B: 0.19 (0.085,0.30) p<0.001]. Disability increased annually in both NDB [B: 0.011 (0.01, 0.012), p<0.001] and VARA [B: 0.022 (0.018, 0.027) p<0.001]. In multivariable models, severe obesity and greater comorbidity were associated with incident disability (Table). Associations for obesity were independent of disease duration, comorbidity, and time-varying CRP and swollen joint count (in VARA). In NDB, 5% weight loss from age 30 to enrollment (9.7% of patients) was associated with a greater risk of incident disability in similar models [HR: 1.13 (1.04,1.23) p=0.004] (Figure). Similarly in VARA, 5% weight loss from enrollment as a time-varying predictor (22.8% of observations) was associated with incident disability independent of time-varying BMI [HR 1.40 (1.15,1.71) p=0.004]. Figure 1 shows that survival without incident disability was shorter among severely obese patients in NDB and among those who lost 5% of weight since age 30.

## **Conclusion:**

Obesity and comorbidity at enrollment predict greater and worsening disability scores in RA- an effect that is independent of disease activity. A direct effect of excess weight on disability over time represents an important confounder of these measures as RA outcomes. Interestingly, prior weight loss also predicts disability, possibly by identifying chronically ill individuals with unintentional weight loss.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Low body mass index (BMI) is associated with more destructive disease in rheumatoid arthritis (RA). Paradoxically, obese patients have been shown in studies to be more likely to discontinue therapy, suggesting a refractory phenotype. The purpose of this study was to examine the association between BMI and DMARD persistence, accounting for factors that may confound this relationship.

## **Methods:**

VA administrative databases were used to define unique initial courses of methotrexate (MTX), self-injectable TNF inhibitors (TNFi), hydroxychloroquine (HCQ), sulfasalazine, and prednisone. Discontinuation was defined as a lapse in drug refill >90 days. The closest values for CRP and BMI within 30 days of treatment start date were linked. Multiple imputation was used to address missing laboratory values. Health factor data and diagnosis codes were linked to treatment courses. Multivariable Cox proportional hazards models were used to evaluate associations between BMI category and time to DMARD discontinuation. Covariates included age, sex, race (Black vs. White), calendar year (2005-2009 vs. 2010-2014), current smoking, CRP, disease duration >5 years, anti-CCP status, other DMARDs, diabetes, hypertension, CHF, history of malignancy, depression, and anxiety, and the Rheumatic Disease Comorbidity Index (RDCI).

## **Results:**

There were 46,970 unique initial DMARD courses (88% male) with RA between 2003-2014. Patients in low (BMI <18.5) and normal (BMI 18.5-25) categories had the greatest likelihood of discontinuing MTX, HCQ, and TNFi (Figure). Severe obesity (BMI >35) was only associated with a greater likelihood of discontinuing prednisone compared to overweight BMI (BMI 25-30) [HR 1.09 (1.02, 1.16)  $p=0.004$ ]. Factors associated with earlier MTX and/or TNFi discontinuation included female sex, black race, older age, greater comorbidity, and a history of depression, malignancy, CHF, active smoking, and recent calendar year (Table). Among TNFi users, concurrent MTX use was associated with a lower likelihood of discontinuation.

## **Conclusion:**

Among US veterans with RA, obesity was not associated with reduced persistence of DMARDs and/or TNFi's, except for prednisone. Conversely, low BMI was associated with reduced drug persistence; this finding may be explained by greater severity of RA and/or other co-morbidities and warrants further evaluation. These data are not consistent with the hypothesis that obesity is a biologic mediator of refractory disease, resulting in failure of drug therapy. In contrast, other co-morbidities are shown to be important predictors of drug persistence.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To analyze the association between osteoprotegerin (OPG) and Dickkopf-related protein 1 (DKK-1) and the annual percent change ( $\Delta\%$ ) in bone mineral density (BMD) in patients with tightly controlled rheumatoid arthritis (RA).

**Methods:** Observational mixed-study. RA patients followed-up with a tight-control strategy were included. Bone densitometries were performed at baseline (T0) and follow-up (T1) and OPG and DKK-1 were measured by ELISA also in T0 and T1; additional clinical variables included disease activity measures, and treatment for RA and osteoporosis. Descriptive bivariate and multivariate analyses, stratified by gender, were performed.

**Results:** We included 97 RA patients (70% female, with a mean age of 53 years, and 76% with low activity by DAS28); 95% were treated with DMARDs and 37% with anti-osteoporotic drugs. Mean lag-time between bone densitometries was 2.7 years. Most patients had their BMD improved. The mean  $\Delta\%$ BMD was +0.42% for lumbar spine, +0.15% for femoral neck and +0.91% for total femur. In men, baseline OPG was significantly associated with higher BMD loss ( $\beta$  coefficient -0.64) at femoral neck. In women, DKK-1 was associated with higher BMD loss at femoral neck ( $\beta$  coefficient -0.09), and total femur ( $\beta$  coefficient -0.11); however, DKK-1 was associated with lower BMD loss at lumbar spine ( $\beta$  coefficient 0.06).

**Conclusion:** In tightly controlled RA patients, we have found no evidence of bone loss. Other factors than OPG and DKK-1, namely smoking and ACPA, may have a larger effect on bone mass than these molecules.

## The Use of Fibroscan in Detecting Early Liver Fibrosis in RA Patients on Long Term MTX with Normal Liver Enzymes

**Malack Alachkar**<sup>1</sup>, T Mathialahan<sup>2</sup>, Sandra Walsh<sup>2</sup> and Vun Lim<sup>3</sup>, <sup>1</sup>Rheumatology, The Pennine Acute Hospitals NHS Trust, Manchester, United Kingdom, <sup>2</sup>Gastroenterology, Wrexham Maelor Hospital, Betsi Cadwaladr University Health Board, Wrexham, United Kingdom, <sup>3</sup>Rheumatology, Wrexham Maelor Hospital, Betsi Cadwaladr University Health Board, Wrexham, United Kingdom

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

FibroScan (FS) is a non-invasive investigation that allows assessment of possible liver fibrosis by measuring liver stiffness. There are studies which confirm that MTX-related liver fibrosis (LF) may not be associated with abnormal liver function tests (LFTs). The aim of this study was to investigate the incidence of possible LF detected by FS in RA patients taking MTX, who had never had abnormal LFTs since commencing MTX.

## **Methods:**

This was a pilot, single-centre, prospective, cross-sectional cohort study. Patients were recruited from the rheumatology department at Wrexham Maelor Hospital, North Wales, UK, between September 2012 and July 2016. We included only patients with RA (seropositive and seronegative), who had never had abnormal LFTs since commencement of MTX, and who had been on MTX for 2 years or more. The hepatology team performed the FS in all patients. The FS score of an average of 10 readings was expressed in kilopascals (KPa). A FS result was considered abnormal if  $\geq 8$ KPa. Patients with abnormal FS results were then assessed by the hepatology team for further clinical evaluation to establish the liver condition. Linear regression test was used to examine the relation between raised FS values and dose and duration of MTX use.

## **Results:**

A total of 104 patients were recruited in this study. FS readings were invalid in 4 patients, and those patients were later excluded from the analysis. There were 65% females and 35% males in this cohort, reflecting the predominance of females in RA. The mean patient age was 65.1 years (SD 9.7). The mean MTX dose was 17.2mg (SD 5.2) weekly. The median duration of MTX treatment was 5.4 years (range 2-16 years) and this gave a total of 347 MTX- years. There were 41 patients on at least one other DMARD (SSZ, LEF, HCQ), and 17 patients on a biologic drug. The median FS score in this study was 4.7 KPa (range 0-14.5). Fifteen patients had abnormal FS readings with a median score of 9.1 (range 8.1-14.5). The incidence of an abnormal FS result was 15% in this cohort. The rate of abnormal FS score was 0.043/100 patient-years. We found no correlation between raised FS score and the dose or duration of MTX use - correlation coefficient  $r$  was 2.8 ( $p$  value 0.09) and 0.57 ( $p$  value 0.45) respectively. All patients with abnormal FS scores were clinically obese (BMI $>30$ ), and were diagnosed by the hepatologist as having fatty liver disease. None of these had MTX-induced liver fibrosis. Only 1 patient had non-alcoholic steatohepatitis with liver fibrosis confirmed on liver biopsy. This patient was advised to stop MTX, and all other patients were advised to lose weight and to continue taking MTX.

## **Conclusion:**

We demonstrated in this study that subclinical MTX-induced LF in RA patients taking long-term MTX with normal LFTs is extremely low. The use of FS as part of routine monitoring for liver fibrosis in clinical practice is not necessary in patients with normal LFTs.

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

Session Type: ACR Poster Session C

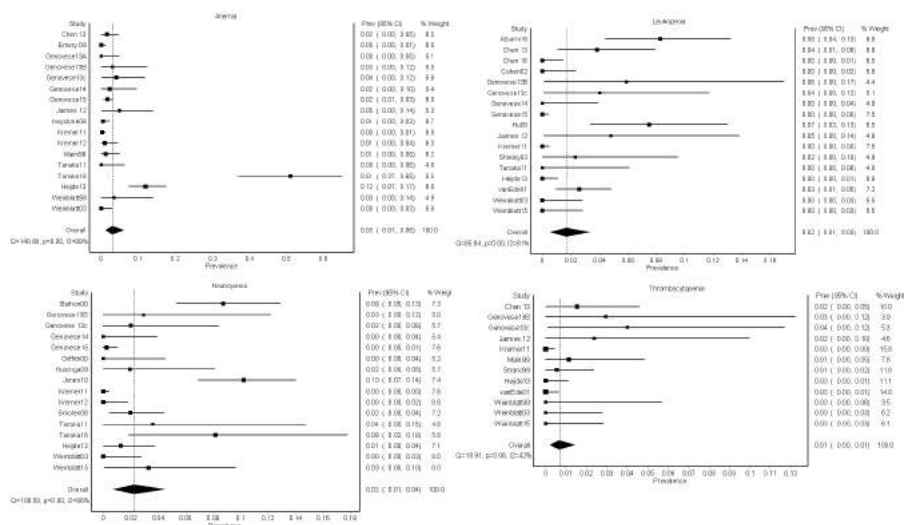

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is known to increase the risk of cytopenias, but the prevalence of hematologic abnormalities among patients taking low dose MTX is poorly defined. We conducted a systematic literature review and meta-analysis to estimate the prevalence of anemia, leukopenia, neutropenia, and thrombocytopenia associated with MTX plus folic acid supplementation among non-oncology patients.

**Methods:** We searched MEDLINE, PubMed, and Embase from inception to August 2016 for all randomized controlled clinical trials (RCTs) with a MTX monotherapy arm. We excluded RCTs for cancer and included only double-blind studies that reported on hematologic adverse events. Studies were excluded if patients did not receive folic acid or leucovorin supplementation. Most trials used MTX as the comparator arm against newer therapies. Full text articles were assessed by two independent reviewers. Risk of bias was assessed per Cochrane Risk of Bias guidelines including selection, performance, detection, attrition, and reporting bias. Pooled prevalence estimates were calculated using random-effects models. The heterogeneity across studies was tested using Cochran's Q and I<sup>2</sup>.

**Results:** Of 1601 studies identified, 30 (1.87%) were included that contained data from 3,858 patients with RA; no other rheumatologic conditions were represented. Seventeen trials reported on anemia (N=2,032), 17 reported on leukopenia (N=2,220), 16 reported on neutropenia (N=2,202), and 12 reported on thrombocytopenia (N=1,507). The mean dose of methotrexate was 15.4 (± 4.5) mg/week with a maximum dose of 30 mg/week, and 41.9% of subjects were using oral corticosteroids. Trial duration ranged from 12-62 weeks with a mean of 32 (±17) weeks. The pooled prevalence for anemia was 3.05% (95% CI 1.04-5.95%), leukopenia 1.67% (95% CI 0.55-3.31%), neutropenia 2.25% (95% CI 0.74-4.48%), and thrombocytopenia 0.67% (95% CI 0.18-1.42%)(Figure). Severe anemia was reported in 4 patients (0.20%), severe neutropenia was reported in 3 patients (0.14%), and no cases of severe leukopenia or thrombocytopenia were reported. The risk of bias assessment showed that most methodological limitations came from a failure to describe randomization procedures (N=23, 76.7%) and selective reporting of only severe hematologic adverse events (N=8, 26.7%). Significant statistical heterogeneity existed across studies for all cytopenias. The I<sup>2</sup> (percentage of variation due to heterogeneity rather than chance) was high: I<sup>2</sup> 89% for anemia, 81% for leukopenia, 86% for neutropenia, 42% for thrombocytopenia.

**Conclusion:** Cytopenias are an uncommon side effect of low-dose MTX with folic acid supplementation among RA patients. Randomized controlled clinical trials vary widely in their reporting of hematologic adverse events, with many failing to report mild and moderate cases. Further research is needed to reach a more precise estimate.

## Reliability of the Biochemical Bone Markers CTX and P1NP during a TNF-Inhibitor Treatment Cycle in Patients with Rheumatoid Arthritis

**Kim Holmsted<sup>1</sup>**, Niklas Rye Jørgensen<sup>2</sup> and Ole Rintek Madsen<sup>1</sup>, <sup>1</sup>Center for Rheumatology and Spine Diseases & The DANBIO Registry, Copenhagen University Hospital Rigshospitalet Gentofte Glostrup, Copenhagen, Denmark, <sup>2</sup>Dept. of Clinical Biochemistry, Rigshospitalet, Glostrup, Denmark

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Patients with rheumatoid arthritis (RA) have an increased risk of developing osteoporosis. Dual Energy X-ray Absorptiometry (DXA) with assessment of BMD is used for diagnosis and monitoring of treatment effect. The access to DXA may be limited and changes in BMD occur only slowly, however. Therefore, the use of biochemical bone turnover markers (BTMs) to control compliance and treatment effect is gaining ground in daily practice. According to the International Osteoporosis Foundation (IOF) the most promising markers for clinical use are s-P1NP (serum procollagen type 1 N-terminal propeptid, µg/L) and s-CTX (serum procollagen type 1 N-terminal propeptid, µg/L) reflecting the bone formation and resorption, respectively. When treating with bisphosphonates, the BTMs are expected to be suppressed already after a few months. However, analytic and biologic variation may influence the results. TNF-inhibitors reduce bone loss and reduce serum levels of P1NP and CTX. The use of BTMs in RA patients treated with anti-osteoporotic agents is tempting, but there is no data on the reliability of BTM during TNF-inhibitor treatment cycles.

## Objective:

To examine the reliability of CTX and P1NP in a group of stable RA patients during a cycle of TNF inhibitor treatment.

## Methods:

27 RA patients with receiving TNF-inhibitor treatment were identified in the Danish Registry for biological treatment (DANBIO). None of the patients were treated with anti-osteoporotic agents. Measurements of fasting morning s-P1NP and s-CTX were performed 1-2 days before and after administration of the biological agent and in the middle of the treatment cycle. Analyses were performed according to standard procedures. Between-test differences were examined using Student's t-test for paired data. Reliability was expressed as the coefficient of variation (CV) % calculated as  $= 100 \times \sqrt{(\sum s_i^2 / (n-1))} / \text{mean}$  and as the corresponding minimal detectable difference (MDD) % calculated as  $= 1.96 \times \sqrt{2} \times \text{CV}(\%)$ . The MDD is the difference between two measurements which would be statistically significant when applied to a reference group (level of significance 0.05).

## Results:

Age was  $61.6 \pm 12.6$  years, DAS28  $2.8 \pm 0.99$  (mean  $\pm$  1SD). 57% of the patients were treated with adalimumab, 18% with certolizumab, 14% with etanercept, 11% with infliximab and 70% with a DMARD (methotrexate (n=17), azathioprine (n=2)). Results of P1NP and CTX measurements are shown in the Table.

Results of CTX and P1NP measured before, after and between administrations of TNF-inhibitor treatment (mean $\pm$ SD)			
Assessment	Before	After	Between
s-CTX ( $\mu\text{g/L}$ )	$0.41 \pm 0.23$	$0.41 \pm 0.22$	$0.40 \pm 0.22$
s-P1NP ( $\mu\text{g/L}$ )	$55.2 \pm 19.5$	$53.5 \pm 22.3$	$54.8 \pm 24.5$
Significant differences between the time points were not found (p-value range 0.36-0.96)			

The CV for P1NP was 18.7 % and the corresponding MDD 52.0 %. The CV for CTX was 20.3% and the MDD 56.3 %.

## Conclusion:

The biochemical bone markers P1NP and CTX were stable on the group level during cycles of TNF-inhibitor treatment in patients with RA. CVs and MDDs were high, however. If treatment with anti-osteoporotic agents is initiated, changes in both P1NP and CTX below 50% in the individual patient may be due solely to measurement error and should therefore be interpreted with caution.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Measuring the degree of frailty can help screen, quantify and predict future risk of adverse health outcomes at a clinical research level and at a healthcare policy level. The evidence assessing the relationship between frailty and risk of adverse health outcomes in rheumatoid arthritis (RA) patients remains limited and sparse in the literature. Therefore we aimed to assess the relationship between frailty and risk of fractures in patients with RA, using data from the Ontario Best Practices Research Initiative (a clinical registry of patients with RA in Ontario, Canada).

### **Methods:**

Patients' data were collected from the participating rheumatologists every 6 months, and from OBRI interviewers every 3 months in the first two years and every 6 months afterwards. The primary outcome was incident fractures during follow-up that led to a hospitalization or emergency room (ER) visit. Frailty was measured as a frailty index (FI) of deficit accumulation that included 32 health-related deficits consisting of 17 co-morbidities, 16 symptoms and signs, and 9 activities of daily living. The FI ranged from 0 to 1, with a higher FI indicating higher frailty. Student's t-test was used for comparison of FI between patients with and without a fracture during follow-up.

### **Results:**

There were 3,153 patients (78% females, mean age 57.5 years) included for analyses. Patients' mean FI at baseline was 0.21 (standard deviation [SD]: 0.17), and the age-invariant 99% upper limit was 0.52. During the mean follow-up of 3.7 years, there were 125 incident fractures reported. As shown in **Table 1**, patients experiencing a fracture were older, more likely to be females, and had a longer RA duration, compared to patients without a fracture. The FI was significantly higher in patients with a fracture compared to controls (0.25 vs. 0.21,  $p < 0.001$ ).

### **Conclusion:**

RA patients experiencing an incident fracture were significantly frailer than patients who did not experience a fracture. Measuring the grades of frailty may assist with the assessment and management of RA patients to predict and reduce their fracture risk.

**Table 1.** Comparison of baseline characteristics between RA patients with a fracture leading to hospitalization or ER visit and patients without fractures during follow-up

Baseline characteristics	Incident fracture that lead to a hospitalization or ER visit		
	Yes (n =125)	No (n = 3,028)	P value
Age: mean (SD), years	61.9 (11.9)	57.3 (12.9)	< 0.001
Female: n (%)	109 (87%)	2,319 (78%)	0.013
RA duration: mean (SD), years	11.6 (11.4)	8.2 (9.7)	0.002
BMI: mean (SD), kg/m <sup>2</sup>	26.5 (5.0)	27.0 (5.6)	0.33
Family history of RA: n (%)	49 (39%)	970 (32%)	0.11
Smoking: n (%)	20 (16%)	504 (17%)	0.82
Alcohol drinking: n (%)	34 (27%)	828 (27%)	0.93
Osteoporosis medication use: n (%)	44 (35%)	826 (27%)	0.059
FI: mean (SD)	0.25 (0.12)	0.21 (0.12)	< 0.001

ER = emergency room; SD = standard deviation; RA = rheumatoid arthritis; BMI = body mass index; FI = frailty index

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Dyspnea on exertion symptoms often prompt clinical evaluation related to respiratory, cardiovascular, and functional status. However, the incidence and predictors of clinically significant dyspnea among

patients with rheumatoid arthritis (RA) has not been previously investigated.

**Methods :** We investigated dyspnea among RA patients using a single-center cohort of patients with RA and up to 12 years of prospective follow-up. We defined significant dyspnea on exertion using the Medical Research Council Dyspnea measure (<sup>3</sup> on 0-5 scale; unable to ambulate without breathlessness or worse, as previously validated), assessed at baseline and annually. We analyzed subjects with complete covariate data and no significant dyspnea at baseline and at least one year of follow-up. We determined the incidence rate (IR) of dyspnea during follow-up. Sociodemographics, lifestyles, clinical factors, and RA characteristics were considered as time-varying predictors assessed prior to the outcome. We used Cox regression to estimate the hazard ratios (HR) for dyspnea occurring one year after predictors were assessed throughout follow-up.

**Results :** We analyzed 991 patients with RA and no significant dyspnea at baseline during mean 5.1 (SD 3.8) years of follow-up. At baseline, mean age was 55.5 (SD 13.6) years and 66.0% were seropositive. During 5,041 person-years of follow-up, 142 (14.3%) subjects developed incident dyspnea (IR 52.5 per 100 person-years). The dyspnea IR was highest in the first year after baseline (IR 26.3 per 100 person-years, **Figure**). Independent predictors of clinically significant dyspnea were: older age (HR 1.03, 95%CI 1.01-1.05 per year, **Table**), female sex (HR 2.32, 95%CI 1.19-4.54), white race (HR 0.50, 95%CI 0.25-0.97 vs. non-white), obesity (HR 1.66, 95%CI 0.98-2.79 vs. normal), worsened functional status by MD-HAQ (HR 2.54, 95%CI 1.64-3.93 per unit), and mild dyspnea (HR 2.72, 95%CI 1.66-4.48 vs. no dyspnea). Biologic use was associated with dyspnea (HR 1.58, 95%CI 1.03-2.42 vs. non-use), but other RA characteristics including DAS28-CRP, seropositivity, duration, methotrexate use, and glucocorticoids were not associated with incident dyspnea.

**Conclusion :** In this long-term prospective study, the development of clinically significant dyspnea on exertion occurred in 14% of patients with RA. We identified sociodemographics (older age, white race, female sex), clinical factors (obesity, mild baseline dyspnea), and RA characteristics (MD-HAQ, biologic use) assessed prior to dyspnea development that inform intervention studies related to decreasing the respiratory and cardiovascular burden of RA.

**Figure.** Cumulative incidence rate (per 100 person-years) for development of clinically relevant dyspnea on exertion among patients with RA during 12 years of prospective follow-up (n=991).

**Table.** Predictors of clinically relevant dyspnea on exertion in RA assessed one year prior to development, in unadjusted and multivariable analyses (n=991).

### Abstract

**Background/Purpose:** Rituximab-based chemotherapy can induce hepatitis B virus (HBV) reactivation (HBVr) in patients with hematological malignancies who have been exposed to HBV infection. However, informative data regarding the risk of Rituximab on HBVr among patients with rheumatoid arthritis (RA) is unsettled.

**Methods:** We retrospectively reviewed RA patients in Taipei Veterans General Hospital and patients with available HBV markers before rituximab administration were enrolled. HBVr was defined as either an increase in HBV DNA >1 Log10 IU/ml compared with baseline or threefold increase in serum alanine aminotransferase (ALT) level accompanied with HBV DNA > 20,000 IU/mL in cases without baseline HBV viral load, or hepatitis B surface antigen (HBsAg) reverse seroconversion in HBsAg-negative cases.

**Results:** Eighty-eight patients were enrolled; 83 (94.3%) were female and the mean age at diagnosis was 54.2 years (Table 1). They received a median of 9 cycles of RTX (range 1-20) without anti-HBV prophylaxis. Four patients were positive for hepatitis B surface antigen (HBsAg) before rituximab administration (Figure 1). In 84 HBsAg-negative patients, 46 were positive for anti-hepatitis B core antigen (anti-HBc), 19 were negative for anti-HBc, and 19 did not have anti-HBc data. Among 46 HBsAg-negative/anti-HBc-positive patients, 31 were hepatitis B surface antibody (anti-HBs)-positive, 6 were anti-HBs-negative, and 9 did not have anti-HBs data. During 10,877 person-months of follow-up, 5 (5.7%) patients developed HBVr. HBVr occurred in 2 (50.0%) of 4 HBsAg-positive patients and the time to HBVr was 40 and 74 months after the start of rituximab, respectively. Among 31 HBsAg-negative/anti-HBc-positive/anti-HBs-positive patients, a decrease in anti-HBs levels was observed in 21 (67.7%) cases after rituximab treatment and anti-HBs disappeared in 6 (19.4%) patients. Three (50.0%) of anti-HBs-disappear patients seroreverted to HBsAg-

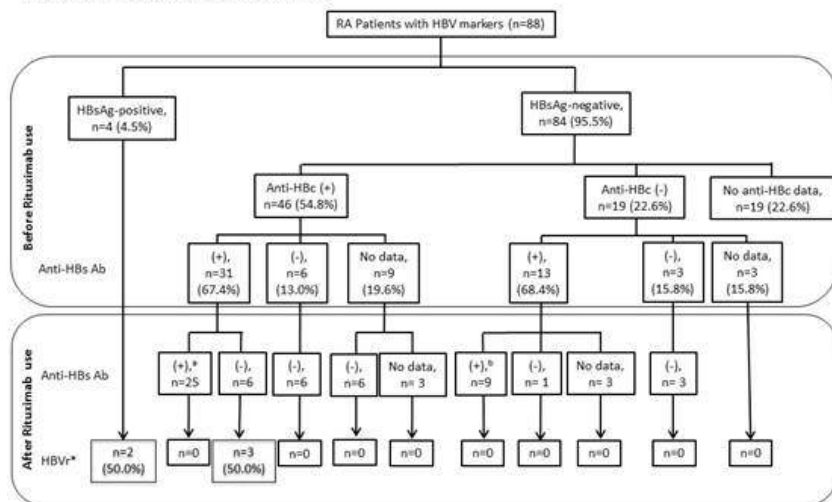

positive and all of them developed HBVr later with the mean time from the start of rituximab to HBVr was 59.3 months (range 56-62months).

**Conclusion:** HBVr is common in HBsAg-positive RA patients under rituximab therapy. More importantly, rituximab may lead to high disappearance rate of anti-HBs in resolved HBV cases, resulting in high risk of HBVr. Monitor HBV status frequently is critical in RA patients who have been exposed to HBV infection during rituximab treatment.

Table 1 Characteristics of patients with RA on rituximab

	Patients
	N = 88
Age of diagnosis (years, mean $\pm$ SD)	54.2 $\pm$ 12.3
Female (n)	83 (94.3%)
Duration before rituximab use (years, mean $\pm$ SD)	5.4 $\pm$ 2.1
<b>Laboratory profile</b>	
ESR (mm/hour)	56.1 $\pm$ 33.4
CRP (mg/dL)	2.6 $\pm$ 2.7
Rheumatoid factor positive	78/88 (88.6%)
Anti-CCP antibody positive	45/50 (90.0%)
DAS28 (ESR)	6.8 $\pm$ 0.8
<b>Comorbidity</b>	
Sjogren's syndrome	30 (34.1%)
SLE	7 (8.0%)
Interstitial lung disease	14 (15.9%)
Autoimmune hepatitis	1 (1.1%)
Pulmonary artery hypertension	2 (2.3%)
Follow up (years, mean $\pm$ SD)	10.3 $\pm$ 1.6

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a systemic inflammatory disease that affects various organs including the lung. The pulmonary involvement is critical for prognosis of the patients and decision of the treatment. Moreover, the pulmonary involvement includes many pulmonary abnormalities such as interstitial lung disease (ILD), nodular lesions and airway disease (AD) and shows various patterns in the progression. Treatment of RA patients, according to the risk factors for the newly developing / worsening pulmonary abnormalities would be required. However, it is not fully identified what the risk factors are. The aim of this study is to identify the risk factors for newly developing pulmonary abnormalities in RA patients under the bDMARDs therapy.

**Methods:** Subjects were consecutive 208 RA patients started treatment with bDMARDs from 2004 to 2015 in our department and received HRCT scan before and after starting the therapy. Pulmonary abnormalities were classified into 4 categories (ILD, nodular lesions, AD and other) and 20 lesions such as ground-glass opacity, reticular pattern, bronchiolitis and bronchiectasis and were recorded in their existence and distribution. Based on the characteristics, clinical features and HR-CT findings, we identified risk factors for newly developing / worsening pulmonary abnormalities which were defined by HRCT findings. For this purpose, logistic regression analysis was conducted.

**Results:** Subjects were M/F; 64/144, mean age; 59.2 year-old and disease duration; 13.1 years. Pulmonary lesions were found in 146 (70.2%) of RA patients before bDMARDs. (ILD; 38.9%, nodular lesions; 21.6%. AD; 55.3%). AD was commonly found as a common pulmonary lesion in the most of patients with pulmonary abnormalities.

Sequential CT was conducted, the reasons for which were respiratory symptom such as cough in 40% and regular follow up of chest abnormalities in 60%. The intervals of the CT scans are 3.26±2.61 years. Newly developing/worsening pulmonary abnormalities were observed in 13.8 /100 person years. The incidence of ILD, nodular lesions, and AD were 8.5, 2.9 and 6.5 /100 person years, respectively.

The risk factors for newly developing / worsening pulmonary abnormalities were older age, older onset, and pre-existing pulmonary diseases (Odds 5.31), particularly AD (Odds 2.41). MTX was the protective factor (Odds 0.53). Multiple logistic analysis has shown that AD was the only an independent risk factor for newly developing/worsening pulmonary abnormalities(Odds 2.51).

Nine patients died of respiratory failure. The risk factors for fatal respiratory failure were pre-existing pulmonary lesions which were ILD (Odds 28.5) and AD (Odds 8.5), but not nodular lesions. Moreover, newly developing/worsening ILD was the risk factor (Odds 12.3), but not emerging nodular lesions or AD were. In addition, sero-positivity or treatment were not identified as risk factors.

**Conclusion:** Newly emerging/ worsening pulmonary abnormalities were observed in approximately 14/100 person-years under bDMARDs. The patients with pre-existing pulmonary lesions, particularly ILD and AD should be observed carefully for newly emerging/ worsening ILD.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

HCV is a major public health problem affecting approximately 2-3% of the world's population with about 130-150 million people chronically infected worldwide. Egypt has the highest HCV prevalence in the world, estimated to be 15% in some studies. Despite this unique HCV epidemic, few studies were done to estimate the prevalence of HCV in Egyptian patients with rheumatoid arthritis (RA). The aim of the current study was to estimate this prevalence.

### Methods:

This was a cross sectional study that included 300 Egyptian patients diagnosed with RA according to the ACR/ EULAR 2010 classification criteria. Patients were enrolled from the rheumatology outpatient clinics at Ain Shams University Hospitals and Ahmed Maher Teaching Hospital, Cairo, Egypt, from June 2015 till February 2017. Patients < 18 years old, with end stage renal disease on dialysis, or with other connective tissue diseases were excluded from the study. All participants were tested for HCV antibodies using 3<sup>rd</sup> generation ELISA and positive patients were tested for HCV RNA by Real Time PCR. DAS28 was used for assessment of RA disease activity.

### Results:

HCV antibodies were detected in 15% of patients (45/300), of which 80% were positive for HCV RNA (36/45). The ratio of RNA to antibody is higher compared to general population (66%). Prevalence of HCV antibodies was higher in females than males (15.3% and 12.5%, respectively) and in patients living in rural areas than those living in urban areas (16.7% and 14.6%, respectively). HCV prevalence increased sharply with age to reach 50% in patients older than 60 years (12/24). There was a statistically highly significant increase ( $p < 0.001$ ) in the mean age and RA disease duration in the HCV antibodies positive group (51.1 vs. 41.2 and 11.7 vs. 5.2 years, respectively). According to DAS28; only 33 patients (11%) were in remission. The majority of patients (62.7%) had high disease activity. There was no statistically significant difference ( $p > 0.05$ ) in DAS28 between HCV antibodies positive and negative patients.

While the majority of the patients used a combination of different DMARDs, 14% used a single drug (42/300). The medications used for treatment of RA in the studied patients are shown in **Table (1)**. There was a statistically highly significant decrease in the use of NSAIDs and methotrexate ( $p < 0.001$ ), while there was a statistically highly significant ( $p < 0.001$ ) increase in the use of sulfasalazine in patients positive for HCV antibodies.

### Conclusion:

We estimated that the prevalence of HCV antibodies in Egyptian patients with RA is 15%. Given this exceptionally high prevalence, we recommend screening of all RA patients in Egypt for hepatitis C at diagnosis and before starting treatment. Our results also suggest that RA patients have a lower spontaneous clearance of the initial HCV infection.

**Table (1): Characteristics of the total study population and HCV antibodies positive and negative patients:**

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporosis, diabetes, hypertension and cardiovascular diseases are the most threatening glucocorticoid (GC)-related comorbidities in rheumatoid arthritis (RA), both from the patients and rheumatologists perspective<sup>1</sup>. The aim of the study was to evaluate gender differences in the prevalence of GC-related comorbidities in patients with RA in the National Database of the German Collaborative Arthritis Centres.

**Methods:** Cross-sectional data of patients with RA with valid information on body mass index (BMI) and comorbidities (n=4,438) were analysed regarding the prevalence of osteoporosis, diabetes, cardiac disease and hypertension in women and men, stratified by age, BMI, disease activity (DAS28), education, smoking and GC use (no/≤5/>5-7.5/>7.5mg prednisone-equivalent per day). Gender differences were compared to those in the age-matched general population. Uni- and multivariable logistic regression analysis was applied to examine background risks in women and men.

**Results:** Data of 3,353 women and 1,085 men were available for analysis. Osteoporosis was more frequent in female (17.9% vs. 9.2%) while diabetes (10.3% vs. 15.9%), cardiac disease (9.4% vs. 18.3%) and hypertension (36.4% vs. 42.3%) were more often reported in male patients. Compared to the general population, the gender difference was 2.5 times higher for hypertension, 1.8-fold for diabetes, 1.2-fold for cardiac disease and 0.9-fold for osteoporosis. The differences persisted after stratification for GC use, disease activity, age BMI, smoking and education (Table 1). After controlling for these factors in multivariable analysis, women still had more osteoporosis (OR 2.06 [1.59-2.68]) and less diabetes (OR 0.65 [0.52-0.81]) or cardiac disease (OR 0.48 [0.38-0.61]).

**Conclusion:** After controlling for GC use and dosage, age, lifestyle and socioeconomic factors, gender was independently associated with comorbidities that may be GC-related. We found more cardiac diseases, hypertension and diabetes in men and more osteoporosis in women. Except for osteoporosis, the gender differences for these comorbidities were higher in RA patients than in the general population.

## Joint Surgery in Rheumatoid Arthritis 1980-2013: A Population-Based Study to Identify Risk Factors and Time Trends in Incidence

**Michael Richter**<sup>1</sup>, Cynthia S. Crowson<sup>2</sup>, Eric L. Matteson<sup>3</sup> and Ashima Makol<sup>3</sup>, <sup>1</sup>Internal Medicine, Mayo Clinic, Rochester, MN, <sup>2</sup>Department of Medicine, Division of Rheumatology, Mayo Clinic, Rochester, MN, <sup>3</sup>Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Background/Purpose:** Over the past two decades, the use of disease modifying anti-rheumatic drugs and treat-to-target strategies have dramatically improved the outcomes of patients with rheumatoid arthritis (RA). This has led to a decline in the rate of joint surgery, which is traditionally reserved for treatment of refractory patients aiming to improve function and quality of life. The goal of this study was to identify risk factors for joint surgery in RA and assess trends in surgery rates over time.

**Methods:** A retrospective medical record review was performed of all orthopedic surgeries following first fulfilment of 1987 ACR criteria for adult-onset RA in 1980-2013 among residents of a geographically defined area with follow up until death, migration or July 1, 2016. Surgeries were classified as small (wrist, hand, foot) or large (shoulder, elbow, hip, knee, ankle) joint. Risk factors were examined using Cox models adjusted for age, sex and calendar year of RA incidence.

**Results:** A total of 1077 patients with RA (mean age ( $\pm$ SD) 55.9 $\pm$ 15.6 years, 69% female, 66% RF and/or ACPA positive) were followed for a median follow-up of 10.7 years during which 112 and 204 underwent at least one joint small and large joint surgery, respectively. Results of risk factor analysis for joint surgery at RA incidence and during follow up are shown in table 1. Advanced age (per 10 year increase) was associated with an increased risk for both small joint surgery (SJS) and large joint surgery (LJS). Other significant risk factors at the time of RA incidence included rheumatoid factor and anti-CCP antibody positivity for both SJS and LJS, and BMI $\geq$ 30 kg/m<sup>2</sup> for LJS. Significant risk factors for SJS and LJS at any time during follow-up included the presence of radiographic erosions or destructive changes, large joint swelling, and methotrexate use. The use of glucocorticoids was associated with increased risk of LJS only. There was a decreased rate of SJS by calendar year of incidence (1994-2013 vs 1980-1993) (hazard ratio 0.53; p=0.001), and a significant decline in SJS incidence after 1995 with less than 1% of patients having surgery each year by the end of the study period (Figure). There were no significant trends in LJS over time.

**Conclusion:** There has been a significant decline in the incidence of SJS in RA but no change in the rate of LJS. Positive serologies, rheumatoid nodulosis, and radiographic erosions are strong predictors for SJS, but are also associated with increased risk for LJS. Increasing age and obesity are predictive of LJS, similar to the general population.

**Table 1.** Risk factors for joint surgery at RA incidence

Characteristics at RA incidence	Small joint surgery		Large joint surgery	
	Hazard ratio* (95% CI)	P value	Hazard ratio* (95% CI)	P value
Age (per 10 year increase)	0.84 (0.74, 0.96)	0.009	1.29 (1.17, 1.42)	<0.001

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

RA patients are at a high risk of osteoporosis and fracture, in part due to frequent glucocorticoid use. Despite recommendations from ACR guidelines on prevention of glucocorticoid-induced osteoporosis (GIOP), use of anti-

osteoporotic medication (AOM) in RA patients remains low. The current study aimed to analyze trends in AOM use over the past 10 years among early RA patients meeting guidelines for GIOP prevention, and to examine predictors of guideline adherence among this population.

### **Methods:**

Data were obtained from a multi-center prospective cohort study of early RA patients. This analysis included participants over age 50, without a diagnosis of osteoporosis at baseline, with at least 6 months of follow up. GIOP guideline adherence was determined based on use of bisphosphonate or denosumab in patients receiving  $\geq 7.5$  mg prednisone daily for  $> 3$  months. Logistic regression was used to determine predictors of guideline adherence adjusting for age, gender, ethnicity, comorbidities, BMI, average glucocorticoid dose, and baseline DAS28-ESR.

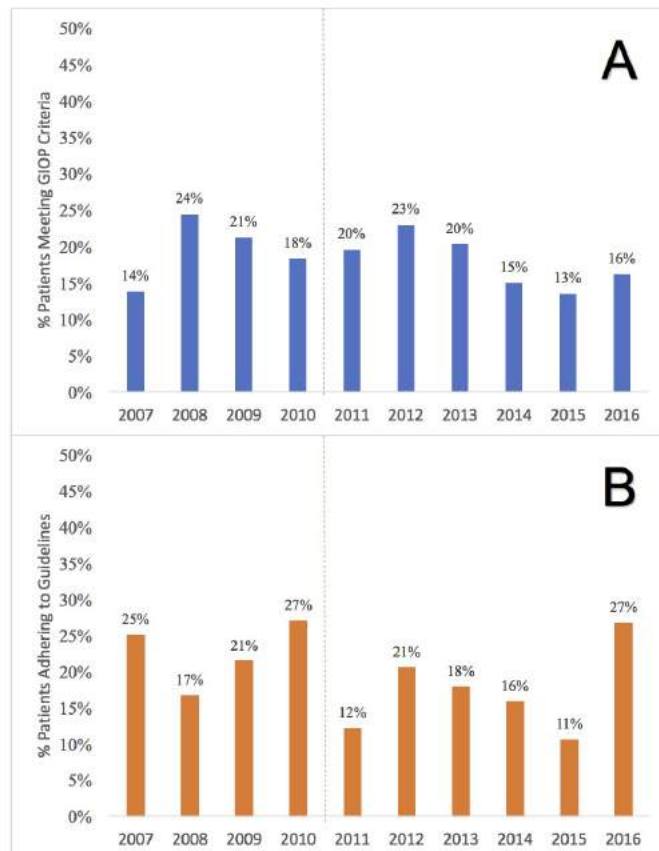

### **Results:**

1468 patients were included with mean age 63 (9), 933 (64%) were female, and mean (sd) DAS28-ESR was 5.0 (1.4). 282 (19%) patients received  $\geq 7.5$  mg prednisone daily for  $> 3$  months, and this number decreased over time (Figure 1A). Overall, only 54 (19%) eligible patients received AOM (Figure 1B), and 105 (37%) received Vitamin D. Chi square analyses showed a significantly higher likelihood of AOM and Vitamin D use in patients on chronic glucocorticoids. In logistic regression analyses, baseline DAS28 significantly predicted guideline adherence, while BMI and glucocorticoid dose showed trends towards significance.

### **Conclusion:**

In this national early RA cohort, approximately 1 in 5 patients met criteria for GIOP prevention according to ACR guidelines. Chronic use of glucocorticoids did decrease over time, suggesting either less frequent use or faster tapering. Adherence to GIOP prevention guidelines was suboptimal and did not change over time. Higher disease activity was significantly associated with guideline adherence. Further research is needed to determine reasons for guideline nonadherence and to develop strategies to improve prevention of GIOP.

**Figure 1A.** The percentage of patients on  $\geq 7.5$  mg prednisone daily for  $> 3$  months by year of enrollment. Dotted line represents the publication of ACR guideline on GIOP prevention (2010). **Figure 1B.** The percentage of patients on  $\geq 7.5$  mg prednisone daily for  $> 3$  months by year of enrollment who also received prescription for bisphosphonate or denosumab.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Few studies have focused on analyzing infection risk in recent-onset rheumatoid arthritis (RA). The main objective of this study was to estimate the incidence of infections in patients with early RA, focusing on a multi-centre Canadian cohort of RA patients enrolled within 12 months of symptom onset.

**Methods:** All patients with early RA (<1 year) enrolled in the cohort were studied. Infections have been reported in a standardized manner by patients at yearly assessments. In each year, a patient was allowed to contribute more than one infection event, provided the event was a new or recurrent (not chronic) infection. From January 2007 to November 2015, we tabulated the total number of infections and generated incidence rates of infections with 95% confidence intervals (CI)

**Results:** A total of 1728 RA patients met study criteria and were followed for an average of 3.2 years. At the time of recruitment, mean (standard deviation, SD) age was 54.2 years (15.0), majority were Caucasian (N=1,419, 82.1%) and female (N=1,245, 72.0%). Mean symptom duration at cohort entry was 5.8 months (3.0). The mean Disease Activity Score 28 was 5.1 (1.4), Simplified Disease Activity Index 28.6 (15.2) and Clinical Disease Activity Index 27.1 (14.4). One third (571, 33%) of these patients were on steroids at baseline and most (N= 1,566, 90.6%) were on DMARDs, with 1,262 (73.0%) patients having been exposed to MTX. Biologics were used only by 41 (2.37%) patients at the time of cohort entry.

Over the study interval, we recorded 452 infections over a total of 5,525 person-years (81.8 events per 1000 patient-years) and over a quarter of these (125 events) involved hospitalization. Eighty four (18%) of all infectious episodes were pneumonia (15.2 events per 1,000 patient years), with half of these pneumonias being associated with a hospitalization.

**Conclusion:** Reported infections in this Canadian cohort with early RA was not negligible. Half of reported pneumonia events in early RA involved hospitalization.

### ABSTRACT

Impact of the Pattern of Interstitial Lung Disease on Mortality in Rheumatoid Arthritis: A systematic review and meta-analysis

**Background/Purpose:** Interstitial lung disease affects 10-15% of rheumatoid arthritis (RA) patients and carries poor prognosis with a median survival of less than 3 years following diagnosis. ILD can be classified into distinct patterns based on computed tomography or lung histopathology, with the usual interstitial pneumonia (UIP) pattern being the most common. While some studies have shown the UIP pattern to have a higher mortality risk, other studies have not found this association. The purpose of this study was to complete a systematic review and meta-analysis of the association between RA-ILD pattern and mortality risk.

**Methods:** Pubmed and Embase databases were searched for relevant, published articles from their inception to March 1<sup>st</sup>, 2017 using the PRISMA guidelines. The MeSH terms used for the search were “rheumatoid arthritis” and “interstitial lung disease”. Inclusion criteria were assessment of ILD pattern (either radiographically or based on histopathology) as a predictor of mortality in RA patients. Studies of connective tissue disease ILD without separate analysis of RA patients were excluded. No exclusions were made based on study design, quality of the study or duration of follow-up. Data was pooled using a random effects model with inverse variance weighting. Cochran’s Q statistic and I<sup>2</sup> test were used to test for heterogeneity among the studies. The Newcastle-Ottawa scale (NOS) was used to assess the risk of bias among the included studies.

**Results:** Five studies fulfilled inclusion and exclusion criteria. Two of the five studies found UIP pattern to be significantly associated with worse survival. In a meta-analytic approach, the UIP pattern was associated with a 2-fold increased risk of mortality (pooled risk ratio=2.03; 95% confidence interval=1.13, 3.66) (Figure 1). The results of the meta-analysis were heterogeneous, I<sup>2</sup>=67% (p=0.02), with risk ratios for the UIP pattern ranging from 1.09 to 8.62. Three of the five studies were of high quality based on the NOS.

**Conclusion:** Using a meta-analytic approach, we found UIP pattern to be associated with higher mortality risk. However, there was substantial heterogeneity between studies and a limited number of studies investigating ILD pattern and mortality risk. Further study of mortality risk in RA-ILD is needed with standardized assessment of other RA and patient related factors such as age, gender, smoking history, autoantibody expression, disease activity and pulmonary function tests.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Patients (pts) with RA are at increased risk for herpes zoster (HZ), which is further increased with tofacitinib treatment.<sup>1</sup> In a subset of pts in the ORAL Strategy<sup>2</sup> randomized controlled trial (RCT), we evaluated the effect of live zoster vaccination (LZV) on HZ rates in methotrexate inadequate responder (MTX-IR) pts with RA who received tofacitinib with or without MTX, or adalimumab (ADA) with MTX.

**Methods:** ORAL Strategy (NCT02187055) was a Phase 3b/4, 1-year, triple-dummy, active-comparator-controlled RCT. Pts were randomized 1:1:1 to receive tofacitinib 5 mg twice daily (BID; tofa mono), tofacitinib 5 mg BID + MTX (tofa+MTX), or subcutaneous ADA 40 mg every other week + MTX (ADA+MTX); target MTX dose was 15–25 mg/week. In countries where LZV was available, pts who were  $\geq 50$  years old received LZV at the investigator's discretion, 28 days before the first dose of study drug. HZ incidence rates (IR; pts with events per 100 pt-years) and 95% confidence intervals (CI) were calculated for each treatment arm and for vaccinated vs non-vaccinated pts.

**Results:** Of 1146 pts who received study drug (mean age: 50.1 years old), 216 received LZV (proportion of pts who received LZV by treatment group: tofa mono: 18.0%; tofa+MTX: 19.9%; ADA+MTX: 18.7%) 28 days before randomization in this RCT; 30 pts self-reported prior vaccination (Table). No pts had zoster-like lesions within 42 days of vaccination; 1 pt had vaccination site erythema. In the overall study population, HZ IR was similar between tofa mono and ADA+MTX, and numerically higher (overlapping CIs) with tofa+MTX. IRs were generally similar for pts who received LZV (18.8% of pts were vaccinated) vs those who did not (81.2%) (Table). Overall, 18/1146 pts had HZ. Among vaccinated pts, 3 (1.4%) had HZ: no events were serious, and 1 (0.5%) event was multidermatomal (with tofa mono). Among pts not vaccinated, 15 (1.6%) had HZ: there were 2 (0.2%) serious HZ events (tofa+MTX: n=1; ADA+MTX: n=1) and 3 (0.3%) multidermatomal events (tofa mono: n=1; ADA+MTX: n=2).

**Conclusion:** In MTX-IR pts with RA, LZV was well-tolerated. HZ IR was numerically similar between tofa mono and ADA+MTX, and higher with tofa+MTX. HZ rates were generally similar in pts who received LZV vs those not vaccinated. LZV has shown efficacy in prevention of HZ in 51% (pts  $\geq 60$  years old) and 70% (50–59 years old) of immunocompetent adults.<sup>3</sup> Efficacy of LZV could not be fully evaluated as a minority (<20%) of pts received LZV and not all geographic regions studied in other tofacitinib studies were represented.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In rheumatoid arthritis (RA), a strategic approach to achieve low-disease activity or remission is now recommended. Controlling joint damage is thus an important concern in daily clinical practice and models are needed to assess predictive variables associated with radiographic progression. Nevertheless, the role of treatments regarding to this event has rarely been questioned and none of models built so far have properly considered exposition to treatments. Therapeutic regimens have often been described as a binary variable or as a mean dose which do not represent correctly drug exposure. In RA, treatment is composed of two types of drugs undergoing multiple switches and dose adjustments: 1) DMARDs and 2) Corticosteroids. If the risk of radiographic progression is related to factors of severity at diagnosis, predictive models must consider variables reflecting the complexity of drug exposure.

This study aims to develop a predictive model of five-year radiographic progression considering both baseline characteristics and time-varying drug exposure to corticosteroids and DMARDs.

**Methods:** Our study population was composed of 403 patients of the ESPOIR cohort with radiographic data at inclusion and at five years of follow-up and classified as RA at the inclusion visit according to the 1987 ACR and 2010 ACR/EULAR criteria. Radiographic progression was defined at 5 years as a change in the Sharp/van der Heijde score (vSHS)  $\geq 5$ . A predictive model considering baseline characteristics and treatments as weighted cumulative exposure (WCE) variables was built. A WCE variable represents drug exposure as the weighted sum of past doses and is able to model complex profile of therapeutic regimens. It allowed the estimation of risks associated to different profiles of drug exposure with adjustments on baseline characteristics.

**Results:** Radiographic progression occurred in 35.5% (143/403) patients. The multivariate model included ACPA status, ESR, swollen joint count and erosion score as baseline predictors and corticosteroids, MTX/LEF and biological DMARDs (bDMARDs) as WCE variables. These baseline characteristics were consistent with the literature. Thirty-six months exposure to bDMARDs had a significant protective effect on radiographic progression. On the other hand, a significant deleterious effect was described for recent cumulative exposure (3 months or less) to corticosteroids (Table 1).

**Conclusion:** The analysis of therapeutic regimens as WCE variables brought new insights on the role of DMARDs and corticosteroids on radiographic progression. If the significant protective effect of bDMARDs has been confirmed, considering corticosteroids as a WCE variable demonstrated their deleterious effect on radiographic progression.

Despite cautious consideration, these results contradict many clinical trials in which corticosteroids have been found protective.

Table 1: Odds Ratio (with 95% Confidence interval) for the association of baseline variables and different patterns of drug regimen with five-year radiographic progression

Variables	Pattern use	Reference	Adjusted OR (95% CI)
Baseline variables	ACPA positivity	—	2.72 (1.63 : 4.48)
	ESR, mm/h	—	1.03 (1.00 : 1.05)
	Swollen joint count >14	—	3.14 (1.89 : 4.23)
	Erythrocyte	—	1.16 (1.08 : 1.25)
Treatment WCE variables	DMARDs	Current user	1 DoseQ, for past month
			1 DoseQ, for past 3 months
			1 DoseQ, for past 12 months
			1 DoseQ, for past 24 months
			1 DoseQ, for past 36 months
	Corticosteroids	Non-User	0.09 (0.04 : 1.00)
			0.03 (0.02 : 1.07)
			0.44 (0.13 : 1.40)
			0.17 (0.03 : 1.09)
			0.15 (0.03 : 0.88)
			1.08 (1.01 : 1.16)
			1.23 (1.02 : 1.48)
			1.40 (1.01 : 1.95)
			3.87 (1.04 : 14.44)
			1.20 (0.75 : 1.91)
			2.05 (0.32 : 13.28)
			1.07 (0.74 : 1.54)
			1.30 (0.30 : 5.87)

The first column identifies the drug, the second describes a clinically relevant pattern of drug use in RA, the third describes the comparator pattern of drug exposure. Bold OR indicates a significant association of drug exposure with five-year radiographic progression. To standardize exposure, DoseQ are ratio between received dose and recommended dose of each drug.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017  
**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities  
**Session Type:** ACR Poster Session C  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To compare the recommendations of clinical practice guidelines (CPGs) and consensus statements (CSs) regarding the management of rheumatoid arthritis (RA) in patients with cancer. We identified similarities, discrepancies, and areas not covered and summarized the key areas for future research.

**Methods:** We searched electronic databases, guideline registries and relevant websites for CPGs and CSs on the management of RA in patients with cancer. Two pairs of reviewers independently selected studies and appraised selected papers according to the 23-item Appraisal of Guidelines for Research and Evaluation (AGREE) II Instrument. Cancer-specific guidelines per drug, cancer type and time frame were extracted and compared.

**Results:** Of 2,980 citations, 51 guidelines were included from 17 countries and seven international collaborations. Of the 29 that reported funding sources, 15 were financed by the pharmaceutical industry, eight by national or international agencies and six by other means. Scores for the AGREE II domains ranged from 32% for 'Applicability' to 85% for 'Scope and Purpose' with the other domains scoring 41 to 66%. Recommendations were categorized as i) malignancy risk associated with RA disease modifying anti-rheumatic drugs (DMARDs), ii) management of RA in de novo malignancies, and iii) management of patients with RA and cancer history. Eleven guidelines discussed the risk of cancer associated with DMARDs and while most note no or unknown increased risk, some urged caution due to suspected increased risk of non-melanoma skin cancer, melanoma and lymphoma. Nine papers referred to the diagnosis of a new malignancy. All agreed that therapy must be re-evaluated: biologic DMARDs should unequivocally be ceased and, while some conventional DMARDs such as sulfasalazine, hydroxychloroquine and gold salts may be continued, cyclosporine, methotrexate and leflunomide must be reconsidered. Three guidelines also required reporting new cancers to pharmacovigilance units. All mentioned that decisions regarding resumption of treatment must be made on a case-by-case basis. Almost all guidelines (46/51) made some mention of past history of cancer. They differed in terms of the drugs evaluated, the cancer types included (solid tumors, skin cancers, lymphoproliferative and/or hematological diseases) as well as the time since treatment (not specified, less than 5 and/or 10 years). The consensus was that caution should be exercised, particularly in the first five years and it is best to consult with the treating specialist before coming to a decision with the patient. Tumor Necrosis Factor inhibitors (TNFi) and cyclosporine are contraindicated in all cases while some conventional DMARDs and non-TNFi agents, particularly rituximab can be used with caution within the five-year time frame.

**Conclusion:** The guidelines for treatment of RA reviewed often failed to meet expected methodologic criteria varying in quality as well as with respect to the question of how to treat RA in patients with cancer. Since there is a lack of evidence, research is needed focusing on the daily practice of healthcare providers or expert opinion to guide and standardize the management of these patients.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Background/Purpose:** To examine humoral and cellular immune responses induced by a live attenuated herpes zoster (HZ) vaccine in patients with rheumatoid arthritis (RA) compared with osteoarthritis (OA) patients.

**Methods:** we performed an observational study of a live attenuated HZ vaccine in 41 RA patients receiving conventional disease modifying anti-rheumatic drugs (DMARDs) and/or low-dose glucocorticoids (median 60 years-old, 92.7% female), 28 OA patients (median 62 years-old, 85.7% female). Blood samples were obtained before and at 12 weeks after HZ vaccination. Immunogenicity was assessed using varicella zoster virus (VZV)-specific interferon gamma (IFN- $\gamma$ ) enzyme-linked immunospot (ELISPOT) assays and an in-house enzyme-linked immunosorbent assay.

**Results:** No vaccinated patients developed HZ during the follow-up period (median, 1.6 years). The HZ vaccine induced a significant increase in the VZV-specific ELISPOT spot-forming units and anti-VZV immunoglobulin G antibodies in both RA and OA patients. The number of spot-forming units was lower in RA patients than in OA patients both at baseline and at 12 weeks after vaccination (Figure). The disease activity score 28 (DAS28) was similar at baseline and at 12 weeks after vaccination. However, six RA patients (15%) experienced a flare-up (increase in DAS28 > 1.2) during the 12 weeks. The HZ vaccine induced VZV-specific cellular and humoral responses in RA patients.

**Conclusion:** Although RA patients showed a weaker vaccine-induced VZV-specific cellular immune response than OA patients, the HZ vaccine may be considered in RA patients receiving conventional DMARDs and/or low dose glucocorticoids.

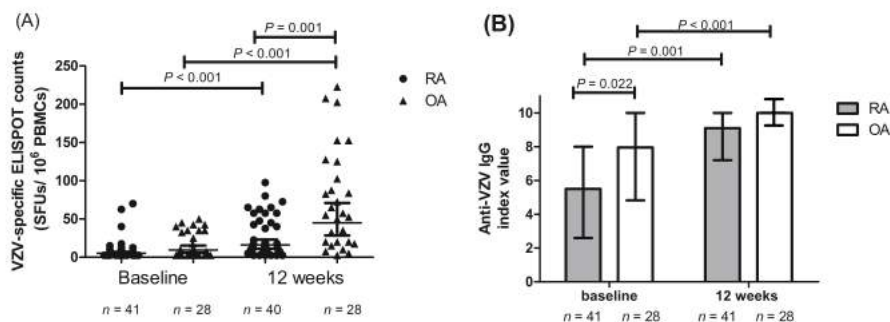

Figure. Vaccine-induced cellular and humoral immune response to varicella zoster virus (VZV) in patients with rheumatoid arthritis (RA) and osteoarthritis (OA).

(A) Number of interferon- $\gamma$  enzyme-linked immunospot (ELISPOT) spot-forming units (SFU) for VZV stimulation (according to time point) for patients with RA (circle) and OA (triangle) after herpes zoster vaccination.

(B) Assay of anti-VZV immunoglobulin G antibodies in serum from RA and OA patients at baseline and at 12 weeks after vaccination.

Data are expressed as the median and interquartile range. Statistical significance was calculated using the Wilcoxon signed-rank test and Mann-Whitney U test as appropriate. *n*, number of subjects who had tested.

## Bilateral Femoral DXA Scan in Patients with Rheumatoid Arthritis

**Marco Massarotti**<sup>1</sup> and Marwan Bukhari<sup>2</sup>, <sup>1</sup>Rheumatology, Royal Lancaster Infirmary, University Hospital of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, <sup>2</sup>Royal Lancaster Infirmary, Lancaster, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** RA is an independent risk factor for osteoporosis and fractures. The diagnosis of osteoporosis is based on T-score at lumbar spine or hip and conventionally femoral BMD is measured at left hip. RA could affect hip BMD results as a consequence of impaired mobility and gait abnormalities related to the disease itself. Since treatment decision in patient with RA is frequently based on the FRAX tool score and it relies on hip BMD results, measuring the left hip only we could miss some patient with low BMD worth to be started on treatment.

Our aim was to assess if measuring BMD at both hips could increase the number of RA patients diagnosed with osteoporosis/osteopenia and potentially to be started on treatment.

**Methods:** RA patients who underwent a DXA scan at Royal Lancaster Infirmary between June 2006 and October 2015, and had both hips scanned were included in our analysis. We compared the prevalence of osteoporosis/osteopenia pending on the results of each hip using simple statistics.

**Results:** 1527 patients were included in our analysis. 1207 (79%) were female, mean age was 64.3 (SD 11.6), BMD levels (neck and total hip) were 0.85 g/cm<sup>2</sup> (SD 0.15) and 0.90 g/cm<sup>2</sup> (SD 0.17) at the left hip and 0.85 g/cm<sup>2</sup> (SD 0.15) and 0.90 (SD 0.17) at the right hip.

According to left hip results (Neck or Total Hip) 198 patients (13%) were classified as osteoporotic and 621 (40.1%) as osteopenic, while according to right hip results 183 patients (12%) were classified as osteoporotic and 598 (39.2%) as osteopenic.

Overall 245/1527 (16%) patients could be diagnosed as osteoporotic with 136/245 patients having BMD levels in the osteoporotic range at both hips (55.5%), 62/245 patients (25.3%) at the left hip only and 47/245 patients (19.2%) at right hip only. No significant differences in terms of age, sex, BMI and steroid exposure were found among patients with discordant results between the two hips. Surprisingly a higher frequency of previous fragility fractures was observed in the group with osteoporosis at the right hip only compared to the one with osteoporosis at the left hip only (28/47 vs 23/62,  $p = 0.020$ ).

**Conclusion:** Measuring BMD at both hips could increase the number of RA patients diagnosed with osteoporosis or osteopenia and consequently the number of patients started on bone sparing treatments. This strategy could eventually lead to a decrease of fragility fractures among patients with RA.

	OP L hip +/R hip - OP L hip -/R hip + p		
Patients	62	47	
Age (Mean +/- SD)	69 +/- 12	71 +/- 11	n.s.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Only few studies have addressed the prognostic impact of chronic obstructive pulmonary disease (COPD) among patients with rheumatoid arthritis (RA), although both diseases are frequent, and smoking is a shared risk factor. The purpose is to estimate the burden of COPD among RA patients and the subsequent mortality.

**Methods:** We included patients who had been assigned a first-time diagnosis of RA in the Danish National Patient Registry between 2004 and 2016. RA patients with COPD were matched for birth year, gender, and age at RA diagnosis with RA patients without COPD. Vital status for all patients was obtained from the Civil Registration System. Mortality risks were assessed using Kaplan-Meier mortality curves. Adjusted hazard rate ratios (aHRRs) for death with 95% confidence intervals (CIs) were estimated using Cox regression models. Adjustment was made for seropositive RA and Charlson Comorbidity Index (CCI).

**Results:** The study population included 31,333 individuals with RA. 3,254 of those (10.4%) had a diagnosis of COPD and were matched to 9,706 RA patients without COPD. The mortality risks in RA patients with COPD and RA patients without COPD within 0-2 months were 3.2% and 0.5% (aHRR = 7.3, CI 4.9-11.0), 4.5% and 1.5% within 2-6 months (aHRR = 3.0, CI 2.3-3.9), and 59.3% and 39.8% within 0.5-10 years (aHRR = 2.1, CI 1.9-2.1).

**Conclusion:** The mortality risk in RA patients with COPD was significantly increased compared with matched RA patients without COPD. The relative mortality risk was most pronounced within the first two months after both diagnoses had been assigned.

# Rheumatoid Arthritis Have Lower Glomerular Filtration Rate Compared to Healthy Population: Role of Inflammation

**Suad Hannawi**<sup>1</sup> and Issa Al Salmi<sup>2</sup>, <sup>1</sup>Rheumatology, Asst.Prof, Dubai, United Arab Emirates, <sup>2</sup>Prof, Muscat, Oman  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Rheumatoid Arthritis-(RA) is associated with subclinical kidney impairment which contributes to increase mortality and morbidity. The role of inflammation on kidney function in inflammatory arthritis is not well studied. The purpose of this study is to investigate associations between estimated-glomerular-filtration-rates(eGFR), traditional cardiovascular risk factors, and markers of inflammation in RA compared to healthy controls.

## Methods:

Participants were recruited from a specialized rheumatology clinic at Ministry of Health and Prevention of UAE, from January 2013 to January 2016. Healthy subjects recruited from the community through brochure advertisement. The Modification-of-Diet-in-Renal- Disease-Study-MDRD-formula was used to calculate the eGFR. ttest and compare laboratory values and kidney function parameters between two groups. Linear regression analysis used to look for the correlation between the eGFR and each of the traditional cardiovascular risk factors and inflammatory markers.

## Results:

98 RA-patients and 82-controls were recruited. None of the participants has history of diabetes, atherosclerosis or kidney impairment. The mean age for total participants was  $49 \pm 13$  years (Min16 –Max 82). The mean eGFR of inflammatory arthritis patients was  $118 \pm 30$  ml/min (range 60 - 227) and  $128 \pm 37$  ml/min (range 62 – 286) for the controls. Patients and control had no significant difference in Systolic-SBP and diastolic-blood-pressure-DBP.

Inflammatory arthritis patients had lower GFR, albumin ( $P<0.001$ ), and total protein ( $p=0.03$ ) levels, and had higher ESR ( $P<0.001$ ), CRP ( $P<0.001$ ), and uric acid level ( $p=0.01$ ),

Negative linear relationships were found as follow: Among RA patients and controls; there was a negative linear relationship between GFR and each of: age of participants; ( $p<0.001$ , CI: -1.24, -0.40 for patients and  $p=0.01$ , CI: -1.82, -0.26 for controls, & SBP; ( $p=0.04$ , CI: -0.61, -.00 for patients and  $p=0.022$ , CI: -0.61, -0.05 for controls.

Among RA patients: GFR had a negative linear relationship with age of participants, age at RA onset ( $p=0.002$ , CI: -1.18, -0.29), dbp ( $p=0.002$ , CI: -1.24, -0.05), ESR ( $p=0.04$ , CI: -0.24,-0.01), CRP ( $p=0.02$ , CI: -0.47, -0.04), uric acid ( $p<0.001$ , CI -0.18, -0.05), and total protein ( $p=0.01$ , CI: -0.91, -0.16). There was a positive linear relationship between eGFR and albumin level ( $p=0.03$ ,  $p=0.14$ , 2.35),

## Conclusion:

non-traditional CVD risk factors such as inflammatory markers are associated with sub-clinical kidney injury in patients with RA. Inflammation is involved in the early stages of impaired kidney function in RA patients. Hence, anti-inflammatory therapies may be effective in slowing down the deterioration of kidney function in the arthritis diseases.

## In Rheumatoid Arthritis: Vitamin-D Deficiency Is an Outcome and a Cause of Subclinical Renal Impairment

Suad Hannawi<sup>1</sup> and Issa Al Salmi<sup>2</sup>, <sup>1</sup>Rheumatology, Asst.Prof, Dubai, United Arab Emirates, <sup>2</sup>Prof, Muscat, Oman

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Vitamin D deficiency is highly prevalent in patients with rheumatoid arthritis (**RA**), and it is linked to RA disease severity. Two steps of hydroxylation are required to activate vitamin-D, the first is carried out in the liver to be converted to 25-vitamin-D and then in the kidney to 1,25 vitamin-D; the active form. Subclinical kidney dysfunction is common in rheumatoid arthritis and might interfere with vitamin-D hydroxylation. This study investigates the relationship between vitamin-D level and kidney function in RA

### Methods:

Patient diagnosed by ACR 1988 criteria for RA. 25-vitamin D level was obtained. Estimated glomerular filtration rate (eGFR) calculated with Modification of Diet in Renal Disease (MDRD) formula. Univariate regression analysis was carried out to determine the relationship between 25-vitamin-D level and eGFR, other renal parameters, and the inflammatory markers

### Results:

55 rheumatoid arthritis patients were included for the study. The mean age was  $45 \pm 15$  year for female and  $46 \pm 21$  year for male. The mean 25-vitamin-D level was  $39 \pm 28$  nmol/l (normal range: 50-80). Mean eGFR was  $130 \pm 25$  ml/min/m<sup>2</sup>.

Univariate linear regression revealed a positive linear relationship between 25-vitamin-D level and weight of the patients ( $p=0.03$ , CI: 0.06, 1.04), body surface area ( $p=0.02$ , CI: 11-119), body mass index (BMI) ( $p=0.009$ , CI: 0.60, 4.00), and calcium level ( $p=0.02$ , CI: 7.25, 130). 25-vitamin-D level was negatively associated with eGFR ( $p=0.040$ , CI: -0.20, -0.01), microalbuminuria level ( $p=0.040$ , CI: -0.63, -0.01), CRP level ( $P=0.01$ , CI: -1.16, -0.16) and neutrophil count ( $p=0.03$ , CI: -1.67, -0.010).

### Conclusion:

The negative linear relationship between 25-vitamin D level and the eGFR indicates high level of 25-vitamin-D due to kidney inefficiency in converting 25-vitamin-D to an active form; 1, 25 vitamin-D. Extrarenal activation of vitamin D require a high level of 25-vitamin-D of more than 78 nmol/l (30 ng/ml) for sufficient activation. Vitamin-D receptors are present in most cells in the body and in the T and B lymphocytes. The active form of vitamin-D (1, 25 vitamin-D) is one of the most potent modulator of the immune system. Hence, the negative relationship between 25-vitamin-D and CRP indicate 25-vitamin-D deficiency role in exacerbation of the inflammatory status, and possibly in a further renal

function deterioration. Screening for 25-vitamin-D deficiency might be an important step to detect subclinical renal insufficiency. Vitamin-D supplement might help in ameliorating the inflammation of rheumatoid arthritis.

## **Rheumatoid Arthritis with Kidney Dysfunction Contributes to Higher Risk of Cardiovascular Disease Development**

**Suad Hannawi**<sup>1</sup> and Issa Al Salmi<sup>2</sup>, <sup>1</sup>Rheumatology, Asst.Prof, Dubai, United Arab Emirates, <sup>2</sup>Prof, Muscat, Oman

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Reduced kidney function render patients with RA rheumatoid arthritis (RA), have an increased risk of cardiovascular disease (CVD), particularly ischemic heart disease (IHD). This higher risk is not related primarily to traditional cardiovascular/atherosclerosis risk factors but to the presence of high inflammation associated with RA. Also, subclinical decreased kidney function has been identified as an independent risk factor for CV events. The potential impact of impaired kidney function on atherosclerosis in RA requires more elucidation. This study assess the role of kidney parameters, alongside inflammation and traditional cardiovascular risk factors in predicting CVD; as manifested by carotid intima media thickness (cIMT) among RA population.

### **Methods:**

68 patients with RA underwent measurement of cIMT and correlated it with kidney function parameters with adjustment for traditional CV risk factors and RA associated inflammation. Glomerular filtration rate (GFR) was estimated with the abbreviated Modification of Diet in Renal Disease formula. Linear regression determined the association between renal parameters and cIMT.

### **Results:**

cIMT was positively associated with 1-demographic characteristics: age of the participants ( $p<0.001$ ), & age at RA symptoms onset ( $p=0.001$ ). 2-traditional cardiovascular risk factors such as systolic blood pressure ( $p<0.001$ ), diastolic blood pressure ( $p=0.016$ ), triglycerid level ( $p=0.016$ ), and low density lipoprotein (LDL) ( $p=0.001$ ), and negatively with high density lipoprotein (HDL) ( $p=0.037$ ), 3-inflammatory markers such as erythrocytes sedimentation rate (ESR) ( $p=0.020$ ) and c-reactive protein (CRP) ( $p=0.020$ ), and 4-renal function parameters such as uric acid level ( $p=0.006$ ), urine microalbumin level ( $p=0.030$ ), and negatively with 24 hours urine creatinine level ( $p=0.020$ ) and glomerular filtration rate ( $p=0.008$ ).

### **Conclusion:**

Even subclinical kidney function in conjunction with traditional and non-traditional CVD risk factors work synergistically to accelerate atherosclerosis in RA population.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-TNF $\alpha$  drugs and several conventional disease-modifying anti-rheumatic drugs (DMARDs) such as methotrexate (MTX) have been involved in the development of Interstitial Lung Disease (ILD).

Our aim was to assess the efficacy and safety of Rituximab (RTX) in RA patients with ILD.

**Methods:** Retrospective multicenter study of RA patients with ILD treated with RTX. ILD was diagnosed by high-resolution computed tomography (HRCT). RTX was used at standard dose (1 g $\times$ 2 and premedication with 100mg iv Methylprednisolone for a six month interval. We assess the the following variables: a) 1-point change in the degree of dyspnea according to the Modified Medical Research Council (MMRC); b) Forced vital capacity (FVC) improvement  $\geq$ 10%; and improvement  $\geq$ 10% in DLCO; c) radiological changes in HRCT scan, and d) changes in the joint assessment measured by DAS28 score.

**Results:** We studied 32 patients (23 women /9 men) with ILD associated to RA. The mean age $\pm$ SD was 63.7 $\pm$ 10.1 years. The median [IQR] to progression of ILD previously RTX was 18 [6-43] months. They had received the following DMARDs previously; MTX (n=16), Leflunomide (LFN) (n=16) mycophenolate (MMF) (n=1) sulfasalazine (SSZ) (n=8), hydroxichloroquine (HCQ) (n=7), azathioprine (AZA) (n=3), gold salts (n=2), D-penicillamine (n=1),

cyclophosphamide (n=2). 14 patients had previously received biological drugs. Cyclic citrullinated peptide antibodies (CCPA) were positive in 29 cases (94%). Besides HRCT, the diagnosis of ILD was confirmed by biopsy in 12 patients. In 3 patients ILD was drug-related: MTX (n=3). RTX was prescribed as monotherapy (n=12) and combined with DMARDs (n=19). The DMARDs prescribed were: LFN (6), SSZ (2), MTX (7), HCQ (3), AZA (3) MMF (1). A significant improvement of the dyspnea was observed. FVC and HRCT showed an improvement in the period between 6 and 12 months. DLCO remained stable in the majority of the patients. DAS28 also improved

TABLE

	Baseline	3 months	6 months	12 months

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Amylin is a 37-amino acid peptide that is stored in pancreatic beta cells and is co-secreted with insulin. Amylin and insulin levels rise and fall in a synchronous manner. It is known that it is deficient in type 1 diabetes and relatively deficient in insulin-requiring type 2 diabetes. Similarly, chronic inflammation has been found to deteriorate insulin resistance (IR) and impair pancreatic beta cell function in rheumatoid arthritis (RA) patients. The aim of this study was to explore the role of amylin in the IR of RA patients.

**Methods:** Cross-sectional study that encompassed 361 non-diabetes individuals; 151 patients with RA and 210 age- and sex-matched controls. IR by homeostatic model assessment (HOMA2), insulin and C-peptide serum levels and amylin serum levels were assessed in patients and controls. A multivariable regression analysis, adjusted for IR related factors, was performed to evaluate the differences between patients and controls in amylin and how amylin is related to IR, disease activity and disease characteristics in RA patients. Fisher r-to-z transformation was used to compare Pearson's r<sup>2</sup> between patients and controls.

**Results:** HOMA2-IR indexes were higher in RA patients compared to controls. Similarly, insulin and C-peptide were superior in RA controls after multivariable analysis that included IR related factors and glucocorticoid intake. However, although amylin was found to be up regulated in the univariate analysis (1.36±8.81 vs. 1.79±1.51 ng/ml, p=0.011), this difference was lost after multivariate analysis (p=0.46). In RA patients, amylin showed a trend to be related with erythrocyte sedimentation rate (beta coef. 0.01 [95%CI -0.00-0.01], 0.07). Similarly, the presence of rheumatoid factor (beta coef. 0.90 [95%CI -0.23-1.56], p=0.009) and disease activity through SDAI was positively associated with amylin (0.01 [95%CI 0.00-0.03], p=0.034). This relation was not found with DAS28 or CDAI. The use of prednisone, methotrexate or anti-TNF therapies was not associated with amylin neither insulin nor C-peptide. Differences in the relation of insulin, C-peptide, amylin and HOMA2 indexes between each other and between populations were assessed. In this sense, relation between insulin and C-peptide (r<sup>2</sup> 0.817 vs. 0.947, p<0.001), between C-peptide and HOMA2-IR (r<sup>2</sup> 0.831 vs. 0.948, p<0.001), between insulin and HOMA2-%B-C peptide (r<sup>2</sup> 0.689 vs. 0.872, p<0.001) and between C-peptide and HOMA2-%B-C peptide (r<sup>2</sup> 0.827 vs. 0.922, p<0.001) were higher in controls compared to RA patients. Amylin had no relation with C peptide, insulin or HOMA2-IR and these relations were not different between patients and controls.

**Conclusion:** The mechanism that produces IR in RA patients may not be mediated by amylin.

## **Use of Dmards after the Diagnosis of Cancers in Patients with RA**

**Young Bin Joo**, Yune-Jung Park, Ki-Jo Kim and Kyung-Su Park, Internal Medicine, St. Vincent's Hospital, The Catholic University of Korea, Suwon, Korea, Republic of (South)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster III: Comorbidities

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although there are many studies about the association of disease-modifying anti-rheumatic drugs (DMARDs) with cancers in patients with rheumatoid arthritis (RA), there are few reports about the use of DMARDs after the diagnosis of cancers. The aim of this study is to investigate use of DMARDs after the diagnosis of cancer in patients with RA.

**Methods:** We did retrospective chart review of 2,164 patients with RA who visited our rheumatology outpatient clinic between Jan 2008 and Feb 2017. We examined the use of DMARDs in RA patients who were diagnosed as having cancers after the onset of RA both at the time of the initial diagnosis of cancers and at the recent outpatient visit.

### **Results:**

We found out 53 patients who were diagnosed with cancers after the onset of RA. At the time of initial diagnosis of cancer, the median age was 67 years (interquartile range; 53, 75) and disease duration was 4.5 years (2.7, 4.5). Female was 37 (70%), seropositive patients were 47 (89%), and those with joint erosions were 28 (53%).

The most frequent cancer was lung cancer (n=12), followed by stomach cancer (n=6) and cervical cancer (n=6). Twenty-five (47%) received surgery, 20 (38%) received chemotherapy, and 8 (15%) received conservative treatment.

At the time of initial diagnosis of cancers, DMARDs were stopped in 22 patients (42%), but resumed in 15 within mean 1.5 months. In 17 patients (32%), DMARDs was changed and 11 of the 17 patients received monotherapy, among which hydroxychloroquine was most frequently used (n=5). Fourteen patients (26%) received the same DMARDs used before the diagnosis of cancer.

At the recent outpatient visit (after the mean follow-up of 2.7 years), conventional DMARDs were used in 32 patients (60%) and biologics in 7 (13%). Fourteen patients (27%) were not on the DMARDs treatment. When it comes to conventional DMARDs, monotherapy was used in 12 patients and combination DMARDs in 20. Methotrexate monotherapy (n=6/32) and the combination of leflunomide and hydroxychloroquine (n=6/32) were the most prevalent DMARDs.

After adjusting for confounding factors, chemotherapy was associated with no DMARDs treatment at a recent outpatient visit (odds ratio 4.6, 95% confidence interval 1.1-19.9). Interestingly, all the RA patients diagnosed with hematologic cancer (n=2) were not on the DMARD treatment.

**Conclusion:** In RA patients with cancer, main treatment patterns at the initial diagnosis of cancer were discontinuation of DMARDs or change to monotherapy mainly hydroxychloroquine. After the mean follow-up of 2.7 years, methotrexate monotherapy, combination of leflunomide and hydroxychloroquine, and biologics were used with nearly equal frequencies. Chemotherapy was associated with no DMARDs treatment at a recent outpatient visit.

**Session Type:** ACR Poster Session C

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Radiographic progression is reported to be highly heritable in rheumatoid arthritis (RA). However, previous study using genetic loci showed an insufficient accuracy of prediction for radiographic progression. The aim of this study is to identify a biologically relevant prediction model of radiographic progression in patients with RA using a genome-wide association study (GWAS) combined with bioinformatics analysis.

**Methods:** We obtained genome-wide single nucleotide polymorphism (SNP) data for 374 Korean patients with RA using Illumina HumanOmni2.5Exome-8 arrays. Radiographic progression was measured using the yearly Sharp/van der Heijde modified score rate, and categorized in no or severe progression. Significant SNPs for severe radiographic progression from GWAS were mapped on the functional genes and reprioritized by post-GWAS analysis. For robust prediction accuracy, 10-fold cross-validation using a support vector machine (SVM) classifier was conducted. Prediction accuracy of our model was compared with that of other models based on GWAS results and SPOT (one of the post-GWAS analyses). The reliability of our model was confirmed using GWAS data of Caucasian patients with RA.

**Results:** A total of 36,091 significant SNPs with a p-value <0.05 from GWAS were reprioritized using post-GWAS analysis and ~2700 were identified as SNPs related to RA biological features. The best average accuracy of 10 groups was 0.6015 with 85 SNPs, and this increased to 0.7481 when combined with clinical information. In comparisons of

prediction accuracy, the 0.7872 AUC in our model was superior to that obtained with GWAS (AUC 0.6586, p-value  $8.97 \times 10^{-5}$ ) or SPOT (AUC 0.7449, p-value 0.0423). Our model also showed superior prediction accuracy in Caucasian patients with RA compared with GWAS (p-value 0.0049) and SPOT (p-value 0.0151).

**Conclusion:** Using various biological functions of SNPs and repeated machine learning, our model could predict severe radiographic progression relevantly and robustly in patients with RA compared with models using only GWAS results or other post-GWAS tool.

## Background/Purpose:

T2 mapping is a non-invasive MRI approach to measure cartilage quality, reflecting cartilage hydration and collagen integrity without using contrast enhancement. It has been demonstrated to be a sensitive tool to determine cartilage damage and is currently spreading into a broader clinical application.(1)The objective of this study was the qualitative and quantitative analysis of structural and biochemical changes in cartilage of MCP joints of patients with RA using T2 mapping in a 3 Tesla-MRI setting.

## Methods:
