## Etanercept Biosimilar GP2015 Has Equivalent Efficacy and Safety to Etanercept Originator in Patients with Moderate to Severe Rheumatoid Arthritis: The Phase 3 Equira Study

Arthur Kavanaugh<sup>1</sup>, Yannick Allanore<sup>2</sup>, Eugeniusz J. Kucharz<sup>3</sup> and Goran Babic<sup>4</sup>, <sup>1</sup>Medicine, University of California, San Diego, La Jolla, CA, <sup>2</sup>Department of Rheumatology, Cochin Hospital, Paris Descartes University, Paris, France, <sup>3</sup>Department of Internal Medicine and Rheumatology, Medical University of Silesia, Katowice, Poland, <sup>4</sup>Clinical development, Biopharmaceuticals, Hexal AG, a Sandoz company, Holzkirchen, Germany

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** The biosimilarity of GP2015 and etanercept originator product (ETN) has been previously demonstrated in patients with chronic plaque-type psoriasis.<sup>1</sup> The randomized, double-blind, phase 3 study, EQUIRA (NCT02638259) compared the efficacy and safety of GP2015 versus ETN in patients with moderate-to-severe RA and an inadequate response to DMARDs. Here, we present the 24-week results (TP1).

**Methods:** Patients (aged  $\geq 18$  years) with active RA (diagnosed according to the ACR 1987 or ACR/EULAR 2010 criteria for  $\geq 6$  months before baseline and active disease defined as DAS28-CRP  $\geq 3.2$ , and CRP  $>5$  mg/L or ESR  $\geq 28$  mm/h), who had an inadequate clinical response to MTX at a dose of 10 - 25 mg/week, were randomized 1:1 to self-administer 50 mg GP2015 or ETN subcutaneously, once weekly, for 24 weeks. All patients continued to receive concomitant MTX (10 - 25 mg/week), at a stable dose throughout the study and folic acid ( $\geq 5$  mg/week until end of study). The primary endpoint was change from baseline in DAS28-CRP at week 24.

**Results:** The baseline demographic and disease characteristics were comparable between the GP2015 (n=170) and ETN (n=156) groups. In the per-protocol set, GP2015 was determined to be equivalent to ETN in the LS mean change from baseline to week 24 in DAS28-CRP, as the 95% CI was within the pre-specified equivalence margin of -0.6; 0.6 (LS means difference between GP2015 vs

ETN: -0.04, 95% CI: -0.24, 0.15). At week 24, the ACR 20/50/70 response rates and the mean change from baseline in DAS28-CRP scores were comparable between GP2015 and ETN groups (Table). In the GP2015 (n=186) vs ETN (n=190) groups (safety set), treatment-emergent adverse events (AEs) occurred in 43.5% vs 49.5% patients, respectively; SAEs occurred in 0.5% vs 3.2% patients, respectively. One patient died in the ETN group. Injection site reactions, as a part of all AEs, were reported in 7.0% of patients in GP2015 and 17.9% of patients in ETN group. Using a very sensitive assay, very low titers of ADAs were transiently detected, however at week 24 none of the patients had significant levels detected.

Table. Efficacy response over 24 weeks (per-protocol set)			
Variables	Time	GP2015	ETN
		N = 170	N = 156
DAS28-CRP, LS means difference (95% CI)	Week 24	-0.04 (-0.24, 0.15)	
DAS28-CRP (mean change)	BL	5.42	5.54
	Week 4	-1.61	-1.71
	Week 12	-2.23	-2.21
	Week 24	-2.78	-2.81
EULAR good response, n* (%)	Week 24	83 (48.8)	75 (48.1)
EULAR moderate response, n* (%)		83 (48.8)	77 (49.4)
ACR20 (% responders)	Week 4	48.8	53.5
	Week 12	79.2	76.8
	Week 24	88.8	93.6
ACR50 (% responders)	Week 4	15.5	19.4
	Week 12	33.9	44.5
	Week 24	63.9	71.2
ACR70 (% responders)	Week 4	4.8	5.2
	Week 12	13.1	16.8
	Week 24	33.7	42.9
*total number of patients achieving responses/remission			
BL, baseline; ETN, etanercept originator product			

**Conclusion:** GP2015 demonstrated equivalent efficacy to ETN in patients with RA who had an inadequate response to DMARDs. Overall, the safety profile was comparable between GP2015 and ETN.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** This double-blind, randomized study evaluated efficacy, safety and immunogenicity of PF-06438179/GP1111, a potential infliximab biosimilar, vs infliximab sourced from the EU (infliximab-EU) in patients (pts) with moderate to severe active RA with inadequate response to MTX and  $\leq 2$  doses of 1 non-depleting, non-infliximab biologic. We report results after the first 30 wks of treatment.

**Methods:** Pts (N=650), stratified by geographic region, were randomized 1:1 to PF-06438179/GP1111 or infliximab-EU (3 mg/kg IV at wks 0, 2, 6 and then every 8 wks), both given with MTX (10-25 mg/wk). Dose escalation to 5 mg/kg was allowed starting at wk 14 for pts with inadequate response. Primary endpoint was ACR20 response rate at wk 14. Secondary efficacy endpoints included ACR20 response rate, Disease Activity Score-28; 4 components based on high-sensitivity C-reactive protein (DAS28-CRP) and other measures of clinical response or remission up to wk 30. Therapeutic equivalence was declared if the 2-sided 95% confidence interval (CI) for the difference between groups in ACR20 at wk 14 was within the symmetric equivalence margin of  $\pm 13.5\%$ . A 2-sided 90% CI was also calculated, as requested by the FDA, using the asymmetric equivalence margin of  $-12.0\%$  to  $+15.0\%$ .

**Results:** Pts (80.3% female; 79.4% seropositive) had a mean RA duration of 6.9 yrs; mean baseline DAS28-CRP was 6.0 in both groups. Wk 14 ACR20 response rates in the intent-to-treat population were 62.7% for PF-06438179/GP1111 and 64.1% for infliximab-EU. Using non-responder imputation for missing data (n=23; 3.5%), the treatment difference was  $-2.39\%$ ; corresponding CIs (95%:  $-9.92\%$ ,  $+5.11\%$ ; 90%:  $-8.75\%$ ,  $+4.02\%$ ) were entirely contained within the pre-specified equivalence margins (symmetric and asymmetric). Response rates through wk 30 were similar, with the ACR20 treatment difference ranging from  $-5.81\%$  to  $-0.83\%$  at the specified visits. Mean change in DAS28-CRP from baseline was  $-2.1$  at wk 30 for both groups. ACR50, ACR70 and European League Against Rheumatism (EULAR) response as well as DAS remission (DAS28  $< 2.6$ ) and ACR/EULAR remission were similar between groups at each study visit. Eighty-three pts each in the PF-06438179/GP1111 (25.7%) and infliximab-EU (25.5%) groups dose escalated at or after wk 14. Incidences of all-causality treatment-emergent adverse events (57.3% vs 54.0%) and serious adverse events (any event: 5.0% vs 6.1%; infections: 1.9% vs 2.8%) were similar between PF-06438179/GP1111 and infliximab-EU, respectively. Infusion related reactions (5.9% vs 6.4%), hypersensitivity (13.6% vs 15.6%), pneumonia (0.9% vs 0.9%) and latent/active tuberculosis (0.3% vs 0.3%) were also similar between PF-06438179/GP1111 and infliximab-EU, respectively. Overall post-dose anti-drug antibody rates through wk 30 were 48.6% for PF-06438179/GP1111 and 51.2% for infliximab-EU.

**Conclusion:** PF-06438179/GP1111 and infliximab-EU showed similar efficacy, safety and immunogenicity in pts with moderate to severe active RA on background MTX. This ongoing trial will evaluate clinical efficacy, safety and immunogenicity after a single transition from infliximab-EU to PF-06438179/GP1111 after 30 or 54 wks of treatment.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** FKB327 is a proposed biosimilar of the adalimumab RP. A randomized, DB, Phase 3 study (NCT02260791) compared the efficacy, safety, pharmacokinetics (PK) and immunogenicity of FKB327 and RP in pts with active RA inadequately controlled on methotrexate (MTX). This was followed by a randomized OLE study with treatment switching (NCT02405780) which assessed long-term safety, efficacy, PK and immunogenicity.

**Methods:** Pts aged  $\geq 18$  years with moderate to severe, active RA (2010 ACR criteria) for  $\geq 3$  months and taking MTX for  $\geq 3$  months (10–25 mg/week stable dose for  $\geq 8$  weeks) were enrolled. In the DB study, pts were randomized 1:1 to FKB327 or RP (40 mg subcutaneously [sc]) every other week (eow) with continuing MTX. The primary endpoint was ACR20 response rate at Week 24 with prespecified equivalence margins of  $-12$  to  $+15\%$  for a two-sided 90% confidence interval (CI), recommended by the FDA. Secondary endpoints included DAS28-CRP at Week 24 and ACR20/50/70 response rates over time. Safety was assessed by the incidence/severity of adverse events (AEs) and laboratory abnormalities. In the OLE, pts completing the DB study with clinical response and no serious AEs were immediately re-randomized to FKB327 or RP so that two-thirds of pts remained on the same treatment as in the DB study and one-third switched to the alternate treatment (40 mg sc eow) for Weeks 0–28 (Part 1), then all received FKB327 to Week 76 (Part 2). The primary endpoint was safety. Interim analysis of the OLE was performed when results of approximately 100 patient-years' continuous treatment were available on both products.

**Results:** In the DB study, 728 pts from 12 countries were treated with FKB327 (n=366) or RP (n=362). Demographics and baseline RA characteristics were similar between the groups, with mean MTX dose of 15.8 mg/week (standard deviation [SD] 4.8) and mean RA duration of 8.5 years (SD 8.0). ACR20 response rate at Week 24 (non-responder imputation, full analysis set) was comparable (FKB327 72.5%; RP 74.3%); 90% CI ( $-7.3$ ,  $3.6$ ) fell within prespecified equivalence margins. DAS28-CRP at Week 24 and ACR20/50/70 response rates over time were highly comparable. Safety profiles, mean serum trough drug concentration at steady state, and prevalence/titer of anti-drug antibodies (ADAs) were all well-matched. Re-randomization in the OLE resulted in 645 pts receiving the following treatment sequences across the DB then OLE (Part 1) studies: FKB327–FKB327, n=216; RP–RP, n=213; FKB327–RP, n=108; and RP–FKB327, n=108. At interim analysis, safety profiles were comparable for all treatment sequences, although group sizes were reduced after switching. ACR20 response rate at Week 30 was comparable after continuous (FKB327–FKB327, 82.5%; RP–RP, 84.3%) and switched (FKB327–RP, 86.5%; RP–FKB327, 89.1%) treatment. No consistent differences in PK and ADA profiles were seen between continuous and switched treatments.

**Conclusion:** The DB study met its primary equivalency endpoint for ACR20 response rate at Week 24; safety, ADA and PK profiles also supported the comparability of FKB327 and RP in pts with active RA. Interim OLE results suggested that long-term safety, efficacy, PK and immunogenicity of FKB327 and RP were comparable on continuous and switched treatment.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## **Background/Purpose:**

TNF-inhibitors (TNFi) have improved treatment of rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA) , Crohn's disease (CD), ulcerative colitis (UC), and chronic plaque psoriasis (Ps). The NOR-SWITCH study was funded by the Norwegian government to investigate if switching from originator infliximab (Remicade®, INX) to CT-P13 (biosimilar infliximab, Remsima®) is safe .

## **Methods:**

The study was designed as a 52-week randomized, double-blind, non-inferiority, phase IV trial with a 26 week open label extension in which all patients received CT-P13. Adult patients with a diagnosis of RA, SpA, PsA ,CD, UC, or Ps on stable treatment with originator infliximab were randomized 1:1 to either continued INX or switch to CT-P13 treatment in the main study <sup>1</sup>. Patients on CT-P13 throughout the 78-week study period (maintenance group) and patients switched to CT-P13 at week 52 (switch group) were assessed for treatment efficacy, safety and immunogenicity. The primary endpoint was disease worsening during follow-up according to disease-specific composite measures and/or a consensus between investigator and patient leading to major change in treatment<sup>1</sup>. Exploratory subgroup analyses were performed to examine disease worsening within each of the six diagnoses. The primary endpoint was analysed using logistic regression, adjusted for diagnosis and treatment duration at baseline.

## **Results:**

Between October 2014 and July 2016, 481 patients (INX 241, CT-P13 240, Full Analysis Set, FAS) were randomized, received treatment and were followed for 52 weeks. Results from the main trial showed that CT-P13 is non-inferior to continued treatment with originator infliximab<sup>1</sup>. 380 patients entered the extension phase of the trial. The main demographic and baseline (52w) characteristics of the extension study population are shown in the table. Disease worsening occurred in 16.8% and 11.6 % of patients in the maintenance and switch arms, respectively (Per Protocol Set, PPS). The frequency of disease worsening in each specific diagnosis is shown in the table (exploratory analyses). Changes in the generic disease variables and disease specific composite measures were similar in both arms (table). During the extension study, 3/197 and 5/183 patients in the maintenance and switch groups (FAS), respectively, developed anti-drug antibodies. Trough drug levels and the frequencies of reported adverse events were comparable between the two groups (data not shown).

## **Conclusion:**

The open-label extension of the NOR-SWITCH trial did not show any difference between patients who maintained CT-P13 vs patients who switched from INX to CT-P13.

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

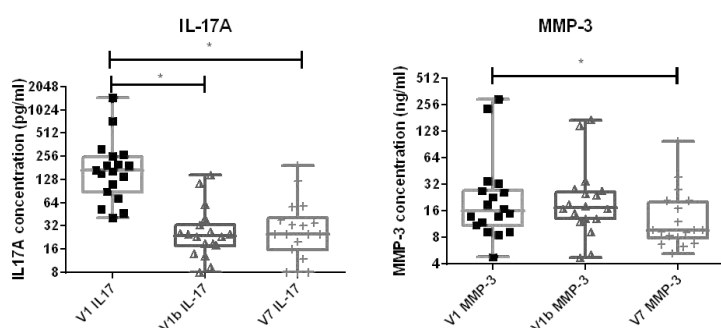

**Background/Purpose:** IL-17A blockade is an effective therapy for AS and PsA, the prototypical forms of spondyloarthritis (SpA). How IL-17A blockade affects the systemic and local immune responses in SpA remains incompletely understood. Our aim was to assess the effect of anti-IL17A treatment with secukinumab on the systemic cytokine responses and the synovial immunopathology in SpA patients with peripheral disease (pSpA).

**Methods:** 20 active SpA patients were included in a 12wk open-label trial followed by 2yrs non-investigational extension. All patients received secukinumab 300mg/wk from baseline (bsl) to wk4 and then every 4wks. TruCulture tubes with SEB and zymosan were drawn at bsl, day3, and wk12. Synovial biopsies were obtained by needle arthroscopy at bsl and wk12, analyzed by immunohistochemistry (IHC) and qPCR.

**Results:** The 20 pSpA patients were 13 PsA, 3 undifferentiated SpA, 2 AS with peripheral arthritis, 1 reactive arthritis and 1 IBD associated pSpA. There were no SAEs in the 12wk core study. Two SAEs occurred in the extension: tonsillitis (suspected related to study drug) and myocardial infarction (non related), both fully recovered. Secukinumab induced a rapid and highly significant improvement in SJC (median bsl: 2,5 [IQR 1-4] vs wk12: 0,5 [IQR 0-1]  $p=0.001$ ), TJC (6 [2-8] vs 0,5 [0-3]  $p<0.001$ ); VAS pt global (46 [28-65] vs 13 [6-24]  $p<0.001$ ). 18/20 patients reached EULAR good or moderate DAS response (Resp) at wk 12 (10 good, and 8 moderate Resp). In parallel, improvements of BASDAI (53 [25-63] vs 20 [9-40]  $p=0.001$ ) and PASI (5,7 [4,5-7,1] vs 0,6 [0,1-1,8]  $p=0.001$ ), CRP (3,85 [1,35-16,6] vs 2 [1,15-6,3]  $p=0.001$ ) and ESR (16 [6-35] vs 6 [2,8-16,3]  $p=0.001$ ) was seen. This was associated with decreased production of MMP-3, a validated biomarker of inflammation in pSpA<sup>(VanDooren, A&R, 2004)</sup> by peripheral blood cells in the TruCulture system (figure). With exception of a decrease in IL-17A, the TruCulture system did not reveal any impact of secukinumab on the capacity of peripheral blood cells to produce a broad panel of cytokines and chemokines. Contrasting this preserved systemic immune response, IHC confirmed the positive impact of 12wks of secukinumab on peripheral joint immunopathology as reflected by a significant decrease of macrophage infiltrate of the synovial sublining (2 [1-3] vs 1,5 [1-2]  $p=0.028$ ) and neutrophils (1 [0,5-3,5] vs 0 [0-1]  $p=0.004$ ), sensitive synovial biomarkers of treatment response in pSpA<sup>(Kruithof, A&R, 2005)</sup> mRNA analysis of synovial biopsies before and after 12wks of secukinumab shows a decrease in IL-17A but not TNF expression.

**Conclusion:** This mechanistic study indicates that IL-17A blockade with secukinumab has a profound beneficial clinical and biological impact on pSpA without compromising systemic immune responses. Further gene expression analysis will delineate which inflammatory pathways are blocked by secukinumab in the diseased target tissue.

**Figure 1** - Reduction in secretion of IL-17 and MMP-3 in response to SEB in the whole blood TruCulture system after treatment with anti-IL17A.

Significance of the comparisons is determined by a paired T-Test. Concentrations shown are pg/ml (IL-17) and ng/ml MMP-3. P value <0.05 was considered significant and indicated with an (\*).

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

Treat-to-target is an accepted strategy in RA; however, it is unknown whether it will reduce/prevent disability, impairment of mobility, and structural damage in patients with early axial SpA (axSpA) who do not meet modified New York criteria for radiographic sacroiliitis. We evaluated the impact of sustained clinical remission on MRI structural parameters. We hypothesized that patients with sustained inactive disease (Ankylosing Spondylitis Disease Activity Score [ASDAS] <1.3) are more likely to achieve reduction in erosion (structural damage) and increase in backfill (a reparative process) on MRI of the SI joints (SIJ).

## Methods:

The EMBARK (NCT01258738) and DESIR (NCT01648907) studies enrolled patients with early axSpA. EMBARK included a 12-week double-blind placebo-controlled period, then open-label etanercept for 92 weeks. DESIR patients had no history of biologic therapy and did not receive biologics for 2 years. T1 weighted MRI images of the SIJ at baseline (BL) and 104 weeks were combined and anonymized; readers were unaware of film chronology and original patient cohort. Three experienced readers evaluated the MRI images using the SpondyloArthritis Research Consortium of Canada (SPARCC) SIJ Structural Score (SSS). Change in erosion or backfill was considered present if 2 of 3 readers measured change in the same direction. ASDAS endpoints were: sustained inactive disease (ASDAS <1.3 for 2 visits 6 months apart) (yes/no); sustained ASDAS <2.1 for 2 visits 6 months apart (yes/no); and best sustained ASDAS response (<1.3, moderate disease activity [MDA, ≥1.3 to <2.1], or neither) for 2 visits 6 months apart. We determined the net proportion of patients with a change in each lesion. The results were unadjusted and also adjusted for covariates that may affect development of lesions on MRI.

## Results:

In EMBARK and DESIR, 150 and 68 patients, respectively, had BL and 104-week MRI images and ASDAS measurements every 6 months. For the patients in EMBARK with sustained ASDAS inactive disease, the proportion with a decrease in erosion was significantly greater than with an increase, and the proportion with an increase in backfill was significantly greater than with a decrease, in both the unadjusted and adjusted analyses (Table). In the adjusted analysis, this was also the case for patients with MDA. This trend was also present for patients with sustained ASDAS inactive disease in DESIR; the difference between proportions was not as great as in EMBARK.

## Conclusion:

These results are important because, for the first time, the data demonstrate a link between achieving sustained ASDAS inactive disease and MRI structural endpoints. The clinical relevance of change in MRI erosion and backfill in the SIJ and their relationship to the development of ankylosis requires further study.

Table. Patients in EMBARK with a decrease or increase in MRI structural lesion according to sustained ASDAS response type

				Unadjusted analysis		Adjusted analysis*	
Sustained ASDAS response type		Lesion decreased n/N (%)	Lesion increased n/N (%)	Net % patients with increase (95% CI)	P-value	Net % patients with increase (95% CI)	P-value

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Sustained remission is an important treatment goal in patients (pts) with non-radiographic axial SpA (nr-axSpA). Factors predicting successful remission maintenance are unknown. We sought to identify predictors of remission maintenance in nr-axSpA pts who achieved remission after open-label (OL) adalimumab (ADA) treatment in the ABILITY-3 trial (NCT01808118) and were subsequently randomized to continuation or withdrawal of ADA therapy.

**Methods:** ABILITY-3 enrolled adult pts with nr-axSpA with objective evidence of active MRI inflammation in the SI joints or spine or elevated high-sensitivity CRP at screening, active disease at baseline (ASDAS  $\geq 2.1$ , BASDAI  $\geq 4$ , and Patient's Assessment of Total Back Pain score  $\geq 4$ ), and inadequate response to  $\geq 2$  NSAIDs (**Table**). Pts received ADA 40 mg every other wk during a 28-wk OL lead-in period. Pts who achieved sustained remission, defined as ASDAS inactive disease [ID] score  $< 1.3$  at wks 16, 20, 24, and 28, were randomized to double-blind withdrawal (placebo; PBO) or continued ADA for 40 wks during period 2 (study wk 68). Stepwise logistic regression was used to identify predictors of sustained remission in those in the continued ADA and withdrawal (PBO) groups who did not experience a flare (defined as ASDAS  $\geq 2.1$  at 2 consecutive study visits) during period 2. Remission maintenance in period 2 was assessed with the following: ASAS partial remission (PR; score  $\leq 2.0$ ) and ASDAS ID at wk 68, ASAS PR and ASDAS ID at every visit, and ASDAS ID for  $\geq 5$  of 10 visits.

**Results:** By wk 68, 100/145 (69%) ADA pts had not flared; shorter symptom duration and very low wk 28 ASDAS were associated with absence of flare. Of those without flare, 58% achieved ASAS PR and 78% ASDAS ID at wk 68; 33% achieved ASAS PR and 42% ASDAS ID at every visit. Very low wk 28 ASDAS predicted sustained remission at all subsequent visits (**Figure 1A**). By wk 68, 70/148 (47%) PBO pts had not flared; lower wk 28 ASDAS was associated with absence of flare. Of those without flare, 59% achieved ASAS PR and 70% ASDAS ID at wk 68; 29% achieved ASAS PR and 31% ASDAS ID at every visit (**Figure 1B**).

Figure 1. Predictors of maintenance of remission through week 68 in patients who have achieved sustained remission after 28-weeks of ADA therapy in (A) patients treated with additional 40 weeks of ADA and (B) patients with ADA withdrawn

ADA, adalimumab; ASAS PR, Assessment of SpondyloArthritis international Society partial remission; ASDAS, Ankylosing Spondylitis Disease Activity Score; Back pain, patient's assessment of total back pain (numeric rating scale); BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BL, baseline; hsCRP, high-sensitivity C-reactive protein; ID, inactive disease; MRI, magnetic resonance imaging; PGA, Physician Global Assessment of Disease Activity; SpA, spondyloarthritis; SPARCC, Spondyloarthritis Research Consortium of Canada. Analysis was done in patients who did not flare in period 2. Study visits were at weeks 32, 36, 40, 44, 48, 52, 56, 60, 64, and 68. Patients with missing predictor data are not included in the regression analyses.

**Conclusion:** In nr-axSpA pts who achieved remission after 28-wk OL ADA therapy, very low ASDAS at week 28 predicted absence of flare in both the continued ADA and withdrawal group. With continued ADA, shorter symptom duration also predicted absence of flare, and achievement of very low ASDAS at week 28 predicted sustained remission using most remission definitions, suggesting early aggressive treatment may be beneficial in achieving sustained remission. No consistent predictors of sustained remission after ADA withdrawal were identified.

## Pregnancy Outcomes in Patients with Ankylosing Spondylitis: A Nationwide Population Study

**Yao-Fan Fang**, Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Taoyuan, Taiwan

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Pregnancy outcomes in patients with ankylosing spondylitis: a nationwide population study.**

**Background/Purpose:** Autoimmune inflammatory diseases influence on pregnancy outcomes. But rare studies have focus on the ankylosing spondylitis (AS) and pregnancy outcomes.

**Methods:** The primary data source was the National Health Insurance database and national birth registry of Taiwan. We obtained records of all pregnancies in Taiwan between 2001 and 2012 from a national insurance database. Maternal and fetal outcomes were obtained from national birth registry.

**Results:** We analyzed data from 2,350,339 women between 2001 and 2012 categorized into 2 groups. Subjects in the reference group (2,347,847 women) had no AS diagnosis, and those in the AS group (2,492 women) had diagnosed with AS before pregnancy. Maternal outcomes in patients with AS revealed a higher adjusted odds ratio for Puerperal cerebrovascular disorders (OR 4.05 95% CI 2.02 to 8.12), Preterm labor (OR 1.18 95% CI 1.00 to 1.38), cesarean delivery (OR 1.08 95% CI 1.01 to 1.15), pulmonary edema (OR 4.99 95% CI 1.24 to 20.10) and gestational diabetes (OR 1.16 95% CI 1.02 to 1.34). The neonatal outcomes in AS group showed a higher adjusted OR for poorer 1 minute Apgar score (<7) (OR 1.38 95% CI 1.10 to 1.75), poorer 5 minute Apgar score (<7) (OR 1.60 95% CI 1.02 to 2.52), fetal abnormalities (OR 1.20 95% CI 1.03 to 1.39), chromosomal abnormalities (OR 1.72 95% CI 1.15 to 2.59) and unspecific abnormalities (OR 1.28 95% CI 1.01 to 1.62).

**Conclusion:** Patients with AS were associated with higher prevalence of adverse birth outcomes.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** There are no large radiographic follow up studies assessing progression in juvenile-onset Ankylosing Spondylitis (JoAS) as compared to adult-onset Ankylosing Spondylitis (AoAS). The purpose of this study is to examine the clinical and imaging aspects of JoAS in a large spondylitis clinic.

**Methods:** The spondylitis clinic has a database of around 1300 patients with confirmed ankylosing spondylitis (AS) as defined by the modified New York criteria. AS patients with symptom onset of back pain at 16 years of age or under were classified as JoAS. They were then matched by gender and duration of back pain to patients with symptom onset of back pain over 16 years old, defined as AoAS, in a 1:2 ratio. Clinical and radiographic data were then extracted. The analysis utilized linear or logistic regression analysis to correct for disease duration, gender, prior anti-TNF exposure, ESR, and HLA-B27 status as appropriate.

**Results:** 158 JoAS patients were identified and matched to 316 AoAS patients. There was a total of 365 males and 106 females. Baseline mean BASDAI was 4.36 for JoAS and 5.00 for AoAS and was not significantly different when adjusted for prior anti-TNF use. However, patient global disease activity was 4.38 for JoAS and 5.16 for AoAS, which was significantly different ( $p=0.032$ ) after adjusting for prior anti-TNF use. Current and previous history of smoking exposure, iritis, and psoriasis did not differ between JoAS and AoAS. There was more associated Crohn's disease in JoAS (13%) versus AoAS (4%),  $p=0.001$ . There was no difference in B27 status between the two groups. Baseline mSASSS was lower in JoAS (3.9%) vs AoAS (11.6%), and was statistically different when corrected for prior anti-TNF, duration of back pain, gender, baseline ESR, and B27 status ( $p<0.001$ ). When followed over time, progression of 1 mSASSS unit or more yearly was lower in the JoAS (11%) vs AoAS (24%), and was still significant when corrected for gender, prior anti-TNF use, ESR, and HLA-B27 status,  $p=0.018$ . Progression of 4 mSASSS units or more over any time period was lower in the JoAS (14%) vs AoAS (35%), and was still significant when corrected for the covariates above,  $p=0.001$ . More JoAS (65%) were on biologics compared to AoAS (47%),  $p<0.001$ . Of the patients on biologics, more JoAS (52%) had switched biologics compared to AoAS (33%),  $p=0.006$ .

**Conclusion:** The rate of axial radiographic progression over time was lower in the JoAS cohort when corrected for covariates. JoAS patients were also on more biologics and switched biologics more regularly compared to AoAS patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Evaluation of imaging is important in spondyloarthritis (SpA) research, but loss to follow up often jeopardizes interpretation of the evaluation. The Interpretation may further be challenged by the fact that often different readers have contributed to scores, in multiple read ‘waves’. A common approach is to evaluate patients (pts) with complete follow up (completers analysis), and aggregate scores of individual readers (eg. agreement  $\geq 2$  out of 3 readers). These approaches are not assumption-free, may cause non-random data loss, and may as such provide spurious estimates and loss of external validity. We investigated if the use of all data in an assumption-free manner (a so called ‘integrated analysis’) affects the precision of estimates for imaging outcomes in pts with axial SpA (axSpA), with completers analysis as reference standard.

**Methods:** Pts from the DESIR cohort fulfilling the ASAS axSpA criteria were included. Radiographs and MRIs of the SIJ and spine were obtained at baseline (BL), 1, 2 and 5 years. Each film was scored by 2 or 3 readers in 3 ‘reading-waves’ (wave 1: BL only; wave 2: BL, 1, 2 years; wave 3: BL, 2, 5 years). Each outcome was analyzed in two ways: i. according to a ‘combination algorithm’ (‘2 out of 3’ for binary and mean of 3 readers for continuous variables); and ii. per individual reader. The change of each outcome was analyzed by generalized estimating equations (GEE) with ‘time’ as explanatory variable. Three analytical approaches were pursued: i) ‘integrated-analysis’ (including all pts with  $\geq 1$  score from  $\geq 1$  reader from all waves); ii) completers-only analysis (including only pts with complete 5-year follow-up, using scores from individual readers from wave 3); iii) aggregated completers analysis using a combination algorithm (the same as ii but using combined scores).

**Results:** In total, 413 pts were included (mean (SD) symptom duration: 1.6 (0.9) years) and 366 completed the 5-year follow up. An analysis with all data from different readers and ‘waves’ (‘integrated analysis’) was more inclusive, but did not result in a meaningful loss of precision (width of 95%CI) of the change-estimates as compared to both completers analyses (table). In fact, for low-incident outcomes (e.g. the formation of new syndesmophytes), an increased incidence was ‘captured’ by the ‘integrated analysis’ but not by the completers analysis with combined scores (% change/year (95% CI): 0.67 (0.34; 1.01) vs 0.39 (-0.10; 0.90), respectively). The same results were seen using continuous outcomes.

**Conclusion:** An efficient and entirely assumption-free usage of all data from different readers and ‘read-waves’ does not compromise precision of the estimates of change in imaging parameters, and may yield increased statistical power for detecting changes with low incidence. In addition, integrated analysis may protect against attrition bias and avoid bias by ‘convenient choices’.

**Table.** Change per year in the percentage of positive cases for binary imaging outcomes over 5-years of follow-up, according to 3 different analytical methods, in early axSpA patients fulfilling the ASAS axSpA criteria from the DESIR-cohort

	Integrated analysis	Completers analysis with individual readers scores	Completers analysis with combined scores for readers
Imaging outcomes	% change per year (95% CI) (N=399-411)	% change per year (95% CI) (N=342-364)	% change per year (95% CI) (N=338-364)

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment IV: Neuropsychiatric Disease and Health Economics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Currently, the diagnosis of cognitive impairment (CI) is often delayed requiring use of a comprehensive battery (CB) which imposes a time- and cost-burden. It would therefore be beneficial to have a more expedient CI screening tool that could be applied in the ambulatory clinic setting. The Automated Neuropsychological Assessment Metrics (ANAM) is a computerized tool that can be used to screen for CI. We determined the ability of ANAM (v4) GNS Battery to predict CI in patients with systemic lupus erythematosus (SLE).

**Methods:** Consecutive consenting SLE patients (n=98), aged 18-65 years, who attended a single center between July 2016 and April 2017 were recruited. Participants were administered the ANAM and CB on the same day. ANAM throughput scores were used to provide an estimate of 'cognitive efficiency'. Patient scores on the ANAM and CB were compared to a normative sample of age- and gender-matched healthy controls to obtain z-scores.

The CB evaluates the following major cognitive domains: manual motor speed and dexterity, simple attention and processing speed, visual-spatial construction, verbal fluency, learning and memory (visuospatial and memory), and executive functioning (untimed and timed). ANAM evaluates the following major cognitive domains: attention and processing speed, memory, visual-spatial processing, executive functioning, abstract language function and fine motor processing. Tests comprising the CB and ANAM are listed in Table 1.

CI was operationalized on the CB and ANAM as a z-score of  $\leq -1.5$  on  $\geq 2$  domains or a z-score  $\leq -2.0$  on  $\geq 1$  domains, or either (Table 2).

The performance of ANAM was compared against the CB using different CI definitions. Descriptive analysis was used to determine prevalence, sensitivity (Sn), specificity (Sp), Positive Predictive Value (PPV) and Negative Predictive Value (NPV).

**Results:** Of the 98 patients (90.8% female), the mean age at SLE diagnosis was  $28.5 \pm 10.2$  and disease duration at enrolment was  $15.5 \pm 10.0$  years. Prevalence of CI using CB ranged between 40.0-44.8 % ( $z \leq -1.5$  in  $\geq 2$  domains and  $z \leq -2.0$  in  $\geq 1$  domains, respectively) and 55.2% for either. Prevalence of CI using the ANAM ranged between 30.8-39.3% % ( $z \leq -1.5$  in  $\geq 2$  domains and  $z \leq -2.0$  in  $\geq 1$  domains, respectively) and 43.0% for either.

ANAM sensitivity/specificity was 52/73% and PPV/NPV was 70/55% [based on  $z \leq -1.5$  in  $\geq 2$  domains or  $z \leq -2.0$  in  $\geq 1$  domains for ANAM and CB (corresponding for A+B and E+F in Table 2)].

**Conclusion:** ANAM is a promising tool for the assessment of CI in SLE. Future studies are required to determine if the sensitivity of the ANAM can be improved against the current CB.

## Longitudinal Assessment of Cognitive Function in SLE: Identification of Trajectories

**Zahi Touma**<sup>1</sup>, Jiandong Su<sup>2</sup> and Patricia P. Katz<sup>3</sup>, <sup>1</sup>Rheumatology, University of Toronto, Division of Rheumatology, Institute of Health Policy, Management and Evaluation, Toronto, ON, Canada, <sup>2</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>3</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment IV: Neuropsychiatric Disease and Health Economics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:**

Cognitive function may change over time in patients with SLE, and cognitive function trajectories (CFTs) have not well been studied. This is the first study to identify CFTs in SLE and their correlates.

## Methods:

Data were from the University of California San Francisco Lupus Outcomes Study, in which participants are followed longitudinally via annual telephone surveys. The Hopkins Verbal Learning Test-Revised (HVLTR; measures verbal memory) was administered in years 2-7 and the Controlled Oral Word Association Test (COWAT; verbal fluency) in years 4-7, providing up to 6 and 4 years of observation, respectively. Individuals with at least 2 assessments were included in analysis. Age- and education-stratified z-scores were derived for HVLTR delayed recall and COWAT.

Proc Traj (SAS) was used to identify group-based trajectory models. One model each was fitted for the HVLTR and COWAT. To select the best model, models with 2-5 trajectories were examined by graphic shapes, number of patients in each group, and model fitting statistics according to Bayesian Information Criterion. Separate univariate/multivariable logistic regression analyses (for HVLTR and COWAT) were then performed to look for factors at baseline associated with CFT, including sex, ethnicity, disease duration, renal problems, treatments, fatigue, depressive symptoms (CESD), and self-reported disease activity.

## Results:

815 patients (92.4% female) with mean age  $34.5 \pm 13.3$  years at SLE diagnosis were studied. 761 and 658 individuals had at least 2 HVLTR and COWAT scores, respectively. Two CFTs were identified for each measure (see Figure): persistently low (29% in HVLTR, 55% in COWAT) and persistent normal (71% in HVLTR, 44.6% in COWAT). In multivariable analyses, persistently normal HVLTR was associated with Caucasian race; renal problems, intravenous glucocorticoids use in the prior year, and higher CESD scores were associated with persistently low HVLTR (Table). Persistently normal COWAT was associated with longer disease duration, while higher CESD score was associated with persistently low COWAT.

## Conclusion:

Cognitive function followed particular trajectories over time in SLE, with some patients having persistently low scores while others had normal scores. Depressive symptoms were associated with persistently low function in both measures. Other factors associated with persistently low function were measure-specific. Additional longitudinal studies including more nuanced measures of cognitive function are needed to further explore long-term patterns of cognitive function in SLE.

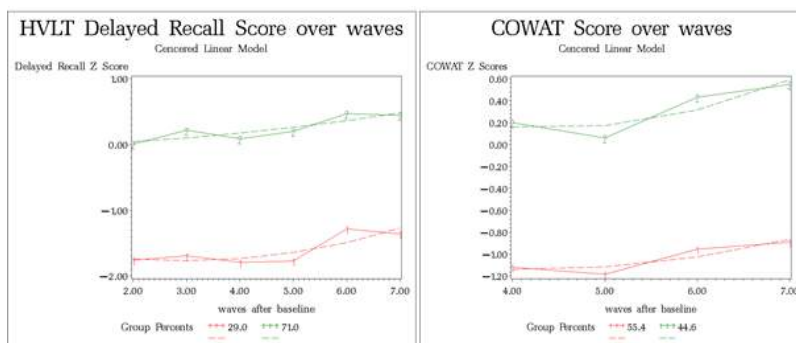

Table. Baseline factors associated with better cognitive function trajectories in univariate and multivariate analysis				
	HVLT-R delayed recall		COWAT	
	Univariate	Multivariate	Univariate	Multivariate
Female	1.3 (0.7, 2.3)	---	1.0 (0.5, 1.8)	---
Caucasian	1.6 (1.1, 2.2)	1.5 (1.02, 2.2)	1.3 (0.9, 1.9)	---
Disease duration, year	1.0 (0.98, 1.02)	---	1.02 (1.0, 1.03)	1.02 (1.001, 1.04)
Renal problems	0.5 (0.4, 0.8)	0.6 (0.4, 0.9)	0.8 (0.5, 1.1)	---
Smoking, ever	0.8 (0.6, 1.2)	---	1.3 (0.9, 1.7)	---
Oral glucocorticoids during baseline year	0.8 (0.6, 1.1)	---	0.8 (0.6, 1.1)	---
Intravenous steroids during baseline year	0.4 (0.2, 0.8)	0.5 (0.2, 0.4)	0.9 (0.5, 1.7)	---
Plaquenil use	0.8 (0.6, 1.1)	---	1.2 (0.9, 1.7)	---
CESD score	0.96 (0.95, 0.97)	0.97 (0.96, 0.98)	0.98 (0.97, 0.99)	0.98 (0.97, 1.0)

Tabled values are odds ratios (95% confidence intervals).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment IV: Neuropsychiatric Disease and Health Economics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

Cognitive impairment is well-documented in SLE with considerable impact on quality of life but attribution is limited by a lack of biomarkers that distinguish SLE disease-related mechanisms from other causes (medications, infection, mood disorders, thrombosis). Cross-reactive anti-dsDNA/NMDA receptor antibodies (DNRAb) have been shown to bind neurons in the mouse hippocampus, specifically place cells, with resulting synaptic signaling changes promoting neuron dysfunction or death and difficulties in spatial tasks<sup>1</sup>. The purpose of this study was to evaluate serum DNRAb associations with spatial memory in SLE using a novel spatial navigation task (SNT).

## Methods:

21 SLE patients that met ACR criteria, had no history of CNS insult and low disease activity and 9 age, gender and ethnically matched healthy controls (HC) were recruited. SLE disease activity was assessed by SLEDAI within 2 weeks of testing. The SNT utilizes a desktop virtual environment to assess spatial memory. Participants were placed at a start point and asked to navigate through a computerized virtual city of 30 intersections (Fig. 1), with one unmarked target intersection set to trigger a congratulatory screen upon entry. Subjects were given a maximum of 5 minutes to complete each of 4 trials to find the target. Serum DNRAb assays were performed by ELISA with the DWEYS consensus sequence. Analyses included the Chi Square and student t tests.

## Results:

Table 1 shows relevant subject characteristics with SLE subjects grouped by DNRAb titer. DNRAb- SLE subjects had slightly higher SLEDAI scores and frequency of anti-DNA antibody titers compared to the DNRAb+ group. Over 4 trials, 77.7% of HC found the target compared to 20% of DNRAb+ subjects ( $p=.01$ ). DNRAb- SLE behaved like HC with a 60% success rate ( $p=.41$ ). Differences between DNRAb+ and - did not reach statistical significance ( $p=.07$ ). These differences in success occurred despite all three groups making the same number of movements ( $p=.83$ ) and turns ( $p=.49$ ) during the trials, covering the same amount of search area ( $p=.76$ ), having a similar amount of computer experience ( $p=.15$ ), and no differences in simple reaction time tasks ( $p=.7$ ).

## Conclusion:

DNRAb+ subjects perform poorly on the SNT compared to DNRAb- SLE subjects who perform similarly to HC. The lack of group differences for mood disturbances, medications and demographics and that the DNRAb- group performed similar to HC despite having higher disease activity and anti-DNA titers suggest that this SNT may provide an objective measure of DNRAb-mediated brain toxicity that will need to be replicated in future studies.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment IV: Neuropsychiatric Disease and Health Economics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Youth with systemic lupus erythematosus (SLE) have high health care utilization, which may be exacerbated by psychiatric disorders, a common comorbidity in this group. We examined the impact of psychiatric diagnoses on utilization of medical services in youth with SLE.

**Methods :** We conducted a retrospective cohort study using administrative claims for 2000 to 2013 from Clinformatics™ DataMart (OptumInsight, Eden Prairie, MN), a large US database of privately insured enrollees. We included youth ages 10-24 years with an incident diagnosis of SLE (³ International Classification of Diseases, Ninth Revision codes for SLE 710.0, each >30 days apart, with ≥ 1 year of preceding continuous enrollment without a code for SLE). We categorized mutually exclusive groups of youth with SLE as those with: 1) no psychiatric diagnosis, 2) a psychiatric diagnosis in the 12 months preceding SLE diagnosis, and 3) an incident psychiatric diagnosis in the 12 months after SLE diagnosis. We calculated mean ambulatory, emergency and inpatient visits for medical services in the year after SLE diagnosis, and used Poisson regression to compare the number of visits among the 3 groups, adjusting for demographic and disease variables.

**Results :** We identified 650 youth with an incident diagnosis of SLE, with mean age of 18.4 years (SD 3.7), composed of 88% females and 25% with nephritis. Depression was diagnosed in 144 (22%), anxiety in 93 (14%), and other psychiatric disorders in 210 (32%). A psychiatric diagnosis was present preceding SLE diagnosis in 122 (19%) and diagnosed in the year after SLE diagnosis in 105 (16%); 423 (65%) had no psychiatric diagnosis. In adjusted models, mean ambulatory visits in the year after SLE diagnosis were higher for those with preceding (14.4, SD 11.7,  $p=0.01$ ) and incident (18.1, SD 14.6,  $p<0.0001$ ) psychiatric diagnoses than among those without a psychiatric diagnosis (11.6, SD 9.9) (Figure). Those with an incident psychiatric diagnosis had more acute care visits compared to those without a psychiatric diagnosis: 9.5 (10.9) vs 5.1 (8.6) for emergency ( $p=0.0001$ ), and 4.9 (10.7) vs 2.8 (7.8) for inpatient ( $p=0.03$ ). Those with a preceding psychiatric diagnosis had 6.9 (13.1) mean emergency and 3.5 (8.2) mean inpatient visits, which were not significantly statistically different from the other groups.

**Conclusion :** In youth with SLE, psychiatric comorbidity is associated with higher utilization of medical services in ambulatory settings in the year after SLE diagnosis, and those with a new psychiatric diagnosis during this period had higher utilization of acute medical care. Interventions to address existing and newly identified psychiatric disorders may decrease health care burden for youth with SLE.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment IV: Neuropsychiatric Disease and Health Economics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

We describe the costs associated with damage states in a Canadian-wide SLE cohort using multi-state modeling, which provides a dynamic representation of damage accrual in real time.

## Methods:

Patients fulfilling the revised ACR or Systemic Lupus International Collaborating Clinics (SLICC) Classification Criteria for SLE from 6 Canadian centres were enrolled. Participants completed validated health resource utilization (including hospitalizations, medications, physician visits, tests, and emergency room visits) and lost productivity questionnaires. Direct costs were calculated by multiplying health resources by their 2017 Canadian prices. Indirect costs included time loss and impaired productivity in labour force and non-labour force activities and were valued using age-sex specific wages from Statistics Canada. Annual costs associated with damage states (SLICC/ACR Damage Index [SDI]) were obtained from multiple regressions adjusting for age, race/ethnicity, and disease duration. To compute long-term estimates of direct/indirect costs, annual costs associated with each level of disease damage were multiplied by the expected duration in each state, forecasted using a multi-state Markov model (*Bruce IN. Ann Rheum Dis 2015;74:1706-13*). Future costs were discounted at a yearly rate of 3%.

## Results:

1361 patients participated, 90.4% female, 71.0% Caucasian, mean age at diagnosis 33.1 years (SD 13.5), mean SLE duration at completion of economic questionnaire 16.8 years (SD 11.6), mean SLE Disease Activity Index (SLEDAI-2K) 2.71 (SD 3.21), and mean SDI 1.54 (SD 1.87). Annual direct and total costs were higher in those with an SDI  $\geq 5$  (Table 1).

Table 1. Predicted Annual Health Costs Stratified by SDI

SDI State	Direct Costs, Mean, 95% CI 2017 Canadian \$	Indirect Costs, Mean, 95% CI 2017 Canadian \$	Total Costs, Mean, 95% CI 2017 Canadian \$
0	4379 (2859, 5900)	24768 (21439, 28098)	29147 (24997, 33298)
1	5846 (4266, 7427)	26625 (23032, 30218)	32472 (28085, 36858)
2	6743 (4899, 8587)	31285 (26910, 35661)	38028 (32845, 43212)
3	10885 (8530, 13240)	23786 (18044, 29528)	34671 (28006, 41336)
4	9427 (6015, 12840)	30272 (21892, 38652)	39699 (30158, 49241)

4	62796 (48335, 77256)	133923 (99189, 168657)	196719 (156907, 236531)	128221 (102706, 153735)	238751 (177875, 299628)	366972 (297288, 436656)
≥ 5	85629 (72802, 98456)	128038 (98415, 157662)	213667 (179094, 248240)	155348 (131815, 178882)	231759 (176993, 286526)	387108 (323758, 450458)

### Conclusion:

Patients with the highest baseline SDIs incurred cumulative direct costs that were 4.2-fold higher and total costs almost 2-fold higher than those with the lowest baseline SDIs. Indirect costs did not vary with SDI and patients with no or minimal damage still experienced considerably reduced productivity. Indirect costs exceeded direct, on average, by 3.9-fold, underscoring the importance of lost workforce productivity, and the need for actionable workplace and systems-level (i.e., government, policies, and society) interventions to improve the employment outcomes of those living with SLE.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment IV: Neuropsychiatric Disease and Health Economics  
**Session Type:** ACR Concurrent Abstract Session  
**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Belimumab, an inhibitor of B lymphocyte stimulator, is approved in adults with active, autoantibody-positive systemic lupus erythematosus (SLE) receiving standard of care. There is limited information on all-cause healthcare resource utilization (HCRU) and costs before/after initiation of belimumab treatment. Data from privately-insured US administrative claims databases can provide valuable descriptive information on HCRU and costs under routine care settings.

**Methods:** A retrospective analysis (study 206345) was conducted using the Truven Health MarketScan® Commercial Claims and Encounters database (Sept 01, 2010 to Dec 31, 2015). Patients were 18–64 years of age with a SLE diagnosis (ICD-9: 710.0 or ICD-10: M32) and  $\geq 1$  belimumab infusion. The index date was the date of the first belimumab infusion. Continuous enrollment was required 6 months pre-index and  $\geq 3$  post-index date. Here, we present data from patients with 6 months of post-index follow-up.

**Results:** This analysis comprised 1879 patients with 6 months of post-index follow-up. The proportion of patients utilizing healthcare services was significantly lower after belimumab initiation versus the pre-index period for inpatient admissions, and for some outpatient services such as emergency room visits, hospital-based outpatient visits and laboratory services (all  $p < 0.001$ ; Table). The number of healthcare services utilized was also significantly lower after initiation versus the pre-index period for inpatient admissions and several outpatient services, including emergency room visits, physician office visits, hospital-based outpatient visits, laboratory services and outpatient pharmacy prescriptions (all  $p < 0.001$ ). Total all-cause healthcare costs were significantly higher following belimumab initiation, compared with the pre-index period ( $p < 0.001$ ). Outpatient service costs, including hospital-based outpatient visits and other outpatient costs, were significantly higher following initiation (all  $p < 0.001$ ). However, inpatient admissions, physician office visits and laboratory costs were significantly lower after initiation (all  $p < 0.001$ ).

Table. All-cause HCRU and costs during the 6-month pre-index period and 6-month follow-up period

	6-month pre-index period (n=1879)	6-month follow-up period (n=1879)	p value
<b>Number of patients utilizing healthcare services, n (%)</b>			
Inpatient admissions	337 (17.9)	174 (9.3)	$p < 0.001$
Outpatient services	1876 (99.8)	1877 (99.9)	$p = 0.655$
Emergency room visits	743 (39.5)	458 (24.4)	$p < 0.001$
Physician office visits	1872 (99.6)	1868 (99.4)	$p = 0.248$
Hospital-based outpatient visits	1550 (82.5)	1324 (70.5)	$p < 0.001$
Laboratory services	1740 (92.6)	1614 (85.9)	$p < 0.001$
Other outpatient services	1839 (97.9)	1830 (97.4)	$p = 0.286$
Outpatient pharmacy prescriptions	1831 (97.4)	1820 (96.9)	$p = 0.034$
<b>Number of healthcare services utilized, mean (SD)</b>			
Inpatient admissions	0.30 (0.84)	0.14 (0.54)	$p < 0.001$
Average length of stays, days	0.74 (2.24)	0.42 (2.07)	$p < 0.001$
Outpatient services	115.25 (82.82)	83.30 (51.32)	$p < 0.001$
Emergency room visits	3.53 (9.43)	1.96 (6.19)	$p < 0.001$
Physician office visits	15.87 (10.59)	8.95 (6.01)	$p < 0.001$
Hospital-based outpatient visits	30.74 (43.19)	21.32 (31.65)	$p < 0.001$
Laboratory services	34.23 (30.07)	19.87 (20.01)	$p < 0.001$
Other outpatient services	30.88 (37.35)	31.20 (26.19)	$p = 0.669$
Outpatient pharmacy prescriptions	51.63 (37.37)	28.73 (20.61)	$p < 0.001$
<b>Healthcare costs*, US\$, mean (SD)</b>			
Total	29,270 (48,032)	41,426 (38,483)	$p < 0.001$
Inpatient admissions	6581 (28,777)	3079 (18,788)	$p < 0.001$
Outpatient services	16,735 (29,473)	32,095 (31,516)	$p < 0.001$
Emergency room visits	972 (2737)	704 (5023)	$p = 0.027$
Physician office visits	1810 (1362)	973 (749)	$p < 0.001$
Hospital-based outpatient visit	7042 (15,990)	11,453 (24,310)	$p < 0.001$
Laboratory services	788 (1060)	377 (697)	$p < 0.001$
Other outpatient services	6124 (22,955)	18,587 (26,226)	$p < 0.001$
Outpatient pharmacy prescriptions	5954 (14,167)	6252 (13,777)	$p = 0.353$

\* $p < 0.001$ ; p value represents comparison between the 6-month pre-index period and the 6-month follow-up period

\*Belimumab cost is likely to be reflected in hospital-based outpatient visits, other outpatient services and prescriptions

**Conclusion:** This study provides valuable real-world information about HCRU and costs before and after initiation of intravenous belimumab in a large sample of US patients with SLE. While total costs increased in the 6-month follow-up period, in part due to the cost of belimumab, significant reductions in inpatient admissions, emergency room visits and physician office visits, as well as the costs associated with these services were observed. The effect of belimumab treatment on HCRU and costs, particularly beyond the first 6 months, requires further exploration.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

### Background/Purpose:

In SLE Apolipoprotein L1 (APOL1) risk variants (RV) associate with cardiovascular and end stage renal disease. APOL1 induction initially promotes cellular maintenance through autophagy; but when prolonged disrupts lipid bilayers causing ion flux, mitochondrial stress, and cell death. We hypothesized that cytokine-induced RV expression impairs autophagy favoring pore formation in endothelial cells (ECs) implicating endothelial dysfunction as a mechanism for broader organ damage.

**Methods:** ECs were isolated from umbilical cords of 11 healthy African American subjects and genotyped for APOL1 by PCR sequencing (G0/G0 n=4, RV/G0 n=4 RV/RV n=3). CD31+ ECs (confirmed by FACS) were treated with IFN $\gamma$  (100 units/mL) for 24 hours and subsequent assessments included: APOL1 and autophagy marker LC3B protein measurements by immunoblot, LC3B staining by immunofluorescence, angiogenesis capacity on Matrigel matrix, and bioenergetic profiling by the Seahorse mitochondrial stress test method.

### Results:

EC were >98% CD31 positive by flow cytometry. Across the genotypes, exposure to IFN $\gamma$  increased APOL1 protein expression 13.3 $\pm$ 9.2 fold (p=0.012). To assess the ability of APOL1 over-expression to initiate autophagy, LC3B positive autophagosomes were counted by immunofluorescence. As expected, in G0/G0 ECs autophagosomes increased 41% when APOL1 was over-expressed. By contrast, autophagosomes decreased 7.1% in RV/G0 and 35.5% RV/RV ECs suggesting an autophagy defect. This result was confirmed by immunoblot. Autophagy-dependent angiogenesis was evaluated by plating resting and IFN $\gamma$  treated ECs on Matrigel matrix. At baseline, RV/RV ECs showed impaired angiogenesis capacity forming fewer junctions (J) and tubules (T) than RV/G0 and G0/G0 ECs (RV/RV: J: 539.9, T: 484.8; RV/G0: J: 841.8, T: 727.7, G0/G0: J: 810.8 T: 719.0, p=0.07). Overexpressing APOL1 with IFN $\gamma$ , impaired angiogenesis in both the RV/RV and RV/G0 ECs but not G0/G0 ECs (RV/RV: J: 353.0 T: 319.8; RV/G0: J: 297.8, T: 296.0, G0/G0: J: 739.0 T: 657.8, p=0.001). As a proof of concept, autophagy inhibitor ABT-737 was added to G0/G0 ECs resulting in a 42% decrease in junctions (p=0.036) and 52% decrease in tubules (p=0.012). Mitochondrial oxygen consumption of resting and IFN $\gamma$  treated ECs, was next assessed by bioenergetic profiling. For baseline, there were genotype-dependent differences in spare capacity (SC) and coupling efficiency (CE) (G0/G0: SC: 41.0 $\pm$ 22.0 pmol/min CE: 439.8%; RV/G0: SC: 22.75 pmol/min $\pm$ 0.18 CE:119.9%; RV/RV SC: 24.6 $\pm$ 4.71 pmol/min CE:100.35%). Upon adding IFN $\gamma$ , Proton leak increased 1.89 pmol/min in the G0/G0 ECs, 1.49 pmol/min in the RA/G0 ECs, and 7.50 pmol/min in the RA/RA ECs. This pattern is consistent with genotype dependent increased cation pore formation with electron escape across the inner mitochondrial membrane.

### Conclusion:

IFN $\gamma$  increases both ancestral and variant APOL1 intracellular accumulation in cultured ECs across genotype. In RV carrying ECs, this increased expression results in aberrant autophagy, angiogenesis, and mitochondrial energy production, all of which likely contribute to endothelial dysfunction, representing an underpin of broader organ damage.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Plasmacytoid dendritic cells are considered the main source of pathogenic IFN in SLE. However, recent work found that elevated serum type I IFN protein was not accompanied by increased type I IFN in circulating pDCs, suggesting the importance of other cellular sources of type I IFN in some patients. Developing transitional B cells are important targets of type I IFN in SLE, and were recently shown to produce IFN $\alpha$ . IFN $\beta$  expression has not been investigated in SLE B cells; in mice, however it has been identified as a prerequisite for efficient TLR stimulation, suggesting that autocrine stimulation of developing B cells with high-affinity IFN $\beta$  may be a prerequisite for subsequent immune-competence to respond to TLR challenges.

**Methods:** Peripheral blood mononuclear cells (PBMCs) from 34 SLE patients and 9 healthy controls were recruited; all SLE patients met the ACR 1997 revised criteria for SLE. Comprehensive clinical data was recorded for each SLE subject in a double-blind fashion. Intracellular analysis of endogenous IFN $\beta$  was carried out using validated reagents on FACS isolated B cells.

**Results:** There was a significant increase in endogenous IFN $\beta$  in transitional ( $p = 0.002$ ), naive ( $p = 0.004$ ) and memory ( $p = 0.031$ ) B cell subpopulations of SLE patients compared to healthy controls. Endogenous IFN- $\beta$  in B cells was significantly higher than endogenous IFN- $\beta$  in CD4 T cells, with levels equivalent to that seen in pDCs. Endogenous IFN $\beta$  was highly correlated with clinical disease including renal disease ( $p = 0.0072$ ) and autoantibodies including anti-dsDNA ( $p = 0.036$ ), anti-Sm ( $p = 0.011$ ) and anti-SSA ( $p = 0.04$ ). Notably, T1/T2 B cell IFN $\beta$  expression was significantly increased in African-American patients ( $p = 0.011$ ) with more severe disease manifestations. T1/T2 IFN $\beta$  expression was also significantly correlated with the percent of 9G4<sup>+</sup> autoreactive B cells ( $p = 0.0001$ ) and CD19<sup>lo</sup>CD38<sup>hi</sup>CD27<sup>+</sup> plasma cell formation ( $p = 0.031$ ). Upregulation of CD69 after TLR7 stimulation with CL264 was highly dependent upon B cell endogenous secretion IFN $\beta$  and could be significantly inhibited in the presence of anti-IFN $\beta$  antibody. The specific requirement for IFN $\beta$  was demonstrated by the lack of additional inhibition in the presence of anti-IFN $\alpha$ R neutralizing antibody, which blocks signaling from all type I IFNs. *In vitro* survival of purified B cells was also dependent on IFN $\beta$  after TLR7 stimulation and was significantly decreased with blockade of IFN $\beta$ .

**Conclusion:** Intracellular IFN $\beta$  production by early-stage transitional B cells is a novel and important B cell intrinsic factor that regulates B cell survival and sensitivity to TLR7 stimulation. B cell endogenous IFN $\beta$  may be an essential factor for their development into autoantibody producing B cells. The present work suggests a need for future human lupus studies into type I IFN dysregulation that pioneer beyond the view of pDC produced IFN $\alpha$ . These results also provide a mechanistic basis for development of more effective therapies to dampen the type I IFN cascade by specifically targeting the high-affinity IFN $\beta$  or the enhanceosome components that promote its induction in a subgroup of lupus patients.

## Pathological Roles By Siglec and Type I Interferons for the Development of Autoimmune Congenital Heart Block

Robert M. Clancy<sup>1</sup>, Marc Halushka<sup>2</sup> and Jill P. Buyon<sup>1</sup>, <sup>1</sup>NYU School of Medicine, New York, NY, <sup>2</sup>Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Given that diseases associated with anti-SSA/Ro such as SLE and Sjögren's syndrome associate with an upregulation of type I interferons, recent attention has focused on a potential role for IFN in the pathogenesis of congenital heart block (CHB). Based on the consistent demonstration of macrophages and multinucleated giant cells in areas of injury, it is relevant that Sialic Acid Binding Ig Like Lectin 1 (SIGLEC1), a receptor on monocytes/macrophages, is upregulated by IFN. Functionally, Siglec-1 expressing macrophages might play an important role as effector cells in fibrosis. Accordingly, this study leveraged both autopsy tissue and freshly isolated macrophages from a fetal heart dying with CHB to address whether IFN- $\alpha$  contributes to the pathogenesis of CHB by regulating activated macrophages in affected cardiac tissue.

**Methods:** Three approaches were taken to evaluate Siglec-1 expression. Transcriptomic analysis was performed on macrophages freshly isolated from a fetal heart dying with CHB at 19 weeks and a heart from an otherwise healthy electively terminated fetus using (DAPI negative cells with isolation by flow using antibodies to CD45). Immunohistochemistry was performed on another fetal heart dying with CHB. In vitro experiments utilized cultured healthy human macrophages transfected with anti-SSA/Ro- associated ssRNA as a proxy for the in vivo conditions.

**Results:** Transcriptomes of the two hearts for each isolated leukocyte fraction were compared. By following 213 IFN inducible genes, there was enrichment of targeted transcripts in CHB vs control ( $p=0.0001$ ) and SIGLEC1, which was 200-fold more abundant in CHB vs control and ranked among the top three differentially expressed candidates. In another fetal heart dying with CHB, Siglec1 staining as detected by antibody HPA053457 was prominent in areas of injury. By morphology, the two cell types expressing Siglec 1 were macrophages and dendritic cells. In vitro experiments were performed in accordance with previous laboratory work, in which a model of anti-SSA/Ro-associated injury exploits macrophages stimulated with the ssRNA component (hY3) of the SSA/Ro immune complex. IFN inducible genes (15 transcripts) were among the 30 most highly upregulated genes in hY3 stimulated conditions and SIGLEC1 was two-fold more abundant in CHB vs control. Given the enrichment of type I IFN-responsive genes in the macrophage transcriptome, a WISH cell line was selected to evaluate supernatants from macrophages transfected with hY3. IFIT1, MX1, and EIF2AK2 transcripts were significantly increased in the WISH cells treated with hY3 macrophage supernatants, but not macrophage supernatants alone ( $N = 7$ ,  $P = 0.02$ ).

**Conclusion:** These data now provide a link between IFN and the inflammatory and possibly fibrosing component of CHB and position Siglec-1 positive macrophages as integral to the process.

### Prediction of connective tissue disease in an at-risk cohort using a novel interferon stimulated gene expression score

**Background/Purpose:** A period of ANA positivity and other immune dysregulation precedes autoimmune connective tissue disease (CTD), providing a potential opportunity for disease prevention. Type I interferons (IFN-I) are important mediators of CTDs but their role in disease initiation is unclear. The objective of this study was to develop biomarkers of progression to CTDs, with a view to enabling early intervention for disease prevention.

**Methods:** A prospective observational study was conducted in 150 patients. At Risk of CTD was defined by (i) ANA; (ii)  $\leq 1$  clinical SLE criteria; (iii) symptom duration  $< 12$  months and (iv) treatment-naïve. Progression was defined by meeting 2012 ACR/SLICC SLE, 2016 ACR/EULAR Primary Sjogren's, or other diagnostic criteria. Using factor analysis, we previously reported a novel IFN score which comprised 30 selected IFN stimulated genes (ISGs), as measured using TaqMan, into two factors scores: (i) "Score A" (composed of IFN- $\alpha$  responsive genes) and (ii) "Score B" (genes responsive to IFN- $\alpha$ ,  $\beta$  and  $\gamma$ ). 50 healthy controls and 150 SLE patients were used as negative and positive controls. Penalised logistic regression using Lasso method was used to identify baseline predictors of CTD progression.

**Results:** 118 patients with 1-year follow-up data were included in this analysis. 104 were female with median age (range) 48 (20-84) years. 20 (17%) patients progressed to CTD (SLE=14, Sjogren's=5) in the following 12 months. At baseline, in At Risk CTD vs healthy controls, only IFN Score A was increased;  $p=0.002$ . IFN Score B was only increased in true established SLE. In At Risk patients, IFN Score B was low in patients who did not progress and increased in those who did progress;  $p<0.001$ . ROC indicated that a Score B level of  $>0.126$  yielded Area Under the Curve (AUC) of 0.82 with 58% sensitivity, 85% specificity, 46% positive predictive value and 90% negative predictive value in predicting progression. However, there was only a trend to difference in IFN Score A between these two groups;  $p=0.058$  (Figure 1). A positive family history of autoimmune rheumatic disease (AIRD); OR 4.22 95% CI (1.07 - 16.73) and Score B; 2.70 (1.38 - 5.28) increased the odds of CTD progression at 12 months in multivariable analysis.

**Conclusion:** A novel ISG score and family history of ARD predict progression from ANA+ to clinical autoimmune disease. These may allow early intervention to prevent CTD. Analyses of other immunological biomarkers and longitudinal tests are in progress as well as a validation cohort.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

**Background/Purpose:** Women with Sjögren's syndrome and autoantibodies against Ro/SSA are at risk for pregnancy complications, including neonatal lupus erythematosus (NLE) and a congenital heart block in the baby. Ro/SSA autoantibodies are also associated with expression of interferon (IFN) regulated genes. Treatment with hydroxychloroquine (HCQ), which alters type 1 IFN activity, is thought to reduce the risk of NLE. The pattern and magnitude of IFN expression and responses in Ro/SSA autoantibody exposed newborns has not been investigated.

**Methods:** Thirteen Ro/SSA autoantibody positive mothers either receiving no medication (Ro/SSA+) or treated with HCQ and/or azathioprine (Ro/SSA+T), and their newborn babies were included in the study, together with 8 healthy mother-baby pairs (HC). Blood was drawn from the mother and baby (cord) at birth, with immediate separation into plasma and PBMC. mRNA expression levels were measured using microarrays and used for calculating IFN scores. Cell surface expression of molecules was investigated by flow cytometry, and IFN- $\alpha$  in plasma and supernatants was analyzed by immunoassay. The ability of PBMCs from newborns to produce IFN- $\alpha$  in response to autoantibody exposure was tested by stimulation with 10% plasma in cell culture for 24h.

**Results:** As expected, mRNA expression patterns in cells of SSA+ mothers showed enrichment of type I IFN pathways compared to HC mothers, and mothers from the Ro/SSA+ group had a higher IFN score and higher levels of IFN- $\alpha$  than HC mothers. Notably, also in newborns of Ro/SSA+ mothers, there was an enrichment of type I IFN pathways and high IFN score compared to newborns of HC mothers, and maternal and baby IFN scores had a significant, positive correlation (Pearson  $r=0.8128$ ,  $p<0.0001$ ). However, babies in the Ro/SSA+T group, whose mothers received immunomodulatory treatment, had an IFN score with values comparable to HC babies, while the maternal Ro/SSA+T IFN scores did not differ from those of non-treated mothers. Activation of CD14+ monocytes, in the form of increased MHC class II surface expression was observed in the Ro/SSA+ exposed newborns. PBMCs from both HC and Ro/SSA+ newborns cultured with Ro/SSA+ plasma produced IFN- $\alpha$ .

**Conclusion:** Babies exposed to Ro/SSA autoantibodies in utero have circulating IFN- $\alpha$ , an IFN-signature in their PBMCs and increased MHC class II expression on the cell surface of monocytes, which was partly reversed by maternal treatment with HCQ or other immunomodulatory drugs. PBMCs from babies are capable of producing IFN- $\alpha$  after exposure to Ro/SSA+ plasma. There is a measurable activation of the type I IFN system in Ro/SSA autoantibody exposed fetuses which may contribute to the risk of NLE.

## Gene Expression Analysis Demonstrates That Multiple Type 1 Interferons Are Involved in Lupus Pathogenesis

**Michelle Catalina**<sup>1</sup>, Prathyusha Bachali<sup>2</sup>, Sushma Madamanchi<sup>1</sup>, Amrie Grammer<sup>1</sup> and Peter Lipsky<sup>1</sup>, <sup>1</sup>Ampel BioSolutions LLC, Charlottesville, VA, <sup>2</sup>Ampel BioSolutions LLC, Charlottesville, MA

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis I

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 2:30PM-4:00PM

## Background/Purpose:

A role for interferon (IFN) in lupus pathogenesis has been inferred from the prominent IFN gene signature (IGS) found in lupus peripheral blood. However, the identification of the major type of IFN up-regulating gene expression in SLE has not been determined. The current experiments were undertaken to differentiate the subtype of IFN driving gene expression perturbations in lupus.

**Methods:** Raw data from lupus cells and tissues were derived from the GEO repository and collaborators. Determination of differentially expressed (DE) genes was done for each dataset. Gene Set Variation Analysis (GSVA) was used as a non-parametric, unsupervised method for estimating the variation of pre-defined gene sets in gene expression samples. Upstream regulator analysis was employed to identify possible upstream regulators of lupus DE genes. For each potential regulator, an activation z-score was calculated from the experimentally observed information provided for the downstream targets. The first reference dataset used was from Chiche et al, 2014, the second was the DE analysis of the in vitro treatment of PBMC with individual IFNs (Waddell et al, 2010) and the third was the IFNB signature in the whole blood of Multiple Sclerosis patients treated with IFNB (Nickles et al, 2013).

## Results:

The IGS was detected in most lupus samples. Comparison of lupus DE genes with previously reported IGS modules or with gene expression data sets obtained by stimulating PBMC with specific IFNs indicated better separation of lupus patient samples from controls using the latter and, additionally, identified patients with TNF and IL12 signatures lacking IFN signatures. Z score calculations to determine the most likely upstream regulator predicted IFNB1 and IFNW as the major IFNs inducing the IGS for SLE skin and kidney. Confirmation of the strong IFNB1 signal was carried out using published microarray data of the IFNB1 signature in Multiple Sclerosis (MS) patients (MS IFNB1). The MS IFNB1 had superior overlap to SLE datasets compared to both IFN-M and the in vitro PBMC IFN Signature. Z score calculations using the MS IFNB1 signature showed high Z scores for all active lupus cells and tissues. The data indicate that IFNB and IFNW are likely IFN family member upstream regulators accounting for the IGS in SLE cells and tissues.

## Conclusion:

The type I and type II IGS overlap significantly and are not distinguishable by previously defined interferon modules. In contrast, GSVA using individual cytokine / interferon signatures from in vitro stimulation of PBMC allows interrogation and stratification of individual lupus patient IGS and separates lupus patient from control samples. Z score calculations demonstrate the likely role of IFNB1 and IFNW1 in SLE pathogenesis and suggest that targeting these interferons may have therapeutic value for SLE.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP: Exemplary Abstracts

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Osteoarthritis (OA) is the number one chronic condition of the joints. Social determinants associated with disability progression due to OA are largely unknown. Efforts to determine if socioeconomic status (SES) is associated with OA disability progression may aid in prevention efforts. This study aims to describe the relationship between SES measures with disability progression among individuals with radiographic knee and/or hip OA from the Johnston County OA (JoCo OA) Project in rural North Carolina.

**Methods:** We examined the association between disability progression and each of four individual SES variables (education, occupation, income, and home ownership) and one community level SES measure (household (HH) poverty) using data from 541 participants in the JoCo OA cohort. In the time to event analysis, disability progression was defined as a change of  $\geq 0.22$  points in the Health Assessment Questionnaire (HAQ) disability score between baseline and last follow-up. Risk of disability progression was evaluated using a parametric time to event Weibull model that accounted for interval censoring. Change in HAQ score was assessed using linear mixed models (LMM). Interaction terms were included to examine disability progression by age. All analyses simultaneously adjusted for other SES measures, as well as age, race, and gender.

**Results:** Based on the time to event analysis, individuals who reported making  $\leq \$30,000$  were more likely to experience disability progression compared to those with an income  $> \$30,000$  (aHR = 1.45; 95% CI: 1.03, 2.04). In contrast, the LMM analysis showed that lack of home ownership was the only SES covariate that had an independent association with disability after accounting for interaction terms ( $\beta$ : 0.14; 95% CI: 0.02, 0.25). Additionally, the interaction between age and HH poverty indicated that as an individual aged, the effect of a 10% increase in HH poverty on increases in HAQ scores was greater ( $\beta$  = 0.03; 95% CI: 0.01, 0.05). This suggests an increased risk of disability progression among individuals living in areas of higher HH poverty as they age.

**Conclusion:** Lower income, lack of home ownership and increased household poverty are independently associated with increased risk of disability progression, suggesting that societal interventions to address these specific SES factors could help to mitigate OA-related disability.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP: Exemplary Abstracts

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Lupus patients commonly report sleep dysfunction, which is associated with upregulation of inflammatory cytokines in healthy people. Studies exploring relationships between self-reported sleep dysfunction and SLE have yielded conflicting results. The objective of our study was to evaluate the relationship between sleep and SLE disease activity in a large, ethnically diverse cohort of adult lupus patients.

**Methods:** 141 patients meeting ACR classification criteria for SLE completed the Patient-Reported Outcomes Measurement Information System (PROMIS) Sleep Disturbance Short Form 8b and Sleep Related Impairment Short Form 8a. Correlations between sleep scores and the SLE Disease Activity Instrument (SLEDAI) were tested by Spearman correlation. Upper and lower quartile proportions and associations were compared by Chi-square. Patients completing sleep assessments at  $\geq 2$  visits (n=69) were examined for intra-patient variability with mixed linear regression to model relationships between SLEDAI and sleep disturbance or impairment.

### Results:

Participants were mostly Caucasian (50.4%) or African American (29.1%) and female (90.1%), with median age of 42. Sleep disturbance and impairment was increased compared to the national average (median T-scores of 56.3 and 55.6, respectively, vs. average of 50). Patients in the upper quartile of SIS and SDS did not differ in SLEDAI score compared to patients in the lowest quartile of SIS and SDS. However, SLE patients with the poorest sleep were more likely to have anti-dsDNA (OR 3.33, 95% CI 1.43, 10.0;  $p < 0.01$ ) and less likely to be scored for arthritis than those with the least sleep impairment (OR 0.185, 0.050, 0.690;  $p < 0.05$ ). Within individuals, sleep disturbance and sleep impairment did not correlate with total SLEDAI scores ( $r^2 = -0.0859$  and  $r = -0.125$ , respectively;  $p > 0.05$ ). Adding medication usage covariates showed that sleep inducing agents (coefficient = -2.02;  $p < 0.05$ ) were associated with a decreased SLEDAI score, and steroid use (0.707;  $p < 0.05$ ) was associated with an increased SLEDAI score.

**Conclusion:** We found higher rates of sleep dysfunction in SLE than the national average which was not accounted for by SLEDAI scores. The possibility of immune phenotypes (anti-dsDNA) or medications contributing to sleep dysfunction should be further studied as improved sleep may be associated with health benefits such as decreased pain, less depression or minimization of co-morbid fibromyalgia.

## A Multidisciplinary Telemedicine Program for Identification of Spondyloarthritis in Medically Underserved Communities

**Christopher Hawke**<sup>1</sup>, Laura Passalent<sup>1</sup>, Nigil Haroon<sup>2</sup>, Robert D Inman<sup>3</sup> and Y. Raja Rampersaud<sup>4</sup>, <sup>1</sup>Allied Health, Toronto Western Hospital, Toronto, ON, Canada, <sup>2</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Spondylitis Clinic, Toronto, ON, Canada, <sup>3</sup>Department of Immunology, University of Toronto, Toronto, ON, Canada, <sup>4</sup>Arthritis Program, Krembil Research Institute, University Health Network, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP: Exemplary Abstracts

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Early diagnosis is critical for optimal management of patients with inflammatory arthritis. Axial spondyloarthritis (AxSpA) has the longest delay in diagnosis among inflammatory joint diseases. Timely access to rheumatological assessment is particularly challenging in remote areas.

**Objectives:** To evaluate the impact of an alternate model of care on detection of AxSpA in remote areas and determine patient satisfaction with the model.

### Methods:

To improve access to assessment of AxSpA, a satellite inter-professional AxSpA screening clinic (SpASC) was established 1000 kilometers away from the parent spondylitis clinic. Two Advanced Practice Physiotherapists (APPs) with extended scope training in

inflammatory arthritis provided standardized assessment onsite for patients with chronic back pain of more than 3 months duration and onset less than age 50. Patients with a previous diagnosis of SpA or those with leg-dominant pain were excluded. A telemedicine platform (OTN) allowed for APPs to consult with the staff Rheumatologist at the parent site at the end of the assessment.

The following investigations were obtained prior to the assessment: X-rays of the pelvis, lumbar, and cervical spine; testing for HLA B27, CRP and ESR levels.

The APP and Rheumatologist independently diagnosed patients as; AxSpA, non-specific back pain or other. The Rheumatologist and APP rated the probability of AxSpA as low, medium or high, scoring confidence of the classification on a 0-10 Likert scale. Radiographs of the sacroiliac joints were scored independently by the APP and rheumatologist using New York grading. For patients thought likely to have AxSpA despite non-diagnostic X-rays, an MRI was ordered. Access was measured by wait time in days and by the geographic area of patients based on postal code. Each patient that attended the satellite clinic was asked to complete a multidimensional patient satisfaction questionnaire.

## Results:

In this analysis, 43 patients who completed the study protocol were assessed. Another 17 patients are awaiting MRI. The patients had a mean age of 36.8 (IQR 27.5-41) years and 28 (68.3%) were female. Nine (20.9%) patients were diagnosed with AxSpA (5 Ankylosing Spondylitis and 4 non-radiographic AxSpA). Thirty-two (74.4%) had non-specific back pain. One patient (2.3%) had a pedicle fracture and one (2.3%) was referred to a specialist clinic, with a subsequent diagnosis of lupus.

Diagnostic agreement between the APP and Rheumatologist was moderate-good (kappa 0.63 (0.38-0.87)). Median wait times were 162 days (July 2016, IQR, 69-176 days) and 131 days (March 2017, IQR, 99-180 days). With local wait time up to 2 years. Of the 60 patients seen in the clinic 47 (78%) travelled less than 50km to the clinic, with 13 (21.6%) travelling between 120-350kms.

Twenty-three patients (51%) returned satisfaction questionnaires after the consultation: 21 (95%) either agreed or strongly agreed that overall they were satisfied with the consultation.

## Conclusion:

Establishing a satellite clinic with ACPAC-trained APPs consulting rheumatologists via telemedicine can offer improved access to care and effective diagnosis of AxSpA. Overall, patients were satisfied and accepting of the alternative consultation process.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP: Exemplary Abstracts

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** EnhanceFitness® (EF) is an evidence-based, community-delivered intervention for older adults; however, its effectiveness in people with arthritis is unknown. The purpose of this pragmatic, community-based, randomized controlled trial was to determine the effectiveness of 12 weeks of EF in improving arthritis symptoms, physical and psychosocial function, and physical activity (PA) in adults with arthritis as compared to a 12-week, wait-list control group.

**Methods:** Community-dwelling adults, aged 18 years or older, were eligible if they were sedentary/low-active ( $\leq 60$  minutes/week of moderate/vigorous-intensity PA), had self-reported physician-diagnosed arthritis, and were medically cleared for exercise. Participants were randomly assigned to the EF (immediate exercise) or wait-list control group. Participants exercised thrice weekly for 12 weeks (36 classes), and completed self-reported and performance-based assessments at baseline and 12 weeks. The outcomes were arthritis symptoms (pain, stiffness, fatigue on a visual analogue scale), physical and psychosocial functioning (SF-12, Self-Efficacy Questionnaire), upper/lower extremity strength (arm curl and 5 times sit-to-stand tests), aerobic endurance (2-minute step test), functional mobility (timed up-and-go test), and PA (minutes/week and kilocalories/week for all PA, CHAMPS Physical Activity Questionnaire). Analysis of Covariance was performed to determine if outcomes improved from baseline to 12 weeks after adjusting for group, age, sex, body mass index, site (northern vs. southern state county), and outcome score at baseline. The proportion of participants meeting national PA guidelines ( $\geq 150$  minutes/week of moderate/vigorous-intensity exercise, National Health Interview Survey Questionnaire) was compared between groups at 12 weeks using a Chi-square test.

**Results:** Twenty-two EF classes were held at 15 community sites in 4 urban and 5 rural counties. Of the 134 participants, 68 were randomized to EF and 66 to the control group. Participants were primarily female (87%) and white (95%), with osteoarthritis (75%) and a mean  $\pm$  SD age of  $67 \pm 11$  years (range 35-89). The EF group experienced significantly lower stiffness (Effect Size [d] -0.9,  $p < 0.001$ ) and fatigue (d -0.8,  $p = 0.03$ ), and improved performance on the arm curl (d 0.9,  $p < 0.001$ ) and timed up-and-go (d -0.8,  $p = 0.03$ ) tests at 12 weeks as compared to the control group. A significantly greater proportion of the EF group were meeting PA guidelines (67%) at 12 weeks as compared to the control group (34%) ( $p < 0.001$ ). There were no significant differences between groups in the remaining variables.

**Conclusion:** A 12-week EF program was effective in improving arthritis symptoms, upper extremity strength, functional mobility, and the proportion meeting PA guidelines in adults with self-reported arthritis. This study demonstrated that an exercise program including the four key components for reducing pain and enhancing physical function (aerobic, strengthening, balance, and flexibility exercises) can substantially improve health in adults with arthritis when delivered in real-world community settings.

Dunlop<sup>4</sup>, David Conroy<sup>1,5</sup>, Julia (Jungwha) Lee<sup>6</sup>, Linda VanHorn<sup>6</sup>, Bonnie Spring<sup>1</sup> and Kenzie Cameron<sup>7</sup>, <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>2</sup>Exercise Science, University of South Carolina's Arnold School of Public Health, Columbia, SC, <sup>3</sup>Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>4</sup>Center for Healthcare Studies, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>5</sup>Kinesiology, The Pennsylvania State University, University Park, PA, <sup>6</sup>Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>7</sup>General Internal Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP: Exemplary Abstracts

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Most patients risk gaining weight in the years after knee replacement, adding further concern to a population that is mostly overweight/obese prior to surgery. Based on patient and stakeholder input and the Self-Determination Theory, we adapted the Diabetes Prevention Program to create the Patient-Centered Weight Loss Program (PACE). The purpose of the study was to compare changes in weight, function, and patient-reported outcomes between PACE programs initiated either before or after knee replacement.

**Methods:** Consented patients scheduled for knee replacement were randomized to a 14 session weight loss program starting either  $\leq 6$  weeks before surgery (PACE) or at 12 weeks post-op (Delayed PACE). All participants were provided a calorie goal to facilitate a 5% weight loss and were encouraged to increase physical activity. Patients were encouraged to self-monitor diet and activity using their preferred method (paper, web, app, Fitbit) and selected weekly or biweekly coaching sessions based on preference. Weight, function,

and patient-reported outcomes using Patient-Reported Outcomes Measurement Information System (PROMIS) were assessed at baseline (pre-op), 12, and 26 weeks after surgery. Repeated measures ANOVAs were used to examine changes in outcomes across time and group.

**Results:** Ten participants (5 randomized to PACE and 5 to Delayed PACE) completed the PACE intervention (mean±SD 62.2±7.9 years, 60% female, 80% White, BMI 35.2±5.4 kg/m<sup>2</sup>). Participants completed an average of 9.6±2.2 coaching sessions that were 15.2±3.4 minutes in duration. A significant effect for time ( $P<0.001$ ) and a time by group interaction ( $P=0.01$ ) were observed on weight change. Improvements over time were seen for all functional outcomes and patient-reported outcomes with the exception of sleep disturbance. No baseline differences were seen between groups.

**Conclusion:** Starting a patient-centered weight loss program either before or after knee replacement resulted in significant weight losses at 12 and 26 weeks post-op. Patients appear to naturally lose weight immediately post-op; hence waiting to start a weight loss program 12-weeks post-op may initiate greater weight loss during the first 6 months after surgery as compared to those who start ≤6 weeks pre-op.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ARHP: Exemplary Abstracts

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Cognitive Dysfunction (CD) is seen among 20-80% of patients with Systemic Lupus Erythematosus (SLE) and adversely affects their quality of life and productivity. Pain, a known correlate of CD, may occur in SLE from the disease itself or concurrent fibromyalgia (FM). Sleep issues and depression, also encountered in SLE, may impact both pain and CD. With the goal of a potential intervention for CD, we explored whether sleep issues and depression mediated the relationship between pain and CD in SLE patients.

**Methods:** 115 consenting SLE patients were recruited from a Rheumatology outpatient clinic. Patients completed questionnaires on demographics, pain (Pain Inventory), stress [Perceived Stress Scale (PSS)], depression (PHQ2), sleep (LupusPROv1.8), and cognition (LupusPROv1.8). Diagnosis of concurrent FM and current steroid use were identified via chart review. Physicians performed disease activity (SELENA-SLEDAI) and damage (SLICC-ACR/ SDI) assessment. Bivariate correlations were used to determine relationships between above variables. Relationships among pain, sleep, depression and CD (primary variables) were assessed with bootstrapped mediation models controlling for race/ethnicity, FM status, current steroid use, SLEDAI, SDI, and stress (covariates).

**Results:** The sample was 90% female: average age was 40 years (SD 13). Racial composition was 52% African-American, 24% White, 11% Hispanic, 5% Asian, and 8% other. There were significant relationships noted among the variables (Table 1), including a positive relationship between pain and CD (r 0.39). Mediation analyses (Figure 1) indicated that the effect of pain on CD was mediated by depression (B 0.33) and sleep (B 0.30). These effects were maintained even after controlling for aforementioned covariates, of which, only SLEDAI (B 0.20) and stress (B.22) were significantly linked to CD [all p's < .05] in the full model.

**Conclusion:** Even after controlling for disease activity and stress, both sleep and depression accounted for the relationship between pain and CD in SLE. These relationships need validation in longitudinal studies with additional measurement modalities. Our findings indicate promising, non-pharmacologic intervention avenues for SLE patients with pain and CD. Cognitive-behavioral therapies for depression and sleep are known to reduce distress and enhance functioning across various psychosocial domains. Given the symptom burden of SLE, interventions that maximize potential benefits without additional pharmacologic treatments may be of particular utility.

Table 1. Correlations among primary study variables and covariates.

	1	2	3	4	5	6	7	8	9
1 Total Pain Index	1								
2 Lupus PRO Sleep	.65**	1							
3 PHQ 2	.42**	.52**	1						
4 Lupus PRO Cog	.39**	-.56**	.57*	1					
5 African American Race	.21*	.20*	.26**	.22*	1				
6 Comorbid FM	.25**	.18	.30**	.30**	.06	1			
7 Takes Steroids	.24*	.04	.15	-.01	.12	-.18	1		
8 SLEDAI	.20*	.01	.03	-.15	.09	-.09	.42**	1	
9 SDI	-.08	-.12	-.07	-.13	.13	-.10	.13	.11	1
10 Perceived Stress	.34**	.37**	.57**	.49**	.19*	.15	.05	.10	.02

Note: \* $p < .05$ , \*\* $p < .01$ ; For ease of interpretation of results, signs for Lupus PRO Sleep and Lupus PRO Cog scores were reversed. Accordingly, higher Lupus PRO Sleep scores = worse sleep and higher Lupus PRO Cog scores = worse cognition.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Genetics, Genomics and Proteomics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Nearly 150 genetic loci are convincingly associated with lupus (SLE) or rheumatoid arthritis (RA) and underlie their incompletely understood mechanisms of pathogenesis. Since 90% of complex disease genetic loci fall in genomic regulatory regions, since we suspect that regulatory elements may be shared across loci, and since other evidence is consistent with Epstein-Barr virus (EBV) contributing to SLE and RA pathogenesis, we tested the hypothesis for both SLE and RA that transcription factors and co-factors (TFs) encoded by EBV selectively bind the human genome at disease risk loci. We also evaluated over 212 TFs in over 150 cell lines and types in 1544 datasets. We selectively evaluated examples of allele specific TF binding.

**Methods:** We used published results, defining disease risk loci for RA and SLE as all variants with disequilibrium  $r^2 > 0.8$  to the most highly associated locus variant. The location of TF binding was taken from 1544 available TF chromatin immunoprecipitation with sequencing (ChIP-seq) datasets. By assigning loci to random sites in the human genome (or to open chromatin in EBV infected B cells) while preserving their locus structure, we used simulation to generate a normal distribution to estimate probability of the observed intersections of TF ChIP-seq binding and the risk loci for 213 diseases or phenotypes. We explored individual variants in ChIP-seq datasets for distorted TF binding to alleles.

**Results:** After Bonferroni correcting for 1544 comparisons we found powerful associations of the Epstein-Barr virus nuclear antigen 2 (EBNA2) ChIP-seq data with the loci of European SLE (26 of 53 loci, OR=6,  $P=1 \times 10^{-25}$ ) and of RA (25 of 84 loci, OR=4,  $P=2 \times 10^{-14}$ ), but not with the other EBV TFs. A set of at least 24 human TFs were similarly strongly associated and clustered with EBNA2 at largely the same loci; many of these human TFs are known to support inflammatory, interferon, or B cell development pathways (RELA, RELB, NFKB1, NFKB2, IKZF1, IRF4, PAX5, etc.) These associations were virtually exclusive to Epstein-Barr virus (EBV) infected B cells and were not found in other tissue types nor in B cell lines that were not EBV infected. These associations were present when limiting the simulation to open chromatin in EBV transformed B cells. EBNA2 is shown to differentially immunoprecipitate specific plausibly causal variant alleles. The loci of nearly 200 other disorders evaluated did not have an association with EBNA2 ChIP-seq data; however, 212 TFs from the 1544 ChIP-seq datasets produced 2264 clearly significant associations, each  $P < 10^{-6}$ , with the risk loci from 94 diseases or phenotypes, including other rheumatic disorders.

**Conclusion:** The indirect binding of EBNA2 to human DNA is associated with the genetic risk loci of both SLE and RA, as also are an associated set of human TFs clustering with EBNA2 at particular genetic loci, identifying different subsets of loci for RA and SLE. In the data now available these relationships in both diseases are found virtually exclusively in EBV-infected B cells. EBNA2 and human TFs bind alleles differentially at some plausibly causal variants. These results are consistent with EBV, the EBV infected B cell, and EBNA2 encoded by EBV DNA participating in SLE and RA pathogenesis.

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Genetics, Genomics and Proteomics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** While genome-wide association studies have identified risk loci for rheumatoid arthritis and other autoimmune diseases, in very few instances have causal variants driving risk been precisely defined.

**Methods:** We fine-mapped 76 autoimmune disease loci outside of the MHC, combining genotype data from rheumatoid arthritis (RA) and type 1 diabetes (T1D) case-control studies. After sequencing 799 1kb regulatory (H3K4me3) regions within these loci in 568 individuals, we observed accurate imputation for 89% of common variants. We applied Bayesian fine-mapping for these loci in RA (11,475 cases, 15,870 controls), T1D (9,334 cases and 11,111 controls) and combined datasets.

**Results:** We reduced the number of potential causal variants to ≤5 in 8 RA and 11 T1D loci. We identified causal missense variants in five loci (**Table**, *DNASE1L3*, *SIRPG*, *PTPN22*, *SH2B3* and *TYK2*) and likely causal non-coding variants in six loci (**Table**, *MEG3*, *TNFAIP3*, *CD28/CTLA4*, *ANKRD55*, *IL2RA*, *REL/PUS10*). In the *DNASE1L3* locus, the previously reported missense RA lead SNP rs35677470 (posterior=0.81) causes a R206C change in DNASE1L3, which abolishes its nuclease function. In *SIRPG*, we identified the rs6043409 missense variant, causing a V263A substitution (posterior=0.25). For the loci with non-coding causal candidates, we performed stringent filtering based on allelic function and enhancer activity. Using this approach, in the *CD28/CTLA4* locus, we identified independent variants associated with RA and T1D: the rs117701653 SNP near *CD28*, associated with RA (posterior=0.82), and the rs3087243 SNP associated with both RA and T1D (posterior=0.91). Functional assays including EMSA and luciferase assay showed allele specific, cell type specific activity for rs117701653 but not rs3087243. Additionally, in the *TNFAIP3* locus in RA, we identified allele specific and cell type specific enhancer activity for the rs35926684 indel (posterior=0.24), but not the previously reported lead variant rs6920220. Finally, in the *MEG3* locus, we identified the rs34552516 indel (posterior=0.37) for T1D with allele specific and cell type specific enhancer activity.

**Conclusion:** This study demonstrates the potential for dense genotyping and imputation to pinpoint missense and non-coding causal alleles.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Genetics, Genomics and Proteomics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Detecting distinct cellular subsets in disease tissues is key to understanding the pathogenesis of immune diseases, for example in synovial tissues in rheumatoid arthritis (RA). Yet this task is complicated by the highly heterogeneous nature of the immune system. Recently, advances in single-cell technologies have enabled us to increase the power to resolve this heterogeneity to find disease relevant and cell type subsets. Integration of single-cell data with bulk data will help identify differentially abundant cell subsets.

**Methods:** We develop a novel statistical method for integrative analysis of any single-cell assay (flow cytometry, single-cell RNA-seq, or mass cytometry) with bulk RNA-seq (Figure 1). Our method has three steps. (1) We find the principal components (PCs) in the bulk RNA-seq data. (2) We model cell type abundances as a linear combination of bulk PCs. With single-cell data, we model a single-cell measurement with each PC to identify important signatures of bulk RNA-seq. The identified subsets are reflected as distinct clusters of cells in single-cell data and explain the variance in the bulk data. In mass cytometry data, we use a logistic model that includes the PC as a variable to predict the cluster identity of a cell. (3) To assess significance, we use permutations to test statistical significance of model coefficients.

**Results:** Using this integrative method, we are able to identify cellular subsets and statistically significant marker genes (permutation  $P < 1e-5$ ) in fibroblasts, B cells, and T cells in AMP Phase 1 RA data (Bulk RNA-seq: 40 RA and 14 OA; Single-cell RNA-seq: 22 RA and 3 OA; Mass cytometry: 15 RA and 11 OA). Synovial fibroblasts separate into lining fibroblasts marked by CD55 and PRG4, and sublining fibroblasts marked by THY1 and CD74. B cells were separated into two distinct subsets: activated B cells that express HLA-DRA, CD37, and CD83 and plasma cells that express XBP1 and FKBP11. T cells were also separated into CD4<sup>+</sup> helper that express CD4, IL7R, and SELL and CD8<sup>+</sup> cytotoxic that express CD8A, CCL5, and HLA-DQA1. We tested subsets of these populations for disease association. We found that fibroblast subset marked by THY1 were significantly associated with RA (logistic regression  $P < 2e-5$ ) when we integrated bulk data with mass cytometry. Derived from the bulk PCs, we observed that a PD1<sup>+</sup> subset of CD4 memory T cells which have been recently described as peripheral T helper cells also expanded in RA ( $P < 0.01$ ).

**Conclusion:** This computational strategy integrates multiple transcriptomic data types from fresh synovial tissue, giving us a view of the cellular heterogeneity relevant to RA. This method may also have promise in integrating single-cell and bulk data from other sources, for example kidney biopsies from systemic lupus erythematosus (SLE) or tumor biopsies. Acknowledgements: We acknowledge AMP RA/SLE network and AMP funding NIH UH2AR067677-01.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Genetics, Genomics and Proteomics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** There is significant clinical and molecular heterogeneity among patients suffering from systemic autoimmune diseases, such as systemic lupus erythematosus (SLE) and primary Sjögren's Syndrome (pSS). Deciphering this heterogeneity could allow the molecular stratification of patients in terms of prognosis and therapeutic targets. Our previous work using a modular repertoire analysis (MRA) has demonstrated that the IFN signature observed in SLE patients is not restricted to a mere type I IFN signature, but involves the gradual activation of 3 distinct IFN modules driven by various IFN types including IFN $\gamma$ . Although a type I IFN signature

has been described in patients with pSS, a detailed MRA in pSS is still lacking. Here we aimed to refine MRA and discover new transcriptional signatures in SLE and pSS, by applying a novel graph-theoretic-approach (GTA) to reveal the progression of module activation patterns in these diseases.

**Methods:** Blood transcriptomic microarray datasets, including that of SLE patients (n=157 samples; LUPUCE cohort) fulfilling ACR-criteria and pSS patients (n=133; UKPSSR) fulfilling American European Consensus Group (AECG)-criteria, were analyzed using MRA followed by GTA. MRA was performed using a blood modular framework comprising 260 modules. A novel GTA, based on the Extended Suppes Bayes Causal Network (ESBCN), was used to generate an ordered, branching progression model of modular activation. Disease-specific causal graphs in selected datasets were built in order to generate hypotheses regarding disease progression for a particular disease. Significance to clinical characteristics was evaluated using Fisher's exact test and ANOVA, for categorical and continuous characteristics, respectively.

**Results:** The GTA-to-MRA analysis confirmed the previously described pattern of gradual activation of IFN modules in SLE patients: first M1.2 (81.5%), then M3.4 (67.5%) and finally M5.12 (22.3%). Interestingly, this gradual IFN signature was also observed in pSS patients who exhibited activation of 1 (64%), 2 (37%) or all 3 (8%) IFN modules. Additionally, GTA-to-MRA identified a dual mode of disease progression in SLE after the activation of the IFN modules M1.2 and M3.4: either completion of the IFN signature, to include the more IFN $\gamma$ -related module M5.12 and with completion of a newly identified 4<sup>th</sup> IFN-related module M8.59, or the activation of a neutrophil module M5.15 associated with renal involvement. In pSS, a dual mode of progression identified comparable completion of IFN signature to include M5.12, ending with the new IFN module M8.59, or activation of a 5<sup>th</sup> IFN-related module M8.95. Solely 6% of pSS patients portrayed a neutrophil signature, not linked to IFN progression, possibly identifying a relevant new pSS subgroup.

**Conclusion:** The application of GTA to blood MRA reveals for the first time the sharing of gradual activation of IFN modules between SLE and pSS, identifies new IFN-related modules through the observation of progression patterns, and discerns a pattern of progression involving a neutrophil signature associated with renal involvement in patients with SLE. Defining distinct molecular subgroups will aid in development of more tailored therapeutic regimens.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Genetics, Genomics and Proteomics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Epigenetics participates in the pathogenesis of rheumatoid arthritis (RA). Epigenetic marks, gene expression and DNA polymorphisms have been investigated but the analyses are limited to few marks and simple combination methods. In the present study, we used a novel algorithm (EpiSeq) to integrate epigenomes for RA FLS in an unbiased fashion combining whole genome histone modifications, open chromatin, RNA expression and DNA methylation. By focusing on the chromatin states of

regulatory elements and using a new computational platform, we identified unexpected pathways that contribute to the pathogenesis of RA.

**Methods:** We applied multiple omics technologies on 11 RA and 11 osteoarthritis [OA] FLS: ChIPseq for histone modifications, ATACseq for open chromatin, RNAseq for transcriptomes and whole genome bisulfite sequencing (WGBS) for DNA methylation. The complex multidimensional relationships were addressed with our novel unbiased method, EpiSig, which is a flexible framework for integrative analysis of any type of sequencing data and identifies epigenomically co-modified regions that share similar patterns. Common epigenetic modification patterns were identified on a global genome scale and the genome was segmented into regulatory/functional elements. The epigenetic state of each element was defined and differentially modified epigenetic regions (DMER) between RA and OA were identified. Pathway evaluation used Ingenuity Pathway Analysis. Bostatistical analyses used Benjamini-Hochberg corrections.

**Results:** 218 genome-wide datasets were generated across FLS samples, including 152 histone modification datasets (H3K27ac, H3K4me1, H3K4me3, H3K36me3, H3K27me3, H3K9me3), 22 DNA methylation datasets, 22 open chromatin datasets and 22 transcriptome datasets. Eighteen epigenomic states were defined with distinct FLS chromatin signatures, including 4 promoter states, 6 enhancer states, 2 transcribed states, 2 states with zinc finger protein genes and 4 repressed states. The genome was segmented into 5 kb regions, and 125 epigenetic clusters with similar epigenetic patterns were determined across FLS. We identified regions that were differentially marked when comparing OA and RA. 13 clusters with significant DMER enrichment in RA were identified, which were grouped into biological pathways based on genes associated with these promoters and enhancers. Among the pathways that were significantly different in RA FLS, Phospholipase C Signaling, p53 Signaling, Integrin Signaling, and Protein Kinase A signaling were particularly notable. Other pathways were unexpected, such as Huntington's Disease Signaling (HDS). To biologically validate the HDS pathway, we showed that one key member of HDS, namely HIP1, is expressed in FLS. HIP1 deficiency induced by siRNA knockdown decreased cultured RA FLS invasion into an artificial matrix by 56% ( $p < 0.001$ ).

**Conclusion:** We developed the first high-resolution global epigenomic landscape for RA and using a novel method to prioritize RA-specific biological pathways. Biologic validation of one unanticipated target in HDS pathway confirms that this unbiased method can identify novel therapeutic targets.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Genetics, Genomics and Proteomics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Histological analysis of salivary glands for decades has been a valuable tool in the characterization of patients with primary Sjögren's syndrome (pSS) and non-Sjögren's sicca (nSS) patients. Importantly, it has helped in understanding the immunopathology of sicca patients. Nonetheless, standardization of histological assessments, e.g. to quantify lymphocytic foci or germinal centers is lacking, contributing to improper classification of disease and assessment of risk of lymphoma for example. Also, detailed and reproducible quantification of the heterogeneity of inflammatory cells and their contribution to immunopathology is

lacking. Recent progress in epigenetics has revealed that cell-specific DNA methylation profiles can be applied to reliably quantify numbers of cells in blood and tissues. The objective of this study was to investigate whether epigenetic cell counting can serve as a novel reliable tool to quantify immune cells in salivary glands of sicca patients.

**Methods:** DNA was isolated from frozen tissue sections of 13 nSS, 12 probable SS, 29 pSS and 7 overlap SS patients. Bisulfite conversion of demethylated DNA sites was followed by cell specific qPCR that was used to calculate the percentage of cell subsets related to the total number of cells quantified by housekeeping gene expression. Percentages of epigenetically counted cells were correlated to gene expression generated by RNA-seq analysis of matched salivary gland tissue and histological and clinical parameters (lymphocytic focus score (LFS), %IgA+ plasma cells, serum IgG, SSA positivity).

**Results:** Strongly increased percentages of epigenetically quantified percentages of CD3, CD4, CD8, B cells, T follicular helper (Tfh) cells and Treg cells in pSS vs nSS patients were observed (all  $p < 0.001$ , CD8  $p < 0.05$ , B cells  $p < 0.01$ ). These inflammatory cell types all strongly correlated with LFS (all at least  $p < 0.001$ , CD8  $p = 0.015$ ), local B cell hyperactivity (% IgA+ cells, all  $p < 0.001$ , except CD8  $p = 0.060$  and B cells  $p = 0.127$ ) and systemic B cell hyperactivity (all at least  $p < 0.01$ , except CD8  $p = 0.052$ ). Th17 cells were not significantly different between nSS and pSS patients. Only CD8 T cells were significantly increased in probable SS patients as compared to nSS patients ( $p < 0.05$ ). Percentages of CD3 and B cells positively correlated with CD3 and CD19 RNA expression ( $r = 0.608$ ,  $p < 0.0001$ ;  $r = 0.598$ ,  $p < 0.0001$ , resp.). Interestingly, percentages of Tfh cells correlated with CXCL13 ( $r = 0.789$ ,  $p < 0.0001$ ), IL7R, CXCR5 and ICOS RNA expression (all  $p \leq 0.0001$ ) and were strongly associated with autoimmunity (SSA positivity,  $p < 0.001$ ).

**Conclusion:** Epigenetic cell counting is a promising novel tool to reproducibly and easily quantify immune cells in the (inflamed) labial salivary gland of sicca patients with relatively low amount of tissue needed ( $< 1 \text{ mm}^3$ ). Considering the potential of this technique to include a huge number of (cell-specific) biomarkers we believe this opens up new standardized ways for salivary gland analysis with high relevance for patient classification, understanding of immunopathology and clinical trials.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Health Services Research I: Cost Drivers in Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Tofacitinib access has been restricted by many US payers to use after treatment with  $\geq 1$  injectable biologic DMARD (bDMARD); there are limited real-world data comparing tofacitinib with bDMARDs in biologic-naïve RA patients (pts). This study compared pt characteristics, treatment patterns, and costs in pts initiating tofacitinib vs adalimumab (ADA) or etanercept (ETN) in a US population with commercial healthcare insurance.

**Methods:** This retrospective cohort study included pts aged 18–64 years with  $\geq 1$  tofacitinib or bDMARD healthcare insurance claim (Truven MarketScan® Commercial Claims and Encounters database) during 1/1/2014–1/1/2017,  $\geq 1$  MTX claim within 12 months prior to index, and  $\geq 1$  diagnosis of RA at index or within 12 months prior. Pts had to be continuously enrolled for  $\geq 12$  months pre-/post-index with no pre-index claims for tofacitinib or a bDMARD. Monotherapy was defined as absence of select conventional synthetic DMARDs within 90 days post-index. Outcomes were treatment persistence at 12 months (index refills with  $< 60$ -day gap after supply expiration), adherence at 12 months (proportion of days covered [PDC]), and 12-month post-index RA-related costs. Statistical analyses were performed using t-statistics (continuous variables) or chi-squared statistics (binary variables) in pairwise comparisons.

**Results:** Pts who met selection criteria and initiated tofacitinib (n=184), ADA (n=1771), or ETN (n=1472) had similar baseline characteristics except for age which was higher in tofacitinib pts (mean 52.6 [SD 9.3], 49.9 [9.5], and 49.9 [10.0] years, respectively), and tofacitinib pts were more often located in the Northeast vs Southern region vs ADA. Tofacitinib pts had higher 12-month pre-index costs vs ADA (mean \$4296 [SD \$8159] vs \$2880 [\$5497], respectively; p=0.0225), more rheumatologist visits 90 days pre-index (mean 1.80 [SD 0.86] vs 1.96 [1.11]; p=0.0435), and higher (worse) Quan Charlson comorbidity index scores (mean 1.65 [SD 0.93] vs 1.50 [0.91]; p=0.0300). Tofacitinib pts had higher monotherapy use (34.2%) vs ADA (21.7%; p=0.0001) and ETN (26.5%; p=0.0263). Persistence at 12 months was similar for tofacitinib pts (46.2%) vs ADA (49.5%) and ETN (50.5%), although more tofacitinib pts restarted index treatment during 12 months post-index (17.9%) vs ADA (9.8%; p=0.0006) and ETN (7.1%; p<0.0001), and fewer tofacitinib pts switched treatment (16.9%) vs ADA (26.5%; p=0.0044) and ETN (29.6%; p=0.0003). Adherence (PDC) at 12 months was also similar between tofacitinib (0.63), ADA (0.67), and ETN (0.67) pts. Total post-index RA-related costs were lower with tofacitinib pts (mean \$29,938 [SD \$19,287]) vs ADA (\$38,733 [\$17,096]; p<0.0001) and ETN (\$38,534 [\$16,261]; p<0.0001).

**Conclusion:** Among biologic-naïve patients with RA and prior MTX, there was higher baseline monotherapy use among those receiving tofacitinib vs ADA and ETN. Persistence and adherence were similar for tofacitinib, and total RA-related costs were lower vs ADA and ETN, despite tofacitinib pts having higher pre-baseline costs.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Health Services Research I: Cost Drivers in Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Although bDMARDs are often able to control the RA, they are expensive and associated with adverse effects. Therefore, it is important to use the lowest effective dose in each patient. Several studies have shown that, disease activity-guided dose reduction without deterioration of disease activity is possible, while saving costs in patients with stable and low disease activity.<sup>1</sup> Despite these positive results, questions remain on the optimal tapering strategy. Different strategies are conceivable, with varying results regarding the balance between the number of flares, utilities and costs. Therefore, the objective of this study was to investigate the most cost-effective TNFi dose reduction strategy for RA patients using a modelling design.

**Methods:** In a cost-utility analysis using Markov modelling based on data from the DRESS study, STRASS study, and the RA Nijmegen cohort, the following strategies were tested: 1. four steps DRESS tapering (figure 1: 100%-67%-50%-0%); 2. Tapering with an extra dosage step of 33%; 3. Tapering without withdrawal; 4. Use of a stricter flare criterion; and 5. Use of a predictor (biomarker: 80% specific, 80% sensitive, €100 per test) for successful tapering. Also, a continuation group (strategy 0) was modelled and used as comparator. Scenario analyses with 30% and 50% drug price discount (biosimilars) and no discounting were executed. In addition, it was examined how well a biomarker should be able to predict to become cost-effective.

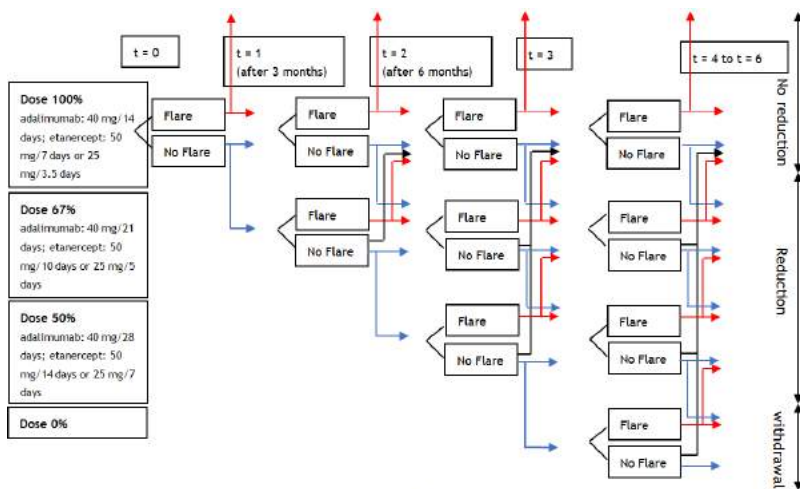

Figure 1: Structure of the modelled DRESS strategy (total duration 18 months)

**Results:** All examined tapering strategies were found to be cost saving, but yielded more short-lived flares compared to strategy 0. The change in utilities was minimal (large overlap in credible intervals) (table 1). Strategy 2 is cost-effective compared to all other strategies (highest incremental net monetary benefit (iNMB)). Due to the large overlap in credible intervals of the NMBs of strategy 1, 2 and 3, the chance that they are actually not different in terms of cost-effectiveness is high. Scenario analyses did not change results. A biomarker becomes cost-effective when it has a sensitivity and specificity of 96% or higher.

Table 1: Main outcomes of each strategy

Outcome measure	0. continuation (comparator)	1. DRESS strategy	2. DRESS 33% strategy	3. Tapering without withdrawal	4. Use of a stricter flare criterion	5. Strategy with a predictor
Costs (€)	21072 (20603-21375)	13192 (12445-13953)	13468 (12774-14208)	13829 (13199-14493)	15947 (15119-16761)	15024 (14001-15961)
QALYs	1.182 (1.166-1.199)	1.177 (1.160-1.192)	1.181 (1.165-1.197)	1.182 (1.166-1.198)	1.189 (1.173-1.204)	1.185 (1.169-1.200)
Mean number of short-lived flares	0.53 (0.35-0.73)	0.97 (0.83-1.12)	0.74 (0.58-0.92)	0.69 (0.52-0.89)	2.07 (1.79-2.40)	0.55 (0.53-0.56)
NMB	73513 (72221-74772)	80958 (79454-82408)	81022 (79492-82494)	80736 (79294-82205)	79165 (77668-80688)	79781 (78179-81420)
iNMB**	-	7445	7509	7223	5652	6268

Data is mean values per patient over 1.5 years (95% credible intervals)

QALYs: quality adjusted life years

NMB = QALYs \* willingness to pay (WTP) - costs

\* Number of flares are higher since the flare criterion is stricter (DAS28-ESR>2.6), so these flares are also less serious and thus not comparable with the other strategies

\*\* (i)NMB are given at a (WTP) of €80,000

**Conclusion:** All dose reduction strategies dominated the continuation strategy. For use in clinical practice, we recommend a choice between strategy 1, 2 and 3, based on shared decision making.

## Cost-Effectiveness of Competing Anticoagulation Strategies in Knee Replacement Patients

Savannah R. Smith<sup>1,2</sup>, Jeffrey N. Katz<sup>3,4</sup> and Elena Losina<sup>3,4</sup>, <sup>1</sup>Orthopedics, Brigham and Women's Hospital, Boston, MA, <sup>2</sup>George Washington University School of Medicine and Health Sciences, Washington, DC, <sup>3</sup>Orthopaedics, Brigham and Women's Hospital, Boston, MA, <sup>4</sup>Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Health Services Research I: Cost Drivers in Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Total knee replacement (TKR) patients are routinely prescribed anticoagulation therapy to prevent deep vein thrombosis (DVT) and pulmonary embolism (PE). Clinical guidelines are ambiguous regarding the specific agent and duration of prophylaxis. We conducted a cost-effectiveness analysis to evaluate the benefits and risks of 14- and 35-day therapy with the most commonly prescribed anticoagulants post-TKR.

**Methods:** We built a probabilistic, state-transition computer simulation model to assess clinical and economic outcomes of 14-day and 35-day anticoagulation therapy after TKR. Complications of TKR and therapy included DVT, PE, bleeding, and prosthetic joint infection (PJI). DVTs could progress to PE and were classified as symptomatic or asymptomatic, with asymptomatic carrying a greater risk of PE. Operative site bleeds were associated with an increased risk of PJI (RR = 11), while non-operative site bleeds (CNS, GI) carried a quality of life decrement and risk of death. We evaluated 5 anticoagulation agents: rivaroxaban, low molecular weight heparin (LMWH), fondaparinux, warfarin, and aspirin. Each was associated with a unique reduction in DVT risk and an increased risk of bleeding compared with no anticoagulation; these risks were estimated from published literature. Costs included the agent and, when applicable, injection administration or monitoring costs (Table). We assumed a 1 year horizon and a willingness to pay (WTP) threshold of \$100,000 per quality adjusted life year (QALY). Strategies with incremental cost-effectiveness ratios (ICERs) below WTP were deemed cost-effective.

**Results:** Aspirin at any duration was associated with the highest incidence of DVT and PE (28% and 5%, respectively). Extended fondaparinux resulted in the largest reduction in thromboses (DVT + PE) and greatest increase in bleeds (14% and 3%, respectively). Extended rivaroxaban reduced DVT incidence to 18% while increasing bleeds to 6%. Extended LMWH was associated with DVT and bleeding incidence of 19% and 4%, respectively. Both extended fondaparinux and rivaroxaban resulted in 0.74 QALYs; all other strategies, including no prophylaxis, resulted in fewer QALYs and higher costs and were therefore dominated (Table). The ICER for extended fondaparinux (\$16.3M) greatly exceeded WTP; thus, extended rivaroxaban was the preferred strategy.

**Conclusion:** Extended rivaroxaban therapy after TKR is a cost-effective strategy to prevent DVT and PE while minimizing bleeding risk. The high cost and risk of bleeding of fondaparinux precluded it from being cost-effective. While there has been increased interest in using lower potency therapies, such as aspirin, these results demonstrate that aspirin's low bleeding risk and low cost do not compensate for its poor efficacy in preventing DVT post-TKR.

Table.

Anticoagulant	Characteristics of Anticoagulation Therapies		
	RR DVT	RR Bleeds	Cost
Rivaroxaban	0.12	2.12	\$7.90
LMWH	0.20	1.23	\$40.90 <sup>b</sup>
Fondaparinux	0.08	2.21	\$46.77 <sup>b</sup>
Warfarin	0.36	1.21	\$7.23/\$3.60 <sup>a</sup>
Aspirin	0.62	1.00	\$0.14
Anticoagulant Strategy	Results		
	Cost	QALY	ICER
Extended Rivaroxaban	\$2,660	0.7398	
Extended VKA	\$2,820	0.7395	Dominated
Standard Rivaroxaban	\$2,870	0.7392	Dominated
Extended ASA	\$2,970	0.7389	Dominated
Standard VKA	\$3,000	0.7390	Dominated
Standard ASA	\$3,130	0.7386	Dominated
Standard LMWH	\$3,370	0.7392	Dominated
Standard Fondaparinux	\$3,390	0.7393	Dominated
No prophylaxis	\$3,410	0.7382	Dominated
Extended LMWH	\$3,700	0.7398	Dominated
Extended Fondaparinux	\$3,780	0.7399	\$16,300,000
<sup>a</sup> Includes cost of monitoring, presented as Week 1/Weeks 2+ due to extra monitoring during first week of treatment			
<sup>b</sup> Includes cost of injection administration			
RR = Relative risk, as compared with no anticoagulation			
QALY = Quality-adjusted life year			
ICER = Incremental cost-effectiveness ratio			
Dominated = Strategy increased cost and decreased quality-adjusted life years

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Health Services Research I: Cost Drivers in Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Rheumatoid arthritis (RA) is associated with high healthcare resource utilization, but knowledge about factors determining healthcare costs is limited. The aim was to identify healthcare cost drivers in RA.

**Methods:** RA patients attending Jyväskylä Central Hospital (JCH) rheumatology unit, Finland, are as of 2007 prospectively enrolled in a structured digital database. We combined this clinical data with well-recorded administrative data on all primary and specialty healthcare in visits in Jyväskylä area from fiscal year 2014. We excluded 46 outliers, defined as patients with annual costs exceeding the geometric mean by two standard deviations. For each patient, we considered the median of time dependent clinical variables: disease activity score (DAS28-3), health assessment questionnaire index (HAQ index, 0-3), and pain on visual analogue scale (VAS, 0-100). In patients with non-zero costs, factors affecting annual costs (€) were assessed with an age-stratified multivariate generalized linear model using Gamma distribution and a log link function. Variables were selected by statistical significance in univariate analyses. All multivariate analyses were adjusted for age in years or disease duration, and sex. To increase interpretability, we calculated marginal effects at the means of the independent variables. This displays how the annual costs are affected when a variable increases by one unit, while the other variables remain unchanged.

**Results:** Three age groups were analysed separately: 18-50 (n = 179), 51-70 (n = 477) and 71-100 (n = 300), with mean per-patient annual healthcare costs being 2,942€, 2,914€ and 4,026€, respectively. The main factor associated with healthcare costs across all age groups was disease activity: an increase in the long-term median level of DAS28(3) of an individual yielded up to a 848€ to 1,063€ increase in annual costs (Table 1). In terms of other clinical measures, strong evidence of an association was present for pain in those 18-50 (31€ per one point increase in VAS, p = 0.002) and for number of comorbidities in those 51-70 (317€ per comorbidity, p < 0.001).

**Conclusion:** A main cost driver in all age groups was disease activity.

**Table 1.** Multivariate generalized linear model for annual costs, stratified by age. The marginal effects were calculated at the means of the independent variables. For continuous variables, the marginal effect displays how the annual costs are affected when the variable increases by one unit, while the other variables remain unchanged. For dichotomous variables, the change represents comparison to the reference group.

Age group		Marginal effect (€)	P-value
18-50 (n = 179)	Age (years)	-118	<0.001

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Health Services Research I: Cost Drivers in Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Regular Physical Activity (PA) at a moderate level of intensity for approximately 2.5 hours per week is recommended in the management of hip and/or Knee osteoarthritis (OA). We aimed to identify evolution patterns of PA components (frequency, duration, intensity, type (weight bearing or not)) and Sedentary Behavior (SB) over five years and to determine baseline predictors for each trajectory in a representative cohort of patient with hip and/or knee OA.

**Methods:** Patients from the KHOALA cohort, a population-based multicenter cohort of 878 patients with symptomatic knee and/or hip OA, aged between 40 and 75 years old were included. For the purpose of the study, we used data collected between inclusion and the fifth year of follow-up. PA and SB were measured by the Modifiable Activity Questionnaire (MAQ). Evolution patterns of PA components and SB were identified using group-based trajectory analysis. Association of socio-demographic and clinical characteristics with PA and SB patterns were identified by multivariate logistic regression.

**Results:** Two groups of trajectories were identified for each PA component and three for the SB (figure1). Baseline sociodemographic and clinical characteristics were associated with Frequency and Type component trajectories: women were more often in the “moderate and stable duration” of PA group and in the “low and stable frequency of weight bearing PA” group than in the high groups; patients aged 60 years and older were in the “high and decreasing frequency” of PA group (OR= 3.2 [1.2-8.1]). Patients with impaired patients reported outcome variables (womac, pain VAS, SF36 vitality) were more often in the group of “low frequency of weight bearing PA” than in the high frequency group. Factors associated with moderate and high SB trajectories were all sociodemographic: being a male, below 60 year’s old, single (OR=1.5 [1.1-2.1]), obese (OR=2.1 [1.4-3.1]), smoking (OR=2.0 [1.1-3.7]), less physical jobs.

**Conclusion:** The determinants of the 5-year evolution of PA were different according to its components. Sociodemographic and clinical characteristics were associated with the frequency and type of PA while symptoms were not associated with SB. Sociodemographic factors associated with SB define populations to target for interventions promoting decrease of SB. Factors associated with components of PA allow for adapting PA practice or can be targets for interventions (e.g. on fatigue or mental health).

## The Additional Economic Burden of Depression Among Adults with Rheumatoid Arthritis in the United States

Nan Li and Steven Peterson, Janssen Research & Development, LLC, Spring House, PA

First publication: September 18, 2017

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Health Services Research I: Cost Drivers in Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

**Background/Purpose:** Depression is significantly more prevalent in patients with rheumatoid arthritis (RA) compared with the general population.<sup>1</sup> It has a significant effect on RA patients, compromising clinical outcomes and increasing mortality. The objective of this study is to compare the healthcare utilization, expenditures, and work productivity among patients with RA to patients with RA and depression.

**Methods:** The Truven Health MarketScan® Research Databases were used in the analysis. Patients ≥18 years of age with at least 2 RA visits, at least 2 months apart, between January 1, 2013 and December 31, 2013 were eligible for inclusion. The date of the first observed claim with an RA diagnosis was defined as the “index date.” Depression was defined as at least 2 visits for depressive disorder, at least 14 days apart, during the 12-month pre-index period in eligible patients. Outcomes were measured during the 12-month post-index period. Propensity score was calculated and controlled in logistics regression or Poisson regression. The incremental adjusted annual cost and 95% confidence interval (CI) were calculated using the bootstrapping method.

**Results:** A total of 46,700 RA patients were eligible for the analysis. Of this sample, 3,478 (7%) patients had RA and depression. The mean age of the study sample was 52 (standard deviation = 9.7) years and 78% were female. Patients with and without depression were significantly different ( $P < 0.05$ ) in terms of age, gender, residence area, relationship to primary insured, joint aspirations/injections, extra-articular manifestations, and difficulty walking, and had a wide variety of heterogeneous comorbidities at baseline. These covariates were used to calculate propensity score. After adjustment for propensity score, RA patients with depression used more healthcare resources annually compared with those without depression (relative risk and rate ratio  $>1$  with  $P < 0.05$  for all outcomes in **Table 1**). The incremental adjusted annual direct cost was \$8,488 (95% CI, \$6,793-\$10,223); while the RA-related incremental adjusted annual direct cost was \$578 (95% CI, \$-98-\$1,243).

**Conclusion:** This study highlights economic burden due to the presence of depression in RA patients. These findings underline the importance of managing RA when treatment algorithms are devised for these patients.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Infection-related Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Chikungunya virus infection is a mosquito-borne disease that causes chronic joint pain for months to years in approximately one half of infected patients. The study objective was to determine if chikungunya virus (CHIKV) persists in the synovial fluid, potentially serving as a causative mechanism of persistent arthritis.

## Methods:

*Design:* Cross-sectional

*Setting:* Atlántico and Bolívar Departments, Colombia

*Participants:* Thirty-eight patients with CHIKV infection during the 2014-2015 epidemic with chronic arthritis, including in the knee joint, and ten healthy controls without prior CHIKV infection were included.

*Measures:* Participants completed a symptom questionnaire. Prior infection with CHIKV was confirmed by serological analysis. The presence of chikungunya viral RNA in blood and synovial fluid were measured by qPCR.

**Results:** Prior CHIKV infection was serologically confirmed in 33/38 (87%) of the cases based on IgM (3%) and IgG ELISA (100%). Confirmed chikungunya arthritis patients were predominantly women (82%), Afro-Colombian (55%), or White-Colombian (33%) with high school or less level of education (94%). CHIKV arthritis patients were a median 22 (IQR 21-23) months post CHIKV infection. Initial symptoms of CHIKV infection included joint pain (97%), joint swelling (97%), joint stiffness (91%), fever (91%), and rash (88%). The most commonly affected joints during initial infection were knees (87%), elbows (76%), wrists (75%), fingers (56%), and toes (56%). None of the participants were qPCR positive for persistent virus in the serum or synovial fluid. Furthermore, no viral proteins were identified in synovial fluid by mass spectrophotometry and synovial fluid was also culture negative. Participants reported an effect on their activities of daily living from their arthritis (82%) and disease severity was moderate, as shown by an average Disease Activity Score-28 of  $4.52 \pm 0.77$ .

**Conclusion:** This is one of the largest observational studies involving chikungunya arthritis patients. Synovial fluid analysis revealed no evidence of CHIKV by PCR, mass spectrometry, or culture. This suggests that immunomodulating medications may be safe in the treatment of chikungunya arthritis and suggests a possible mechanism whereby CHIKV causes arthritis through induction of host autoimmune pathology.

## Apoptotic Bodies Containing dsDNA Covalently Modified By Parvovirus B19 Non-Structural Protein NS1 Induce dsDNA Autoantibodies and End Organ Damage in Non-Autoimmune Mice

Stanley J. Naides<sup>1</sup>, Kanoktip Puttaraksa<sup>2</sup>, Heidi Pirttinen<sup>2</sup> and Leona Gilbert<sup>2</sup>, <sup>1</sup>Immunology, Quest Diagnostics Nichols Institute, San Juan Capistrano, CA, <sup>2</sup>Department of Biological and Environmental Science and Nanoscience Center, University of Jyväskylä, Jyväskylä, Finland

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Infection-related Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Persistent viral infections can induce aberrant immune responses and are implicated in the development of autoimmunity. Parvovirus B19 (B19V) non-structural protein, NS1, a helicase, covalently modifies self dsDNA and induces apoptosis. This study was undertaken to determine whether resulting apoptotic bodies (ApoBods) containing virally modified dsDNA could induce autoimmunity in an animal model.

**Methods:** Non-autoimmune BALB/c mice were inoculated with B19V NS1, pristane or staurosporine induced ApoBods and serum tested for dsDNA autoantibodies by *Crithidia luciliae* staining and ELISA. Brain, heart, liver and kidney pathology was examined by bright field and confocal microscopies. Deposition of self-antigens and ApoBods in glomeruli was examined by staining with labeling antibodies to dsDNA, histones H1 and H4, and TATA-binding protein.

**Results:** Innoculation with B19V NS1-induced ApoBods induced dsDNA autoantibodies in a dose dependent fashion, whereas staurosporine induced ApoBods did not. Histopathological features of immune mediated organ damage was evident in pristane-induced and B19V NS1-induced ApoBod groups and severity score was significantly higher in these groups than in staurosporine treated groups, and was B19V NS1-induced ApoBod dose dependent. Nucleosomal antigens were deposited in pristane-induced and B19V NS1-induced ApoBod groups, but not in the staurosporine-induced ApoBod group.

**Conclusion:** This study demonstrated proof of principle in an animal model that virally modified dsDNA in apoptotic bodies could break tolerance to self dsDNA and induce dsDNA autoantibodies and end-organ damage. The study helps explain observations suggesting a viral contribution to the development of systemic lupus erythematosus.

## Practice Patterns of Pneumocystis Pneumonia Prophylaxis in Connective Tissue Diseases: a Survey of Infectious Disease Physicians

Rachel M. Wolfe<sup>1</sup>, Susan E. Beekmann<sup>2</sup>, Philip M. Polgreen<sup>2</sup> and James E. Peacock Jr.<sup>3</sup>, <sup>1</sup>Internal Medicine, Section on Rheumatology and Immunology, Wake Forest Baptist Health, Winston-Salem, NC, <sup>2</sup>Internal Medicine, Division of Infectious Diseases, Carver College of Medicine, Iowa City, IA, <sup>3</sup>Internal Medicine, Section on Infectious Disease, Wake Forest Baptist Health, Winston-Salem, NC

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Infection-related Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Potent immunosuppressive therapy for connective tissue diseases (CTDs) imparts an increased risk for opportunistic infections including Pneumocystis pneumonia (PCP). High mortality rates have been reported in CTD patients with PCP which raises the question as to if and when prophylaxis for PCP is indicated. Unfortunately, the specific risk factors and precise indications for PCP prophylaxis in CTD patients remain poorly defined and are guided only by expert opinion and personal experience. Wide variations in PCP prophylaxis patterns among rheumatologists have been previously established. This study was aimed to evaluate patterns among infectious disease physicians.

**Methods:** An electronic survey on PCP prophylaxis in CTD patients was emailed to 1,264 adult infectious disease physicians who are members of the Infectious Diseases Society of America Emerging Infections Network.

**Results:** 631 (50%) physicians responded to the survey. Respondents were significantly more likely to work in an academic/university system ( $p = 0.02$ ) and either be early ( $<5$  years) or late ( $\geq 25$  years) in their careers ( $p = 0.0002$ ). Almost half (43%) reported that they did not make recommendations for PCP prophylaxis in non-HIV patients. Of those making recommendations for prophylaxis, there was little agreement on indications for prophylaxis. The greatest consensus for specific CTDs was for granulomatosis with polyangiitis (GPA) with 53% advocating for PCP prophylaxis. Only about a third recommended prophylaxis for other vasculitides, lupus, lupus nephritis, inflammatory myositis and rheumatoid arthritis on high dose corticosteroids. Interestingly, the most frequent single response was "Not Sure" (35%) but this option was also often selected along with other specific CTDs (41% of total respondents). When questioned about specific therapies, corticosteroids  $\geq 20$  mg/day was the most frequently cited indication for PCP prophylaxis (87%). Few recommended PCP prophylaxis with DMARD therapy (both biologic and non-biologic) without concurrent high dose corticosteroids (2-12% versus 69-77%). Surrogate laboratory markers were not routinely used to guide decisions about prophylaxis (21%). There was no consensus for the specific indices although CD4 alone was the most frequent response. While the majority recommended discontinuation of PCP prophylaxis with tapering of corticosteroids (65%), there was considerable variability in the specific dose at which it should be discontinued. The most frequent response was below 16-20 mg/daily. 89% of respondents felt that guidelines about PCP prophylaxis would be helpful in their practice.

**Conclusion:** There is little consensus about PCP prophylaxis in CTDs among infectious disease physicians although certain diseases (GPA) and immunosuppressants (higher dose corticosteroids) are common indications to recommend prophylaxis. There remains much uncertainty in clinical practice with respect to the role for PCP prophylaxis in patients with CTD, both by infectious disease physicians and rheumatologists. Guidelines for PCP prophylaxis would be an important adjunct in caring for these complex patients.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Infection-related Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Prosthetic joint septic arthritis (PJSA) complicates about 1 to 2 percent of joint replacement surgeries. The management of PJSA usually includes a combination of surgery and antibiotics. Resection arthroplasty with re-implantation for PJSA may be performed in one or two stages. There is a lack of comparative trials comparing the two strategies and there is no consensus regarding which option should be recommended.

**Objective:** To define the epidemiology, clinical characteristics and outcomes of patients with PJSA for whom a one-stage procedure was performed as compared with patients with PJSA for whom a two-stage procedure was performed.

**Methods:** We conducted a retrospective study that included all patients aged 18 years and older admitted to a single, tertiary-care hospital between 1998 and 2015 who were diagnosed with monoarticular PJSA and were surgically treated with either a one-stage or two-stage joint replacement. We excluded cases of native joint infection or septic bursitis.

**Results:** Of the 65 patients with PJSA treated with either one- or two-stage procedure, 18 had a one-stage procedure while 47 had a two-stage procedure. There were no differences in average age or gender between the two groups [Table 1]. Chronic kidney injury and end-stage liver disease were significantly more common in patients who had a two-stage procedure ( $p=0.006$  and  $p=0.02$  respectively) while patients who had a one-stage replacement were more often febrile (50% vs. 27.7%;  $p=0.11$ ), had higher peripheral white blood cell (WBC) counts (14.6 vs. 10.7 thousand cells/mm<sup>3</sup>;  $p=0.01$ ) and had a greater mean percentage of peripheral polymorphonuclear (PMN) leukocytes (85.5% vs. 76.5%,  $p<0.001$ ). While one-stage procedures were split evenly between knee and hip replacements, two-stage knee replacements were more common (75% of cases) than two-stage hip replacements (25% of cases) [Table 2]. Outcomes between the two strategies were similar [Table 2].

**Conclusion:** In our institution, two-stage joint revision for PJSA is more common than one-stage procedures, especially when the knee is involved. Although this study might have been underpowered to detect small differences, there were no clear differences in clinical features or outcomes of patients with PJSA undergoing revision arthroplasty based on the type of operation. Surgeons seem to favor two-stage for patients with comorbidities while preferring one-stage for patients presenting with early PJSA infection. Larger prospective trials are needed to identify which circumstances should lead surgeons to choose one strategy over the other.

Table 1. Demographic and clinical features of patients with PJSA who had one-stage or two-stage joint replacement surgery.

	One-stage (n=18)	Two-stage (n=47)	P-Value
<b>Demographic Data:</b>			
Age (yrs), mean (SD)	61 (11.42)	61.2 (12.28)	0.96

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Infection-related Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Hemophagocytic syndrome or hemophagocytic lymphohistiocytosis (HLH) is an increasingly-recognized condition in adults, characterized by a wide range of etiologies, symptoms and outcomes, but with a common etiopathogenic pathway leading to organ damage: an excessive hyperinflammatory response. We analyzed the role of infections as triggers of adult hemophagocytic syndrome in a National Cohort Registry.

**Methods:** In June 2013, the Study Group on Autoimmune Diseases (GEAS) of the Spanish Society of Internal Medicine created the national registry of patients with HLH. Patients fulfilled the diagnostic guidelines for HLH proposed by the Histiocyte Society in 1991 and updated in 2004. We investigated infections (viruses, bacteria, parasites and fungi) as causative external factors potentially involved in initiate the disease.

**Results:** On June 15, 2017, a total of 147 patients with HLH were included in the GEAS-SEMI Registry, 87 (59%) men and 60 (41%) women, with a mean age at diagnosis of HLH of 44; 18% were not born in Spain. The main signs and symptoms at presentation consisted of fever in 132 (90%) patients, splenomegaly in 80 (54%), polyadenopathies in 71 (48%) and hepatomegaly in 22 (15%) patients. The main internal organ involvements included pulmonary in 49 (33%) patients, renal in 46 (31%), gastrointestinal in 41 (28%) and CNS in 32 (22%) patients. The main analytical markers consisted of ferritin > 500 ng/mL in 143 (97%, mean 15498 ng/mL), thrombocytopenia <100,000/mm<sup>3</sup> in 123 (84%), anemia < 9 g/dL in 106 (72%), and neutropenia <1000/mm<sup>3</sup> in 65 (44%). Tissue hemophagocytosis was confirmed in 133/143 (93%) patients. Death occurred in 79 (54%) patients; a higher mortality rate was found in patients with an underlying neoplasia (33% vs 16% in survivors, p=0.023) and in those with severe anemia (85% vs 60%, p=0.001) and thrombocytopenia (95% vs 72%, p<0.001). Mean age at diagnosis was higher in patients who died in comparison with survivors (56.8 vs 42.1 yrs, p<0.001). An infectious trigger was detected in 88 (60%) of patients, mainly viruses in 37 (25%, Epstein-Barr virus infection in 16 cases), bacteria in 23 (16%, mycobacterium infection in 9 cases), fungi in 14 (10%, candida in 5 cases) and parasites in 9 (6%, leishmaniasis in 8 cases).

#### **Conclusion:**

The rate of mortality of adult patients diagnosed with hemophagocytic syndrome exceeds 50% of cases, especially in patients with underlying hematological diseases and in those with advanced age. An infection as trigger of the hyperinflammatory response was demonstrated in 60% of cases, with EBV, mycobacterium and leishmanial being the microorganisms more frequently isolated. Active infections in a patient with suspected HLH should always be treated appropriately.

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Infection-related Rheumatic Disease

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Whipple's disease should be considered in patients with recurrent episodes of seronegative arthritis in the large limb, various symptoms (fever, uveitis,...) or biological abnormalities (eosinophilia, C-reactive protein elevation, anaemia, thrombocytosis...) but none of these findings is specific. To determine when *Tropheryma whipplei* polymerase chain reaction (PCR) is appropriate in patients evaluated for rheumatological symptoms.

**Methods:** In a retrospective observational study done in five hospitals, we assessed the clinical and radiological signs that prompted *T. whipplei* PCR testing between 2010 and 2014, the proportion of patients diagnosed with Whipple's disease, the number of tests performed and the number of diagnoses according to the number of tests, the patterns of Whipple's disease, and the treatments used. Diagnosis of Whipple's disease was based on 1- at least one suggestive clinical finding; 2- at least one positive PCR test; and 3- a dramatic response to antibiotic therapy. There were divided in: CWD: Classic Whipple's disease (duodenal biopsy PAS staining + or *T. whipplei* immunohistochemistry, or as blood positive by PCR); FWD: Focal Whipple's disease (joint fluid positive by PCR but duodenal biopsy negative by PAS staining and immunohistochemistry); CTWAA: Chronic *T. whipplei*-associated arthritis (duodenal biopsy, stool, or saliva positive by PCR but duodenal biopsy and joint fluid negative).

**Results:** At least one PCR test was performed in each of 267 patients. Rheumatic signs were peripheral arthralgia (n=239, 89%), peripheral arthritis (n=173, 65%), and inflammatory back pain (n=85, 32%). The main extra-articular signs were constitutional symptoms (n=111, 41.8%), diarrhoea (n=70, 26.5%), fever (n=53, 20%), lymphadenopathy (n=14, 5.3%), and neurological signs (n=11, 4.2%). Whipple's disease was diagnosed in 13 patients (4.9%). The main samples tested and the more frequently positive tests in the centres with diagnoses of Whipple's disease were saliva and stool. In the centres with no diagnoses of Whipple's disease, arthritis was less common, whereas constitutional symptoms, fever, and lymphadenopathy were more common. 11 patients with Whipple's disease had CRP elevation. The annual incidence ranged across centres from 0 to 3.6/100000 inhabitants. The group with Whipple's disease had a higher proportion of males, older age, and greater frequency of arthritis. When both stool and saliva PCR are positive the predictive value is 91%. When both stool and saliva PCR are negative the negative predictive value is 99%.

**Conclusion:** Males aged 40-75 years with unexplained intermittent seronegative peripheral polyarthritis, including those without constitutional symptoms, should have *T. whipplei* PCR tests on saliva, stool and, if possible, joint fluid. When both stool and saliva PCR are positive the positive predictive value is 91%.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies I: Gout Risk of Disease Activity, Cardiovascular Disease and Mortality

**Session Type:** ACR Concurrent Abstract Session

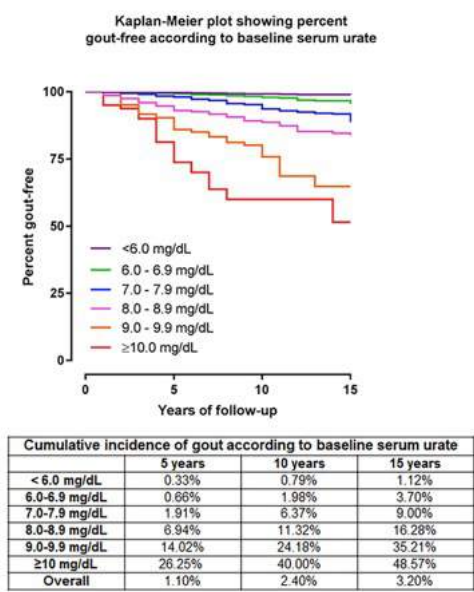

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Elevated serum urate concentration (hyperuricemia) is considered to be a key risk factor for developing gout. However, the relationship between serum urate and incident gout is unclear, with variation in estimates of risk depending on different published studies. We undertook the largest individual participant data analysis to date to examine the relationship between serum urate concentration and incident gout.

**Methods:** Publically available cohort studies with both baseline serum urate and incident gout data were identified through a systematic search of PubMed and the Database of Genotype and Phenotype, and individual participant data were extracted for analysis. Kaplan-Meier plots were generated and the cumulative incidence of gout was calculated according to the baseline serum urate category. We evaluated the relation of serum urate categories (<6mg/dL as referent group) to risk of gout using Cox proportional hazards modelling, adjusted for potential confounders (age, sex, ethnicity, cohort).

**Results:** Four cohorts with publically available data were identified (Atherosclerosis Risk in Communities Study, Coronary Artery Risk Development in Young Adults Study, and the Original and Offspring cohorts of the Framingham Heart Study), with a total of 18,889 participants who were gout-free at baseline, mean (SD) 11.2 (4.2) years of follow-up, and 212,363 total patient-years included in the analysis. The overall cumulative incidence (95% CI) of gout by 5 years was 1.1 (0.9-1.3)%, by 10 years was 2.4 (2.2-2.6)% and by 15 years was 3.2 (2.8-3.6)%. The cumulative incidence at each time point varied according to baseline serum urate concentrations, with 15 year cumulative incidence (95% CI) ranging from 1.1 (0.9-1.4)% for <6mg/dL to 48.6 (30.5-66.6)% for 10mg/dL or more (Figure and Table). Compared with baseline serum urate <6mg/dL, the adjusted hazard ratio (95% CI) for baseline serum urate 6.0-6.9 mg/dL was 2.7 (2.0-3.6), for 7.0-7.9 mg/dL was 6.6 (5.0-8.8), for 8.0-8.9 mg/dL was 14.9 (11.1-20.1), for 9.0-9.9 mg/dL was 29.7 (20.8-42.3), and for 10mg/dL or more was 64.0 (42.5-96.1).

**Conclusion:** Serum urate is a strong concentration-dependent predictor of incident gout. Nonetheless, only about half of those with serum urate concentrations of 10mg/dL or more develop gout over 15 years, implying a role for additional factors in the pathogenesis of gout and a long duration of hyperuricemia preceding the onset of clinical gout. This analysis provides cumulative incidence estimates to guide discussions with hyperuricemic individuals about their risk of developing gout over time.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies I: Gout Risk of Disease Activity, Cardiovascular Disease and Mortality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Gout, a disorder of uric acid deposition, is commonly treated with xanthine oxidase inhibitors like febuxostat and allopurinol. While it is well-known that patients with gout are at increased risk of cardiovascular (CV) disease, little evidence is available with regard to comparative CV safety of febuxostat and allopurinol in the general older population.

**Methods:** Using claims data from U.S. Medicare (2008-2013), we conducted a cohort study among gout patients aged  $\geq 65$  initiating febuxostat versus allopurinol. All patients were continuously enrolled in Medicare parts A/B/D for  $\geq 1$  year free of a given drug prior to the 1<sup>st</sup> dispensing date (index date). The primary outcome was a composite CV endpoint of myocardial infarction (MI) or stroke. Secondary outcomes comprised MI, stroke, coronary revascularization, and new and recurrent heart failure (HF) requiring hospitalization. Follow-up time began the day after index date to the earliest day of the following: drug discontinuation, insurance disenrollment, occurrence of outcome, death, nursing home admission or last day of the study period. To adjust for  $\geq 55$  baseline covariates and index year, we used propensity score (PS) matching with a 1:3 ratio. Cox proportional hazards regression compared the risk of primary and secondary outcomes in the PS-matched cohorts of febuxostat and allopurinol initiators.

**Results:** We included 24,900 febuxostat initiators PS-matched on 74,700 allopurinol initiators. The median age was 76 years, 52% were male, and 32% had CV disease at baseline. During the mean (SD) follow-up time of 1.1 (1.1) years among febuxostat initiators and 1.2 (1.2) years among allopurinol initiators, the incidence rate (IR) per 100 person-years for the primary endpoint (MI or stroke) was 3.45 (95% CI, 3.24-3.68) in febuxostat and 3.34 (95% CI, 3.23-3.46) in allopurinol initiators. Hazard ratios (HR) for MI or stroke were 1.02 (95% CI, 0.95-1.10) in the febuxostat versus allopurinol groups. The risk of developing secondary outcomes was also similar in both groups (**Table**). For new-onset HF hospitalization, the IR in the febuxostat group was 5.72 (95% CI, 5.39-6.08) per 100 person-years with a HR of 1.04 (95% CI, 0.97-1.12) compared to allopurinol. Among patients with baseline HF, the IR of first-time HF exacerbation was 42.66 (95% CI, 41.12-44.26) per 100 person-years among febuxostat initiators with a HR of 0.95 (95% CI, 0.91-0.99) versus allopurinol.

**Conclusion:** Among 99,600 older patients with gout enrolled in Medicare, there was no difference in CV risk (including MI, stroke, coronary revascularization and new/recurrent HF) between patients initiating febuxostat compared to allopurinol.

<b>Table. Risk of overall cardiovascular events and heart failure (HF) in febuxostat initiators versus allopurinol:</b>							
<b>1:3 fixed ratio PS-matched</b>							
	<b>Febuxostat</b> <b>(n=24,900)</b>			<b>Allopurinol</b> <b>(n=74,700)</b>			
<b>Outcome</b>	Event (n)	Person- years	IR * (95% CI)	Event (n)	Person- years	IR * (95% CI)	HR (95% CI)

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies I: Gout Risk of Disease Activity, Cardiovascular Disease and Mortality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

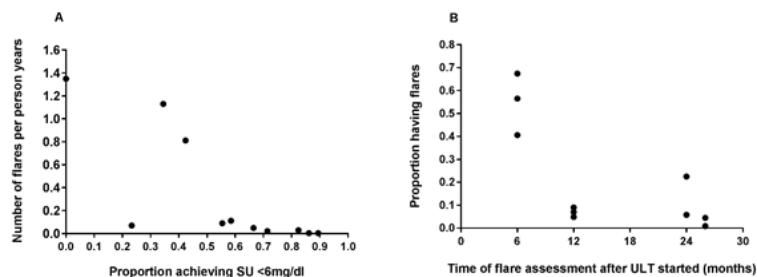

**Background/Purpose:** The primary efficacy measure in urate lowering therapy (ULT) trials is usually serum urate (SU). However, it is unknown whether the strength of the association between SU and clinically relevant outcomes is sufficient for SU to be considered a surrogate. The aim of this study was to examine the strength of a possible association between SU and flares, indirectly providing support for SU as an important biomarker in clinical practice.

**Methods:** A systematic literature review was undertaken to identify all relevant studies. First, randomized controlled trials (RCTs) comparing any ULT in people with gout with any control or placebo,  $\geq 3$  months duration were included. The maximum RCT duration of 12 months and studies where the proportion of individuals with  $SU < 6\text{mg/dL}$  and the proportion having a flare were assessed in close temporal proximity may obscure any relationship. Therefore, open label extension (OLE) and longitudinal observational studies were included in secondary analyses. Standardized data elements were extracted by two independent reviewers. Association between the variables were analyzed by simple correlation between gout flare rate either as a proportion or converted into events over patient-years (dependent variable[s]), scattered against the proportion achieving  $SU < 6\text{mg/dL}$  and the duration of the trial. The CORR procedure (SAS) provided a nonparametric measure of association between the variables; we used Spearman's rank-order correlation to test the potential association between variables.

**Results:** Of the 2,775 records, 9 RCTs were identified. 3 OLE studies and 11 observational studies were identified. Using data from the 9 RCTs, of which the maximum trial duration was 12 months, meta-regression analysis did not reveal a statistically significant association between the proportion of individuals with  $SU < 6\text{mg/dL}$  and the observed flare rate ( $P=0.82$ ). The ratio of the time in months at which the proportion of individuals having a flare was reported/time in months at which the proportion of individuals with  $SU < 6\text{mg/dL}$  was reported was calculated and those studies where the ratio was  $< 2$  were excluded. Using the remaining 5 studies (incl. 11 data points) there was a clear association between proportion of individuals achieving  $SU < 6\text{mg/dL}$  and the observed gout flares (over patient years; Fig A; Spearman rho= -0.888,  $P=0.0003$ ). Duration of ULT was also strongly inversely associated with the proportion of patients experiencing a flare (Fig B; Spearman rho= -0.878,  $P= 0.0004$ ).

**Conclusion:** From observational data,  $SU < 6\text{mg/dL}$  is strongly associated with reduced gout flares but the duration of the RCTs needed to reveal possible causation, with clinically relevant benefit takes longer than the usual RCT duration. These associations provide some support that SU may be a suitable biomarker for gout clinical trials.

Figure: Proportion of those with  $SU < 6\text{mg/dL}$  having gout flares

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies I: Gout Risk of Disease Activity, Cardiovascular Disease and Mortality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

There is recognized higher mortality among gout patients, with cardiovascular (CV) mortality having been previously reported. The present study aimed to examine cause-specific mortality beyond CV diseases in patients with gout compared to general population.

### Methods:

We used the Swedish SkCene Healthcare Register, which contains data regarding healthcare visits for all residents of the large region, and the Causes of Death Register (high validity), both with diagnoses registered according to International Classification of Diseases, version 10 (ICD-10) system. We identified subjects with incident gout (ICD-10: M10) diagnosed between 2003 and 2013. We matched each person with gout with up to 10 comparators free of gout by age and sex. Subjects were followed from the date of gout diagnosis or a matching index date for the comparators until relocation outside SkCene, death or end of study period (12/31/14). Using information on the underlying cause of death, we estimated hazard ratios (HR) of mortality for specific causes of death in a multi-state Cox model accounting for competing risks, adjusting for potential confounders (Table), and also stratified by sex.

### Results:

Among a source population of 832,258 subjects, there were 19,497 persons with an incident gout diagnosis who were matched with 194,947 comparators free of gout. Persons with gout had higher prevalence of chronic kidney disease, metabolic and CV comorbidities, but lower prevalence of dementia than comparators. The all-cause mortality rate per 1000 person-years was 63.6 among those with gout and 47.3 among those without gout. The causes of death among those with and without gout, respectively, were: CV diseases, 49.5% and 41.4%; neoplasms, 18.2% and 21.9%; diabetes, 3.4% and 2.2%; infections, 5.7% and 5.8%; kidney diseases, 1.6% and 0.8%; dementia, 3.8% and 8.4%. Gout was associated with an 18% increased risk of all-cause mortality (HR 1.18, 95% CI 1.14-1.21). In terms of cause-specific mortality, the largest association was seen for the relation of gout to risk of death due to renal disease (HR of 1.47) (Table). Gout was associated with lower risk of death due to dementia (HR 0.80), while elevated risk of CV-related mortality in gout was confirmed (HR 1.25). While men had higher mortality overall, in the stratified analyses, the effect of gout on cause-specific CV-, infection-, neoplasm-, and renal-related mortality was modestly higher among women than men, potentially reflecting generally lower baseline risk of mortality in women (Table). Similar results were obtained with the Fine & Gray method.

**Table: Relation of gout to cause-specific mortality**

Cause of Death	HR* [95% CI]	Fully adjusted** HR [95% CI]
CV-related mortality	1.75 [1.68-1.83]	1.25 [1.19-1.31]
Dementia-related mortality	0.67 [0.59-0.77]	0.80 [0.69-0.93]
Diabetes-related mortality	2.27 [1.95-2.65]	1.08 [0.91-1.27]
Infection-related mortality	1.45 [1.30-1.63]	1.19 [1.06-1.35]
Neoplasm-related mortality	1.17 [1.10-1.25]	1.10 [1.03-1.18]
Renal disease-related mortality	3.23 [2.58-4.05]	1.47 [1.12-1.92]
Other† causes of mortality	1.33 [1.24-1.41]	1.14 [1.07-1.23]

STRATIFIED BY SEX:	Fully adjusted** HR [95% CI]	
	Men	Women***
CV-related mortality	1.22 [1.15-1.29]	1.32 [1.23-1.43]
Dementia-related mortality	0.81 [0.66-0.99]	0.79 [0.64-0.98]
Diabetes-related mortality	1.13 [0.92-1.37]	1.02 [0.76-1.37]
Infection-related mortality	1.07 [0.92-1.26]	1.42 [1.17-1.71]
Neoplasm-related mortality	1.07 [0.98-1.15]	1.21 [1.07-1.37]
Renal disease-related mortality	1.23 [0.87-1.73]	2.04 [1.28-3.24]
Other† causes of mortality	1.12 [1.02-1.22]	1.22 [1.09-1.36]

\*Adjusted for age, sex, year of entry into the study

\*\*Adjusted for age, sex, year of entry into the study, marital status, income, education, birth outside Sweden, and comorbidities diagnosed within 5 years preceding index date: diabetes, cerebrovascular disease, ischemic heart disease, heart failure, hypertension, dyslipidemia, chronic kidney disease, dementia, neoplasm, obesity, tobacco use, alcohol use.

\*\*\*Not adjusted for tobacco use and alcohol use due to low numbers.

†Other causes of mortality included: COPD, unspecified.

HR: hazards ratio; CI: confidence interval; CV: cardiovascular.

## Conclusion:

A novel finding is the ~50% increased risk of renal-related mortality among gout patients that highlights the need for improved understanding and management of gout and kidney disease. The finding of ~20% lower dementia-related mortality calls for attention to the relation between hyperuricemia and dementia.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Metabolic and Crystal Arthropathies I: Gout Risk of Disease Activity, Cardiovascular Disease and Mortality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Hyperuricemia and gout aggregate in families. The objectives of this study were to estimate the prevalence of asymptomatic monosodium urate (MSU) crystal deposition in men with a parent with gout, and to describe the sites involved in early crystal deposition.

**Methods:** People with gout who participated in previous research at Academic Rheumatology, University of Nottingham, UK, were mailed a letter about the study accompanied by a study pack to be posted to their son(s) ≥20 years in age. Sons interested in participating returned a reply slip and underwent telephone screening to exclude gout or inflammatory arthritis. Eligible sons were invited for a study visit at which information about disease and demographic characteristics was obtained, musculoskeletal assessment

performed and venesection undertaken. A trained ultrasonographer (AA) performed ultrasound of 1<sup>st</sup> meta-tarsophalangeal joints (MTPJs), talar domes, femoral condyles, patella and triceps tendons, wrist triangular cartilage and 2<sup>nd</sup> meta-carpophalangeal joints (MCPJs) blinded to the SUA level person specific characteristics [1]. The images were scored for double contour sign (DCS), tophus, calcification, hyaline linear bodies and effusion. Doubtful images were scored blindly by a second sonographer with >10 years' experience (PC). This study was approved by the Nottinghamshire Research Ethics Committee-II. N (%), mean (standard deviation (SD)) were used for descriptive purpose. Chi-square tests were used to compare categorical values.

**Results:** 1435 parents were invited to post the study packs to their sons if applicable. 249 replies were received, 134 sons agreed to participate, and 130 of these completed assessments to date. Their mean (SD) age, body mass index, and SUA were 43.86 (11.22) years, 27.10 (4.76) kg/m<sup>2</sup>, and 6.42 (1.13) mg/dl respectively. 64.6% sons had SUA >6 mg/dl, and 30% of them had MSU crystal deposition defined as presence of either DCS or tophus. All had MSU deposition at either 1<sup>st</sup> MTPJ, and one participant had DCS at the ankle. None of the other joints had a tophus or a DCS. The prevalence of MSU deposit was 0%, 18.8%, 35.7%, 38.3% and 34.2% in those with SUA <5, 5-5.66, 5.67-6.33, 6.33-7 and >7 mg/dl respectively. Participants with MSU crystal deposition were more likely to have calcification at patellar tendons (23.1% vs. 7.7%, p=0.01).

**Conclusion:** Sons of people with gout frequently have asymptomatic MSU deposits. MSU crystal deposits appear at the MTPJs and in the tendons before appearing in other joints such as the ankle or the knee. In this high risk population MSU crystal deposition occurred at SUA <6.3 mg/dl which suggests that pro-nucleating changes in the connective tissue matrix may have a role in crystal deposition.

**Session Title:** Metabolic and Crystal Arthropathies I: Gout Risk of Disease Activity, Cardiovascular Disease and Mortality

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Allopurinol is a cornerstone therapy in gout management. Despite this, allopurinol use is suboptimal as providers often fail to follow the treat-to-target paradigm endorsed as a best practice in gout. We conducted a large cluster-randomized study to examine the impact of a pharmacist-driven intervention to optimize allopurinol therapy in gout.

**Methods:** Medical offices in the Kaiser Permanente Southern California health system were cluster randomized (n = 103 clusters) to deliver either a pharmacist-led intervention or usual care to patients receiving new allopurinol prescriptions. The intervention allowed

the study pharmacist to assume responsibility for most elements of allopurinol prescribing. Patient outreach was conducted primarily via telephone interactive voice recognition (IVR) system to assess adherence, encourage serum urate (sUA) and other gout-related lab monitoring, provide patient-focused gout education, and adjust allopurinol dosing. Primary outcomes were achievement of a sUA <6.0 mg/dl and allopurinol treatment adherence at one year. Patients were considered adherent if the proportion of days covered (PDC), based on allopurinol prescription fills, was  $\geq 0.8$ . Treatment (n=77) and control (n=147) patients without a follow-up sUA were assumed not to have reached sUA goal (i.e. non-responder imputation).

**Results:** Usual care (n=782) and intervention (n=630) patients were similar in age, sex, mean household income, BMI, baseline sUA (mean 8.4 mg/dl in both groups), creatinine, and starting allopurinol dose (mean 188 mg/day in both groups). Intervention patients were more often Caucasian (45% vs. 38%) and less often reported Asian race (20% vs. 26%) than those receiving usual care (p=0.01). The proportion achieving sUA goal, 1-year adherence, ending allopurinol dose, and changes in sUA are shown in the Table. The intervention met all primary outcomes and showed significant improvements compared to usual care. With a mean of 2.4 ( $\pm 2.4$ ) IVR/pharmacist contacts, intervention patients were approximately 3-times more likely than usual care patients to receive allopurinol dose escalation (32% vs. 12%, p<0.001).

**Conclusion:** A relatively simple intervention leveraging ambulatory pharmacists and automated telephone technology led to improved treatment adherence and achievement of sUA goal in gout patients initiating allopurinol. However, almost 7 of 10 intervention patients failed to achieve a sUA < 6.0 mg/dl. Thus, while this light-touch, low-tech intervention was effective for some patients, additional efforts will be needed to optimize allopurinol administration in gout care.

**Table:** Study outcomes

	Control (n=782)	Treatment (n=630)	P- value	Adjusted OR (95% CI)*
sUA < 6.0 mg/d	20.6%	31.3%	<0.001	1.75 (1.37, 2.24)
PDC $\geq 0.8$ at 1 year	35.4%	47.6%	<0.001	1.69 (1.30, 2.19)
Change in sUA, mg/dl	-1.35 (1.86)	-1.67 (1.84)	<0.001	N/A
PDC at 1 year	0.59 (0.29)	0.66 (0.29)	<0.001	N/A
Ending allopurinol dose, mg/d	203 (103)	235 (104)	<0.001	N/A

OR = odds ratio; CI = confidence interval; \*Multivariable logistic regression; adjusted for race and calendar year

## Pain and Functional Trajectories in Symptomatic Knee Osteoarthritis over a 12-Week Period of Non-Pharmacological Exercise Interventions

Augustine Lee<sup>1</sup>, William F. Harvey<sup>2</sup>, Xingyi Han<sup>1</sup>, Lori Lyn Price<sup>3,4</sup>, Jeffrey B. Driban<sup>1</sup>, Raveendhara R. Bannuru<sup>1</sup> and Chenchen Wang<sup>2</sup>, <sup>1</sup>Rheumatology, Tufts Medical Center, Boston, MA, <sup>2</sup>Rheumatology, Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA, Boston, MA, <sup>3</sup>Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, <sup>4</sup>Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation

**Session Type:** ACR Concurrent Abstract Session

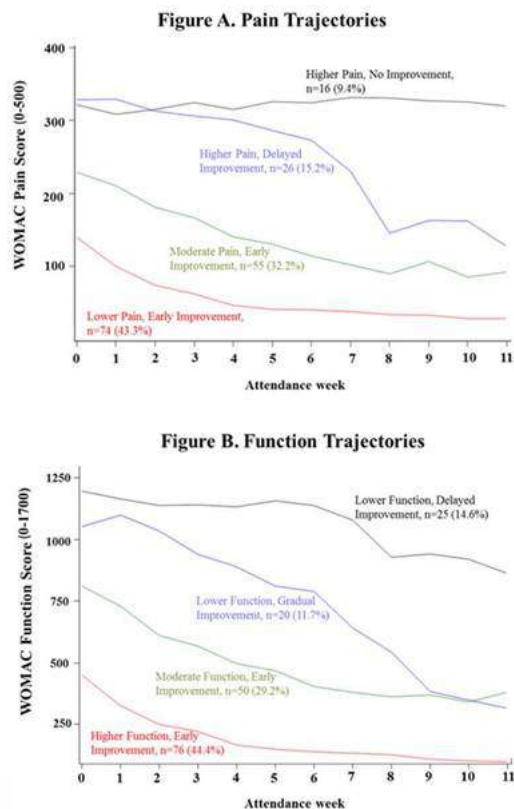

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Exercise is the recommended treatment for knee osteoarthritis (OA). However, heterogeneous patterns in treatment response are poorly understood. Our purpose was to identify pain and functional trajectories from exercise interventions among adults with symptomatic knee OA, and to determine their association with baseline factors.

**Methods:** Secondary analysis of a single-blind, randomized trial comparing 12-week Tai Chi and Physical Therapy exercise programs among adults with symptomatic knee OA (ACR Criteria). We used weekly measures of WOMAC pain (0-500) and function (0-1700) to identify trajectories using group-based trajectory models. Associations between baseline factors and trajectories were examined using multinomial logistic regression.

**Results:** We examined 171 participants (mean age 61 years, BMI 32kg/m<sup>2</sup>, 71% female, 57% white), and identified four pain trajectories: Lower-Early Improvement (43.3%), Moderate-Early Improvement (32.2%), Higher-Delayed Improvement (15.2%), and Higher-No Improvement (9.4%) (**Figure**). We found similar trajectories for function, except that the lower function trajectories diverged into gradual (11.7%) or delayed improvement (14.6%). Compared with the Lower-Early Improvement pain trajectory, moderate and higher pain trajectories were significantly associated with younger age, obesity, black race, and poorer physical health (**Table**). Importantly, psychological morbidities, such as greater depressive symptoms were significantly associated with Higher-Delayed (Odds Ratio [OR]: 1.06; 95% CI, 1.004-1.12) and Higher-No Improvement pain trajectories (OR: 1.07; 95% CI, 1.01-1.13) compared with the Lower-Early Improvement group. A similar pattern of significant associations were found among the functional trajectories (data not shown).

**Conclusion:** Using innovative analytical techniques, we found four distinct trajectories for pain and function over 12-week exercise interventions among adults with symptomatic knee OA. While most participants experienced early improvements, subgroups with greater baseline pain/physical disability had either gradual, delayed, or no improvements. Notably, psychological morbidities tended to distinguish non-responders or delayed-responders from early responders. These findings help disentangle the heterogeneity of treatment response and may advance patient-centered care for these patients.

**Figure. Pain and Functional Trajectories from Exercise Interventions:** WOMAC= Western Ontario and McMaster Osteoarthritis Index. **Panel A:** Pain Trajectories. WOMAC Pain subscale range: 0-500, higher scores = greater pain. **Panel B:** Function Trajectories. WOMAC Function subscale range: 0-1700, higher scores = poorer physical function.

## Jakinibs Decrease Chronic Low Back Pain and Increase Function: A Proof of Concept Trial

**Maria Greenwald**<sup>1</sup> and JoAnn Ball<sup>2</sup>, <sup>1</sup>Desert Medical Advances, Palm Desert, CA, <sup>2</sup>rheumatology, Desert Medical Advances, Palm Desert, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Low back pain (LBP) is ubiquitous and estimated to affect 26% of Americans in any 3 month period. Why would rheumatoid arthritis patients be any different? We noted improvement in chronic LBP among patients using JAK inhibitors (JAKinibs) in a prospective program.

**Methods:** Sequential RA patients over age 40 were first educated, to explain that RA is not a typical cause chronic LBP. Patients with over 3 months of chronic LBP with or without radiculopathy, then signed informed consent and completed questionnaires. At baseline, patients scored > 6 on the LBP intensity score (out of 11 maximum score), a disability score of 12 (max score 24), and a response of fair, poor, or very poor in the Leikert patient's global assessment (PGA). These responses were specific to the back. Often LBP had been present for a decade preceding RA. Excluded for thirty days prior and during the study were narcotics, corticosteroids, gabapentin, pregabalin, anti-depressants, acetaminophen, and muscle relaxants. All patients had moderate to severe RA where JAKinibs were appropriate treatment. Patients answered questionnaires specific to LBP every 2 weeks for a 12 week period. They were randomized by birth year. This phase 1 study was single blind. All assessments of LBP were by the patient (blinded to therapy). This was a phase 1 exploratory trial for improvement in LBP with JAKinibs.

**Results:** 74 patients enrolled; 37 each to JAKinhib and placebo for 12 weeks. There were 74% women, average age 59.6 years, BMI 27.4, Caucasian 58%, Hispanic 41% and Asian 1%. Despite no differences at baseline, chronic LBP in the JAKinib group improved compared to placebo. The pain score decreased 2.1 (31%),  $p < 0.01$ ; the disability score improved 3.9 (21%),  $p < 0.01$ ; the PGA improved 0.8 (19%),  $p < 0.01$ ; and stiffness in the back improved 0.7 (16%),  $p < 0.02$ . Originally, patients reported 4.5 lost work hours due to chronic LBP, out of a 40 hour week. The JAKinib group reported no loss in work hours after 12 weeks. The improvements began at 2 weeks and were sustained during the 12 week observation period.

**Conclusion :** This is a proof of concept trial evaluating JAKinibs for the treatment of LBP. In the past decade, many trials have attempted to find LBP therapy among anti-inflammatory and anti-cytokine therapies, including a study with etanercept as an epidural injection therapy. None have been found effective. In recent large RA trials where JAKinibs are being evaluated for the treatment of RA, adverse events of LBP were less frequent in the JAKinibs groups than the placebo. Given that LBP is ubiquitous and RA patients are susceptible to mechanical LBP, we prospectively tracked in randomized patients, pain, disability, PGA, stiffness and work loss. In each category, the JAKinhib group improved compared to placebo in LBP. Perhaps this immunotherapy JAKinib, can provide mild to moderate benefit in the treatment of chronic LBP.

#### JAKinibs net improvement effect on chronic LBP (compared to placebo)

Pain	Stiffness of Back	Disability	PGA	Work
-2.1 (31%)	-0.7 (16%)	3.9 (21%)	0.8 (19%)	+4.5 hr/wk

- All results were statistically significant ( $p < 0.01$  for pain, disability, PGA and  $p < 0.02$  for stiffness).
- Results record improvements in the JAKinib group compared to the placebo group. The WOMAC recorded pain and stiffness, the Roland-Morris questionnaire recorded disability (24 point scale), and the patient global assessment (PGA) was a 5-point Leikert scale. Pain and stiffness improvement is recorded as a negative. Both improvement in disability and PGA is recorded as positive in these scales.
- N= 37 patients were randomized to JAKinibs, and 37 were randomized to placebo for 12 weeks.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The population is rapidly aging, and by 2060, more than 12 million women will be ages 85 years and older in the United States. As millions of women with total knee (TKR) and total hip (THR) replacements for osteoarthritis (OA) reach old age, it is important to understand which modifiable factors predict disability-free survival after surgery. Although indicators of adiposity, such as high body mass index (BMI), waist circumference (WC), and waist-hip ratio (WHR) are associated with increased risk of OA and utilization of total joint replacement (TJR), their associations with late-life mobility after TJR are unknown. The purpose of this study was to examine associations of BMI, WC, and WHR with mobility limitation at age 85 among women with TKR or THR for OA.

**Methods:** This was a prospective study of women (aged 65-79 years at baseline) from the Women's Health Initiative (WHI) recruited during 1993-1998 and followed through 2012. WHI data were linked to Medicare claims data to determine TKR (n=1,867) and THR (n=944) for OA. Women were followed for up to 18 years after undergoing TJR to determine mobility status at age 85. Women who reported that their health limited their ability to walk one block or climb one flight of stairs were classified as having mobility limitation. BMI was defined as normal-weight ( $\leq 24.9$  kg/m<sup>2</sup>), overweight (25-29.9), obese I (30-34.9), or obese II ( $\geq 35.0$ ). WC and WHR were defined according to cutpoints for abdominal obesity. Multinomial logistic regression models were used to evaluate associations of adiposity measures with mobility limitation at age 85 and death before age 85 (reference category=mobility intact at age 85).

**Results:** Among women with THR, 45.7% had mobility limitation at age 85, 34.8% had intact mobility at age 85, and 19.6% died before age 85. Among women with TKR, 47.9% had mobility limitation at age 85, 30.4% had intact mobility at age 85, and 21.8% died before age 85. Compared with normal-weight women with THR, overweight (odds ratio [OR]=1.53; 95% confidence interval [CI]=1.04-2.25), obese I (OR=2.40; 95% CI=1.49-3.85), and obese II (OR=4.37; 95% CI=1.96-9.74) women had increased risk of late-life mobility limitation. Obese II women also had increased risk of death before age 85 (OR=6.08; 95% CI=2.39-15.49). Women with THR and WC >88 cm relative to  $\leq 88$  cm had increased risk of mobility limitation (OR=1.65; 95% CI=1.17-2.33). WHR was not associated with survival outcomes among women with THR. Among women with TKR, associations of BMI and WC with survival outcomes varied by age at TKR and were strongest in the youngest age group (67-74 years at TKR; OR for mobility limitation=3.24; 95% CI=1.40-7.50 for obese II vs. normal-weight). In the oldest age group (80-82 years at TKR), obesity was associated with increased risk of mobility limitation at age 85 (OR=1.78; 95% CI=1.03-3.06) and death (OR=3.78; 95% CI=1.23-11.67), and WC >88 cm was associated with risk of mobility limitation (OR=1.61; 95% CI=1.07-2.43) but not death.

**Conclusion:** Among women with THR or TKR for OA, general and abdominal obesity were associated with increased risk of late-life mobility limitation and death. These findings support maintenance of healthy body weight among women with THR or TKR to lessen mobility loss in late life.

## Widespread Pain Prior to Total Knee Replacement (TKR) Is Associated with Increased Risk of No Clinical Improvement in Pain Among Women

Ernest Vina<sup>1</sup>, Di Ran<sup>2</sup>, Erin L. Ashbeck<sup>2</sup> and C. Kent Kwok<sup>3</sup>, <sup>1</sup>Rheumatology, University of Arizona, Tucson, AZ, <sup>2</sup>The University of Arizona Arthritis Center, Tucson, AZ, <sup>3</sup>University of Arizona, Tucson, AZ

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Up to 47% of individuals may not have clinically significant improvement following joint replacement surgery. Evidence also suggests that women are less likely to benefit from TKR surgery than men, but the reasons are unclear. The objective of this study is to evaluate the association between pre-operative widespread pain (WP) and failure to experience clinical improvement 2 years following TKR separately for men and women.

## Methods:

Osteoarthritis Initiative participants who underwent TKR surgery prior to the 7-year follow-up visit were included in the analysis. WP was defined based on a modified ACR definition of chronic WP and was assessed with a questionnaire which included a homunculus figure. Pain and disability were assessed at the clinic visit prior to TKR as well as 2 years later, using WOMAC pain, WOMAC disability, and Knee Injury and Osteoarthritis Outcome (KOOS) pain scores. Medication use for osteoarthritis (OA)-related symptoms was also determined. Clinically significant improvement was defined as improvement in WOMAC subscale (or KOOS pain) score  $\geq$  to the minimal important difference (based on previously published literature). Relative risk (RR) of no clinical improvement was estimated using log-binomial regression, comparing participants with and without WP, stratified by gender.

## Results:

Our sample consists of 120 with and 178 without WP who underwent TKR surgery. Those with WP, compared to those without, were more likely to be women (70.0% vs. 56.2%), with  $<$ \$50K/year income (48.21% vs. 37.1%), and obese (55.3% vs. 46.8%). Two years after their pre-operative pain assessment, ~12% of men and ~15% of women reported no clinical improvement in knee pain. OA-related medication use after surgery was also more common in women with WP than those without (69.2% vs. 50.0%,  $p=0.0311$ ).

Among women, WP prior to surgery was significantly associated with an increased risk of no clinically significant improvement following TKR based on WOMAC pain (RR 2.35, 95% CI [1.06-5.20],  $p=0.0351$ ) and results were suggestive, though not significant, for KOOS pain (RR 1.93, 95% CI [0.97-3.85],  $p=0.0626$ ). After adjustment for sociodemographic and clinical characteristics, the magnitudes of association were stronger (WOMAC pain, RR 3.50, 95% CI [1.05-11.65],  $p=0.0409$ ; KOOS pain, RR 2.49, 95% CI [1.00-6.18],  $p=0.0490$ ). No association among men was observed between pre-TKR WP and failure to improve in WOMAC or KOOS pain score following surgery (Table 1). No strong evidence for an association between WP and failure to improve in WOMAC disability was seen for either gender.

## Conclusion:

WP prior to TKR was significantly associated with increased risk of no clinical improvement in knee OA pain 2 years later among women. However, no evidence of an association between WP and TKR outcome was found among men, though the prevalence of WP pain among men was also limited. WP assessment may help identify patients at risk of failure to benefit from TKR surgery.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The increased volume of TJA due to the aging population requires a better understanding of the effect of physiological frailty, in addition to chronological age, on TJA-associated complications. If frailty is associated with poor outcomes, it is potentially modifiable.

**Methods:** Community-dwelling patients  $\geq 65$ yo scheduled for elective total knee (TKA) or hip (THA) arthroplasty were recruited from a musculoskeletal specialty hospital. All patients were medically approved for surgery. Pre-operative frailty was defined as at least 3/7 frailty characteristics based on the Fried frailty phenotype and a composite frailty score previously validated in surgical populations (Table 1). Pre-operatively subjects completed the PROMIS-29, SF-12, Depression Screening (CES-D 10), Lubben Social Network Scale (LSNS-18), Katz Index of Independence in Activities of Daily Living (ADL), and Hip/Knee Injury and Osteoarthritis Outcome Score (HOOS/KOOS). Grip strength was measured and normalized by age and gender. Adverse events were obtained from medical records and by phone 30 days post-discharge. Stepwise multivariable logistic regressions were performed to ascertain if frailty, or any of its components, were independent risk factors for short-term adverse events (AEs).

**Results:** 464 subjects enrolled (mean age 73 (range 65-94), 95% white, 61% female, 60% TKA, 40% THA). 8% were frail (9% THA, 8% TKA). 17% had difficulty with at least 1 Katz ADL (14% THA, 19%TKA).

Among patients who reached 30-day follow-up, 180/373 (48%) had 263 AEs and 35/373 (9%) had 51 severe AEs. There were no significant differences in AEs or severe AEs between frail and non-frail patients. Controlling for gender, age, and which joint was replaced, independent predictors of having  $\geq 1$  AEs included pre-operative anemia (OR=3.14; 95% CI 1.08-9.15) and PROMIS-29 Anxiety (OR=1.05; 95% CI 1.02-1.08). Having a hip rather than knee replaced decreased the risk of severe AEs (OR=0.39; 95% CI 0.17-0.88).

For THA patients, older age was associated with increased risk of AEs (OR=1.07; 95% CI 1.01-1.13), while better SF-12 PCS was protective (OR=0.94; 95% CI 0.90-0.98).

For TKA patients, a higher PROMIS Anxiety score was associated with an increased risk of AEs (OR=1.04; 95% CI 1.003-1.08). Having  $\geq 1$  Katz ADL dependency was associated with an increased risk of severe AEs (OR=2.51; 95% CI 1.03-6.11).

Our composite measure of frailty did not predict AEs in any model.

**Conclusion:** A substantial proportion of medically-cleared TJA patients at this high-volume center were frail. Having ADL dependency was associated with a 2.5x increased risk of severe AEs among TKA. Whether frailty is associated with long-term AEs, pain, or function needs to be established in longitudinal trials.

**Table 1: Frailty Characteristics**

	Total Hip Replacement (N=277)	Total Knee Replacement (N=187)	All (N=464)
<b>Individual Frailty Characteristics, %</b>			
Unintentional weight loss of $\geq 10$ lbs in last year	2.7	2.6	2.6
$\geq 1$ Dependency on the Katz ADL	13.5	18.5	16.5
Weakness (grip strength $>1$ SD below mean for age/gender norm)	33.2	39.4	36.9
Anemia (pre-operative hematocrit $<35\%$ )	6.1	5.8	6.0
Poor nutrition (pre-operative albumin $<3.4$ g/dL)*	0	0	0
$\geq 1$ falls in past 6 months	16.6	14.2	15.2
Exhaustion (answered “moderate” or “most” for CES-D 10 questions about effort and getting going)	29.5	20.4	24.0
Frailty: $>3$ characteristics, %	8.6	8.1	8.3

\* 277/464 (115 THA, 162 TKA) patients had albumin levels recorded.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Orthopedics, Low Back Pain and Rehabilitation

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Gait speed has been associated with many clinical outcomes (e.g. frailty, mortality, joint replacement need, etc.) relevant for rheumatologic conditions. Measuring Gait speed (stride length x step count/time) typically requires significant clinician/staff time or a gait lab with specialized equipment. Our formative work was to measure “step count” via smartphones as a first step in making gait speed measurement available for patient home follow-up.

**Methods:** We developed and tested a mobile App-based method to count steps, comparing a hardware (pedometer) vs. software (“Shake algorithm”) approach. Shake algorithm software allows for adjustment of amplitude (how big a shake equates a step) and refresh rate (how often the software counts a shake/step). We conducted calibration and validation phases. In both, subjects carried iOS

and Android phones (one in each front pants pocket) simultaneously, and electronic gait timers measured the time it took to cover pre-measured distances.

Calibration phase: Subjects walked a 20m course at normal and slow (<1.0 m/s) speeds for 9 different shake algorithm settings (x3 walks for each). We determined which setting most closely matched investigator observed step counts. Validation phase: we used the selected shake algorithm settings for the smartphones and recruited subjects to each complete walks (x3) of 6, 10 and 20m at both slow and normal (>1.0m/s) speeds.

We compared step difference (absolute difference) from observed step counts to hardware (pedometers) and software (shake algorithm) derived step counts. We used generalized estimated equation adjusted (participant level) negative binomial regression models of absolute step difference from observed step counts, to determine optimal settings (calibration) and subsequently to gauge performance of the shake algorithm settings and pedometers across different distances and speeds (validation).

**Results:** Calibration: 270 observations across 5 individuals were used to determine optimal smartphone shake algorithm settings for slow and fast walking speeds. Validation: Compared to observed step count, the shake service outperformed pedometer across all distances at slow, and at 6m for normal speed on iOS. On the Android phone, the shake service outperformed the pedometer at slow speed for 6 and 20m, and at 20m for normal speed (Table).

**Conclusion:** Software based approaches such as the shake algorithm, which can have parameters adjusted for optimized measurement of step can be adjusted to outperform fixed hardware such as pedometers. These results will facilitate bringing the capture of performance based metrics such as gait speed to patient home follow-up, using technology users already own (smartphones) to optimize data capture for research and clinical care across rheumatologic conditions.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Juvenile Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** IV abatacept (ABA) 10 mg/kg every 4 weeks is well tolerated and effective in reducing the signs and symptoms of polyarticular juvenile idiopathic arthritis (pJIA) in patients (pts) aged 6–17 years (y).<sup>1</sup> The objective of this study was to investigate the pharmacokinetics (PK), effectiveness, safety and immunogenicity (IMG) of SC ABA in pts with active pJIA aged 2–17 y over a 2-y period. **Methods:** Pts with pJIA and an inadequate response/intolerance to  $\geq 1$  DMARD were enrolled into this 2-y, single-arm, open-label, Phase III study (NCT01844518) and grouped into 2–5-y and 6–17-y cohorts. Pts received SC ABA weekly for 4 months (M) based on body-weight tier (10–<25 kg [50 mg]; 25–<50 kg [87.5 mg];  $\geq 50$  kg [125 mg]). JIA-ACR criteria 30 (JIA-ACR30; ACR Pediatric 30) responders at 4 M could receive abatacept for another 20 M. Primary endpoint was ABA steady-state serum trough concentration ( $C_{\min ss}$ ) at 4 M in pts aged 6–17-y at enrollment. Other endpoints included PK, JIA-ACR30, 50, 70 and 90, inactive disease (no active joints, Physician Global Assessment of disease activity  $\leq 10$  mm, CRP  $\leq 0.6$  mg/dL) response rates, safety and IMG over time. **Results:** For the 2–5-y and 6–17-y cohorts, baseline characteristics and cumulative drug exposure for 2-y period are shown in Table 1. Overall, the number of pts completed, discontinued (D/C) and ongoing in the cumulative 2-y period in the 2–5-y cohort were: 24 (52.2%), 7 (15.2%) and 15 (32.6%); in the 6–17-y cohort: 132 (76.3%), 36 (20.8%) and 0. D/C due to lack of efficacy were 5 (10.9%) and 17 (9.8%) in the 2–5-y and 6–17-y cohorts, respectively. Target ABA  $C_{\min ss}$  ( $>10$   $\mu$ g/mL) was achieved at 4 M and was comparable across weight-tiered dose groups and age cohorts. Pts responded early to ABA and showed robust JIA-ACR30, 50, 70 and 90, and inactive disease responses over time (Figure). No new or unexpected safety events were reported (Table 2). IMG response was low: 4 (8.7%) 2–5-y and 4 (2.3%) 6–17-y pts while on treatment.

**Conclusion:** In this analysis of pts with pJIA aged 2–17 y during the cumulative 2-y period, SC abatacept was well tolerated and demonstrated robust efficacy and targeted PK with no new safety concerns.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Juvenile Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Tocilizumab (TCZ) is approved for the treatment of systemic juvenile idiopathic arthritis (sJIA) based on clinical trials in patients  $\geq 2$  years of age. This phase 1 study (NP25737), the first of a biologic in patients with sJIA  $< 2$  years of age, evaluated the pharmacokinetics (PK), pharmacodynamics (PD), efficacy, and safety of TCZ.

**Methods:** Patients with uncontrolled sJIA and symptoms for  $\geq 1$  month prescreening whose treatment with corticosteroids and NSAIDs failed and who had no history of allergy to TCZ or other biologics received open-label TCZ 12 mg/kg intravenously every 2 weeks (dose calculated each visit based on body weight). Patients were treated up to Week 12 and could continue until they reached 2 years of age or were treated for 1 year from baseline. End points included PK (primary), safety (secondary), PD, and efficacy (exploratory) at Week 12. Comparison was made with data from a previous trial in sJIA patients  $\geq 2$  years of age (WA18221) that formed the basis for approval of TCZ in sJIA.

**Results:** Eleven patients were enrolled; mean (SD) age was 1.3 (0.33) years, and weight was 9.97 (1.38) kg. Serum TCZ concentrations, estimated using population PK analysis, peaked immediately after infusion; median (range) maximum concentration was 282 (195-347) mcg/mL (steady state reached by Week 12), and median (range) trough concentration was 34.3 (19.2-59.7) mcg/mL. Peak and trough exposures were within the exposure range in older children (244 [109-382] to 54.3 [10.9-117] mcg/mL) (Figure). Observed mean $\pm$ SD soluble IL-6 receptor levels increased from 47.65 $\pm$ 16.40 ng/mL at baseline to 1461.14 $\pm$ 852.71 ng/mL at Day 85. CRP and ESR levels, which were elevated at baseline, decreased to 3.35 $\pm$ 3.77 mg/L and 3.50 $\pm$ 0.84 mm/h, respectively. Mean $\pm$ SD Juvenile Arthritis Disease Activity Score-71 improved from 22.27 $\pm$ 10.09 at baseline to 4.90 $\pm$ 6.11 at Day 85. By Week 12, 10 patients had 32 adverse events (AEs); 4 withdrew due to AEs. Infections or infestations were the most frequently reported AEs (10 events, 9 patients). Five serious AEs (SAEs) occurred in 3 patients; all had SAEs of hypersensitivity that led to treatment withdrawal, and 1 of these 3 patients then experienced SAEs of foot and mouth disease and sJIA flare after study withdrawal. No deaths occurred during the study.

**Conclusion:** TCZ exposures achieved in this study fell within the exposure range of the previous trial in sJIA patients  $\geq 2$  years of age. This study provides evidence that TCZ is effective in sJIA patients  $< 2$  years of age and achieves PK and efficacy similar to those demonstrated previously in older patients. The safety profile was similar to that observed in patients  $\geq 2$  years of age in types of AEs observed, with the exception of a higher incidence of serious hypersensitivity events.

Comparison of trough and peak concentrations from two studies in patients with sJIA dosed with IV TCZ (WA18221 in patients aged 2-17 years and NP25737 in patients aged <2 years).

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Juvenile Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Background/Purpose:** Our objective was to assess the efficacy of tocilizumab (TCZ) at short and long term follow-up for severe juvenile idiopathic arthritis-associated uveitis.

**Methods:** A Multicentre study of 25 patients who had inadequate response or intolerance to traditional treatment with corticosteroids and at least one conventional immunosuppressive drug including biological therapy. The outcome variables were the degree of inflammation of the anterior chamber and vitreous, visual acuity and macular thickness. The results are expressed as mean  $\pm$ SD for normally distributed variables, or as median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.

**Results:** We studied 25 patients (21 women/ 4 men); mean age;  $18.6 \pm 8.3$ . Uveitis was bilateral in 22. JIA subsets were oligoarthritis (n=17), polyarthritis (5), psoriatic (2) and enthesitis-related arthritis (1). Ocular sequelae found at initiation of TCZ included cataracts (13), glaucoma (7), synechiae (10), band keratopathy (12), maculopathy (9), and amblyopia (5). Pattern of uveitis was: anterior (17), panuveitis (4), intermediate (2) and posterior (2). Before TCZ, patients had received corticosteroids, conventional immunosuppressive drugs (Methotrexate (MTX) 24) and biologic agents, including adalimumab (24), etanercept (8), infliximab (7), abatacept (6), rituximab (2), anakinra (1), and golimumab (1). TCZ dosage regimen was 8 mg/kg IV every 4 weeks (21), every 2 weeks (2), every 8 weeks (1), or 2.9 mg/kg subcutaneously every week (1). It was used in combination with conventional immunosuppressive drugs in 22 patients. All of the outcome variables showed rapid and maintained improvement in all ocular parameters (**TABLE**) after a follow up of one year (n=21), 2 years (n=11), and 3 years (n=5). A reduction in the daily median dose of prednisone from 10 mg [0-15 mg] to 0 mg [0-0 mg] in 3 years, ( $p < 0.05$ ) was observed. After a median follow-up of  $20.5 \pm 11.7$  months in 4 patients, the interval between TCZ doses was increased to 5 weeks (n=2), 6 weeks (1) and 7 weeks (1) because of sustained clinical remission. TCZ had to be withdrawn due to articular inefficiency (1) or articular and ocular inefficiency (1). The main adverse effects were severe autoimmune thrombocytopenia, autoimmune anemia and thrombocytopenia, pneumonia, viral conjunctivitis and bullous impetigo in 1 patient each.

# Conclusion:

TCZ is useful at short and long term follow-up for severe Juvenile Idiopathic Arthritis-associated uveitis. It is possible to optimize the TCZ dose.

## Validation of Biomarkers to Predict Flare in Polyarticular JIA upon Stopping Anti-TNF Therapy

Daniel J Lovell<sup>1</sup>, Sarah Ringold<sup>2</sup> and P. Scott Eastman<sup>3</sup>, <sup>1</sup>PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>2</sup>Seattle Children's Hospital, Seattle, WA, <sup>3</sup>Senior Director, New Product Development, Crescendo Bioscience, South San Francisco, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Juvenile Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** More than 40% of children with polyarticular forms of Juvenile Idiopathic Arthritis (JIA) experience clinical inactive disease on medication (CR). No clinical variable or biomarker has been identified to predict which patients in CR can effectively stop anti-TNF biologic therapy.

**Methods:** In a 16 center, prospective protocol driven clinical trial, 106 JIA pts. (polyarticular RF+/RF- and extended oligoarticular) in CR while on anti-TNF treatment stopped anti-TNF therapy (all other meds remained stable) and were followed prospectively for up to 10 mos. Flare was determined by prespecified criteria. Serum drawn at the time of stopping anti-TNF therapy were analyzed for 12 individual biomarkers included in the multi-biomarker disease activity score (MBDA; Vectra DA) using multiplexed immunoassay methods previously described<sup>1,2</sup>: vascular cell adhesion molecule-1 [VCAM-1], epidermal growth factor [EGF], vascular endothelial growth factor A [VEGF-A], interleukin-6 [IL-6], tumor necrosis factor receptor 1 [TNF-R1], matrix metalloproteinase-1 [MMP-1], matrix metalloproteinase-3 [MMP-3], human cartilage glycoprotein-39 [YKL-40], leptin, resistin, serum amyloid A [SAA], and CRP (1,2). The Vectra DA score (range 1 to 100) was calculated with a validated algorithm. Six additional biomarkers were also assayed: interleukin-8 [IL-8], interleukin-1B [IL-1B], macrophage-derived chemokine [MDC], interleukin-6 receptor [IL-6R], intercellular adhesion molecule 1 [ICAM-1] with a custom multiplex assay (MSD, Bethesda, MD). S100A12 levels were determined as previously described<sup>3,4</sup>. Univariate analysis with students t-test for significance and multivariate discriminant analysis was used to calculate relationship of clinical and biomarker variables with risk for flare.

### Results:

39/106 (37%) of the pts. Flared, mean/median/SEM for time to flare was 212/250/9.8 days. Univariate analysis of correlations with flare/no flare status shown in Table 1. Multivariate discriminant analysis identified a model that includes 7 variables (MMP-3, JIA duration, JIA Dx age, VCAM-1, CR duration, VEGF, and resistin) with an AUC 0.80, correct prediction in 79% of cases, sensitivity 79%, specificity 79%, PPV 91%, NPV 79%.

Table 1.

Metric	p-value
Ln MMP-3	0.014
Ln Disease Duration	0.016
Age Diagnosis	0.037
VCAM-1	0.063
ID duration at baseline (yrs)	0.069
VEGF-A	0.21
Resistin	0.38
MBDA	0.97
IL-6	1.00
Ln S100A12	1.00

### Conclusion:

37% of the pts. flared  $\leq$  10 mos of stopping anti-TNF. The MBDA did not discriminate significantly flare/no flare. A combination of clinical and lab biomarkers predicted not flaring accurately in 79% of cases.

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Juvenile Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

The measurement of the level of disease activity plays a pivotal role in the care of patients with juvenile idiopathic arthritis (JIA). To serve this purpose, the Juvenile Arthritis Disease Activity Score (JADAS) was developed in 2009. More recently, a version excluding the acute phase reactant was tested (cJADAS). Cutoff values for the state of remission, low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) were recently developed for the original JADAS score and for the clinical version. These cutoff values are ideally suited for pursuing tight disease control in a treat-to-target strategy, with treatment escalation if the desired JADAS score is not reached. However, although cutoffs were validated in a large and multinational cohort of patients, they were developed in a dataset of patients from a single pediatric rheumatology center and partly before the advent of the so-called biologic era. Aim of the study is to develop the JADAS and cJADAS cut-off values of remission, LDA, MDA, and HDA for oligoarthritis and RF-negative polyarthritis in a large multinational cohort of JIA patients

**Methods:** The EPidemiology, treatment and Outcome of Childhood Arthritis (EPOCA) study is aimed to obtain information on the frequency of JIA subtypes in different geographic areas, the therapeutic approaches adopted by pediatric rheumatologists practicing in diverse countries or continents, and the disease and health status of children with JIA currently followed worldwide. More than 9,000 patients with JIA from 118 pediatric rheumatology centres in 49 countries were collected so far. For the development of cut-offs,

patients with oligoarthritis and polyarthritis followed in the 20 Centres with the highest frequency of these 2 subtypes were retained. In each centre, the 75<sup>th</sup> centile of JADAS and cJADAS distribution in patients who were subjectively rated by the attending physician as being in remission and LDA, and the 25<sup>th</sup> centile of JADAS and cJADAS in patients rated as in HDA, were calculated. The obtained values at each centre were then averaged to obtain the preliminary cut-offs for each disease activity state.

**Results:** The cutoffs validation cohorts were made of 930 patients with oligoarthritis from 20 pediatric rheumatology Centres and 1.004 patients with RF-neg polyarthritis from 20 pediatric rheumatology Centres. Preliminary cut offs values for each versions of JADAS and cJADAS are presented in table.

	JADAS10	JADAS27	JADAS71	cJADAS10	cJADAS27	cJADAS71
<b>Oligoarthritis</b>						
<b>Remission</b>	1.5	1.5	1.5	1.2	1.2	1.2
<b>LDA</b>	3.9	3.7	3.9	3.4	3.3	3.4
<b>HDA</b>	16.4	16.2	16.4	14.3	14.1	14.3
<b>Polyarthritis</b>						
<b>Remission</b>	2.6	2.6	2.6	2.4	2.3	2.4
<b>LDA</b>	5.1	4.9	5.1	5.1	4.9	5.1
<b>HDA</b>	18.9	18.9	22.7	19.0	20.0	25.3

**Conclusion:** New JADAS and cJADAS tentative cut-offs for remission, LDA, and HDA were calculated. Obtained values will be tested in the validation analysis. The preliminary values are higher than currently available cut-offs.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Juvenile Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Enthesitis-related arthritis (ERA) is a category of juvenile idiopathic arthritis encompassing most cases of juvenile spondyloarthritis. Two different clinical patterns (axial /peripheral) have been recognized, possibly identifying distinct subpopulations. Different pro-inflammatory cytokines linked to Th1 and Th17 T-cell subsets have been implicated in the pathogenesis of ERA. Our objectives were to assess Th1 and Th17 cell subsets in ERA patients and to examine the association between clinical features and Th1 / Th17 cell subsets.

**Methods:** Patients with ERA (ILAR criteria) were included in a cross sectional study. Patients were classified according to their pattern of joint involvement into axial or peripheral as per ASAS<sup>1</sup> criteria. Patients were clinically assessed on the same day blood samples were collected. Recorded features: active joint count (AJ), pain score (0-10), sacroiliac pain (SIP), lumbar pain (LP), lumbar limitation (LL) by Schöber's test, patient wellbeing using a visual analogue scale (VASp, 0-10), disease activity according to the physician (VASphy), JADAS-10, JSpADA (Juvenile Spondyloarthritis Disease Activity index), ESR/CRP, active enthesitis (AE), functional capacity (CHAQ), radiologic sacroiliitis (MRI/X-rays) and therapy with TNF inhibitors (TNFi). Inactive disease was defined as JADAS-10 ≤ 1 and JSpADA =0. Quantification of Th-1 and Th-17 cells was done by flow cytometry in PBMCs stimulated with PMA/IO in the presence of Brefeldin A. Staining with surface and intracellular components defined Th1 and Th17 phenotypes (CD4+ IFN+ and CD4+ IL-17+ respectively). Mann-Whitney U-test and Chi<sup>2</sup> were used as appropriate.

**Results:** 30 patients (90 % M) were included. HLA-B27 was positive in 13 (45%). Median age was 12 years, disease duration was 4 years. Clinical features (medians): AJ 1 (0-16), pain 0 (0-8.5), VASp 0.75 (0-8.5), VASphy 0 (0-8.5), JADAS-10 4.75 (0-25.8), JSpADA 1.75 (0-5.5); LL 4.5 (3-7) cm, ESR 15 (4-95) mm/h; CRP 1.64 (0-57) mg/dl. SIP in 13 (43%), LP in 18 (60%), AE in 1 (3%), CHAQ ≥ 0.5 in 7 (23%), and sacroiliitis in 18(60%) children. All patients fulfilled ASAS criteria: 17 (57%) ASAS-peripheral and 13 (43%) ASAS-axial; 8 patients (27%) met modified New York Criteria for Ankylosing Spondylitis (AS). Twenty (67%) patients were treated with TNFi. Ten (33%) patients showed inactive disease according to JADAS-10 and 6 (20%) according to JSpADA. Th1 cell percentage was 8.5±3.4 (4-17.4), Th17 cell % 0.90±0.44 (0.39-2.34%) in the whole group. Patients with peripheral and axial involvement showed similar Th1 cell percentage: 7.55±2.83 (4.3-14.9) and 10.1± 3.84 (4-17.4) and different Th17 cell percentage: 0.70±0.32 (0.39-1.72) and 1.10±0.44 (0.82-2.34) respectively (p=0,0009). Patients with AS exhibited higher Th17 cell percentage (p=0.01). LP (p=0.0001) and sacroiliitis (p=0.0024) showed significant associations with Th17 cell.

**Conclusion:** ERA patients with axial pattern exhibit peripheral Th17 cell expansion. These findings suggest a pathogenic role for Th17 cells and support the potential use of IL-17 blocking strategies for the treatment of these patients.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects V: Predicting Treatment Response

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

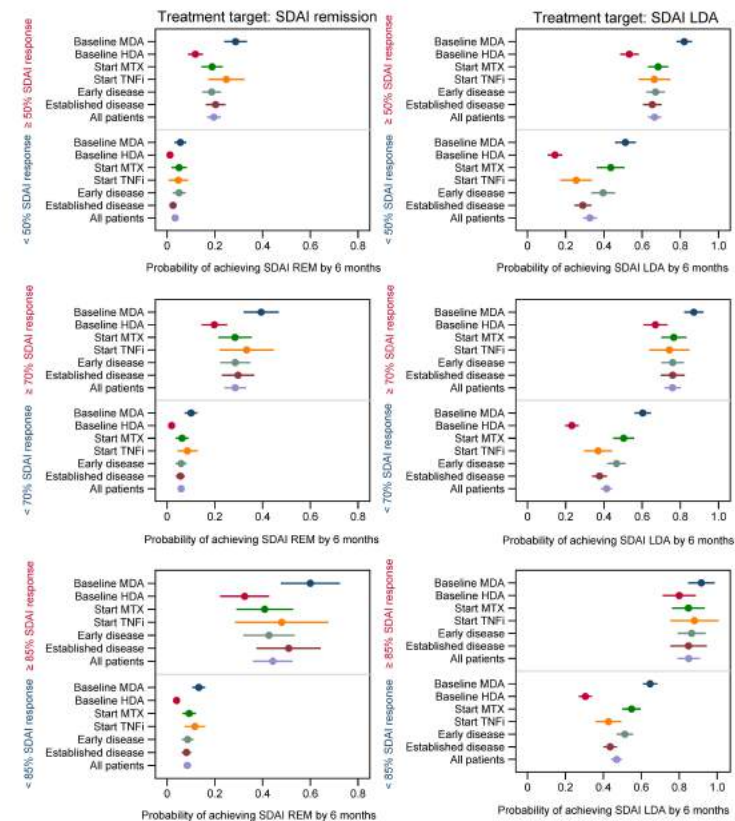

**Background/Purpose :** In a treat-to-target strategy in rheumatoid arthritis (RA) treatment adoptions are recommended in case of poor improvement in disease activity 3 months after initiating therapy with disease modifying anti-rheumatic drugs (DMARDs), or if remission or low disease activity (LDA) has not been reached by 6 months.<sup>1</sup> A pooled analyses from several pivotal RCTs showed that

RA patients who did not achieve a minor treatment response within 3 months were unlikely to reach the treatment target by 6 months.<sup>2</sup> We aimed to investigate which response levels at 3 months are predictive of achieving the treatment targets at 6 months in a routine clinical setting.

**Methods :** Data were provided by NOR-DMARD, a prospective, multicentre, observational study. We selected biological DMARD-naïve RA-patients enrolled in the period 2000-2012, who had at least moderate disease activity according to the Simplified Disease Activity Index (SDAI) when initiating therapy. All analyses were performed for the total group of included patients (n=1610), as well as for the following sub-groups: disease duration more/ less than 12 months (n=895/681), baseline SDAI moderate/ high disease activity (n=825/ 785), DMARD-naïve patients starting methotrexate (n=237) and biological DMARD-naïve patients starting a tumour necrosis factor inhibitor (n=248). We used a diagnostic test approach with receiver operating characteristic curves to explore the association between SDAI 50/70/85 response at 3 months and achievement of the treatment targets of SDAI remission or SDAI LDA at 6 months.

**Results:** At inclusion mean (SD) SDAI was 28.3 (12.8) and median (25-75% percentile) disease duration was 2 (0.2-8.8) years. At 6 months 46.8% of all patients had achieved LDA and 10.8% had reached remission. Not achieving at least 50% SDAI response at 3 months was associated with failing to reach remission, with low negative likelihood ratios (LRs) for all analysed groups (LR- 0.15-0.36). Patients with high disease activity at baseline were likely to fail reaching remission at 6 months if they achieved less than SDAI 70% response at 3 months (LR- 0.25), and to not reach LDA if they achieved less than SDAI 50% response (LR- 0.30). Achieving SDAI 85% response at 3 months was associated with reaching the treatment targets in all analysed groups, with high positive LR for both remission (LR+ 4.77-9.64) and LDA (LR+ 4.56-8.06).

Figure 1: SDAI response at 3 months and probability of achieving the treatment target by 6 months

SDAI, Simplified Disease Activity Index; LDA, low disease activity; MDA, moderate disease activity; HDA, high disease activity; MTX, methotrexate; TNFi, tumour necrosis factor inhibitor; early disease= disease duration ≤12 months; established disease= disease duration >12 months

**Conclusion :** These results from a routine clinical setting confirm results from RCTs demonstrating a predictive association between levels of treatment response at 3 months and achievement of the treatment target after 6 months in RA-patients. Assessments at 3 months can inform clinicians to continue or adjust ongoing DMARD-therapy in a treat-to-target strategy aiming for remission or LDA within 6 months.

## **Diverse Disease Activity Measures Demonstrate That the Routine Assessment of Patient Index Data with 3 Measures (Rapid-3) Assesses Only Non Inflammatory Components of Disease and Should Not be Utilized in a Treat to Target Strategy in Rheumatoid Arthritis**

**Craig Wiesenhuber**, Coeur d'Alene Arthritis Clinic, Coeur D Alene, ID

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects V: Predicting Treatment Response

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

Treating Rheumatoid Arthritis (RA) patients to target (T2T) has been shown to result in better outcomes in patients with RA. Surrogate measures of disease activity help decision making in the clinic. The ACR has published recommendations for use in clinical practice. One of the five recommended measures included the Routine Assessment of Patient Index Data with 3 Measures (Rapid-3).

The Rapid-3 has been a popular choice for such a purpose. It is a patient questionnaire and requires no provider input or lab data. Also validity has been felt to be “good” and moderate correlations are found with more rigorous but time consuming tools, such as the Clinical Disease Activity Score with 28-joint counts (DAS28). However, the concern remains that this tool measures subjective, not inflammatory components of disease activity. The purpose of this paper is to analyze numerous disease activity measures (DAMs) and lab test, including more “objective” diverse DAMs, to determine whether the RAPID-3 measures predominately inflammatory, or subjective non inflammatory components of disease.

### **Methods:**

Patients at a community based rheumatology clinic undergo disease activity measures (DAMs) and many other clinical and lab assessments on a routine basis as part of the implementation of T2T strategy. These assessments include the disease activity score in 28 joints (DAS28), a power Doppler joint count (UPDJC), which is an objective measurement of hyper vascularization of the synovium, and the 12-multipoint disease activity test (MBDA), as well as several other commonly assessed DAMs including the Rapid-3, Health Assessment Questionnaire. (HAQ), etc. The UPDJC includes scoring at six dorsal wrist and six dorsal MCP sites. The average duration of RA in patients at this clinic is > 10 years. Correlations were determined by Pearson’s coefficients, and linear regression models were employed.

#### Conclusion:

Correlations between separate components of numerous disease activity measures including two diverse disease activity measures (UPDJC and Vectra DA 12-biomarker test), laboratory studies including phase reactants, serologies, and interleukins versus the Routine Assessment of Patient Index Data with 3 Measures (Rapid-3) clearly shows a complete lack of association with measures of inflammation.

Correlations with valid disease activity measures, such as the DAS28, are with the subjective components of the measurement, i.e. patient global, and and painful joint count, not with the objective components.

Linear multivariate regression analysis demonstrates that the vast majority of the Rapid-3 measure can be explained by two very subjective components, Patient pain, and the HAQ, neither of which pertain to inflammatory processes.

The Rapid-3 should not be used in a treat to target strategy in the management of rheumatoid arthritis.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects V: Predicting Treatment Response

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Early and targeted treatment strategies have led to increasing numbers of patients with RA achieving sustained clinical remission. If and when to taper Disease Modifying Anti-Rheumatic Drug (DMARD) therapy is an emerging question for both clinicians and patients. Unfortunately, data on clinical, biochemical or imaging modalities that can reliably predict relapse following therapy withdrawal are limited to date. The objectives of our study were two-fold; first to generate unsupervised serum proteomic

profiles using baseline samples from patients with RA in remission. We also aimed to identify serum biomarkers that predict relapse following DMARD withdrawal.

**Methods:** The RETRO (Reducing therapy in Rheumatoid Arthritis Patients in ongoing Remission) study is a multicentre, randomized, prospective trial enrolling RA patients in sustained clinical remission (DAS28 2.6) to undergo DMARD withdrawal. 130 baseline serum samples from the RETRO study were analyzed using SOMAscan (SOMalogic Inc.), allowing the generation of comparative quantitative levels of > 1300 proteins. Unsupervised clustering analysis was performed to identify subgroups of patients. Unique clusters were analyzed with Ingenuity Pathway Analysis (QIAGEN). Differentially expressed proteins between patients who relapsed, and those who remained in remission were combined to synthesize a predictive biomarker scoring algorithm. A multivariate logistic regression model that included seropositive status, current treatment, both disease and remission duration, and the biomarker score was used to analyze predictors of relapse.

**Results:** Unsupervised clustering analysis distinguished 4 unique subpopulations of patients. Compared to the remaining population, Cluster 3 (n = 14) had shorter disease duration (p = 0.012), higher seropositivity rates (p = 0.02) and no use of biologic DMARDs (p = 0.001). Cluster 3 had 145 proteins with significantly (p < 0.05) reduced expression (log2 difference = 0.50 - 1.17) compared to the remaining population. Pathway analysis of these proteins suggested downregulation of Acute Phase Response signaling. Additionally, we created a predictive biomarker withdrawal score (SOMA score; range = 1.5 to 26.0) comprised of 8 unique biomarkers using our data. Patients failing DMARD withdrawal had higher mean SOMA scores compared to those who sustained remission (13.4 vs 8.0, p < 0.001). 83.7% of patients who failed withdrawal had scores greater than a cut off of 9.64, while only 25.6% of those remaining in remission had scores above this cut off. Multivariate regression analysis identified SOMA score as the only independent predictor for relapse after DMARD withdrawal (OR = 15.5, 4.5 - 53.4, p < 0.001).

**Conclusion:** Unsupervised proteomic analysis of RA patients in sustained clinical remission generates distinct clusters of subpopulations. We discovered a unique protein signature in a group of patients who, despite being seropositive, achieved sustained clinical remission without requiring biologic therapy. We constructed a serum protein biomarker score that successfully predicts failure of DMARD withdrawal. Validation of our predictive score will be undertaken to assess its use as a clinical decision-making tool.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects V: Predicting Treatment Response

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Anti-acetylated-peptide antibodies (AAPA) have been found in rheumatoid arthritis (RA) patients and may be additional markers for diagnosis, particularly in rheumatoid factor (RF)/ anti-citrullinated protein antibodies (ACPA) negative patients. Here we investigated whether the presence of AAPA may be useful for prediction of Tumor-Necrosis-Factor-inhibitor (TNFi) treatment response.

**Methods:** RA patients starting their first TNFi treatment were identified and tested for AAPA (by ELISA using two acetylated peptides derived from vimentin), RF (by nephelometry), and ACPA (by ELISA) at baseline. Based on logistic regression analysis, Odds Ratios

(OR) including 95% confidence intervals (95% CI) for association with a 50% response of the Simplified disease activity index (SDAI50) and for reaching SDAI low disease activity (LDA) or remission at 6 months were calculated. We also performed longitudinal analysis by General Estimated Equation analyses (GEE) and Cox-regression.

**Results:** Among the 93 patients starting on a TNFi (85% female, mean disease duration:  $7.7 \pm 7$  years; mean SDAI:  $20 \pm 13$ ), 53% were positive for AAPA, 57% for ACPA and 61% for RF; 35.5% were triple positive, and 7.5% only for AAPA. There was a higher proportion of RF+ and ACPA+ patients in the AAPA+ group.

Presence of AAPA was associated with significantly higher rates of SDAI50 response (44% vs. 18%; OR 3.58 95%CI: 1.1-11.6;  $p=0.034$ ) and LDA (72% vs. 48%; OR: 3.01; 1.05-8.64;  $p=0.041$ ). Analogous analysis for RF or ACPA did not show such association either with achieving SDAI50 (RF: 35% vs. 30%; OR: 1.15; 0.39-3.39;  $p=0.796$ ; ACPA: 38% vs. 25%; OR: 1.66; 0.532-5.21;  $p=0.282$ ) or LDA (RF: 68% vs. 52%; OR: 2.08; 0.74-5.82;  $p=0.163$ ; ACPA: 67% vs. 52%; OR: 2.17; 0.75-6.27;  $p=0.155$ ).

AAPA+ patients showed significantly higher relative changes in SDAI ( $p=0.021$ ), CDAI ( $p=0.025$ ), DAS-ESR ( $p=0.022$ ) and DAS-CRP ( $p=0.014$ ) compared to AAPA- patients. Respective analyses for RF and ACPA were not significant for any of the indices.

Longitudinal analyses of the SDAI in patients on TNFi revealed significant difference in SDAI over time between AAPA+ vs. AAPA- patients ( $p=0.045$ ); again, this was not seen in the analyzes of RF ( $p=0.597$ ) or ACPA ( $p=0.407$ ). Treatment retention was significantly higher for AAPA+ patients (Hazard Ratio, HR: 0.506; 0.310-0.829;  $p=0.007$ ); this effect remained significant after adjustment for RF and ACPA (HR=0.556; 0.327-0.946;  $p=0.03$ ; **Figure**). For RF or ACPA the crude HR were 0.689 (0.420-1.131;  $p=0.141$ ) and 0.613 (0.376-1.000;  $p=0.050$ ), respectively.

**Figure:** Treatment retention of TNFi in RA patients shown for AAPA positive and negative adjusted for RF and ACPA

**Conclusion:** Although validations in other cohorts are warranted for confirmation, in this observational cohort, AAPA positivity appeared to be good discriminator of response to the first TNFi-treatment and associated with more favorable long-term control of disease activity and treatment retention.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects V: Predicting Treatment Response

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Despite the clinical role of synovial histology in the differential diagnosis of arthritis, there are still profound unmet needs regarding predictors for diagnosis, disease progression and response to treatment. Nevertheless, histological examination of the synovium allows for the most robust appraisal of levels of local synovial inflammation.

The most common validated disease activity score is the DAS28, incorporating either CRP or ESR. As CRP is now widely accessible, and is responsive in a more timely manner to changes in systemic inflammatory activity, the DAS28—CRP is widely used today.

It is noteworthy that RA registry data for over 9000 patients has shown that more than half did not have elevation of ESR or CRP, but had ongoing disease activity as determined by joint counts and global assessments (1).

## Methods:

223 consecutive subjects with RA with knee arthralgia underwent arthroscopy. Serum samples were taken and serum CRP levels measured, immediately before the procedure. A macroscopic score of synovitis on a visual analogue scale ranging from 0-100mm was recorded by the operator at arthroscopy. Based on the Haematoxylin and Eosin staining, a tissue inflammatory score for each biopsy was applied by a hospital pathologist with extensive experience examining synovial biopsies (1=normal synovium, 2=mildly inflamed and 3=moderately to severely inflamed).

## Results:

A statistically significant positive correlation was observed between the CRP as well as the DAS28-CRP, and the level of inflammation in the biopsy retrieved (n=197, rho=0.42, CI 0.30 to 0.53, p<0.0001; n=189, rho=0.23, CI 0.09 to 0.36, p=0.0011 respectively) and these results are depicted in figure 1 a and b.

Figure 1

Tissue inflammation scores were available for 75 subjects with a normal CRP (<5mg/l). 49.3% of patients had histological evidence of inflammation in their synovium, despite having normal serum CRP levels, and 10.6% had moderate to severe synovitis as assessed at arthroscopy. Tissue inflammation scores were available for 14 subjects defined as being in clinical remission by DAS28-CRP criteria (<2.6), and 71.4% of these subjects had histological evidence of inflammation in their synovium. Despite being classified as being in remission by these criteria, 21.4% had moderate to severe synovitis at arthroscopy.

## Conclusion:

Better biomarkers are required in RA to accurately appraise CRP. It is conceivable that there are a subset of RA patients where disease cannot be normally monitored by CRP; more work is needed to determine if such patients can be identified at the outset.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Pharmacodynamic Markers and Therapeutic Intervention

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** In RA-BEAM (NCT01710358), baricitinib (BARI), an oral selective inhibitor of Janus kinase (JAK) 1 and JAK 2, yielded significant improvements in patients (pts) with active RA who had an inadequate response to methotrexate compared to placebo (PBO) or adalimumab (ADA).<sup>1</sup> We analyzed molecular pathways modulated by BARI compared with ADA after 4 and 12 weeks (wks) of treatment relative to PBO.

**Methods:** Pts (N=1307) were randomized 3:3:2 (PBO [switched to BARI after 24 wks], BARI 4 mg once daily, ADA 40 mg every other week) for 52 wks. Total RNA extracted from whole blood collected at baseline (BL), wk 4, and wk 12 was analyzed using the GeneChip Human Transcriptome Array 2.0 (Affymetrix). Probeset level data were summarized to a data-driven transcript level and analyzed using a mixed effects model on a log2 transformed response. Multiplicity was adjusted for by testing both within and between transcripts.

**Results:** Pathway analysis revealed that there was little overlap of the immune pathways modulated by both BARI and ADA at wk 4 with no significant overlap by wk 12 (Table). BARI downregulated JAK/Signal Transducer and Activator of Transcription (STAT) signaling pathways, such as those induced by IFNs, IL-6, GM-CSF, IL-5, and IL-3. Expression of interferon responsive genes (IRGs) was downregulated by BARI and upregulated by ADA. BARI reduced IRGs by 75% at wk 4 in pts that had high IFN gene expression at BL. ADA modulated complement pathways. Of interest, STAT transcripts were reduced at wk 4 by BARI (STAT1, 2, 3, 5A, 5B, 6); by wk 12 several STATs (STAT 1, 2, 5A) did not differ from PBO. In addition to different pathways being modulated, there were additional differences noted in the number of genes modulated by each treatment (Figure). Using PBO as standard, BARI modulated more genes than ADA at wks 4 and 12; BARI resulted in more gene modulation at wk 12 than at wk 4, whereas ADA gene modulation was similar

at wks 4 and 12. In addition, both the numbers and types of genes modulated by BARI diverged further from ADA at wk 12 than at wk 4.

**Conclusion:** While BARI and ADA both showed significant benefits compared to PBO in the RA-BEAM trial,<sup>1</sup> gene expression profiling revealed significant differences between treatments. Notably, BARI and ADA modulated JAK/STAT or complement pathways, respectively, and the drugs had opposite effects on interferons. This analysis indicates that different, and possibly complementary mechanisms of action underlie each targeted therapy.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Pharmacodynamic Markers and Therapeutic Intervention

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

About 30-40% of patients with RA do not respond to MTX, the first-line therapy in RA. Early identification of responders may allow the use of alternative DMARDs in patients unlikely to respond, thus preventing long-term damage. CD39, an ectonucleotidase highly expressed on regulatory T cells (Tregs), is responsible for the production of adenosine, an important anti-inflammatory mediator of MTX action. CD39 expression on Tregs improves their suppressive capacity. Therefore, we aimed to study the role of CD39<sup>+</sup> regulatory T cell (CD39<sup>+</sup> Treg) frequency as a biomarker for MTX responsiveness in RA.

### **Methods:**

Patients with active RA (fulfilling 2010 ACR/EULAR classification criteria and having DAS28-CRP >3.2) who were naive to DMARDs were enrolled. Frequency of CD39<sup>+</sup> Tregs (CD39<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup>FoxP3<sup>+</sup> T cells) and CD39<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup> cells was determined by flow cytometry in peripheral blood before start of therapy. After 4 months of treatment with MTX monotherapy (no corticosteroids were given), patients were classified into two groups based on EULAR response criteria: responders (moderate/good response; MTX-R) and non-responders (MTX-NR). All patients who needed rescue therapy after 2 months were classified as non-responders. All patients were genotyped for single nucleotide polymorphism (SNP) rs11188513 in CD39 gene using TaqMan probe method. The data (median and IQR) was analyzed using non-parametric tests.

### **Results:**

Among the 70 patients who completed at least 2 months follow-up (60 females, median age: 39 years and median disease duration: 24 months), 53 patients were RF positive and 57 were anti-CCP positive. The baseline median DAS-28 CRP was 5.15 (4.45-5.89). After 4 months of follow-up, 54 patients were classified as MTX-R and 16 as MTX-NR.

There was no difference in the two groups as regards age, disease duration, disease activity or baseline frequency of Tregs [1.4% (1.0%-2.3%) vs 1.1% (0.7%-1.8%),  $p = \text{NS}$ ]. However, the baseline CD39<sup>+</sup>Treg frequency was significantly higher in the MTX-R compared with the MTX-NR [78.0% (68.3%-87.4%) vs 67.8% (24.7%-84.3%),  $p < 0.05$ ]. At a cut-off of CD39<sup>+</sup> Treg frequency of 75.1%, the positive predictive value (PPV) to identify responders was 86%.

As Foxp3 staining takes time we also saw if the frequency of CD39<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup> T cells could be utilized for prediction of MTX response. The baseline CD39<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup> T cells frequency was also significantly higher in the MTX-R compared with the MTX-NR [43.6% (36.0%-52.7%) vs 32.6% (25.0%-39.7%),  $p < 0.01$ ]. At a cut-off frequency of 41.7%, PPV to identify responders was 91%. MTX treatment did not alter the CD39<sup>+</sup> Treg frequency [75.9% (61.8%-87.0%) vs 67.2% (51.3%-84.0%),  $p = \text{NS}$ ].

CC genotype at SNP rs11188513 of CD39 gene was associated with a significantly lower frequency of both CD39<sup>+</sup> Tregs ( $p < 0.01$ ) as well as CD39<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup> T cells ( $p < 0.01$ ).

#### Conclusion:

Higher frequency of CD39<sup>+</sup> Tregs in the peripheral blood is associated with response to MTX in RA and hence, this should be considered as a potential biomarker for prediction of response to MTX treatment.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Pharmacodynamic Markers and Therapeutic Intervention

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The head-to-head AMPLE study compared the safety and efficacy of abatacept (co-stimulatory modulator) versus adalimumab (TNF $\alpha$  inhibitor) for treatment of RA over 2 years. The objective of this initial analysis was to determine molecular pharmacodynamic (PD) changes in whole blood associated with abatacept and adalimumab treatment; this is the first step toward defining predictive biomarkers of response. **Methods:** RNA was isolated from the whole blood of patients at baseline, Day 85, Year 1, and Year 2, then profiled using Affymetrix U219 GeneChip (628 patients, 2049 total samples). Differential expression between study arms over time was assessed using a linear model with clinical covariates and a multiple testing correction. Single-sample Gene Set Enrichment Analysis (ssGSEA)<sup>1</sup> was used to calculate enrichment for gene modules derived from literature. Transcription profiling of naïve and activated immune cell types was used to generate immune gene signatures as a proxy for cell abundance measurements.<sup>2</sup> **Results:** Differential gene expression analysis revealed many changes that fit with expected mechanisms of action (MoA). Genes that encode proteins associated with T-cell co-stimulation and antibody production were lower in the abatacept arm; genes transcribed in response to pro-inflammatory signals were lower in the adalimumab arm (Table). Some of the most differentially expressed genes have not been previously associated with RA (e.g. PI3/elafin, ALPL, PROK2, GBP5, ZNF683) or are poorly studied. Using immune cell type gene expression signatures as proxies for abundance, we found plasma cells, B cells and natural killer cells were all lower in the abatacept arms by Year 2; conversely, polymorphonuclear leukocytes were higher in the abatacept arm (Figure).

**Conclusion:** This first analysis shows PD differences consistent with the expected MoA of abatacept and adalimumab. Further analysis of this rich time course dataset may reveal predictive biomarkers of response and disease progression, and novel targets for therapeutics.

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Pharmacodynamic Markers and Therapeutic Intervention

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

**Background/Purpose:** Tocilizumab (TCZ) is an anti-IL6R monoclonal antibody approved for the treatment of Rheumatoid Arthritis (RA). There is limited data on synovial tissue histology changes. The aim of this study was to characterize the synovial tissue histological changes after treatment with TCZ and to investigate the effect of treatment on citrullination.

**Methods:** 15 patients with definite RA, according to ACR 1987 criteria, independent of disease duration, who failed treatment with at least one conventional synthetic or biologic disease modifying anti-rheumatic drug (DMARD) were included. Synovial biopsies were obtained before and after 8 weeks of treatment with TCZ from all patients. Clinical evaluation was performed at baseline and at the time of the second synovial biopsy. We evaluated by immunohistochemistry (IHC) expression of citrullinated proteins (CP) and protein arginine deiminase (PAD) enzymes in synovial tissue before and after treatment with TCZ (C03, B09, BVCA1, PAD2, PAD4). Negative controls were used for each antibody. Expression of CD68, CD3 and CD55 was also evaluated. Evaluation of all IHC variables was performed by two blinded independent observers using a semiquantitative score on a 0–3 scale (0, no staining; 1, low amounts of staining; 2, moderate amounts of staining; 3, high amounts of staining). Paired-wised Wilcoxon Signed Ranks Test was used to compare the median value before and after treatment.

**Results:**

The median (IQR) age, disease duration, N. prior biologic DMARDs and DAS28 at baseline was 66 (58-79), 4 (1-13), 1 (0-2), 6 (5-7), respectively. 93% were female, 53% were RF + and 60% ACPA+, 53% had concomitant glucocorticoids and only 27% had concomitant conventional synthetic DMARDs. Significant reductions in DAS28, swollen and tender joint count (SJC and TJC, respectively), and acute phase reactants (ESR and CRP) were observed between baseline and 8 weeks (table 1). By IHC, TCZ induced significant decrease in the number of CD3, C03 and CD55, but not in the number of the other CP, PAD2, PAD4 and CD68 (table 1). No significant correlations between reduction in disease activity (by ΔDAS28, ΔSJC, ΔTJC, ΔESR, ΔCRP) and reduction in CP, CD68 or CD3 were found.

**Conclusion:** IL6R blockade leads to significant decrease in synovial T-cell count. No clear impact on citrullination was observed. Interestingly, no effect on the number of macrophages was found.

	Baseline	12 weeks	Wilcoxon Signed Ranks Test

Session Date: Tuesday, November 7, 2017

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Pharmacodynamic Markers and Therapeutic Intervention

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

**Background/Purpose:** Baricitinib (bari), an oral selective Janus kinase (JAK) 1/2 inhibitor, has been approved in the EU for the treatment of adults with moderately to severely active RA. We compared the *in vitro* cellular pharmacology of bari to upadacitinib (ABT), filgotinib (filgo), and tofacitinib (tofa), three JAK inhibitors (JAKis) currently approved or in clinical development.

**Methods:** Peripheral blood mononuclear cells from healthy donors (n=6-12) were incubated with different JAKis over a 7-point concentration range. Following cytokine stimulation, levels of phosphorylated signal transducer and activator of transcription (pSTAT) were measured and IC<sub>50</sub> calculated in phenotypically gated leukocyte subpopulations. Therapeutic dose relevance of the *in vitro* analysis was assessed using calculated mean concentration-time (CT) profiles over 24 h obtained from JAKi-treated subjects (bari 4 mg QD; ABT 15 & 30 mg QD; filgo 100 & 200 mg QD; tofa 5 & 10 mg BID). Time above IC<sub>50</sub> (T>IC; h/day) and average daily % inhibition of pSTAT formation (%SI) were calculated for each JAKi, cytokine, and cell type.

**Results:** The cytokines tested did not signal in all cell types (Table 1). When signaling was detected, IC<sub>50</sub>, %SI, and T>IC for a particular JAKi were similar across cell types and exhibited dose dependent inhibition (Tables 1 & 2). For JAK1/3 dependent signaling across 4 cytokines (IL-2, 4, 15, 21), IC<sub>50</sub> for ABT and tofa were more potent than bari; filgo was the least potent. Overlaid on CT profiles, these results indicated generally higher %SI and longer T>IC for ABT and tofa compared to bari and filgo. For IL-6 (JAK1/2), %SI and T>IC was tofa > bari/ABT > filgo and for IL-10 (JAK1/TYK2), %SI was tofa > bari/ABT > filgo. IFN-γ (JAK1/2) was modulated by bari, ABT, and tofa, but not by filgo. IFN-α (JAK1/TYK2) signaling was most potently inhibited with bari and ABT, and less with filgo. Filgo did not appear to modulate GM-CSF signaling (JAK2/2), while %SI and T>IC were similar between bari and ABT.

**Conclusion:** JAKis display different *in vitro* pharmacologic profiles which, coupled to their *in vivo* pharmacokinetics, suggest that they modulate distinct cytokine pathways to differing degrees and durations over 24 h. Bari and filgo inhibited JAK1/3 signaling to a lesser extent than ABT and tofa. Consistent across JAKis, no agent potently or continuously inhibited an individual cytokine signaling pathway throughout the dosing interval as assessed by %SI or T>IC, respectively. These observations may have implications for the varying efficacy and safety profiles observed with JAKis across disease states.

## Anti-RA33 (hnRNP-A2/B1) Autoantibodies Are Associated with the Therapeutic Response to Methotrexate and Anti-TNF Treatment in Patients with Rheumatoid Arthritis

Daniela Sieghart<sup>1</sup>, Paul Studenic<sup>1</sup>, Farideh Alasti<sup>2</sup>, Daniel Aletaha<sup>3</sup>, Josef S. Smolen<sup>1</sup> and **Günter Steiner**<sup>2</sup>, <sup>1</sup>Medical University Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria, <sup>2</sup>Rheumatology, Medical University of Vienna, Vienna, Austria, <sup>3</sup>Department of Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Pharmacodynamic Markers and Therapeutic Intervention

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Besides the determination of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA), anti-RA33 antibodies (which are directed to the nuclear antigen hnRNP-A2/B1) could be of additional diagnostic and/or prognostic value in patients with rheumatoid arthritis (RA) because they are also found in RF/ACPA negative patients.

## Methods:

To determine the diagnostic sensitivity and specificity of anti-RA33 subtypes sera from 255 RA patients, 258 disease controls and 100 healthy subjects were tested by a prototype anti-RA33 EliA® (Thermo Fisher Scientific) for the presence of anti-RA33 IgG, IgA and IgM antibodies. ACPA and RF were routinely measured by EliA® and nephelometry, respectively. All RA patients had initially been treated with conventional synthetic drugs (mostly methotrexate, MTX) and were subsequently treated with at least one TNF inhibitor (TNFi). Therapeutic responses to MTX and TNF blocking biologicals were analyzed in an inception cohort (n=104) who had started their DMARD therapy at our clinic. To define therapeutic responses the simplified disease activity index (SDAI) and American College of Rheumatology (ACR) responses were calculated.

## Results:

Diagnostic specificity was >96% for all 3 anti-RA33 subtypes. Among the 255 RA patients, 11% tested positive for anti-RA33 IgG antibodies, 15% for IgM antibodies and 6% for IgA antibodies. Altogether, 62 patients (24%) had at least one type of anti-RA33 antibody: 24 patients were RF-negative, 26 were ACPA-negative and 18 were RF/ACPA double negative. Thus, in 32 patients (13%), anti-RA33 was the only antibody specificity. Regarding response to therapy, the percentage of SDAI50 responders (24%) was significantly lower ( $p=0.0117$ ) in the group of patients testing positive for anti-RA33 antibodies of any isotype (with or without concomitant RF and/or ACPA) than in anti-RA33 negative (but RF/ACPA positive) patients (42% responders) and similar to the group of completely seronegative patients (21% responders). In contrast, regarding responses to MTX the percentage of SDAI50 responders was significantly higher ( $p<0.0001$ ) among anti-RA33 positive patients (with or without cocomitant RF and/or ACPA) (59% responders) compared to anti-RA33 negative (but RF/ACPA positive) patients (37% responders) and seronegative patients (24% responders).

## Conclusion:

Apart from their added diagnostic value anti-RA33 antibodies of any isotype may have also prognostic value for prediction of therapeutic responses to MTX and TNFi treatment. Therefore anti-RA33 antibodies may be taken into consideration as additional diagnostic and prognostic markers that might become helpful tools in therapeutic decision making.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Sjögren's Syndrome II: Pathogenesis, Autoantibodies and T-Cells

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

A hallmark feature of primary Sjögren's syndrome (pSS) is B cell hyperactivity, including presence of autoantibodies, aberrant presence of B cells and plasma cells in the salivary glands, elevated serum IgG levels and increased risk of lymphoma development. The mTOR pathway is essential for cell growth, survival and proliferation of B cells and mTOR inhibition has been shown to be effective in immune B cell suppression in transplant patients and in treatment of B cell lymphomas. Interestingly, in a murine pSS model mTOR targeting inhibited lymphocytic infiltration in the lacrimal gland. However, mTOR activation in B cells has not been studied in pSS patients.

**Methods:** The expression of mTOR pathway related genes (*MTOR*, *RPTOR*, *RICTOR*, *DEPTOR*, *AKT1*, *IGF1R*, *IGF1*, *PTEN*) was measured in purified peripheral blood B cells and monocytes from pSS patients (n=12), non-Sjögren's sicca patients (n=17) and healthy controls (HC, n=9). Gene expression was scrutinized for correlation with clinical parameters (lymphocytic focus scores (LFS), anti-SSA/SSB auto-antibodies, EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI), EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), serum IgG levels, ESR), as well as correlation with B cell subset distribution, utilizing Flow Cytometry. Next, culture experiments were performed to study inhibition of the mTORC1 pathway by rapamycin (phosphorylated S6, kinase activity downstream of mTORC1) and its effect on B cell proliferation and IgG production by mTOR inhibition. Immunofluorescence was performed on pSS salivary gland tissue using colocalizing CD20 and pS6.

**Results:** *RPTOR* and *IGF1R* expression were significantly increased in B cells from pSS patients ( $p=0.019$  and  $p=0.018$ , respectively) and correlate with serum IgG levels ( $r=0.429$ ,  $p=0.020$ , and  $r=0.462$ ,  $p=0.012$ ). We did not observe a significant difference in monocytes. To better gauge the combined upregulation of mTOR related genes, we calculated a combined index statistic to indicate an mTOR signature. This signature was significantly elevated in pSS ( $p=0.027$ ), correlating with serum IgG levels ( $r=0.463$ ,  $p=0.011$ ). Frequencies of memory and naïve B cells did not differ between pSS and HC in this cohort. Activation of B cells in culture resulted in phosphorylation of S6, B cell proliferation and IgG production in both HC and pSS. In the salivary glands of pSS patients immunofluorescent colocalization showed presence of large percentages of B cells with mTORC1 activity (pS6) at the lymphocytic loci. Inhibition of mTOR by rapamycin reduced B cell proliferation ( $80.8\pm9.9$  vs  $19.1\pm15.8\%$ ,  $p<0.001$ ), IgG+ B cells ( $39.5\pm15.5$  vs  $11.1\pm5.7\%$ ,  $p=0.001$ ) and IgG production ( $800.0\pm321.8$  vs  $37.9\pm70.4$  ng/mL,  $p=0.0014$ ).

#### Conclusion:

The increased mTORC1 signature in peripheral and salivary gland B cells from pSS patients correlates with B cell hyperactivity and IgG levels and can be targeted by rapamycin in vitro, representing a novel potential therapeutic strategy for pSS.

#### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Sjögren's Syndrome II: Pathogenesis, Autoantibodies and T-Cells

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Some reports on DNA microarray analysis in labial salivary glands (LSGs) of Sjögren's syndrome (SS) and healthy controls (HCs) showed that the genes associated with mononuclear infiltration were up-regulated in SS. However, since the controls were healthy individuals, it is possible that the results reflected nonspecific gene expression due to inflammatory cell infiltration. The purpose of this study was to examine the genes expressed specifically in LSGs of patients with SS by comparing them with those of patients with IgG4-related disease (IgG4-RD), which also show mononuclear inflammation and to identify the genes involved in the pathogenesis of SS.

#### Methods:

1) Gene expression in LSGs of SS patients (n=5), IgG4-RD patients (n=5) and HCs (n=3) was analyzed by DNA microarray. All patients with SS and IgG4-RD fulfilled the Japanese Ministry of Health criteria for the diagnosis of SS (1999) and the diagnostic criteria for IgG4-RD proposed in 2011 by the All Japan IgG4 team, respectively. After the obtained microarray data were normalized by FARMs algorithm, differentially expressed genes (DEGs) up-regulated in SS were identified in pairwise comparisons with IgG4-RD (false discovery rate<0.05) by rank products method. Approval for this study was obtained from the local ethics committee and a signed informed consent was obtained from each subject.

2) Validation of the results was performed by quantitative PCR (qPCR) using LSGs obtained from other patients with SS (n=15), IgG4-RD (n=12), and HC (n=6) than those examined by DNA microarray.

3) Protein production of the validated gene in LSGs was examined by immunofluorescence (IF) assay.

4) The molecular functions of the validated gene under the pathological condition of SS were examined using peripheral blood CD4<sup>+</sup> T cells in vitro.

## Results:

1) In patients with SS, 1785 up-regulated probe sets (corresponding to 1320 up-regulated genes) were identified as DEGs in comparison with those with IgG4-RD.

2) CXCL9, NR4A2, CD26, SGK1, IRF4 and PDK1 were selected as candidate genes for validation, according to rank<150, high expression levels, small variance and relation to T cell functions. qPCR confirmed up-regulation of NR4A2 in LSGs of SS compared with IgG4-RD.

3) IF staining showed higher production of NR4A2 in nuclei of CD4<sup>+</sup> T cells and IL-17-producing cells in LSGs of SS, compared with IgG4-RD.

4) Overexpression of NR4A2 mRNA was observed in peripheral CD4<sup>+</sup> T cells of SS patients, compared with HCs. The percentage of IL-17-producing peripheral CD4<sup>+</sup> T cells under Th17-polarizing conditions correlated significantly with NR4A2 mRNA expression at baseline. Nuclear NR4A2 expression in Th17-polarized CD4<sup>+</sup> T cells determined by cellular IF was significantly higher in SS than in HC. Importazole, an inhibitor of importin-β, inhibited nuclear transport of NR4A2 and Th17 polarization via suppression of IL-21 expression in naïve CD4<sup>+</sup> T cells under Th17-polarizing conditions, but did not alter RORC expression.

**Conclusion:** NR4A2 seems to promote Th17 polarization via increased expression and intranuclear localization in CD4<sup>+</sup> T cells of SS patients, which could play a critical role in the pathogenesis of SS.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Sjögren's Syndrome II: Pathogenesis, Autoantibodies and T-Cells

**Session Type:** ACR Concurrent Abstract Session

**Background/Purpose:** Primary Sjögren's syndrome (pSS) is an autoimmune and lymphoproliferative systemic disease with B cell hyperactivity and increased risk of non-Hodgkin lymphoma (NHL) evolution. In pSS, the salivary gland (SG) epithelium plays a crucial role in modulating the autoimmune response. Thymic stromal lymphopoietin (TSLP) is an epithelial lymphopoietic cytokine involved in the maintenance of immune tolerance at interfaces with the environment and in regulating lymphocyte homeostasis, acting also as a B cell growth factor. The aim of this study is to investigate TSLP expression in serum and SG biopsies, as well as TSLP function on peripheral blood lymphocytes (PBLs) in pSS patients, stratified according to their lymphoproliferative histopathologic status, from fully benign MALT lesions (fbSS) to myoepithelial sialadenitis (MESA) and to NHL.

**Methods:** Serum TSLP levels were determined by ELISA in 38 pSS patients (13 fbSS, 13 MESA, 12 NHL; all positive for the latest pSS ACR/EULAR Classification Criteria and for anti-SSA antibodies) and 33 controls (20 healthy blood donors, HBDs, and 13 non-autoimmune sicca, nSS). TSLP expression was also studied by RT-PCR and by immunohistochemistry in SG biopsies of all the pSS patients and nSS controls. Immunofluorescence double-staining was performed to characterize TSLP positive cells in SG. Correlations with clinical and histopathologic parameters were investigated. Finally, PBLs from both patients and controls were cultured and stimulated with TSLP and phenotypic changes evaluated by flow cytometry.

**Results:** TSLP serum levels were significantly higher in fbSS compared to nSS ( $p=0.048$ ) and to HBDs ( $p<0.0001$ ). A significant increase in TSLP levels occurred from fbSS to MESA ( $p=0.0015$ ) and to NHL (vs fbSS  $p<0.0001$ ; vs MESA  $p=0.0025$ ), where the increase was dramatic. A positive significant correlation between serum TSLP and ESSDAI was found ( $p<0.0001$ ). By contrast, in SG biopsies TSLP showed a pattern opposite to the serum by immunohistochemistry both in the salivary epithelium and in the whole inflammatory infiltrate: a significant declining staining of TSLP was in fact found from fbSS to MESA and NHL. Strikingly, however, the number of TSLP positive B cells progressively increased with the progression of lymphoproliferation, with the maximum number of TSLP positive B cells being detected in NHL. *In vitro* stimulation assays on cultured pSS PBLs showed a marked TSLP ability to promote proliferation and activation of B cells, and to induce IgG production.

**Conclusion:** A pathogenetic role of TSLP is herein suggested in pSS for the first time. Overall TSLP, which promotes B cell expansion, shows a progressive increase from benign to malignant B cell lymphoproliferation in pSS. The increasing serum levels of TSLP, coupled with the increasing expression by B cells themselves, may support a possible autocrine pathogenetic mechanism. By contrast, the observed decreasing production by the salivary epithelium suggests an insufficient response to regulate B cell expansion. Further studies are definitely worthwhile, including the analysis of TSLP as a biomarker to stratify pSS.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Sjögren's Syndrome II: Pathogenesis, Autoantibodies and T-Cells

**Background/Purpose:** Immunologic heterogeneity in primary Sjogren's syndrome (pSS) poses a challenge when selecting a therapeutic for a given patients or when assembling patient cohorts for research or clinical trials. Heterogeneity in the IFN pathways within pSS is established, but little is known about potential variations in other immune pathways that may influence the disease course or response to treatment. This study characterized and clustered pSS patients by molecular phenotypes.

**Methods:** All pSS patients (n=52) met AECG classification criteria, had at least one systemic manifestation and had stimulated salivary flow of >0.1 mL/min. Patients were assessed for proteomic and genomic markers to enable systems level molecular phenotyping of these patients. Proteomic analysis included 30 serum cytokines, chemokines, soluble receptors which passed stringent quality control measures, and 13 anti-nuclear autoantibodies (anti-dsDNA, chromatin, ribosomal P, Sm, Sm/RNP, RNP, centromere B, Scl-70, and Jo-1) by multiplex, bead-based assay and ELISAs. Correlated gene expression signatures were derived from gene expression microarray data based on the most informative molecular variables by random forest methods.

**Results:** Expression modules identified three distinct clusters of pSS patients. Cluster 1 showed no significantly elevated gene expression signatures in interferon or inflammation and only modest elevations in platelet or erythrocyte expression profiles. Cluster 2 showed the strongest interferon and inflammation signatures. Patients in Cluster 3 had a moderate interferon signature, but with a weak inflammation signature. Anti-Ro and anti-La responses were present in patients in all three clusters. Cluster 2 showed the highest levels of IP-10, MIG, LIGHT, and BLYS, corresponding to the strong interferon and inflammation signatures. Cluster 3, characterized by a weak inflammatory signature and mixed interferon patterns, showed increased IP-10 compared to Cluster 1, and non-significant increases in IL-2RA, IL-1 $\alpha$ , and sEselectin compared to Clusters 1 and 2 (Figure).

**Conclusion:** Molecular profiles encompassing interferon, inflammation, and other molecular signatures can be used to separate patients with pSS into distinct groups. Profiles correlating with treatment effects may be useful for clinical trial design or treatment selection.

## Analysis of Autoantibody Reactivity to the Complete Human Peptidome By Phage Immunoprecipitation Sequencing Does Not Identify a Predominant Novel Autoantibody in Sjogren's Syndrome

Tiezheng Yuan<sup>1</sup>, Michelle Petri<sup>2</sup>, Alan N. Baer<sup>3</sup> and H. Benjamin Larman<sup>1</sup>, <sup>1</sup>Pathology (Immunology), Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Medicine (Rheumatology), Division of Rheumatology, Johns Hopkins University School of Medicine, MD, USA, Baltimore, MD, <sup>3</sup>Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Sjögren's Syndrome II: Pathogenesis, Autoantibodies and T-Cells

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

An unbiased and comprehensive approach to the analysis of Sjögren's syndrome (SS) antibody repertoires would provide important data on its pathogenesis. Phage ImmunoPrecipitation sequencing (PhIP-seq) utilizes next generation DNA sequencing analysis of a phage-displayed human peptidome to characterize the binding specificities of autoantibody repertoires. We utilized PhIP-seq to define the serum autoantibody repertoire in SS, with the goal of revealing novel, shared SS-specific, self-antigens, which are involved in disease pathogenesis.

### **Methods:**

The study cohort consisted of 193 SS patients consecutively evaluated in the Hopkins Sjögren's Center, each with independent anti-Ro60 [immunoprecipitation (IP) using IVTT generated S<sup>35</sup>-Ro60] and anti-Ro52/-SSB (ELISA) antibody testing and positive results in 181 (94%). Control cohorts included 47 SLE patients with positive anti-SSA/SSB serology but without SS (Hopkins Lupus Center) and 301 healthy individuals (United Kingdom repository). Serum from each individual was screened against an overlapping 90-mer human peptidome library using automated PhIP-seq. Peptide enrichments were quantified as number of standard deviations from expected abundance, based on analysis of negative control (no serum) IPs ('z-scores'). For each protein, analyses of the most enriched peptide were used to identify autoantibodies that associate non-randomly among these subsets of SS patients and controls.

### **Results:**

The top SS-associated antibodies were anti-Ro60 and anti-Ro52, the benchmark SS autoantibodies. When analyzed using a z-score cutoff of 10 and compared to conventional assay results, the sensitivity and specificity of PhIP-seq autoantibody detection in the SS cohort was 49% and 88% for anti-Ro60, 84% and 88% for anti-Ro52, and 32% and 99% for anti-SSB. By PhIP-seq, most anti-SSA positive SS patients had either anti-Ro52 alone (40.6%) or both anti-Ro52 and -Ro60 (58.6%), but rarely anti-Ro60 alone (0.8%). In both SS and SLE controls, anti-Ro52 was directed primarily to the 1-90 and 136-205 amino acid epitopes and anti-Ro60 to the 181-270 and 226-295 amino acid epitopes. Using a minimum frequency cut-off of 3% and a SS-association of 3-fold versus lupus and healthy controls, we identified antibodies to 4 autoantigens, including 2 previously discovered SS-associated minor antigens.

### **Conclusion:**

A comprehensive analysis of the antibody repertoire to the complete human peptidome in SS using PhIP-seq did not reveal a predominant novel autoantigen. This technology is limited to detection of antibodies that recognize linear epitopes, and thus may fail to reveal antibodies directed against conformational or post-translationally modified epitopes. In this SS cohort, antibodies to linear Ro60 epitopes were rarely formed in the absence of antibodies targeting linear Ro52 epitopes. The two novel SS-associated autoantigens are undergoing additional validation.

**Session Title:** Sjögren's Syndrome II: Pathogenesis, Autoantibodies and T-Cells

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

## Background/Purpose:

Lymphopenia is a frequent finding in primary Sjögren's syndrome (pSS) affecting mostly the CD4+ T-cell population. Here we examine possible underlying defects in thymic output and premature senescence of CD4+ T-cells.

## Methods:

We included 47 pSS patients and 50 healthy controls (HCs) in a prospective, cross-sectional study. Patients and HCs were separated into two distinct age-groups for analysis of age-dependent differences ( $\leq 48$  years [SS n=10, HC n=26];  $>48$  years [pSS n=37, HC n=24]). Prevalence of T-cell subpopulations was assessed by flow cytometry according to standard surface staining protocols. Naïve CD4+ T-cells were isolated by MACS technology for telomere length and T-cell receptor excision circle (TREC) assessment by real-time PCR. Moreover, telomerase activity was analyzed according to the Telomeric Repeat Amplification Protocols (TRAP).

## Results:

We found lower numbers of CD4+ T-cells in pSS patients compared to age matched healthy controls (560/ $\mu$ l vs. 943/ $\mu$ l,  $p<0.0001$ ). The reduced naïve subset accounted for most of this difference (203/ $\mu$ l vs. 429/ $\mu$ l,  $P=0.0001$ ). Furthermore, the number of TRECs in naïve CD4+ T-cells was already reduced in young pSS patients (58 copies/ng DNA vs. 2058 copies/ng DNA,  $p<0.0001$ ) and was furthermore decreased in older patients (14 copies/ng DNA vs. 117 copies/ng DNA,  $p=0.000$ ) suggesting reduced thymic output or extensive proliferative history. To test for a proliferative history we performed telomere length as well as telomerase activity analysis. Young patients displayed significantly shortened telomeres compared to age-matched controls (6.5kbp vs. 7.0kbp,  $p=0.011$ ) while telomeres of old patients were not significantly different from age-matched controls. In healthy individuals shorter telomeres resulted in an elevation of telomerase activity, a finding that we could not observe in pSS patients.

## Conclusion:

Our data indicate an extensive replicative history of naïve CD4+ T-cells in pSS resulting in premature shortening of telomeres. In contrast to HC, naïve CD4+ T-cells in pSS are unable to induce telomerase activity. This may lead to the reduction of the naïve CD4+ T-cell pool resulting in CD4+ T-cell lymphopenia.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment IV

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Evaluate efficacy and safety of guselkumab (GUS) in patients (pts) with active psoriatic arthritis (PsA) over 56 weeks (wks).

**Methods:** Pts w/active PsA (defined as  $\geq 3$  tender &  $\geq 3$  swollen joints, C-reactive protein  $\geq 3$  mg/L) and  $\geq 3\%$  body surface area (BSA) of plaque psoriasis despite current or previous treatment w/standard-of-care therapies, including previous TNF inhibitor therapy, were eligible to participate and were randomized 2:1 to receive GUS 100 mg subcutaneously or placebo (PBO) at wk 0, 4, and every 8 wks thereafter through wk44. At wk16, pts from either group with  $<5\%$  improvement from baseline in both swollen and tender joint counts were eligible for early escape (EE) to open-label ustekinumab. All remaining PBO pts crossed-over to receive GUS 100 mg at wks24, 28, 36, and 44. At wk56, a post-treatment follow-up visit was conducted. Efficacy post wk24 through wk44 and wk56 was evaluated in pts who did not EE and continued treatment at wk24 (post wk24 efficacy analysis set) based on observed data. The wk24 data in this population were included as a reference.

**Results:** 149 pts were randomized to receive study agent (PBO: 49, GUS: 100). The study met its primary and all secondary endpoints through wk24. At wk24, 29 pts in the PBO group crossed over to receive GUS, of which 28 completed treatment through wk44. 86 pts in the GUS group continued treatment at wk24 and 84 pts completed treatment through wk44. Post wk24, ACR 20/50/70 and PASI 75/90/100 responses improved in PBO to GUS crossover pts and were well-maintained in GUS pts through wk44 (last efficacy assessments while on drug) and wk56 (final follow-up visit) (Table). The efficacy results from wk24 through wk44 and wk56 are summarized in Table.

Through wk56, 17.2% of PBO→GUS, 46.0% of GUS, and 39.5% of the combined GUS pts had  $\geq 1$  AEs, of which infections and infestations were the most commonly reported (3.4%, 27.0%, and 21.7%, respectively). Post wk24, there was no disproportional increase in overall AE frequency, or infections and infestations among GUS pts with longer exposure. Through wk56, among 129 pts who received GUS, there was 1 pt with malignancy (basal cell carcinoma), 1 pt with 2 serious infections (both pneumonia), 6 pts reported  $\geq 1$  SAEs (myocardial infarction, osteoarthritis, pupils unequal, radius fracture, pneumonia, ulcerative keratitis), 2 pts discontinued treatment due to AEs, 1 pt had neutropenia meeting NCI-CTCAE toxicity grade 3, and 6 pts were positive for antibodies to GUS. No deaths occurred through wk56.

**Conclusion:** In pts with active PsA and  $\geq 3\%$  BSA of psoriasis, GUS demonstrated substantial benefits on joint symptoms, physical function, psoriasis, enthesitis, dactylitis, and quality of life, and efficacy was well-maintained through wk56. GUS was well-tolerated with no unexpected safety findings in this population after ~1 year of exposure.

Table. Efficacy Results from Wk24 through Wk44 and Wk56 in Post Wk24 Efficacy Analysis Set Based on the Observed Data

## Switching from Adalimumab to Chs-1420: A Randomized, Double-Blind Global Clinical Trial in Patients with Psoriasis and Psoriatic Arthritis

Jennifer Hodge, Hong Tang, Paula O'Connor and **Barbara Finck**, Coherus BioSciences, Inc., Redwood City, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment IV

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** CHS-1420 is a proposed biosimilar to adalimumab. A phase 3, randomized, double-blind, multicenter study evaluated the equivalence of CHS-1420 to adalimumab in patients with moderate-severe plaque PsO, including patients with psoriatic arthritis (PsA).

**Methods:** Male and female patients (aged  $\geq 18$  years) were randomized 1:1 to CHS-1420 or adalimumab (80 mg, then 40 mg every other week) for 16 weeks (Treatment Period 1). At Week 16, half the patients receiving adalimumab were switched to CHS-1420, and half continued adalimumab; all patients receiving CHS-1420 continued CHS-1420 for 8 weeks (Treatment Period 2).

**Results:** 545 patients were randomized into the study. A total of 503 patients (92.3%) completed Treatment Period 2, including 250 patients in the CHS-1420/CHS-1420 group, 124 subjects in the switching group, and 129 subjects in the adalimumab/adalimumab group. Equivalence of CHS-1420 to adalimumab was established based on the primary endpoint (PASI75 at Week 12). A PASI75 at Week 24 was achieved by 84.6%, 81.6%, and 88.3% of patients in the CHS-1420/CHS-1420, switching, and adalimumab/adalimumab groups, respectively, demonstrating maintenance of response. No statistically significant difference was found between treatment groups.

For patients with PsA, the median change from baseline in HAQ-DI (ranging from 0-3) at Week 24 was -0.6, -0.4, and -0.8 in the CHS-1420/CHS-1420 group (n=60), switching group (n=30), and adalimumab/adalimumab group (n=26), respectively. The median change from baseline in hs-CRP (mg/L) at Week 24 was -2.8, -2.6, and -2.1 in the CHS-1420/CHS-1420, switching, and adalimumab/adalimumab groups, respectively. No statistically significant differences were found between treatment groups.

Treatment-emergent adverse events (TEAE) were reported in 48.9% and 45% of patients in the CHS-1420 and adalimumab groups, respectively, through Week 16, and in 20.1%, 19.4% and 16.3% of patients in the CHS-1420/CHS-1420, switching, and adalimumab/adalimumab groups, respectively, during Weeks 17-24. Anti-drug antibodies were reported in 90.1% and 93.4 % in the CHS-1420 and adalimumab groups through Week 16, and in 4.0 %, 0.8% and 2.3% in the CHS-1420/CHS-1420, switching, and adalimumab/adalimumab groups during Weeks 17-24.

**Conclusion:** This randomized, double-blind, global clinical trial demonstrated equivalence of CHS-1420 to adalimumab based on the primary endpoint (PASI75 at Week 12). Patients who switched from adalimumab to CHS-1420 at Week 16 had similar efficacy and safety results at Week 24 compared to patients who received only CHS-1420 or adalimumab. Results in patients with PsA were similar across treatment groups.

**Title:** Clinical Evolution of Patients with Inflammatory Back Pain: a Population-Based Longitudinal Cohort Study

**Authors:** Runsheng Wang<sup>1</sup>, Cynthia Crowson<sup>2</sup>, Kerry Wright<sup>2</sup>, Michael Ward<sup>3</sup>

1. Columbia University Medical Center, New York, NY
2. Mayo Clinic, Rochester, MN
3. NIH/NIAMS, Bethesda, MD

**Background/Purpose:** Inflammatory back pain (IBP) is an early manifestation and a key feature of spondyloarthritis (SpA). However the natural history of IBP has not been well defined. Significant differences exist between the prevalence of IBP (3-6%) and prevalence of SpA (0.5-1%), suggesting either that IBP often resolves or is due to conditions other than SpA. The objective of this study was to investigate the long-term outcomes of IBP, and clinical predictors of progression to SpA.

**Methods:** A population-based cohort of patients with incident IBP in 2000-2003 among residents of a geographically defined area was established retrospectively. Using diagnostic codes for back pain on clinic visits, we screened and validated the presence of new-onset IBP among patients age 16 to 35 via manual medical record review. Verified patients either met the Calin, Berlin, or ASAS criteria, or were considered by their treating rheumatologist to have IBP. We collected data on clinical SpA features, HLA-B27 status, inflammatory markers, and imaging, and followed their outcomes until July 2016. Aalen-Johansen methods (a multistate generalization of cumulative incidence with adjustment for competing risks) were used to examine their evolution to one of 3 outcomes: progression to SpA, progression to a non-SpA diagnosis, or resolution of back pain. Recursive partitioning with a time to event outcome was used to identify predictors for progression to SpA.

**Results:** After screening 5304 patients, we identified 124 subjects with new-onset IBP from 2000 to 2003. After a median of 13.2 years of follow up, progression to SpA occurred in 39 patients (Figure). The probability of having SpA at 5, 10, 15 years was 24%, 30%, and 33%, respectively. In almost half of the patients, their IBP resolved during follow up. Progression was seen in 85% of 13 patients with a history of uveitis, and 26% of 111 patients without history of uveitis by 15 years after IBP incidence. Among those without a history of uveitis, progression was seen in 32% of men and 14% of women by 15 years.

**Conclusion:** Less than 1/3 of patients with new-onset IBP progress to SpA over more than a decade of follow up, while many resolve. History of uveitis is the most important predictor for progression.

Figure. Progression from IBP to SpA, non-SpA conditions, back pain resolved, and persistent back pain.

## Pre-Existing Psoriasis Is Predictive for Clinical Relapse after Drug-Free Remission Induced By Therapy with Golimumab in Early Peripheral Spondyloarthritis

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment IV

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The use of new treatment strategies in early stages of spondyloarthritis (SpA) makes it possible to achieve remission or low disease activity in more patients than before. Furthermore, one could speculate that there is a possibility of a “window of opportunity” for drug-free remission in peripheral SpA (pSpA), referring to the existence of a transient time frame in which the disease is more susceptible to treatment leading to better outcomes. The objective is to evaluate drug-free clinical remission after induction therapy with golimumab (GLM) in patients with active pSpA in a very early stage of the disease. To identify patient characteristics predicting sustained remission or occurrence of relapse after drug withdrawal.

**Methods:** CRESPA (Clinical REMission in peripheral SPondyloArthritis) is an ongoing monocentric study of golimumab treatment in pSpA patients. Eligible patients were  $\geq 18$  years and fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for pSpA. All patients had a symptom duration  $< 12$  weeks. Clinical remission was defined as the absence of arthritis, enthesitis and dactylitis on clinical examination. If patients were in clinical remission at two consecutive major visits (at week 12, 24, 36 and 48), treatment was withdrawn. Patients were prospectively followed to assess the rate of sustained drug-free clinical remission and clinical relapse.

**Results:** Patient demographics, baseline characteristics and 24-week results of the placebo-controlled phase have been described previously<sup>1</sup>. 82% (49/60) of patients fulfilled sustained clinical remission criteria. At week 24, 30 patients already fulfilled criteria for sustained remission; at weeks 36 and 48, respectively 11 and 8 patients additionally reached this status. At present, 53% (26/49) of these patients are still in drug-free sustained clinical remission (follow-up between 18 and 58 months). The mean time for clinical relapse upon medication withdrawal was 31 weeks. Pre-existing psoriasis at baseline was predictive for clinical relapse whereas polyarticular disease (SJC $> 5$ ) and psoriasis were not predictive for sustained clinical remission after treatment withdrawal. Fig 1 shows

the percentages of patients that achieved sustained clinical remission, that are still in drug-free remission or experienced clinical relapse after treatment withdrawal for the total group and by subtype SpA.

**Conclusion:** Very early treatment with GLM resulted in sustained clinical remission in more than 80% of patients with pSpA, including PsA. Upon drug withdrawal, more than 50% remain in drug-free remission (with a minimum follow-up of 18 months). Clinical relapse is more often observed in PsA patients. Retreatment with golimumab upon clinical relapse resulted in similar responses.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment IV

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Ankylosing spondylitis (AS) is an immune-mediated inflammatory disorder of spine and sacroiliac joints, which could lead to bony fusion of vertebral joints. TNF-blockers have a high efficacy in treating AS, yet up to 40% of AS patients show poor or even no response to this treatment. We aim to build an approach to predict the response prior to clinical treatment.

**Methods:** Ninety-two AS patients undergoing etanercept treatment were recruited and patients who did not fulfill BASDAI50 or ASAS40 at week 12 after starting treatment were considered poor-responders. The IgG galactosylation (IgG-Gal) ratio was calculated and candidate SNPs in patients treated with etanercept were examined. Machine-learning models and cross-validation were conducted to predict responsiveness.

**Results:** Both IgG-Gal ratio at each drug delivery and differential IgG-Gal ratios between week 0 and weeks 2, 4, 8, 12 showed significant differences between responders and poor-responders (Fig. 1A, B). AUC of the IgG-Gal ratio prediction model was 0.8 after cross-validation, significantly higher than current clinical indices, including CRP, ESR, BASDAI, BASFI and ASDAS. In addition, one *MYOM2* SNP was found significantly associated with drug response (Table 1) ( $p=0.000576$ ). Thus, a three-stage approach consisting of baseline IgG-Gal ratio, differential IgG-Gal ratio in 2 weeks, and the *MYOM2* SNP genotype was conducted as follows (Fig. 2): **Stage I:** The IgG-Gal ratio of all AS patients were evaluated prior to etanercept treatment. Patients whose IgG-Gal ratio values were over 0.8 were predicted to be responders. **Stage II:** The others were examined after one dose of etanercept and repetitive IgG-Gal ratio evaluation was performed at week 2, among which patients whose IgG-Gal ratio value were below -0.1 were predicted to be responders. **Stage III:** The remains were subjected to *MYOM2* SNP genotyping, revealing patients with CT/TT genotype to be poor-responders and patients with CC genotype to be responders.

**Conclusion:** We propose a novel three-stage approach to combine genetic markers and post-translational modifications to predict precisely the response to the TNF blocker (Etanercept) in AS patients with an accuracy of 100% for poor-responders and 98% for responders.

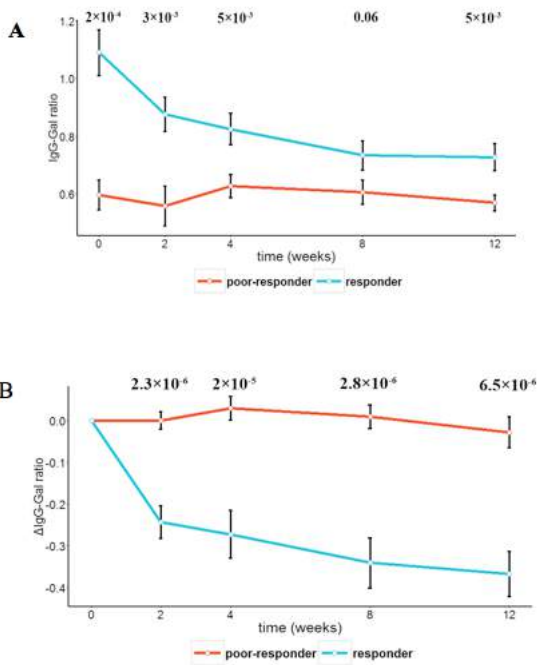

Figure 1. A: IgG-Gal ratio variance during treatment;

B: ΔIgG-Gal ratio change during treatment;

Red line: poor-responders, blue line: responders.

p values between responders and poor-responders of each time point were listed.

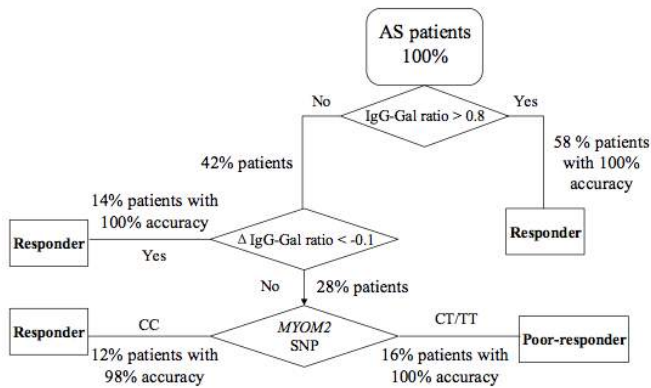

Figure 2. Flowchart of the novel three-stage method in prediction of etanercept patient

response. IgG-Gal ratio: IgG galactosylation ratio, ΔIgG-Gal ratio: The difference of IgG-Gal ratio between weeks 0 and 2.

Table 1. Distribution of a single nuclear polymorphism in *MYOM2* between responders and poor-responders

Genotype	CC (%)	CT (%)	TT (%)	P value
Responder	52 (81.3)	11 (17.2)	1 (1.5)	$5.76 \times 10^{-4}$
Poor-responder	12 (42.9)	15 (53.6)	1 (3.5)	
Allele	C	T	P value	OR (95% CI)
Responder	115	13	$1.10 \times 10^{-3}$	3.82 (1.59-9.42)
Poor-responder	39	17

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment IV

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** SCORE tables underestimate the Cardiovascular Risk (CVR) for patients with Rheumatoid Arthritis (RA) and EULAR recommends multiplying by 1.5 the CVR obtained from them in RA patients [1]. A concern exists that CVR in Psoriatic Arthritis (PsA) might be underestimated [2,3]. Several studies show that the carotid intima-media thickness (CIMT) and the presence of cholesterol plaques (CP) detected with Ultrasound (US) are significantly associated with CVR [4,5]. The objective of this study was to assess the CVR profile in PsA patients using the SCORE/European recommendations, and to study the presence of subclinical CV disease by US techniques.

**Methods:** Transversal descriptive multicenter study of PsA patients followed up in Rheumatology Units. Variables: Age, gender, psoriasis and PsA duration, PsA type and therapy; classic CVR factors (BMI, hypertension, dyslipidaemia, smoking, diabetes); prevalent personal and familiar CV events (coronary, cerebrovascular and thromboembolic events, sudden death). The probability of fatal atherosclerotic CV events over a 10 year period was calculated (Spanish SCORE chart/European recommendations). Then all patients underwent bilateral US carotid study (GE LOGIQ S7 Expert US Equipment). The common CIMT was measured in both common carotids using an automatized lecture of the distal intima-media wall in a surface of 1.39 cm or 300 points, 1 cm caudal to the carotid bulb. Plaques were defined according to the Mannheim consensus [6]. Statistical analysis: Descriptive, univariate and multivariate analyses (ANOVA) were performed.

**Results:** 176 PsA patients from three hospitals were included: mean age 55.2 yo (SD11.8) (50.6% male). Clinical characteristics summarized in Table 1. 62% of the patients had at least one classical CV risk factor. In the US study, a CIMT greater than 0.9 mm or the presence of plaques were found in 55 patients (31.2%). Cardiovascular Risk was upgraded to very high because of the US results in 53 patients (30.1%). Finally, 33.5% of the patients were considered as very high risk. The risk distribution before and after the US study is depicted in Table 2.

**Conclusion:** CV risk factors are frequent among PSA patients. A substantial proportion of patients with PsA are at a very high risk of a fatal CV event. The SCORE/European classification seems to underestimate the CV risk, as 30.1% of the patients were upgraded to a higher risk after the US study.

**Table 1. Clinical characteristics of the PsA patients included**

<b>DISEASE TYPE</b>	Only axial	8 (4.5%)
	Peripheral	168 (95.5%)
	Only peripheral	124 (70.5%)
	Psoriasis duration (months)	222.61

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic sclerosis (SSc) is characterized in part by chronic activation of the innate immune system with fibrosis. Anabasum is a non-immunosuppressive, synthetic, orally administered selective CB2 agonist that activates resolution of innate immune responses in animal models of SSc and healthy humans. This study evaluated safety and efficacy of anabasum in diffuse cutaneous SSc (dcSSc).

**Methods:** A double-blind, randomized placebo (PBO)-controlled 16-week Phase 2 trial (JBT101-SSc-001) enrolled subjects with dcSSc ≤ 6 years duration on stable medications including immunosuppressive drugs. Subjects received anabasum 5 mg QD, 20 mg QD, or 20 mg BID x 4 weeks, then 20 mg BID x 8 weeks, or PBO x 12 weeks. Subjects were followed off study drug x 4 weeks. The primary efficacy outcome was ACR Combined Response Index in diffuse cutaneous Systemic Sclerosis (CRISS).

**Results:** Forty-two subjects received study drug: anabasum N = 27 and PBO N = 15. Baseline patient characteristics were similar in both groups. There were no serious, severe or unexpected adverse events (AEs) related to anabasum. Severity and relationship of AEs to study drug were similar in both groups. AEs in ≥ 10% of anabasum subjects were dizziness and fatigue. Anabasum subjects had greater improvement in ACR CRISS scores than PBO subjects over 16 weeks (Fig. 1, p = 0.044, 1-sided, mixed model repeated measures included baseline mRSS and disease duration). Anabasum subjects had greater improvement and less worsening in individual CRISS core measures including modified Rodnan Skin Score (mRSS), Patient Global Assessment (PtGA), Physician Global Assessment (MDGA), and HAQ-DI (Fig. 2).

Figure 1. CRISS Scores

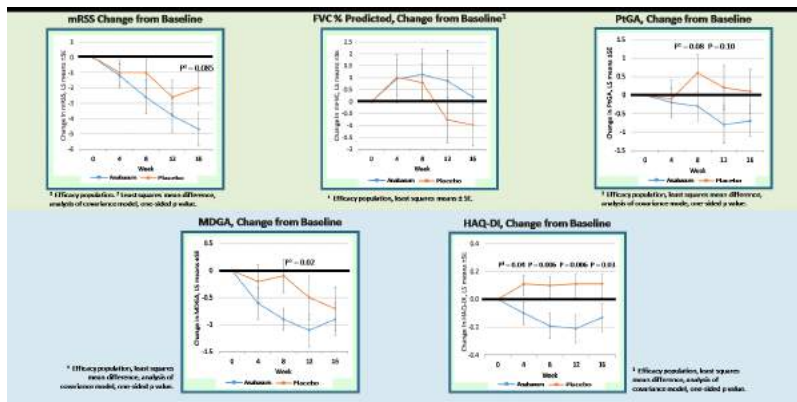

Figure 2. CRIS Core Measures

There were strong correlations of CRIS scores with change from baseline in mRSS ( $r = -0.894$ ,  $p < 0.0001$ ) and MDGA ( $r = -0.591$ ,  $P < 0.0001$ ) with weaker correlations with FVC % predicted ( $r = 0.280$ ,  $P = 0.0006$ ), PtGA ( $r = -0.270$ ,  $P = 0.0008$ ), and HAQ-DI ( $r = -0.294$ ,  $P = 0.0003$ ). Patient-reported outcomes of SSc skin symptoms, itch, and PROMIS-29 physical function, pain interference, and sleep also improved ( $P < 0.05$  for all). Evaluation of gene transcripts in skin biopsies showed anabasum but not placebo reduced expression of key genes implicated in SSc and gene ontology pathways associated with inflammation and fibrosis.

**Conclusion:** Anabasum had acceptable safety and tolerability in this Phase 2 trial in dcSSc and demonstrated consistent evidence of clinical benefit. Changes in gene expression were consistent with biologic effects of anabasum on pathways relevant to SSc. Further evaluation of anabasum in treatment of dcSSc is warranted.

## Tadalafil Reduces Skin Fibrosis and Profibrotic Genes Expression in Patients with Systemic Sclerosis

Sakir Ahmed, Mohit Kumar Rai, Durga Prasanna Misra and Vikas Agarwal, Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

### Background/Purpose:

Currently, drugs that modify skin fibrosis in Systemic Sclerosis (SSc) have efficacy in certain subgroups of patients only. Phosphodiesterase-5 inhibitors (PDE5i) are known to reduce fibrosis in Peyronie's disease and renal fibrosis. We studied the efficacy of Tadalafil, a long acting PDE5i, in reducing the skin fibrosis in SSc.

### Methods:

In this prospective open-labeled study, 24 patients meeting ACR 2013 classification criteria for systemic sclerosis were recruited. Twelve received Tadalafil in addition to standard of care whereas the rest were continued on standard of care. Demographic and clinical details including Modified Rodnan Skin Score (mRSS) were recorded at baseline and at 6 months. Paired forearm skin biopsies of 5mm diameter were taken at baseline and at 6 months. Expression of profibrotic genes COMP, THBS1, SIGLEC1, IFI44, TN-C, COL1A1, COL1A2, ACTA2 and CTGF [Abbreviations in Table 2] in skin biopsies were compared to housekeeping gene GAPDH using real time polymerase chain reaction.

### Results:

Baseline characteristics were similar in both the groups [Table 1]. One patient was lost to follow-up in each group. Amongst patients on Tadalafil, median mRSS decreased from 22 to 13 ( $p=0.005$ ) whereas median mRSS in the other group had a statistically non-significant increase from 15 to 19 ( $p=1$ ) at 6 months [Figure 1].

In the Tadalafil group, there was decrease in the expression of COMP, SIGLEC1, CTGF and IFI44 that was statistically significant (Table 2). In the other group, there was significant increase in the expression of IFI44, THBS1 and TN-C that was absent in the Tadalafil group. Overall change in mRSS ( $\Delta$ mRSS) correlated with change in SIGLEC1, IFI44, THBS1 and COL1A1 (Spearman;  $p<0.05$ ).

### Conclusion:

Tadalafil significantly reduced the skin fibrosis in SSc with down-regulation or prevention of upregulation (or both) in 6 of the 9 profibrotic genes tested.

### SESSION INFORMATION

Session Date: Tuesday, November 7, 2017

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

**Background/Purpose:** Rituximab (RTX), a monoclonal B cell depleting antibody, is one of the few new drugs that has been shown to have beneficial effects on the fibrotic process in patients with systemic sclerosis (SSc). Whether long-time treatment with RTX might lead to hypogammaglobulinemia or lymphopenia that increase the susceptibility to infections in these patients is unknown. The purpose of this observational study was to analyse the levels of IgG and IgM as well as the number of lymphocytes and the frequency of serious infections in our cohort of SSc patients.

**Methods:** SSc patients (n=24; 18 female) with signs of alveolitis in the CT scan were started on a continuous intensified RTX treatment (500mg within 2 weeks every 3 months). The serum levels of IgG, IgM and the total lymphocyte counts were determined before the first RTX application and before the last RTX cycle within this year. Mean duration (95%CI) of RTX therapy was 40 months (30-50). Serious infections were evaluated by analyzing the medical records for hospitalisation because of infections. In addition, the European Scleroderma Study Group (EScSG) activity index as well as the modified Rodnan skin score (mRSS) and the diffusing capacity for carbon monoxide (DLCO) were used to estimate the therapeutic efficacy of RTX.

**Results:** The EScSG activity index decreased significantly ( $p<0.0001$ ), with a mean ( $\pm$ SE) of 3.5 ( $\pm$ 0.3) at baseline and 0.4 ( $\pm$ 0.1) after the last RTX cycle. In addition, the mean ( $\pm$ SE) mRSS was significantly lower in the last visit ( $8.0 \pm 1.4$ ) compared to baseline value ( $23.9 \pm 2.4$ ;  $p<0.0001$ ). The DLCO (95% CI) value improved from 69.2% (61.4-77.5%) to 72.3% (64.5-80.1%), but did not reach significant levels ( $p=0.1612$ ). The mean number of lymphocytes per  $10^9/L$  ( $\pm$ SE) was not significantly altered during the treatment period ( $p=0.0890$ ) and ranged from  $1.58 \pm 0.12$  at the beginning and  $1.42 \pm 0.1$  after the last cycle (normal range 1.0 to 4.8). The mean IgG and IgM levels  $\pm$ SE decreased significantly from  $12.9g/L \pm 0.4$  and  $1.3g/L \pm 0.1$  to  $10.4 \pm 0.4$  ( $p=0.0002$ ) and  $0.7 \pm 0.1$  ( $p<0.0001$ ), respectively. Interestingly, only 3 patients had IgM levels below the normal range of 0.4g/L. None of our patient had to be admitted to the hospital because of serious infections.

**Conclusion:** The intensified RTX protocol is an effective and safe therapeutic option for SSc patients. In contrast to patients with rheumatoid arthritis, in our SSc patients the total number of lymphocytes was not related to the clinical response to RTX.

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Systemic sclerosis (SSc) comprises diverse clinical phenotypes with variable disease courses. Some SSc patients take miserable and fatal clinical course due to rapid progressive skin sclerosis and organ fibrosis in spite of intensive treatments. Establishment of effective therapy for severe SSc has been awaited. Autologous hematopoietic stem cell transplantation (HSCT) enables the patients to be given enough high dose of cyclophosphamide (CY) to delete autoreactive lymphocytes and lead to normal immune reconstruction. A randomized clinical trial showed HSCT led SSc patients to longer event-free survival than conventional CY therapy, however, HSCT has limited evidence on its feasibility and long-term efficacy for patients with severe SSc.

**Methods:** We conducted a phase II clinical trial approved by the local ethics committee. Patients with SSc diagnosed within the last three years and the following clinical features were included: rapidly progressive diffuse skin sclerosis, refractory digital ulcer, or interstitial lung disease. Patients over 60 years with severe organ failure were excluded. The mobilization regimen comprised

intravenous CY (4 g/m<sup>2</sup>) and recombinant human granulocyte colony-stimulated factor. HSCT was performed after treatment with intravenous CY (200 mg/kg, divided into four days). We used the modified Rodman total thickness skin score (mRTSS) to assess the improvement of skin sclerosis. Good response was defined as more than a 50% decrease in mRTSS from baseline within six months after HSCT. Pulmonary function was also evaluated using spirometry, high resolution CT, and serum KL-6 level.

**Results:** Between 2000 and 2012, 15 patients who met the criteria and signed the informed consent were enrolled in the trial and 14 patients were given HSCT; one was not transplanted because of her mobilization failure. Median follow-up period was 137 months. Eight patients (57%) showed a good response to HSCT in the improvement of skin sclerosis, but skin sclerosis relapsed in two patients and interstitial lung disease progressed in another patient. Five patients (36%) kept a long-term efficacy of HSCT. Four in six patients without a good response to HSCT required additional treatments due to progression of diffuse skin sclerosis or interstitial lung disease. Adverse effects related to HSCT occurred in five patients (36%). Engraftment syndrome developed in two patients and hemophagocytic syndrome in one patient, successfully treated with corticosteroids. Hemorrhagic cystitis associated with Adeno Virus occurred in one patient, leading to irreversible vesicoureteral reflux requiring urinary catheter. Cardiopulmonary arrest due to severe cardiomyopathy occurred in two patients. One patient could be rescued after intensive care including percutaneous cardiopulmonary support and intra-aortic balloon pumping, but another one couldn't.

**Conclusion:** Although HSCT brings the favorable results to some patients with severe SSc, we should carefully consider the selection of the patients for HSCT as the treatment of SSc.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Little is known about systemic sclerosis (SSc)-associated myopathy (SScAM) treatment. Intravenous immunoglobulin (IVIg) are used off-label in SScAM. Herein we aimed to evaluate the use of IVIg in SScAM.

**Methods :** We conducted a retrospective study of patients with SScAM followed between 1993 and 2017 who received IVIg in the department of internal medicine of Cochin University Hospital. All patients fulfilled the ACR/EULAR criteria for SSc. SScAM was

defined as a histologically proven myopathy or the association of myalgia and/or muscle impairment associated with elevation of muscle enzymes or myositic alteration at MRI.

**Results :** Fifty-four patients were included in the study comprising 23 (42.6%) with limited cutaneous SSc and 27 (50%) with diffuse cutaneous SSc. SScAM occurred at a median [interquartile range (IQR)] time of 1 month [0 – 13] after the diagnosis of SSc. Thirty-six patients (66.7%) had muscle impairment, 29 (53.7%) had myalgia and 24 (44.4%) had dysphagia. Fifty-two patients (96.3%) had increased creatine kinase level. An electromyography was performed in 26 patients (48.1%) and was abnormal in 22 patients (84.6%). A MRI was performed in 13 patients (24.1%) and was pathological in 10 patients (76.9%). A muscle biopsy was performed in 52 patients (96.3%) and showed muscle involvement in 50 patients (92.6%), mainly inflammatory infiltrates (65.3% of the biopsies), and necrosis (57.4% of the biopsies). Twenty patients (37%) received IVIg. IVIg was initiated to treat SScAM because of worsening muscle involvement in 18 patients (90.0%) and was given in combination with corticosteroids in all patients. Adverse events (AEs) occurred in 7 patients (38.9%) including serious AEs in 2 patients (10%). After a median follow-up of 9 years [range 61-164], 18 patients (90%) had achieved clinical remission, every patient (100%) had achieved biological remission. When compared to patients who did not receive IVIG, there was no difference in remission rates, modified Rodnan skin score, lung function tests but patients who were treated with IVIg had a statistically significant higher decrease of corticosteroids at 6 and 12 months after treatment initiation (Figure 1).

**Conclusion:** This study shows the benefit of IVIg as adjunctive therapy, with an acceptable tolerance profile, and supports its use, especially as a corticosteroid-sparing agent, in SScAM.

**Figure 1. Corticosteroid sparing after intravenous immunoglobulin infusion in patients with systemic sclerosis-associated myopathy**

Box and whiskers show the minimum to the maximum corticosteroid decreased dose of 20 patients who received IVIG for systemic sclerosis-associated myopathy (SScAM) at 3, 6, 12 months and at the end of the follow-up period (>M12). Controls (n=34) were patients with SScAM who did not receive IVIG. Mann-Whitney test was used for comparisons. \* p-value < 0.05, \*\*\* p-value < 0.001

### SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Current treatments for Raynaud's phenomenon (RP) have limited efficacy, which was mainly demonstrated by physician/patient reported outcomes. Aminaphtone is a vasoactive drug recently suggested to improve RP symptoms and among other mechanism is also able to down-regulate endothelin-1 production by endothelial cells (1-3). The aim of this study was to evaluate the clinical symptoms related to RP and skin blood perfusion changing, during aminaphtone treatment in primary RP (PRP) and secondary RP (SRP) patients, during a six-month follow-up.

**Methods:** Forty-six patients with active RP were enrolled in November 2015 after informed consent (11 PRP, mean age 49±19 SD years, mean RP duration 6±3 years; 35 SRP in systemic sclerosis (SSc) (ACR/EULAR criteria) (mean age 61±17 SD years, mean RP duration 11±9 years). Aminaphtone was administered off label 75 mg twice daily in addition to current treatments (patients were on stable drug regimen from at least two months, and they did not modify it during follow-up). Blood perfusion was measured, in perfusion units (PU), in all patients by Laser speckle contrast analysis (LASCA) (4,5) at the level of fingertips, periungual areas, dorsum and palm of hands and face at baseline (W0), after one (W1), four (W4), twelve (W12) and twenty-four (W24) weeks of treatment. Raynaud condition score (RCS) and both Raynaud's attack frequency and duration were also assessed at the same times. Forty-six patients with RP (9 PRP, mean age 56±12 SD years, mean RP duration 8±4 years; 37 SRP in SSc, mean age 63±11 SD years, mean RP duration 12±10 years) were also enrolled as control group, and evaluated at T0 and T24. Statistical analysis was performed by non parametric tests.

**Results:** A progressive statistically significant decrease of RCS (median at W0, W1, W4, W12, W24 respectively: 7, 6, 4, 4, 4;  $p<0.0001$ ), Raynaud's frequency (median 2, 2, 1, 1, 1 attacks/day;  $p<0.0001$ ) and duration (median: 20, 20, 10, 4, 4 minutes;  $p<0.0001$ ) was observed from W0 to W12. A progressive statistically significant increase of blood perfusion was observed from W0 to W12 in all skin areas (median PU at W0, W1, W4, W12, W24 respectively: fingertips 55, 88, 101, 107, 98; periungual areas 44, 88, 91, 92, 92; dorsum of hands 38, 61, 71, 75, 75; palm of hands 56, 85, 89, 94, 82; face 127, 138, 144, 159, 129;  $p<0.001$  for all areas). No further statistically significant amelioration of either RP symptoms or blood perfusion was observed from W12 to W24. The results were similar for both PRP and SRP patients ( $p=0.4$ ). In the control group no statistically significant changes regarding blood perfusion from W0 to W24 were observed ( $p=0.9$  for all areas).

**Conclusion:** Aminaphtone treatment improves RP-related clinical symptoms and rapidly increases skin blood perfusion, also in SSc patients. A randomized blind clinical trial need to confirm these results.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Health Services Research II: Methods and Technology in Care and Research

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Varicella zoster virus infections (VZV) can be associated with significant morbidity in immunosuppressed hosts. However, methods do not exist to systematically identify which patients with rheumatic diseases are at highest risk for VZV, information critical for implementing preventive strategies such as vaccination or antiviral prophylaxis. Machine learning methods that can combine large amounts of information from across the electronic health record (EHR) are increasingly being explored in healthcare. In this study, we derived and compared machine learning algorithms to classify the development of VZV using health system wide EHR data.

**Methods:** We used data from an EHR with over 800,000 patients from a university-based health system from 2012-2016. We identified incident VZV using a combination of ICD code (B02.xx) and a text string processing algorithm (terms: “zoster” and/or “shingles”). All structured (immunizations, vitals, allergies, medications, laboratories, insurance, encounters, providers, demographics) and unstructured data (i.e. text from clinical notes) from before the VZV event were used. A sample of 201 patients was selected and chart reviewed to validate case status (n=100 cases, 101 controls). We used a supervised approach to identify predictors of VZV and compared performance metrics of 6 machine learning algorithms, including: logistic regression, elastic net, random forests, support vector machine, generalized boosted models, and naïve Bayes. Various datasets were evaluated using information at 1, 3, 6, 12, and 18 months prior to index date with repeated cross-fold validation.

**Results:** Preliminary results indicate that generalized boosted models based on 3 months of data prior to VZV outperformed all other algorithms (AUC 0.85; accuracy 0.80; Kappa 0.60) (Table 1). Random forest models also performed well (AUC 0.81; accuracy 0.72), but had a lower reliability (Kappa =0.44). Logistic regression and naïve Bayes models performed the poorest (AUC 0.58 and 0.50, respectively). Top variables associated with VZV included sociodemographics (age, sex, race), clinical (blood pressure, BMI, medications), and health care utilization (number of encounters).

**Conclusion:** Generalized boosted models outperformed other algorithms in identifying VZV in a large university health system, with algorithms that used 3 months of data prior to infection as having the best performance. Further refinement of algorithms with a larger sample size and incorporating more data will assist in developing a highly accurate classification algorithm for VZV that can be used to inform clinical decision making in real-time. This proof-of-concept study highlights the promise of leveraging all the data available through EHR to flag patients who may be at risk for adverse drug events or medical complications before they occur.

**Table 1. Algorithm performance results using 3 months of electronic medical record data (n=201)**

## Do Certain Dmards Increase Risk of New-Onset Type 2 Diabetes in RA Patients? a Disease Risk Score Analysis Using Administrative Databases

E Alemao, Z Guo and L Burns, Bristol-Myers Squibb, Princeton, NJ

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Health Services Research II: Methods and Technology in Care and Research

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Data on the association between RA and type 2 diabetes mellitus (T2DM) are inconsistent, suggesting RA treatments such as glucocorticoids (GCs) and hydroxychloroquine could impact T2DM risk.<sup>1–3</sup> Recent randomized controlled trials demonstrated that biologic (b)DMARDs such as abatacept (ABA) improve pancreatic beta cell function in T1DM and have a lower risk of T2DM in RA patients (pts) in clinical practice.<sup>4,5</sup> The objective of this analysis was to evaluate the development of T2DM in RA pts treated with ABA, other bDMARDs and conventional (c)DMARDs. **Methods:** Administrative claims data from Optum Clinformatics Data Mart (database A) and QuintilesIMS<sup>TM</sup> PharMetrics Plus (database B) from 2006 to 2016 were used. Study inclusion criteria were: 2 diagnosis codes for RA plus 1 DMARD prescription; aged  $\geq 18$  yrs; and  $\geq 3$  mths baseline (pre-index date) and 3 mths of follow-up (post-index date). Mutually exclusive treatment groups were created based on the first prescription (index date) using hierarchy of ABA, other bDMARD and cDMARD. Also, an RA group without record of DMARD (NoDMARD) was identified. The index date for NoDMARD was first diagnosis date for NoDMARD. Incident T2DM was identified using 1 ICD-9 or ICD-10 diagnosis code for T2DM. Assessment of T2DM risk between treatment groups was based on traditional regression and a disease risk score (DRS) approach. DRS is the probability of developing T2DM estimated using a Cox model with a pre-specified list of 27 covariates. Adjusted incidence rate for T2DM was based on Cox model (stratified by DRS groups categorized into 4 equal groups based on quartile scores) with treatment as independent variable. **Results:** From database A, 105,683 (72.8% female, 58.3 [16.0] yrs) and from database B, 266,842 (73.1% female, mean [SD] age 51.6 [13.3] yrs) RA pts were included. Respectively, 2.9%, 10.4%, 34.8% and 51.8% were prescribed ABA, bDMARD, cDMARD and NoDMARD in database A; and 2.7%, 13.0%, 35.4% and 48.9% in database B. Based on the overall pooled sample size of 372,525 RA pts, the incidence rate per 1000 pt-yrs for new-onset T2DM was 37.8 (95% CI 37.4, 38.1). Pooled hazard ratios (HRs) for T2DM were significantly higher for bDMARDs vs ABA in both DRS-based and regression-based approaches; HRs for cDMARDs were also higher (vs ABA) but were significant only in the regression approach. NoDMARD group (vs ABA) had the highest HRs for incidence of T2DM (Table).

**Conclusion:** We observed a lower incident risk of T2DM in RA pts treated with abatacept (vs risk in pts treated with other bDMARDs and cDMARDs) in two large real-world databases, warranting further comparisons. NoDMARD group should be interpreted with caution as it comprises a heterogeneous pt population.

### SESSION INFORMATION

Session Date: Wednesday, November 8, 2017

Session Title: Health Services Research II: Methods and Technology in Care and Research

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

**Background/Purpose:** SLE patients frequently utilize the ED irrespective of their access to care, which raises concern for inadequate quality of care in the outpatient setting. In the general population, previous studies have shown that most high-utilizers only use the ED frequently for a brief period of time (<12 months), however, a subgroup continue to use the ED persistently over years. We sought to investigate the characteristics and patterns of healthcare resource utilization among SLE patients who persistently frequent the ED in order to identify opportunities to improve outpatient care.

**Methods:** We identified SLE patients who persistently frequented the ED from 2013-2016. Persistent use was defined as having 3 or more ED visits during the 12 months in a calendar year, for at least 2 out of the 4 years, consecutive or non-consecutive, during the study period. Patient demographics, general health status, SLE history, long-term opioid therapy (LOT), encounter specific information and disposition were collected through retrospective electronic health record review. Each ED encounter was categorized into the following groups; SLE-, infection-, pain-related, or other. We used multivariate logistic regression to evaluate patient characteristics associated with each encounter category group. Variables with p-value <0.1 in univariate analysis were included in the multivariate model.

**Results:** Seventy-seven SLE patients having 1143 encounters were identified as persistently frequent ED users. Most were female (91%) and had SLE for longer than 10 years (54%). The mean age was 42 (SD 15), and 69% were African American, 14% were Caucasian, and 17% were Hispanic. All had some form of insurance with 49% having Medicaid as their primary insurance. Approximately one third had diagnosis of depression (31%) and 38% were on LOT. Most were on hydroxychloroquine (77%) and/or an additional disease modifying rheumatic drug (51%). Of all ED encounters, 32% were pain-related (Figure 1), and of these most were either discharged from the ED (69%) or within 48 hours of admission (20%). In multivariate analysis, SLE patients with pain-related encounters accounting for >10% of ED use were more likely to be obese, have more comorbid conditions, and be on LOT (Table 1).

**Conclusion:** Pain is major cause of ED use among SLE patients, and associated with LOT. SLE patients who utilize the ED for pain are more likely to be non-critically ill, as evidenced by frequent discharges from the ED and short stay admissions. Thus, SLE patients who persistently frequent the ED for pain may represent a viable target for interventions to improve outpatient care and care co-ordination.

**Table 1:** Multivariate analysis of factors associated with SLE patient who persistently frequented the ED having pain-related encounters account for more than 10% of total ED utilization

Variables	OR (95% CI)	p-value
Age	1.00 (0.95-1.06)	0.870
Race		
African American	Reference	-
Caucasian	0.25 (0.02-3.09)	0.283
Hispanic	0.02 (0.00-0.17)	<0.001
Area of Deprivation Index	1.05 (0.98-1.12)	0.201
No. of co-morbidities	0.54 (0.33-0.89)	0.015
Long-term opioid therapy	7.50 (1.19-47.43)	0.032
Body Mass Index	1.12 (1.01-1.24)	0.034
Additional DMARD	2.55 (0.50-12.97)	0.258

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Health Services Research II: Methods and Technology in Care and Research

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** The Veterans Affairs (VA) Rheumatoid Arthritis (RA) (VARA) registry is an observational cohort study at 12 VA medical centers that prospectively collects clinical and laboratory outcome measures, which are recorded in the VARA database. To replace manual entry and reduce missing data, a Natural Language Processing (NLP) system was developed to extract outcome measures recorded in standardized text templates embedded in the electronic health record (EHR) notes for US Veterans enrolled in the registry. This study compared pre- and post-implementation experiences with this system.

**Methods:** VARA database entries for follow-up observations between January 1, 2016 and April 30, 2016 (pre-implementation) were compared to similar entries after NLP implementation January 1, 2017 to April 30, 2017 (post-implementation) with the number of notes containing outcome measures reported. Laboratory measure were automatically collected from EHR reports. At six VARA sites, missing data reports were provided to VARA investigators and clinic notes were reviewed to determine if outcome measures could be retrieved from documentation outside the standardized template. Note addendums were then entered to provide additional data when available.

**Results:** In comparison to 640 notes on 540 patients from 8 VARA sites in the pre-implementation period, 798 notes on 671 unique patients were recorded in the VARA database from 11 VARA sites during the post-implementation period. This represents an increase of 24.7%, 24.3%, and 37.5% in the number of notes, unique patients captured, and sites engaged, respectively. This increase in data capture was much larger than the 8.3% increase in VARA patient enrollment during the same period. The successful capture of specific outcome measures is listed in the Table, which shows an absolute increase in all elements between observation periods. In a pilot effort to do data corrections at six VARA test sites, missing data on 31 notes were evaluated to see if corrections were possible. Investigators were able to retrieve additional information for 10 (32%) notes from data outside the standard template and use note addendums to report these data. An automated NLP extraction was then employed to add this additional information to the database. Permanently missing data were universally due to the failure to document information at the point-of-care, as opposed to failure of the algorithm.

**Conclusion:** This study demonstrates that NLP can be leveraged in conjunction with standardized EHR templates to successfully retrieve patient data from across a national health care system, eliminate the need for manual data entry, and substantially increase the rate of data capture. By facilitating the collection of clinical and laboratory measures in RA patients, these efforts will further enhance the feasibility of conducting epidemiologic and outcomes studies of RA.

Notes with RA Clinical and Laboratory Measures Successfully Captured in VARA Database: Pre and Post Implementation of Natural Language Processing Data Extraction N (%)			
	Pre-implementation* (N = 640)	Post-implementation** (N = 798)	Change after implementation

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Health Services Research II: Methods and Technology in Care and Research

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Rural Veterans with inflammatory arthritis (IA) lack access because of geographic and other barriers. A national shortage of rheumatologists exists, particularly in rural settings, and recent data suggest rural IA patients have poorer outcomes than those in close proximity to large cities and tertiary care. Synchronous Telemedicine (TM) is an emerging care delivery modality which has been employed in a variety of disease settings which holds great promise in relieving some of these disparities. Limited program evaluation of TM in rheumatologic care has been conducted, including examination of specialty-specific and patient centered outcomes, quality of care, patient satisfaction, or cost-effectiveness longitudinally for care delivered in this fashion.

**Methods:** Veterans with IA (including crystalline, rheumatoid arthritis (RA), and spondyloarthritis) in a widely disbursed VA health care system were enrolled in periodic TM follow-up. Data were collected longitudinally before and after entering the program, including patient-centered outcomes (e.g. RAPID3), and select patient satisfaction instruments adapted from the Survey of Health Experience for Patients (SHEP). Demographics were recorded. Similar data were collected on a convenience sample of concurrent IA patients enrolled in usual care (UC) clinics. Descriptive statistics, linear regression, and t-tests were performed.

**Results:** 60 patients were observed, including 19 in an initial TM cohort, and 41 UC patients. Mean age was 64.2, 90% were male, and 70% carried a clinical diagnosis of RA. No differences in these demographics were noted between groups. RAPID3 scores did not vary between TM and UC groups at baseline, with mean scores of approximately 11 (moderately active). Multiple SHEP instrument scores varied between groups initially (e.g. 8.3 vs 5.7 on a 1-10 Likert scale,  $p < 0.01$ ) and the TM cohort initially travelled greater distance (459.4mi vs 86.9mi,  $p < 0.01$ ) and spent more money (\$157.72 vs \$40.27,  $p < 0.01$ ) per visit than UC patients. Multivariate regression analyses suggest SHEP scores were predicted by disease activity status ( $\beta = -0.10$ ,  $p = 0.04$ ) only when also accounting for additional patient-centered factors including cost ( $\beta = 0.01$ ,  $p < 0.01$ ) and distance ( $\beta = -0.01$ ,  $p < 0.01$ ). In longitudinal follow-up via TM, SHEP instrument scores improved significantly among TM patients ( $\beta = 3.54$ ,  $p < 0.01$ ). Distance travelled (-454.4mi/visit,  $p < 0.01$ ) and costs (\$-134.78/visit,  $p < 0.01$ ) were also significantly reduced in this group, with no significant changes in RAPID3 observed.

**Conclusion:** Synchronous TM may be a viable alternative to routine follow-up for IA care in rural settings and represents a radical change towards patient-centered care paradigms. Long-term follow-up and additional study including outcomes validation in TM care in rheumatology are warranted.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Health Services Research II: Methods and Technology in Care and Research

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:**

Juvenile dermatomyositis (JDM) is a rare autoimmune disease that causes significant morbidity and quality of life impairment. Little is known about JDM inpatient burden in the US. This study analyzes the prevalence and predictors of hospitalization, length of stay (LOS), and cost of care in US patients with JDM.

**Methods:**

Data on 14,401,668 pediatric hospitalizations from the 2002-2012 Nationwide Inpatient Sample (NIS), a 20% stratified sample of all acute-care hospitalizations in the US was analyzed. Previously validated ICD-9-CM codes were used to identify hospitalizations with a primary (i.e. condition chiefly responsible for inpatient admission) vs. secondary diagnosis of JDM. The control group included all hospitalizations without any diagnosis of JDM. Survey logistic regression models evaluated predictors of hospitalization for JDM. Adjusted ORs were obtained via multivariate regression including age, sex, race/ethnicity, season, insurance, number of chronic conditions, and hospital location. Linear regression models with log transformed cost of care or LOS evaluated predictors of cost of hospitalization and LOS using the aforementioned covariates.

**Results:**

There were 909 and 495 weighted admissions with a primary or secondary diagnosis of JDM, respectively. In multivariable analysis, older age, female sex, non-winter season, metropolitan area and Western geographic region, and other types of financial coverage aside from Medicaid and private insurance (i.e. Children’s Health Insurance Program (CHIP), other federal/state/local government programs) were all associated with higher rates of hospitalization for JDM (Table 1). The weighted total LOS and inflation-adjusted cost of care for patients with a primary diagnosis of JDM was 19,159 days and \$49,339,995 with geometric means [95% CI] of 2.50 [2.27-2.76] days and \$7,350 [\$6,228-\$8,674]. LOS in secondary JDM and cost in primary and secondary JDM were significantly higher compared to no JDM. Hispanic and other non-white race/ethnicity were associated with increased LOS (log-linear regression; adjusted beta [95% confidence interval]) (Hispanic: 0.28 [0.14-0.41]; other non-white: 0.59 [0.31-0.86]). Hispanic patients had higher cost of care (0.30 [0.05-0.55]) (Table 2).

**Conclusion:**

JDM adds to inpatient burden in the US, especially via increased LOS and cost of care. Rates of hospitalization for JDM differed by age, gender, season, form of financial coverage, and geography/region, while Hispanic patients had increased LOS and cost of care.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Metabolic and Crystal Arthropathies II: Mechanisms of Crystal Inflammation and Metabolism

**Session Type:** ACR Concurrent Abstract Session

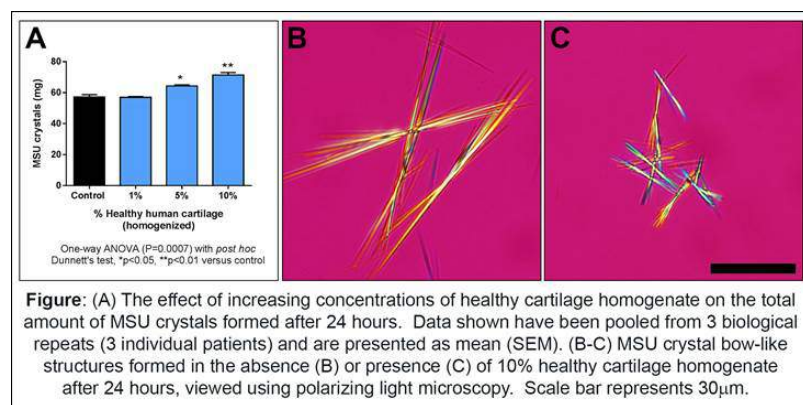

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Monosodium urate (MSU) crystal deposition and gout flares frequently affect joints that have been damaged or are affected by osteoarthritis. The aim of this study was to examine the effects of healthy, osteoarthritic and degraded human cartilage on the three key steps of MSU crystallization; reduced urate solubility, crystal nucleation (appearance of MSU crystals), and crystal growth.

**Methods:** Paired macroscopically-healthy and macroscopically-diseased knee cartilage samples were obtained from patients undergoing orthopedic surgery. Cartilage was homogenized using the FreezerMill 6870 (SPEX CertiPrep Ltd) and the resulting powder dispersed in sterile water for preparation of cartilage homogenates. In crystallization assays, cartilage homogenates were added to solutions of sodium urate at 37°C and pH adjusted to 8.9. The cartilage-urate solutions were sampled over 24 hours for assessment of urate concentration (Cobas c311 autoanalyser, Roche Diagnostics), and crystal growth and morphology (by polarizing microscopy and ImageJ software). After 24 hours, total MSU crystal weight was determined. In separate assays, time to nucleation was determined by polarizing microscopy. The following cartilage preparations were tested: 1%, 5% and 10% healthy homogenized cartilage; 5% healthy and 5% diseased homogenized cartilage; and 5% healthy homogenized cartilage and 5% healthy enzyme-degraded cartilage.

**Results:** The addition of 5% and 10% healthy cartilage homogenates increased the total weight of MSU crystals formed compared to control (no added cartilage) (1-way ANOVA,  $P=0.0007$ , **Figure A**). Addition of healthy cartilage did not change urate solubility or time to nucleation compared to control. MSU crystals grown in the presence of healthy cartilage homogenates were significantly shorter (2-way ANOVA,  $P<0.0001$ ). In morphological analysis, MSU crystal bow-like structures were observed both in the presence and absence of healthy cartilage homogenates, and the bows formed in the presence of healthy cartilage were also significantly shorter compared to control (**Figure B and C**). There were no differences between healthy cartilage and diseased cartilage homogenates in all assessments. For the enzyme-degraded cartilage, the lengths of MSU crystals and MSU crystal bows grown in the presence of degraded cartilage were significantly shorter than those grown in the presence of homogenized cartilage (2-way ANOVA,  $P<0.0001$  for both), with no difference in other measures.

**Conclusion:** In crystallization assays, addition of human cartilage increases the amount of MSU crystals formed and also influences MSU crystal size. These findings may provide an explanation for the clinical presentation of gout in osteoarthritic joints.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Metabolic and Crystal Arthropathies II: Mechanisms of Crystal Inflammation and Metabolism

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### A non-coding genetic variant maximally associated with serum urate levels is functionally linked to HNF4A-dependent PDZK1 expression

**Background/Purpose:** Genome-wide association studies have revealed several dozen genetic variants associated with serum urate levels. These loci are dominated by genes encoding renal and gut uric acid transporters (*SLC2A9*, *ABCG2*, *SLC17A1-4*, *SLC22A11*, *SLC22A12*) and auxiliary molecules such as *PDZK1*. The precise molecular mechanisms by which causal genetic variant(s) affect serum urate are largely unknown, although the majority of influence will be through control of gene expression. Here we functionally link the maximally associated genetic variant (*rs1967017*) at the *PDZK1* locus to elevated *PDZK1* expression via the HNF4A transcription factor, revealing a new mechanism for serum urate control.

**Methods:** We performed expression quantitative trait locus (eQTL) and likelihood analyses (PAINTOR and COLOC) followed by gene expression assays in zebrafish and human cell lines. Zebrafish were used to determine the ability of *rs1967017* to direct tissue-specific gene expression, and luciferase assays in HEK293 and HepG2 cells were used to detect the effect of *rs1967017* on transcription amplitude.

**Results:** PAINTOR analysis revealed *rs1967017* to be the most likely causal variant in the region (*Posterior Prob*=0.93). *Rs1967017* is a cis-acting eQTL for *PDZK1* in the colon and small intestine with a high probability for the association signal with urate levels and the association signal with *PDZK1* to be the same (*COLOC Posterior Prob*=0.93), meaning that *rs1967017* likely influences urate levels through an influence on *PDZK1* expression. The region harboring *rs1967017* was capable of directly driving green fluorescent protein expression in the kidney and intestine of zebrafish embryos, indicating a conserved ability to confer tissue-specific expression. The urate-increasing T-allele of *rs1967017* introduces a binding site for the transcription factor HNF4A. siRNA depletion of HNF4A reduced endogenous *PDZK1* expression in HepG2 cells. Luciferase assays showed that the T-allele of *rs1967017* gains enhancer activity relative to the C-allele, with T-allele enhancer activity abrogated by HNF4A depletion (Figure).

**Conclusion:** Our data predict that the urate-raising T-allele of *rs1967017* enhances HNF4A binding to the *PDZK1* promoter, thereby increasing *PDZK1* expression. Because *PDZK1* is a scaffold protein for uric acid transporters, its increased expression may contribute to reduced excretion of uric acid.

## **New Mouse Model of Gout Risk Variant, ABCG2 Q141K, Reveals Unexpectedly Severe Molecular and Functional Defect in ABCG2 Mediated Intestinal Uric Acid Secretion**

Kazi M. Hoque and **Owen M. Woodward**, Physiology, University of Maryland School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Metabolic and Crystal Arthropathies II: Mechanisms of Crystal Inflammation and Metabolism

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### **Background/Purpose:**

Gout is a common arthritic disease resulting from deposition of monosodium urate crystals in joints and is a consequence of having elevated circulating uric acid (UA) levels (hyperuricemia). Previously, we discovered that *ABCG2* codes a high-capacity UA efflux transporter, that when dysfunctional causes hyperuricemia and significantly increases the risk for gout. Recent work from others has demonstrated ABCG2 mediated secretion is important in extra-renal, specifically, intestinal excretion of UA. Although ABCG2 is thought to be important for both renal and extra-renal UA excretion, in human cohort studies, ABCG2 dysfunction confers a disproportionate risk for the Renal Overload (ROL) type of hyperuricemia (Matsuo et al 2014), a finding highlighting a disconnect in our understanding of the ABCG2 risk alleles and extra-renal UA excretion.

### **Methods:**

To study the molecular and physiological consequences of a common gout causing *ABCG2* mutation on intestinal UA excretion, we created a mouse model of the Q141K mutation (Q140K in mouse) using CRISPR Cas9 gene editing techniques on a C57BL6 mouse background.

### **Results:**

In a comparison of wildtype and mutant litter mates, we found in the wild type mice ABCG2 expression varies along the GI track with the highest levels in the jejunum and ileum, but surprisingly low levels in the colon. These data are consistent with the observed low level of ABCG2 expression in the human colonic Caco-2 cell line. The localization of the wild type ABCG2 protein was exclusive to the brush border of villus cells and luminal membrane of the crypt cells, optimized to facilitate UA secretion into the intestinal lumen. In contrast, both one or two copies of the Q140K *Abcg2* allele resulted in significant decreases (53% and 88% respectively) in total intestinal expression and apical membrane staining in villus cells. Using an intestinal ligation loop model, we tested the acute UA secretion of the small intestines and found the Q140K mutation reduced UA flux 40%. The reduction in the UA flux in the Q140K loop model was comparable to the reduction observed when the wild type ABCG2 loop was treated with the ABCG2 inhibitor FTC (30%), suggesting the Q140K mutation approximates a complete loss of ABCG2 function in the small intestines.

### **Conclusion:**

We conclude that the Q141K gout causing ABCG2 mutation (Q140K mouse) results in severe loss of ABCG2 mediated UA secretion in the small intestine, contrary to the current dogma that the Q141K ABCG2 is a less severe mutation with only partial (50%) loss of function. Our findings illustrate a potential explanation as to why just one copy of the Q141K ABCG2 allele dramatically increases risk of the ROL type of hyperuricemia.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Metabolic and Crystal Arthropathies II: Mechanisms of Crystal Inflammation and Metabolism

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Recent data show that neutrophils are able to release chromatin and granular enzymes in web-like structures called neutrophil extracellular traps (NETs). The release of NETs has a physiological role in the innate immunity response by trapping microbes. However, further data indicate that neutrophils are able to release NETs under different conditions such as in the presence of monosodium urate (MSU) and calcium pyrophosphate dihydrate (CPPD) crystals. In particular, it has been postulated that an increasing release of NETs up to a critic threshold during gout attack may lead to the rapid resolution of the inflammatory phase of the disease by packaging MSU crystals and degrading proinflammatory cytokines. Nowadays, the gold standard for the diagnosis of crystal-induced arthropathies remains the identification of crystals in synovial fluid. Interestingly, at standard wet synovial fluid analysis, besides cells and crystals, clumps of non-refractile fibril-like material are commonly observed. These fibrillar aggregates, primarily composed by fibrin and collagen fibrils, appear as ragged and angulated meshes where crystals remain often trapped, making their identification easier. Since crystals appear concentrated on these networks, we found intriguing to understand whether these clumps of non-refractile fibril-like material may contain NETs.

**Methods:** Synovial fluid samples from MSU and CPPD arthropathies (n=3 for each group) were collected for wet analysis by polarizing, compensated microscopy and then immediately fixed and processed for fluorescence microscopy. Samples were stained on poly-L-lysine-coated glass coverslips with DAPI nucleic acid stain and with anti-neutrophil elastase (NE, rabbit polyclonal) and anti-histone H3 citrullinated antibodies (H3, mouse monoclonal) (Abcam, UK and LS-Bio, US, respectively) in order to visualize NETs' components.

**Results:** The definitive diagnosis of crystal-induced arthropathy was confirmed by the identification of MSU or CPPD crystals in synovial fluid. In addition, fibril-like aggregates trapping crystals and cells were observed in all the samples analyzed. After immunostaining, web-like NET structures containing DNA, NE and H3-histone were visualized by immunofluorescence. NET structures appeared as networks trapping MSU or CPPD crystals.

**Conclusion:** NETs can be visualized in synovial fluid from MSU and CCPD crystal-induced arthropathies. NETs appear as part of the clots of fibril-like material frequently observed in synovial fluid trapping crystals

# Osteoarthritis-Associated Calcium-Containing Crystals and Biomaterial Microparticles Both Drive M1 Macrophage Polarization in a Syk and MAP Kinase-Dependent Manner

Geraldine M. McCarthy<sup>1</sup>, Olwyn Mahon<sup>2</sup>, Sarah O'Hanlon<sup>3</sup>, Daniel Kelly<sup>4</sup> and Aisling Dunne<sup>5</sup>, <sup>1</sup>Div of Rheumatology, Mater Misericordiae University Hospital, Dublin, Ireland, <sup>2</sup>School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland, <sup>3</sup>School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland, <sup>4</sup>Trinity Center for Bioengineering, Trinity College Dublin, Dublin, Ireland, <sup>5</sup>School of Biochemistry and Immunology, Trinity College Dublin, Dublin 2, Ireland

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Metabolic and Crystal Arthropathies II: Mechanisms of Crystal Inflammation and Metabolism

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Intra-articular basic calcium phosphate (BCP) crystals are associated with advanced osteoarthritis (OA) and synovitis. OA-associated synovium exhibits increased numbers of macrophages compared with non-OA joints. Total joint replacements (TJR) are performed for advanced OA but periprosthetic osteolysis remains a complication. The local generation of prosthesis-associated wear particles (WP) over time leads to an inflammatory cascade which culminates in implant loosening. Studies suggest that WP-activated macrophages assume a classically activated M1 inflammatory phenotype that overcomes the M2 macrophage-associated activities required for healing. This in turn contributes to the initiation and progression of peri-implant inflammation. Modulating macrophage cytokine production could be a treatment option for periprosthetic inflammation and also OA synovitis. However, the effect of BCP crystals and hydroxyapatite (a component of BCP crystals and commonly used biomaterial) on macrophage polarization has not been previously reported.

We sought to examine 1) macrophage polarization in response to BCP crystals and 2) the signalling pathways involved in BCP crystal, hydroxyapatite (HA) and polymethyl methacrylate (PMMA) bone cement-induced macrophage polarization in primary human macrophages and to determine whether pharmacological blockade of these pathways can impact on M1 macrophage phenotype and inflammatory gene induction.

**Methods:** Primary human macrophages were stimulated with PMMA (500 µg/ml) or hydroxyapatite particles (250 µg/ml) over the course of 30 minutes. Activated Syk, p38 and ERK were detected by immunoblotting using phospho-specific antibodies. mRNA expression levels of M1 and M2 macrophage markers were analysed by q-PCR 24 hrs post-stimulation while cytokine production was measured by ELISA. Statistical analysis was performed by one way analysis of variance (ANOVA) with Tukey post-test where applicable or student's t test when comparing only two observations.

**Results:** We demonstrate that BCP crystals as well as PMMA and HA particles promote macrophage polarization and pro-inflammatory cytokine production via activation of the membrane proximal kinase, Syk, and members of the mitogen-activated protein kinase (MAPK) family of signaling molecules. Pre-treatment of macrophages with Syk or MAPK inhibitors, not only prevents macrophage polarization, but also attenuates production of key pro-inflammatory mediators implicated in periprosthetic osteolysis (Fig) as well as OA

**Conclusion:** Both BCP crystal and WP-induced macrophage polarization and cytokine production is dependent on activation of specific intracellular signalling molecules. Improved understanding of the biological cascades activated by microparticles could lead to new treatments to modulate OA synovitis as well as aseptic implant loosening.

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Metabolic and Crystal Arthropathies II: Mechanisms of Crystal Inflammation and Metabolism

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Lubricin/proteoglycan-4 (PRG4) is a mucinous glycoprotein secreted by synovial fibroblast and superficial zone chondrocytes. PRG4 has a multifaceted homeostatic role in the joint including boundary lubrication, friction lowering of apposed cartilage surfaces and prevention of synovial overgrowth. PRG4 is abundant in the synovial fluid (SF) and its levels are reduced in SF from patients with inflammatory arthropathies. Therapeutically, the recombinant and native form of PRG4 has been shown to exhibit a disease-modifying effect in pre-clinical osteoarthritis (OA) models. Recent studies have suggested that PRG4 may have anti-inflammatory properties in MSU-crystal induced arthritis. Inflammasomes are protein platforms linking recognition of danger-associated molecular patterns such as MSU by cytosolic sensory proteins to caspase-1 activation. The objective of this study was to further evaluate the anti-inflammatory mechanisms of rhPRG4 in the inflammasome in MSU in acute gout inflammation.

**Methods:** We evaluated the impact of recombinant human PRG4(rhPRG4) on MSU-induced release, secretion and expression of interleukin-1 beta (IL-1b), tumor necrosis factor alpha (TNF-a), interleukin-8 (IL-8), by ELISA, immunohistochemistry, and western-blot analysis in MSU-stimulated THP-1 cell. Cytosolic and nuclear levels of nuclear factor kappa B (NFkB) p50 and p65 subunits, Ikb were studied using western blot. We also evaluated the role of rhPRG4 in the expression of the NLRP3 inflammasome components using qPCR, immunohistochemistry and western-blot analysis. Immunoprecipitation experiments were performed to evaluate if rhPRG4 inhibited NALP3 inflammasome assembly by binding to ASC and prevent caspase-1 activation and cytokine release.

**Results:** In THP-1 cell line, rhPRG4 significantly inhibited IL-1b, TNF-a and IL-8 production to MSU-crystals using ELISA, western blot analysis and immunohistochemistry in a dose dependent manner. rhPRG4 inhibited the expression of NALP3, PYCARD, Caspase-1 and IL-18 using immunohistochemistry, western blot analysis and qPCR in a dose dependent manner compared to colchicine. rhPRG4 inhibited nuclear factor kappa B (NFkB) and Ikb. Considering the activation of the NALP3 inflammasome requires oligomerization of the proteins NALP3, ASC and procaspase, we explored changes in the association of these proteins in response to rhPRG4 in MSU-stimulated THP-1 cells. After immunoprecipitation of ACS, there was a decrease in association of NALP3, activated (cleaved) caspase-1 in rhPRG4 treated THP-1 cells exposed to MSU-crystals.

### **Conclusion:**

Our findings advance our understanding of the complex anti-inflammatory mechanisms of PRG4 in joint homeostasis. rhPRG4 retards the progression MSU-crystal induced inflammatory arthritis by inhibiting the expression and assembly of the NALP3 inflammasome. Our findings provide a better understanding of the molecular mechanism(s) of PRG4 in MSU-crystal induced arthritis with important implications in the development of novel biological strategies in gout.

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Immune checkpoint inhibitors (ICIs) have emerged as an important treatment for advanced malignancies. ICIs are a form of immunotherapy which block negative co-stimulation of T-cells, thereby causing generalized immune activation. De novo inflammatory arthritis (IA) is a potential consequence of ICI use, but there is limited information to guide management of this often severe immune-related adverse event.

**Methods:** We evaluated clinical data from our longitudinal cohort of patients with ICI-induced IA. Patients with rheumatologist-confirmed IA occurring during or after ICI treatment with no prior history of IA or other systemic autoimmune disease were included. Patients were excluded if they were missing initial joint counts/description of clinical phenotype, or their ICI agent was unknown (e.g. blinded clinical trial). Data was analyzed by ICI treatment regimen to evaluate for differences in presentation and treatment response.

**Results:** Of the 31 patients included, 18 received anti-PD-1 or anti-PD-L1 monotherapy, 13 received anti-CTLA-4/anti-PD-1 combination therapy and none received anti-CTLA-4 monotherapy (table 1). Median age was 59, and 41.9% were female. Melanoma and non-small cell lung cancer were the most common tumors. Eighty-four percent (26/31) required systemic immunosuppression (corticosteroids, DMARDs). The other 5 patients received NSAIDs and intra-articular steroids. Initial joint involvement and CRP differed significantly by treatment regimen; those treated with combination therapy had higher CRP levels and were less likely to have initial small joint involvement. All cases of reactive arthritis (arthritis plus urethritis/conjunctivitis) were in the combination therapy group. Six patients received therapy with TNF-inhibitors (TNF-i), 4 received methotrexate, and 1 received leflunomide. Of those treated with TNFi, 4 had a persistent anti-tumor response to ICIs, and none lost the response while on TNF-inhibition. Duration of treatment with TNFi ranged from 2-21 months. 3-month follow up data was available on 20 patients after cessation of ICIs (7 still on therapy, 4 died/lost to follow up). Of these 18 had continued IA symptoms requiring treatment.

**Conclusion:** Baseline clinical features of ICI-induced IA differ by ICI regimen, specifically CRP levels, initial joints affected, and presence of the reactive arthritis triad. The majority of patients referred to rheumatology required systemic immunosuppression to manage their IA symptoms. Tumor progression was not seen in patients requiring TNFi.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** IgG4-related disease (IgG4-RD) is a systemic disorder characterized by severe fibrosis in lesions. In previous reports, CC-chemokine ligand 18 (CCL18) level is a substantial biomarker for fibrotic diseases such as idiopathic pulmonary fibrosis and systemic sclerosis. However, the possible involvement of CCL18 in fibrotic pathogenesis of IgG4-RD remains unknown. The objective of this study was to investigate association between serum CCL18 levels and clinical and laboratory findings including treatment response in patients with IgG4-RD.

**Methods:** Twenty-eight consecutive treatment-naïve patients with IgG4-RD and 16 healthy volunteers were enrolled. The patients were diagnosed as IgG4-RD according to the 2011 comprehensive IgG4-RD diagnostic criteria. Disease activity of the patients was assessed based on the IgG4-RD responder index (IgG4-RD RI). Serum concentration of CCL18 was measured by using human CCL18/PARC Quantikine ELISA Kit (R&D Systems Inc., Minneapolis, MN, USA). The correlation between serum CCL18 levels and clinical and laboratory parameters were examined by Spearman correlation coefficient.

**Results:** The mean age of patients with IgG4-RD was 59.7 years, and the proportion of female was 50% (14/28). The involved organs of the patients were lacrimal gland and orbits (22 cases, 78.6%), salivary gland (19 cases, 67.9%), lymph node (11 cases, 39.3%), lung (7 cases, 25%), pancreas (7 cases, 25%), kidney (5 cases, 17.9%), retroperitoneum (3 cases, 10.7%), aorta (2 cases, 7.1%), skin (2 cases, 7.1%), breast (1 case, 3.6%) and paravertebral mass (1 case, 3.6%). Serum concentration of CCL18 in patients with IgG4-RD (mean 44.7 ng/mL, range 3.6–120.9 ng/mL) was significantly higher than that of healthy volunteers (mean 18.5 ng/mL, range 0.1–63.8 ng/mL;  $P = 0.01$ ). Of note, serum CCL18 concentrations positively correlated with IgG4-RD RI scores ( $\rho = 0.54$ ,  $P < 0.005$ ), number of affected organs ( $\rho = 0.56$ ,  $P < 0.005$ ), or serum levels of IgG4 ( $\rho = 0.50$ ,  $P < 0.01$ ), but not serum IgE levels ( $\rho = -0.05$ ,  $P = 0.79$ ) or blood eosinophil counts ( $\rho = 0.18$ ,  $P = 0.38$ ), suggesting that serum CCL18 concentrations reflect IgG4-RD state rather than allergic condition. Moreover, serum CCL18 concentrations significantly decreased after glucocorticoid treatment in patients with IgG4-RD (44.7 ng/mL vs. 12.7 ng/mL,  $P < 0.01$ ), which were paralleled with disease improvement.

**Conclusion:** Serum CCL18 concentration is a novel biomarker potentially valuable for evaluating disease activity and treatment response in IgG4-RD. Our results suggest that CCL18 contribute to the fibrotic process in IgG4-RD.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** CS is a life-threatening condition that accounts for 85% of sarcoidosis-related deaths in Japan and 13-25% in America. The objective is to evaluate the effectiveness and tolerance of TNFI treatment in CS.

**Methods:** From a French multicenter cohort of patients with extra-thoracic sarcoidosis, we retrospectively analyzed patients who fulfilled following inclusion criteria 1) a definite histologically proven extra-thoracic sarcoidosis, 2) a CS based on the 2011-Heart Rhythm Society consensus and 3) who received a TNFI. The response to TNFI treatment was analyzed on multiple criteria including (i) cardiac clinical symptoms/signs i.e. New York Heart Association (NYHA) class for dyspnea, heart failure, and cardiac rhythm or conduction disturbances; (ii) NT-pro-BNP and BNP serum levels, and (iii) cardiac imaging abnormalities on echography, scintigraphy, MRI, or 18 FDG PETscan. Patients were classified as complete responders when they showed a complete normalization of all baseline abnormal exams (clinical, biological and imaging). Non responders were defined by the absence of improvement of all baseline abnormal exams or an aggravation of at least one exam. All other cases were defined as partial responders.

**Results:** We analyzed 25 patients, aged 38 years, 36.4% had chest pain/heart failure, and abnormal findings on EKG (73%), cardiac MRI (55%), echocardiography (40%), 18 FDG PETscan (30%) and scintigraphy (10%). 42% had > 4 organs involved by sarcoidosis. Sarcoidosis duration before starting TNFI was 136 months [19; 311]. CS was refractory to other immunosuppressants i.e. methotrexate (n=24/25), cyclophosphamide (n=12/25), azathioprine (n=8/25), and mycophenolate mofetyl (n=6/25). After a follow up of 50.7 months after starting TNFI (infliximab n=24, etanercept n=1), 36% patients were complete responders, 48% partial responders and 16% non-responders. 8% had a CS relapse and were treated by a second course of TNFI with a good response. Corticosteroids were given at baseline in all patients; mean daily dose of steroids was 21 mg [5;50] at baseline versus 10 mg [1;40] at the last visit, and they were stopped in 28%. Eight patients had to withdraw TNFI because of adverse events, i.e. infection (n=5), allergy (n=1), and cardiac arrest (n=2). Two patients died, from a sudden death and an unknown cause (two months after stopping TNFI).

**Conclusion:** TNF alpha inhibitors showed a complete/partial cardiac response in 84% of patients with cardiac sarcoidosis refractory to immunosuppressive therapy, with a steroid sparing-effect. Adverse events led to TNF alpha inhibitors withdrawal in one third of patients.

## TET2 Mutation Is Significantly Associated with the Development of Autoimmune Disorder in Patients with Myelodysplastic Syndrome

Yoon-Jeong Oh<sup>1</sup>, Dong-Yeop Shin<sup>2</sup>, Sang Mee Hwang<sup>3</sup>, Eun Young Lee<sup>4</sup>, Yeong Wook Song<sup>5</sup>, Dong-Soon Lee<sup>3</sup> and Jin Kyun Park<sup>6</sup>,

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Myelodysplastic syndrome (MDS) is characterized by ineffective hematopoiesis in bone marrow and peripheral cytopenia. Various genetic mutations contribute to MDS. Common mutations affect genes regulating epigenetic control, protein translation among others. A recent study demonstrated that certain autoimmune manifestations were associated with specific karyotypic abnormalities in patients with MDS. The aim of this study was to investigate whether particular genetic mutations are associated with the occurrence of autoimmune disorders in MDS.

**Methods:** A total of 88 genetic mutations that are commonly associated with MDS were sequenced in 73 MDS patients. The association of each mutation with autoimmune disease (AID) was analysed.

**Results:** The mean age of MDS patients was 65.1 years, and 49 (67.1%) were male. During the follow-up duration, 19 (26.0%) developed AIDs; 7 (9.6%) thyroiditis, 5 (6.8%) immune thrombocytopenia (ITP) and haemolytic anemia (HA), and 1 (1.4%) rheumatoid arthritis (RA), 1 (1.4%) ankylosing spondylitis (AS), 1 (1.4%) systemic lupus erythematosus (SLE), 1 (1.4%) panniculitis, 1 (1.4%) psoriasis, 1 (1.4%) neutrophilic dermatosis, and 1 (1.4%) uveitis. Baseline demographic and laboratory parameters did not differ between patients with AID.

Of 73 MDS patients, 57 (78.1%) carried mutation at least in 1 of the 88 selected genes. The presence of mutation (73.7% vs. 79.6%,  $p=0.75$ ) and the number of mutations (2.32 vs. 2.04,  $p=0.56$ ) were similar between the patients with or without AID. Strikingly, the TET2 mutation was significantly higher in patients with AID compared to those without AID (26.3% vs. 5.6%,  $p=0.017$ ). Five (62.5%) of 8 MDS patients with TET-2 mutation exhibited AID (RA, AS, ITP, panniculitis, and neutrophilic dermatosis).

**Conclusion:** Mutation of TET2, an epigenetic regulator, might be associated with increased risk of developing autoimmune diseases in patients with MDS.

Table. Baseline characteristics in patients with MDS

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Coccidioidomycosis (Cocci) is a fungal infection endemic to seven states in the US. Biologic response modifiers (BRMs) have been shown to increase the risk of serious infections including fungal infections, but data are limited on the risk of Cocci with BRMs and corticosteroids (CSTs). Our objective was to examine the association between use of DMARDs, BRMs, and CSTs and subsequent risk of Cocci infection among Medicare beneficiaries with rheumatic or autoimmune diseases.

**Methods:** In a retrospective cohort study using 2011-2013 Medicare claims data (5% representative sample), we restricted the analyses to continuously enrolled, fee-for-service beneficiaries who resided in Arizona, California, New Mexico, Nevada, Texas, Utah, and Washington. Among beneficiaries having any of ten rheumatic/autoimmune diseases (i.e., RA, SLE, psoriasis, PsA, AS, PM, DM, IBD, ReA, and SSc), we identified those who initiated DMARDs, BRMs, CSTs or did not use any DMARDs/BRMs/ CSTs. The index date was defined as the earliest date of the rheumatic/autoimmune disease diagnosis or first prescription of CSTs, DMARDs, or BRMs. Individuals with diagnosed Cocci infection prior to the index date were excluded. Based on the refill days supplied, we created time-varying exposure variables of DMARDs, BRMs, and CSTs, and applied a 90 day lag period following drug cessation. We used multivariable Cox proportional hazard regression to examine DMARD, BRM, and CSTs use and the risk of subsequent Cocci infection, adjusted for age, sex, race, Medicaid eligibility, low income subsidy, RxHCC risk score, Elixhauser comorbidity index, disability, metropolitan area, opioid use, and NSAID use within 3 months of the index date. Cox models included indicator variables for CSTs, DMARDs, and BRMs simultaneously.

**Results:** Among 14,931 beneficiaries (mean age: 68.7; white: 75.3%, black: 7.6%), 51 individuals were diagnosed with Cocci during the study period (1.6 per 1,000 person-years). Increased risk of Cocci was observed among beneficiaries prescribed any CSTs (HR=1.94, 95%CI: 1.10, 3.42) and any BRMs (HR=2.25, 95%CI: 1.02, 4.95), though not for individuals prescribed any DMARDs (HR=1.02; 95%CI: 0.54, 1.91), seen in Table 1.

**Conclusion:** The overall incidence of Cocci was low among Medicare beneficiaries with rheumatic or autoimmune diseases in the southwestern United States from 2011 to 2013. Our findings suggest that BRM and CSTs users may have higher risk of Cocci compared to non-users, but no evidence of increased risk was observed for those who used DMARDs. Cocci is a serious infection, and warrants consideration for regular screening among clinicians for individuals on BRMs and CSTs.

**Table 1. Use of Disease-Modifying Antirheumatic Drugs, Biologic Response Modifiers and Corticosteroids, and Subsequent Cocci risk: Multivariable Cox Models**

	No. Cocci Cases	Crude Rate (per 1,000 person-years)	Unadjusted HR (95% CI)	Adjusted HR <sup>a</sup> (95% CI)
CSTs				
No	29	1.2	Reference	Reference
Yes	22	2.5	1.95 (1.11, 3.42)	1.94 (1.10, 3.42)
DMARDs				
No	35	1.5	Reference	Reference
Yes	16	1.8	1.05 (0.56, 1.94)	1.02 (0.54, 1.91)
BRMs				
No	43	1.5	Reference	Reference
Yes	8	3.1	2.20 (1.01, 4.83)	2.25 (1.02, 4.95)

**Abbreviations:** BRMs: biologic response modifiers; Cocci: Coccidioidomycosis; CSTs: corticosteroids

<sup>a</sup> Adjusted HRs were estimated by including sociodemographics and health status covariates and indicator variables for CSTs, DMARD, and BRM, simultaneously. For example, the HR for BRMs compares the risk of Cocci for those exposed to BRMs compared to participants not exposed to BRMs, adjusted for concurrent CSTs exposure and DMARD exposure.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Miscellaneous Rheumatic and Inflammatory Diseases II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

IgG4-related disease (IgG4-RD) is an immune-mediated condition which clinical spectrum encompasses single or multiple organ involvement. Enlargement of major and minor salivary glands is one of the main disease features. Whether salivary gland enlargement is associated with systemic involvement has not been previously evaluated. The purpose of this study was to elucidate if salivary gland enlargement is associated with systemic disease.

**Methods:** We included patients with an established diagnosis (definitive: organ involvement, biopsy proven and high IgG4 levels; probable: organ involvement, biopsy proven without high IgG4 levels; possible: organ involvement, high IgG4 levels without histology) of IgG4-RD according to the Comprehensive Diagnostic Criteria, who regularly attend a tertiary referral center in Mexico City (2000-2017). We retrospectively collected demographics, clinical (organ involvement, disease activity and damage assessed by the IgG4-RD

Responder Index [IgG4-RD RI] at basal and at 6 months of follow-up, number of relapses, remission and treatment), basal laboratory (C3, C4, ESR, PCR, total eosinophil count, IgG4 levels) as well as imaging and histologic data.

## Results:

We included 32 patients, 17 (53.1%) men, mean age  $50.2 \pm 14.1$  years and median disease duration 20.5 months. Seven (21.9%) have a definitive diagnosis, 12 (37.5%) probable and 13 (40.6%) possible. Overall we identified 21 anatomic sites affected, mainly pancreas 56.2%, lymph nodes 56.2%, lacrimal glands 37.5% and bile duct 34.3%. Salivary gland involvement was present in 12 (37.5%) patients (2 parotid, 3 minor salivary gland and 7 both). Among these patients, only 5 (41.6%) referred dry mouth and in 7 patients (58.3%) glandular enlargement was the onset disease feature. Salivary glandular enlargement was identified only radiologically in 5 patients (41.6%) and both clinical and radiologically in 7 (58.3%) patients. When we compared patients with (n=12) vs. without (n=20) salivary gland enlargement, the first group had a higher number of affected organs (6.5 vs. 2,  $p=0.0001$ ) and absolute eosinophil's count ( $348$  vs.  $137.5/\text{mm}^3$ ,  $p=0.05$ ), a higher prevalence of lacrimal glands (75% vs. 15%,  $p=0.002$ ), lymph nodes (91.7% vs. 35%,  $p=0.002$ ) and lung involvement (33.3% vs. 0%,  $p=0.01$ ), azathioprine use (83.3% vs. 30%,  $p=0.003$ ), as well as a higher basal IgG4-RD RI (12 vs. 6,  $p=0.001$ ) and a longer delay in diagnosis (64 month vs. 6.5 months,  $p=0.001$ ). We did not find differences regarding gender, age, IgG4 serum levels, C3, C4, ESR, PCR, antinuclear antibodies, rheumatoid factor, anti-Ro/SSA and anti-La/SSB antibodies (negative in all patients), number of relapses, remission at 6 months and damage. We performed a logistic regression analysis (only including the number of organs, the basal IgG4-RD RI and time of follow-up) and found an association of salivary gland enlargement with the basal IgG4-RD RI (OR 1.63, 95% CI 1.12-2.35,  $p=0.009$ ).

**Conclusion:** Our study highlights the systemic nature of IgG4-RD. Patients with salivary gland enlargement should be routinely screened for systemic involvement.

**Session Title:** Rheumatoid Arthritis – Clinical Aspects VI: Comorbidities of Rheumatoid Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

The prevalence of depression among individuals with rheumatoid arthritis (RA) may be as high as 40% but persistence of depression over time is relatively unknown. Uncontrolled inflammation may drive severe disease and, in turn, inflammation and high disease activity are hypothesized to mediate depressive symptoms. The aims of this analysis were to: (1) describe the prevalence of depression at baseline and determine how often depression persists over time; (2) determine whether there is an association between changes in disease activity and depression over time among individuals with early RA (ERA).

### Methods:

ERA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) with ERA ( $\leq 1$  year disease duration) and  $\geq 2$  years of follow-up were included. Persistent depression was defined as self-reported depression at baseline and at  $>50\%$  of visits over the first 2 years. The association between baseline disease activity, measured by the Clinical Disease Activity Index (CDAI), and depression at

baseline or persistent depression was evaluated with multivariate logistic regression. The General Estimation Equation was also used to explore the association between changes in CDAI disease activity over time and risk of depression.

## Results:

469 patients with ERA (72.9% female) were included with a mean (SD) age of 56.8 (13.6) years. Mean (SD) disease parameters were: CDAI: 22.9 (14.1); DAS28: 4.6 (1.5); and HAQ disability Index: 1.1 (0.75). At baseline, the prevalence of depression was 26%, and 23% reported persistent depression. Persistent depression was significantly higher in patients with moderate CDAI (19%) and high CDAI (29%) compared to those in CDAI low disease activity (LDA) or remission (16%,  $p=0.02$ ). After adjusting for potential confounders (sex, rheumatoid factor status, prior use of csDMARDs, current use of bDMARDs, HAQ disability index, number of comorbidities), increased CDAI at baseline was significantly associated with both baseline depression and persistent depression (OR: 1.04; 95%CI: 1.01-1.06,  $p=0.002$ ). Female gender (OR: 3.17; 95%CI: 1.50-6.68  $p=0.002$ ) and greater number of comorbidities at baseline (OR: 1.68; 95%CI: 1.47-1.93,  $p<0.001$ ) were also associated with persistent depression. Over the course of follow-up, the risk of depression was significantly higher among patients with moderate disease activity compared to those in CDAI LDA or remission (OR: 1.16; 95%CI: 1.04-1.29,  $p=0.006$ ). The risk of depression was substantially greater for those with high disease activity (OR: 1.32; 95%CI: 1.15-1.52) over time compared to those achieving LDA or remission states.

## Conclusion:

Depression in ERA is common and initial high disease activity increases the risk of depression as well as its persistence. High CDAI during the early years of follow-up was also an independent predictor of depression. This highlights the importance of intervening during the “window of opportunity” to control disease activity and the potential to mitigate adverse health outcomes, including depression.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects VI: Comorbidities of Rheumatoid Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

## Background/Purpose:

The aim of treatment of rheumatoid arthritis is to control disease activity and to inhibit joint damage. Progression of damage is analysed by conventional radiographs. High radiographic progression has, to our knowledge, not been analysed in detail.

**Objectives:** To analyse RA patients depending on their individual peak radiographic progression.

**Methods:** We selected for the highest (peak) radiographic progression in every individual patient of the Swiss registry SCQM with at least two scored sets of radiographs of hands and feet. The individual radiographic progression was analysed as change of Ratingen erosion scores/year (follow up 1998 – 2015). The baseline disease characteristics were compared using standard descriptive statistics (Kruskal-Wallis or Chi-square tests). The change of DAS 28 and HAQ-DI scores before and after peak progression was analysed with the Wilcoxon signed rank tests.

## Results:

Of the 4'033 patients in the analysis 3'049 patients had a peak radiographic progression rate between 0 and  $\leq 10$ /year, 773 between 10 and  $\leq 20$ , 150 between 20 and  $\leq 30$ , and 61 of  $>30$  (defining groups 1-4). Rheumatoid factor and ACPA were more frequent in patient groups with higher peak radiographic progression (RF: 73.6, 80.0, 88.9, 90.0; ACPA: 66.8, 73.4, 74.3, 82.1, groups 1-4, respectively). Peak radiographic progression at a rate  $>20$ /year (groups 3 and 4) were not detected after December 2012. When the rate of radiographic progression before and after peak progression was analysed, 69.7%, 74.7%, 76.9%, and 93.3% of the patients had a radiographic progression of 25% or lower as compared to peak progression before and 76.1%, 81.8%, 91.1%, and 93.8% after this peak progression, respectively for patients in groups 1 to 4 (Figure A).

The disease activity, as assessed by DAS 28, was significantly higher in all patient groups before peak progression and lower thereafter ( $p < 0.001$ ). Average HAQ-DI scores increased after peak radiographic progression in group 4 ( $p = 0.005$ ) whereas it is stable or even decreases among the patients of the other patient groups.

**Conclusion:** These data show that high radiographic progression is rare and gets less frequent over the last years. Higher disease activity precedes radiographic peak progression. Radiographic progression before and after the individual peak radiographic progression was far lower as compared to the time of radiographic peak progression. Only the highest individual peak (change of Ratingen score  $>30$ /year) radiographic progression was followed by an increase of HAQ-DI scores.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects VI: Comorbidities of Rheumatoid Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Clinical measures of disease activity, such as the DAS-score and ultrasound (US) scores of disease activity can be sometimes yield discordant results. Little research has attempted to understand the reasons for these discordances. Moreover, it is not well known what the implications of such discordances are or how clinical and US assessments evolve over time in this situation

**Objectives :**First: to determine the percentages of patients presenting discordances between DAS and US assessments in a real-life cohort. Second: to describe associated factors. Third: to evaluate the evolution of both measures of disease activity over time.

**Methods:** All patients with at least one concomitant US- and DAS-score assessment, performed since the introduction of validated US (SONAR) score in the SCQM between 2009 and January 2017 were included. Disease activity was categorized as remission, low, moderate and high activity based on previously established cut-offs for the DAS and the US-score. Potential predictors of discordance were extracted from the SCQM database, including age, gender, seropositivity, duration of illness, number of swollen and tender joints, global physician assessment of disease activity, HAQ, presence of fibromyalgia, type of treatment, patients followed in private practice and other. A longitudinal analysis was performed in all the patients with at least two subsequent visits with US and DAS assessment performed simultaneously

**Results:** 2367 assessments could be analyzed, of which 1072 (45%) were considered concordant based on identical disease activity states with the DAS- and the US score. The proportion concordant assessments significantly differed by clinical disease status ( $p < 0.001$ ); more frequent in clinical remission (78.4% of agreement) compared to active disease status (21% in low or moderate DAS, 45% in high DAS). Among the discordant assessments, disease activity state tended to be more frequently over-estimated by the DAS compared to US-score (38%), than the other way round (17%), ( $p < 0.05$ ) .

Factors associated with the presence of discordant results were the swollen joint count ( $p < 0.001$ ), the overall estimation of the disease activity ( $p < 0.001$ ) by the clinician, the duration of the disease ( $p < 0.02$ )

For 1181 patients, several DAS and US assessments were available during follow-up. The proportion of discordances during the follows up was similar to the initial evaluation. Initial discordance/concordances could however change status without obvious reason, especially in the moderate and low disease activity subgroup (75 % new discordances).

**Conclusion:** Discordances between DAS and US assessments appear to be higher than expected in real life. Both outcome measures can lead to over- or under-estimations of the true disease activity, Discordant assessments seem to be linked essentially to inaccuracies in the clinical evaluation in particular (inadequate swollen joint counts) and /or to limitations of the US procedure (especially poor distinction between moderate and low activity disease

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects VI: Comorbidities of Rheumatoid Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Rheumatoid Arthritis (RA) is a multi-system disease which causes joint damage and is associated with increased cardiovascular (CV) morbidity and osteoporosis. Our purpose is to examine the relationship between bone mass and mortality in patients with RA.

**Methods:** We recruited patients with RA from public and private rheumatology practices in San Antonio, Texas. In addition to demographic data, baseline measures were obtained including the extent and severity of joint involvement, the presence of CV risk factors (such as the presence of diabetes, tobacco use, hypercholesterolemia, and hypertension), and the bone mineral density (BMD), calculated from appendicular bone mass via Digital X-ray Radiogrammetry (DXR) of anteroposterior hand radiographs (Sectra AB, Linköping, Sweden). During annual follow-up, all deaths were identified from relatives, physicians, obituaries, or national databases. We obtained certificates for all deaths. Patients were divided into groups according to BMD quartile. We used the Kaplan-Meier method to examine the association of BMD with mortality. We then adjusted for potential confounding variables using Cox proportional hazards regression analysis.

**Results:** Our study included 653 patients with RA. Their mean age  $\pm$  standard deviation [SD] was  $58.1 \pm 12.7$  years and 72% were women. We had a total of 8,653 person-years [PY] of observation and noted 252 deaths over the course of the study for a mortality rate of 2.9 per 100 PY. Mortality was highest in the lowest BMD quartile at 5.2 per 100 PY (95% confidence interval [95% CI] 4.3-6.3). Higher BMD quartiles had less mortality, most notably in the two highest quartiles with a mortality rate of 1.9 per 100 PY (95% CI 1.4-2.6) and 1.6 per 100 PY (95% CI 1.2-2.2), respectively. The mortality hazard ratio (HR) was 0.74 per each decigram/cm<sup>2</sup> increase in

BMD (95% CI 0.62-0.90, P-value less than or equal to 0.01) after adjusting for age, sex, ethnicity, CV risk factors, and measures of RA inflammatory disease activity (counts of tender and swollen joints and erythrocyte sedimentation rate) and joint damage (Sharp score of radiographic erosions and joint space narrowing).

**Conclusion:** Low BMD in RA patients is independently associated with increased mortality rate. Together with other known risks factors and comorbidities, the presence of a low BMD suggests worse outcomes in patients with RA. BMD measurements via DXR may be of utility in the clinic as hand radiographs are routinely trended over time and readily obtained. Further research is needed to understand the mechanisms underlying the association between BMD and mortality in RA.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects VI: Comorbidities of Rheumatoid Arthritis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

Inflammation is the hallmark of disease activity in rheumatoid arthritis (RA). RA is characterized by fatigue and cognitive/affective disturbances, and these symptoms often worsen during a disease flare. However, surprisingly little is known about the neural correlates of inflammation in autoimmune disease. Here we used MRI to investigate how neuroimaging outcomes are associated with levels of peripheral inflammation in this patient population.

**Methods:** RA patients, fulfilling ACR/EULAR 2012 criteria, were recruited and underwent a multi-modal MRI brain scan which was repeated 6 months later to validate our findings. Recruitment was stratified (1:1) by disease activity (swollen joint count  $\geq 1$ ). The clinical evaluation included measures of inflammation (ESR) and self-reported levels of fatigue and pain (VAS) as well as depression (Hospital Anxiety and Depression Scale). Images were acquired by a 3 Tesla, 8 channel phased array head coil using a T2\*-weighted gradient-echo echo-planar imaging pulse sequence. Functional connectivity was assessed during a simple cognitive task and conducted through Independent Components Analysis (ICA) to investigate the relationship of established neural networks with other brain regions. Structural analyses were conducted using voxel-based morphometry (VBM). The primary outcomes of interest were brain regions where connectivity varied with levels of ESR. These regions were then examined post-hoc for associations with VBM findings, and clinical symptoms. Primary results were significant on the cluster level with a false discovery rate (FDR) p value  $<0.05$  derived from an uncorrected voxel level p value  $<0.001$ .

**Results:** Fifty-four subjects participated (mean age 54.9 years; 75.9% female; mean disease duration 11.5 years; mean ESR 19.4 [2-62]; mean DAS28 3.6 [range 1.5-6.4]). Several regions were identified that showed positive connections to the Dorsal Attention Network (DAN), Salience Network (SLN), and Default Mode Network (DMN) as ESR increased. The right (R) frontal pole ( $r=.56$ ,  $p=.002$  FDR), and left (L) inferior/superior parietal junction ( $r=.58$ ,  $p=.001$ ) showed positive connections to the DAN while the L inferior parietal lobule, L mid-temporal gyrus and several frontal regions, demonstrated positive connections to the DMN and SLN (all  $p < .05$  FDR). Positive connections between the R frontal pole and L parietal with the DAN were replicated at the second time point ( $p<.05$ ). In the same parietal region, higher inflammation was associated with decreased grey matter volume. The degree of connectivity in most of the identified regions was associated with more severe fatigue and pain scores.

**Conclusion:** The neurobiology of fatigue, cognitive dysfunction, and pain in RA, and their relationship with inflammation are poorly understood, yet these are some of the most common and debilitating symptoms in rheumatic diseases. The present study identified brain regions that may serve as inflammatory “hubs” in RA. Several of these regions play important roles in higher-order cognitive processing and therefore may represent key areas underpinning the development of symptoms such as fatigue and cognitive impairment in RA.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects VI: Comorbidities of Rheumatoid Arthritis

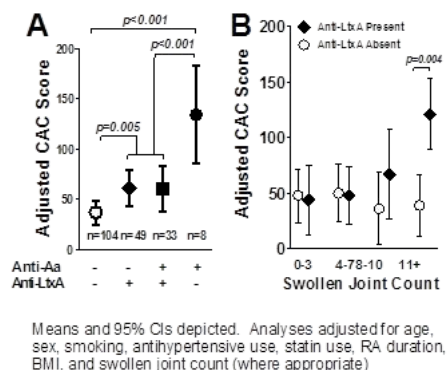

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** The oral pathogen *Aggregatibacter actinomycetemcomitans* (Aa) generates citrullinated proteins targeted by autoantibodies in RA through its pore-forming toxin leukotoxin A (LtxA). Aa-derived LtxA is implicated in atherogenesis and atherosclerotic plaque instability, conditions over-represented in RA. No prior studies have explored the potential link between Aa, Aa-derived LtxA, and atherosclerosis in RA.

**Methods:** RA patients underwent cardiac computed tomography (CT) with coronary arterial calcification (CAC), a measure of coronary atherosclerosis, assessed. Serum levels of IgG antibodies against Aa serotype b and purified LtxA were measured by ELISA. Healthy controls cutoffs for seropositivity were used. Multivariable robust regression was used to model the associations of anti-Aa and anti-LtxA with CAC, adjusting for pertinent confounders.

**Results:** A total of 194 RA patients [mean age=59 years; 60% female; median RA duration=9 years; 79% RF or anti-CCP seropositive] were studied. Anti-Aa was detected in n=41 (21%) and anti-LtxA in n=82 (42%). Adjusting for relevant confounders (listed in Fig), those with anti-LtxA had a mean CAC score 65% higher than those without anti-Aa or anti-LtxA (61 vs. 37 units, respectively;  $p=0.005$  (Fig1a)). Those anti-Aa<sup>+</sup>/anti-LtxA<sup>-</sup> had a mean adjusted CAC score 262% higher than those with neither antibody (134 vs. 37 units, respectively;  $p<0.001$ ) and 120% higher than those with anti-LtxA, with or without concomitant anti-Aa. Among CAC-associated features, swollen joint count (SJC) was differentially associated with CAC depending on the context of anti-LtxA. In anti-LtxA<sup>-</sup> patients, SJC was not associated with CAC (Figure 1B, open circles). However, in anti-LtxA<sup>+</sup> patients, each swollen joint was associated, on average, with a 6 unit higher CAC score ( $p<0.001$ ). The interaction of anti-LtxA and swollen joints was significant ( $p=0.002$ ). The association was not linear, with a marked difference noted in those with >10 swollen joints (Figure 1B, solid diamonds). Combining the two above groups with higher CAC scores [i.e. anti-Aa<sup>+</sup>/anti-LtxA<sup>-</sup> and anti-LtxA<sup>+</sup> and >10 swollen joints; n=32 (16% of the cohort)], the adjusted mean CAC was 171% higher vs. those without these features (114 vs. 42 units, respectively;  $p<0.001$ ).

**Conclusion:** Infection with the periodontal pathogen Aa may contribute to atherosclerosis in RA. Anti-LtxA, a marker of exposure to leukotoxic Aa strains, was significantly associated with more CAC and identified patients in which synovitis was robustly and independently associated with the extent of CAC. A subgroup of RA patients with isolated antibody positivity to the leukotoxic Aa serotype b showed markedly higher risk of atherosclerosis. Additional studies are warranted to elucidate the underlying mechanism, and whether Aa-specific screening and treatment may reduce CVD risk in RA patients.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Data support that anti-CCP antibodies likely originate at a mucosal site prior to the onset of inflammatory arthritis (IA) in the development of RA. Our group identified anti-CCP in the lungs of subjects without IA who are At-Risk for future RA. However, a portion of serum CCP+ subjects did not exhibit anti-CCP in the lung, suggesting another mucosal site of generation. Based on a higher incidence of RA in women, the dynamic nature of immune responses in the cervicovaginal (CV) mucosa and our

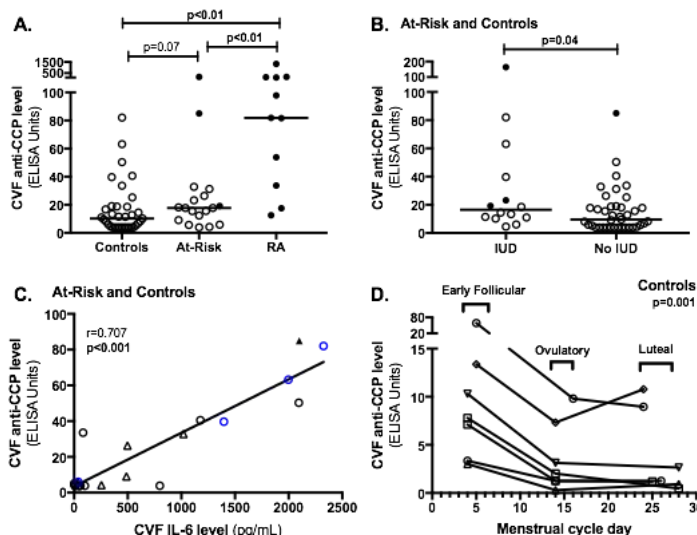

preliminary data that serum anti-CCP-IgG is associated with intrauterine device (IUD) use in first-degree relatives (FDR) of RA patients, we sought to evaluate anti-CCP antibodies in the CV mucosa of women with and without RA.

**Methods:** We studied premenopausal women: 11 serum CCP+ with classified RA, 18 At-Risk for RA (15 serum CCP- FDRs and 3 serum CCP+ from clinics) and 35 serum CCP- healthy Controls. A CV fluid (CVF) sample was collected between days 14-28 of the menstrual cycle. Paired serum and CVF was tested by ELISA for CCP3 (IgG, Inova). In 24 of the non-RA women, CVF was also tested for 11 inflammatory cytokines/chemokines (Meso Scale). In addition, 7 Controls collected serial CVF samples from 3 different menstrual cycle phases. No interference by hemolysis was found on CVF CCP results.

**Results:** CVF anti-CCP levels were higher in RA (Figure Panel A). In non-RA subjects, CVF anti-CCP levels were higher in current IUD users ( $p=0.04$  in all non-RA;  $p=0.04$  in Controls only; Panel B). There was no association between CVF anti-CCP levels and self-report of smoking, pregnancy, genital infection or other contraception type. In non-RA subjects, CVF anti-CCP significantly correlated with CVF markers of inflammation including IL-6, monocyte chemoattractant protein (MCP)-1, macrophage inflammatory protein (MIP)-1 $\alpha$  and MIP-1 $\beta$  ( $p\leq 0.001$  for all; Panel C shows IL-6). In addition, CVF anti-CCP was higher in the early follicular phase compared to ovulatory and luteal phases ( $p=0.001$ , Panel D), and in 4 Controls that were tested, CVF IL-6, MIP-1 $\alpha$  and MIP-1 $\beta$  increased with anti-CCP levels in the early follicular phase.

**Conclusion:** We demonstrate for the first time that anti-CCP antibodies are elevated in CVF of women with and without RA. Importantly, these elevations were associated with markers of local CV inflammation. Furthermore, the 2 factors associated with higher CVF anti-CCP levels were IUDs and the early follicular phase, and both have previously been associated with local CV inflammation (Shanmugasundaram 2016; Macneill 2012). Of note, several serum CCP- women had elevated CVF anti-CCP levels suggesting that the CV mucosa may be a unique site of anti-CCP generation in some women, which could provide insight into the higher rates of RA in women. Additional studies are needed to identify specific mechanisms of CV anti-CCP generation and factors associated with transitions to systemic autoimmunity.

**Figure. Anti-CCP (IgG) Levels in Cervicovaginal Fluid (CVF).** Panel A depicts CVF anti-CCP levels in premenopausal healthy Controls, subjects At-Risk for RA and RA patients. Panel B compares CVF anti-CCP levels in At-Risk and Control subjects who do or do not have a current intrauterine device (IUD). Panel C depicts the relationship between CVF anti-CCP and IL-6 levels (Blue color=IUD user). Panel D depicts the change in CVF anti-CCP level during 3 different menstrual cycle phases in 7 Controls who have regular menstrual periods. In all panels, Open symbol=Serum anti-CCP(-) and Closed symbol=Serum anti-CCP(+). P-value in Panels A and B=Non-parametric Mann-Whitney U, in Panel C=Spearman's correlation and in Panel D=Non-parametric repeated measures Friedman test. While Panel C only depicts IL-6 results, CVF was also tested for IL-1 $\beta$ , TNF- $\alpha$ , IFN- $\gamma$ , IL-8, MCP-1, MIP-1 $\alpha$ , MIP-1 $\beta$ , MCP-4, MDC and IP-10. Only IL-6, MCP-1, MIP-1 $\alpha$  and MIP-1 $\beta$  were significantly correlated with CVF anti-CCP levels after considering multiple comparisons (Bonferroni's  $p < 0.004$ ).

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Generated under oxidative stress, malondialdehyde-acetaldehyde adducts (MAA), and antibody responses to MAA appear to facilitate loss of immune tolerance and generate pro-inflammatory responses in rheumatoid arthritis (RA). Both MAA adduct formation and anti-MAA antibody levels are enriched in joint tissues of RA patients compared to those with non-inflammatory arthritis, and MAA appears to co-localize with citrullination in joint tissue. Because oxidative stress and autoimmunity are also key components of extra-articular complications of RA, including interstitial lung disease (ILD), we assessed MAA and anti-MAA antibody responses in RA-ILD.

**Methods:** Using banked serum from the Veterans Affairs Rheumatoid Arthritis (VARA) registry, we assessed serum anti-MAA antibody concentrations (IgA, IgM, and IgG via ELISA) in RA patients with and without diagnosis codes for ILD. Log-transformed anti-MAA antibody concentrations were compared by group using t-tests and linear regression models adjusted for age, sex, smoking status, disease activity, and anti-CCP antibody positivity. Additionally, we analyzed lung tissue sections from subjects with RA-ILD, non-RA ILD, emphysema, and controls (n=2 per group) available through the NIH's Lung Tissue Resource Consortium. Sections were stained using a MAA-specific rabbit polyclonal antibody and a citrulline-specific mouse IgM monoclonal antibody, and imaged with a confocal laser scanning microscope.

**Results:** In a male predominant (90%), established RA patient cohort (mean duration 11 years) with frequent smoking history (78%), 103 subjects had a diagnosis code for ILD. Serum concentrations of IgA and IgM anti-MAA antibody were significantly higher in RA-ILD subjects, even after adjustment for anti-CCP antibody positivity, disease activity, and smoking status (**Table 1**). IgG anti-MAA antibody concentrations were also marginally higher in RA-ILD subjects, but were not statistically significant. Lung tissue demonstrated staining for MAA in non-RA ILD and emphysema; however, qualitatively, staining was highest in RA-ILD (**Figure 1**). In addition, staining demonstrated that MAA and citrulline co-localized in lung tissue from RA-ILD.

**Conclusion:** Anti-MAA antibodies, IgA and IgM, are higher in RA patients with a diagnosis of RA-ILD. Along with the enhanced staining of MAA-modified proteins in lung tissue samples from RA-ILD, our findings suggest that MAA adduct formation and resulting adaptive immune responses could play an important role in the pathogenesis of RA-ILD and also serve as informative disease biomarkers.

**Table 1.** Associations of RA-ILD with serum anti-MAA antibody expression.

	RA-ILD N=103	RA, no lung disease N=1468	P value
<b>IgA anti-MAA<sup>±</sup></b>

## The Presence of a Large Number of Autoantibodies at Baseline Is Favourable for Early Treatment Response but Unfavourable for Drug-Free Remission in RA Patients

**Emma de Moel**<sup>1</sup>, Veerle Derksen<sup>1</sup>, LA Trouw<sup>1</sup>, Holger Bang<sup>2</sup>, R.J. Goekoop<sup>3</sup>, I Speyer<sup>4</sup>, TWJ Huizinga<sup>1</sup>, CF Allaart<sup>1</sup>, REM Toes<sup>1</sup> and Diane van der Woude<sup>5</sup>, <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Orgentec Diagnostika GmbH, Mainz, Germany, <sup>3</sup>Haga Hospital, The Hague, Netherlands, <sup>4</sup>Haaglanden Medical Center, The Hague, Netherlands, <sup>5</sup>Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

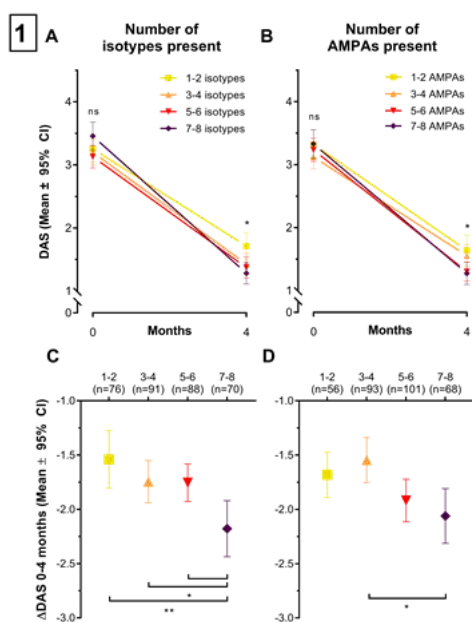

**Background/Purpose:** The autoantibody response of seropositive RA is very diverse and consists of various numbers of isotypes and antibodies to multiple post-translational modifications. It is yet unknown whether this varying breadth of the autoantibody profile associates with treatment outcomes. Therefore, we aimed to comprehensively characterize the number of isotypes and anti-modified peptide antibodies (AMPAs) present in RA and investigate whether the breadth of the autoantibody profile, as a reflection of the underlying immunopathology, associates with early treatment response and rates of sustained drug-free remission (SDFR).

**Methods:** In baseline sera of 399 seropositive RA patients in the IMPROVED study<sup>1</sup>, we measured IgG, IgM, and IgA isotypes for anti-cyclic citrullinated peptide-2, rheumatoid factor, and anti-carbamylated protein antibodies, and reactivity against 4 citrullinated peptides (vimentin 59-74, fibrinogen  $\beta$  36-52 and  $\alpha$  27-43, enolase 5-20) and 2 acetylated peptides (lysine and ornithine). We investigated associations between autoantibody profile and 1) change in disease activity score (DAS)-44 between 0 and 4 months and 2) sustained drug-free remission (SDFR) (drug-free DAS44 < 1.6 lasting  $\geq 1$  year).

**Results:** A broad baseline autoantibody isotype profile dose-dependently associated with a favourable early treatment response:  $\Delta$ DAS 0-4 months of 7-8 vs 1-2, 3-4, and 5-6 isotypes, respectively: -2.2 vs -1.5 [ $p < 0.001$ ], -1.7 [ $p = 0.04$ ], and -1.8 [ $p = 0.04$ ] (Figure 1). A similar trend was observed for AMPA-number. Conversely, a broad autoantibody profile was associated less chance of achieving early SDFR between 1-2 years (Figure 2). In the long run (2-5 years), not the breadth of the autoantibody response, but rather seropositivity per se was associated with not achieving SDFR.

**Conclusion:** Not only the presence of autoantibodies, but also the breadth of the autoantibody profile has prognostic value in RA. Seropositive patients with a broader autoantibody profile have a better early response to immunosuppression, likely reflecting an active but readily suppressible humoral immunity. However, in the long-term this autoimmunity cannot be quenched without continued therapy.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Neutrophil activation is associated with inflammation and autoimmunity, including rheumatoid arthritis (RA), where neutrophil infiltration to joints participates in tissue destruction and development of arthritis. In RA, neutrophils may spontaneously, or upon engagement with inflammatory cytokines and autoantibodies, undergo a programmed form of necrosis, NETosis, upon which neutrophil extracellular traps (NETs) are extruded. Due to their inflammatory capacity *in vitro*, as well as containing key autoantigens, such as citrullinated histones and vimentin, NETs have been suggested to be an important contributor to the RA pathogenesis. However, the clinical utility of NETs has not been carefully addressed. The aim of the current study was to investigate if markers of neutrophil activation and NETosis were increased in RA, and related to disease activity and severity.

**Methods:** Markers of neutrophil activation (S100A8/A9) and NETosis (8-OHdG DNA, MPO-DNA complexes, cell-free DNA, citrulline) were analyzed by ELISA, fluorimetry and enzymatic assays in healthy controls (HC, n=24) and RA patients (n=101). Serum-mediated neutrophil activation was analyzed by flow cytometry. The RA patients were female (74%), age 53 (range 20-78) of Caucasian origin (64%), with an average CDAI score of 13.8 (range 0-46) and 80% of the patients being seropositive.

**Results:** RA patients had significantly elevated levels of NET-related markers as compared to HCs ( $p<0.0001$ ), with several markers, including S100A8/A9 and cell-free DNA, being increased in patients with active disease ( $p<0.01$  and  $p<0.05$ , respectively). Further, S100A8/A9 correlated with CDAI ( $r=0.52$ ,  $p<0.0001$ ) as well as number of swollen joints ( $r=0.55$ ,  $p<0.0001$ ). In contrast to CRP ( $p=0.16$ ), S100A8/A9 and NETs predicted active disease in seropositive RA patients (OR 9.2,  $p<0.05$ , and OR 6.6,  $p<0.05$ , respectively). The sensitivity and specificity was 56.9% and 87.5% (S100A8/A9), and 68.6% and 75% (NETs), suggesting superior clinical utility of NETs and S100A8/A9 as compared to CRP in determining active disease. Further, levels of NETs, but not S100A8/A9, were able to distinguish seronegative RA from HCs (OR 20.8,  $p=0.007$ ). Consistent with the hypothesis of NETosis being a major source of citrullinated proteins in RA, we found that patients with elevated NET levels had increased citrulline levels in the circulation (OR 5.1,  $p=0.006$ ). Further, NETosis was associated with increased levels of inflammatory 8-OHdG DNA ( $p<0.0001$ ). As autoantibodies and inflammatory cytokines have been suggested to induce NETosis in RA we next assessed the capacity of RA serum to support neutrophil activation *in vitro*. RA sera induced increased neutrophil activation ( $p<0.0001$ ) as compared to HC sera, partly dependent on FcγRIIA activation ( $p<0.05$ ), with serum-mediated neutrophil activation being in particular elevated in patients with erosive disease ( $p=0.02$ ).

**Conclusion:** Our results demonstrate a clear contribution of neutrophils in the RA pathogenesis, and identifies several biomarkers able to monitor disease activity and severity in RA patients, with superior clinical utility as compared to CRP.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

## Background/Purpose:

Autoantibodies including rheumatoid factor (RF) and antibodies to citrullinated protein antigens (ACPA) are known to be present in the serum of individuals prior to the development of rheumatoid arthritis (RA) (Majka, 2008). These autoantibodies may initially be generated at a mucosal surface given their discovery in the induced sputum of RA and arthritis-free subjects (Willis, 2013). However, there is limited knowledge of the temporal evolution of RF isotypes prior to RA onset, although appearance in the circulation of IgA prior to IgG autoantibody isotypes would support a possible early role for mucosal triggering of autoimmunity in RA.

## Methods:

Using the resources of the Department of Defense Serum Repository (DoDSR), we evaluated 214 RA Cases and 158 matched Controls. All RA Case and Control samples were tested for IgA and IgG RF isotypes (Inova). In addition, cut-off for these antibodies were determined using a level that was positive in <5% of a separate group of 58 military controls. The time at which IgA and IgG RF levels differed between RA Cases and Controls prior to diagnosis of RA was evaluated using a linear mixed model after log transformation of IgA and IgG levels. Linear contrasts were used at various times to estimate what time point prior to diagnosis of RA that mean levels of each RF isotype differed between RA Cases and Control, with this analysis serving to identify the earliest time point at which these autoantibodies could be considered abnormal when compared to Controls. For RA Cases, the mean time prior to diagnosis of first positivity of each isotype was also compared using a t-test.

## Results:

Descriptions of the RA Cases and Controls are presented in the Table. RF-IgA levels were significantly elevated in Cases compared to Controls at 13 years 7 months prior to RA diagnosis. In contrast, RF-IgG levels were significantly higher in Cases compared to Controls at 11 years 1 month prior RA diagnosis. These differences in time of elevation of autoantibodies in Cases compared to Controls, 13 years 7 months vs. 11 years 1 month were statistically significant ( $p<0.01$ ). Moreover, among RA Cases IgA RF positivity occurred first (mean -1671 days, SD 1761), followed by IgG RF (mean -1359 days, SD 1461) prior to RA diagnosis ( $p=0.30$ ).

## Conclusion:

In analyses of these preclinical RA samples, we found IgA RF to be present prior to the appearance of IgG RF. Given the known relationship of IgA with mucosal inflammation in general, these findings support a potential early mucosal origin for RF generation. In addition, the transition to IgG RF may also play a role in the development of joint symptoms. Future studies should evaluate the role of other factors on the evolution of RF isotypes, as well as the evolution of ACPA isotypes.

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### **Background/Purpose:**

Airways abnormalities that are consistent with inflammation are common in anti-CCP2 positive subjects without inflammatory arthritis. Anti-CCP2 antibodies are associated with HRCT parenchymal lung abnormalities in patients with early RA. This study aims to examine the association between ACPA fine specificities and HRCT lung changes in an early RA cohort and to assess these changes after 6 months.

### **Methods:**

Patients (n=106) with newly diagnosed RA according to the ACR 1987 criteria and naïve to treatment with oral glucocorticoids or DMARDs were included. HRCT was performed in order to assess the presence parenchymal (nodules, ground-glass opacities, opacities, fibrosis, emphysema) and airway abnormalities (bronchiectasis, air trapping, air wall thickening). EliA system (Phadia) was used to detect RF IgA and IgM, anti-CCP2 IgA and IgG, and peptide microarray (Phadia) was used to detect antibodies against 10 citrullinated (Cit) peptidic antigens: CCP-1 (Filaggrin), CEP-1 ( $\alpha$ -enolase), Vim 2-17, Vim 60-75 (Vimentin), Fib  $\alpha$  36-50, Fib  $\alpha$  573, Fib  $\alpha$  591, Fib  $\alpha$  621-635, Fib  $\beta$  36-52, Fib  $\beta$  60-74 (Fibrinogen). Most of the patients (n=93) were followed up after 6 months. Logistic regression analysis was performed to examine associations between HRCT lung changes at the time of RA diagnosis and autoantibodies.

## Results:

HRCT parenchymal and airway changes was present in 58 (54.7%) and 68 (64.2%) patients, respectively. The forced vital capacity (FVC) was significantly lower in the presence of airway abnormalities, while the ratio FEV<sub>1</sub>/FVC was significantly lower in patients with parenchymal lung changes. Higher age, RF IgA, CCP2 IgG, ever smoking and pack-years above 24 were significant predictors of parenchymal lung changes. Some ACPA fine specificities, especially against Cit Fib and Vim peptides, were associated to parenchymal lung changes in ever smokers. The risk of having parenchymal changes increased parallel to the increase in number of ACPA specificities. Having more than 5 ACPA specificities at the time of diagnosis increased the risk of having parenchymal lung abnormalities in current smokers (OR=13.8, 95% CI=1.0-196.2, p=0.05). Of the patients that were followed up after 6 months 4 had progression of fibrosis and 3 had new fibrosis. No difference in airway changes were observed at follow-up. There was a significant decrease in DAS28 at follow-up (Mean $\pm$ SD: 5.5  $\pm$  1.1 vs 3.2 $\pm$ 1.3 P value < 0.001). The titers of some but not all of the ACPA fine specificity was significantly decreased after 6 months of treatment CCP-1 (Mean $\pm$ SD 46.6 $\pm$ 289.7 vs 101.6 $\pm$ 235.3), CEP-1 (59.1 $\pm$ 120.1 vs 35.9 $\pm$ 76.3), Vim 60-75 (338 $\pm$ 488.1 vs 220.3 $\pm$ 327.2), Vim 2-17 (25.7 $\pm$ 59.3 vs 17 $\pm$ 37.8), Fib  $\beta$  60-74 (237.3 $\pm$ 411 vs 136.4 $\pm$ 241.5), Fib  $\alpha$  621-635 (187.3 $\pm$ 306.3 vs 115.9 $\pm$ 203.2).

## Conclusion:

The presence of RF IgA, anti-CCP2 IgG and antibodies to Cit Fib and Vim peptides were associated with parenchymal lung changes in early-untreated RA. The more ACPA fine specificities, the higher the risk of having parenchymal lung changes already at the time of RA diagnosis. Treatment with DMARDs significantly reduces the disease activity and titers of some of the ACPA fine specificities.

## Comparative Rates of Osteoporotic Fractures Among U.S. Medicaid Enrollees with and without Systemic Lupus Erythematosus

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Longterm Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Fractures are potentially avoidable and highly morbid. We studied non-vertebral fracture rates among SLE patients enrolled in Medicaid, the U.S. health insurance program for low-income people, and compared them to age- and sex-matched Medicaid patients without SLE.

**Methods:** Among patients aged 5-65 years enrolled >180 days during 2007-2010, we identified an SLE and a lupus nephritis (LN) cohort using previously described algorithms (SLE:  $\geq 3$  ICD-9 codes for SLE  $\geq 30$  days apart; LN: SLE +  $\geq 2$  ICD-9 codes for kidney

disease  $\geq 30$  days apart). Four age- and sex-matched non-SLE patients were included for each SLE patient. Subjects were followed from index date (SLE definition met, or a matched date for non-SLE patients) through end of follow-up (12/31/10) or censoring (death or disenrollment). During the baseline period (180 days before index date), we assessed sociodemographics, SLE- and prescriptions, and comorbidities. Incident fractures of the pelvis, hip, wrist, and humerus were identified via validated algorithms using ICD-9 + current procedural terminology codes. Within each cohort, we calculated cumulative incidence rates (IRs) and 95% confidence intervals (CI) for any fracture and for each fracture type. Poisson regression models, adjusted for all covariates, estimated cumulative IR ratios (IRRs), comparing SLE and LN to non-SLE patients. Age-stratified analyses investigated differences in fracture rates, using age 45 years as a cutoff based on mean age at menopause in SLE.

**Results:** 39,918 SLE patients were matched to 159,672 non-SLE patients. Mean age was 40.1 ( $\pm 13.4$ ) years and 92.2% were female. 9,096 SLE patients (22.8%) had LN. Black race comprised 43.3% of SLE, 53.1% of LN, and 23.1% of the non-SLE cohort. Average prednisone equivalent during baseline was  $\geq 7.5$ mg/day in 11.5% of SLE, 20.1% of LN, and 0.3% of non-SLE patients. Fracture IRs were 1.48/100,000 person-years in SLE (**Table**) and 2.06/100,000 person-years in LN. Compared to matched non-SLE patients, fracture rates were 39% higher in SLE patients and 69% higher in LN patients, even after adjusting for medications associated with bone density loss. Hip fracture rates were almost 3.5 times higher and pelvic fracture rates were more than doubled among SLE patients  $\leq$  age 45 compared to matched non-SLE patients after adjustment. Hip fracture rates were 5 times higher among LN patients  $\leq$  age 45 compared to matched non-SLE patients (adjusted IRR 5.02 [1.46-17.19]).

**Conclusion:** Compared to age- and sex-matched Medicaid enrollees without SLE, SLE and LN patients had much higher non-vertebral fracture rates, particularly hip and pelvic fractures in patients  $\leq 45$  years of age. These results highlight the need for fracture prevention measures among young SLE patients.

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Longterm Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

## Background/Purpose:

Lupus nephritis is a major complication of systemic lupus erythematosus (SLE), occurring in up to half all SLE patients and progressing to end-stage renal disease (ESRD) in 20% of those affected. Renal transplantation is a preferred treatment, but this is a limited resource, and the survival benefit of transplantation has not been well-characterized in this population. We assessed survival impact following waitlisting for a renal transplant in patients with SLE in the US.

## Methods:

We identified all incident cases of ESRD due to SLE (ICD9=710.0) in the United States Renal Data System (USRDS) between 1995 and 2014. The USRDS captures nearly all patients with ESRD in the US and includes the cause of ESRD by ICD9 code as well as demographics, comorbidities, and dates of waitlist entry, transplantation and death including its causes. We included all patients with ESRD due to SLE who were waitlisted for a renal transplant during the study period and followed patients until death or January 1, 2016. We restricted our analysis to patients waitlisted for transplant to limit the potential bias of confounding by indication. We used a time-varying Cox regression analysis to estimate the hazard ratio (HR) for death following renal transplantation compared to those who remained on the waitlist, while adjusting for age, sex, body mass index, tobacco use, comorbidities, and first ESRD treatment modality at baseline. We also assessed differences in cause of death using cause-specific hazard models.

## Results:

During the study period, 9,852 patients with ESRD due to SLE were waitlisted for a renal transplant, and 5,914 (60%) of these patients received a transplant. The majority were female (82.1%) and non-white (59.3%). The average age at ESRD onset, waitlisting, and transplant were 35.7 years, 37.7 years, and 38.5 years, respectively, and the average time from ESRD diagnosis to being waitlisted was 1.5 years. Over a mean follow up time of 7.6 years following waitlisting, 2,722 died. Transplantation was associated with a 67% reduction in overall mortality (HR 0.33 [95% CI 0.29-0.38]) among those waitlisted. In cause-specific analyses, patients who remained on the waitlist had a higher risk of cause-specific death from CVD (adjusted HR, 9.2 [95% CI, 7.9-10.7]) cancer (adjusted HR, 3.8 [95% CI, 2.3-6.1]) and infection (adjusted HR, 7.4 [95% CI 5.8-9.3]).

## Conclusion:

In this nationwide study of transplantation for ESRD due to SLE, renal transplantation was associated with a 67% reduction in mortality. Patients who were waitlisted but never received a transplant were more likely to die from CVD, cancer, and infection. Our findings highlight the survival benefits associated with renal transplantation for patients with SLE ESRD and call for the need to improve access to transplantation in this patient population. Patients on the waitlist may benefit from improved interventions to minimize CVD, cancer and infection risk.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Longterm Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

Lupus nephritis is a known predictor of mortality; we have previously shown an increased frequency of nephritis in North American Indian (NAI) and Asian (ASN) lupus patients. We examined the risks of end-stage renal disease (ESRD) and death among lupus nephritis patients, and included the impact of ethnicity, low income (LowInc), lack of education (LowEduc), and living >500 km from rheumatology care (Remote).

### Methods:

Patients from a single academic center were followed from 1990-2016 using a custom database. Records of all SLE patients were abstracted. Variables included birthdate, diagnosis date, ethnicity, ACR classification criteria (ACRc), SLICC Damage Index (SDI) including ESRD, treatment and date of death. Ethnicity was categorized into NAI, Caucasian (CAU), ASN and Other. In patients who had developed nephritis, Kaplan Meier and Cox proportional hazard models were used to compare ESRD and survival between vulnerable groups.

### Results:

Nine hundred forty-four SLE patients were identified: 240 (25%) NAI, 576(60%) CAU, 104(11%) ASN and 24(2.5%) Other. “Other” patients were excluded. Mean disease duration was 14 years, 89% female. Nephritis developed in 39% of CAU (n= 224), 57% of NAI (n=136; OR 2.1; 95%CI 1.5-2.8), and 75% of ASN (n=76; OR 4.7; 95%CI 2.9-7.6), p<0.001. Twenty percent of patients had not completed high school, 20% were LowInc, and 11% were Remote; LowInc, LowEduc, and Remote did not increase the odds of nephritis. Among nephritis patients, ESRD developed in 11%, and 17% died. Comparing nephritis patients (N=436), NAI (29±15) and ASN (29±13) years were younger at diagnosis; CAU (36±16), p<0.001. Disease duration was similar in NAI and ASN, both (11years±13); and longer in CAU (16±11); p<0.001. There were no differences in additional ACRc met between ethnic groups. SDI in addition to ESRD was similar in NAI (1.8±2.2) and CAU (2.0±2.5) and lower in ASN (1.2±1.4), p=0.04. Odds of ESRD were increased in NAI (OR 2.6; 95%CI 1.3-5.5) and ASN (OR 3.7; 95%CI 1.6-8.2) compared to CAU. LowInc, LowEduc, and Remote did not increase odds of ESRD. Odds of death were increased in NAI (OR 1.9; 95%CI 1.1-3.2), but not in ASN (OR 0.6; 95%CI 0.2-1.4) compared to CAU. LowInc did not increase odds of death, but LowEduc (OR 3.2; 95%CI 1.8-5.5), and Remote (OR 2.9; 95%CI 1.4-6.0) did. In separate models, after adjustment for age, gender, SDI, ACRc, and age at diagnosis, risk of ESRD was increased in NAI (HR 2.8; 95%CI 1.0-8.1) and ASN (HR 4.0; 95%CI 1.6-10.3) compared to CAU. LowInc, LowEduc, and Remote did not increase risk of ESRD. Only LowEduc (HR 2.1; 95%CI 1.1-3.9) increased the adjusted risk of death; ethnicity, LowInc and Remote were not significant.

### Conclusion:

Compared to CAU, NAI and ASN not only have a higher risk of nephritis, but among those with nephritis, risk of ESRD is 3-4 fold higher in NAI and ASN. Lack of education, rather than ethnicity, was the major risk factor for death. Reasons for these differences may include renal pathology, care pathways, comorbid conditions and additional socioeconomic factors and need to be further explored.

## A Propensity Score-Matched Study of Organ Damage in Patients with Systemic Lupus Erythematosus from the BLISS Long-Term Extension Trials Versus the Toronto Lupus Cohort: A Post Hoc Longitudinal Analysis

**Murray Urowitz**<sup>1</sup>, Robert L. Ohsfeldt<sup>2,3</sup>, Ron Wielage<sup>3</sup>, Kari A. Kelton<sup>3</sup>, Yumi Asukai<sup>4</sup> and Sulabha Ramachandran<sup>5</sup>, <sup>1</sup>Medicine, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada,

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Longterm Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Two Phase 3, randomized controlled trials (BLISS 52/76) studied the efficacy and safety of belimumab plus standard of care (SoC) in systemic lupus erythematosus (SLE) over 52/76 weeks. A pooled analysis (201223) of the BLISS long-term extension (LTE) studies (BEL112233/NCT00724867; BEL112234/NCT00712933) reported low levels of organ damage accrual in patients who received belimumab plus SoC for 5 years (measured by the Systemic Lupus International Collaborating Clinics [SLICC]/American College of Rheumatology Damage Index [SDI]).<sup>1</sup> These studies were open-label with no SoC arm. In order to compare belimumab plus SoC to SoC alone, we conducted a post hoc, propensity score-matched (PSM) analysis (BEL206347) of changes in SDI scores of US patients treated with belimumab plus SoC in the BEL112233 LTE versus patients treated with SoC alone in the Toronto Lupus Cohort (TLC) over 5 years.

**Methods:** The TLC was identified as the most suitable source of SoC comparator data for the LTE studies.<sup>2</sup> A literature review identified potential patient and disease characteristics that impact organ damage for use in the PSM. Propensity scores for each LTE and TLC patient were compared to find an acceptable match (1:1 match, 20% caliper). The primary endpoint was the difference in change in SDI from baseline to Year 5 between patients treated with belimumab plus SoC versus SoC alone, based on the US BLISS LTE and the TLC. A regression augmented inverse PS weighting (IPSW) model tested the robustness of the results. Secondary analyses included parametric hazard models of the time to first increase in SDI score and a proportions test of the magnitude of year-to-year increases in SDI.

**Results:** 17 clinical variables were used to calculate the PS; all were well balanced in the sample after PSM. The primary outcome results (5-year SDI change) demonstrated that belimumab was associated with a 0.444 smaller increase (95% confidence interval [CI]: -0.697, -0.191) compared with SoC (Table). The regression augmented IPSW model demonstrated a similar treatment effect estimate (coefficient, -0.450; standard error (SE) 1.115; p>0.001).

Belimumab was associated with a significantly slower rate of organ damage progression (any increase) compared with SoC (hazard ratio: 0.312; SE: 0.087; 95% CI: [0.226, 0.605], p<0.001). Among patients with SDI increases, those treated with SoC alone were more likely to experience an increase of 2+ compared to belimumab plus SoC (30.56% vs 6.06%; p=0.006).

Table. Summary of 5-year SDI change in patients with ≥5-year follow-up: PS 1:1 match with caliper

	z-value	Baseline (SE) [95% CI]	5 years (SE) [95% CI]	Change from baseline (SE) [95% CI]	Treatment effect (SE)
Belimumab + SoC (N=99)	-3.46	0.768 (0.135) [0.502, 1.033]	1.051 (0.154) [0.748, 1.353]	0.283 (0.059) [0.166, 0.340]	-0.444 (0.128) p=0.001
SoC (N=99)		0.717 (0.099) [0.523, 0.911]	1.444 (0.150) [1.149, 1.740]	0.727 (0.114) [0.503, 0.952]	

**Conclusion:** This longitudinal PSM study comparing belimumab plus SoC to SoC alone indicates that belimumab had a clinically significant impact in slowing the rate of organ damage, measured by SDI.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Longterm Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

We have previously shown that Latin American SLE patients treated with Antimalarials (AMs) have a 25% lower risk of damage accrual than patients not receiving them<sup>1</sup>. The present study was conducted to assess the effects of AMs over the 12 items of the SLICC Damage Index, (SDI).

### Methods:

Patients with a recent SLE diagnosis ( $\leq 2$  years) from the GLADEL cohort were studied. End-point: Increase in the 12 items SDI since cohort entry.

Independent (socio-demographic, clinical laboratory and treatment) variables were included. The effect of AMs as a time dependent variable on items of the SDI (adjusting for potential confounders) was examined with a multivariable Cox regression model. Multivariate models were developed for the most common SDI items.

**Results:**

Of the 1,466 patients included in this analysis 1049 (72%) received AMs during follow-up (as defined); median exposure time: 30 months (Q1-Q3: 11–57 months). Total damage accrual occurred in 665 (45%) patients during a median follow up time of 24 months (Q1-Q3: 8-55) months. Within the 12 items of the SDI there were 301 integument, 208 renal, 149 neuropsychiatric, 98 musculoskeletal, 88 cardiovascular, 65 ocular, 43 pulmonary, 42 peripheral vascular, 33 gastrointestinal, 22 premature gonadal failure, 16 diabetes and 9 malignancy. After adjusting for potential confounders, at any time during follow-up a patient on AMs had a 35% and 30% lower risk of renal and neuropsychiatric damage accrual respectively than a patient not on AMs (adjusted HR 0.65, 95%CI 0.47–0.90 and HR 0.70, 95% CI 0.48–1.02). Such protective effect was not evident for integument, musculoskeletal and cardiovascular damage.

**Conclusion:**

After adjustment for possible confounding factors related to AMs use and damage accrual, AMs were independently associated with a reduced risk of renal and neuropsychiatric damage accrual in this cohort.

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Longterm Outcomes

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### **Background/Purpose:**

Little is known about the association of healthcare costs and damage accrual. We describe the costs associated with damage progression using multi-state modeling.

### **Methods:**

Patients fulfilling the revised ACR Criteria for SLE from 32 centres in 11 countries were enrolled in the SLICC Inception Cohort within 15 months of diagnosis. To supplement the primary data collection, patients were sampled cross-sectionally at a single time between 4 and 17 years of disease duration on healthcare use and lost labour force/non-labour force productivity over the preceding year. Healthcare use was costed using 2017 Canadian prices (direct costs) and lost productivity using 2017 Statistics Canada age-sex specific wages (indirect costs). Annual costs associated with damage states (SLICC/ACR Damage Index [SDI]) were estimated from multiple regressions adjusting for age, sex, race/ethnicity, and disease duration. Five and 10-year cumulative costs were estimated by multiplying annual costs associated with each SDI state by the expected duration in each state, forecasted using a multi-state model and longitudinal SDI data from the SLICC Inception Cohort (*Bruce IN. Ann Rheum Dis 2015;74:1706-13*). Future costs were discounted at a yearly rate of 3%.

## Results:

457 patients participated, 88.2% female, 44.6% Caucasian, mean age at diagnosis 33.6 years, mean disease duration at time of the economic data 10.0 years, mean SLE Disease Activity Index (SLEDAI-2K) 2.97, and mean SDI 1.07. Annual direct costs were higher in those with an SDI  $\geq 5$  (Table 1). At SDI  $\geq 2$ , hospitalizations and medications accounted for 54.3% of direct costs, whereas at SDI  $\geq 3$ , dialysis was responsible for 55.6%.

Table 1. Predicted Annual Health Costs Stratified by SDI

SDI State	Direct Costs, Mean, 95% CI 2017 Canadian \$	Indirect Costs, Mean, 95% CI 2017 Canadian \$	Total Costs, Mean, 95% CI 2017 Canadian \$
0	4642 (3187, 6098)	22611 (16130, 29091)	27253 (20394, 34112)
1	5937 (4472, 7401)	28 934 (22358, 35509)	34870 (27911, 41830)
2	5895 (3763, 8027)	30 573 (21 839, 39 307)	36 468 (27223, 45713)
3	9074 (5387, 12760)	26 743 (12937, 40549)	35 817 (21204, 50429)
4	4241 (0, 9825)	24197 (3364, 45029)	28437 (6387, 50488)
$\geq 5$	20014 (14270, 25757)	26758 (6481, 47035)	46771 (25310, 68233)

Cumulative 5 and 10-year direct costs increased with increasing baseline SDI (Table 2). Indirect costs did not vary with baseline SDI.

Table 2. Predicted 5 and 10- Year Cumulative Costs Stratified by Baseline SDI

## Conclusion:

Patients with the highest baseline SDIs incurred cumulative 5 and 10-year direct costs approximately 4-fold higher than those with the lowest SDIs. However, indirect costs were influenced by factors other than SDI (potentially disease activity, quality of life, fatigue, plateauing of expectations regarding productivity later in the disease) and patients incurred considerable indirect costs even with no or minimal damage. This work demonstrates the substantial increase in direct costs in patients with higher damage, highlighting the cost savings potentially achieved by earlier introduction of therapies more effective at attenuating damage progression.

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Systemic sclerosis (SSc) is a connective tissue disease characterized by dysregulated fibrosis of the skin. During fibrosis, macrophage release of transforming growth factor (TGF- $\beta$ ) and resistin like-alpha (RELM- $\alpha$ ) leads to myofibroblast over-activation and excessive extracellular matrix deposition. However, the role of post-translational fucosylation in fibrosis has yet to be examined. Herein, we demonstrate mechanisms by which fucosyltransferase-1 (Fut1) contributes to macrophage driven fibrosis and to TGF- $\beta$  signaling in murine and SSc DFs.

**Methods:** Wild type (WT) and Fut1 knockout (Fut1<sup>-/-</sup>) mice were intradermally injected with bleomycin or PBS and euthanized at days 1, 3, 5, and 9 to evaluate the longitudinal involvement of macrophages in skin fibrosis. Following euthanasia, fibrotic murine skin was harvested to assess cytokine expression by qPCR or pro-fibrotic macrophage ingress by immunofluorescence. To determine whether Fut1 was critical to macrophage-induced myofibroblast differentiation, WT and Fut1<sup>-/-</sup> macrophages were co-cultured with WT DFs for 48h. Co-culture supernatants were collected for ELISAs for pro-fibrotic cytokines TGF- $\beta$ , RELM- $\alpha$ , IL-6, and MCP-1. DF alpha smooth muscle actin ( $\alpha$ -SMA) and type 1 collagen (Colla1) expression were assessed via qPCR. WT and Fut1<sup>-/-</sup> DFs were stimulated with TGF- $\beta$  and downstream transcription factor expression assessed via qPCR. Fucosylation of TGF- $\beta$ R1 by Fut1 was confirmed by ulex europaeus agglutinin 1 (UEA1) immunoprecipitation. Lastly,  $\alpha$ -1,2 fucosidase treatment of SSc DFs was performed to determine whether Fut1-added fucose was critical to TGF- $\beta$ R1 function.

**Results:** Fut1<sup>-/-</sup> mice were resistant to bleomycin-induced fibrosis. At day 5, Colla1, TGF- $\beta$ , and RELM- $\alpha$  mRNA were significantly reduced in Fut1<sup>-/-</sup> compared to WT fibrotic skin. Additionally, at day 5 and 9, Fut1<sup>-/-</sup> mice exhibited significantly fewer F4/80+ RELM- $\alpha$ + macrophages in skin lesions, suggesting the involvement of Fut1 in pro-fibrotic macrophage function. IL-6, MCP-1, M-CSF, and RELM- $\alpha$  expression in supernatant were significantly reduced in WT DF co-culture with Fut1<sup>-/-</sup> compared to WT macrophages.

Consequently, WT DF expression of  $\alpha$ -SMA and Col1a1 mRNA was significantly diminished in Fut1<sup>-/-</sup> compared to WT macrophage co-culture, suggesting the involvement of Fut1 in macrophage-induced myofibroblast differentiation. TGF- $\beta$ R1 is fucosylated by Fut1 in murine and SSc DFs, as suggested by UEA1 immunoprecipitation. Fut1<sup>-/-</sup>DFs exhibit diminished expression of TGF- $\beta$  associated transcription factors compared to WT, pointing to the involvement of Fut1 in TGF- $\beta$ -mediated functions. Finally,  $\alpha$ -1,2 fucosidase diminished TGF- $\beta$ R1 expression detected by flow cytometry, indicating that Fut1 regulates TGF- $\beta$  signaling via the critical addition of  $\alpha$ -1,2 fucose to TGF- $\beta$ R1.

**Conclusion:** Overall, this work provides novel evidence that Fut1 mediates macrophage-driven fibrosis and that Fut1-catalyzed fucosylation of TGF- $\beta$ R1 regulates TGF- $\beta$  signaling. The multi-faceted involvement of Fut1 in fibrosis points to its candidacy as a novel therapeutic target in the treatment of SSc.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Previous global gene expression studies of SSc patients revealed presence of a prominent type I interferon (IFN) signature. IRF7 is a key transcription factor in the IFN signaling pathway. Polymorphisms in *IRF7* gene are associated with SSc susceptibility. In our more recent global gene expression studies examining established disease, IRF7 was predicted to be the most activated upstream transcription factor in SSc skin and blood cells. Therefore, IRF7 might play a key role in the interplay between inflammation and fibrosis in this multifaceted disease. However, the specific role of IRF7 in SSc pathogenesis and fibrosis has not been identified.

**Methods:** Skin punch biopsies were collected from early diffuse SSc patients (n=57) and age-, gender-, and ethnicity-matched healthy controls (n=33) for global gene expression studies. IRF7 activation was also determined in tight skin 1 (TSK1/+ mouse) model. Next, we investigated the impact of IRF7 KO on skin fibrosis in TSK1 mice. We utilized loss-of-function approaches in TSK1/+ mice, to generate TSK1/+ IRF7 -/- double transgenic mouse model. Twelve weeks old TSK1+/IRF7 KO mice skin tissue (n=7) was analyzed for collagen,  $\alpha$ -SMA and fibronectin mRNA and protein expression.

**Results:** In agreement with our data in established disease, the global gene expression profiling of early diffuse SSc skin (median disease duration = 1.1 years) revealed that IRF7 was the **top activated upstream transcription factor** (activation z-score=8.101,  $p=1.3 \times 10^{-25}$ ). Several other transcription factors in type I IFN signaling pathway such as STAT1, STAT4, IRF1, and IRF3 were also among top 10 activated transcription factors. Consistent with our previous data in bleomycin induced dermal fibrosis model, TSK1/IRF7 KO transgenic mice showed reduced type I collagen mRNA and protein expression compared to TSK1/+ mice. Col1a2 mRNA levels were lower in TSK1/IRF7 KO mice ( $1.41 \pm 0.21$  folds) vs. in TSK1/+ mice ( $2.64 \pm 1.06$  folds) compared to control wildtype mice. Hypodermal thickness in TSK1/IRF7 KO mice was also significantly reduced compared to TSK1/+ mice ( $303.4 \pm 72.5$   $\mu$ m Vs.  $715.2 \pm 161.9$   $\mu$ m;  $p=0.036$ ). Finally, the myofibroblast marker  $\alpha$ -SMA and fibronectin in the skin tissue was also significantly reduced in the TSK1/IRF7 double transgenic mice compared to TSK1/+ mice skin on immunohistochemistry.

**Conclusion:** Activation of IRF7 might play a pivotal role in the type I IFN driven inflammatory response followed by fibrosis in SSc. IRF7 may therefore represent a promising novel therapeutic target in SSc.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Signal transducer and activator of transcription 3 (STAT3) is a transcription factor that regulates key cellular processes such as proliferation, apoptosis, invasion, angiogenesis, metastasis and immune responses. STAT3 can be phosphorylated and activated by various kinases, several of which have been implicated in aberrant fibroblast activation in fibrotic diseases including systemic sclerosis (SSc). We hypothesized that profibrotic signals converge on STAT3 and that STAT3 may be an important molecular checkpoint for tissue fibrosis.

**Methods:** Activation of STAT3, JAK1, JAK2, SRC, c-ABL and JNK was analyzed in SSc patients and in experimental models of SSc by real-time PCR, Western Blot and immunohistochemistry. Selective inhibitors in conjunction with knockdown and knockout strategies were used to target STAT3 signaling and its upstream kinases *in vitro* and *in vivo*. The anti-fibrotic potential of genetic and pharmaceutical inactivation of STAT3 was evaluated in two mouse models of SSc: bleomycin-induced fibrosis and fibrosis induced by overexpression of a constitutively active TGFβ receptor type I (TBRact).

**Results:** Accumulation of phosphorylated and thus active STAT3 (P-STAT3) was detected in fibroblasts in the skin of SSc patients as compared to healthy volunteers. Enhanced STAT3 signaling was also found in murine models of SSc. The upregulation of P-STAT3 was found to be mediated by TGFβ signaling. Expression profiling and functional studies *in vitro* and *in vivo* demonstrated that the activation of STAT3 is mediated by the combined action of JAK, SRC, c-ABL and JNK kinases. STAT3-deficient fibroblasts were less sensitive to the pro-fibrotic effects of TGFβ. Fibroblast-specific knockout of STAT3 also ameliorated experimental fibrosis. In the model of bleomycin-induced fibrosis, dermal thickening was decreased by 77%, collagen content by 52% and myofibroblast counts by 58% compared to littermates with normal expression of STAT3. STAT3 knockout mice were also protected from TBRact-induced fibrosis. Pharmacological inhibition of STAT3 using the small molecule inhibitor S3I-201 exerted potent anti-fibrotic effects and inhibited TGFβ-induced fibroblast activation, bleomycin- and TBRact-induced experimental fibrosis in pharmacologically relevant and well tolerated doses.

**Conclusion:** We demonstrate that STAT3 integrates several profibrotic signals in SSc and might thus be a novel core mediator of fibrosis. Inhibition of STAT3 prevented fibroblast activation and demonstrated potent anti-fibrotic effect in different preclinical models of SSc. Considering the potent anti-fibrotic effects observed in this study and the fact that several STAT3 inhibitors are currently tested in clinical trials, STAT3 might be an interesting candidate for molecular targeted therapies of SSc.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Canonical Wnt/ $\beta$ -catenin signaling has emerged as a core pathway of fibrosis. Their role of non-canonical Wnt signaling, however, has not been systematically studied. In this study we aimed to characterize the role of non-canonical WNT signaling in the pathogenesis of fibrotic diseases such as systemic sclerosis (SSc).

**Methods:** The expression of Wnt ligands was analyzed in patients with SSc, idiopathic pulmonary fibrosis (IPF) and sclerodermatous chronic graft-versus-host disease (cGvHD). The functional role of non-canonical WNT signaling was evaluated in full thickness skin grafts, in bleomycin-induced fibrosis and in experimental cGvHD. WNT signaling was modulated *in vitro* and *in vivo* using small molecule inhibitors, siRNA mediated knockdown, fibroblasts specific recombination and soluble decoy receptors.

### Results:

Profiling of all non-canonical WNT ligands demonstrated that WNT5A is the predominant non-canonical Wnt ligand in skin and lungs with pronounced overexpression in patients with SSc, IPF and cGvHD as compared to non-fibrotic controls. WNT5A induced fibroblast-to-myofibroblast transition and collagen release in conventional cell culture and in full-thickness skin models *in vitro* and was sufficient to induce dermal and pulmonary fibrosis *in vivo*. Fibroblast-specific knockout of Wnt5a ameliorated bleomycin-induced fibrosis and experimental cGvHD. The profibrotic effects of WNT5A were independent of canonical Wnt signaling and of WNT/Calcium signaling, but were mediated by the planar cell polarity pathway (PCP). Genetic or pharmacologic inactivation of JNK or of cJUN abrogated the profibrotic effects of WNT5A. Further profiling revealed that WNT5A activates ROR2 and RYK receptors and that RAC1, RHOA and PI3K are essential further signaling intermediates. Of note, WNT5A stimulation also induced SMAD3 phosphorylation within 10 min in a PCP-dependent manner. SMAD3 phosphorylation was not mediated by JNK-dependent transphosphorylation of SMAD3 or dependent on transactivation of TGF- $\beta$  receptor by RYK, but induced by a rapid increase in the fraction of active, but not of total TGF- $\beta$ . Activation of latent TGF- $\beta$  by WNT5A/PCP signaling required MMPs, thrombospondin-

1(TSP-1) and integrin  $\alpha_V$ , but not ROS generation. Inactivation of MMPs, TSP-1 or integrin  $\alpha_V$  prevented WNT5A induced SMAD3 phosphorylation and ameliorated WNT5A-induced fibroblast activation.

**Conclusion:** We characterize WNT5A-induced PCP signaling as a novel pro-fibrotic mediator in fibrotic diseases. WNT5A contributes to the increased activation of TGF- $\beta$  signaling in fibrotic diseases. We also provide evidence that WNT5A/PCP signaling may be a potential target for therapeutic intervention in fibrotic diseases.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Systemic sclerosis (SSc) is a multisystem disease that has a higher prevalence in African Americans (AA), with a more severe phenotype, internal organ involvement, and increased mortality. Genetic risk factors contributing to the AA SSc phenotype are largely unknown.

**Methods:** The Genome Research in African American Scleroderma Patients consortium (GRASP) was established to recruit AA patients to investigate the genetic basis of SSc. The Illumina MEGA array was used to genotype 934 patients and 946 controls to conduct the first genome-wide association study (GWAS) of SSc in AA. A total of 1.7 million variants were genotyped and after quality control filtering 1.4 million variants remained and were imputed into the 1000 Genomes Phase 3 v5 reference panel. We utilized HiChIP, a protein-centric chromatin conformation method, to elucidate the role of these variants.

**Results:** Admixture and principal component analysis (PCA) confirmed that the patients and controls were well-matched.  $\lambda_{GC}$  was 1.03, suggesting no major population stratification. The MHC region demonstrated the strongest association after accounting for the top 10 PCAs (Figure 1). The rs35915063 was the top scoring variant in the *HLA-DQB1* gene  $P=2.2 \times 10^{-17}$ , OR=1.96 (95% CI 1.7-2.3). Stepwise conditional regression analysis using an additive model revealed the *DQA1* gene variant rs9271620 ( $P=1.01 \times 10^{-8}$ ) and the *DPB1* gene variant rs2071354 ( $P=5.8 \times 10^{-8}$ ) as independent risk variants. eQTL databases revealed a reduction in *DQB1*, *DQA1*, and *DRB1* expression and an increase in *DPB1* and *DQA2* expression based on the associated allele of these three variants. The rs59063398 variant showed the strongest non-MHC association with  $P=2.0 \times 10^{-8}$ , OR=0.47 (95% CI 0.4-0.6) (Figure 2A). This variant is part of an evolutionarily conserved haplotype in the *IFT43* gene region that is African ancestry specific. Overlaying our GWAS data on the H3K27ac HiChIP data in Th17 and Treg cells highlighted *IFT43* intronic variants falling under the *TGFB3* promoter peak, suggesting potential alteration of *TGFB3* promoter activity and in turn regulation of *TGFB3* expression (Figure 2B).

**Conclusion:** This first GWAS of SSc in AA confirms MHC as a susceptibility locus and identifies a novel (*TGFB3*), non-MHC locus, as a SSc susceptibility gene. *IFT43*/*TGFB3* region variants are non-polymorphic in Europeans, suggesting an explanation for the increased prevalence and severity of SSc in AA. *TGFB3* has a role in fibrosis and in development of effector Th17 cells, raising the possibility of therapies targeting these pathways.

**Figure 1** GWAS of Illumina MEGA array using 934 SSc cases and 946 controls. Data shown here are from trend test after correcting for the top ten PCAs. Pink line denotes p-value for genome-wide significance ( $P=5 \times 10^{-8}$ ) and purple line denotes  $P=5 \times 10^{-5}$ .

**Figure 2 A.** Chr 14 region association analysis showing genotyped (red) and imputed (blue) variants in 934 SSc cases and 946 controls. Data shown here are from trend test after correcting for the top ten PCAs. **B.** Imputed Chr 14 GWAS data overlaid with H3K27ac HiChIP data in Th17 and Treg cells. The tall peak is anchored on *TGFB3* promoter. Pink arrow highlights the *IFT43* variants that fall under the *TGFB3* promoter peak.

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** While skin fibrosis is a hallmark of systemic sclerosis (SSc), internal organ involvement is the primary cause of morbidity and mortality, often related to pulmonary disease and gastrointestinal (GI) dysfunction. Here we tested the hypothesis, generated from a meta-analysis of ten different SSc datasets, that any single patient with SSc would have the same deregulated molecular signatures across multiple organ systems, consistent with the systemic nature of the disease.

**Methods:** RNA sequencing (RNA-seq) was performed on at least four organ biospecimens (skin, esophagus, fundus, duodenum, and/or blood) from 14 patients who met 2013 ACR/EULAR criteria for SSc. RNA was sequenced by 75bp paired-end RNA-seq at >80 million reads per sample and aligned to the reference genome (hg19). Each sample was assigned to an intrinsic subset (inflammatory, proliferative, or normal-like) using Support Vector Machine (SVM) classification and unsupervised hierarchical clustering with profiles of normalized Reads Per Kilobase of transcript per Million mapped reads (RPKM) values.

**Results:** Hierarchical clustering of the RPKM data showed that samples from a single tissue type cluster tightly together. Analysis of skin and esophagus individually also recapitulated the intrinsic subsets previously observed in these organs. Furthermore, for the first time, the inflammatory, proliferative, and normal-like intrinsic subsets were identified in the fundus and duodenum. The blood of patients with SSc also displayed gene expression signatures of the inflammatory, proliferative, and normal-like intrinsic subsets. Subsequent normalizing for tissue type in an agglomerative analysis of all tissues results in the identification of intrinsic gene expression subsets across organ systems. Importantly, all five organs assessed were represented in each intrinsic subset. The majority of patients (9/14) showed >60% concordance of intrinsic subset assignment across the multiple organs analyzed. Moreover, tissues from the gastrointestinal tract tended to belong to the same subset (5/14 with 100% concordance).

**Conclusion:** We have performed the first molecular analysis of biospecimens from multiple organs within an individual patient with SSc. Our data suggest that SSc molecular subsets are reproducible in different tissues and that deregulated molecular pathways are conserved across organ systems within the same patient. These data indicate that intrinsic subsets are common feature of end-organ pathology in SSc. We cannot rule out the possibility that pathogenic mechanisms of disease activity and progression are discordant in

time in each organ, consistent with clinical observation. Further work is focused on using functional genomic networks to assess consistent and organ-specific mechanisms of disease. A subset of the samples have been queued for DNA methylation array and ATAC-seq.

**Session Title:** Vasculitis III: Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Takayasu arteritis (TA) and giant cell arteritis (GCA) are large-vessel vasculitis characterized by vascular remodelling involving endothelial cells (ECs) and vascular smooth muscle cells, leading to ischemic events. We hypothesized that mammalian target of rapamycin (mTOR) pathway could drive vascular inflammation and remodelling in large-vessel vasculitis.

**Methods:** To study activation of mTOR pathway in injured vessels from patients with TA and GCA, we evaluated phosphorylation of S6RP (p-S6RP) and AKT (p-AKT Ser 473) by immunofluorescence analysis on aorta and temporal arteries biopsies, which reflect activation of mTORC1 and mTORC2, respectively. To investigate the potential role of antibodies binding to ECs in the activation of mTOR pathway, sera from patients with TA, GCA and healthy controls (HCs) were screened for the presence of antibodies against ECs (AECA) using indirect immunofluorescence (IIF) and cellular ELISA. We evaluated *in vitro* the effect of purified IgG from patients with AECA on mTOR pathway activation and cell proliferation. Target antigens of AECA were investigated by Western-blotting.

**Results:** Immunofluorescence analysis on tissues revealed that adventitial vessels from aorta's vasa vasorum from TA patients were strongly positive for both p-S6RP and p-AKT (Ser 473) in ECs but not in vascular smooth muscle cells, showing that both mTORC1 and mTORC2 were specifically activated in ECs in TA, but not in ECs from GCA patients and HCs (**Figure 1**). Using IIF and cellular

ELISA, we observed higher levels of AECA in TA patients compared to GCA and healthy controls (HCs) with these two techniques. Using Western blot, we demonstrated that purified IgG from TA patients caused mTORC1 activation in ECs, whereas this effect was not observed with purified IgG from GCA or HCs. mTORC1 was activated through PI3K-AKT pathway, suggesting that recruitment of AKT to the cell membrane is necessary for activation of the mTOR pathway induced by serum IgG in TA. Finally, purified IgG from TA induced a significant ECs proliferation compared to GCA and HCs IgG, and this effect was decreased after ECs exposure with sirolimus, a specific mTOR inhibitor, and PI3K inhibitor. Sera obtained from TA patients with positive screening of AECA bound predominantly to an endothelial cell antigen with a molecular weight between 60 and 65 kDa.

**Conclusion:** Our results suggest that antibodies against ECs drive vascular inflammation leading then to vascular remodelling in TA through activation of mTOR pathway in ECs, but not in GCA. Inhibition of mTOR pathway could represent an alternative therapeutic option in TA.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Vasculitis III: Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Adventitial microvascular networks (vasa vasora) control the access to the wall structure of medium and large arteries and thus guard the immune privilege of the aorta and its branches. In giant cell arteritis (GCA), CD4 T helper 1 (Th1) and Th17 cells obtain access to the arterial wall layers, where together with macrophages they form granulomatous infiltrates. Whether the small adventitial vessels have a pathogenic role in GCA is unknown.

**Methods:** Tissue transcriptomes were examined in tissue biopsies of patients with temporal arteritis or GCA aortitis, and genes-of-interest were confirmed by immunohistochemical staining. Unprimed CD4 T cells were collected from peripheral blood of patients with active GCA and age-matched healthy controls. Effector cell differentiation was analyzed by detecting intracellular cytokines by flow cytometry or immunohistochemistry. Microvascular endothelial cell (mvEC)-T cell interactions were studied in an ex vivo and in vivo system. Relevant signaling pathways were identified by iRNA technology (Notch1, Raptor), small molecule inhibitors (NOTCH and mTORC1 inhibitors) and monoclonal antibodies

## Results:

Microvascular endothelial cells (mvEC) in the adventitia of GCA-affected temporal arteries and aortas expressed abundant Jagged1, a ligand for the cell-fate-regulating receptor Notch1. Patients with active GCA had high frequencies of Notch1+ CD4 T cells, which had left the quiescent state and acquired effector cell characteristics. Jagged1-expressing mvEC were able to instruct CD4 T cells to enter differentiation and commit to Th1 and Th17 differentiation. In vivo, upregulation of Jagged1 on adventitial microvessels intensified the inflammatory activity of the vasculitogenic lesions by increasing the frequency of tissue-residing IFN- $\gamma$ -producing effector cells. Jagged1-induced T cell instruction was dependent on the mTORC1 signaling pathway; commitment to either the Th1 or the Th17 lineage was sensitive to mTORC1 inhibitors.

**Conclusion:** Adventitial microvessels form an instructive tissue niche, that protects medium and large arteries from inflammatory attack. In GCA, this immune-protective mechanism fails and Jagged1-expressing mvEC stimulate and instruct Notch1+ CD4 T cells. This signal is sufficient for CD4 T cells to invade into the tissue site and acquire pathogenic effector functions. Vasculitogenic functions depend on the mTORC1 signaling pathway. Overall, these findings identify multiple actionable steps in the pathogenesis of GCA

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Vasculitis III: Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Macrophages are key effector cells in the vessel wall inflammation of the atherosclerotic plaque as well as in the intramural infiltrates of giant cell arteritis (GCA). The histomorphology of both diseases is distinct; GCA macrophages are arranged in granulomatous lesions and form giant cells, whereas plaque-residing macrophages facilitate lipid uptake and participate in a fibro-inflammatory reparative process. Whether the profile of inflammatory macrophage functions is comparable in both conditions and which signaling pathways drive macrophage activation in the vessel wall lesions is insufficiently understood.

**Methods:** Tissue-residing macrophages were analyzed in biopsies from atherosclerotic plaques and from GCA-affected temporal arteries. Monocyte-derived macrophages were generated from peripheral blood CD14+ precursor cells by differentiating the cells with

M-CSF over a 5-day culture. Macrophages were stimulated with 100 U/ml IFN- $\gamma$  and 100 ng/ml LPS. Patients were enrolled if they had (a) at least one documented myocardial infarct or (b) a temporal artery biopsy positive for GCA. Tissue transcriptomes and gene expression panels from macrophages were established by RT-PCR. Protein expression was examined by flow cytometry and by immunohistochemical staining of tissue sections.

**Results:** In macrophages from patients with CAD glucose transporters and enzymes of the glycolytic pathway were strongly upregulated (Glut1, HK2, GAPDH, PKM1, PGM1, HIF1 $\alpha$ , and c-myc). Glucose and its breakdown product pyruvate directly controlled the production of inflammatory cytokines (IL-1b, IL-6) and regulated the expression of co-stimulatory (CD80, CD86) and co-inhibitory ligands (PD-L1). Most plaque-residing macrophages were PD-L1<sup>hi</sup> expressors. In contrast, the glycolytic machinery was not upregulated in GCA macrophages. Profiling for chemokines and cytokines revealed high expression of CXCL9, 10 and 11 in GCA macrophages, but the inflammatory cytokines IL-1, IL-6 and TNF were indistinguishable in GCA patients versus normal controls. Opposite to CAD macrophages, GCA macrophages were characterized by low expression of the co-inhibitory ligand PD-L1. Tissue-residing cells in temporal artery lesions also had the PD-L1<sup>low</sup> phenotype.

**Conclusion:** Signaling pathways driving the activation of macrophages in the atherosclerotic plaque and in GCA lesions are fundamentally different. CAD macrophages are characterized by a metabolic defect, over-utilize glucose and are functionally a hybrid between excess cytokine release and high expression of PD-L1. GCA macrophages are biased towards chemokine production. The low expression of the immuno-inhibitory ligand PD-L1 enables them to strongly promote T cell effector functions.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Vasculitis III: Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

Prior studies have suggested a potential link between nasal microbes, in particular *Staphylococcus aureus*, and granulomatosis with polyangiitis (GPA; Wegener's) but these studies relied on culture-dependent methods. This study comprehensively examined the entire community of nasal microbiota in patients with GPA compared to healthy controls using deep sequencing methods.

### Methods:

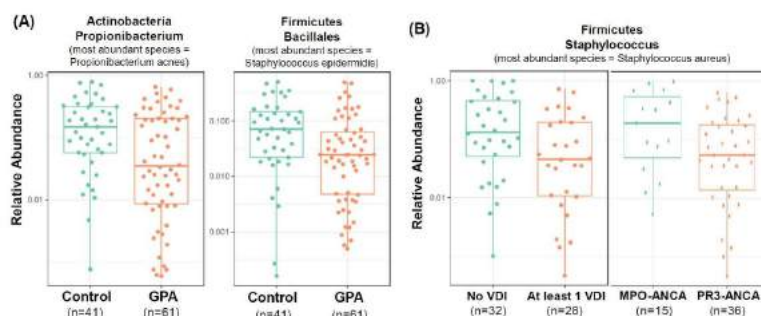

The nasal microbiota of 61 patients with GPA and 41 healthy controls was sampled using nasal swabs and analyzed by sequencing of the bacterial 16S rRNA gene (V1-V2 region). The abundance profiles of the 11 most abundant bacterial taxa were compared using the Wilcoxon rank sum test, correcting for multiple comparisons. Additional comparative analyses within the GPA cohort were performed by ANCA type (PR3 vs MPO), presence or absence of sinonasal Vasculitis Damage Index items (VDI), and disease activity (active vs remission). The effects of antibiotics and immunosuppressive therapies (both current and within the past 6 months) were evaluated using generalized linear models.

### Results:

*Corynebacterium*, *Propionibacterium*, and *Staphylococcus* featured as prominent bacterial taxa in the nasal swab samples, consistent with previous reports. After clustering the sequence reads into operational taxonomic units, we identified two abundant groups of *Staphylococcus* in the data: one closely related to *S. aureus* and the other similar to *S. epidermis*. The *S. epidermis* cluster and *Propionibacterium* were decreased in abundance in GPA vs controls (**Figure 1A**). In multivariate analyses, patients with GPA receiving non-glucocorticoid immunosuppressive therapy had a higher abundance of *Propionibacterium* ( $p = 0.01$ ) that was similar to the abundance seen in healthy controls. Among patients with GPA, there was a lower abundance of the *S. aureus* cluster in i) subjects with PR3- vs MPO-ANCA; and ii) subjects with at least 1 sinonasal VDI item vs. those without a sinonasal VDI item (**Figure 1B**). In multivariate analyses, ANCA type remained significantly associated with abundance of *S. aureus* independent of medications and presence of a sinonasal VDI item ( $p = 0.01$ ).

### Conclusion:

Nasal microbial communities differ between patients with GPA and controls as well as between clinically-distinct subsets of GPA. Interestingly, a lower abundance of *Propionibacterium* (which prior studies have suggested may negatively interact with *S. aureus*) was found in patients with GPA, particularly among those off immunosuppressive therapies, raising the possibility that a loss of the “protective” effect of *Propionibacterium* may increase susceptibility to colonization by pathogens such as *S. aureus*. These data support the theory that microbes are involved in the disease process of GPA and that a deeper understanding of dysbiotic microbial communities in GPA could lead to novel preventative or therapeutic strategies.

**Figure 1: Bacteria with Differential Abundance Between Patients with Granulomatosis with Polyangiitis (GPA) and Controls and within GPA Subgroups.** (A) Compared to healthy controls, patients with GPA had a lower proportion of *Propionibacterium*, primarily composed of *P. acnes* ( $p = 0.04$ , corrected for false discovery rate), and *Bacillales*, primarily composed of *S. epidermidis* ( $p = 0.04$ , corrected for false discovery rate). (B) There was a lower abundance of *Staphylococcus*, primarily composed of *S. aureus*, among patients with at least 1 sinonasal VDI item compared to none ( $p = 0.02$ ) and among patients with PR3-ANCA compared to MPO-ANCA ( $p = 0.04$ ).

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Vasculitis III: Pathogenesis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

## Background/Purpose:

The current study is aimed to assess the effect of B-cell depletion on the distribution of effector T-cell subsets in AAV-patients. Alterations in CD4<sup>+</sup> Th effector cell (Th1/Th2/Th17/T<sub>FH</sub>) homeostasis may contribute to the therapeutic effect of rituximab (RTX) as Th-effector imbalances are involved in the emergence of autoimmune diseases.

## Methods:

Patients with active AAV were treated in a randomized, controlled trial with corticosteroids combined with RTX 375 mg/m<sup>2</sup> weekly x 4 or oral cyclophosphamide (CYC) 2m/kg/d for 6 months as induction therapy. Blood samples from 69 of these AAV-patients were obtained at baseline, 2 months, and 6 months (primary endpoint), and time of assessment for clinical remission. The frequency of circulating Th1 (producing IFN $\gamma$ ), Th2 (producing IL-4), Th17 (producing IL-17), and T<sub>FH</sub> (producing IL-21) cells were assessed at all time-points using flow cytometry upon *in vitro* stimulation with PMA and Calcium Ionophore.

## Results:

At baseline, the four circulating effector Th-cell subsets were comparable in frequency between the RTX-group and the CYC-group. Among the RTX-treated patients, the frequency of Th2 cells decreased steadily, whereas, no significant changes were seen in frequencies of Th1, Th17, and T<sub>FH</sub> cells. The frequencies of Th2 and T<sub>FH</sub> cells in CYC-treated patients remained unchanged during the follow-up compared to baseline; whereas, a significant increase was observed in Th17 and Th1 cells at 2 and 6 months, respectively. Interestingly, the decrease in the percentage of Th2 cells among the RTX-treated patients at 6 months was restricted to patients who achieved complete and sustained remission up to 18 months (n=24); whereas, no such changes were observed in patients who relapsed after the achievement of complete remission at 6 months (n=9). Moreover, among the CYC treated patients, the increases in Th17 cells at 2 and 6 months were restricted to patients who achieved complete and sustained remission (n=15) in comparison to those who experienced relapses (n=7).

## Conclusion:

In patients with active AAV, B-cell depletion therapy, as well as treatment with oral CYC influences blood Th cell homeostasis. Changes in Th cell during induction therapy with RTX or CYC may contribute to long-term clinical outcome.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Vasculitis III: Pathogenesis  
**Session Type:** ACR Concurrent Abstract Session  
**Session Time:** 9:00AM-10:30AM

### **Background/Purpose:**

Host genetics influence susceptibility to Kawasaki disease (KD), an acute pediatric vasculitis, and genome wide association studies (GWAS) have detected variants with modest effects on disease susceptibility. Recently we performed a pathway analysis using a European descent KD GWAS dataset. We reported that the antigen processing and presentation pathway was one of the top 50 pathways associated with KD susceptibility with 9 single nucleotide variants (SNVs) located near HLA-B and C in the HLA class I region driving the association. We speculated that these SNVs in the HLA class I region influence antigen presentation and KD susceptibility.

### **Methods:**

Nine SNVs in the HLA region from our European descent GWAS were tested for association with KD using a Japanese GWAS dataset. To explore the influence of these SNVs on KD susceptibility, we performed expression quantitative trait loci (eQTL) analysis using a US multi-ethnic cohort (n=146) and analyzed the associated polymorphic amino acid sequence of HLA-B and -C by HLA typing an independent U.S. multi-ethnic cohort (n=78) and a Japanese cohort (subset of Japanese GWAS n=275).

### **Results:**

Two SNVs (rs6906846 upstream of HLA-C and rs2254556 upstream of HLA-B) were significantly associated with KD susceptibility in both the European descent and Japanese GWAS datasets (combined nominal  $p=1.0 \times 10^{-4}$  for rs6906846 and  $p=7.0 \times 10^{-5}$  for rs2254556). HLA typing in both our U.S. multi-ethnic cohort (n=78) and the Japanese cohort (n=275) revealed association of the risk allele at this locus with specific HLA-C types (e.g. HLA-C\*07:02 U.S. and Japanese combined  $p=2.8 \times 10^{-30}$ ) and with specific amino acid sequences at multiple HLA-C positions, including several in the peptide binding groove that could influence peptide binding and presentation. The risk allele (A) at rs6906846 was associated with higher expression of HLA-C by microarray (n=146, AA vs. GG  $p<1.0 \times 10^{-4}$ ) and targeted amplification of whole blood RNA in an independent U.S. multi-ethnic cohort (n=42, AA vs. GG  $p<5.0 \times 10^{-2}$ ). We extended the eQTL analysis using our U.S. multi-ethnic array data (n=146) to 5 previously reported SNVs associated with KD that were located in/near genes in the HLA class I pathway from the Japanese GWAS: rs2854251 (proximal to antigen peptide transporter (TAP) 1/2 and proteasome subunit beta (PSMB) 8/9) and a Taiwanese GWAS: rs149481 (Endoplasmic reticulum aminopeptidase (ERAP)1/2 region), and rs1873668, rs4243399, and rs16849083 (coatamer protein complex subunit beta 2 (COPB2) region). In our U.S. multi-ethnic cohort (n=146), we found increased transcript levels of TAP2 (GG vs. AA  $p<5.0 \times 10^{-3}$ ) and PSMB8 (GG vs. AA  $p<5.0 \times 10^{-2}$ ), and reduced ERAP2 transcripts (AA vs. AC  $p<5.0 \times 10^{-3}$ ) associated with the corresponding risk alleles.

**Conclusion:** SNVs that influence the amino acid sequence in the HLA peptide binding groove and that serve as eQTL for HLA-C pathway proteins influence KD susceptibility in diverse ethnic groups. These findings suggest the importance of HLA-C antigen presentation to CD8+ T cells and/or NK cell regulation in KD pathogenesis.

## **Is Synovial Hypertrophy without Doppler Activity in Rheumatoid Arthritis Joints Sensitive to Change ? – Results of a Longitudinal Ultrasound Study**

Lene Terslev<sup>1</sup>, Mikkel Østergaard<sup>1</sup>, Joseph Sexton<sup>2</sup> and Hilde B Hammer<sup>2</sup>, <sup>1</sup>Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Denmark, Copenhagen, Denmark, <sup>2</sup>Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Imaging of Rheumatic Diseases II: Focus on Rheumatoid Arthritis and Systemic Sclerosis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Ultrasound (US) is used to assess diseases activity in rheumatoid arthritis (RA). Gray scale (GS) US shows the synovial hypertrophy (SH) and Doppler the amount of hyperemia which is believed to reflect disease activity. Some joints with SH may have no Doppler activity despite the use of high-end US equipment and these joints are generally believed to be inactive without potential to change. The aim is to investigate if joints with SH but no Doppler activity is sensitive to change during treatment with biological DMARD (bDMARD) in RA patients

**Methods:**

RA patients initiating or changing bDMARD treatment were included. US examination was performed at baseline, 3 and 6 months using Siemens Antares US equipment with Doppler settings for slow flow. 36 joints were evaluated at each visit. SH and Doppler activity was graded from 0-3 according to the US atlas by Hammer et al. The GS score for SH in joints without Doppler activity was registered for the individual joints using GS SH>1 as threshold. The changes were compared to changes in SH in joints with Doppler activity.

**Results:**

157 patients (83.2% women, 81.3% seropositive for anti-CCP and 75.8% for rheumatoid factor) were included, with a mean (SD) age of 51.5 (13.3) years and mean disease duration of 9.9 (8.1) years. At baseline, 52.2% used prednisolone (mean (SD) 7.7 (4.6) mg, range 2.5-25mg). The patients had a mean (SD) baseline DAS28 of 4.5 (1.5). At baseline 27% of the joints had SH without Doppler activity and 28% of the joints had SH with Doppler activity. Joints without Doppler had overall lower grades of SH (mean 0.72) than joints with Doppler (mean 1.21).

Of the joints that had SH without Doppler at baseline, 54% had a decrease in SH at 3 months, and 56% at 6 months. For joints with SH with Doppler at baseline, 52% had a decrease in SH at 3 months, and 60% at 6 months. The overall proportion of joints improving in SH was similar in joint with and without Doppler activity but when adjusting for the baseline score of SH, SH in joints without Doppler activity had a higher tendency towards decrease than those with Doppler activity (3 months:  $p < 0.0001$ ; 6 months  $< 0.0005$ ).

**Conclusion:**

SH in joints without Doppler activity improves during bDMARD, i.e is sensitive to change. Thus, SH without Doppler activity is not a sign of inactive disease. These findings document that both Doppler and SH should be evaluated when assessing disease activity by US.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Imaging of Rheumatic Diseases II: Focus on Rheumatoid Arthritis and Systemic Sclerosis

**Session Type:** ACR Concurrent Abstract Session

## Clinical Correlate of Synovial Proliferation in Early Rheumatoid Arthritis

**Background/Purpose:** To determine whether semi-quantitative, quantitative assessment of synovitis severity or synovial perfusion data correlates best with clinical symptoms and inflammatory markers.

**Methods:** 116 patients (88 females, 28 males, mean age,  $53 \pm 13$  years) with early (i.e. symptoms < 24 months) RA underwent 3T dynamic contrast-enhanced (DCE) MRI of the most symptomatic wrist. Sequences obtained were: fat-saturated T1-weighted axial; fat-saturated T2-weighted coronal; T1-weighted coronal and fat-saturated post-contrast T1-weighted axial.

Analyses undertaken included:

1. Semi-quantitative grading of (a) synovial proliferation (RAMRIS) and (b) tenosynovitis.
2. Quantitative measurement of enhancing synovial volume using segmentation method ( $\text{cm}^3$ ) (Fig 1).
3. Maximum enhancement (ME) and enhancement slope (ES) of enhancing synovium derived from time-intensity curves of DCE MRI data (Fig 2).
4. Clinical assessment (Simple Disease Activity Index) and inflammatory markers (erythrocyte sedimentation rate, C-reactive protein).

Clinical evaluation included a determination of morning stiffness (minutes), pain score (0-10), disease activity by the Simple Disease Activity Index (which reflects the number of swollen  $\pm$  tender joints) and serological inflammatory markers (ESR, CRP).

**Results:** Synovitis and tenosynovitis was present in 113 (97%) and 81 (70%) of the 116 wrists examined. Tenosynovitis was associated with more severe synovial proliferation. Regarding clinical correlation, quantitative parameters correlated much better with patient symptoms than semi-quantitative parameters. Morning stiffness and pain correlated with total synovial and tenosynovial volume ( $r=0.407$ ,  $p=0.028$ ) but not with RAMRIS ( $r=0.165$ ,  $p=0.196$ ). SDAI best correlated with ME and ES ( $r=0.502$ ,  $p<0.001$ ). ESR ( $r=0.380$ ,  $p=0.002$ ) and CRP ( $r=0.469$ ,  $p<0.001$ ) only correlated with ES.

**Conclusion:** Quantitative correlated with patient symptoms and serological inflammatory markers better than semi-quantitative parameters. Synovial volume was more related to morning stiffness and pain while perfusion parameters were more related to disease activity and inflammation.

**Fig 1.** Automated segmentation of enhancing synovium of the distal radioulnar joint (A) and following manual removal of adjacent vasculature (B). Joint synovial proliferation is seen as red, tenosynovial proliferation as green.

**Fig 2.** ERA patient (SDAI=40.46) with severe synovitis. The DCE perfusion curve was fit and  $E_{max} = 102.37$ ,  $E_{slope} = 526.08$  respectively.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Imaging of Rheumatic Diseases II: Focus on Rheumatoid Arthritis and Systemic Sclerosis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Some studies revealed an association of Power Doppler (PD) ultrasound (US)-detected residual synovitis (PDUSS) and risk of relapse and radiographic progression (RP), in rheumatoid arthritis (RA). However, the longitudinal relationship between clinical remission and repeated US residual lesions during follow-up is not so well-known.

**Objectives:** 1/ to determine the longitudinal relationship between clinical course and US findings in RA in remission; 2/ to evaluate the ability of PDUSS to predict relapse or RP at 1 year.

**Methods:** RA patients  $\geq 18$  years fulfilling 2010 ACR-EULAR criteria, treated with synthetic (cs) or biologic (b) DMARDs and in clinical remission (DAS28-ESR  $< 2.6$  and no clinically active synovitis)  $\leq 6$  months, were included in the longitudinal prospective SONORE study (ClinicalTrials.gov identifier: NCT02618954). Clinical and biological characteristics of patients were collected at baseline, and every 3 months (M) during 1 year. RA treatment had to be stable during follow-up. A standard US examination on 40 joints for the presence of synovial hypertrophy and PD signal was performed by an independent investigator blinded to clinical and radiographic data at each visit during 1 year. Presence of US synovitis was defined by a PD signal  $\geq 1$  in  $\geq 1$  joint. Radiographs of hands, wrists and feet were scored at baseline and 1 year. Outcome measures: RP was defined by an increase  $\geq 1$  point of the modified total Sharp score. A relapse was defined by a DAS28  $> 3.2$  at  $\geq 1$  follow-up visits AND a change of DMARDs, excluding change due to safety issues; or an increase in the DMARD or Corticosteroid (CS) dosage ( $\geq 5$ mg/d). Baseline variables, including PDUSS and its persistence during the follow-up, were assessed for their association with time to progression to relapse or RP using univariate then stepwise multivariate Cox regression analyses to obtain adjusted HRs.

**Results:** The 115 included patients had a mean (SD) age of 58.9 ( $\pm 12.8$ ) years, mean disease duration of 9.3 ( $\pm 9.3$ ) years, a mean duration of remission of 2.1 ( $\pm 2.3$ ) months. 74.8% were female, 79.1% were anti-CCP positive, 51.4% had erosive disease. The mean DAS28-ESR was 2.03 ( $\pm 0.63$ ). 79.5% received csDMARD, 63.3% bDMARD and 26.5% CS. PDUSS was detected in  $\geq 1$  joint in 75 patients (72.1%) at baseline, 60 at M3, 53 at M6, 40 at M9, 27 at M12. 41/75 (54.7%) had persistence of at least one PDUSS during the follow-up. 19 (17.1%) had a relapse (1 at M3, 6 at M6, 10 at M9, 2 at M12) and 12 (11.7%) had a RP at 1 year. In multivariate analysis, persistence of at least one PDUSS during the follow-up (HR= 5.24 [1.74-22.5],  $p=0.009$ ) and baseline number of tender joints (HR=1.32 [0.95-1.68],  $p=0.052$ ) were predictors of relapse or RP at 1 year. Duration of remission, other baseline US findings including baseline PDUSS, autoantibodies, and erosive disease had no additional predictive value.

**Conclusion:** PDUSS slowly decrease with time in RA patients in remission. Persistence of a PDUSS during the follow-up, rather than baseline PDUSS, predicts unfavorable outcome at 1 year. This suggests that initial US findings are not sufficient to justify therapeutic change, but that the persistence of a residual PDUSS requires careful follow-up, and might even potentially merit strategy adaptation.

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Imaging of Rheumatic Diseases II: Focus on Rheumatoid Arthritis and Systemic Sclerosis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### **Background/Purpose:**

To assess whether achieving sustained SDAI remission in patients with early rheumatoid arthritis (ERA) facilitates repair of existing bone erosions as measured by high-resolution peripheral quantitative computed tomography (HR-pQCT).

### **Methods:**

In this prospective study, 63 ERA patients were treated with a tight-control protocol aiming at remission using csDMARDs. HR-pQCT examinations were performed at baseline and one-year post-baseline. Changes in erosion size (maximal width, depth, volume) and density of the surrounding bone (marginal osteosclerosis) of erosion near the second metacarpal-phalangeal joint (MCP2) were quantified using HR-pQCT at baseline, 6 months and 12 months. Patients were sub-grouped according to whether or not they achieved sustained simplified disease activity score (SDAI) remission (SDAI < 3.3) at month 6, 9 and 12.

### **Results:**

19 (31%) patients achieved (Group 1) and 44 (69%) patients did not achieve (Group 2) sustained SDAI remission. At baseline, no significant differences in erosion size and marginal osteosclerosis were present between the two groups. In group 1, significant reduction in erosion volume and increase in marginal osteosclerosis was observed between baseline and 12 months (Table 1). In contrast, erosion width significantly increased in group 2 at 6 and 12 months compared to baseline. At 12 months, change in erosion volume was significantly different between the two groups.

### **Conclusion:**

In ERA patients who achieved sustained SDAI remission, HR-pQCT revealed a reduction in erosion volume and an increase in marginal osteosclerosis, indicating that partial erosion repair seems to be possible as long as effective reduction of inflammation is achieved.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Imaging of Rheumatic Diseases II: Focus on Rheumatoid Arthritis and Systemic Sclerosis

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

Despite extensive involvement of the feet in early RA, few studies report clinical and imaging changes in the feet over time. In this observational study, we aimed to 1) characterize 1-year changes in the feet using US, physical exam, and patient-reported outcomes; and 2) determine the associations between 1-year changes in these assessments.

### Methods:

Patients with early RA (ACR criteria, DMARD naïve) were examined at baseline, 6 weeks, 3 months, 6 months, and 1 year. At each time point, the 2<sup>nd</sup> -5<sup>th</sup> MTP joints were examined by a rheumatologist [swollen joint count (SJC), tender joint count (TJC)], and imaged using US. Synovial thickening (ST) and power Doppler (PD) on US were graded semiquantitatively (0-3, max. score=24/patient for each). Patients also completed the Leeds Foot Impact Scale (LFIS) and Health Assessment Questionnaire (HAQ) at each visit.

### Results:

Forty patients were enrolled [mean (SD) age=52.1(10.4) years, n=32 female]. Paired t-tests revealed significant 1-year improvements in inflammation on US (ST and PD), SJC and TJC, and patient-reported outcomes (Table 1). Over 1-year, ST scores improved in 30 patients and worsened in 7; PD scores improved in 16 patients and worsened in 5. Total ST and PD scores significantly correlated with each other at baseline ( $r=0.53$ ,  $p<0.05$ ) and 1-year ( $r=0.37$ ,  $p<0.05$ ); 1-year change scores were also correlated ( $r=0.42$ ,  $p<0.05$ ). Changes in PD scores, but not ST scores, significantly correlated with changes in LFIS and HAQ (Table 2). US findings did not significantly correlate with clinical exam at any time point or over 1-year. Associations between changes in SJC and TJC and patient reported outcomes are shown in Table 2.

Table 1: Mean scores of US, joint counts, and patient-report questionnaires at baseline and 1-year, and their respective paired t-test results.

	Mean (SD)			t-test
	Baseline	One year	Paired Differences	
PD	2.17 (4.11)	0.44 (1.05)	1.73 (4.01)	t=2.76**
ST	9.07 (5.37)	5.12 (3.96)	3.95 (5.97)	t=4.24***
SJC	1.27 (1.70)	0.61 (1.16)	0.66 (1.93)	t=2.18*
TJC	3.98 (2.89)	2.93 (3.06)	1.05 (3.02)	t=2.23*
LFIS	23.33 (14.00)	19.44 (13.33)	3.90 (9.87)	t=2.47*
HAQ	1.12 (0.69)	0.72 (0.62)	0.40 (0.55)	t=4.61***

\* p<0.05, \*\* p<0.01, \*\*\* p<0.001

Table 2: Correlations between 1 year change in US findings, joint counts, and patient-reported questionnaires, accounting for their respective baseline values as covariates.

	Standardized $\beta$	
	Change in LFIS	Change in HAQ
Change in PD	0.42**	0.34*
Change in ST	0.19	0.25
Change in SJC	0.42**	0.20
Change in TJC	0.81	0.05

\* p<0.05, \*\* p<0.01

**Conclusion:** Although all indicators of disease activity showed significant improvements after 1-year, only change in PD and change in SJC significantly correlated with change in patient-reported outcomes. Changes in ST may take longer to develop than 1-year, which may account for its insignificance. The lack of association between US and joint counts suggests that swelling and tenderness in the feet may be influenced by factors other than inflammation.

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

To assess whether ultrasonographic scoring of (i) both parotid and submandibular salivary glands and (ii) all components of the Hoyer scoring system<sup>1</sup>, is needed for classifying patients as primary Sjögren's syndrome (pSS).

### Methods:

Ultrasound examination of the major salivary glands (sUS) was performed in 204 consecutive outpatients, diagnosed or clinically suspected with pSS.

Parenchymal echogenicity, homogeneity, hypoechogenic areas, hyperechogenic reflections and salivary gland posterior border were scored in the right and left parotid and submandibular glands<sup>1</sup>. Univariate and multivariate logistic regression analyses were performed to assess which salivary glands and sUS components significantly predicted classification as pSS or non-pSS according to the 2016 ACR-EULAR criteria<sup>2</sup>.

## Results:

116 (57%) patients were classified as pSS, the remaining 88 (43%) patients as non-pSS. The correlation between the sUS scores of both parotid glands ( $\rho=0.909$ ), both submandibular glands ( $\rho=0.868$ ) and between the left and right glands ( $\rho=0.926$ ) was excellent. The correlation between the sUS scores of the left parotid and left submandibular gland ( $\rho=0.731$ ) and between the right parotid and right submandibular gland ( $\rho=0.734$ ) was slightly lower.

Multivariate analysis showed that sUS scores of one parotid gland and one submandibular gland contributed independently to ACR-EULAR classification. Instead of scoring both sides (area under the curve,  $AUC=0.856$ ; Nagelkerke  $R^2=0.527$ ), sUS scoring of only the right ( $AUC=0.850$ ;  $R^2=0.518$ ) or left ( $AUC=0.852$ ;  $R^2=0.511$ ) parotid and submandibular glands is enough to significantly predict classification of patients according to the ACR-EULAR criteria.

In univariate analysis, all individual components of the Hoyer scoring system significantly predicted ACR-EULAR classification. Hypoechogenic areas showed the highest explained variance ( $R^2=0.508$ ). Multivariate analysis showed that only parenchymal echogenicity and hypoechogenic areas independently predicted ACR-EULAR classification ( $AUC=0.857$ ;  $R^2=0.539$ ). Taking only the sUS scores of the right glands into account, multivariate analysis showed that only parenchymal echogenicity and hypoechogenic areas contributed independently to ACR-EULAR classification ( $AUC=0.855$ ;  $R^2=0.539$ ). However, when scoring only hypoechogenic areas on one side, results were comparable ( $AUC=0.846$ ;  $R^2=0.498$ ). Similar results were found when the analyses were repeated for the left glands.

## Conclusion:

sUS examination of a parotid and submandibular gland on one side is enough to predict classification of patients according to the ACR-EULAR criteria.

Presence of hypoechogenic areas is the best predictor of ACR-EULAR classification. Although parenchymal echogenicity also independently predicted ACR-EULAR classification, its reliability is limited.<sup>3</sup> Therefore, we conclude that sUS scoring of only hypoechogenic areas in one parotid and submandibular gland is enough to predict ACR-EULAR classification. These findings may increase the feasibility of sUS in outpatient clinics worldwide.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Osteoarthritis – Clinical Aspects II: Structural Progression and Incidence

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Epidemiology for hand osteoarthritis (OA) incidence is lacking and few large cohorts have sufficient size to explore subsets. We previously characterized a subset of adults who develop an accelerated form of knee OA, in which they progress from normal radiographic appearance to advance-stage disease within 4 years and often in < 12 months. It is unknown whether such a novel subset exists among adults with hand OA. We aimed to characterize individuals who develop accelerated hand OA (AHOA) and compare them to those who do not.

**Methods:** We evaluated 3489 participants in the Osteoarthritis Initiative (OAI) with complete data for baseline and 48-month radiographic hand OA. One reader scored posteroanterior radiographs of the dominant hand using a modified Kellgren-Lawrence (KL) scale (weighted kappa > 0.84) and another reader scored the presence of central or marginal erosions (kappa > 0.79). We defined hand OA as a hand with at least 1 joint with KL grade  $\geq 2$  on at least 2 fingers (digits 2 to 5). We defined AHOA as a hand with at least 1 joint that progressed from a KL grade of 0 or 1 at baseline to KL 3 or 4 at 48 months. We ran descriptive statistics to characterize AHOA.

**Results:** The overall rate of AHOA was 1.12% over 4 years, with 38 hands having 1 joint affected and 1 hand with 2 joints affected. At baseline, adults who developed AHOA were more likely to have radiographic hand OA (69% vs 36%), central erosions (21% vs 7%), and marginal erosions (8% vs 2%) in other joints compared to those who did not develop AHOA (see Table). Only 1 joint that developed accelerated OA had an erosion (marginal) at baseline. Adults with AHOA were more likely to develop new erosions in either the same or any other joint over 48 months (central n = 13, 34%; marginal n = 3, 8%) than those who did not develop AHOA (central n = 162, 5%; marginal n = 51, 1%). Eight (21%) people who developed AHOA had an incident erosion in the same joint that worsened. Only 1 person (3%) with AHOA had a fracture during the observation period, compared to 48 people (2%) with fractures in the control group. The most common locations of accelerated OA were the thumb and second digit (Figure 1).

**Conclusion:** Adults who developed AHOA were more likely to have erosive hand OA than those without AHOA, confirming that erosive hand OA is a more rapid progressing phenotype. Furthermore, the majority of those who developed AHOA were affected at the second metacarpophalangeal joint (28%) or the first carpometacarpal joint (26%). This suggests the digits commonly used for pinching and fine motor skills are particularly susceptible to accelerated OA compared to other digits.

Table 1. Baseline Characteristics of Adults Who Develop Accelerated Hand Osteoarthritis (OA)

	No Accelerated OA n = 3489	Accelerated OA n = 39
	mean (SD) or n (%)	mean (SD) or n (%)
Female n (%)	2020 (58%)	24 (62%)
Pre-menopause n (%)	295 (15%)	3 (13%)
Peri-menopause n (%)	291 (14%)	2 (8%)
Post-menopause n (%)	1423 (71%)	19 (79%)
Physician Diagnosed Hand OA n (%)	581 (17%)	6 (15%)
Prevalent Hand Pain n (%)	835 (24%)	6 (15%)
Radiographic Hand OA n (%)	1246 (36%)	27 (69%)
Central Erosions (≥ 1 joint) n (%)	239 (7%)	8 (21%)
Marginal Erosions (≥ 1 joint) n (%)	84 (2%)	4 (11%)*
Metabolic Syndrome (2-4 components) n (%)	1933 (58%)	26 (67%)
Self-Reported Diabetes n (%)	268 (8%)	1 (3%)
Use of Lipid Medications n (%)	988 (28%)	7 (18%)
High Blood Pressure n (%)	2110 (60%)	28 (72%)
Large Waist Circumference n (%)	2553 (74%)	31 (79%)
Age (years)	60.9 (9.2)	60.6 (9.1)
Body Mass Index (kg/m <sup>2</sup> )	28.7 (4.8)	29.1 (5.0)
Body Weight (kg)	81.6 (16.4)	81.2 (15.7)

Notes on missing data: Only included people with body weight, and status of self-reported hand pain (yes or no) and physician diagnosed hand OA (yes and no or unknown) at baseline. Missing data: Less than 3% missing data for menopause status, central erosions, marginal erosions, diabetes status, and waist circumference. Metabolic syndrome (n missing = 137 controls). No other missing data. \* 1 marginal erosion occurred in the same joint that developed accelerated hand osteoarthritis and 3 had marginal erosions in a different joint.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Osteoarthritis – Clinical Aspects II: Structural Progression and Incidence

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Hand OA (HOA) is a painful, destructive and deforming polyarticular disorder that impairs an individual's ability to perform manipulative activities of daily life and has a strong association with increasing age. Telomeres are specialized chromatin structures at the end of linear eukaryotic chromosomes that perform a capping function, protecting chromosomes from degradation, recombination, and fusion between chromosomes. After each round of DNA replication there is a progressive loss of terminal telomere sequences, so telomeres progressively shorten with ageing in replicating somatic cells. There is also evidence that telomeric structure may be damaged as a result of oxidative stress. Ultimately, the telomeric sequence array may become critically shortened and trigger replicative senescence or apoptosis, contributing to processes related to aging. Peripheral blood leukocyte (PBL) telomere length is a biomarker for biological age and longevity. Data from cross-sectional studies are conflicting on whether telomere length is shorter in subjects with OA.

**Methods:** This used a convenience sample of Caucasian participants in the Osteoarthritis Initiative who had right hand x-rays at 0 and month 48; and PBL telomere length measured at baseline using real-time quantitative PCR. We defined interphalangeal OA (IPOA) as KL  $\geq 2$  in a finger or thumb joint (excluding thumb-base); and *incidence* if KL score increased from  $\leq 1$  to  $\geq 2$ . We defined *symptomatic* IPOA as KL  $\geq 2$  in  $\geq 1$  joint on 2 different fingers *and* report of hand pain ("During the past 30 days, pain, aching or stiffness on most days") after baseline. We analyzed the standardized log of telomere length as a predictor for OA incidence at a joint level and across all joints using generalized linear mixed models to control for confounders and account for within-person correlation among joints.

**Results:** 275 participants were eligible for the analysis (mean baseline age 59.1y [s.d.8.7], 56.7% female, BMI 27.4 Kg $m^{-2}$ [4.4], 39 [14.2%] physician-diagnosed hand OA). 494 joints had OA at baseline and 47 developed incident IPOA. Prevalent IPOA at baseline was cross-sectionally associated with older age (OR=2.2; 95% CI 1.8, 2.6) and shorter telomere length (OR=1.3; 1.1, 1.6) but not with gender or BMI (all mutually adjusted). In prospective analyses with adjustment for age, BMI and gender, shorter telomere length predicted IPOA incidence in a joint (OR=1.5, 1.07, 2.1 -i.e. for every s.d. decrease in log of telomere length there is 50% increase in the likelihood of OA incidence); and the increase in number of affected joints ( $\beta=0.06$ ,  $p=0.02$ ), as well as incidence of *symptomatic* IPOA (OR=1.7, 1.1, 2.7). This association was consistent in the smaller subset without HOA at baseline (OR=1.7, 0.99, 2.8).

**Conclusion:** Shorter PBL telomere length is strongly and independently associated with prevalent and incident OA in finger joints and development of symptomatic IPOA. This may indicate an accelerated ageing phenotype associated with impaired chondrocyte function and capacity of cartilage and joint structures to maintain health and respond to biomechanical and inflammatory/metabolic stressors, leading to OA.

## Identifying Rapid Structural Disease Progression in Knee Osteoarthritis

Jamie E. Collins<sup>1,2</sup>, Jeffrey N. Katz<sup>2,3</sup> and Elena Losina<sup>1,2</sup>, <sup>1</sup>Orthopaedic and Arthritis Center for Outcomes Research, Department of Orthopedic Surgery, Brigham & Women's Hospital, Boston, MA, <sup>2</sup>Harvard Medical School, Boston, MA, <sup>3</sup>Rheumatology, Immunology, and Allergy, Brigham & Women's Hospital, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Osteoarthritis – Clinical Aspects II: Structural Progression and Incidence

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Knee OA is a heterogeneous disease, with some patients experiencing rapid deterioration and others experiencing slow disease progression. Identifying patients likely to experience rapid disease worsening is a top research priority; this would allow better recruitment strategies for clinical trials, optimizing the execution of trials focused on disease modifying drugs, and would help physicians make better treatment decisions.

**Methods:** We used data from the Osteoarthritis Initiative (OAI), a multicenter, longitudinal, observational study of knee OA. We selected patients with baseline (BL) Kellgren-Lawrence (KL) grade 1 - 3, with knee pain, and with joint space width (JSW) assessed at BL and  $\geq 1$  follow-up. Medial minimum JSW was assessed with a fixed-flexion knee radiograph annually through year 4; total follow-up was 9 years. We used latent class growth analysis (LCGA) to identify distinct subgroups of JSW progression. LCGA allows for the modeling of distinct subgroups based on longitudinal trajectory. We included random effects for intercept and slope to allow for within-subject variability. After identifying the number of trajectories, we used logistic regression to assess the association between BL characteristics and JSW trajectory group.

**Results:** We used data from 1,755 OAI study participants. BL radiographic severity was KL1 in 16%, KL2 in 52%, and KL3 in 32%. The mean (SD) JSW was 4.0mm (1.3) and the range was 0.7 – 8.5mm. LCGA identified 2 distinct JSW trajectories [Figure]. The majority of patients (90%) had stable JSW over 4 years of follow-up (Non-progressor group) with a mean (SD) JSW of 4.1 (1.2) at BL and 3.9 (1.4) at 4 year follow-up, for a yearly decrease of 0.05mm. A subgroup of patients experienced rapid disease progression (Progressor group), with a BL mean (SD) JSW of 3.8 (1.5) and a 4 year follow-up JSW of 1.7 (1.3), for a yearly decrease of 0.53mm. 5% of the Non-progressors went on to have total knee replacement between years 5 and 9, compared to 23% of the Progressors. BL KL, obesity, and alignment were associated with progression group: in a multivariable model, the odds of being a Progressor were 2.4 (95% CI: 1.4, 3.9) times higher for participants with KL 3 vs. KL 1; 1.6 (1.1, 2.1) times higher for obese participants vs. non-obese, and 1.2 (0.8, 1.8) times higher for those with varus alignment vs. neutral. 30% of the cohort had 0 risk factors, 6% were Progressors; 43% had 1 risk factor, 10% were Progressors; 23% had 2 risk factors, 15% were Progressors; 5% had 3 risk factors, 26% were Progressors.

**Conclusion:** We found a subgroup of patients experiencing rapid structural progression in JSW. These patients may be appropriate candidates for clinical trials of disease modifying drugs. A strategy that required 2 or 3 risk factors for inclusion into a trial could enrich the cohort for progressors by two-fold compared to a strategy of enrolling non-selectively.

Figure. JSW over time for the trajectory groups. Solid line and band represent observed values and 95% confidence intervals; dashed line represents predicted value.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Osteoarthritis – Clinical Aspects II: Structural Progression and Incidence

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Osteophytes are formed through reactivation of endochondral ossification. In adults, reactivation of endochondral ossification may occur in the context of fracture repair. As yet, the rationale for the genesis of osteophytes in osteoarthritis (OA) remains unclear. We investigated whether bone marrow lesions (BMLs) (representing subchondral remodeling due to increased loading) and inflammation (assessed as effusion-synovitis on non-contrast-enhanced MRI) were associated with the presence and progression of osteophytes in OA knees.

**Methods:** We analyzed data from 600 participants included in the FNIH Biomarkers study within the Osteoarthritis Initiative. Osteophytes and BMLs were scored according to size (0-3) on MRI in the medial and lateral femur and tibia, and effusion-synovitis was scored in the whole knee according to severity (0-3, where 0 means absent) using the MRI OA Knee Score (MOAKS). BMLs and effusion-synovitis were considered present when a score  $\geq 1$  for each feature was given. Osteophyte severity was categorized into grades 0 (absent), 1 (small) and 2-3 (medium to large). We examined the cross-sectional and longitudinal relation between the baseline presence of BMLs and effusion-synovitis to osteophyte severity and progression (increase in size in  $\geq 1$  grade) in each joint compartment on MRI over 24 months. Ordinal regression was used for the cross-sectional analysis and binary logistic regression for the longitudinal analysis adjusted for covariates. We assessed the interaction effect between BMLs and knee alignment, measured by goniometer on physical examination (neutral, varus or valgus), using interaction terms.

**Results:** At baseline, BMLs were present in 10.8% to 53.3% depending on the knee compartment and effusion-synovitis was present in 61% of the knees. Presence of BMLs was strongly associated with baseline osteophytes in all four knee compartments (Table), with odds ratios (OR) ranging from 1.63 (95% confidence interval [CI] 1.15, 2.30) in the medial femur to 7.13 (4.92, 10.93) in the lateral femur. Presence of effusion-synovitis was also associated with osteophytes, except in the medial tibia. At baseline, the interaction analysis showed no effect of alignment in the association between BMLs and osteophytes. Over 24 months, osteophyte progression mostly occurred in the medial tibia (7.3%) and was strongly associated with the presence of baseline BMLs in the same joint compartment (OR 3.89 [1.84, 8.23]). Baseline effusion-synovitis was also associated with an increase in osteophyte size in the medial femur and tibia.

**Conclusion:** Bone marrow lesions were strongly associated with the presence of osteophytes and with osteophyte progression on MRI over 24 months. Although inflammation may also play a role in the development of osteophytes, BMLs appear to be more strongly related to the reactivation of endochondral ossification process.

Table. Cross-sectional and longitudinal associations between BMI status and osteophyte on MRI

	Osteophyte MT	Osteophyte LT	Osteophyte MT	Osteophyte LT
Sample Size (N, %)	1087 / 36.5	88 / 9	1087 / 36.5	1087 / 36.5
Crude OR (95% CI)				
Baseline				
Osteophyte MT	1.13 (0.84, 1.51)	3.77 (1.06, 13.6)	1.35 (0.46, 3.93)	1.64 (0.38, 7.20)
Osteophyte LT	1.84 (1.01, 3.33)	1.71 (1.10, 2.65)	1.51 (1.25, 1.80)	7.11 (4.02, 12.5)
Longitudinal progression over 4 years				
Osteophyte MT	3.5	5.2	5.2	4.8
Osteophyte LT	3.52 (1.05, 12.4)	3.59 (2.06, 6.20)	3.96 (1.81, 8.68)	1.41 (0.56, 3.62)

# Distinct Trajectories of Medial Fixed Joint Space Width Loss over Four Years of Follow-up Among Knees with and at Risk for Knee Osteoarthritis

C. Kent Kwoh<sup>1,2</sup>, Di Ran<sup>2,3</sup>, Erin L. Ashbeck<sup>2</sup> and Jeffrey Duryea<sup>4</sup>, <sup>1</sup>Division of Rheumatology, Department of Medicine, The University of Arizona, Tucson, AZ, <sup>2</sup>The University of Arizona Arthritis Center, Tucson, AZ, <sup>3</sup>Department of Epidemiology and Biostatistics, Mel and Enid Zuckerman College of Public Health, Tucson, AZ, <sup>4</sup>Radiology, Brigham & Women's Hospital/ Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Osteoarthritis – Clinical Aspects II: Structural Progression and Incidence

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Knee OA (KOA) is typically described as a slowly progressive disease, though it is recognized that some patients experience rapid structural deterioration. Identification of knees at risk for rapid structural deterioration would be useful for recruitment to randomized controlled trials (RCTs) and observational studies of KOA. Our objectives were to identify distinct trajectories of medial fixed joint space width (fJSW) loss and estimate the expected percentage of knees in each trajectory based on two measures of KOA severity, Kellgren-Lawrence grade (KLG) and knee pain.

**Methods:** Osteoarthritis Initiative participants with baseline radiographs centrally read as KLG 0-3, measured medial fJSW (location x=0.250), and participant-reported knee pain severity in the past 30 days based on a numerical rating scale (NRS; 0-10) were selected. One knee per participant was randomly selected when two knees were available, providing a sample size of 3,163 knees. Distinct trajectories of medial fJSW loss over 4 years of follow-up were identified using a group-based discrete mixture model for clustering of longitudinal data. Predicted probability of loss trajectories based on combinations of baseline KLG and NRS were generated with multinomial logistic regression, with NRS categorized as 0, 1-3, and 4-10.

**Results:** Three distinct trajectories of medial fJSW loss were identified (Figure 1), including knees that remained stable over 4 years (2,030; 64.2%, mean posterior probability of group membership 0.92); knees that experienced slow loss (960; 30.4%, mean probability 0.88); and knees with fast radiographic worsening (173; 5.5%, mean probability 0.94). Among KLG 2 knees, the proportion that experienced slow progression was 28.6-31.8%, while 3.3-7.3% of knees underwent fast progression, depending on the baseline NRS (Figure 2). Among KLG 3 knees, 42.1-49.0% had slow progression, while 6.8-13.0% underwent fast progression. The combination of KLG 3 and knee pain severity 4-10 yielded the highest estimated proportion of knees that experienced subsequent fast progression.

**Conclusion:** Three distinct trajectories of medial fJSW loss, representing stable, slow, and fast loss of joint space, were identified across the spectrum of KOA disease severity. Recruitment based on KLG and knee pain severity enriches the proportion of expected progressors, both slow and fast, though fast progressors are still not highly represented. Additional risk factors are needed to enrich studies for participants at high risk of rapid structural deterioration.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Osteoarthritis – Clinical Aspects II: Structural Progression and Incidence

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Cartilage damage, which is a precursor and feature of knee osteoarthritis (OA), has been linked to both obesity and excessive joint loading. Assessment of the combined effect of obesity and repetitive joint load as experienced during daily walking to represent *cumulative load* may provide additional insights into the risk for cartilage pathology in OA. The purpose of our study was to examine the relation of cumulative load to prevalent cartilage damage in the tibiofemoral (TF) and patellofemoral (PF) joints in people with or at high risk of knee OA.

**Methods:** Data from the 60-month visit of the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of persons with or at risk of knee OA, was used for this study. Subjects had accelerometry data over 7 days (StepWatch Activity Monitor, Orthocare Innovations) and knee MRIs (1.0T, OrthOne) obtained at this visit. The primary exposure of interest was categories of cumulative load, defined using BMI and objectively measured physical activity (i.e. average steps/day). We categorized participants as Non-obese (BMI < 30 kg/m<sup>2</sup>) or Obese (BMI ≥ 30 kg/m<sup>2</sup>), and then into tertiles of daily walking as High, Middle, and Low steps/day. Cartilage morphology was scored in 14 subregions (10 TF, 4 PF) using the Whole Organ Magnetic Resonance Imaging Score (WORMS). We examined the relation of cumulative load to the presence of cartilage damage, defined as any WORMS score ≥ 2, using logistic regression with generalized estimating equations (GEE) to account for the correlation between subregions within a knee. Analyses were adjusted for age, sex, and frontal plane knee alignment.

**Results:** We included 987 MOST subjects (62% women, age 66.9 ± 7.5 years, BMI 29.7 ± 4.8) that contributed 9610 TF observations and 3734 PF observations. The prevalence of TF cartilage damage was 27% (2619/9610 subregions) and 48% (1791/3734 subregions) for PF cartilage damage. Cumulative load was not associated with TF cartilage damage (see Figure 1). In the PF joint, there was a higher likelihood of prevalent PF cartilage damage for those in the Obese-High 1.3(0.99-1.7), Obese-Low 1.6(1.2-2.2), and Non-obese-Low 1.5(1.1-1.9) groups compared with the reference (Non-obese, High steps/day) group (see Figure 2).

**Conclusion:** Greater cumulative load may be associated with prevalent cartilage damage in the PF, but not TF joint. Insufficient cumulative load (i.e. low steps/day) may also be associated with prevalent PF cartilage damage. These preliminary findings support the need to encourage weight loss for people who are obese and at risk of knee OA in addition to an active lifestyle.

Figure 1. Adjusted odds ratios (OR) for TF and PF cartilage damage based on categories of cumulative load. Error bars represent the 95% confidence intervals for each OR estimate. Reference category (REF) = Non-obese, High steps/day.

\*Adjusted for age, sex, and frontal plane knee alignment.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes III

**Session Type:** ACR Concurrent Abstract Session

**Background/Purpose:** A standardized validated definition for gout flares (or attacks) is not available. Two provisional definitions published in 2012 were based on patient-reported elements (patient-defined attack, pain at rest greater than 3 in a 0-10 numeric rating scale, presence of at least one swollen joint, presence of at least one warm joint). These definitions had acceptable sensitivity and specificity but lacked external validation which would facilitate its adoption in gout clinical studies. Our objective was to perform external validation of previously published preliminary gout flare definitions in patients with gout.

**Methods:** We enrolled 509 participants with gout from 17 international sites in a cross-sectional study performed during routine clinical care. All patients met the 2015 ACR/EULAR classification criteria for gout. Criteria from the previously published gout flare definitions were collected by a site investigator and the final adjudication of a gout flare status was done by a local expert rheumatologist, through an evaluation independent from that of the site investigator. Logistic regression, Bayesian statistics, and receiver-operator curves were used to calculate the final diagnostic performance of the gout attack definitions which were based on number of criteria and a classification and regression tree (CART) approaches.

**Results:** The mean age of participants was 57.5 years (standard deviation [SD] 13.9) and 89% were men. Mean disease duration was 12.3 (SD 10.3) years, 35.4 % had tophi, and 75% were taking urate-lowering therapies. The previously published and favored number of criteria definition requiring the presence of 3 or more out of 4 criteria was found, using the current study data, to be 85% sensitive and 95% specific in confirming the presence of flare in patients with gout (Table). The concurrent logistic regression model had an area under the curve of 0.97. The previously published definition based on a CART algorithm (entry point pain at rest > 3 followed by patient-defined attack “yes”) was 73% sensitive and 96% specific using the current study data (Table). The number of criteria approach with a cut-point at 3 or more out of 4 criteria had higher diagnostic accuracy using the current study data than in its initial 2012 description (92% versus 84%). Finally, using current study data the number of criteria approach at 3 or more out of 4 criteria had higher accuracy to the CART algorithm based approach (92% versus 89%) but with a much better sensitivity (85% versus 73%).

**Conclusion:** The definition requiring the presence of 3 or more out of 4 patient-reported criteria is validated to be sensitive, specific, and accurate in identifying flares in patients with gout using an independent large international sample. Having a validated gout flare definition will improve ascertainment of outcomes in gout clinical studies.

Table. Diagnostic performance of gout attack (flare) definitions: “number of criteria” and classification and regression tree (CART)

Number of criteria	Patients with gout flare (n=157)	Patients without gout flare (n=352)	Sensitivity% (95% CI)	Specificity% (95% CI)	PPV% (95% CI)	NPV% (95% CI)	Accuracy% (95% CI)
1 or more	157	119	100 (98-100)	66 (61-71)	57 (53-60)	100 (100)	77 (73-80)
2 or more	152	43	97 (93-99)	88 (84-91)	78 (73-82)	98 (96-99)	91 (88-93)
3 or more	134	18	85 (79-90)	95 (92-97)	88 (83-92)	94 (91-96)	92 (89-94)
All 4	96	6	61 (53-69)	98 (96-99)	94 (88-97)	85 (82-87)	87 (84-90)
CART†	114	13	73 (65-79)	96 (94-98)	90 (84-94)	89 (86-91)	89 (86-92)

CI = confidence interval, PPV= positive predictive value, NPV= negative predictive value, CART = classification and regression tree

\*Criteria include: patient-defined gout flare, pain at rest > 3 on a 0-10 numeric rating scale, presence of at least one swollen joint, presence of at least one warm joint

†CART rule: Pain at rest > 3 followed by patient- defined gout flare positive

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** The Patient (Pt) Reported Outcomes Measurement Information System (PROMIS [P]) questionnaires developed by the NIH have been validated and are a feasible assessment tool for rheumatoid arthritis (RA) patients (pts) (Bartlett 2015). AWARE (Comparative and Pragmatic Study of Golimumab Intravenous [IV] Versus Infliximab in RA) is a large, pragmatic multi-center United States based, real-world evidence study of golimumab IV (GLM) vs. infliximab (IFX) in RA, and is using PROMIS assessments as one measure of pt response to therapy. Here we report interim results of the responsiveness of multiple PROMIS short forms and profiles with treatment of RA using GLM or IFX.

**Methods:** AWARE is a prospective, noninterventional study in which 1,200 adult pts will be enrolled upon initiation of treatment with GLM or IFX. PRO assessments of pt response to treatment include use of PROMIS-29 Profile v2.0 (P29v2), P Pain Interference Short Form-6b (SF6b) and P Fatigue Short Form-7a (SF7a), 36-Item Short Form Health Survey (SF-36v2) and the Clinical Disease Activity Index (CDAI). We report results of an interim analysis of pt response to PROMIS questionnaires. PROMIS questionnaire results are normalized to the US population and reported as a “T-score” (mean of 50 and standard deviation (SD) of 10). Data shown are mean  $\pm$  standard deviation baseline score (month 0) and change from baseline (months 2 and 5), and interpreted as an effect size.

**Results:** GLM pts were  $61.0 \pm 13.0$  years and IFX pts were  $57.2 \pm 13.0$  years. RA disease duration of GLM pts was  $9.0 \pm 9.3$  years and IFX pts was  $6.8 \pm 9.7$  years. Mean baseline CDAI score for GLM pts was  $31.1 \pm 14.6$  and for IFX pts was  $34.3 \pm 16.2$ . with most starting in high (71.4% GLM/72.0% IFX) or moderate disease activity (21.8% GLM/23.4% IFX). A total of 573-586 pts contributed data at the 2 month time point, and 169-173 pts at the 5 month time point. PROMIS domain T-scores of GLM and IFX pts at baseline and mean change from baseline are shown (Table). The mean changes in PROMIS T-scores were generally in the 1-4 unit range, consistent with a small to moderate size effect, with all mean changes in the expected direction that reflected clinical improvement.

PROMIS Domain	Mon. of Tx	GLM		IFX		PROMIS Domain	Mon. of Tx	GLM		IFX	
		Mean (SD)	N	Mean (SD)	N			Mean (SD)	N	Mean (SD)	N
Fatigue SF7a	0	59.4 (8.5)	377	59.2 (8.6)	305	Fatigue P29v2	0	58.7 (9.7)	369	59.0 (10.2)	304
	2	-1.9 (6.1)	317	-1.1 (5.5)	269		2	-1.6 (7.0)	307	-1.7 (7.0)	266
	5	-2.3 (6.0)	74	-2.7 (6.6)	101		5	-2.6 (7.5)	72	-3.6 (8.1)	98

Pain Interference P29v2	0	63.2 (7.8)	376	63.9 (7.5)	305	Sleep Disturbance P29v2	0	55.0 (8.6)	371	56.1 (8.9)	301
	2	-2.6 (6.6)	319	-2.6 (6.6)	267		2	-1.4 (6.5)	312	-1.3 (6.7)	262
	5	-2.4 (6.9)	73	-3.7 (7.6)	100		5	-1.8 (7.9)	71	-3.0 (7.3)	98
Depression P29v2	0	52.3 (10.1)	372	52.6 (10.6)	305	Ability to Participate Social Roles P29v2	0	43.4 (8.4)	371	42.8 (8.9)	304
	2	-1.3 (6.8)	315	-1.6 (6.6)	266		2	1.6 (6.2)	314	0.7 (5.7)	266
	5	-2.9 (6.9)	72	-2.3 (8.4)	101		5	3.0 (6.8)	70	2.2 (6.6)	100
Anxiety P29v2	0	53.3 (10.3)	372	54.5 (10.5)	302	Pain Intensity P29v2 (0-10 unit scale)	0	6.0 (2.3)	371	6.1 (2.1)	304
	2	-1.3 (7.6)	316	-2.0 (7.0)	262		2	-0.9 (2.0)	314	-0.9 (1.9)	266
	5	-2.4 (7.5)	72	-2.9 (9.4)	101		5	-1.0 (2.5)	71	-1.2 (2.2)	98

Mon. = Month, Tx = Treatment

**Conclusion:** These interim data support the use of PROMIS questionnaires to evaluate RA pts in trials and to measure improvement across a range of domains. As additional pts reach later time points (future interim analyses and primary endpoint assessment), the magnitude of change will become more apparent. Analyses using the fully enrolled AWARE study evaluated over 3 years and analysis of PROMIS changes relative to other outcome measures will further define the practical utilization of PROMIS in RA pts.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Juvenile Idiopathic Arthritis (JIA) is a common chronic childhood illness associated with negative impact on health-related quality of life (HRQL). As teens mature, they are expected to assume greater responsibility in disease management. There is evidence to suggest that psycho-educational treatments can improve health outcomes in teens with JIA. However, the vast majority do not receive comprehensive self-management education. An Internet-based intervention was developed to help improve accessibility and disease self-management for teens with JIA. This intervention consisted of disease education, self-management strategies, and social support. A randomized controlled trial design was used to determine the effectiveness of the intervention.

**Methods:** Participants were between 12-18 years old with JIA across 11 pediatric centers in Canada. Most teens participated with a parent/caregiver. Intervention participants reviewed 12 modules focused on disease education and self-management strategies. Control participants reviewed standard disease education modules without self-management material. Over the 3-month program, health coaches had monthly check-ins with teens, but only reviewed modules with intervention participants. Parents in both groups reviewed modules on promoting independence and disease self-management in their teen. Participants completed outcome measures at 4 time points: baseline, program completion, 3-months, and 6-months after the program. Primary outcomes were: pain and HRQL. Secondary outcomes were: emotional symptoms, adherence, coping, knowledge, and self-efficacy.

**Results:** In total, 333 teens (n = 109 male, n = 224 female; mean age = 14.5, SD = 1.7) and 306 parents (n = 52 male, n = 254 female) were enrolled. Of the 164 intervention participants, 62.8% (n = 103) completed the study over an average 189.8 days (SD=113.5). Of the 169 control participants, 87.0% (n = 147) completed the study over 123.6 days (SD=70.6). Analyses indicate a significant overall reduction in pain interference in enjoying daily life for intervention participants compared to control after adjusting for baseline level of interference (intervention: M=1.03, SE=0.16; control: M=1.62, SE=0.13; p=0.004). There was also a significant difference interaction between intervention group and time (p=0.001) for HRQL related to treatment problems. Specifically, the intervention group reported improved HRQL versus control participants by 12 months (Mean difference at 12 months=3.22, SE=1.56, adjusted p=0.040). Participants in both groups showed non-significant improvements over time, compared to baseline, in pain coping, self-efficacy, disease knowledge, and HRQL. The majority of teens in the intervention found the coach calls helpful and were satisfied with call frequency. Most teens also found the website text content, videos, graphics/animations, and relaxation exercises helpful.

**Conclusion:** Teens and parents enjoyed being part of the study and the program improved aspects of HRQL. Education and social support factors may be key determinants of improving patient reported outcomes. The intervention website has been launched to the general public (**URL:** [teens.aboutkidshealth.ca/jia](http://teens.aboutkidshealth.ca/jia)).

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Although survival in SLE has improved, quality of life (QOL) remains poor. Physicians aim to reduce suffering and improve health outcomes, while maximizing efficiency and reducing costs. Patient satisfaction with care (SC) correlates with adherence, health behaviors and outcomes. However, SC may be influenced by patient, provider, care-processes and disease variables. This study aims to determine the modifiable and non-modifiable correlates of SC in SLE.

**Methods:** 1262 consenting patients, meeting ACR criteria for SLE, were recruited for this study from 2009-2016. Demographics, disease activity (SELENA-SLEDAI) and QOL (LupusPROv1.7) were collected. LupusPROv1.7 includes a four-item domain on SC covering physician accessibility, education, physician discussion and monitoring of medication side effects, and physicians' understanding of impact of lupus on patients' lives. Regression analyses were conducted using patient (age, gender, ethnicity, education, social support) and disease (duration, disease activity, damage, medications, QOL) variables as independent predictors.  $P \leq 0.05$  was considered significant.

**Results:** Mean (SD) age was 41.7 (13.5) yrs; 93% were female. Ethnic composition was: African American 10%, Caucasian 23%, Hispanic 18%, Asian 48%. On univariate analysis, age, Asian ethnicity, current steroid use and QOL (desires-goals) were inversely associated with SC, while Hispanic and African-American ethnicity, disease activity (total score, pyuria, proteinuria, hematuria, urine casts), QOL (cognition, social support, coping) were directly associated with SC (Table 1). On multivariate analysis, ethnicity (positive for African Americans and Hispanics, negative for Asians), disease activity (pyuria) and QOL (desires-goals, social support and coping) remained independent predictors of SC.

With stepwise regression modelling (Table 1), African American and Hispanic ethnicity, total SLEDAI and pyuria, and QOL (social support and coping) were positively associated with SC, while Asian ethnicity and QOL (desires-goals) were negatively and independently associated with SC.

**Conclusion:** Asian patients have worse SC even after adjusting for demographics, disease activity, treatment and QOL. This requires further investigation into the role of culture, health behaviors and healthcare systems, but also suggests physicians need to be more attentive to the needs of Asian patients. Patients with greater disease activity have better SC, perhaps from greater interactions with physicians and ancillary services. SC thus may not be a good surrogate for tracking patients' health outcomes and quality of care. Social support and coping are potentially modifiable. Evaluation of patients' external and internal resources (social support and coping) using a bio-psychosocial model of health for SLE is suggested.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

The movement for patient engagement in research aspires to greater inclusion of and collaboration with patients at virtually every point in the research cycle. Currently there is little empirical evidence concerning how patient engagement in research affects the lives of the patients involved. Our objective was to examine the experience of what it takes to be involved in research as a patient partner, focusing on occupational (relating to activities of daily life) aspects of their involvement, and how the conditions of involvement shape the nature of their participation and who can participate.

### Methods:

This project was designed in a collaboration with patients with arthritis who had experience as research partners. Eligible participants were current or past members of a patient advisory board in an arthritis research centre. Participants were invited to take part in an hour-long interview. A semi-structured topic guide with prompts and probes was used to elicit detail about the benefits and challenges of being a patient engaged in research. An iterative thematic analysis of the interviews was conducted using constant comparison method. Discussions with patient partners informed the development of themes.

### Results:

In 2015-2016, 22 participants were recruited, 21 (95%) were female, ages ranged from 26 to 68 years, and time spent as a patient engaged in research ranged from 1 month to 10 years. Twelve (55%) had inflammatory arthritis, 5 (23%) had OA, 4 (18%) had both, and one (4%) did not report. Fourteen (64%) had at least one university degree. 12 participants (55%) were employed fulltime, 9 (41%) were retired, 2 (9%) were students and 2 (9%) were on disability benefits. Two themes emerged from the findings, the first concerned *maintaining occupational balance as a patient partner*, in which many participants described their experience as volunteers in a patient advisory board as being rewarding and purposeful, though sometimes difficult to balance with priorities such as family, work, and health. Some described their volunteer work as akin to a full-time job, drawing on professional skill sets developed in the past. Many emphasized the time and effort it took to develop the knowledge-base to participate. The second theme was drawn from the participants' concern at the *difficulty of making patient engagement more diverse* and reaching under-represented populations, specifically noting issues such as gender imbalance, and poorer representation from marginalized communities, lower socio-economic classes and people with limited educational opportunities.

#### **Conclusion:**

Our findings show that for patients who have had the opportunity to be partners in research, it can be both rewarding and burdensome. Our participants also identified, with concern for the democratic ideal of inclusivity, that there are populations lacking the opportunity to be engaged in research and are not being reached or represented. This is of concern due to the important role that the social determinants of health play in determining quality of life for people affected by arthritis. Our findings suggest that increased efforts and resources as well as new strategies are needed to bring increased diversity to patient engagement in arthritis research.

#### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Best practice recommendations can increase quality of care and improve clinical outcomes, however the impact of recommendations on outcomes that matter most to patients have not been evaluated. We compare changes in patient reported outcomes (PROs) valued most by people with RA in the first year of follow up, as well as prior (2007-10) and subsequent (2011-16) to the 2010 release of Treat to Target and 2011 Canadian RA Treatment Recommendations.

**Methods:** Data included ERA adults enrolled in CATCH (Canadian early Arthritis CoHort) between 2007-16 who met 1987 or 2010 RA criteria and had active disease at enrolment. Standardized visits included clinical assessments, questionnaires, and laboratory tests

every 3 months. Treatment was at the discretion of the rheumatologist and cohort investigators met annually to discuss ways to improve outcomes. We examined changes in DAS28, pain, fatigue, patient global and HAQ at 6 and 12 months prior to and after guidelines release.

**Results:** The sample included 1942 adults who were mostly female (72%) with a mean (SD) age of 55 (15), 2 (2) comorbidities, and symptom duration of 6 (3) months. At enrollment, almost all (95%) were in DAS28 moderate or high disease activity [MDA (42%), HDA (53%)], and were initially treated with csDMARDS (92%) and MTX (75%). CDAI, DAS28 and PROs by DAS28 disease levels are shown in the Table. As mean DAS28 scores decreased over the first year, similar clinically meaningful improvements in patient global, pain, and fatigue were also evident (-3.0, -2.8, -2.3, -0.6; p's<.001). When comparing change in PROs in 2007-2010 vs 2011-2016, there were more rapid improvements in patient global and pain at 6 and 12 months (p's<.001; Figure) and similar improvements in HAQ and fatigue.

**Conclusion:** Results from this large country-wide study suggest that better disease control in the first year of RA translated to similar improvements in pain, fatigue and disability--symptoms that patients identify as important--resulting in greater overall well-being. These data offer additional evidence supporting the importance of early identification and control of disease activity to improve long term outcomes and quality of life in people with RA.

Participant characteristics.					
Mean (SD)	Total	LDA	MDA	HDA	
N (%)	1942	(93, 5%)	(828, 42%)	(1021, 53%)	
DAS28	5.2 (1.3)	2.9 (0.2)	4.2 (0.5)	6.2 (0.8)	
CDAI	28.1 (13.8)	10.8 (5.3)	19.4 (8.0)	36.9 (11.8)	
Patient Global (0-10)	6.0 (2.8)	3.2 (2.2)	4.9 (2.7)	7.2 (2.4)	
Pain (0-10)	5.7 (2.8)	3.3 (2.3)	4.6 (2.6)	6.8 (2.4)	
Fatigue (0-10)	5.4 (3.0)	3.8 (2.8)	4.6 (2.9)	6.1 (2.9)

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects III: Lupus, Dermatomyositis, and Scleroderma

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** At present no clear evidence based guidelines exist to standardize the tapering and discontinuation of corticosteroids (CS) in juvenile dermatomyositis (JDM). To provide evidence-based recommendations for CS tapering/discontinuation through the analysis of the patients in the PRINTO new onset JDM trial and to identify predictors of clinical remission and CS discontinuation.

**Methods:** New onset JDM children were randomized to receive either prednisone (PDN) alone or in combination with MTX or CSA, according to a specific steroid protocol. Major therapeutic changes (MTC) were defined as the addition or major increase in the dose of MTX/CSA/other drugs or any other reasons for which patients were dropped from the trial. Patients were divided according to clinical remission into two major groups. Group 1 included those on clinical remission, who could discontinue PDN, with no MTC, and represented the reference standard for the best clinical outcome. Group 1 was compared with those who did not achieve clinical remission, without or with MTC (group 2 and 3, respectively). JDM core set measures (CSM) were compared in the 3 groups. We also calculated the gold standard group (group 1) median change in the CSM in the first 6 and over 24 months and applied a logistic regression model to identify the predictors of clinical remission with PDN discontinuation.

**Results:** 139 children were enrolled in the trial: 47 on PDN, 46 on PDN+CSA and 46 on PDN+MTX. We identified 30 (21.6%) patients for group 1, 43 (30.9%) for group 2 and 66 (47.5%) for group 3. At baseline all 3 groups had a high level of disease activity with no differences in the CSM. Already in the first 2 months a clear differential trend in disease activity measures, according to clinical remission status and PDN discontinuation, could be identified. From the observation of the median change in the CSM of group 1 in the first 6 months, the following recommendations could be extrapolated: decrease corticosteroids from 2 to 1 mg/kg/day in 2 months if the MD-global, parent-global, CHAQ, DAS, CMAS, MMT or Phs measures have a change of at least 50%; from 1 to 0.5 mg/kg/day in the following 2 months if the MD-global, CHAQ, DAS, CMAS have a change of at least 20%; in the following 2 months (month 4-6) corticosteroids can be tapered up to the safe dose of 0.2 mg/kg/day, if the disease activity measures remain at low/normal values. We finally ran a logistic regression model that showed that the achievement of PRINTO criteria 50-70-90 at 2 months from disease onset, an age at onset >9 years and the combination therapy PDN+MTX, increase the probability of clinical remission from 4 to 7 times. (table 1)

**Conclusion:** We propose evidence based specific cut-offs for CS tapering/discontinuation based on the change in JDM CSM of disease activity, and identify the best predictors for clinical remission.

**Table 1. Logistic regression model for the outcome remission**

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects III: Lupus, Dermatomyositis, and Scleroderma

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** There are minimal data and no longitudinal studies regarding the long term cardiac health of children with cardiac manifestations of neonatal lupus (NL). This study was performed to evaluate risk factors for morbidity over time and provide evidence based guidance regarding the course of cardiac NL.

**Methods:** Echocardiograms throughout life were evaluated in 200 individuals born with cardiac NL from the Research Registry for Neonatal Lupus: 111 from ages 0-1 years, 156 ages 1-17 years, and 63 >17 years. A composite adverse outcome defined as qualitatively decreased left ventricular (LV) function or concurrent use of cardiac medications was assessed. Aortic dilation (root or ascending aorta z-score >2.0) was also recorded. Analyses were performed to associate the composite adverse outcome and aortic dilation with maternal medications, pacing, and fetal disease status, including a severity score based on mortality risk factors such as lower fetal heart rate and extranodal disease.

**Results:** The composite adverse outcome for cardiac dysfunction was identified in 18.9% of echos in children ages 0-1, 11.3% ages 1-17 and 20.6% ages >17. In 89 children in which echos were available at ages 0-1 and 1-17, 4/14 with dysfunction at ages 0-1 were also affected at ages 1-17, while 10 reverted to normal, and only 7/75 developed new dysfunction during age 1-17. In 31 cases with echos at ages 1-17 and >17, 1/2 cases with dysfunction at age 1-17 was also affected >17, and 3/29 developed new dysfunction in adulthood. Earlier age at pacemaker placement was associated with dysfunction in the 0-1 age group (p=0.018), but not in later ages. Cardiac dysfunction was significantly associated with number of years paced at ages >17 (p=0.001), but not earlier. A lower fetal ventricular heart rate at initial heart block detection was associated with cardiac dysfunction in all age groups (p=0.038, 0.009, 0.016 respectively). Fetal extranodal cardiac disease was associated with dysfunction (p=0.046) in ages >17. Higher fetal severity score associated with postnatal dysfunction in all age groups (p=0.063, 0.03, 0.005). Aortic dilation was present in 15.3% at ages 0-1 and 17.6% at ages 1-17, but at >17, dilation only occurred in 7.9%. There was no association of postnatal cardiac dysfunction or aortic dilation with maternal medication use, maternal rheumatic disease, fetal age at heart block detection or gestational age of birth.

**Conclusion:** Cardiac dysfunction in the first year normalizes by later childhood in the majority of cases, possibly due to the short term effects of cardiac pacing or resolution of inflammation with the clearance of maternal autoantibodies. Aortic dilation can continue for longer periods, but also decreases in frequency with age. Nevertheless, cardiac dysfunction does persist in a fifth of cases and in adulthood there are associations with fetal extranodal disease and heart rate at detection. Patients who develop morbidity in utero may have subclinical damage or be more susceptible to future insults that manifest later in life, which can be exacerbated by prolonged pacing. Close monitoring and aggressive treatment of early extranodal disease in cardiac NL may have long term benefit in preventing subsequent morbidity.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects III: Lupus, Dermatomyositis, and Scleroderma

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Childhood-onset systemic lupus erythematosus (cSLE) is characterized by changing disease activity: episodes of improvement are often followed by episodes of worsening, i.e. flares. Considering changes of previously defined core response variables (proteinuria [mostly from protein creatinine ratio, PCR], disease activity (SLEDAI, BILAG), physician global assessment of cSLE activity), and ESR, preliminary flare algorithms have been derived by Classification Tree Analysis (CART) and multinomial logistic regression (MLR), respectively. International consensus yielded 4 preferred criteria for detection of cSLE flares, based on initial validation in 2010-11. These algorithms yield *flare-scores*, with higher scores reflecting worse flares. Our objective was to validate the preliminary cSLE flare algorithms, and delineate flare scores that reflect mild/moderate/major flares.

**Methods:** A total of 1,860 Patient Profiles (PPs) providing relevant data at baseline and follow-up were generated from existing international prospective cSLE cohorts, with systematic imputation of missing algorithm variables. Pediatric rheumatologists (PP-raters) were asked to judge disease courses between baseline and follow-up as: improved, no change, mild flare, moderate flare, or major flare. Based on majority opinion of PP-raters, each PP was assigned a true disease course, against which the flare algorithms were tested for accuracy. Using two complementary approaches (distribution-weighted, MLR-based) potential threshold flare-scores for flare severity (mild, moderate, major) were derived and tested for accuracy via area under the receiver operating characteristic curve (AUC). Analyses were reviewed by an expert panel that used nominal group technique to achieve consensus ( $\geq 75\%$  agreement).

**Results:** Among 503 invited, feedback from 274 PP-raters (53% response rate) was available for analysis. Based on PP-rater feedback, true disease courses were as follows: 540 no change or improved and 510/483/325 PPs as mild flare/ moderate flare/ major flare. There was consensus to use MLR estimates for all flare thresholds. As shown (Table 1), CART-based models, though maintaining very good to excellent accuracy (AUCs for mild/moderate/major flares all  $>70\%$ ), were less suited to discriminate mild and moderate flares. Algorithms from MLR maintained outstanding accuracies (all AUC  $> 90.79\%$ ) and had sensitivities/specificities for mild/moderate/major flares all  $>82\%/>82\%$  in the 2017 validation analyses. This was true for both BILAG and SLEDAI-based algorithms (see Table 1).

**Conclusion:** The provisional criteria for flare of global disease of cSLE have outstanding accuracy in identifying flare in cSLE with different degrees of severity. Based on our results and consensus, the BILAG and the SLEDAI-based algorithm from MLR are equally acceptable to measure flares in cSLE.

	<b>Table 1: Comparison of the Performance of the Preliminary Flare Algorithm in the Development and Validation Dataset</b>				
Method	Preliminary Flare Algorithms*	Flare severity	Threshold scores from logistic regression	Area under ROC curve	
				<b>2010 data</b>	<b>2017 data</b>
<b>Logistic regression</b>	0.5 x SLEDAI + 0.45 X PCR + 0.5 X MD- global+ 0.02 x ESR	Major	6.4	95.12%	93.11%
		Less than or equal to Moderate	3.0	85.14%	93.94%
		Less than or equal to Mild	0.6	85.99%	93.11%
	0.4 x BILAG + 0.65 X PCR + 0.5 X MD-global + 0.02 x ESR	Major	7.4	93.10%	90.79%
		Less than or equal to Moderate	3.7	84.92%	92.04%
		Less than or equal to Mild	2.2	84.81%	93.06%
<b>Classification tree analysis (CART)</b>	S4 if 3 less than or equal to SLEDAI; S3 if 0.7 less than or equal to PCR; S2 if 2 less than or equal to MD- global; S1 Other	Major	4	85.14%	76.21%
		Less than or equal to Moderate	3	79.52%	80.17%
		Less than or equal to Mild	3	83.86%	89.01%
	S4 if 2 less than or equal to BILAG; S3 if 0.7 less than or equal to PCR; S2 if 2 less than or equal to MD-	Major	4	85.92%	70.66%
		Less than or equal to Moderate	3	79.52%	74.59%
		Less than or equal to Mild	3	82.24%	84.12%

	global; S1 Other

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

## Background/Purpose:

Juvenile systemic sclerosis (jSSc) patients with overlap features seems to have a better long term outcome<sup>1</sup>. There is currently no data, where the clinical characteristics of patients with and without overlap features were compared.

## Methods:

Patients, fulfilling the PRES jSSc-classification criteria were included. Organ involvement was assessed using the standardized assessment. Patients were classified to diffuse (dcjSSc) and limited (lcjSSc) subtype and grouped as patients with and without overlap features.

## Results:

Till April 2016 eighty patients were enrolled. We present data at time point of the enrollment. 11 of the patients had overlap features (ojSSc). 6 of 58 (10%) in the dcjSSc and 5 of 22 (23%) in the lcjSSc. Most patients were Caucasian. Female/male ratio differed in the groups, in the nojSSc 3.9:1 and in the ojSSc 11:1 (p=0.1). Mean disease duration was 3.6 years in the non-overlap features group (nojSSc) and 3.2 years in the ojSSc group. Patients with nojSSc were 35% Scl-70 positive and ojSSc group none (p=0.032). Decreased DLCO occurred in 48% in the nojSSc and in 100% in the ojSSc group (p=0.088). Renal involvement was more frequent in the ojSSc group with 18% compared to 4% the nojSSc (p=0.078). Swollen joints occurred in 63% in the ojSSc and in 29% in the nojSSc group (p<0.001). Muscle weakness combined with joint contractures occurred in 43% in the ojSSc and in 8% in the nojSSc group (p=0.011).

## Conclusion:

Patients with overlap features have distinct characteristics compared with patients with nojSSc. This characteristics were no Scl-70 positivity, higher portion of interstitial lung disease, renal involvement, arthritis and muscle involvement accompanied by joint contractures. The future larger patient data collection in our cohort will help to make the differences more accentuated.

Kwa<sup>2</sup>, Anne Laumann<sup>2</sup> and Kaveh Ardalan<sup>3,4</sup>, <sup>1</sup>Dermatology, Preventive Medicine and Medical Social Sciences, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>2</sup>Dermatology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>3</sup>Departments of Pediatrics and Medical Social Sciences, Northwestern

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects III: Lupus, Dermatomyositis, and Scleroderma

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

## Background/Purpose:

Juvenile dermatomyositis (JDM) is an autoimmune disease that causes vasculopathy and inflammation of skin and muscles. Previous studies in adult dermatomyositis suggest increased risks of cardiovascular disease, but such assessments in JDM remain underexplored. This study evaluates cardiovascular risk factors and outcomes in children with versus without JDM.

## Methods:

Data were analyzed from the 2002-2012 Nationwide Inpatient Sample, containing a representative 20% stratified sample of all hospitalizations in the United States. Primary (i.e. condition chiefly responsible for inpatient admission) vs secondary diagnoses of JDM (age <18 years) were identified using the previously validated *ICD-9-CM* code 710.3. Comorbidities were identified using *ICD-9-CM* codes in NIS for each patient discharge. Survey weighted logistic regression models were used to determine associations of JDM with comorbidities. Multivariate models included age, sex and race/ethnicity (model-1), as well as obesity, hypertension and diabetes (model-2) as binary covariates. A 2-sided *p*-value <0.05 was considered statistically significant.

## Results:

From 2002-2012, 909 primary and 498 secondary diagnoses of JDM were identified (from 14,535,620 pediatric hospital discharges). JDM inpatients were 34.6% male, 49.0% white, 18.5% black and 24.1% Hispanic. Twelve of 13 cardiovascular comorbidities were significantly associated with JDM (Table 1). Hypertension was the most common comorbidity in children with JDM (8.78% JDM patients vs 0.43% those without JDM, OR [95% CI]: 22.25 [15.51-31.92]). JDM was also associated with higher rates of obesity, uncomplicated diabetes, and lipid abnormalities. JDM inpatients had higher odds of cardio/cerebrovascular disorders, i.e. peripheral/visceral atherosclerosis, late effects of cerebrovascular disease, personal history transient ischemic attack/cerebral infarction, pulmonary circulatory disorder, arrhythmia, bradycardia, and hypotension. In multivariate regression models adjusting for age, gender and race/ethnicity, associations with JDM remained significant in 10 of 13 comorbidities.

## Conclusion:

JDM is associated with higher odds of cardiovascular and cerebrovascular risk factors and disease. The possible interaction of chronic inflammation, vasculopathy, and treatment side effects with sociodemographic and cardiovascular risk factors requires further study.

Table 1. Association between juvenile dermatomyositis and cardiovascular comorbidities in US children.

Comorbidity	No (n=14,485,143)		Dermatomyositis		Yes (n=1,407)

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects III: Lupus, Dermatomyositis, and Scleroderma

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** JDM presents with proximal muscle weakness and atrophy is frequent. Still, body composition (BC) in JDM has not been widely studied, but is known to be unfavourably altered in other CTDs and associated with physical disability. It has also been proposed that monocyte chemoattractant protein-1 (MCP-1), acting as a myokine, may promote inflammation in skeletal muscle in idiopathic inflammatory myopathies. Aim of study was to compare BC and myokines in JDM patients with controls and explore associations between measures of BC and myokines with physical function outcomes.

**Methods:** 59 JDM patients and 59 age- and sex-matched controls were included. BC including total and appendicular lean mass (LM) and fat mass (FM), was measured by DXA. MCP-1 and IL-6 in serum were quantified. Functional outcomes were short form-36 physical component summary (SF-36), childhood or adult HAQ (CHAQ/HAQ), manual muscle testing (MMT-8) and 6 minute walking test distance (6 MWD). Multiple linear backward regression was used to identify indicators of appendicular lean mass (ALM) and appendicular fat mass percentage (AFM%) and to assess associations between physical function outcomes and ALM, AFM% and myokines.

**Results:** Table 1 presents characteristics, BC and myokine levels in patients and controls. Median disease duration was 16.8 years; 61% were female; 28% were on prednisolone or DMARDs at follow-up. Patients had significantly higher ESR, lower SF-36, MMT-8, 6 MWD, and physical activity than controls.

BMI was comparable in patients and controls ( $P=0.752$ ). Patients had 8% lower total lean mass, 10.4% lower appendicular LM and 6% lower trunk LM compared to controls (all  $P$ 's  $\leq 0.032$ ). Total body FM% was 10.6% higher, AFM% was 10.6% higher and android:gynoid fat ratio was 34.3% higher in patients than controls (all  $P$ 's  $\leq 0.017$ ). MCP-1 and IL-6 were higher in patients than controls ( $P$ 's  $\leq 0.017$ ).

In JDM patients, MCP-1 was an independent indicator of ALM ( $\beta=-0.041$ , 95%CI(-0.081, -0.001)) and CRP and DAS muscle independent indicators of AFM% ( $\beta=0.8$ , 95%CI (0.3, 1.3);  $\beta=1.3$ , 95%CI(0.3, 2.2)).

When identifying independent indicators of physical outcomes, ALM was associated with SF-36 and MMT-8 ( $\beta=0.6$ , 95%CI(0.1, 1.0);  $\beta=0.370$ , 95% CI(0.190-0.550)); AFM% with CHAQ/HAQ, MMT-8 and 6MWD ( $\beta=-0.005$ , 95%CI(0.001, 0.009);  $\beta=-0.132$ , 95%CI(-0.203, -0.062);  $\beta=-1.968$ , 95%CI (-2.931, -1.006)) and MCP-1 with CHAQ/HAQ and 6MWD ( $\beta=0.004$ , 95%CI(0.001, 0.008) and  $\beta=-1.512$ , 95%CI(-3.264, -0.241)).

**Conclusion:** JDM patients assessed after long-term disease duration had unfavorable alterations in BC compared with controls, including lower LM and higher FM percentage. MCP-1 was higher in patients compared with controls, and independently associated

with lower ALM and poorer functional outcomes in patients. Low ALM and high AFM percentage were also independently associated with impaired physical function in patients.

Table 1. Characteristics and body composition data in JDM patients and controls.

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy V: Imaging and Cardiovascular Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Although previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO) for the treatment of rheumatoid arthritis (RA),<sup>1,2</sup> changes in active intra-articular inflammation after discontinuation of methotrexate (MTX) in patients achieving good clinical control with TCZ + MTX have not been evaluated. Magnetic resonance imaging (MRI) effectively images synovitis and osteitis and can detect changes in bone erosion with greater sensitivity than radiography.<sup>3</sup> This study used MRI to assess differences in joint damage between patients with RA who achieved low disease activity with TCZ + MTX and then continued or discontinued MTX in the COMP-ACT trial (NCT01855789).

**Methods:** US patients with RA who were inadequate responders to MTX were enrolled; initial combination therapy included MTX ( $\geq 15$  mg/week orally) plus TCZ 162 mg subcutaneous (SC) either weekly or every 2 weeks. Patients who achieved DAS28-ESR  $\leq 3.2$  at week 24 were randomized 1:1 to receive TCZ-MONO or continue TCZ + MTX until week 52 (double blind). A subset of these patients was included in this MRI substudy; 1.5 Tesla MRI was used to obtain images of bilateral hands and wrists at Weeks 24 and 40. Two independent radiologists evaluated images at a central reading facility using RAMRIS (synovitis, osteitis, erosion) and CARLOS (cartilage loss). Outcomes included changes in MRI scores from Week 24 to 40 and the proportion of patients with progression of each score.

**Results:** Of the 296 patients who achieved DAS28  $\leq 3.2$  at Week 24 and were randomized to TCZ + MTX or TCZ-MONO, 79 were enrolled in the MRI substudy (n = 41 and 38, respectively); 74.7% were women, and the mean (SD) age was 56.3 (12.8) years. Patient demographics in the MRI substudy were similar to overall study demographics. Mean changes from Week 24 to 40 in bone erosion, synovitis, osteitis and cartilage loss scores were not significantly different between the TCZ + MTX and TCZ-MONO groups for both bilateral hands and the dominant hand (**Table**). There were no significant differences between the groups in the proportion of patients with no progression in each outcome measure (range, 89.7% to 97.4% with TCZ + MTX and 87.9% to 100.0% with TCZ-MONO).

**Conclusion:** In patients who achieved low disease activity with TCZ + MTX, MRI changes were minimal and showed no difference in the response of active intra-articular inflammation in patients who discontinued MTX vs those who continued TCZ + MTX within the period of observation, consistent with the result of similar mean change in DAS28 between the groups in the primary analysis.

**Table.** MRI Changes in Patients Receiving TCZ in Combination With MTX or TCZ as Monotherapy

	Both Hands			Dominant Hand		
Mean change from Week 24 to 40*	TCZ + MTX (n = 41)	TCZ-MONO (n = 38)	Difference (95% CI) (TCZ-MONO minus TCZ + MTX)	TCZ + MTX (n = 41)	TCZ-MONO (n = 38)	Difference (95% CI) (TCZ-MONO minus TCZ + MTX)
Bone erosion score (0-250), mean (SE)	-0.06 (0.18)	0.18 (0.19)	0.24 (-0.21 to 0.68)	0.06 (0.25)	0.49 (0.25)	0.43 (-0.14 to 1.01)
Synovitis score (0-24), mean (SE)	-0.24 (0.15)	-0.18 (0.15)	0.06 (-0.30 to 0.41)	-0.22 (0.12)	-0.11 (0.12)	0.11 (-0.18 to 0.40)
Osteitis score (0-75), mean (SE)	-0.16 (0.34)	0.37 (0.36)	0.53 (-0.30 to 1.36)	-0.39 (0.52)	0.69 (0.54)	1.07 (-0.18 to 2.33)
Cartilage loss score (0-100), mean (SE)	0.20 (0.14)	-0.03 (0.15)	-0.23 (-0.58 to 0.11)	0.11 (0.18)	-0.05 (0.19)	-0.16 (-0.59 to 0.27)

MTX, methotrexate; TCZ, tocilizumab; TCZ-MONO, TCZ monotherapy.

\* ANCOVA model for estimated means includes Week 24 bone erosion as a covariate, treatment group and the randomization stratification factors: DAS28 remission status at Week 24 (< 2.6, ≥ 2.6 to ≤ 3.2), patient anti-TNF exposure (Yes or No) and baseline weight-by-dosing group (< 80 kg q2w, 80 to < 100 kg q2w, 80 to < 100 kg qw, ≥ 100 kg qw).

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy V: Imaging and Cardiovascular Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Ultrasound (US) is an established non-invasive tool for sensitively assessing disease activity at the individual-joint level in rheumatoid arthritis (RA). Synovial thickness is detectable on grey-scale US and synovial vascularity by power Doppler US (PDS).<sup>1</sup> Studies have shown that PDS correlates with clinical assessment of disease activity and synovial histopathology.<sup>2</sup>

Furthermore, PDS can detect subclinical synovitis.<sup>3</sup> Sirukumab (SIR), a human monoclonal antibody that selectively binds to IL-6 with high affinity, demonstrated efficacy in RA in several phase 3 studies including SIRROUND-H (active comparator monotherapy study). The ability of grey-scale US and PDS to evaluate changes in synovitis was assessed following SIR and adalimumab (ADA) treatment in patients (pts) with moderate to severe RA in a substudy of SIRROUND-H.

**Methods:** In SIRROUND-H, US assessment was carried out at 9 clinical sites in a nested subset of 41 pts, with 27 pts pooled from SIR 50mg q4w/SIR 100mg q2w and 14 pts in the ADA 40mg q2w treatment groups. Assessments were performed at baseline (BL), and Wks 2, 4, 8 and 24. 12 joints (10 metacarpal [MCP] plus wrists) were evaluated and synovial vascularity (VASCi), thickness (STI) and tenosynovitis/hyperemia (wrist) scores were reported for each timepoint. Significance of differences between baseline and post-treatment timepoints were tested using Wilcoxon signed-rank and Mann-Whitney tests ( $\alpha=0.05$ ).

**Results:** BL VASCi and STI scores correlated with BL disease activity (DAS28[CRP], CDAI, and swollen and tender joint counts). Pts who were ACPA and RF positive had significantly higher BL VASCi and STI scores. Initial analysis of post-treatment changes in PDS outcomes showed no significant differences from BL at the population level. However, a significant proportion of the study cohort (36.6% or 15/41) had a BL VASCi score  $<1$ , leaving little room for evaluable improvement. When the analysis of post-treatment changes was restricted to pts with a BL VASCi  $>1$  ( $n=26$ ), both SIR and ADA treatment showed significant reductions in VASCi starting at Wk 4 and sustained through Wk 24 ( $P<0.05$  vs BL). Wk 24 DAS remission was associated with lower BL VASCi and STI ( $P<0.05$ ). The Wk 24 changes in VASCi and STI did not correlate with Wk 24 DAS28(CRP) or DAS28(ESR) changes from baseline. STI was not changed with SIR or ADA treatment over the course of the study duration (24 wks) and there was no observed difference in effect on vascularity or thickness between patients treated with SIR vs ADA.

**Conclusion:** Our study demonstrates the utility of non-invasive PDS of small joints to detect synovial changes following drug treatment in RA patients with high baseline VASCi scores. Both SIR and ADA similarly improved VASCi scores from Wk 4. A correlation between changes in PDS score and disease activity was not observed in this small substudy, consistent with reports in the literature.<sup>3</sup> In conclusion, PDS can detect changes in joint pathology with treatment and is feasible for use in global clinical studies.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy V: Imaging and Cardiovascular Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Clinicians rely on time-efficient, validated disease activity assessments to help accurately predict disease progression in patients with RA. The utility of the Routine Assessment of Patient Index Data 3 (RAPID3)<sup>1</sup> in predicting structural damage progression is largely unknown, while that of DAS28 (CRP)<sup>2</sup> and modified (M-)DAS28 have been previously reported.<sup>3</sup> This *post hoc* analysis using data from the AVERT (NCT01142726) study investigated the value of baseline clinical measures for predicting structural damage progression with MRI as a measure of progression. **Methods:** AVERT was a 24-month, active-controlled trial with a 12-month, double-blind treatment period, during which MTX-naïve, ACPA-positive patients with early active RA were randomized (1:1:1) to abatacept 125 mg weekly plus MTX or abatacept or MTX monotherapy, followed by a 12-month withdrawal period, during which all treatment was stopped.<sup>4</sup> Logistic regression analysis, corrected for age, sex and corticosteroid use at baseline, was used to assess the correlation between baseline measures of disease activity (DAS28 [CRP], SDAI, CDAI, M-DAS28 and RAPID3) and the degree of structural joint damage, as assessed by MRI at 6 and 12 months. MRI erosion progression was defined as change from baseline greater than the smallest detectable change, which was calculated as SD/square root (2) x 1.96 (where SD is standard deviation of paired differences of change from baseline in total score between two readers). **Results:** Logistic regression analysis was carried out for all randomized and treated patients who received abatacept + MTX (n=119) or MTX monotherapy (n=116). For these patients, DAS28 (CRP), M-DAS28 and RAPID3 at baseline were significant predictors of radiographic progression at Months 6 and 12 (Figure). Baseline SDAI was a significant predictor at Month 12 but not Month 6, and baseline CDAI was not a significant predictor at either time point (Figure). At Months 6 and 12, receiver operating characteristic curves showed that RAPID3 had the highest predictive value (area under the curve) for MRI progression (Table).

**Conclusion:** In this *post hoc* analysis of MTX-naïve, ACPA-positive patients with early RA, DAS28 (CRP), M-DAS28 and RAPID3 were significant predictors of structural damage progression at Months 6 and 12, as measured using MRI, with RAPID3 showing the highest predictive value for MRI progression. 1. Yazici Y, et al. *J Rheumatol* 2008;**35**:603–9. 2. Salaffi F, et al. *BMC Musculoskeletal Disord* 2011;**12**:120. 3. Baker JF, et al. *Arthritis Rheumatol* 2014;**66**:794–802. 4. Emery P, et al. *Ann Rheum Dis* 2015;**74**:19–26.

**Figure. Logistic Regression Model of the Correlation Between Disease Activity at Baseline and MRI Progression at Months 6 and 12 (all Randomized and Treated Patients)**

**Table. Area Under ROC Curves for the Impact of Disease Activity at Baseline on MRI Progression at Months 6 and 12 (all Randomized and Treated Patients)**

Disease activity measure*	AUC at Month 6	AUC at Month 12
DAS28 (CRP)	0.6322	0.6466
RAPID3	0.7181	0.7047
M-DAS28	0.6488	0.6823
CDAI	0.5666	0.5958
SDAI	0.6549	0.6647

\*M-DAS28 was calculated based on a different statistical model (which also included DAS28 [CRP] and RAPID3) due to a different number of patients with non-missing values. In the other model, the AUC for DAS28(CRP) and RAPID3 at Month 6 were 0.6281 and 0.7157, respectively. At Month 12 the values were the same for both models  
AUC=area under the curve; M-DAS28=modified DAS28; ROC=receiver operating characteristic

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy V: Imaging and Cardiovascular Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** The aim of this study was to evaluate left ventricular myocardial function with two- dimensional speckle tracking echocardiography (STE), in addition to conventional Doppler and tissue Doppler echocardiography, in order to detect subclinical left ventricular myocardial dysfunction in patients with RA.

**Methods:** The study involved 30 outpatients who fulfilled the 2010 ACR/EULAR) criteria for RA (11 males and 19 females; mean age 54.63±9.36 years, median disease duration 2 years), at baseline at after 18 months of treatment with anti-TNF drugs and 30 healthy controls matched in terms of age, gender and other anthropometric characteristics. All patients underwent a complete physical examination and routine laboratory analysis. Disease activity was assessed by means of Disease activity score 28 (DAS 28).

Cardiovascular (CV) risk profiles were assessed by means of standard ECG, conventional and stress trans-thoracic echocardiography with the measurement of CFR, carotid ultrasonography and pulse wave velocity (PWV). Two-dimensional echocardiographic images were obtained using the apical 4-chamber view at a high frame rate of 70-80 frames/s, and three cardiac cycles were stored in cine-loop format for off-line analysis using commercially available QLAB 9 software (Philips Medical System, USA) in order to assess end-systolic LV longitudinal strain ( $\epsilon$ ).

## Results:

None of the patients showed any signs or symptoms of CV disease, pulmonary involvement, or any other complication. The patients' mean LVEF and E/A ratios were respectively  $58.43 \pm 3.07\%$  and  $0.75 \pm 0.35$ , which were not significantly different from those of the controls ( $60.45 \pm 5.24\%$  and  $0.85 \pm 0.29$ ); however, although within the normal range. The results of the speckle tracking analysis were significantly different between the two groups, with global longitudinal strain deformation in the apical 4-chamber view (Long.  $\epsilon$  4c) being significantly lower in the RA patients (Long.  $\epsilon$  4c %: median 18.78, IQR 15.80-20.82 vs 20.16, IQR 19.03-21.89;  $p < 0.05$ ). Right and left pulse wave velocity (PWV) (PWV right, m/sec: median 7.92, IQR 7.14-8.60 vs 6.85, IQR 6.41-7.88;  $p = 0.07$  and PWV left, m/sec: median 7.90, IQR 6.99-8.16 vs 6.85, IQR 6.36-7.84;  $p = 0.06$ ) and right and left coronary intima media thickness (cIMT) (cIMT right, mm: median 0.90, IQR 0.75-1.08 vs 0.75, IQR 0.50-0.85;  $p < 0.05$  and cIMT left, mm: median 0.89, IQR 0.74-0.99 vs 0.74, IQR 0.49-0.85;  $p < 0.05$ ) values were all higher in the RA patients, and the differences of cIMT were statistically significant. Furthermore a significant improvement in Long.  $\epsilon$  4c of LV in RA patients at 18 months of the biological treatment was observed (Long.  $\epsilon$  4c %: median 18.78, IQR 15.80-20.82 vs 19.24, IQR 17.02-21.29  $p < 0.01$ ) at FUP, such as a minimal reduction of arterial stiffness and cIMT parameters ( $p = \text{NS}$ ).

**Conclusion:** LV myocardial longitudinal  $\epsilon$  measured by means of speckle tracking echocardiography was impaired in RA patients in the absence of any clinical evidence of CV disease and echocardiographic evaluations negative. This data suggests an early myocardial alteration, but further studies are required to define more precise methods of assessing CV disease in RA population.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy V: Imaging and Cardiovascular Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

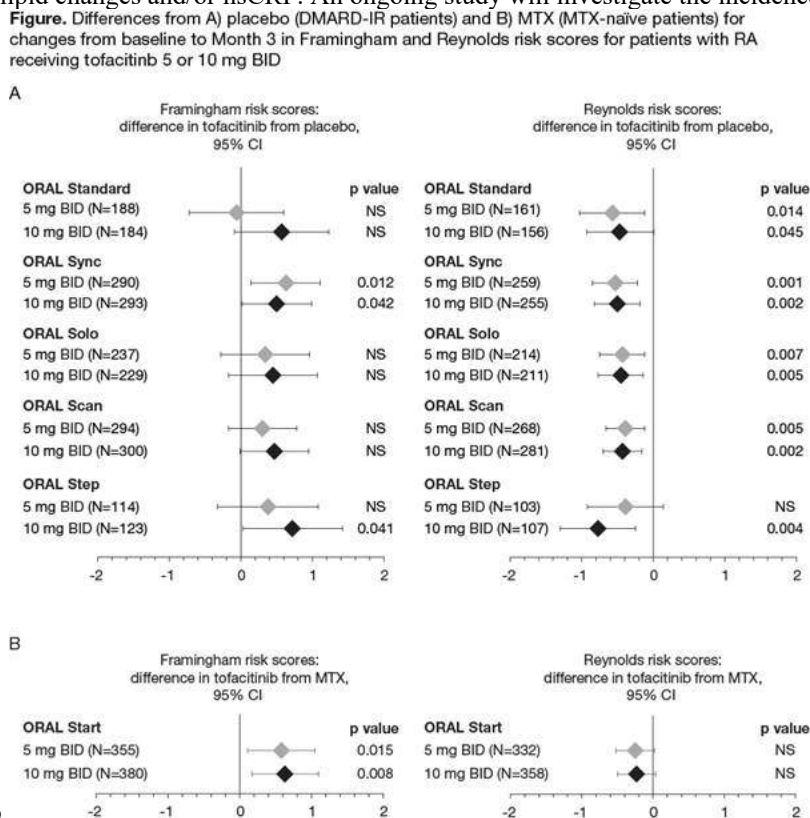

**Background/Purpose:** Patients (pts) with RA are at increased risk of myocardial infarction and stroke not fully explained by usual cardiovascular (CV) risk factors. Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Small, dose-dependent increases from baseline in total, LDL-c, and HDL-c have been noted in some pts. Major adverse cardiovascular events (MACE) are infrequent in the tofacitinib clinical program. The Framingham and Reynolds risk scores calculate the 10-year risk of developing CV disease; Reynolds risk score includes high-sensitivity C-reactive protein (hsCRP) as a variable, Framingham risk score does not. We scored pts receiving tofacitinib to investigate the impact of changes in lipids and hsCRP on CV risk scores.

**Methods:** This was a post-hoc analysis of 6 Phase 3 randomized controlled trials (disease-modifying antirheumatic drug [DMARD]-inadequate responders [IR] in ORAL Standard [NCT00853385; N=471]; ORAL Sync [NCT00856544; N=729]; ORAL Solo

[NCT00814307; N=574]; ORAL Scan [NCT00847613; N=739]; ORAL Step [NCT00960440; N=353]; methotrexate [MTX]-naïve pts in ORAL Start [NCT01039688; N= 906]). Pts received tofacitinib 5 or 10 mg BID either as monotherapy (ORAL Solo, ORAL Start), with background MTX (ORAL Standard, ORAL Scan, ORAL Step), or csDMARDs (ORAL Sync). All trials were placebo (pbo) controlled except ORAL Start (tofacitinib vs MTX). Pts with diabetes were excluded from this analysis. Framingham and Reynolds CV risk scores were calculated at baseline (BL) and Month 3. Change from baseline was assessed using a linear mixed model for repeated measures, controlling for treatment.

**Results:** 2/5 trials in DMARD-IR pts (ORAL Sync [tofacitinib 5 mg p=0.012; tofacitinib 10 mg p=0.042] and ORAL Step [tofacitinib 10 mg only p=0.041]), showed a significantly higher change from BL to Month 3 in Framingham risk score with tofacitinib vs pbo (Figure); Reynolds risk scores were significantly (all <0.05) reduced from BL to Month 3 with both doses of tofacitinib vs pbo except ORAL Step, in which there was no significant difference in change from BL to Month 3 between tofacitinib 5 mg BID and pbo (Figure). Change from BL to Month 3 in Framingham risk score was significantly higher with tofacitinib 5 mg and 10 mg vs MTX in ORAL Start; however, for Reynolds risk score there was no significant difference between either dose of tofacitinib and MTX.

**Conclusion:** In this analysis, the 10-year Framingham CV risk score was not significantly increased with tofacitinib vs pbo in 3 out of 5 Phase 3 trials, although a higher CV risk score was identified vs MTX. The 10-year CV risk calculated by Reynolds risk score, which includes hsCRP as a variable, was significantly reduced with tofacitinib vs pbo and there was no difference vs MTX. CV risk with RA treatment is a function of lipid changes and/or hsCRP. An ongoing study will investigate the incidence of MACE with tofacitinib vs

etanercept or adalimumab.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy V: Imaging and Cardiovascular Outcomes Therapy

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** While, a Treat-to-Target strategy (T2T), treating patients with rheumatoid arthritis (RA) towards a certain target (eg. clinical remission; T2T-REM), is highly recommended, several patients in clinical remission often have residual synovitis on ultrasound-imaging (US). This may result in silent radiographic progression and clinical flare. It is arguable whether targeting US-synovitis may result in ‘deeper’ remission in clinical practice. We aimed to assess whether using US in a T2T strategy leads to more patients meeting clinical remission than using only clinical information.

**Methods:** Patients with RA who started or changed csDMARD and/or anti-TNF treatment followed in centers with expertise in US and participating in BIODAM (2-year multicenter prospective observational cohort) were included. Clinical and US data [by the US7-score that includes 7 joints of the clinically dominant hand and foot for synovitis and tenosynovitis on gray-scale US (GSUS) and power-doppler US (PDUS) and erosions on GSUS] were collected every 3 months. Per visit and per protocol was decided whether the patient was treated according to the clinical definition of T2T with DAS44 remission as benchmark (T2T-DAS44). Though not mandatory, US-data could also be used for this purpose. T2T-DAS44 was considered correctly applied if: either i) a patient already had a disease activity score below the remission target (i.e. DAS44 remission) or ii) if not, treatment was intensified. A T2T strategy taking also US data into account (T2T-DAS44-US) was considered correctly applied if: either i) both DAS44 and US remission (all joints included in the US7-score with GSUS synovitis <2 and PDUS synovitis=0) were present; or ii) if not, the treatment was intensified. The main outcome was DAS44 remission. The effect of adding US to T2T (T2T-DAS44-US) on clinical remission 3 months later compared to a clinical remission benchmark only (T2T-DAS44) was analyzed using generalized estimating equations.

**Results:** In total 1,028 visits of 130 patients were included. T2T-DAS44-US was correctly followed in 41% of the visits, T2T-DAS44 in 23%, and any of these in 36%. Remission according to the DAS44 definition was achieved in 39% of the visits. Compared to the conventional T2T-DAS44 strategy, using a combined clinical and US benchmark for T2T led to a 40% lower – instead of higher - likelihood of DAS44 remission 3 months later [OR (95%CI): 0.59 (0.39; 0.91)(table).

**Conclusion:** Our results, from a non-randomized study, did not suggest an advantage of using US of 7 joints in addition to clinical examination as a T2T benchmark as compared to clinical examination alone in getting RA patients into clinical remission.

**Table.** Effect of following a T2T strategy taking both clinical and US data into account (T2T-DAS44-US) compared to the clinical definition of T2T (T2T-DAS44; reference) in meeting the targets 3 months later and over a period of 2 years.

T2T approach	Outcome	DAS44 remission aOR* (95% CI)
No T2T vs T2T-DAS44 alone <sup>§</sup>		0.69 (0.42; 1.15)
T2T-DAS44-US vs T2T-DAS44 alone <sup>§</sup>		<b>0.59 (0.39; 0.91)</b>

\*Adjusted for age, gender, HAQ-score, RF, ACPA, previous use of DMARDs, smoking-status, education and number of comorbidities. § Clinical definition of T2T (T2T-DAS44) was used as the comparator for each of the presented treatment strategies.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment V

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Patients with psoriatic arthritis (PsA) have a high disease burden with increased pain and more fatigue than the general population. Physical exercise is recommended for arthritis patients, although little research has been done assessing its utility. A pilot study suggests decreased disease activity in patients with spondyloarthritis (1) after high intensity interval training (HIIT).

The primary aim of this study was to measure the efficacy of HIIT on fatigue, secondly the efficacy on disease activity in PsA.

**Methods:** PsA patients satisfying CASPAR criteria were recruited from clinics to this randomized clinical trial. The intervention group (N=32) performed HIIT, defined as 4 times 4 minutes supervised training at 85-95% of maximum heart rate on a stationary bicycle twice a week, in addition to one additional self-guided HIIT session a week for 11 weeks. The control group (N=31) was instructed not to change their pre-study physical exercise habits during 11 weeks of the study. Before the intervention period, all participants tested their maximum heart rate and VO2max.

Fatigue and Patient Global Assessment (PGA) of overall disease activity were measured on a 100 mm VAS. Activity of arthritis was measured by DAS44. Measurements were performed at baseline and at 3 months. Mean differences within and between groups were analyzed using linear mixed models.

**Results:** Of the 63 patients included, 29 in the intervention group and 28 in the control group completed the trial period. Mean (SD) age was 51(11) years in the intervention group and 45(12) years in the control group. The proportion of women was 68% in the intervention

group and 63% in the control group. HIIT was associated with reduced fatigue at 3 months (mean difference 12.95; 95% CI -25.97 to 0.05), and changed from 48.6 to 32.8 ( $p=0.002$ ) in the intervention group; from 48.6 to 45.8 ( $p=0.569$ ) in the control group. There was no effect of HIIT on DAS44 (mean difference 0.08; 95% CI -0.36 to 0.20) or PGA (mean difference 0.56; 95% CI -10.99 to 9.86). DAS44 was reduced from 1.98 to 1.61 ( $p=0.001$ ) in the intervention group and from 1.98 to 1.69 ( $p=0.006$ ) among controls, whereas PGA declined from 40.0 to 34.3 ( $p=0.158$ ) in the intervention group and from 40.0 to 34.9 ( $p=0.195$ ) in controls. Medication did not change during the study period.

**Conclusion:** Fatigue was significantly reduced at 3 months in the intervention group. HIIT was well tolerated in PsA patients concerning disease activity measured by DAS44 and PGA. This study suggests that HIIT may be of benefit to PsA patients. Thus, HIIT could be an important contribution to cost-efficient treatment strategies as supplementary to medical treatment for this group of patients.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment V

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets interleukin-17A. In patients with active psoriatic arthritis (PsA) who had an inadequate response to tumor necrosis factor inhibitors (TNFi), IXE was superior to placebo (PBO) in improving the signs and symptoms of PsA after 24 weeks of treatment (SPIRIT-P2; NCT02349295).<sup>1</sup> The objective

of this study is to report the Week 52 interim efficacy and safety findings of IXE treatment during the Extension Period (EP) of SPIRIT-P2 (Weeks 24-156).

**Methods:** SPIRIT-P2 is a phase 3, multicenter, double-blind study. All 363 patients had an inadequate response to one or two TNFi or were intolerant to TNFi. During the Double-Blind Treatment Period (DBTP; Weeks 0-24), patients were randomly assigned 1:1:1 to subcutaneous administration of either 80 mg IXE every 4 weeks (Q4W; N=122) or every 2 weeks (Q2W; N=123) following a 160 mg starting dose at Week 0, or PBO (N=118). Of these, 310 patients completed the DBTP and entered the EP (Weeks 24-156). Patients randomized to IXE at Week 0 continued the same dose regimen in the EP. PBO patients were re-randomized (1:1) to IXE Q4W or Q2W at Week 16 (inadequate responders) or 24. In this interim analysis, efficacy (up to Week 52) and safety (up to Week 156) were analyzed using the EP population, defined as all patients who received at least 1 dose of study drug in the EP. Missing values were considered non-response for categorical data and were imputed by modified baseline observation carried forward for continuous data.

**Results:** In the DBTP, a significantly higher percentage of patients achieved ACR20 at Week 24 with IXE Q4W (53%) or Q2W (48%) than with PBO (20%).<sup>1</sup> For patients who entered the EP, the mean age was 52 years, 47% were male, the mean time since PsA onset was 12 years, and mean tender and swollen joint counts at baseline (Week 0) were 23 and 12, respectively. For EP patients who were initially randomized to IXE Q4W or Q2W during the DBTP, ACR20 responses at Week 52 were 68% and 59%, respectively. For patients treated with PBO during the DBTP and re-randomized to IXE Q4W or Q2W during the EP, ACR20 responses at Week 52 were 61% and 50%, respectively. Additional efficacy measures are depicted in the Table. The frequency of adverse events (AEs) in the EP are presented in the Table; the majority were mild or moderate in severity. Serious AEs occurred in 15 patients, and one death occurred in the EP population: a myocardial infarction in a PBO/IXE Q2W patient 502 days after starting IXE.

**Conclusion:** IXE demonstrated sustained improvement in the signs and symptoms of PsA across treatment groups during the EP. The safety profile of IXE observed in the EP population was consistent with the safety profile of the intent-to-treat population in the DBTP of SPIRIT-P2.<sup>1</sup>

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment V

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose :** Patients (pts) with psoriatic arthritis (PsA) may experience structural damage and irreversible functional impairment if not treated appropriately. Treatment with TNF inhibitors in rheumatoid arthritis (RA) pts showed inhibition of radiographic progression larger than expected based on the control of clinical disease activity.<sup>1</sup> Preliminary results showed that such a disconnect phenomenon may also be observed in PsA pts following treatment with adalimumab (ADA).<sup>2</sup> The objective of this analysis was to further examine the relationship between inhibition of radiographic progression and control of clinical disease activity using different disease activity measures following treatment with originator ADA versus placebo (PBO) in pts with active PsA.

**Methods :** ADEPT<sup>3</sup> was a 24-week (wk), randomized, double-blind trial comparing the safety and efficacy of ADA with PBO in pts with active PsA. In this post hoc analysis, radiographic progression, defined as change from baseline (BL) to wk 24 in modified total Sharp score ( $\Delta$ mTSS)  $>0.5$ , was calculated in pts with evaluable radiographs at both time points. Pts were classified based on achieving minimal disease activity (MDA) and different subcategories of disease activity (remission, low, moderate, or high) based on time-averaged (TA) DAS28(CRP), DAPSA, and PASDAS. The associations between  $\Delta$ mTSS and disease activity were assessed by Pearson ( $r_p$ ) or Phi ( $r_\phi$ ) correlation coefficients.

**Results :** Of the 296 pts (ADA, N=144; PBO, N=152) included in this analysis, higher proportions of pts receiving ADA compared with PBO achieved MDA and remission/low disease activity status across all the outcome measures. There was a significant interaction between treatment and disease activity status with respect to radiographic progression ( $P < 0.001$  for all outcome measures). In addition, treatment with ADA for 24 wks compared with PBO resulted in significantly lower mean  $\Delta$ mTSS even in pts with moderate or high disease activity (TA-DAPSA or TA-PASDAS) or not achieving MDA (**Table**). Radiographic progression showed a weak, but significant correlation with disease activity status in pts treated with PBO ( $r_p \geq 0.3$ ,  $P < .001$  for TA-DAS[CRP], TA-DAPSA, and TA-PASDAS;  $r_\phi = -0.14$  [95% CI:  $-0.20$  to  $-0.09$  for MDA]), but not ADA.

**Conclusion :** The results showed that the relationship between disease activity as determined by various outcome measures differed between ADA and PBO treated pts. ADA provided inhibition of radiographic progression which was somewhat larger and independent of the control of clinical disease activity. This supports the disconnect phenomenon in PsA following ADA treatment.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment V

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

Clinical joint assessment by the rheumatologist is a key examination of patients with psoriatic arthritis (PSA). A clinically swollen joint is predicting subsequent joint damage. Since joint assessment is regarded time-consuming, a tension exists between comprehensiveness, e.g. using complete joint counts (JC; 76/78 or 66/68), and feasibility. Reduced JC, such as the 28 joint count, however, may be less valuable in PSA than RA due to differences in joint patterns.

Here, we examined the validity of a reduced 28 swollen and tender JC, using the extended JC as comparators.

### Methods:

We analyzed data from a random subset of 80% of patients enrolled in the ADEPT (n=264) and the IMPACT-2 trial (n=163). In ADEPT a 76/78 JC was performed, in IMPACT-2, it was the 66/68 JC only. At week 24 of the two trials, patients with a complete absence of SJC or TJC by the 28-count were analyzed for their residual joint activity. Sensitivity and NPV for each joint count were calculated for each study. Finally, we analyzed the residual tender and swollen joints of 76/78 and 66/68 JC remained active in patients with a 28-joint count of 0 at endpoint.

### Results:

As summarized in table 1, investigation of SJC at week 24 in ADEPT showed that 63 of all 264 patients (23.9 %) achieved a SJC28=0; of these 63 patients, 51 (81%) also had a SJC66=0 and 50 (79.4 %) had a SJC76=0. Twelve and 13 patients, respectively, had residual SJC76 or SJC66 while having a SJC28=0. Of the 52 patients with a TJC28=0, 41 and 39, respectively, had also TJC78=0 and TJC68=0, while 11 and 13 patients had residual TJC68 or TJC78.

In IMPACT2, 50 of 163 patients (30.7%) achieved SJC28 remission, with 15 patients (30%) of these remaining active by SJC66. TJC28 remission was achieved by 44 patients, with 17 patients (38.6 %) not achieving complete TJC68 remission.

Exploration of individual residual swollen and tender joints showed mainly foot and ankle joints being active/tender at week 24, as can be seen in figure 1.

### Conclusion:

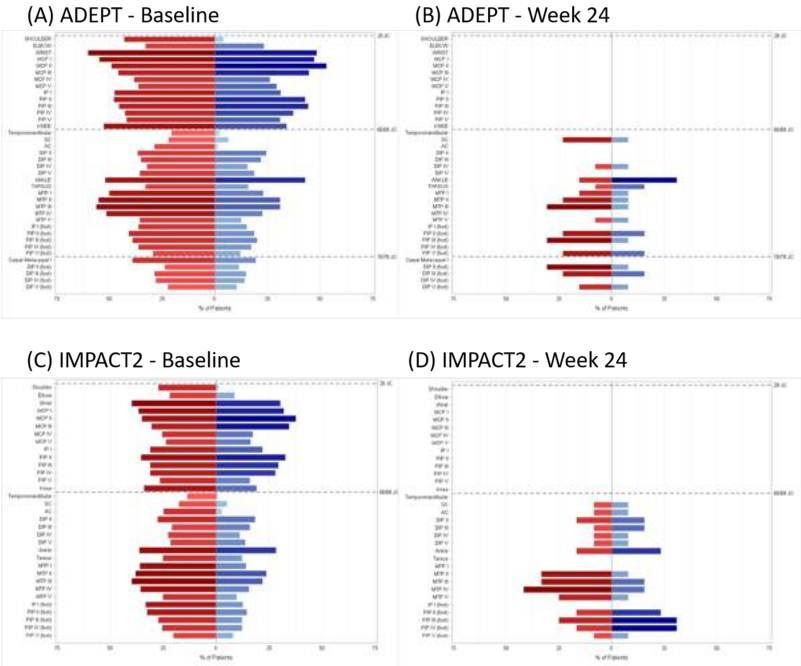

Absence of swelling by the 28 joint count in PsA seems to not adequately reflect the situation of all relevant joints, as in at least one of four patients residual clinical activity is detectable by more comprehensive 76/78 and 66/68 joint counts. Assessment of ankle and foot joints, especially MTPs, contributed numerically most to the missed joints. These limitations should be considered when treating PsA patients to target.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment V

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** There is conflicting data on the risk of myocardial infarction (MI) and cerebrovascular accidents (CVA) in patients with Ankylosing Spondylitis (AS). This study attempts to assess the future risk of newly recorded MI and CVA events among incident cases of AS compared to non-AS controls from the general population by utilizing physician billing, medication, and hospitalization data that covers the entire province of British Columbia (BC), Canada.

**Methods:** Our data includes all outpatient visits and hospitalizations (1990-2012) and all dispensed medications (1996-2012) for all BC residents. We conducted a retrospective matched cohort study of all patients > 18 years of age satisfying the following criteria: **1)** two ICD-9 or 10 codes (720.0 or M45) for AS at least two months apart and within a 2-year period by any physician or hospitalization; **2)** all AS cases had at least a 7-year run-in period before the 1st ICD code for AS in order to consider the case as incident. Each AS patient was matched with up to 10 controls by birth year, sex, and entry cohort time. The outcomes were a newly recorded MI (ICD-9-CM: 410 or ICD-10-CM: I21) or CVA (ICD-9 codes: 433-434, ICD-10 codes: I63-I66) event from hospital or death certificates. We estimated relative risks (RRs), adjusting for age, sex, and entry cohort time as well as multivariable models adjusting for confounders including glucocorticoids and non-steroidal anti-inflammatory drugs using a Cox proportional hazard model.

**Results:** 7,190 individuals with newly diagnosed AS were identified (48.7% female, mean age of 45.8 yrs). 7,148 and 7,107 were free of previous CVA/MI, respectively. 80 developed CVA (incidence rate= 1.8 per 1000 patient years) and 115 had MI (incidence rate= 2.6 per 1,000 patient years) (**Table 1**). The age-, sex-, and entry-time-matched RR for CVA was 1.60 (95% CI, 1.25-2.03) and MI was 1.52 (95% CI, 1.24-1.85). When adjusted for cardiovascular risk factors (obesity, angina, COPD, hospitalizations in year before index date, Charlson's comorbidity index, oral glucocorticoids, cardiovascular drugs, anti-diabetic medication, HRT, contraceptives, fibrates, statins, NSAIDs, and Cox-2 inhibitors), the estimated RR was 1.34 (1.04-1.73) for CVA and 1.21 (0.98-1.49) for MI.

**Conclusion:** This large population-based study demonstrates an increased risk of CVA, but not for MI. These findings support that increased monitoring for this potentially fatal outcome and its modifiable risk factors is warranted for AS patients.

**Table 1:** Relative risk of incident CVA and MI according to AS status

	<b>AS</b> (N=7,148)	<b>Non-AS</b> (N=71,489)
<b>CVA events, n</b>	80	492
Incidence Rate of CVA /1000 Person-Years	1.81	1.13
Incidence Rate Ratio of CVA (95% CI)	1.60 (1.25-2.03)	1.0
Multivariable RR of CVA (95% CI)	<b>1.34 (1.04-1.73)</b>	1.0
	<b>AS</b> (N=7,107)	<b>Non-AS</b> (N=71,033)
<b>MI events, n</b>	115	748
Incidence Rate of MI /1000 Person-Years	2.62	1.73
Incidence Rate Ratio of MI (95% CI)	1.52 (1.24-1.85)	1.0
Multivariable RR of MI (95% CI)	<b>1.21 (0.98-1.49)</b>	1.0

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment V

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

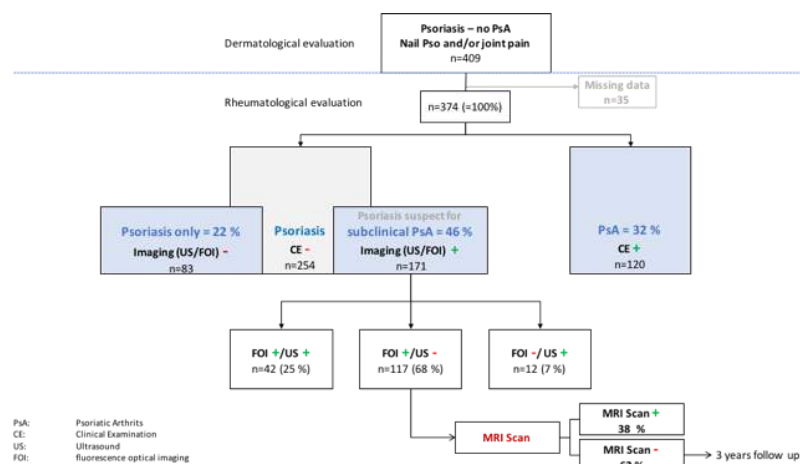

**Background/Purpose:** Psoriasis (Pso) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to Pso whereas the skin manifestation appears usually years before PsA-related symptoms emerge. Biomarkers for its early detection are missing In early PsA manifestations, changes in synovial vascularisation combined with increased

expression of proangiogenic factors appear first. Therefore, imaging biomarkers for detection of changes in vascularisation can be useful for early detection of joint disease. Fluorescence-optical imaging (FOI) is a new method to detect changes in microvascularisation of the hands and might be of value in early detection of (subclinical) signs of inflammation in Psoriasis patients

**Methods:** 411 patients with dermatologically confirmed Pso were included without diagnosis of PsA but risk factors for its development (nail psoriasis and/or joint pain or swelling within the last 6 months). Clinical examination (CE; swollen (66) and tender (68) joint count, enthesitis, dactylitis assessment) and standardised ultrasound (US) assessment was performed by a qualified rheumatologist to assess PsA symptoms. Additionally, FOI was performed. Data was analysed for an increased vascularisation of musculoskeletal structures of hands as marker of inflammation. In cases of discrepant results (positive FOI and negative results for CE and US), MRI was performed to validate the FOI-surrogate indicator of inflammation. Patients with negative MRI results are followed up over a 24-month period (XTEND) to evaluate rate of PsA-development.

**Results:** 45.5% of the Pso patients (mean age 55.8 years, 57% female, baseline BSA 6.6%, mean duration of Pso 19.1 years) were diagnosed positive for PsA by rheumatologists either by CE (32%) or US. In a total 73.3% of the patients an increase of fluorescence signal intensities of the hands was detectable by FOI (figure 1). In 22% of the patients neither in CE and US nor in FOI any signs of musculoskeletal inflammation could be detected. In 38% of the patients suspected inflammation by FOI was confirmed by MRI scan. 13.1% of the patients were identified for follow-up measurement in XTEND.

**Conclusion:** In this cohort of patients with active Pso and not yet diagnosed PsA, more than 40% of the patients were classified as PsA by CE and US only. Additionally, in another 28.7% signs of inflammation were detected by FOI technique while MRI scan was only positive in 38 % of these patients. FOI might have the potential for early detection of musculoskeletal involvement in patients with Pso. Its possible high sensitivity in the detection of inflammation will be further evaluated: patients with positive FOI and negative MRI will be repetitively re-evaluated for a 24-month follow-up period to evaluate the predictive value of positive FOI in development of (clinical) active PsA.

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** SLE is characterized by the dysregulation of humoral immunity including high levels of autoreactive IgG VH4.34 antibodies recognized by the rat anti-human idiotype antibody 9G4 (9G4+). VH4.34 antibodies have a germ line encoded anti-self specificity for blood antigen glycolipids and glycolipid epitopes of the B220 isoform of CD45 expressed on naïve B cells. As a consequence, naïve B cells from SLE patients can have high levels of 9G4 staining *ex vivo* due to surface bound VH4.34 antibodies. Serum 9G4+ IgG is correlated with high disease activity, lupus nephritis and anti-dsDNA. The role of B cell binding (BCB) 9G4+ in lupus pathogenesis and its potential clinical correlates is unclear.

**Methods:** 161 SLE (4 or more ACR criteria) patients were analyzed, including 24 patients with active nephritis. SLE patients were compared to 30 healthy controls or 15 RA, 15 Dermatomyositis, 26 scleroderma, and 7 pSS patients analyzed as autoimmune controls. 9G4+ BCB was measured *ex vivo* by flow cytometry and BCB was quantified as the ratio of the median fluorescence intensity of naïve B cells to that of switched memory. The resulting B cell binding ratio (BR) ranged from 1 (no binding) to 20 (very high binding) patients with a BR higher than 2.5 were considered positive. 9G4+ IgG, IgM, and IgA were measured by ELISA, capturing with the rat monoclonal 9G4 and detecting with goat anti-human IgG, IgM, or IgA.

## Results:

BCB binding was highly specific for SLE as 33% of SLE patients were BCB positive compared to only 1.6% of autoimmune control patients and none of the HCD. Lupus patients with high disease activity or active nephritis were significantly more likely to have BCB than patients with low disease activity (47% and 54% as compared to 24% for low disease activity). When we compared BR to serum 9G4+ IgG concentration we found only a weak correlation ( $p=0.04$ ,  $r=0.26$ ). However, SLE patients had elevated 9G4+ IgM and IgA and the concentration of these isotypes was more strongly correlated with BCB (IgM  $p>0.001$ ,  $r=0.586$ ) (IgA  $p>0.001$ ,  $r=0.4602$ ). IgA BCB was demonstrated directly by the detection of both surface 9G4 and IgA staining of healthy control donor naïve B cells after incubation with serum from an SLE patient. Patients with high BR had higher disease activity ( $p=0.021$ ) and were more likely to have a history lupus nephritis ( $p=0.002$ ) but this was not true for serum 9G4+ isotypes measure in either isolation or combination.

## Conclusion:

The degree of B cell bound 9G4+ in some SLE patients is striking. Here we show that this auto-reactivity is specific to lupus and is more common in patients with active disease and active lupus nephritis. Interestingly, this association between B cell bound 9G4+ and disease activity is stronger than the association between serum 9G4+ IgG. As suggested by our data, this may be consequence of BCB measuring 9G4+ antibodies of multiple isotypes. The combination of IgA and IgG anti-dsDNA is more predictive of disease activity than either isotype alone and the same may be true for BCB 9G4+. In this light our finding that 9G4+ IgA is elevated in SLE patients and can bind B cells is intriguing. BCB 9G4+ may be a useful assay for stratifying SLE patients into clinically and immunologically distinct groups in future clinical and mechanistic studies.

## **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### **Background/Purpose:**

Juvenile-onset systemic lupus erythematosus (JSLE) is an autoimmune disorder characterized by immune cell dysregulation, chronic inflammation and increased cardiovascular risk. Disease onset dominates mid-puberty and the female to male ratio is 4.5:1, suggesting a hormonal importance in disease pathogenesis. JSLE patients have more aggressive disease, more major organ involvement and increased standardised mortality ratios compared to patients with adult-onset SLE yet research into JSLE is uncommon. Our previous findings show that defects in immune cell lipid metabolism contribute to disease pathogenesis in adult-onset SLE. However, in JSLE little is known about the immune profile or whether abnormal lipid metabolism also contributes to pathogenesis. Here we performed in depth immune and metabolic profiling in a cohort of JSLE patients and age and gender matched healthy donors (HCs).

### **Methods:**

Flow cytometry was carried out using two 15-colour panels to immune-phenotype peripheral blood mononuclear cells from 39 healthy donors (HCs, 17 male, 22 female, mean age 18) and 35 JSLE patients (12 male, 23 female, mean age 19). Data was analysed by cluster and phenotype-phenotype correlation. Flow cytometry was also used to measure functional and metabolic marker expression on immune cell subsets. Data was correlated with clinical assessments of disease.

### **Results:**

Patients with JSLE were characterised by increased naïve and decreased memory B-cell and T-cell subsets and increased monocyte frequency ( $p=0.0013$ ) compared to HCs. Furthermore, phenotype-phenotype correlation analysis identified differential associations between naïve and memory immune cell subtypes when comparing the HC and JSLE cohorts.

CD4<sup>+</sup> and CD8<sup>+</sup> T-cells from JSLE patients had elevated membrane lipid raft ( $p=0.0185$ ,  $p=0.0087$ ) and glucose transport receptor (GLUT-1) ( $p=0.0205$ ,  $p=0.0017$ ) expression suggesting that they were more metabolically active. Metabolic defects were also found in monocytes and plasmacytoid dendritic cells. The expression of these metabolic markers on different subsets correlated with cell frequency suggesting a role of cell metabolism in driving the JSLE phenotype. Furthermore the metabolic immune-phenotype in JSLE correlated positively with disease activity, erythrocyte sedimentation rate and dsDNA titre and negatively with complement protein C3 supporting the hypothesis that altered metabolism is associated with JSLE development and severity.

Unsupervised hierarchical cluster analysis of patient clinical data revealed that JSLE patients in this cohort could be stratified into 5 groups each with a unique clinical identity mainly associated with disease activity markers and the presence of anti-cardiolipin antibodies. Each group had a unique immune-phenotype and metabolic profile.

### **Conclusion:**

Differences in the metabolic profiles of immune cell subsets in JSLE contribute to disease pathogenesis and severity. Cellular metabolic regulators may therefore have therapeutic benefit for JSLE patients. Defining these patient groups further may help to determine the therapeutic benefit of these and other therapeutics and allow for the treatment patients in a more effective and personalised manner.

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** SLE is a prototype systemic autoimmune disease. Genome-wide association studies have fine mapped a 67kb risk haplotype that spans the Ubiquitin-conjugating enzyme E2 L3 (*UBE2L3*) gene to confer disease risk in SLE. *UBE2L3* encodes an E2 ubiquitin-conjugating enzyme (UbcH7) involved in the ubiquitin signaling pathway. The *UBE2L3* risk haplotype is found to significantly increase *UBE2L3* expression. In this study, we aim to identify the potential SLE causal variant candidates among the single nucleotide polymorphisms spanning *UBE2L3* risk haplotype that can increase *UBE2L3* expression.

**Methods:** Five variants within the *UBE2L3* risk haplotype that overlap the chromatin accessible regions (Assay for Transposase Accessible Chromatin - ATAC peaks) in T or B lymphocytes or Monocytes from SLE patients were selected for screening causal variant candidates. Electrophoretic Mobility Shift Assays (EMSAs) were performed to evaluate the differential binding ability of non-risk and risk alleles of individual variants to nuclear proteins. Nuclear proteins were extracted from T lymphocytes (Jurkat cells) with or without PMA/Ionomycin stimulation for 2hrs. Three-Dimensional (3D) chromatin topology modeling was used to identify physical interactions among the variants. 3D DNA looping data was generated by HiChIP assay to CCCTC-binding factor (CTCF) and histone 3 lysine 27 acetylation (H3K27ac) in EBV-transformed human B cell lines.

**Results:** In EMSA assays, variants rs140490, rs12484550, and rs3747093 showed increased binding of nuclear protein complexes to the risk alleles compared to non-risk when incubated with Jurkat cell nuclear extracts, with or without stimulation. Variant rs9621715 demonstrated increased binding to the risk allele only in the unstimulated nuclear extract. Variant rs5998599 showed decreased binding to the risk allele compared to the non-risk in nuclear extracts with or without stimulation. Increased binding of nuclear proteins observed in 4 out of the 5 risk variants tested, is suggestive of enhanced transcription factor binding and might therefore account for increased *UBE2L3* expression associated with SLE risk. 3D chromatin architecture regulates gene expression by facilitating long-range interaction between distant enhancer and promoter elements in spatial proximity. Our 3D DNA looping data reveals that YdjC chitoooligosaccharide deacetylase homolog (*YDJC*) promoter (rs3747093) interacts with *UBE2L3* promoter (rs140490) via H3K27ac loop and with 3'UTR of *UBE2L3* via CTCF loop. The risk variants in the first intron (rs12484550, rs9621715, rs5998599) of *UBE2L3*, also extends H3K27ac loops to *YDJC* and *UBE2L3* promoter elements. 3D chromatin landscape of these risk variants, thus demonstrates significant long-range interactions with the *UBE2L3* promoter and could promote *UBE2L3* expression.

**Conclusion:** Our results suggests that SLE risk variant candidates functions through enhanced binding of nuclear protein complexes that may likely enhance the strength of long-range DNA looping interactions with *UBE2L3* promoter to promote enhanced *UBE2L3* expression associated with SLE risk. Genome editing techniques will be used to further explore each of these individual risk variant candidates.

**SESSION INFORMATION**

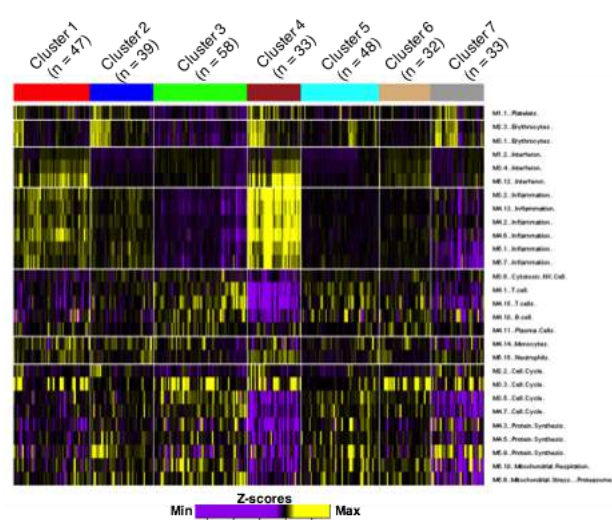

**Session Date:** Wednesday, November 8, 2017  
**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis II  
**Session Type:** ACR Concurrent Abstract Session  
**Session Time:** 11:00AM-12:30PM

**Background/Purpose :** Remarkable clinical and pathophysiological diversity complicate diagnosis, treatment and therapeutic development in systemic lupus erythematosus (SLE). This study used molecular phenotyping to identify more homogeneous subsets of lupus patients.

**Methods:** Plasma, serum and RNA serial or single samples (n=290) were collected from 184 SLE patients who met ACR classification. Disease activity was assessed by modified SELENA-SLEDAI. Immune pathways were evaluated by modular transcriptional analysis of Illumina Beadchip Microarray gene expression data. Plasma soluble mediators (n=32) and 13 antinuclear autoantibodies (anti-dsDNA, chromatin, ribosomal P, Sm, Sm/RNP, RNP, centromere B, Scl-70 and Jo-1) were assessed by multiplex, bead-based assay and ELISAs. Spearman correlations were used for univariate and multivariate analysis using R. Patients were clustered on transcriptional module scores and soluble mediators using Random Forest and tSNE.

**Results:** We identified seven clusters of SLE patients with distinct molecular profiles. Cluster 4 had the highest inflammation and interferon (IFN) signatures, followed by Cluster 1. These clusters differed in IFN, T cell and inflammation module scores. Other clusters showed no elevation of IFN nor inflammation modules, but were distinguished by monocyte, neutrophil, plasma cell and T cell module scores. All three IFN expression modules strongly correlated with circulating IFN-related mediators, including IFN $\alpha$ , IFN $\gamma$ , IP10, MCP1, MIG, MIP1a, and MIP1b. The clusters with high IFN and inflammation scores had elevated IL-10, as did Cluster 6, which had the highest plasma cell module score and had only moderate IFN and inflammation module scores. Clinically, Clusters 1 and 4 were similar, displaying the highest SLEDAI scores, as well as increased rates of low complement, DNA binding antibodies, proteinuria and hematuria. Cluster 2 showed slight elevations in IFN and inflammation modules, but had low SLEDAI scores and reduced prevalence of low complement and DNA binding antibodies. Clusters 3, 5, 6, and 7 had higher rates of rash, alopecia and arthritis.

**Conclusion:** Molecular profiles encompassing IFN, T cell, neutrophil, plasma cell, and inflammation signatures distinguish groups of SLE patients and reveal multiple potential pathways of clinical disease. These profiles can potentially contribute to clinical trial design and individualized treatment.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

### Background/Purpose:

Regulatory T cells (Treg) are impaired in human Systemic Lupus Erythematosus (SLE) and contribute to T cell activation. However, the mechanisms responsible for the Treg deficiency in SLE remain unclear. Our group recently reported that OX40L was expressed by myeloid APCs in blood and in inflamed tissues of SLE patients. OX40L stimulation induced human CD4<sup>+</sup> T cells to express TFH associated molecules, and was sufficient to induce memory and naïve CD4<sup>+</sup> T cells to become functional B cell helpers.

OX40L has been also shown to block Treg functions both in mice and in humans. We hypothesized that OX40L/OX40 axis was implicated in Treg and regulatory follicular helper T cell (TFR) dysfunction in human SLE.

**Methods:** Flow cytometry was used for analysis of cell surface and intracellular molecules expressed on blood cells of SLE patients (n = 61) and healthy donors (HD)(n = 16). Using recombinant sOX40L, *in vitro*-generated SLE-DCs expressing OX40L, and DCs from patients, the impact of OX40/OX40L axis on the function of cTregs (CD4<sup>+</sup>CXCR5<sup>+</sup>CD25<sup>high</sup>Foxp3<sup>+</sup>) and TFR (CD4<sup>+</sup>CXCR5<sup>+</sup>CD25<sup>high</sup>Foxp3<sup>+</sup>) purified from HD was studied in co-culture experiments.

### Results:

OX40L/OX40 axis engagement on Tregs and TFR not only specifically impaired their ability to regulate T effector cells proliferation but also their ability to suppress TFH-dependent B cell activation, and immunoglobulin secretion. Indeed, we observed that soluble and membrane-bound OX40L decreased suppressive Treg function (p<0.05), without inducing Treg cell death. Treg suppressive function was restored when *in vitro*-generated SLE-DCs expressing OX40L were pre-incubated with a blocking anti-OX40L mAb. Furthermore, purified tonsils TFR cells previously cultured or not with sOX40L were cultured with purified TFH and memory B cells in the presence of SEB. We observed a higher immunoglobulin production and an increased differentiation of B cells into CD38<sup>+</sup> plasmablasts in co-cultures with TFR exposed to sOX40L.

APCs from active SLE patients (n = 5) mediated Tregs dysfunction in an OX40L-dependent manner (mean % of inhibition 25.5±22 vs 72.9±9.6 with APCs purified from 7 HD, p=0.01). We also observed an inverse correlation between OX40L expression on SLE-APCs and their ability to hamper Tregs cell suppressive function (r=-0.85, p=0.0001).

OX40L-expressing cells co-localized with FoxP3 positive cells in active SLE skin lesions, suggesting that OX40L<sup>+</sup> cells-Treg contact actually operates *in vivo* within inflammatory tissues.

*In vitro*, engagement of OX40L/OX40 axis resulted in FoxP3 down-regulation in Tregs. FoxP3 expression in SLE Tregs negatively correlated with the proportion of circulating OX40L-expressing mDCs, suggesting that OX40L-dependent Foxp3 down-regulation also operates *in vivo*.

**Conclusion:** These data support that OX40L/OX40 signals are implicated in T regulatory cell dysfunction in human SLE. Thus, blocking OX40L/OX40 axis appears as a promising therapeutic strategy.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Lupus Erythematosus – Human Etiology and Pathogenesis II

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease characterized by immune complexes, especially those with nuclear molecules bound by antinuclear antibodies. Although the source of these antigens is not fully known, increased apoptosis and defective clearance of dead cells have been proposed. During apoptosis and cell activation, microparticles (MPs) are released extracellularly. MPs are small membrane-bound particles that can contain molecules arising from both the nucleus and cytoplasm. Moreover, these MPs are often covered with immunoglobulins, thus forming MP-immune complexes (mpICs).

**Methods:** Plasma samples from 47 patients with SLE (43 of 1982 ACR criteria) and 24 healthy controls were investigated. MPs and mpICs were analyzed by flow cytometry and defined by size; MPs (< 7.0 µm) or mpICs (> 7.0 µm). Samples were labeled with MitoTracker deep red FM to investigate mitochondrial content. Flow cytometry was also used to assess outer mitochondria markers by staining with anti-Tom-20 and anti-hexokinase I. The presence of IgG was evaluated with an anti-IgG reagent.

**Results:** Levels of both MPs and mpICs in SLE patients were significantly elevated compared to controls (Fig 1A). Although MP concentrations were higher than those of mpICs, mpICs contained more mitochondria compared to MPs (Fig 1B). mpICs also displayed IgG and exposed the outer mitochondria markers. The number of mpICs containing mitochondria correlated strongly to the presence of anti-dsDNA antibodies (Fig 2) as well as to levels of TNF- $\alpha$  ( $r^2$  0.2,  $p < 0.05$ ), IL-6 ( $r^2$  0.23,  $p < 0.01$ ) and IL-7 ( $r^2$  0.24,  $p < 0.01$ ). Moreover, compared to patients with inactive renal disease, patients with active renal disease had significantly higher levels of IgG-coated mpICs containing mitochondria ( $p < 0.01$ ). Patients with SLAM above 6, had significantly higher numbers of mpICs containing mitochondria and exposing outermitochondria markers Tom-20 and hexokinase I ( $p < 0.05$ ).

**Conclusion:** MPs and mpICs are significantly more abundant in the blood of SLE patients compared to controls. Importantly, the majority of the mitochondria were present in the larger mpIC sup-population. Moreover, mpICs that contain mitochondria also display outer mitochondria markers, with levels correlating with levels of anti-dsDNA antibodies, disease activity and pro-inflammatory cytokines. mpICs may therefore contribute to SLE pathogenesis, with mitochondria representing a source of cell antigens that can trigger innate and adaptive immune responses as well as deposit in the tissue.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose :** Systemic sclerosis (SSc) is a major cause of pulmonary arterial hypertension (PAH). Murine models indicate key roles of chemokines CCL19/21 and their receptor CCR7 in lung inflammation leading to PAH. We aimed to assess the chemokine CCL19/21 axis in SSc-PAH.

**Methods:** Sera from two independent prospective SSc cohorts including Oslo University Hospital (OUH, n=298) and Lund University Hospital (LU, n=28), idiopathic PAH (n=12) and controls (n=100) were analysed for CCL19/CCL21 by ELISA. Levels were defined as high or low using [mean + 2SD] in controls as cut-off. Risk stratification at time of PAH diagnosis was performed according to 2016 European Society of Cardiology guidelines. PAH related events were defined as; (a) PAH progression (b) end-stage PAH (c) hospitalization for PAH worsening and (d) all-cause mortality. Cellular sources of CCL21 and CCR7 within SSc-PAH lung tissue were determined by immunohistochemistry.

**Results:** CCL21 was higher in SSc than controls, and stable across time of PAH diagnosis. Clinical and demographics are shown in Table 1. 129/298 SSc patients underwent RHC at OUH, 41 were diagnosed with PAH and 25 with PH-ILD; at LU 16 patients had PAH. PAH was more frequent in patients with high CCL21 (>0.4 ng/ml) than low CCL21 (33.3% versus 5.3%, p<0.001) and higher than in PH-ILD and idiopathic PH (Figure 1). In multivariate analyses, CCL21 was associated with PAH (HR 5.1 95% CI 2.39-10.76, p<0.001) and predictive for new onset PAH (HR 3.3, 95% CI 1.52-7.10, p=0.003). CCL21 was associated with occurrence of PAH related events (HR 4.7, 95%CI 2.12-10.46, p<0.001). Risk stratification at PAH diagnosis alone did not predict PAH related events, but when combined with CCL21 (HR 1.3, 95% C 1.03-1.60, p=0.027). Survival at 5- and 10-years differed between high and low CCL21 subsets (87% and 71% versus 96% and 91%, p<0.001). Main cellular sources of CCL21 in SSc-PAH lungs were vascular endothelial cells and circulating mononuclear cells (Figure 2), while CCR7 marked infiltrating vascular wall mononuclear cells.

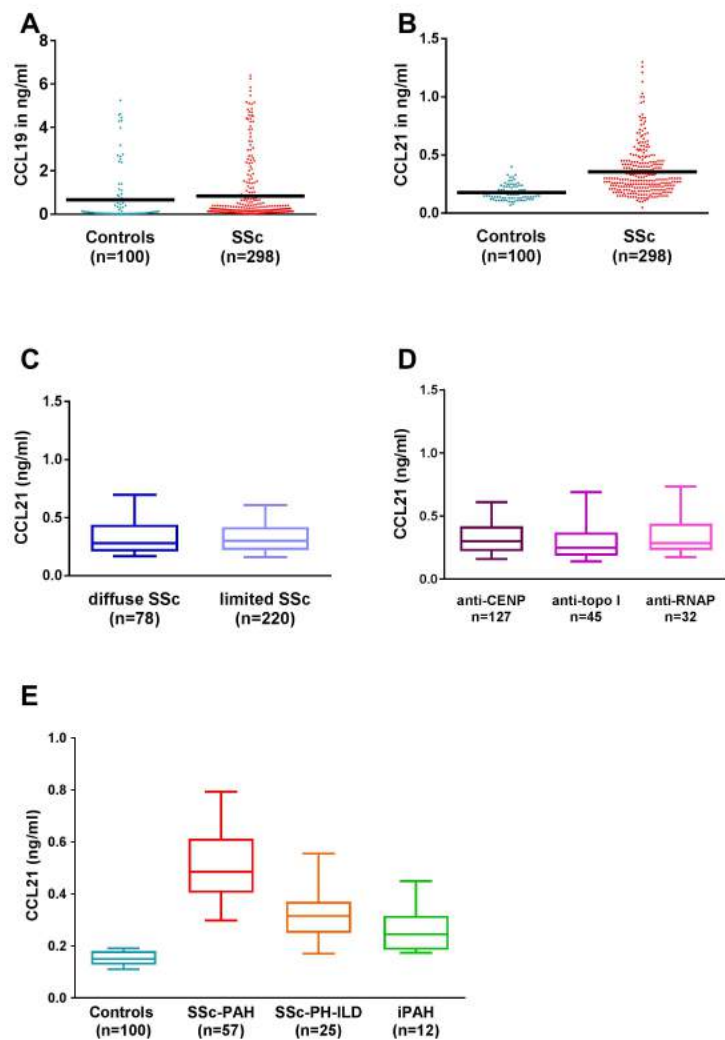

**Conclusion:** CCL21 appears as a promising marker for SSc-PAH risk prediction and PAH progression. CCL21 may be part of a deregulated immune pathway linked to development of lung vascular damage in SSc.

**Table 1:**

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Treatment with Interleukin-6R inhibitor, tocilizumab (TCZ), in early progressive systemic sclerosis (SSc; the faSScinate trial) resulted in consistent, but not statistically significant, improvements in skin sclerosis at wks 24 and 48<sup>1</sup>. The CRISS index, a composite outcome measure for trials in SSc<sup>2</sup>, is a 2-step process that assigns a probability of improvement for each subject ranging from 0.0 [no improvement] to 1.0 [marked improvement]. Step 1 assesses clinically meaningful decline in cardio-pulmonary-renal involvement with a probability of 0.0. For remaining subjects, probability of improvement examined 5 variables: FVC%, Rodnan skin score (mRSS), patient (PTGA) and physician global assessments (MDGA), and HAQ-DI. We assessed the performance of CRISS in the faSScinate at wks 24 and 48.

**Methods:** Pts ≥18 y with active SSc were randomized 1:1 to TCZ 162 mg or placebo (PBO) subcutaneously wkly for 48 wks. Step 1 for CRISS was captured using review of serious adverse event data. Step 2 calculated the CRISS index as previously defined. Non-parametric Wilcoxon test and proportion z-tests were used to assess whether significant differences exist between the CRISS score in both its continuous and binary form in TCZ and PBO. Analyses utilized all subjects, with missing data imputed using the best-fitting linear mixed model determined through Chi-square significance test on the deviance. The linear mixed models selected included a subject-specific random intercept, an indicator for treatment and a function of time. PD Protocol WA27788 Amendment 4 p.50-53,101

**Results:** 87 pts (43 TCZ, 44 PBO) were enrolled. 14.10.15\_CSR WA27788 (Week 24), pg51-54 4 subjects in the PBO and none in TCZ met the pre-defined definition of worsening cardio-pulmonary-renal involvement (Step 1) thus given a score of 0.0. Using the CRISS as a continuous measure, the median scores statistically significantly favored TCZ compared to the PBO at wks 24 and 48 (p=0.01 and 0.002; Table).

**Conclusion:** In this post-hoc analysis using patient-level data from FaSScinate, CRISS discriminated TCZ from PBO, supporting its validity in an independent cohort from its development cohort.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

Retrospective cohorts have demonstrated that African Americans (AAs) with scleroderma are more likely to have severe disease and higher mortality than non-AAs. A prior study concluded that this excess risk was not fully explained by differences in rates of diffuse disease and autoantibody status (Gelber 2013). Our study sought to further evaluate this risk among matched AAs and non-AAs at our site.

### Methods:

A single-center, retrospective study comparing AA and non-AA patients with scleroderma was performed. Patients were evaluated by the senior author between 2008 and 2016. AA and non-AAs were matched based on sex, age at first visit, date of first visit, disease duration at first visit, and limited vs. diffuse cutaneous disease. Demographic, serologic, and clinical features were compared. Mortality risks were assessed in an unadjusted manner and by a Cox proportional hazards model with covariates of race, median household income by ZIP code, marital status, education level, employment status, and insurance type.

### Results:

AAs comprised 203 of the 402 patients analyzed. The groups were statistically similar regarding all factors by which they were matched. Table 1 shows our findings. AAs had significantly reduced FVC and DLCO, more severe fibrosis per CT, a higher prevalence of any type of pulmonary hypertension, and more severe cardiac involvement. As expected, autoantibody profile statistically differed among the two groups ( $p < 0.001$ ). Death during follow-up was 21.2% in AAs vs. 11.1% in non-AAs ( $p = 0.006$ ). AA status demonstrated an unadjusted hazard ratio for death during follow-up of 2.037 ( $p = 0.007$ ), but when adjusted for the aforementioned socioeconomic covariates, the hazard ratio of AA status declined to 1.256 (95% CI 0.494 – 3.191,  $p = 0.633$ ). The only statistically significant covariate was median income in thousands of dollars by ZIP code, with a hazard ratio of 0.983 (95% CI 0.968 – 0.999,  $p = 0.033$ ).

### Conclusion:

African American patients with scleroderma have more severe pulmonary disease and a higher unadjusted risk of mortality than matched non-African Americans. Adjusting for available socioeconomic factors, African American race was not a significant risk factor for mortality, but lower median household income by ZIP code was an independent risk factor for increased mortality.

Table 1 - Morbidity and mortality in African Americans and non-African Americans

	African American (n = 203)	Non-African American (n = 199)	p-value
Sex (female)	176 (86.7)	173 (86.9)	0.944

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Mortality and worsening of organ function would be desirable endpoints for clinical trials in systemic sclerosis (SSc). However, these events are relatively rare, making clinical trial design with these endpoints challenging. To enrich for patients with these events, predictive factors have to be identified. The aim of this study was therefore to identify predictive factors in a population of patients with diffuse SSc from the large European Scleroderma Trials and Research (EUSTAR) group database.

**Methods:** Inclusion criteria were diagnosis of diffuse SSc and a follow-up after 9–15 (12±3) months. This timeframe was chosen to reflect typical clinical trial design. Disease worsening/organ progression was fulfilled if any of the following events occurred: new renal crisis, decrease in forced vital capacity (FVC) ≥10%, new left ventricular ejection fraction (LVEF) <45% or decrease in LVEF by >10% for patients with baseline LVEF <50%, new pulmonary (arterial) hypertension on echocardiography, or death. These parameters had been defined by expert nominal group technique. Methodologically, two main limitations had to be addressed: (1) the problem of missing data and (2) the low number of events, which prohibits the simultaneous exploration of the set of predictors in a regression model. We addressed these issues by (a) imputing multiple predictors on the basis of different algorithms (multiple imputation), and by (b) using least absolute shrinkage and selection operator (LASSO) regression, thus 42 clinical parameters were entered as predictors into the analysis.

**Results:** Of the 1451 patients who met the inclusion criteria, 706 had complete data available on all parameters for disease worsening; there were no clinically meaningful differences between patients with and without complete data. Of 706 patients originally evaluated, 228 (32.3%) had disease progression, most of which was either a decrease in FVC (103 patients, 14.6%) or death (92 patients, 13.0%) within the observation period (12±3 months). Of the 42 clinical parameters introduced into the model as outcome predictors, eight remained in the final regression model which was chosen by the Bayesian information criterion (Table 1). The probability, in our model, e.g. for a 60-year-old patient with diffuse SSc, lung fibrosis and active digital ulcers as well as muscle weakness to develop organ progression within the next 12 months increased to >60% compared with 32.3% in the total population. Bootstrap with 10000 repetitions successfully validated the model. The Receiver Operating Characteristic was 0.711 for the final model and 0.705 for the validation. The maximum absolute error in predicted probability was 0.026.

**Conclusion:** The use of the predictive factors presented here could enable cohort enrichment with patients at risk for overall disease worsening in clinical trials.

**Table 1: Predictive factors in the final LASSO regression model.**

	Estimate	SE	p-value	OR	95% CI
(Intercept)	-2.74	0.405	< 0.0001	0.06	0.03–0.14

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Clinical Aspects and Therapeutics III

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** Malnutrition and severe gastrointestinal (GI) dysfunction are the cause of mortality in 4-15% of systemic sclerosis (SSc) patients whereas overall GI involvement is observed in 75-90% of cases. Tools, reliable in other metabolic diseases, such as the Malnutrition Universal Screening Tool (MUST), or adiponectin to leptin ratio (A/L), have not yet been explored for the prediction of severe malnutrition in SSc. Our aim was to explore the performance of MUST and A/L to identify a combined index for stratification of risk of weight loss at 12 months in patients with SSc.

**Methods:** 180 consecutive SSc patients were enrolled in this multicentre longitudinal study (University of Leeds n=70, University of Messina n=60, University of Padova n=50). Serum levels of adiponectin and leptin were measured and their ratio calculated (A/L). Malnutrition risk was evaluated through MUST, which includes BMI and weight loss reported by the patient in the last 3-6 months, and the score corresponds to the malnutrition risk (0=no, 1=mild, ≥2=moderate/severe). Weight loss ≥10% of baseline weight after 12 months was also calculated.

**Results:** No statistical differences were observed at baseline among the single centres cohorts. Overall, we observed a BMI decrease over time (24.1 vs 23.1, p<0.0001). 40/180 (22%) SSc patients had a weight loss ≥10% after 12 months. These patients were older (median 63 vs 55, p=0.02), more frequently with the diffuse form (48% vs 31%, p=0.05), Scl70 positive (32% vs 17%, p=0.04), had higher modified Rodnan skin scores (median 10 vs 6, p=0.01), and HRCT evidence of pulmonary fibrosis (55% vs 30%, p=0.003), with concordant lower TLC (mean: 76.7 vs 93.7, p<0.001), and lower FVC (mean: 74.6 vs 83.5, p=0.04). No differences were observed in CK serum levels. In the group of patients with ≥10% weight loss baseline A/L was 2.34 (vs 0.37, p<0.0001), baseline MUST was 1.54 (vs 0.57, p<0.0001), while baseline BMI was 21.4 (vs 24.9, p<0.0001). Using ≥10% weight loss at 12 months as gold standard, we built receiver operating characteristic (ROC) curves for BMI, MUST, A/L and combined indexes. BMI and A/L had a better AUC (0.84; 95% CI: 0.77-0.84) vs MUST (0.77; 95% CI: 0.69/0.77). By combining BMI and A/L in logistic regression, we defined the predictor of malnutrition in systemic sclerosis (PREMASS) with the formula: 3.33 - (0.25 \* baseline BMI) + (1.71 \* baseline A/L). A PREMASS score >0.21 showed an AUC of 0.80 (95% CI: 0.80 D 0.87), 85% sensitivity (95% CI: 74-96) and 83% specificity (95% CI: 77-89) for

≥10% weight loss with an overall 59% positive predictive value (95% CI: 46-71) and 95% negative predictive value (95% CI: 91-99) and a relative risk of 11.9 (95% CI: 5.3-26.8).

**Conclusion:** Here we propose a novel combined index, PREMASS, for stratification for risk of severe weight loss in the following 12 months in SSc. Further validation in independent cohorts will confirm the clinical value of PREMASS index for the clinical management and risk stratification for weight loss in SSc patients.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ARHP Epidemiology and Public Health

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### **Background/Purpose:**

Omega fatty acids have immunomodulatory properties; omega-3 (n-3) fatty acids are generally anti-inflammatory and omega-6 (n-6) pro-inflammatory. High n-6:n-3 ratios (up to 16:1) are common in Western diets and are thought to contribute to chronic diseases. In small studies omega-3 supplementation in SLE has been associated with reduction of disease activity in systemic lupus erythematosus (SLE), but no study has examined their impact on patient reported outcomes (PROs). We performed a population-based cross-sectional study based on the MILES Program to examine the association between dietary intake of n-3 and n-6 fatty acids and PROs in SLE.

### **Methods:**

The MILES Program includes a population-based cohort of SLE cases from southeast Michigan. Data on dietary intake of omega fatty acids was collected at baseline using questions from the National Cancer Institute's Diet History Questionnaire II (DHQ II). Patient reported outcome data included the Systemic Lupus Activity Questionnaire (SLAQ), RAND 36 Health Survey, Fibromyalgia (FM) Scale, PROMIS Sleep Disturbance (short form 8b) and PROMIS Depression (short form 8b). Multivariable regression, adjusted for covariates (age, sex, race, energy intake, and body mass index), was used to assess the association between n-3 and n-6 fatty acid intake and patient reported outcomes.

### **Results:**

456/462 (98.7%) of SLE cases enrolled in MILES completed dietary questionnaires at baseline. 425 (93.2%) were female, 207 (45.4%) were black, and mean age at baseline visit was 52.9 years. Controlling for covariates, increasing n-6:n-3 ratios were associated with SLE disease activity (SLAQ score);  $\beta$  0.322 (95% CI 0.069, 0.574;  $p=0.013$ ). Intake of n-3 fatty acids was significantly associated with better sleep quality ( $\beta$  -1.114, 95% CI -2.029, -0.198) and trended towards significant decreases in depressive symptoms ( $\beta$  -0.884, 95% CI -1.916, 0.148) and presence of comorbid fibromyalgia (OR 0.817, 95% CI 0.655, 1.020). Associations between fatty acid intake and general health-related quality of life were not observed.

## Conclusion:

This large, population-based study suggests that dietary intake levels of n-3 and n-6 fatty acids may impact patient reported outcomes in SLE. Future dietary intervention studies modulating the absolute intake and ratios of n-3 and n-6 fatty acids should be considered in SLE.

## Moderate and Serious Psychological Distress Among US Adults with and without Arthritis, 2002 to 2015

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ARHP Epidemiology and Public Health

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** US population-health surveys frequently measure current mental health status using the Kessler-6 (K-6) which indicates psychological distress level. Among all US adults, moderate and serious psychological distress predict high health care utilization. Higher prevalence of serious psychological distress (SPD) among adults with arthritis compared with those without is well documented; however, little is known about moderate psychological distress (MPD) prevalence by arthritis status. We examined MPD and SPD prevalence, by arthritis status, for 2002 to 2015.

**Methods:** We analyzed National Health Interview Survey (NHIS) data; NHIS is an ongoing population-based survey designed to provide annual estimates representative of US civilian, non-institutionalized population. Participants had arthritis if they responded “yes” to “Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus or fibromyalgia?”. Using the K-6, NHIS respondents rated frequency (0 [none of the time] to 4 [all of the time]) that they felt each of 6 items (sad, worthless, nervous, restless, hopeless, and everything was an effort) in the past 30 days. We categorized rating sums into 3 psychological distress levels: none-mild (0-4); moderate (5-12); serious ( $\geq 13$ -24) and estimated age-standardized (2000 US projected population) prevalence and 95% confidence interval (CI). All analyses accounted for NHIS’ complex design. Moving averages were 3 year means. Tests for trend were conducted using linear orthogonal contrasts ( $\alpha = 0.05$ ).

**Results:** MPD prevalence was 12 percentage points higher among adults with arthritis (27.4%; CI=25.2-29.7) compared with those without (15.4%; CI=14.8-16.0); SPD was also more prevalent among adults with arthritis (arthritis=8.5%; CI=7.2-10.0; without arthritis=2.6%; CI=2.3-3.0). From 2002 to 2015, only MPD increased significantly (5 percentage points) among adults with arthritis whereas both MPD and SPD prevalence increased significantly for those without arthritis (Figure).

**Conclusion:** In 2015, approximately 1 in 3 US adults with arthritis experienced either MPD or SPD compared with almost 1 in 5 adults without arthritis. From 2002 to 2015, SPD prevalence remained constant among adults with arthritis but MPD prevalence increased indicating that psychological distress is a growing problem. Mental health issues can reduce adherence to clinical treatment and practicing healthy behaviors. Engaging in physical activity and self-management education (e.g., Chronic Disease Self-Management Program) are proven to reduce arthritis symptoms (e.g., pain) and symptoms of mood disorders, but psychological distress may be a barrier to participation. Thus, ensuring that psychological distress is identified and addressed is an important step in helping adults with arthritis to manage their arthritis well.

## Characteristics of People with Work-Related Versus Non-Work Related Carpal Tunnel Syndrome: National Health Interview Survey, 2010 & 2015

**Nancy A. Baker**, Department of Occupational Therapy, University of Pittsburgh, Pittsburgh, PA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ARHP Epidemiology and Public Health

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** The underlying causes of carpal tunnel syndrome (CTS) are complex and may be unrelated to work status. Yet, too often, CTS is viewed and researched only as a work-related disorder. There is almost no research that compares the characteristics of work-related versus non work-related disorders. In this study we used data from the 2010 and 2015 National Health Information Survey (NHIS), representative of the U.S. civilian non-institutionalized population, to determine which characteristics are risk factors for non work-related CTS compared to work-related CTS.

**Methods:** We analyzed adults (age 18+). CTS cases were defined as “Have you EVER been told by a doctor or other health professional that you have a condition affecting the wrist and hand called carpal tunnel syndrome?” and we designated whether CTS was work/non work-related by the response in those with CTS to the question “Have you ever been told by a doctor or other health professional that your CTS was probably work-related.” Arthritis and diabetes were self-reported in a similar fashion. Obesity was those with Body Mass Index (BMI)  $\geq 30$ , and smoking as those who never or ever smoked. To identify occupational type, respondents were categorized in three major Standard Occupational Classification System categories (SOC): 1) Management, Professional, and Related & Service (MP&S); 2) Sales and Office (SO); 3) Natural Resources, Construction and Maintenance & Production, Transportation, and Material Moving (NCM&PTM), each of which represent progressively greater exposure to high-repetition, forceful tasks which are considered an important risk factor for work-related CTS.

We completed simple descriptive characteristics as well as a logistical regression using appropriate NHIS weights.

**Results:** Of our sample of 60,759 adults, 8.6% (95%CI: 8.4, 7.8) had CTS. Of these 65.5% (62.4, 68.6) were work-related and 34.5% (31.4, 37.6) were non work-related.

Characteristics associated with non work-related CTS were age greater than 65 (Odds Ratio [OR] 2.5: 95%CI 1.4, 4.3), working in jobs which do not typically have exposure to high-repetition, forceful tasks (MP&S OR 1.9: 1.3, 2.3; SO OR 1.6: 1.0, 2.8) and ever having smoked (OR 1.4: 1.0, 1.9) (See Table 1).

**Conclusion:** While work-related CTS is more common than non work-related CTS, at least a third of CTS cases are non work-related. Characteristic of those with non work-related CTS are similar to those with work-related CTS. The exceptions are age over 65, when people typically are not working, and those who do not generally have high repetition forceful jobs. Although co-morbidities, such as arthritis and obesity did not increase the risk of reporting non work-related CTS, ever having smoked was an independent risk factor. This study supports the need to examine all causes of CTS and consider it as a potential upper extremity issue, regardless of work-status.

Table 1: Multivariable adjusted odds ratios (OR) with 95% confidence intervals (95% CI) for adults with work-related and <u>non work-related</u> carpal tunnel syndrome: NHIS 2010 & 2015 (event = non work-related)

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ARHP Epidemiology and Public Health

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

### Background/Purpose:

Gout affects more than 4% of adults in the United States, and it is the most common form of inflammatory arthritis among men. Studies show that excessive intake of alcoholic beverages, red meat, soft drinks and fruit juices increase the risk of developing gout. Similarly, dairy products and coffee seem to have a protective effect, as they increase the excretion of uric acid. Water is one of the best universal solvents and may be a readily available remedy for gout. As described in previous papers, water helps in the excretion of excess uric acid from the body and will replenish the dehydrated patient but no causal association has been established. Our objective of the study is to look at the association between water intake and uric acid levels in gout patients

### Methods:

17,321 individuals from the general population were surveyed by the National Health and Nutrition Examination Survey (NHANES) between 2009-2014. From this data set, 539 participants with a gout diagnosis were selected for the current study after excluding all patients with chronic kidney disease.. Our primary definition of hyperuricemia was a serum uric acid level of  $\geq 6.0$  mg/dL. While participants with  $< 6.0$  mg/dL uric acid were labeled as normal or low Serum uric acid level. Water intake was considered high for men taking  $\geq 3000$ mg and for women taking  $\geq 2200$ mg; while intake was considered low for men taking  $< 3000$ mg and for women taking  $< 2200$ mg. Statistical modeling adjusted for demographic characteristics, body mass index, alcohol use, hypertension, diabetes mellitus, and other factors. All analyses were performed with use of SAS version 9.4's (Cary, North Carolina) Proc survey methodology.

## Results:

Thirty nine percent of participants had a uric acid level  $< 6$ mg/dL, the remainder had uric acid  $\geq 6.0$  mg/dL The high uric acid group had significantly more obesity and hypertension, as well as having a significantly higher proportion of males. Multivariate logistic regression showed a significant association between low water intake and hyperuricemia. The odds of developing hyperuricemia was 58% less with high water intake (OR = 0.421, 95% CI: 0.262-0.679, p-value = 0.0007) after adjusting for age, sex, race diabetes, BMI, and hypertension.

Table 1. Multivariate Logistic Regression Analysis for Uric Acid ( $\geq 6$  mg/dL vs.  $< 6$  mg/dL)

Effect	Odds Ratio	95% CI	P-value
Water intake (high)	0.421	0.262-0.679	0.0007
Gender (female)	0.574	0.298-1.107	0.0958
Race	1.132	0.868-1.478	0.3530
BMI	1.491	0.955-2.330	0.0779
Age	0.974	0.956-0.992	0.0054
Hypertension	1.644	0.954-2.834	0.0723
Diabetes	1.153	0.633-2.097	0.6355

## Conclusion:

In summary, there is a strong association between low water consumption and hyperuricemia. These findings support the physiology of increased uric acid excretion with excess water intake. High water intake may allow for significant benefits to those suffering from gout and warrants further study as a therapeutic intervention.

## Is Risk of Retinopathy Among Hydroxychloroquine Users of SLE Patients Accurate? a Simulation Study Accounting for Competing Risk of Death

Na Lu<sup>1</sup>, Hyon K. Choi<sup>2</sup>, April Jorge<sup>3</sup> and Yuqing Zhang<sup>4</sup>, <sup>1</sup>Clinical Epidemiology, Boston University School of Medicine, Boston, MA, <sup>2</sup>Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>3</sup>Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, <sup>4</sup>School Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ARHP Epidemiology and Public Health

**Session Type:** ARHP Concurrent Abstract Session

**Background/Purpose:** Hydroxychloroquine (HCQ) is used for the long-term treatment of systemic lupus erythematosus (SLE) patients. HCQ is generally well-tolerated with wide-ranging benefits, including reduced disease activity and improved survival; a critical adverse effect is vision-threatening retinopathy. Historically, the risk was considered to be very low. However, a recent retrospective case-control study (N=2,361 taking HCQ for  $\geq 5$  years) reported the prevalence estimate of HCQ retinopathy to be 7.5%, which is  $>3$  times higher than that of previous studies (Melles R, et al. JAMA Ophthalmol.; 2017). This study served as the key basis for the 2016 revised American Academy of Ophthalmology (AAO) recommendations for HCQ retinopathy screening. However, this study did not take into account the competing risk of death (e.g., a 2-fold increased mortality risk in SLE) and thus, the reported retinopathy risk could be overestimated. We conducted a simulation study to estimate potential impact of competing risk of death on risk of retinopathy among patients with SLE.

**Methods:** In the simulation studies we assumed that (1) the hazard rates of toxic retinopathy for three different doses of HCQ (i.e.,  $>5\text{mg/kg}$ ,  $4\text{--}5\text{mg/kg}$  and  $<4\text{mg/kg}$ ) change over time according to a Weibull distribution; (2) the survival rate in the general population from 55 to 75 years old was based on 2013 Life Table in US; (3) mortality rate in SLE patients is 2-fold higher than that in the general population; and (4) the risk of retinopathy was 70%, 40%, and 15% for 25 years, respectively, based on the previous study. We estimated the risk of retinopathy and depicted survival curves using K-M curve with and without accounting for competing risk of death. We simulated 6000 independent observations based on 1000 replications.

**Results:** As shown in Figure 1, the shape and magnitude of risk of retinopathy for each HCQ dose category were similar to the findings of the previous study. After accounting for competing risk of death, the risk of toxic retinopathy was 29.9% (95% CI: 28.8% to 30.1%), 20.4% (95% CI: 19.4% to 21.5%), 10.7% (95% CI: 9.9% to 11.6%), respectively, for each dose over 25 years. The risk of retinopathy from HCQ without accounting for competing risk death may overestimate the true risk of retinopathy for each category of HCQ by 40.2%, 96.0% and 134.1% over 25 years of use, respectively.

**Conclusion:** Although high dose and long-term HCQ use increase the risk of toxic retinopathy, the reported risk of retinopathy from the recent study without accounting for competing risk of deaths in SLE patients is likely to be overestimated particularly in the long-term follow-up. Prospective studies are needed to accurately estimate the risk of retinopathy attributed to HCQ.

# Is a Growing Waistline over 8 Years Associated with Incident Functional Limitation and Low Health-Related Quality of Life in Knee Osteoarthritis?

Meredith Christiansen<sup>1</sup>, Louise Thoma<sup>1</sup>, Hiral Master<sup>1</sup>, Dana Mathews<sup>2</sup> and Daniel White<sup>3</sup>, <sup>1</sup>Physical Therapy and Biomechanics and Movement Science, University of Delaware, Newark, DE, <sup>2</sup>Physical Therapy, Biomechanics and Movement Science, University of Delaware, Newark, DE, <sup>3</sup>Department of Physical Therapy, University of Delaware, Newark, DE

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ARHP Epidemiology and Public Health

**Session Type:** ARHP Concurrent Abstract Session

**Session Time:** 11:00AM-12:30PM

**Background/Purpose:** A large waist circumference (WC) is associated with walking difficulty in people with or at risk for knee osteoarthritis (OA). To date, it is unclear whether a meaningful increase in WC is also associated with walking difficulty and poor health. This is important to study since minimizing gains in WC may be important to reduce functional limitation and low health-related quality of life (HRQoL), which are common in knee OA. The purpose of this study was to investigate the association of increasing WC with function and HRQoL in people with or at risk for knee OA.

**Methods:** Data was extracted from the Osteoarthritis Initiative, a large prospective cohort study of people with or at risk for knee OA. Our primary exposures of interest were baseline WC and a meaningful increase in WC. WC was measured around the participant's mid torso at the largest circumference with a tape measure. Baseline WC was classified into two groups using established thresholds: 1) Large WC (males > 102cm, females > 88cm) and 2) Small WC (males ≤ 102cm, females ≤ 88cm). A meaningful increase in WC over an 8-year timeframe was classified into two groups: 1) Increase (> 5cm) and 2) Maintain (≤ 5cm). Our two outcome measures of interest were function and HRQoL at the 8-year follow up measured by 1) gait speed (m/s) during a 20-meter walk test and 2) Short Form 12 Physical Summary Scale (SF12-P). Gait speed < 1.2 m/s and a SF12-P < 40 indicated functional limitation and poor HRQoL, respectively. We calculated risk ratios and 95% confidence intervals RR(95%CI) to examine the association of increased WC with study outcomes, adjusted for potential confounders.

**Results:** Of 4796 participants with baseline WC data (58% female, age 61± 9, BMI 28.6 ± 4.8), 2543 and 2238 people were free of the outcome at baseline and had 8-year follow up data for SF12-P and gait speed, respectively. The Large WC-Increase group had the greatest risk of developing functional limitation and poor HRQoL compared with the Small WC-Maintain group (Table 1). Those in the Large WC-Maintain group had a greater risk of developing a functional limitation compared with the Small WC-Maintain group, but were at similar risk for poor HRQoL (Table 1). Participants in the Small WC-Increase group were at similar risk as the Small WC-Maintain group for developing functional limitation and poor HRQoL (Table 1).

**Conclusion:** People with large WC had greater risk of functional limitation and poor HRQoL 8 years later, irrespective of increasing WC, compared with those with a small WC. Those with a large WC who increase WC had the highest risk compared to those with a small WC who maintained WC. Educating people with knee OA to avoid WC gains, particularly those already with a large WC, may mitigate future functional limitation and poor HRQoL.

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Despite the lack of evidence to support the use of opioids in the treatment of adult fibromyalgia syndrome, approximately 30% of patients receive an opioid prescription (Fitzcharles, *Am J Med.* 2011). The prevalence of and risk factors for opioid prescribing for juvenile fibromyalgia syndrome (JFMS), however, have not been established.

**Methods:** We performed a retrospective cohort study using de-identified healthcare claims data from Clinformatics™ DataMart (OptumInsight, Eden Prairie, MN) from May 2000 - June 2013. The index date was the first ICD-9 code for fibromyalgia (729.1). JFMS was defined as subjects  $\geq 2$  and  $< 18$  years of age at the index date with  $\geq 2$  codes for fibromyalgia within 12 months and continuous enrollment 6 months prior to and 12 months after the index date. Subjects with burns, sickle cell disease, or malignancy were excluded. Opioid exposure was defined as  $\geq 1$  prescription within 6 months prior to or any time after the index date. Healthcare utilization was assessed by provider type and place of service and defined as  $\geq 1$  co-variate prior to first opioid prescription. Acute care visit included an urgent care and/or emergency department encounter. Multivariate logistic regression modeling (adjusting for demographics, co-morbidities, and healthcare utilization) was used to identify independent risk factors associated with opioid use.

**Results:** Of 26516 subjects who met study criteria, 5296 (20%) received an opioid prescription. Subjects were predominantly female (55%) and Caucasian (80%). Median age at index date was 14 years (IQR: 11.0, 16.0) and at first opioid prescription was 16 years (IQR: 13, 17). Codeine (71%), tramadol (21%) and oxycodone (14%) were the most commonly prescribed opioids. Diagnosis of anxiety and depression occurred in 14% and 15% of children, respectively. In multivariate logistic regression (Table 1), opioid exposure was positively associated with female sex (OR = 1.26;  $p < 0.001$ ), Caucasian race (OR = 1.31;  $p < 0.001$ ), preceding acute care visit (OR: 1.41;  $p < 0.001$ ), hospitalization (OR: 2.38;  $p < 0.001$ ) and anesthesiology encounters (OR: 1.09;  $p = 0.04$ ). Compared to the Northeast, subjects from the Western United States had an increased risk of opioid exposure (OR: 1.20;  $p < 0.01$ ). Presence of a mental health comorbidity and an encounter with a mental health provider were associated with decreased risk of opioid use (all  $p < 0.05$ ). Children seen by a chiropractor or emergency medicine physician also had a decreased risk of opioid use (OR: 0.35 and OR: 0.83, respectively; both  $p < 0.001$ ).

**Conclusion:** Opioids were prescribed for 20% of children with JFMS. Increased physician education in acute care and inpatient settings is needed to reduce prescribing of opioids for JFMS. Increased availability of mental health resources and non-pharmacologic treatment options might represent effective strategies to reduce opioid exposure in children with JFMS.

### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ACR/ARHP Combined: Pediatrics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) is the most common, chronic, childhood rheumatic disease and an important cause of disability. It is characterized by persistent inflammation of the joints, with onset in childhood. A pronounced improvement in functional outcome has been documented in the past decade - largely due to advances in clinical diagnosis and treatment regimes. However, 5-10% of patients still have serious functional disability five years post diagnosis. Outcomes will be further improved by advances in the standardization of clinical diagnostics, disease tracking, and further refining of the treatment regimen.

The diverse nature of JIA, the lack of specific biomarkers and its concomitant progression have made standardizing diagnosis and tracking of the disease difficult. Currently, diagnosing and tracking JIA relies on subjective physical exams, reported symptoms, and imaging studies. There exists a need for a non-invasive, safe, radiation-free technique for objectively and accurately assessing the status of affected joints.

## Methods:

Joint sounds can be used to quantitatively assess the joint. Microphones can be used to capture information regarding the underlying physiologic processes of a joint. This technique is safe, radiation-free, objective, and quantitative. The joint sounds change with the biomechanics of the joint: internal friction between articulating structures in the knee create various frequencies of vibrations that can be detected at the surface of the knee. The inflammation and altered biomechanical properties provide the opportunity for utilizing this technology to diagnose and monitor the condition.

We performed joint sound recordings on four JIA patients and seven healthy controls that were age and sex matched. The knee sounds of the subjects were recorded using a custom hardware setup consisting of LED motion tracking and accelerometers for vibration detection (Figure 1A shows a leg in flexion with recording apparatus). The subjects performed ten flexion/extension cycles with the recording apparatus (1B exercise and microphone schematic).

## Results:

The results can be seen in Figure 1C. The top graph shows the angle of the knee, while the bottom plot shows the sound profile. The plots of JIA patients are more chaotic with periodic peaks. After treatment, the sounds of JIA patient more closely resembled the knee sounds of quiet healthy control. Signal analysis was performed between two groups. We found that RMS power and the standard deviation of the signals were substantially different between the groups (1D).

## Conclusion:

The substantial differences in joint sound signals between healthy children and children with JIA are encouraging for the further development and refinement of this acoustic recording system and associated knee health algorithm for the diagnosis and objective monitoring of JIA.

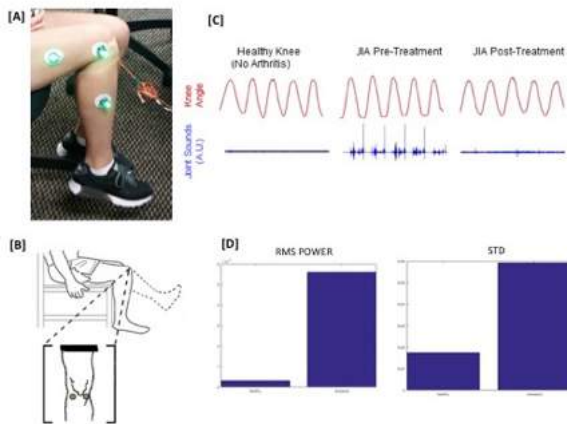

Figure 1 Experimental Setup (A,B), Time domain signal (C) and Signal Comparison (D).

## Improving Outcomes Using a Treat to Target Approach and Clinical Decision Support in Polyarticular Juvenile Idiopathic Arthritis

**Lisa Buckley**<sup>1</sup>, Eileen Ware<sup>2</sup>, Genna Kreher<sup>2</sup>, Lisa Wiater<sup>1</sup>, Jay Mehta<sup>1</sup> and Jon (Sandy) Burnham<sup>1</sup>, <sup>1</sup>Pediatric Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA, <sup>2</sup>Office of Clinical Quality Improvement, Children's Hospital of Philadelphia, Philadelphia, PA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ACR/ARHP Combined: Pediatrics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Polyarticular juvenile idiopathic arthritis (Poly-JIA) causes pain, functional disability, and joint damage. Variation in Poly-JIA clinical assessment and treatment likely has a negative impact on outcomes. Our goal was to improve Poly-JIA outcomes by standardizing disease activity scoring, ensuring disease activity review at the point of care, and implementing clinical decision support (CDS) to reduce treatment variation.

**Methods:** In January 2016, we began documenting JIA disease activity at outpatient visits. For Poly-JIA, we iteratively designed and tested CDS algorithms to standardize medication selection, dosing, and treatment duration. In April 2016, we implemented CDS (Phase 1) for Poly-JIA reactivation. In October-November 2016, we began disease activity target review for all JIA patients and CDS (Phase 2) for patients with new Poly-JIA and those in remission. Process measures included visit-level clinician target attestation (goal > 50%) and CDS use (goal > 15%). The outcome measure was the three-variable clinical Juvenile Arthritis Disease Activity Score (cJADAS), which is the sum of the physician and patient/parent global assessment (both 0-10), and active joint count (maximum 10). We calculated the monthly population cJADAS mean using the patients' last recorded value in patients with two or more visits. Our goal was to improve the Poly-JIA cJADAS by  $\geq 10\%$ . Data were analyzed for special cause variation using standard statistical process control (SPC) and run chart methodology.

**Results: From February 2016-March 2017,** we longitudinally assessed 112 patients with Poly-JIA and 358 with other JIA subtypes. After October 2016, the mean monthly disease activity target attestation in all JIA patients was 74%. In Phases 1 and 2, we used CDS in 5-17% and 41-88% of Poly-JIA encounters, respectively. From July 2016-June 2017, Poly-JIA cJADAS scores decreased from a baseline of 5.5 to 3.5 (36%) (Figure). Special cause variation was identified in January 2017, when the cJADAS score decreased to 4.0, which was less than the lower confidence limit. During this period, the proportion of patients in clinician-defined remission increased from 31% to 49%. Significantly fewer joint injections were performed from December 2016-June 2017. In other JIA subtypes observed over the same period in whom target attestation was used without CDS, cJADAS scores decreased from 3.9 to 3.4 (13%), which did not achieve special cause variation.

**Conclusion:** After exceeding our target attestation and CDS use goals, Poly-JIA disease activity improved by 36%. We estimate that approximately 22 more patients are currently in remission. Therefore, using a treat to target approach paired with CDS can improve Poly-JIA disease activity substantially. We plan to study changes medication use, assess pain and functional outcomes, and develop additional CDS algorithms.

# Pathogens in the Inflammatory Process of Periodontal Disease and Juvenile Idiopathic Arthritis

Nancy Delnay<sup>1</sup>, Neil McNinch<sup>2</sup> and Mary Toth<sup>3</sup>, <sup>1</sup>Rheumatology, Akron Children's Hospital, Akron, OH, <sup>2</sup>Rebecca Considine Research, Akron Children's Hospital, Akron, OH, <sup>3</sup>Rheumatology, Children's Hospital Medical Center, Akron, OH

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ACR/ARHP Combined: Pediatrics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

## Background/Purpose:

Juvenile idiopathic arthritis (JIA) and periodontal disease (PD) are both diseases of inflammation that can result in bone loss when the inflammatory process is prolonged. In periodontal disease redness and swelling to gums represents infection of bacteria such as *Porphyromonas gingivalis* (Pg). Hitchon (2010) linked anti-p.gingivalis antibodies and anti-cyclic citrullinated peptide (CCP) antibodies in adult patients with rheumatoid arthritis. CCP antibodies are linked with erosive joint disease. In 2016 Lange investigated antibody responses to oral pathogens of children with JIA, concluding that children with CCP-positive JIA have higher antibody titers to p.gingivalis. The purpose of this study is to determine the presence of the bacteria (Pg) in children with JIA who are positive for rheumatoid factor (RF) or CCP.

## Methods:

A convenience sample of 12 children ages 10-21 with a diagnosis of JIA and either RF positive or CCP positive was selected from a hospital-based rheumatology clinic. A full exam, including an oral exam, was completed to assess for JIA and PD disease activity. During the exam a saliva sample was collected to identify the presence of common pathogens associated with gum disease and increased risk of systemic disease. Genomic DNA was extracted from the saliva sample and tested for bacteria associated with periodontal disease. The bacteria were tested by PCR amplification followed by fluorescent endpoint detection of sample bacterial concentrations. Pathogenic bacteria were reported as low, moderate or high risk for association with periodontal disease. Differences in the bacterial profile were compared to an age and gender matched control group with periodontal disease. Fisher's exact test and Wilcoxon test were used to compare the groups.

## Results:

Upon physical examination 7 of 12 children (58%) examined showed signs of localized oral inflammation to one or more teeth, none of the 12 had generalized oral inflammation. Only 2 of 12 children (17%) had presence of Pg: neither had bleeding with brushing or flossing and one exhibited localized gum redness. Exploratory analysis of common pathogens associated with periodontal disease: JIA status was not associated with Pg, Fisher's Exact Test  $p = 0.68$ . Calculated Pg bacterial load was not different by JIA status, Wilcoxon Rank Sum Test  $p = 0.63$ . Infection status was associated with JIA status, Fisher's Exact Test  $p < 0.01$ . 4 of 12 children (33%) exhibited presence of high risk bacteria: Pg, *Aggregatibacter actinomycetemcomitans* (Aa), *Tannerella forsythia* (Tf) and *Treponema denticola* (Td). There was no significant difference in high risk bacterial counts by JIA status ( $p = 0.63, 0.30, 0.35$  &  $0.61$  respectively). The results of this study were limited by sample size.

## Conclusion:

Children with CCP-positive or RF positive JIA have similar bacterial profiles as children with periodontal disease placing them at risk for development of periodontal disease. This reinforces the need for inclusion of oral health exam within the JIA population. Further studies with larger sample sizes are needed to understand the association between oral pathogens and the inflammatory process.

#### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ACR/ARHP Combined: Pediatrics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

**Background/Purpose:** Childhood onset systemic lupus erythematosus (SLE) is a chronic autoimmune condition with high morbidity that requires long-lasting care through adulthood. Transition from pediatric to adult care is difficult and poor transition can be associated with worse outcomes. Resilience is the ability to respond positively to adversity. It is a mutable trait that can be improved through interventions. In other chronic conditions, resilience has been found to be an important predictor of transition readiness. The purpose of this study is to evaluate if resilience is predictive of transition readiness. A secondary aim is to explore other factors that may influence transition readiness in SLE.

**Methods:** Sixty-two adolescent SLE patients from the Stanford Children's Health Pediatric Rheumatology clinic were enrolled in a cross-sectional study. Inclusion criteria included diagnosis of SLE confirmed using American College of Rheumatology or Systemic Lupus International Collaborating Clinics (SLICC) classification criteria before age 18 and disease duration more than 6 months. Participants completed questionnaires on transition readiness, resilience, depression, anxiety and fatigue. Resilience was evaluated using Resilience Scale (RS-14), a validated measure in adolescents and adults. Transition readiness was evaluated using Transition Readiness Assessment Questionnaire (TRAQ), a validated scale in adolescents with chronic disease. Data regarding SLE disease characteristics, disease duration, disease activity and socioeconomic status was obtained. A multivariable linear regression model was created to evaluate association between transition readiness and resilience.

**Results:** The majority of participants were mostly (87%) and Asian (47%). The mean age was 18.6 years and mean disease duration was 5.1 years. TRAQ scores were significantly correlated with resilience, RS-14 ( $p=0.39$ ,  $p=0.002$ ) and current age ( $p=0.47$ ,  $p<0.001$ ). There was no correlation with disease duration, fatigue, anxiety, depressive symptoms, disease damage (SLICC Damage Index) or disease activity (SLEDAI score). A Wilcoxon rank sum test indicated that the TRAQ score was greater for individuals with public insurance (Median=87.5) than for privately insured patients (Median=75),  $p=0.002$ . There was no difference in scores between genders, or in individuals with depression or anxiety or history of severe disease. A multiple regression analysis model was calculated to predict TRAQ score based on resilience, controlling for insurance status, age and disease duration. Resilience ( $\beta=0.33$ ,  $p=0.002$ ), age ( $\beta=0.49$ ,  $p=0.001$ ), and insurance status ( $\beta=0.31$ ,  $p=0.004$ ) were significant predictors in this model. The overall model fit was  $R^2$  of 0.44 ( $p<0.0001$ ).

**Conclusion:** In adolescent SLE patients, preparation for transition is important. Correcting for age, and other confounding factors, resilience score appears predictive of transition readiness. In addition to current care, it may be important to include resilience building into transition programs to assist with improved outcomes.

## Patient and Family Reported Psychosocial Areas of Concern within Pediatric Rheumatology: Quality Improvement Data and Implications for Practice

Nicole Tennermann and Melissa Hazen, Rheumatology, Boston Children's Hospital, Boston, MA

**First publication:** September 18, 2017

#### SESSION INFORMATION

**Session Date:** Wednesday, November 8, 2017

**Session Title:** ACR/ARHP Combined: Pediatrics

**Session Type:** ACR Concurrent Abstract Session

**Session Time:** 9:00AM-10:30AM

### **Background/Purpose:**

Psychosocial factors greatly impact the subjective disease experience and outcomes of children with rheumatic conditions. Attention to the psychosocial aspects of patients' needs is essential in the multidisciplinary care of children with rheumatic disease. Such understanding can aid the assessment of presenting and persisting symptoms and shed light on barriers to treatment adherence.

In order to obtain baseline data regarding the psychosocial needs impacting pediatric rheumatology patients at our center, a quality improvement survey was undertaken. Here, we will discuss its implementation, review our findings, and outline modifications made to enhance multidisciplinary, patient-centered rheumatic care.

### **Methods:**

Psychosocial needs assessment questionnaires are administered to every patient seen in the Rheumatology Program beginning in October 2016. We have reviewed 1714 questionnaires to date. Assessments ask about 8 areas of psychosocial concern frequently associated with social determinants of health: insurance, food insecurity, transportation to medical appointments, school concerns, housing instability/homelessness, safety, substance abuse, mental health/behavior, and coping with one's medical condition. Responses can indicate concerns or no concerns in any area, and a follow-up question asks whether help addressing the concerns is desired. Questionnaires are completed by parents/caregivers or by adolescent/young adult patients. Patients can complete questionnaires at multiple office visits and can select as few or as many areas of concern as indicated. All questionnaires are administered in English.

### **Results:**

Preliminary analysis demonstrates that approximately 25% of all questionnaires indicate concerns in at least one domain. In any given area of psychosocial concern, desires for help with addressing the need ranged from 0% (for assistance with substance abuse) to 100% (for assistance with food insecurity/homelessness). The areas of concern most often identified by families include school (61%), mental health/behavior (54%), and coping with rheumatic disease (46%). Overall, this means that 12% of questionnaires endorsed a concern for which social work assistance was requested.

### **Conclusion:**

This quality improvement initiative demonstrates that a sizeable number of patients and families experience psychosocial stressors that may negatively impact the disease process and health outcomes. While we have a robust survey response rate and reproducible findings, there are limitations like self-presentation bias and the confines of the questionnaire design, including being available only in English. Nonetheless, we suspect these limitations lead to the under-reporting of need and requests for assistance. As a result of these findings, we have implemented programmatic changes to more effectively address our patients' psychosocial needs. Specifically, the data gleaned from this quality improvement initiative is being used to enhance patient care through increased social work presence in the clinic, development of psychosocial support programs for patients and professional education for providers.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Session

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 4:30PM-6:00PM

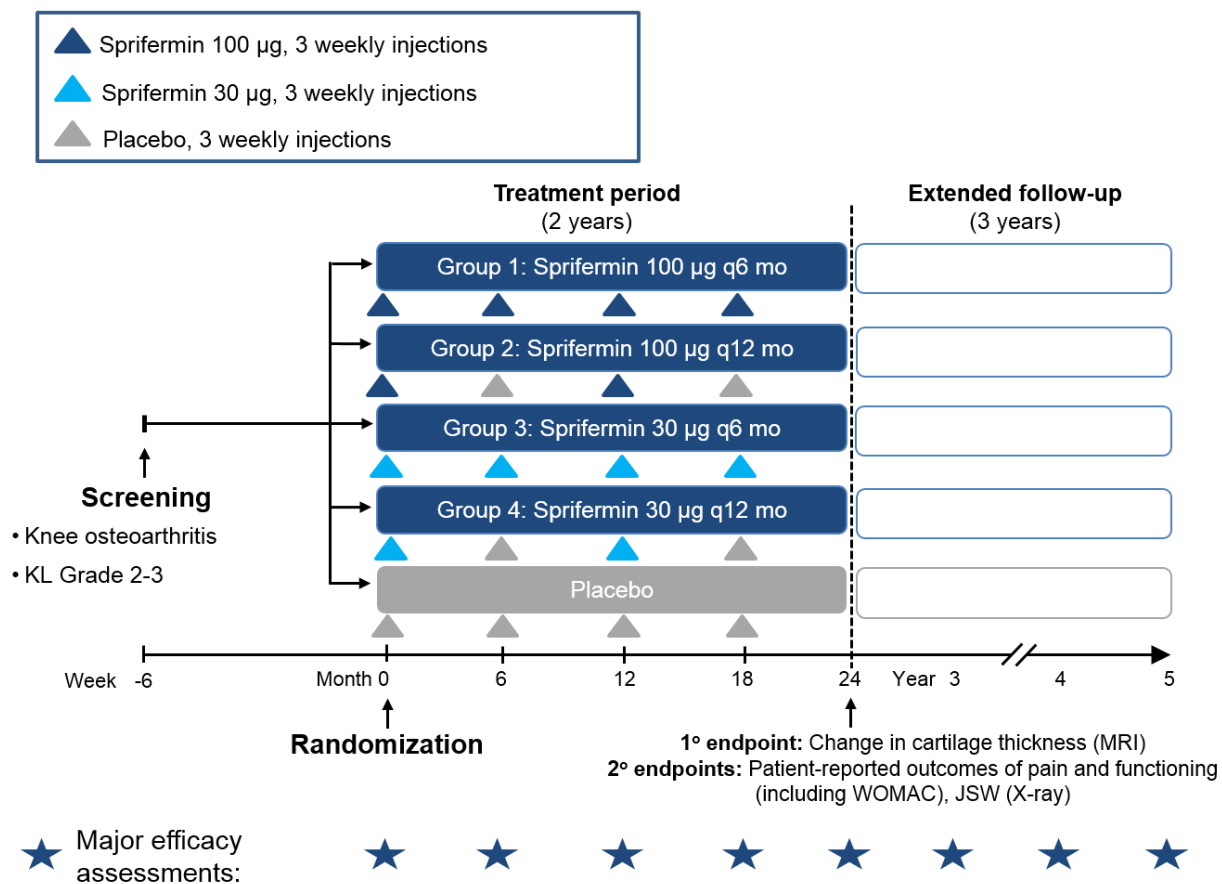

**Background/Purpose:** Sprifermin, a novel recombinant human fibroblast growth factor-18 is currently investigated as a potential disease-modifying osteoarthritis (OA) drug. Two-year primary data from a 5-year Phase II trial (FORWARD) is presented.

**Methods:** Patients (pts) aged 40–85 years with symptomatic radiographic knee OA, KLG 2 or 3, and medial mJSW  $\geq 2.5$  mm in the target knee were randomized (1:1:1:1:1) to receive 3 weekly intra-articular injections with double-blinded placebo (PBO) or sprifermin, administered in cycles every 6 or 12 months (Fig 1). The primary endpoint was the change in total tibiofemoral joint (TFJ) cartilage thickness from baseline (BL) to Year 2. The ITT population (all randomized pts) was used for non-MRI endpoints; and the mITT (all ITT pts with BL and  $\geq 1$  post-treatment MRI up to Year 2) for MRI endpoints.

**Results:** The ITT population included 549 pts: median age 65 years, 69% women, 80% white, and 69% KLG2. Of these, 12.2% (sprifermin) and 19.4% (PBO) discontinued treatment within 2 years. The primary endpoint was met (Fig 2); there was a dose-dependent increase in total TFJ cartilage thickness, with significant differences for sprifermin 100µg q6 mo (Group 1) and 100µg q12 mo (Group 2) vs PBO (+0.03 vs -0.02 mm;  $p<0.001$ , and +0.02 vs -0.02 mm;  $p<0.001$ , respectively). Furthermore, significant differences in change of cartilage thickness were observed between sprifermin vs PBO in medial (Group 1: +0.02 vs -0.03 mm;  $p=0.003$ ) and lateral TFJ compartments (Group 1 and 2: both +0.04 vs -0.01 mm;  $p<0.001$ ), and in central medial TFJ sub-regions (Group 1: +0.054 vs -0.11;  $p<0.001$ ). Changes in mJSW observed with X-ray were significantly different between sprifermin Group 1 and PBO in the lateral but not the medial compartment. Total WOMAC scores improved by ~50% in all treatment groups including PBO. AEs and serious AEs were balanced between groups, and an overall acceptable safety profile was observed.

**Conclusion:** To our knowledge, sprifermin is the first investigational agent to show prevention of cartilage loss in both the lateral and medial (including central medial) femorotibial compartments. These structural benefits associated with sprifermin suggest that it may be efficacious for disease-modifying treatment of OA, and should be further evaluated in clinical trials.

**Figure 1. FORWARD study design**

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Session

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Interleukin-23 (IL-23), a key regulator of multiple effector cytokines (including IL-17, IL-22, and TNF), has been implicated in psoriatic lesions, synovitis, enthesitis, and bone erosion. Risankizumab (RZB) is a potent humanized IgG1 mAb that inhibits IL-23 by specifically binding its p19 subunit. The purpose of this Phase 2 study was to investigate the safety and efficacy of RZB in patients (pts) with active psoriatic arthritis (PsA).

**Methods:** Pts with active PsA were randomized in a 2:2:2:1:2 ratio to receive RZB (150 mg at weeks [Wks] 0, 4, 8, 12, and 16 [Arm 1], 150 mg at Wks 0, 4, and 16 [Arm 2], 150 mg at Wks 0 and 12 [Arm 3], 75 mg single dose at Wk 0 [Arm 4]) or matching placebo (PBO, Arm 5) in this ongoing double-blind, parallel-design, dose-ranging Phase 2 study. Pts were stratified at randomization by prior TNFi use and concurrent MTX use. The primary efficacy endpoint was ACR20 response at Wk 16. Additional efficacy endpoints included ACR50/70, minimal disease activity (MDA), DAS28(CRP), dactylitis count, SPARCC enthesitis index, pain on visual analog scale (VAS), and HAQ-DI; PASI responses were assessed only in pts with psoriasis (PsO) affecting  $\geq 3\%$  body surface area (BSA) at baseline (BL).

**Results:** Among the 185 pts who were randomized and received the study drug, 172 (93.0%) completed 16 wks of treatment. BL demographics and disease characteristics

were similar across treatment arms. The median age was 51 years; 80 (43.2%) pts were female and 89 (49.4%) pts had PsO  $\geq 3\%$  BSA. At BL, dactylitis or enthesitis was present in 56 (30.4%) and 119 (64.7%) pts, respectively; 45 (24.3%) pts had prior TNFi exposure and 106 (57.3%) pts were receiving concomitant MTX. At Wk 16, ACR20 responses were significantly greater in pts receiving RZB (across all arms, 57.1–65.0%) compared with PBO (37.5%, **Table 1**). PASI75/90/100 responses at Wk 16 were significantly higher in RZB-treated pts compared with PBO. ACR50 responses were numerically higher and improvements in HAQ-DI and enthesitis from BL were numerically greater in RZB arms. At Wk 16, RZB-treated pts achieved significantly higher ACR70 and MDA responses as well as greater improvements in DAS28(CRP) and Pain–VAS. Treatment-emergent adverse events (TEAEs) were comparable across treatment arms (**Table 2**); the most common TEAE was infection. There were no deaths or cases of tuberculosis in RZB-treated pts; 1 adjudicated major adverse cardiovascular event was reported in RZB arm.

**Conclusion:** In this Phase 2 study, RZB significantly improved joint and skin symptoms in pts with active PsA. RZB was well-tolerated with no new or unexpected safety findings.

**Table 1. Summary of Efficacy Results at Week 16<sup>a</sup>**

Arm 1, 150 mg RZB at weeks 0, 4, 8, 12, and 16; Arm 2, 150 RZB at weeks 0, 4, and 16 (PBO at weeks 8 and 12); Arm 3, 150 mg RZB at weeks 0 and 12 (PBO at weeks 4, 8, and 12); Arm 4, 75 mg RZB at week 0 (PBO at weeks 4, 8, 12, and 16); Arm 5, PBO at weeks 0, 4, 8, 12, and 16.

<sup>a</sup>Investigator assessed AE as possibly related to study drug.

<sup>b</sup>No serious adverse event type was reported in more than one patient.

<sup>c</sup>The most frequently reported AE was upper respiratory tract infection.

<sup>d</sup>1 patient with urinary tract infection, influenza, and sepsis; 1 patient with gastroenteritis and pyelonephritis.

<sup>e</sup>An event of investigator reported anaphylactic reaction occurred after the 1<sup>st</sup> injection of risankizumab. The sponsor assessed the event details as not consistent with IgE-mediated anaphylaxis.

<sup>f</sup>1 patient with type 1 myocardial infarction.

<sup>g</sup>1 patient with possible cancer.

AEs = adverse events; IgE = immunoglobulin E; MACE = major adverse cardiovascular event; PBO = placebo; RZB = risankizumab;

TEAE = treatment emergent adverse event.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Session

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** Secukinumab, a fully human anti-interleukin-17A monoclonal antibody, reported improved signs and symptoms of ankylosing spondylitis (AS) in the MEASURE 1 trial.<sup>1</sup> Here, we report efficacy, including imaging outcomes, and safety from the MEASURE 1 extension trial (NCT01863732) out to 4 years (208 weeks [wks]).

**Methods:** In the core study, 371 patients (pts) with active AS were randomized to secukinumab or placebo (PBO). Pts on secukinumab had a 10 mg/kg iv loading dose at baseline (BL), Wks 2 and 4, and then 150 mg sc (IV→150 mg) or 75 mg sc (IV→75 mg) every 4 wks from Wk 8 (same schedule for PBO). Based on ASAS20 response at Wk 16, PBO pts were re-randomized to secukinumab 150 or 75 mg sc at Wk 16 (non-responders) or Wk 24 (responders). Efficacy data at Wk 208 are reported for pts originally randomized to secukinumab 150 mg (approved dose with sc loading). Lateral radiographs of the cervical and lumbar spine at BL, Wk 104 and Wk 208 were read centrally by 2 independent readers, blinded to treatment arm and radiograph sequence, using the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). For this analysis, radiographs performed at BL and Wk 104 were re-read for pts who completed 208 wks of treatment. Descriptive statistics on observed or imputed data are provided.

**Results:** Of the 274 patients in this extension study, 89.7% (78/87) originally assigned to secukinumab 150 mg completed 208 wks. Mean ( $\pm$ SD) change in mSASSS from BL to Wk 208 was lower with secukinumab 150 mg ( $1.2\pm3.91$ ) vs 75 mg ( $1.7\pm4.70$ ). No radiographic progression was seen in 73% (mSASSS change from BL  $\leq 0$ ) and 79% (mSASSS change from BL  $< 2$ ) of pts with secukinumab over 208 wks (Figure). Mean mSASSS changes at Wk 208 were numerically higher in males vs females, pts with elevated vs normal BL hsCRP, and pts with vs without BL syndesmophytes. Sustained efficacy in signs/symptoms was seen through Wk 208, evidenced by ASAS 20/40, BASDAI, BASFI, BASMI and ASDAS inactive disease (Table). Efficacy responses were numerically lower with secukinumab 75 mg vs 150 mg. Across the entire treatment period (secukinumab exposure [mean $\pm$ SD]:  $3.4\pm1.44$  years), exposure-adjusted incidence rates for serious infections, Crohn's disease, uveitis and malignant/unspecified tumors were 1.0, 0.6, 1.8 and 0.5 per 100 pt-years, respectively.

**Conclusion:** Secukinumab 150 mg demonstrates lower radiographic progression vs 75 mg at 4 years. These 4-year results confirm the sustained efficacy and known safety profile of secukinumab.<sup>1</sup>

**First publication:** October 19, 2017

**SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Session

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** IgG4-related disease (IgG4-RD) is an immune-mediated condition causing fibro-inflammatory lesions that can lead to irreversible organ damage and death. No approved therapies exist. A novel monoclonal antibody, XmAb5871, is a humanized anti-CD19 antibody with an Fc engineered for increased affinity to FcγRIIb. Co-ligation of CD19 and FcγRIIb leads to inhibition of B lineage cells. Because of the importance of B cells and plasmablasts (PB) in IgG4-RD pathogenesis, an open label pilot of XmAb5871 in IgG4-RD was performed.

**Methods:** IgG4-RD patients with active disease defined by an IgG4-RD Responder Index (RI) of  $\geq 3$  were administered XmAb5871 (5 mg/kg) IV every 14 days for 12 doses. The primary outcome measure was the proportion of patients on Day 169 with a decrease in the IgG4-RD RI of  $\geq 2$  points compared to baseline. Secondary endpoints included the proportion of patients achieving an IgG4-RD RI of 0 with no corticosteroids (CS) after month 2. Other immunosuppressive medications were not allowed. Mechanistic studies were performed at baseline and at selected intervals.

**Results:** 15 patients enrolled between March 2016 and January 2017. The median age of the 15 patients was 63 years (43 to 77 years). Two-thirds were male. 12 of 15 patients had elevated baseline serum IgG4 concentrations (median IgG4: 220 mg/dL; 25 – 2415). 10 had undergone treatment with other therapy before entry. The median baseline IgG4-RD RI was 12 (2 – 30), with active inflammatory disease in a median of 5 organ systems (1-10). The organs most commonly affected were lymph nodes (73% of patients), submandibular glands (60%), parotid glands (53%), and lacrimal glands (47%). 5 patients (33%) had kidney involvement, 4 (27%) had lung findings and 3 each (20%) had orbital lesions, nasal cavity involvement or heart/pericardium findings. 12 patients (80%) completed the study and all 12 achieved the primary endpoint of at least a 2-point reduction in the IgG4-RD RI on Day 169. None of the 12 required CS after month 2. 8 patients (53%) achieved remission (IgG4-RD RI of 0 and no CS after 2 months) and the other 4 achieved IgG4-RD RI scores of  $\leq 4$  at Day 169. 14 of 15 patients (93%) achieved a decrease of  $\geq 2$  in the IgG4-RD RI, most within 2 weeks. One patient had been on baseline CS for 2 years (15 mg/day) and was able to discontinue CS within 2 months. 4 others received CS at the start of the trial and tapered off within 2 months. 3 patients had minor, transient GI side-effects during the 1st infusion; all completed the study. Two SAEs of pneumonia and recurrence of pneumonia due to lack of compliance were seen in 1 patient (who completed). 3 patients discontinued early. One was an atypical patient with laryngeal involvement only who did not respond to XmAb5871 or to subsequent rituximab. A 2nd responded well, but flared at 12 weeks and did not respond to

subsequent rituximab therapy. The 3rd responded well but developed infusion-related symptoms including transient rash and arthralgias following the 5th infusion. She concurrently developed anti-drug antibodies.

Mean B cell counts decreased to ~40-55% of baseline and circulating PBs decreased by ~70% following XmAb5871.

**Conclusion:** XmAb5871 is tolerated well in patients with active IgG4-RD and is a promising treatment approach for IgG4-RD.

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Session

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 4:30PM-6:00PM

### **Background/Purpose:**

Inclusion body Myositis (IBM) is the most frequent myositis in patients over 50 years old. Conventional immunosuppressive drugs are today ineffective or even aggravate muscle deficits. Rapamycin is a mTOR inhibitor used in organ transplantation. Potentially, rapamycin can deplete T effector cells, preserve T regulatory cells and induce autophagy (protein degradation), all parameters impaired during IBM.

### **Methods:**

RAPAMI is a prospective, randomized, controlled, double blind, monocentric, phase IIb trial evaluating the efficacy of rapamycin against placebo (NCT02481453). The primary endpoint was stabilization of maximal voluntary quadriceps isometric strength assessed with a dynamometer (Biodex System3 pro). Secondary endpoints included safety, other muscle groups strength, distance walked in 6 minutes (6MWD), pulmonary functional tests, functional scales, and muscle quality assessed by quantitative nuclear resonance magnetic exams (NRM).

### **Results:**

Forty-four patients were treated by oral rapamycin (2 mg/d, n=22) or placebo (n=22) during 12 months (M12). Twelve months after the initiation of the treatment, the quadriceps strength decreased significantly and similarly in both groups (mean relative change: -11.07% vs. -12.36 %). Nevertheless, in comparison to the placebo group, 6MWD was unchanged (mean change: -4.1 m vs. -38.5 m, p=0.035), IBM weakness composite index was less degraded (11.91% vs. 24.26%, p=0.038) and forced vital capacity significantly improved (mean relative change: +12.3% vs. 1.6%, p=0.016). Additionally, NRM showed significant less fat muscle replacement (difference between M12 and baseline in %) in quadriceps (1.7 vs. 4.4, p=0.025) or hamstrings (0.9 vs. 7.3, p=0.027). Finally in NRM, the loss between M12 and baseline of contractile cross-sectional area (mm<sup>2</sup>) was less pronounced in quadriceps (-3.7 vs. -10.7, p=0.005).

**Conclusion:** Even if the primary endpoint was not reached, these first results showed coherent data in favor of rapamycin. Notably for the first time in a RCT, an improvement of the 6MWD is observed during IBM.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Session

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 4:30PM-6:00PM

**Background/Purpose:** The IL-12/23 pathway has been implicated in the pathogenesis of SLE. The anti-IL12/23 monoclonal antibody ustekinumab (UST) is efficacious in the

treatment of psoriasis, psoriatic arthritis, and Crohn's disease. Here, we evaluated the safety and efficacy of UST in patients (pts) with active SLE.

**Methods:** We conducted a phase 2, placebo (PBO)-controlled study in 102 adults with seropositive (ANA, anti-dsDNA, and/or anti-Smith antibodies) SLE by SLICC criteria and active disease (SLEDAI score  $\geq 6$  and  $\geq 1$  BILAG A and/or  $\geq 2$  BILAG B scores) despite standard-of-care therapy. Pts (n=102) were randomized (3:2) to receive UST IV  $\sim 6$  mg/kg or PBO at wk0, followed by SC injections of UST 90mg q8w or PBO, both added to standard care; stratification factors were consent for skin biopsy (y/n), disease features, (eg, presence of lupus nephritis, baseline concomitant SLE medications, SLEDAI score), site/region, and race. The primary endpoint was the proportion of patients achieving SLE response index (SRI)-4 response at wk24. Major secondary endpoints at wk24 included change from baseline in SLEDAI-2K, change from baseline in Physician's Global Assessment (PGA), and proportion of pts with BICLA response. Endpoint analyses included all pts who received  $\geq 1$  dose of study agent, had  $\geq 1$  measurement prior to administration, and had  $\geq 1$  post-baseline measurement. Patients with missing data and treatment failures were imputed as nonresponders.

**Results:** Baseline pt demographic and disease characteristics were well-balanced between treatment groups (female=91%; mean age=41 (18-66) years; mean SLEDAI-2K= 10.9). At wk24, 60% of pts in the UST group had an SRI-4 response vs 31% in the PBO group (p=0.0046), with a treatment effect favoring UST beginning at wk12. Pts in the UST group had greater median change from wk0 to wk24 in SLEDAI-2K and PGA vs PBO (Table). No difference was observed in the proportion of pts achieving a BICLA composite response at wk24, although among BICLA nonresponders, a greater proportion of UST pts had no BILAG worsening vs PBO. The risk of a new BILAG flare ( $\geq 1$  new BILAG A or  $\geq 2$  new BILAG B) was significantly lower in the UST group vs. PBO (HR 0.11 [95% CI 0.01-0.94]; p=0.0078). UST demonstrated improvement in musculoskeletal and mucocutaneous disease features vs PBO. Improvements in anti-dsDNA and C3 levels were also noted through wk24 with UST. Through wk24, 78% of UST pts and 67% of PBO pts had  $\geq 1$  adverse event; 8.3% and 9.5%, respectively, had  $\geq 1$  serious adverse event (Table). There were no deaths in the study. Safety events were consistent with the UST safety profile in other studied indications.

**Conclusion:** UST showed significantly better efficacy in clinical and laboratory parameters in the treatment of active SLE compared with placebo, while demonstrating a comparable safety profile. UST may be an effective therapy with a novel mechanism of action in the treatment of SLE.

<b>Table. Efficacy and safety results at Week 24.</b>		
	Placebo	Ustekinumab
Patients randomized, n	42	60
<b>Efficacy</b>		
Patients with SRI-4 response, n (%)	13 (31.0)	36 (60.0)

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

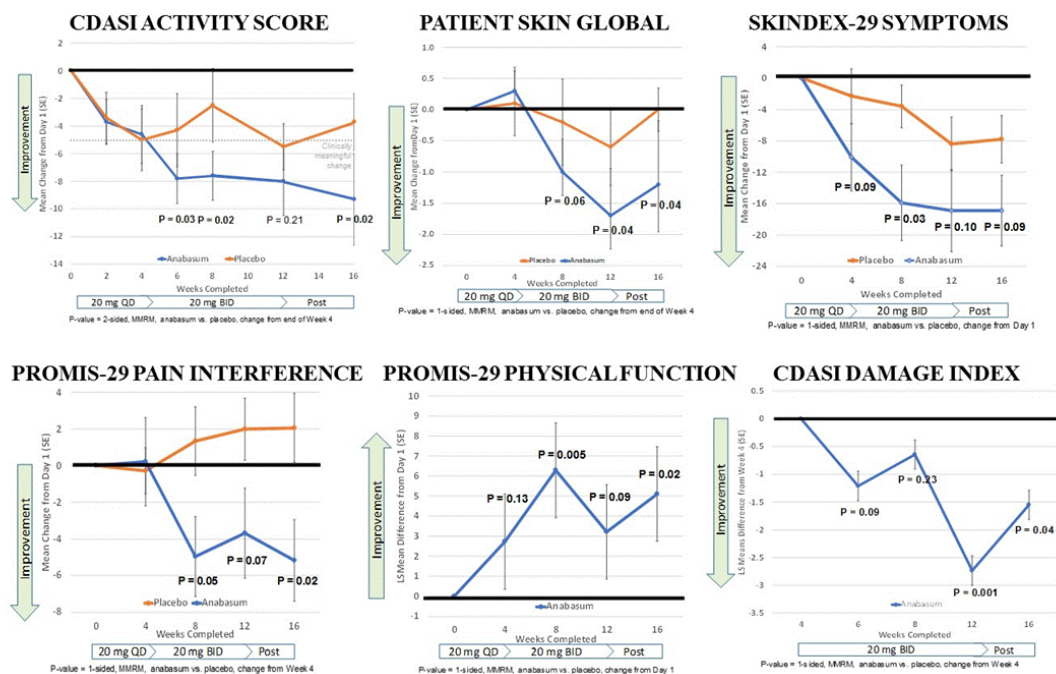

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Effective treatment options are limited for refractory skin disease in dermatomyositis (DM). Anabasum is a non-immunosuppressive, synthetic, oral preferential CB2 agonist that triggers resolution of innate immune responses and reduces cytokine production by PBMC from DM patients. The purpose of this study was to test safety and efficacy of anabasum in DM subjects with refractory, moderate-to-severely active skin disease.

**Methods:** A double-blind, randomized placebo-controlled 16-week Phase 2 trial (JBT101-DM-001) enrolled adults with documented DM and a Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity score  $\geq 14$ , minimal active muscle involvement and failure or intolerance to hydroxychloroquine and stable DM medications including immunosuppressants. Subjects received 2 escalating doses of anabasum (20 mg QD X 4 weeks, then 20 mg BID X 8 weeks) or PBO X 12 weeks. Subjects were followed off study drug X 4 weeks. Safety and efficacy outcomes were assessed from Day 1 through end of study at Week 16. The primary efficacy objective was to assess efficacy of anabasum using CDASI activity score.

**Results:** 11 adults each received anabasum and PBO (N = 22). Demographic and disease characteristics were similar in both cohorts. Both cohorts had mean CDASI activity scores in the severe range (33-35) despite immunosuppressants (19/22 subjects). Anabasum subjects had clinically meaningful improvement in CDASI activity scores with mean reduction  $\geq 5$  points at all visits after 4 weeks. Improvement had statistical significance at end of study (Fig. 1,  $P = 0.02$ , 2-sided MMRM) that first became apparent after 4 weeks. Anabasum provided greater improvement than placebo in CDAI damage index, patient-reported global skin disease and overall disease assessments, skin symptoms including photosensitivity and itch, fatigue, sleep, pain interference with activities, pain, and physical function (examples in Fig. 1). Improvements in secondary efficacy outcomes reached statistical significance ( $P \leq 0.1$ , 1-sided MMRM) at multiple visits after week 4 (Fig. 1). There were no serious, severe or unexpected adverse events (AEs) related to anabasum. Tolerability of anabasum was excellent with no study drop-outs. Subjects in the anabasum cohort had numerically more mild AEs than placebo subjects (29 vs. 19) and fewer moderate AEs (4 vs. 7). AEs in  $\geq 3$  subjects in any cohort were diarrhea, dizziness (lightheadedness), fatigue and dry mouth.

**Figure 1. Effects of Anabasum on Efficacy Outcomes in Refractory, Skin-Predominant DM**

**Conclusion:** Anabasum demonstrated consistent evidence of clinical benefit across multiple efficacy outcomes and had acceptable safety and tolerability in this Phase 2 trial in refractory skin disease in DM. Further evaluation of anabasum in the treatment of DM is warranted.

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Hydroxychloroquine (HCQ) is widely used in the treatment of chronic rheumatic diseases. Its long-standing use has been associated with retinopathy in a daily and cumulative dose dependent manner by weight. Less frequently, ‘bull’s eye maculopathy’ may be found, which is irreversible and can result in blindness. We examined the prevalence of ocular toxicity in a large cohort of patients in a tertiary center in the United States treated with HCQ for inflammatory arthritis and systemic lupus erythematosus (SLE).

**Methods:** Our retrospective cohort study identified 2898 patient from 1999 to August 2017 with diagnoses of rheumatoid arthritis (RA), inflammatory polyarthritis, SLE, subacute cutaneous lupus and discoid lupus erythematosus who had a prescription written for HCQ. 31 patients were identified as having a diagnosis of ‘blindness’ or ‘toxic maculopathy’ in their electronic medical record (Epic) and were chart reviewed. Patient weight and dose of HCQ at initiation and discontinuation, dose of HCQ at the time of any ocular symptoms, duration of HCQ use, rheumatologic diagnosis, reason for blindness or vision impairment, comorbidities and the use of tamoxifen were extracted into REDCap database.

## **Results:**

Of our 31 patients with a diagnosis of ‘blindness’ or ‘toxic maculopathy’, 11 had documented blindness of one or both eyes. In each of these cases, a diagnosis other than HCQ ocular toxicity was confirmed as the cause of blindness: stroke (27%), pre-existing macular disease (18%), diabetic retinopathy (18%), hypertensive retinopathy (9%) and cataracts (9%).

Three out of the 31 patents in our cohort had HCQ retinal toxicity, each without blindness or change in vision.

Two cases were identified with bull's eye maculopathy attributed to HCQ, diagnosed on fundus and macular optical coherence tomography (OCT) exam. Case one was a 51 year old female who had been treated for SLE with HCQ 400 mg daily for over 20 years at 7.1-8.2 mg/kg dose based on documented weight over 15 years. Case two was a 66 year old female who had been treated for SLE on HCQ 400 mg daily for at least 18 years at 7.3-8.2 mg/kg dose based on documented weight over 13 years. Comorbidity of case one was chronic kidney disease, whereas case two had hypertension and cataracts (not visually significant), both without prior use of tamoxifen.

One patient had HCQ toxicity without bull's eye maculopathy but with pigmentary changes on fundus exam and loss of photoreceptor inner segment and outer segment junction in mid periphery on OCT exam. She was 57 years old with 25 years use of HCQ 400 mg daily at 6.3 mg/kg dose based on documented weight over 11 years. She had underlying myopia controlled with glasses without vision complaints.

**Conclusion:** There were no cases of blindness attributable to toxic maculopathy from HCQ use in our cohort of 2868 patients. We identified two patients with bull's eye maculopathy (0.10%) and one with HCQ toxic maculopathy (0.07%) in this cohort; all 3 patients received HCQ for greater than 18 years, and none had functional vision loss at diagnosis. Our findings suggest that comorbid conditions that are common in RA and SLE contribute substantially to vision loss and blindness and should not be ignored.

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Serum induced IFN gene expression (IFN-score) is considered a golden standard to assess IFN activity in SLE. So far, IFN-scores have not been compared to serum levels of type I, II and III IFNs. The study aimed to investigate how IFN-scores and SLE manifestations relate to serum levels of IFNs type I( $\alpha$ s), II( $\gamma$ ) and III( $\lambda$ 1).

## **Methods:**

461 SLE patients and 322 controls were included. IFN-score was measured by WISH cell assay. INF- $\alpha$ s and IFN- $\lambda$ 1 were measured by ELISA. IFN- $\gamma$  was measured by MSD 30-plex assay.

## **Results:**

SLE patients had higher IFN-scores and higher levels of IFN- $\alpha$ s, IFN- $\gamma$  and IFN- $\lambda$ 1 ( $p < 0.001$ ). IFN-scores correlated with levels of IFN- $\gamma$  and IFN- $\alpha$  ( $\rho = 0.39$ , and  $\rho = 0.25$ ,  $p < 0.0001$ ). Further, patients were grouped according to the high levels ( $\geq 3^{\text{rd}}$  quartile) of each IFN/IFN-score. The group with high IFN-scores had higher disease activity (SLAM, SLEDAI): weight loss (41%), fatigue (33%), fever (39%), rash (44%), lymphadenopathy (45%), arthritis (40%), nephritis (55%) ( $p < 0.01$ ). Interestingly, incidence of neuropsychiatric SLE, antiphospholipid (aPL) antibodies (abs), and also damage score was lower ( $p < 0.05$ ).

The characteristics of IFN- $\gamma$  high group included higher disease activity (SLAM, SLEDAI), and specifically: active nephritis (52%), lymphadenopathy (40%), arthritis

(42%), lymphopenia (37%), anemia (35%) and positivity for Sm (41%), SmRNP (36%) and RNP68 (45%), Ro52 (35%) and Ro60 (33%)( $p<0.03$ ).

The common features of IFN- $\alpha$  high group included younger age, shorter disease duration, active rash (34%), lymphadenopathy (43%), Ro52 (38%) and La (43%)( $p=0.01$ ). Presence of aPL abs and previous vascular events were lower and renal affection was uncommon ( $p<0.01$ ).

In general, high IFN-scores reflected SLE manifestations that could be further stratified by high IFN- $\gamma$  levels and to a lesser extent by high IFN- $\alpha$ . High IFN- $\lambda$ 1 did not define any phenotype of active SLE, except presence of anti-nucleosome abs.

### **Conclusion:**

We demonstrate that high IFN-score associate more strongly with type II rather than type I IFNs. Importantly, major manifestations of SLE: active nephritis and arthritis, and also anti-Sm/SmRNP antibodies associate with IFN- $\gamma$ ; while rash associate with IFN- $\alpha$ .

Our findings are of major importance while tailoring clinical trials with anti-IFN therapies and demonstrate that importance of IFN- $\gamma$  has so far been underscored.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Upadacitinib (ABT-494, UPA), an oral, selective JAK-1 inhibitor was effective in 2 ph2 trials in rheumatoid arthritis (RA) pts with inadequate response (IR)/intolerance to csDMARDs/ bDMARDs.

**Methods:** Pts with active RA (TJC $\geq$ 6, SJC $\geq$ 6; hsCRP $\geq$ 3 mg/L) on stable csDMARDs were randomized 2:2:1:1 to receive UPA 15 mg or 30 mg once daily (QD) or PBO for 12 wks followed by UPA 15 mg or UPA 30 mg QD starting at Wk 12. The primary endpoints were the proportion of pts who achieved ACR20 and the proportion who achieved DAS28-CRP  $\leq$ 3.2 at Wk 12 (NRI).

**Results:** Of 499 randomized pts, 498 received study drug; 451 (90.6%) and 419 (84.1%) completed Wks 12 and 24 respectively. Baseline disease characteristics indicated long-standing severe, refractory disease: (means) duration since diagnosis 13 yrs; DAS28CRP, 5.8; TJC68, 27.9; SJC66, 16.8; 53% experienced  $\geq$ 2 prior bDMARDs. At Wk 12, significantly more pts ( $p<.001$ ) on UPA 15 and 30 vs PBO achieved the primary endpoints (ACR20: 64.6% and 56.4% vs 28.4%; DAS28-CRP $\leq$ 3.2: 43.3% and 42.4% vs 14.2%) and other secondary endpoints (**Table 1**). By Wk 1, significantly more pts achieved ACR20 on UPA 15 and 30 vs PBO (27.4% and 24.8% vs 10.7%,  $p<.001$ ). At Wk 12, significant improvements were observed on UPA 15 and 30 vs PBO for HAQ-DI (LS mean change -0.39 and -0.42 vs -0.17,  $p<.001$ ). At Wk 24, responses were similar or greater for pts originally on UPA and comparable for pts who switched to UPA after 12 wks of PBO.

In the first 12 wks, frequency of AEs was comparable for PBO and UPA 15, but higher for UPA 30 (**Table 2**). Overall AE rates (E/100 PY) through Wk 24 for UPA 30 were similar or slightly higher than UPA15; more AEs led to study drug discontinuation in

UPA 30. Occurrence of infections was similar in all arms, but there were more serious infections and herpes zoster cases in UPA 30. Malignancies were observed in 4 pts over 12 wks with 1 additional case through Wk 24. Through Wk 12, pulmonary embolism (PE) was reported in 2 pts (1 each on UPA 15 and 30), none with DVT; through Wk 24, PE were reported in 4 more pts (UPA 15: 3, 1 of whom also had a DVT; UPA 30:1). All had risk factors for DVT/PE. Two deaths were reported (UPA 30: 1 prior to Wk 12; UPA 15:1 after Wk12).

**Conclusion:** In this treatment-refractory, bDMARD-IR RA population, rapid, significant improvements in signs and symptoms were observed with UPA at both doses vs PBO during 12 wks of treatment, and maintained through 24 wks. No new safety signals were identified vs previous ph2 studies. PE and DVT cases observed in this study have not been reported for the only other ph3 study with unblinded data to date. Overall data from the ph3 program will allow a comprehensive evaluation of the benefit:risk profile of UPA in RA.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The safety of treatment with biological DMARDs (bDMARDs) has been carefully studied for the past 15 years, however, it is still largely unknown whether this treatment is safe in arthritis patients with a history of cancer. We studied the risk of a second malignant neoplasm (SMN) and mortality in rheumatoid arthritis (RA) patients with a history of a primary cancer diagnosis and treated with bDMARDs.

### **Methods:**

In total, 1678 RA patients registered in the DANBIO Register during 2000-2011, had a primary cancer according to the Danish Cancer Registry. Hazard Ratios (HR) for SMN and death were calculated.

## **Results:**

There were 190 RA patients who had received bDMARDs *before* their primary cancer diagnosis only, 220 only *after*, 92 both before and after, while 1176 arthritis patients with cancer had *never* received bDMARDs. Among 502 patients ever treated with bDMARDs, the HR (cancer site adjusted) for developing a SMN was 1.11 (95% Confidence interval (CI) 0.74-1.67) compared with never treated, Table 1. The HR for death among patients treated with bDMARDs *before* the primary cancer diagnosis *only*, was 1.53 (95% CI 1.13-2.09). After further adjustment for extent of the primary cancer, the HR for death was 1.20 (95% CI 0.88-1.63) among patients treated with bDMARDs *before* the primary cancer diagnosis *only*, 1.36 (95% CI 0.78-2.39) among patients treated only *after* the cancer and 1.22 (95% CI 0.70-2.13) among patients treated *both* before and after the cancer.

## **Conclusion:**

RA patients with a history of cancer and treated with bDMARDs had no increased risk of a SMN compared with never treated. No clear conclusion can be drawn regarding mortality in bDMARD-treated patients.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Activated macrophages play a critical role in RA by perpetuating inflammation via TNF $\alpha$  release and participating in the destruction of bone and cartilage. Notably, macrophages are the dominant cell type in the synovial sublining of RA-affected joints. Thus, specific detection of activated macrophage infiltration in RA patients may

provide valuable immunodiagnostic insight towards joint inflammation, destruction and overall disease progression.

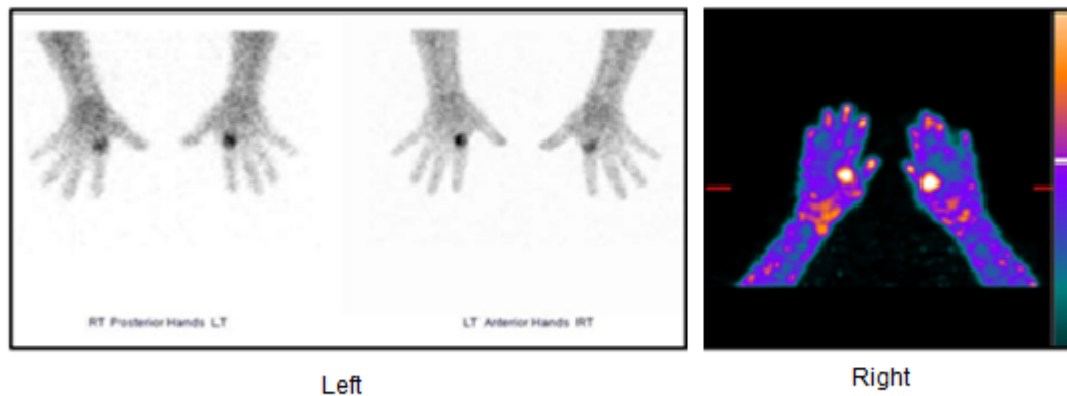

Tc 99m Tilmanocept is a synthetic radiopharmaceutical imaging agent that binds to the activated macrophage mannose receptor (CD206) with high affinity. It is currently under investigation for intravenous (IV) administration in subjects with RA in a dose escalation study. The purpose of this report is to communicate safety and imaging findings from RA subjects who received the maximum study dose of 400 µg tilmanocept/10 mCi Tc 99m.

**Methods:** Nine subjects with clinically diagnosed RA were enrolled in the trial. All subjects received IV administration of 400 µg of tilmanocept radiolabeled with either 10 mCi (n=3), 5mCi (n=3), or 1 mCi (n=3) Tc 99m. Static planar gamma emission images of the whole body and affected joints were acquired at 60 and 180 min post injection with additional SPECT/CT imaging of affected joints.

**Results:** No adverse events were observed after IV administration of 400 µg Tc 99m tilmanocept radiolabeled with 1, 5, or 10 mCi of Tc 99m. There was strong correlation of radiotracer localization to affected joints observed in gamma emission imaging. SPECT/CT imaging further demonstrated that Tc 99m tilmanocept localization is specific to the PIP, MCP, knees, ankle, shoulder, elbow, and periarticular synovial spaces and not in cortical bone or osseous marrow spaces.

**Conclusion:** Overt joint-specific localization of Tc 99m tilmanocept activity was visualized in affected joints of all subjects who had undergone multiple RA flares despite previous successful treatments, which demonstrates macrophage infiltration of these joints as a key component of disease. IV injection of Tc 99m tilmanocept at the maximum study dose was well-tolerated with no adverse events. These findings, in addition to prior biopsy evaluations from other subjects, confirm activated CD206 macrophage infiltration to be a key component of RA pathology which can be safely and effectively visualized on gamma emission imaging with Tc 99m tilmanocept.

**Figure 1.** Static planar gamma emission imaging (left) and maximum intensity projection (MIP) SPECT/CT imaging (right) demonstrating site-specific localization activity to an affected joint.

**Figure 2.** Fused SPECT/CT images of RA subjects defining the localization of Tc 99m tilmanocept to the periarticular synovial space of the knee (left) and ankle (right).

## **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The current Phase 2 study was designed to evaluate safety, tolerability and preliminary efficacy of TPX-100 by IA administration in subjects with mild to moderate patellofemoral osteoarthritis (PFOA) involving both knees. TPX-100, a 23-amino acid peptide derived from Matrix Extracellular Phosphoglycoprotein (MEPE), has been shown to induce articular cartilage proliferation and improve healing after experimental injury in large and small animal models after IA administration. A unique feature of this clinical trial was the use of each subject as his/her own control, intended to minimize effects of age, sex, genetic factors, and activity levels that can complicate inter-subject comparisons. Knee-specific patient-reported outcomes (PROs) used in this study, including the Knee Osteoarthritis Outcome Score (KOOS), were recorded separately for left and right knees.

**Methods:** Adult men and women with bilateral PFOA (ICRS grade 1-3, confirmed by screening MRI) were enrolled at 15 sites. One knee was randomly assigned to receive TPX-100 for 4 weekly injections, while the contralateral knee (control) received identical placebo (saline) injections. Investigator, subject, site and sponsor were blinded as to treatment assignment. The study had two parts: in Part A, 4 dose cohorts (n=6-9 subjects/cohort; 20, 50, 100 and 200mg/injection) were enrolled. Safety/tolerability of each cohort was evaluated by a Safety Review Committee (SRC) before the next cohort

was enrolled. There were no dose-limiting toxicities or safety concerns at any dose, and the 200 mg dose was selected dose for Part B of the study.

**Results:** A total of 118 subjects (236 knees) were enrolled, 29 in Part A and 89 in Part B. The study population was fairly representative of the knee OA population in the U.S. regarding age (median 60 years) and Body Mass Index (29.2). There were no drug-related SAEs and no dose-limiting toxicities across doses from 20-200 mg/injection. Common adverse events such as knee pain had virtually identical incidences in control and TPX-100-treated knees. Efficacy results were based on the “per-protocol” population of 93 subjects (186 knees) who received 4 weekly injections of 200mg TPX-100 (from Part A or Part B) in the knee randomly assigned to active drug and had at least one MRI after baseline. Quantitative MRI revealed no measurable between-knee differences in cartilage thickness or volume at 6 or 12 months. However, statistically significant ( $P<.05$ ) and clinically meaningful differences, per literature criteria, in knee function were demonstrated in favor of TPX-100-treated knees compared with controls at 6 and 12 months, including activities of daily living, sports activities, and knee-related quality of life, and a significant reduction in pain going up or down stairs. Subjects’ use of analgesics, including non-steroidal anti-inflammatory medications, declined markedly during the study. Results will be provided in detail.

**Conclusion:** Improving the functional status of patients with knee OA is a central therapeutic goal of OA treatment. In the present proof-of-concept study, TPX-100, administered in 4 weekly intra-articular injections, was safe and associated with robust functional benefits for up to 12 months.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The need for drugs that achieve structure modification in OA is imminent but their development has been burdened by the need for large, long term studies. New imaging biomarkers using structured machine learning offer opportunity for shorter duration and smaller DMOAD trials. MIV-711, a potent and selective cathepsin K inhibitor reduced CTX-I and CTX-II after once-daily administration for up to 28 days in healthy volunteers. Our aim was to examine the efficacy (symptoms and structure) and safety of MIV-711 in knee OA patients.

## Methods:

Patients with ACR knee OA, KL2-3 and pain  $\geq 4$  &  $< 10$  on 0-10 NRS were enrolled at one of 6 European sites and randomised to receive MIV-711 100mg or 200mg or matched placebo qd. Participants remained on usual analgesic medication. Clinical (pain, function, QoL) and safety data were recorded serially and MRI was performed at baseline and wk26. Primary outcome was change in NRS pain score with the key secondary endpoint of change in MRI bone area (medial femur). The main analyses were conducted using linear mixed models.

## Results:

244 participants were enrolled (100mg n=82, 200mg n=82, placebo n=80), 69% women, mean age 62, mean BMI ~32. NRS pain scores; function and QoL measures were not

statistically significantly reduced compared to placebo. However, there was a trend to reduction for MIV-711 on the NRS (Figure 1) and across the majority of patient-reported outcomes. Significant reduction in medial femur bone area change for both MIV-711 doses (unadjusted p-values =0.002 and 0.004) were observed at wk26, with no evident differences between the 2 doses (Figure 2A). MIV-711 treated participants demonstrated reduced loss of cartilage thickness on the medial femur versus placebo (unadjusted p=0.023 for 100mg dose, 0.125 for 200mg dose, Figure 2B); medial tibia cartilage loss was not significant. The reductions observed for the biomarkers CTX-I and –II were substantial and of a similar magnitude, indicating strong target engagement for both doses. There was generally good tolerability and safety, with infrequent musculoskeletal symptoms, infections and rashes.

### **Conclusion:**

MIV-711 demonstrated significant reduction in OA bone disease progression, and also reduced cartilage progression, in the femur. Although there was no statistically significant reduction in pain, the study duration required to fully realize the symptom benefits expected from structure modification is unclear. Further evaluation of this novel agent is now warranted.

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** CR845 is a selective *kappa* opioid receptor agonist with a peripheral mechanism of action. Here we report preliminary results from a Phase 2b study designed to characterize the analgesic efficacy of orally administered CR845 in patients with osteoarthritis (OA) of the hip or knee (ClinicalTrials.gov NCT02944448).

**Methods:** 476 male and female patients (ages  $\geq 25$  years) with moderate to severe pain (numeric rating scale [NRS]  $\geq 5$ ) associated with hip or knee OA were enrolled at 33 sites in the US. Following a 14-day screening period, patients were randomized 2:1 to CR845 or placebo, respectively. CR845 (1.0, 2.5, or 5.0 mg) or placebo were administered BID for a total of 8 weeks, with doses administered at least 2 hours before or after a meal.

Patients started on 1.0 mg or placebo, then during the 4-week post-randomization period, titrated upward to 2.5 or 5.0 mg to effect in a double-blind fashion and maintained for 4 weeks on the final individualized effective dose. The primary outcome measure was change from baseline in the weekly mean pain intensity score (0-10, NRS) at the index joint with CR845 compared to placebo at Week 8/Day 57. Secondary outcome measures included differences between CR845 and placebo in the Western Ontario and McMaster Osteoarthritis Index (WOMAC) total and sub-scores and in the Patient Global Impression of Change (PGIC) scale. Safety and tolerability measures were also captured over the 8-week treatment period.

**Results:** Efficacy was assessed in 118 hip OA patients (CR845, n=78; placebo, n=40) and 358 patients with knee OA (CR845, n=238; placebo, n=120). The primary efficacy results comparing CR845 (all doses) vs placebo were not statistically significant. However, patients with hip OA maintained on 5.0 mg (n=66) exhibited a statistically significant 69% reduction in mean joint pain score over placebo (p=0.043) accompanied by a 41% reduction over placebo in use of rescue medication at Week 8. The proportion of patients who titrated to the 5.0 mg dose and reported a PGIC score of "very much improved" or "much improved" was statistically higher in patients with knee OA (p<0.005 vs placebo) and hip OA (p<0.006 vs placebo). Patients maintained on the 1.0 and 2.5 mg doses did not exhibit statistically significant reductions in mean joint pain scores compared to placebo nor did patients with knee OA at any dose. Doses were generally well tolerated with no drug-related serious AEs. The most common AEs with  $\geq 5\%$  incidence were constipation (13%), dizziness (8%), and dry mouth (6%). There were no clinically significant changes in serum sodium levels during the 8-week treatment period for any dose group.

**Conclusion:** Post-hoc analyses demonstrated that hip OA patients receiving CR845 5.0 mg had significant pain reduction compared to placebo patients. The PGIC measure of pain in hip and knee patients combined also showed significant benefit of 5.0 mg CR845 while other pain measures showed improvement but not statistical significance. These beneficial effects and a positive safety profile warrant further clinical study.

## SESSION INFORMATION

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase (JAK) inhibitor that preferentially inhibits signaling by JAK3 and JAK1, with functional selectivity over JAK2. Potential increased risk of venous thromboembolic events (VTE) in patients (pts) with rheumatoid arthritis (RA) has been reported for a JAK 1/2 inhibitor.<sup>1</sup> To assess VTE risk with tofacitinib, data were reviewed from the tofacitinib development program in RA, psoriasis (PsO), psoriatic arthritis (PsA), and ulcerative colitis (UC).

**Methods:** Data from Phase (P) 2 (RA, PsO, UC) and P3 (RA, PsO, PsA, UC) randomized clinical studies of tofacitinib as monotherapy or in combination with conventional synthetic (cs)DMARDs were included. Two cohorts were defined; 1) the placebo (PBO)-controlled cohort: pts randomized to tofacitinib 5 or 10 mg BID, or PBO up to Month (M) 3 in RA, PsO, and PsA studies, and pts randomized to tofacitinib 10 mg BID or PBO for the 9-week induction period in UC studies; 2) the dose-comparison cohort: pts randomized to tofacitinib 5 or 10 mg BID, adalimumab (ADA) 40 mg SC Q2W (RA and PSA only) or methotrexate (MTX) 20 mg QW (RA only) throughout the P2/3 studies for RA (up to M24), PsO (up to M12), and PsA (up to M12), and for the 12-month P3 UC

maintenance study. First deep vein thrombosis (DVT) and pulmonary embolism (PE) events were identified using the MedDRA embolic and thrombotic SMQ preferred terms restricted to the respiratory, thoracic, mediastinal, and vascular disorder System Organ Classes; incidence rates (IRs; pts with events/100 pt-years) were based on single events occurring during treatment or  $\leq 28$  days after the last dose or up to the cohort cut-off date. IRs for PE in pts with RA were compared with Corrona Registry data.

**Results:** Up to M3 in the PBO-controlled cohort, DVT and PE were both independently reported in 1 pt with RA and 1 with UC, who both received PBO; no pts receiving tofacitinib had DVT or PE events (Table). In the dose-comparison cohort there were 2 DVT events in tofacitinib-treated pts with RA (5 mg BID, n=1; 10 mg BID n=1) and 1 DVT event in a pt with PsA (tofacitinib 10 mg BID) (Table). IRs were 0.1 (95% CI: 0.0, 0.3) for both tofacitinib doses in RA, and 0.5 (95% CI: 0.0, 2.8) for tofacitinib 10 mg BID in PsA. Five PE events occurred in the dose-comparison cohort, all in RA (5 mg BID, n=2; 10 mg BID, n=3). IRs were 0.1 (95% CI: 0.0, 0.4) for tofacitinib 5 mg BID and 0.2 (95% CI: 0.0, 0.4) for 10 mg BID. IRs for PE with tofacitinib in RA were similar to those reported by the Corrona Registry in pts with RA treated with tofacitinib (0.1 [95% CI: 0.0, 0.4]), biologic DMARDs (0.2 [95% CI: 0.1, 0.3]), and csDMARDs (0.2 [95% CI: 0.0, 0.5]). DVT were reported twice with MTX, and none with ADA.

**Conclusion:** Analysis of DVT and PE across randomized clinical studies for RA, PsO, PsA, and UC showed no evidence of an increased risk of events with tofacitinib.

### **SESSION INFORMATION**

**Session Date:** Tuesday, November 7, 2017

**Session Title:** ACR Late-Breaking Abstract Poster

**Session Type:** ACR Late-breaking Abstract Session

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Secukinumab, a fully human monoclonal antibody that selectively neutralizes IL-17A, has shown significant and rapid efficacy in psoriatic arthritis (PsA). We present primary results of FUTURE 5 (NCT02404350), the largest randomized controlled trial (RCT) of a biologic conducted to date in PsA, assessing efficacy of

subcutaneous (sc) secukinumab 300 mg and 150 mg, including radiographic inhibition of structural damage, and safety.

**Methods:** Adults (n = 996) with active PsA, stratified by previous anti-TNF use, were randomized 2:2:2:3 to sc secukinumab 300 mg with loading dosage (LD), 150 mg with LD, 150 mg without LD, or placebo (PBO). All groups received secukinumab or PBO at baseline (BL), Wks 1, 2, 3, and 4, and then every 4 wks. At Wk 16, PBO non-responders (patients [pts] with <20% improvement from BL in tender or swollen joint counts) were switched to secukinumab 300 mg or 150 mg; remaining PBO pts were switched at Wk 24. The primary endpoint was ACR20 at Wk 16. The key secondary endpoint was radiographic structural progression, as measured by modified total van der Heijde Sharp score (mTSS), assessed by two blinded readers, based on hand/wrist/foot X-rays obtained at BL, Wk 16 (non-responders), and Wk 24. Statistical analyses used non-responder imputation for binary variables, linear extrapolation for radiographic data, and missing at random assumption for continuous endpoints. Testing results used a pre-defined hierarchical hypothesis testing strategy to adjust for multiplicity.

**Results:** BL characteristics were balanced across arms. Approximately 30% of pts had experienced an inadequate response or intolerance to previous anti-TNF therapy. Secukinumab significantly improved ACR20 at Wk 16 vs. PBO. Radiographic progression (mTSS) was significantly inhibited at Wk 24 in all secukinumab arms vs. PBO (**Table**). A greater proportion of pts had no radiographic progression (change from BL in mTSS  $\leq 0.5$ ) with secukinumab vs. PBO: 88% (300 mg), 79% (150 mg), 83% (150 mg without LD), and 73% (PBO). All hierarchical endpoints were significant for secukinumab vs. PBO at Wk 16, except for enthesitis and dactylitis resolution for 150 mg without LD (**Table**).

**Table.** Summary of hierarchical primary endpoints

<b>Week 16 Data<sup>†</sup></b>	<b>Secukinumab 300 mg sc (n=222)</b>	<b>Secukinumab 150 mg sc (n=220)</b>	<b>Secukinumab 150 mg sc without LD (n=222)</b>	<b>Placebo (n=332)</b>
<b>ACR20 (% responders)</b>	62.6*	55.5*	59.5*	27.4
<b>mTSS structural progression (mean change from BL to week 24)</b>	0.08 <sup>¥</sup>	0.17 <sup>∞</sup>	−0.09 <sup>¥</sup>	0.50

<b>Enthesitis resolution (%)</b>	55.7 <sup>†</sup>	54.6 <sup>†</sup>	41.9	35.4
<b>Dactylitis resolution (%)</b>	65.9*	57.5 <sup>†</sup>	56.3	32.3

\* $P < 0.0001$ ; † $P < 0.001$ ; ‡ $P < 0.01$ ; ∞ $P < 0.05$  un-adjusted p-values vs. placebo. ‡Week 24 data for mTSS. ACR, American College of Rheumatology response criteria; BL, baseline; DAS28-CRP, Disease Activity Score-28-joint count C-reactive protein; HAQ-DI, Health Assessment Questionnaire – Disability Index; LD, loading dosage; LS, least squares; mTSS, modified total van der Heijde Sharp score; PASI, Psoriasis Area and Severity Index; sc, subcutaneous

Efficacy across all endpoints was greater in pts who were anti-TNF-naïve. The 300 mg and 150 mg groups had an earlier onset of response vs. pts who received 150 mg without LD. Adverse event (AE) rates at Wk 16 were 51.8% (300 mg), 52.7% (150 mg), 52.7% (150 mg without LD) and 58.7% (PBO); non-fatal serious AE rates were 2.3%, 3.2%, 1.4%, and 3.0%, respectively. No deaths were reported.

**Conclusion:** Subcutaneous secukinumab 300 mg with LD and 150 mg with and without LD, inhibited radiographic structural progression and provided rapid and clinically significant improvements in the signs, symptoms and physical function of pts with PsA. The safety profile was consistent with that previously reported with no new safety signals identified.

## **Background/Purpose:**

RITAZAREM (ClinicalTrials.gov: NCT01697267) is an international, randomized, controlled trial comparing rituximab with azathioprine as maintenance therapy after induction of remission with rituximab and glucocorticoids for relapsing ANCA-associated vasculitis (AAV). Since all patients receive rituximab for induction, the RITAZAREM trial is also the largest prospective study of the use of rituximab in patients with relapsing AAV.

## **Methods:**

188 patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) were enrolled and received remission-induction therapy with rituximab (4 x 375 mg/m<sup>2</sup>) and a higher- or lower-dose glucocorticoid regimen, depending on physician choice: reducing from either prednisone (or prednisolone) 1 mg/kg/day or 0.5 mg/kg/day to 10 mg/day by 4 months. Severe disease was defined as an organ- or life-threatening manifestation. Patients who achieved remission (BVAS/WG  $\leq$  1 and prednisone  $\leq$  10 mg daily) by month 4 were randomized to either repeat dose rituximab (1 g every 4 months) or azathioprine (2 mg/kg/day) for a total treatment period of 24 months. Preliminary results of the 4-month induction phase are reported.

## **Results:**

95/188 (51%) subjects were male, median age 59 years (interquartile range (IQR) 47.5-68.0), disease duration of 5.0 years (IQR 1.85-10.15). 149/188 (79%) had previously received cyclophosphamide and 67/188 (36%) had previously received rituximab. 137/188 (73%) had PR3-ANCA positive disease, and 51/188 (37%) MPO-ANCA positive disease. 118/188 (63%) of relapses were severe, 56/188 (30%) received the higher-dose glucocorticoid regimen and 132/188 (70%) received the lower-dose glucocorticoid regimen (Table 1). The median BVAS/WG at enrollment was 5, maximum 14.

Data on responses at month 4 was available on 181 patients. 165/181 (91.2%) of patients achieved remission. 11/181 (6.0%) patients failed to achieve remission: 9/11 had PR3-ANCA positive disease; 9/11 had ear, nose, and throat involvement at baseline; 7/11 had severe disease at enrollment; and 9/11 received the lower (0.5 mg/kg) glucocorticoid dosing regimen. 5 (2.8%) patients died in the induction phase; causes of death included: pneumonia (2), cerebrovascular accident (1), alveolar hemorrhage/respiratory failure (1), and colon cancer (1).

53 severe adverse events (SAEs) occurred in 30 patients during the induction phase; 15/53 (28%) SAEs were severe infections. 52/188 (28%) patients developed an IgG level  $<$ 5g/l in the induction phase.

## Conclusion:

Data from the first phase of RITAZAREM, the largest reported cohort of patients with relapsing AAV, demonstrates that rituximab, in conjunction with glucocorticoids, is highly effective at re-inducing remission in patients with AAV who have relapsed, with an acceptable safety profile. The maintenance phase of the RITAZAREM trial is ongoing.

<b>Table 1. Distribution of study subjects based on severity of relapse at enrollment and glucocorticoid induction regimen</b>			
<b>Glucocorticoid induction regimen (oral prednisone/prednisolone)</b>	<b>Relapse Severity at Enrollment (%)</b>		<b>Totals (%)</b>
	<b>Severe</b>	<b>Non-Severe</b>	
<b>High-dose (starting at 1mg/kg/day)</b>	45 / 188 (24%)	11 / 188 (6%)	56 / 188 (30%)
<b>Low-dose (starting at 0.5mg/kg/day)</b>	73 / 188 (39%)	59 / 188 (31%)	132 / 188 (70%)
<b>Totals (%)</b>	118 / 188 (63%)	70 / 188 (37%)
