## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We recently discovered that lysophosphatidylcholines (lysoPCs) to phosphatidylcholines (PCs) ratio was associated with knee osteoarthritis (OA), suggesting that the conversion of PCs to lysoPCs catalyzed by phospholipases A2 (PLA2) was over activated. The aim of the study was to examine the gene expression levels of multiple PLA2 enzymes in human cartilage and identify the specific one that is important in OA.

**Methods:** Human cartilage samples were collected from patients undergoing total hip/knee joint replacement surgery due to primary OA or hip fractures as controls. RNA was extracted from the cartilage tissues. mRNA levels of three PLA2 enzymes, namely PLA2IIa, IVa, and V, and three cytokines, namely IL-6, IL-1 $\beta$ , and TNF- $\alpha$  were measured by real-time quantitative PCR (qPCR). Expression levels in each sample were calculated as fold changes in relation to the calibrator using Livak method.

**Results:** A total of 33 OA cases (24 hip OA and 9 knee OA) and 21 healthy controls were included. We found that PLA2V expression level was substantially increased by 445% in OA-affected cartilage compared to OA-free cartilage ( $p=0.003$ ), but not PLA2IIa and PLA2IVa ( $p>0.05$ ). Similarly, the expression level of TNF- $\alpha$  was significantly increased by 193% in OA-affected cartilage compared to the OA-free cartilage ( $p=0.007$ ), but not IL-6 and IL-1 $\beta$ . Further, the expression level of PLA2V was highly correlated with TNF- $\alpha$  expression with a correlation coefficient of 0.71 ( $p<0.0001$ ).

**Conclusion:** Our data indicated that inflammatory process was involved in OA and resulted in substantial over expression of PLA2V and excessive conversion of PCs to lysoPCs, suggesting PLA2V could be a novel therapeutic target for OA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoarthritis (OA) is the most common form of arthritis, and is the major source of joint pain and disability. The aim of the study was to estimate the percentage of non-responders to total joint replacement therapy (TJR) in OA (hip and knee) patients and identify factors and biomarkers that associated with it.

**Methods:** TJR patients due to OA were recruited at the surgery and followed up for 4 years on average. The WOMAC pain and function subscales at pre- and post-surgery were used to assess the improvement of joint pain and function. Based on the minimal clinically important difference (MCID), participants were classified as non-responders if the change score of less than 7 points (of 20 points total) for WOMAC pain subscale from pre-surgery to post-surgery. For physical function, participants were non-responders if the change score was less than 22 points (of a total of 68) from pre-surgery to post-surgery. Metabolic profiling (186 targeted metabolites) was performed on plasma samples collected at baseline. Demographic and medical information was collected systematically using standardized questionnaires.

**Results:** A total of 242 TJR patients were included, 20% were hip replacements and 80% were knee replacements. 42% of them were males and 58% were females. Mean age was  $65.6 \pm 7.4$  years old. 16.5% of the study participants were classified as non-responders to TJR, as they failed to reach MCID for pain. A similar percentage for non-responders was noted for physical function. There was no difference between knee and hip replacements. About 63% of the non-responders as defined by pain score were also non-responders in physical function. No association was noted between the non-responders in pain and physical function and clinical epidemiological factors including age, sex, BMI, and comorbidities (cardiovascular disease, metabolic related disease, and cancers). However, four amino acids – histidine, sarcosine, phenylalanine, and serine levels were significantly associated with non-responders in physical function (all adjusted p values (FDR) $<0.05$ ). Phenylalanine level was also associated with non-responders in pain although the significance didn't pass the multiple testing adjustments by FDR (unadjusted  $p=0.02$ ).

**Conclusion:** Our data indicated that over 16% of OA patients did not reach MCID from TJR in either pain or physical function and non-responders to TJR were associated with higher levels of several amino acids. While further confirmation is needed, our findings have great potential in the clinical decision-making process when contemplating TJR for knee or hip OA.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Development of disease-modifying drugs for OA has been challenging, partly due to lack of predictive biomarkers. Our primary objective was to identify baseline (BL) biomarkers predicting greater treatment effects on WOMAC pain among knee OA subjects in the ABT-981 ILLUSTRATE-K trial (NCT02087904).

**Methods:** Subjects (N=347) with Kellgren-Lawrence (KL) grade 2–3 knee OA, synovitis on MRI or ultrasound, and knee pain score 4–8 (range, 0–10) were randomized to placebo (PBO) or ABT-981 25, 100, or 200 mg subcutaneously every 2 wk for 50 wk. The primary endpoints were change from BL (CFB) in WOMAC pain at wk 16 and CFB in MRI synovitis at wk 26. Demographics, patient-reported outcomes (WOMAC, ICOAP, global assessment [PGA]), x-ray joint space width, and Whole Organ MRI Score (WORMS) were determined at BL. The Patient Rule Induction Method, Sequential Batting, and the Adaptive Index Model were used to identify BL predictive biomarkers and OA subsets with greater ABT-981 treatment effects. Continuous efficacy endpoints were assessed using

ANCOVA with treatment, age group, and KL grade as main factors and BL measurements as covariates with LOCF imputation for WOMAC pain.

**Results:** WORMS Global Total Osteophyte Score (GTOS), which semi-quantitatively summates osteophyte severity from 14 regions of the knee, identified a subset of subjects with a greater ABT-981 treatment effect vs PBO; the optimal GTOS cutoff for discriminating treatment effects was 14 (**Figure 1**). Among subjects with a GTOS  $\geq 14$ , the PBO WOMAC pain response was markedly reduced and only marginally improved for ABT-981. At wk 16, among subjects with GTOS  $\geq 14$ , the standardized mean difference (95% CI) of WOMAC pain for the ABT-981 100-mg dose group vs PBO was  $-0.62$  ( $-0.16$  to  $-1.09$ ) vs  $-0.30$  ( $0$  to  $-0.61$ ) for all subjects. Compared with the total study population, the 41% of subjects with GTOS  $\geq 14$  not only had a greater ABT-981 treatment effect vs PBO on WOMAC pain, but also other measures of OA symptoms (**Table 1**). BL systemic markers of synovitis (serum CIM and C3M) and potential markers of macrophage activation by IL-1 (serum alkaline phosphatase) were positively associated with greater ABT-981 treatment effects vs PBO but to a lesser extent than GTOS. Other data supported the robustness of the GTOS predictive marker (**Table 2**).

**Conclusion:** The GTOS biomarker predicted improvement of knee OA pain and other symptoms with ABT-981 treatment. We hypothesize that subjects with more severe osteophytes may have had more inflammation-dependent pain that was less responsive to PBO, suggesting that IL-1 inhibitors should be studied further as a treatment for knee OA symptoms in this subset of patients.

Figure 1

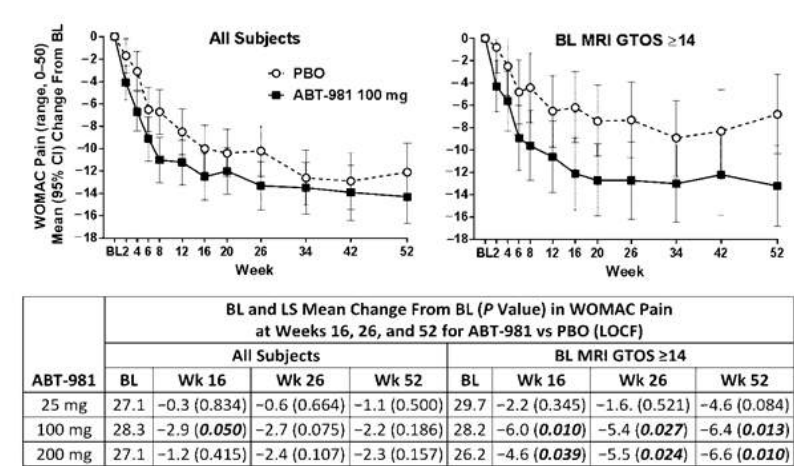

Table 1. Additional outcome measures with greater treatment effects in the subset of subjects with GTOS  $\geq 14$ . LS mean change from BL (p value) at wk 16 for ABT-981 vs PBO.

Week 16 Change From BL		ABT-981 25 mg vs PBO		ABT-981 100 mg vs PBO		ABT-981 200 mg vs PBO	
		All subjects	GTOS $\geq 14$ subjects	All subjects	GTOS $\geq 14$ subjects	All subjects	GTOS $\geq 14$ subjects
WOMAC	Function (LOCF)	-1.1 (0.818)	-6.9 (0.366)	-7.6 (0.109)	-15.7 (0.035)	-3.4 (0.465)	-13.4 (0.068)
	Stiffness	0.4 (0.530)	-0.4 (0.701)	-0.6 (0.398)	-2.3 (0.027)	0.0 (0.939)	-2.0 (0.048)
PGA		-0.1 (0.728)	-0.5 (0.307)	-0.4 (0.219)	-1.1 (0.025)	-0.1 (0.673)	-1.1 (0.040)
ICOAP	Constant	0.9 (0.756)	-5.1 (0.298)	-5.6 (0.068)	-15.3 (0.002)	-1.4 (0.649)	-6.0 (0.217)
	Intermittent	0.7 (0.804)	-3.5 (0.434)	-1.1 (0.699)	-8.4 (0.056)	1.4 (0.636)	-2.9 (0.513)

Table 2. Factors supporting robustness of GTOS $\geq 14$  as a biomarker of ABT-981 treatment response.

Factor	Rationale
A priori, KL grade used to stratify subjects	While KL grade is not as sensitive as GTOS as a predictive biomarker, baseline KL-3 subjects had a greater WOMAC pain treatment effect than KL-2 subjects ( $-4.6$ ( $P=0.055$ ) vs $-1.8$ ( $P=0.342$ ), respectively).
Biological plausibility	Osteophyte formation is directly linked with synovial macrophage numbers in humans and animal models. Synovial macrophages are the predominant source of IL-1 in OA. IL-1 is an important mediator of pain.
Balanced subject characteristics	Among subjects with a high GTOS score ( $\geq 14$ ), baseline characteristics and demographics were similar compared with subjects with a low GTOS ( $< 14$ ).

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Osteoarthritis – Clinical Aspects Poster I: Clinical Trials and Interventions

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Bone marrow lesions (BMLs) are important contributors to pain and progression of knee OA. There has been recent interest in bisphosphonates as a potential disease modifier through amelioration of BMLs; however, there is theoretical concern that long-term suppression of bone turnover may be detrimental to healing of BMLs. One randomized controlled trial demonstrated beneficial effects of intravenous zoledronic acid on BML volume at 6 months, though this effect was no longer statistically significant at 12 months. We sought to determine the effect of commonly prescribed oral bisphosphonates on BML volume over 12 months.

**Methods:** We identified women in the Osteoarthritis Initiative who newly initiated an oral bisphosphonate (alendronate or risedronate) and who had a MRI at the visit at which they reported initiating a bisphosphonate as well as the following clinic visit (i.e., 12 months later) after initiation. We excluded women who reported use of other bone-active agents, such as PTH, calcitonin, or raloxifene. We propensity-score matched (see Table for covariates) bisphosphonate initiators to women who did not initiate bisphosphonate use with greedy matching, and used multiple imputation to address missing covariate data. BML volume was assessed using the sagittal turbo spin echo fat-suppressed intermediate-weighted MR images (slice thickness 3mm). A validated semi-automated process was used to segment the subchondral OA-related BMLs in the distal femur and proximal tibia to determine the total volume of BMLs based upon the number of voxels (0.382 mm<sup>3</sup>) within the outlined region of interest (intra- and inter-reader reliability: 0.96, 0.97, respectively). We evaluated the mean change in BML volume over 12 months among the bisphosphonate initiators compared with the non-initiators using multiple linear regression, as well as by proportion with changes in BMLs over 12 months.

**Results:** We identified 145 bisphosphonate initiators, who were well-matched to their comparators (mean age 65, mean BMI 26.2). A similar proportion of bisphosphonate initiators and non-initiators had BMLs at their index visit (51% vs. 47%, p=0.3). The proportion of subjects with decrease, increased, or unchanged BML volumes over time were similar in both groups, though there was a trend towards decreased BMLs in the bisphosphonate initiators (**Table**). However, mean change in total BML volume for the whole sample, regardless of presence of baseline BMLs, was not significantly different between the two groups (difference in mean change in total BML volume: 98.8mm<sup>3</sup>, 95% CI -156.6 to +354.2, p=0.4).

**Conclusion:** In this ‘real-world’ setting of women starting bisphosphonates, we found no clear evidence of benefit or harm of oral bisphosphonate use over a 12-month period on BML volume. Longer term follow-up is likely necessary to better appreciate the effects of bisphosphonates on BMLs in knee OA.

Table: Relation of incident bisphosphonate use to BML volume change over 12 months			
	Bisphosphonate Initiator (N=145)	Bisphosphonate non-initiator (N=145)	P-value
BML volume:			
Decreased	28%	22%	p=0.07
Unchanged	32%	36%	
Increased	30%	32%	
Propensity score was adjusted for baseline values of: age, race, BMI, minimum adult weight, marital status, education, income, employment, health insurance, blood pressure, SF-12, activity limitation, comorbidity score, renal disease, WOMAC function, knee pain, gait speed, physical activity, worst KL grade, inflammatory arthritis, prednisone use, total dietary intake, dietary calcium intake, calcium supplement use, vitamin D prescription or supplements, estrogen use, fractures, falls, ovariectomy/hysterectomy, smoker, alcohol use

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Current algorithms for identifying patients at high risk of fracture focus on long-term risk. We developed simple 10- and 3-predictor models and points-based risk scores to enable pragmatic identification of patients at near-term (12-24 months) risk of fracture. Physicians and patients could benefit from such models to ensure timely care.

**Methods:** This retrospective cohort study included women  $\geq 50$  years who had dual-energy x-ray absorptiometry (DXA) bone mineral density (BMD) data and were members of an integrated healthcare delivery system in the United States. Clinic location determined inclusion in the development vs. validation cohort. Using randomly selected outpatient visits (2008- 2012) as index dates, we followed women up to 2 years for the occurrence of “any fracture” – closed fracture other than skull/face/fingers/toes. We adapted our previously validated 10- and 3-predictor models to predict 2-year fracture risks among the subgroup of women with recent BMD T-scores, using Cox regression. We used predictor coefficients from these models to develop risk score points.

**Results:** 68,589 women in the development cohort (mean $\pm$ sd age 67.0 $\pm$ 9.6 years, 1,816 fractures) and 58,812 women in the validation cohort (age 67.2 $\pm$ 9.8 years, 1,440 fractures) had an overall 2-year fracture rate of 2.6% and 2.4%, respectively. We developed a 10-predictor model for “any fracture,” which included age, race/ethnicity, body mass index (BMI), BMD T-score, fracture in the prior year, fall risk, tobacco use, and use of antidepressant, narcotic, and glucocorticoid medications. This model discriminated risk effectively in both the development cohort (c-statistic = 0.75) and the external validation cohort (c-statistic = 0.76). Our reduced, 3-predictor model included age, recent fracture, and BMD T-score, and explained 88.4% of the variation in the 10-variable model. Discrimination was 0.72 in the development and 0.73 in the external validation cohorts. Calibration plots revealed excellent agreement between observed and predicted risks. A 2-year predicted risk  $\geq 10\%$  in the 3-predictor model accounted for 4% of patients and 20% of fractures in the total study population (Table 1). We also developed a points-based risk score for easy implementation of the model to identify patients at high near-term fracture risk (Table 2).

**Conclusion:** Our data suggest that models using as few as 3 variables can perform well in estimating near-term fracture risk. Our simple models can aid in identification of patients in greatest need of impactful interventions to quickly lower fracture risk.

**Table 1. Agreement between observed (Kaplan-Meier) and predicted two-year fracture risks in external validation cohort, with the range of risk score points for the three-predictor model of all fractures.**

Predicted risk	Number of Patients	Number of any fracture (crude risk, %)	KM observed risk (%)	Mean $\pm$ SD predicted risk (%)	Median predicted risk (%) (q1-q3)	Range of risk score points
0 to 1.49%	12,830	86 (0.67)	0.66	0.9 $\pm$ 0.3	0.8 (0.7-1.2)	0 to 44
1.50 to 4.99%	37,280	716 (1.92)	1.79	2.4 $\pm$ 0.9	2.3 (1.6-2.9)	47 to 91
5.00 to 9.99%	6,403	359 (5.61)	5.51	6.8 $\pm$ 1.4	6.5 (5.8-7.8)	92 to 120
10.00 to 14.99%	1,480	151 (10.20)	10.27	11.9 $\pm$ 1.4	11.6 (10.6-12.9)	121 to 137
$\geq 15.00\%$	819	128 (15.63)	17.12	22.3 $\pm$ 7.9	19.5 (16.7-25.0)	$\geq 138$

**Table 2. Contribution of individual predictors to points-based risk score from the three-predictor model**

Age	Points	BMD T-score	Points	History of fracture	Points
50 to 54	0	$\geq -1.0$	0	No	0
55 to 59	12	$-2.5$ to $< -1.0$	29	Yes	40
60 to 64	19	$-3.5$ to $< -2.5$	45		
65 to 69	15	$-4.5$ to $< -3.5$	60		
70 to 74	25	$< -4.5$	71

## Fracture Incidence and Characteristics in Young Adults Age 18 to 49 Years: A Population-Based Study

Joshua N. Farr<sup>1</sup>, L. Joseph Melton III<sup>1</sup>, Sara J. Achenbach<sup>1</sup>, Elizabeth J. Atkinson<sup>1</sup>, Sundeep Khosla<sup>1</sup> and Shreyasee Amin<sup>2</sup>, <sup>1</sup>Mayo Clinic, Rochester, MN, <sup>2</sup>Rheumatology, Mayo Clinic, Rochester, MN

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While fractures in both the elderly and pediatric populations have been extensively investigated, comparatively little attention has been given to the age-group in between. Thus, we determined incidence rates for all fractures in young adult residents from a defined geographic population (age range, 18 to 49 years), in 2009-11, and compared the distribution of fracture sites and causes in this young adult cohort with those age  $\geq 50$  years old from the same population.

**Methods:** Using a unique medical records linkage system that allows access to all (inpatient and outpatient) community medical records for the population under study, we identified all fractures that occurred among young adult residents during the 3-year period. All medical records were reviewed by trained nurse abstractors to validate all fractures identified and to determine their antecedent cause (pathological process [e.g., metastatic malignancy], severe trauma [e.g., motor vehicle accidents, falls from greater than standing height] and those due to no more than moderate trauma [by convention, equivalent to a fall from standing height or less]). Comparable results that we previously reported in residents age  $\geq 50$  years old (JBMR 2014) were used for comparisons.

**Results:** During 2009-2011, 2,482 residents age 18-49 years experienced one or more fractures. There were 1,730 fractures among 1,447 men compared to 1,164 among 1,035 women, and the age-adjusted incidence of all fractures was 66% greater among the men (1,882 [95% CI, 1,793-1,971] vs. 1,135 [95% CI, 1,069-1,201] per 100,000 person-years;  $p < 0.001$ ). Of all fractures, 80% resulted from severe trauma compared to 33% in residents age  $\geq 50$  years who sustained a fracture in 2009-11. Younger residents (ages 18-49 years) had a greater proportion of fractures than older residents (age  $\geq 50$  years) of the hands and feet (40% vs. 18%) with relatively few fractures observed at traditional osteoporotic fracture sites (wrist, shoulder, spine or hip) (14% vs. 43%). Vertebral fractures were still more likely to be due to moderate trauma than at other sites in younger residents, especially in women (57% vs. 32% in men, 26% vs. 72% in women, for severe vs. moderate trauma vertebral fractures, respectively).

**Conclusion:** In conclusion, whereas elderly populations often fracture from no more than moderate trauma, young adults, and more commonly men, suffer fractures primarily at non-osteoporotic sites due to more significant trauma. The main exception is vertebral fractures in young women, which are still more likely to be secondary to moderate trauma.

## Chest Radiography As a Screening Tool to Detect Fragile Spine Fractures

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporosis screening is essential in the management of rheumatoid arthritis, and evaluation of fragile spine fractures is one of the recommended examinations. Digital chest radiography is widely available, and the spine can be evaluated by focusing on its lateral view. Therefore, we assessed the usefulness of lateral-view chest radiography in the screening of fragile spine fractures.

**Methods:** We retrospectively evaluated patients who newly met the 2010 American College of Rheumatology/European League Against Rheumatism rheumatoid arthritis criteria and underwent osteoporosis screening, including chest radiography, spine radiography, FRAX, and dual-energy X-ray absorptiometry within a 1-month interval, from April 2016 to March 2017. The incidental identification of vertebral fracture was evaluated using a semiquantitative approach by two board-certified musculoskeletal radiologist. Radiography was used as the gold standard by both readers to detect vertebral fractures in the thoracic and lumbar spines. We calculated the sensitivity and specificity of chest radiography and compared these with those of the gold standard performed by each radiologist. In addition, kappa statistics between the radiologists were calculated reproducibly.

**Results:** We identified 35 eligible patients (Table 1). Both readers agreed that at least one moderate or severe thoracic fracture was present in 6 patients (17.1%) on spine radiography. The kappa statistics between the radiologists who detected fragile spine fractures using lateral-view chest radiography was 0.982 (95% confidence interval: 0.685–1.000). For thoracic vertebral fractures, the sensitivity and specificity of lateral-view chest radiography in detecting fractures were respectively 100% and 97.1% for radiologist 1 and 100% and 97% for radiologist 2. For lumbar vertebral fractures, the sensitivity and specificity were both 100% for radiologists 1 and 2.

**Conclusion:** Chest radiography is useful for the screening of fragile spine fractures.

Table 1. Patient Characteristics

Clinical characteristic	Total n=35	Spine Xray positive n=6	Spine Xray negative n=29	p value
Female sex	30 (85.7%)	6 (100%)	24 (82.9%)	0.272
Age mean (year)	66.1	75.2	64.3	0.001

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Current WHO definition of osteoporosis excludes cervical fractures. However, in atraumatic odontoid fractures, mainly reported by orthopedic surgeons, bone status has not been described yet [1].

To investigate bone status in elderly patients sustaining a low energy odontoid fracture.

### Methods:

We conducted a prospective study from January 2016 to January 2017 in patients > 65 years old, hospitalized in Nice University hospital for low energy odontoid fracture. An evaluation of bone status was proposed within 3 months after fracture event. Evaluation included demographic data, clinical risk factors of osteoporosis, bone mineral density (BMD) at spine and hip and vertebral fracture assessment (VFA) by dual X-ray absorptiometry and serum analysis to detect secondary osteoporosis.

## Results:

38 patients were hospitalized for odontoid fracture: 8 patients < 65 years always after a major trauma (mean age 37.1 ±14.5 y) and 30 patients ≥ 65 years including 3 after a high energy impact. 27 odontoid fractures followed a low energy impact: 18 women and 9 men, mean age 83.8 y. (±10.7). 8 patients died before bone status assessment (5 men and 3 women), 6 died during hospitalization with a mean delay of 3.5 days (±1.87) and 2 after discharge (1 month and 5 month). 3 patients refused bone status evaluation, 5 were lost to follow-up and 1 is awaiting evaluation. Finally 10 patients had bone status evaluation, all women, mean age 84.2 y. (±8.9). None had parental history of hip fracture, 1 had an early menopause, 1 received aromatase inhibitors for breast cancer and 2 had a history of steroid therapy (> 3 months). 3 patients had previously received hormone replacement therapy, 1 received bisphosphonate for 5 years and 4 had calcium + vitamin D supplements. Lumbar spine mean T-score was -1.45 (±1.08), femoral neck: -2.37 (±.040) and total hip: -1.99 (±0.6). VFA analysis revealed 4 unknown vertebral fractures. The table summarizes population bone status: 8 patients out of 10 fulfilled diagnostic criteria of osteoporosis, including 6 with previous fractures. 2 patients with T-score > -1.DS didn't have hip BMD assessment because of bilateral hip replacement but had previous major osteoporotic fractures. No secondary osteoporosis was detected. Serum vitamin D concentration was < 30 ng/ml in 5 patients, including 2 with concentration < 10 ng/ml.

Lowest T-score	No fracture (n)	Previous minor osteoporotic fracture (n)	Previous major osteoporotic fracture (n)
T-score > -1 DS	0	0	2  (1 patient: 2 femoral neck fracture,  1 patient: pelvic and humeral fractures,  Both patients had vertebral fracture on VFA)
-1 DS > T-score ≥ -2.5	1	1  (1 wrist)	2  (1 patient: humeral and vertebral fracture on VFA,  1 patient: 5 ribs fractures)
T-score < -2.5	2	1 (2 wrist fractures)	1 (vertebral fracture on VFA)

## Conclusion:

Our study reveals that odontoid fractures mainly occur in elderly osteoporotic patients after a low energy impact. Although WHO osteoporosis definition excludes cervical fractures, odontoid fracture may be considered as an osteoporotic fracture. Further studies are required to confirm these results.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The worldwide incidence of hip fractures in men is rising, and by 2050 is projected to increase by 310%. Increased hip fracture rates may be due to the number of undiagnosed, and therefore untreated, cases of osteoporosis. Established coordinated models for fracture care aim to improve treatment of osteoporosis following fragility fractures, and their implementation has been associated with reduction of subsequent fractures. However, these models vary and have not been uniformly adopted as a standard of care. The aim of this study was to assess osteoporosis management patterns in males with fragility fractures, using a VA system to identify an appropriate population of males at risk for osteoporosis and fractures.

### **Methods:**

We performed a retrospective chart review using the VA Computerized Patient Record System. All patients who underwent bone densitometry (DEXA) between 2011 and 2016, and therefore presumed to be at potentially high risk for osteoporosis and fractures, were identified. Subjects were then stratified into two subgroups: those who had DEXA scans ordered in response to a fragility fracture (subgroup 1), and those who suffered a fragility fracture following their first DEXA (subgroup 2). To identify the impact of treatment on subsequent fractures, post-fracture management was evaluated in both groups. We assessed whether patients were treated following their fracture, whether they sustained a recurrent fracture, and what percentage of treated patients sustained subsequent fractures compared to the percentage of untreated patients who sustained subsequent fractures. Data was collected by three investigators, following a validated algorithm.

### **Results:**

From among 45,000 patients with active records in the study time period, 1848 patients had undergone DEXA. Manual review of records for these 1848 patients identified 485 who had experienced a fragility fracture, including 170 of the 485 patients (9%) who had DEXA scans ordered in response to a fracture (subgroup 1). Overall, 68 (40%) of subgroup 1 patients subsequently suffered a recurrent fracture. 51 (30%) patients in subgroup 1 were treated for osteoporosis following their fracture; of these, 11 (23%) suffered a recurrent fracture, compared with 54 of 119 untreated patients (46%). Further, we evaluated post-fracture care in 315 patients who suffered a fragility fracture after a DEXA was obtained (subgroup 2). 22 of these patients (7%) were on treatment at the time of their initial fracture. Overall, 78 of 315 patients (25%) suffered a second, recurrent fracture. 198 (63%) were initiated on treatment following their first fracture. Among those receiving treatment, 26 of 198 (13%) suffered a recurrent fracture, compared with 28 of the 117 (24%) who did not receive treatment.

### **Conclusion:**

Our data confirms the ability of treatment to reduce the risk of primary and secondary osteoporotic fractures in men, but underline that the number of male patients actually treated in response to DEXA and fracture is well below that mandated by available guidelines. Physicians should be educated on appropriate management of osteoporosis following fractures and an established model of care following fragility fractures may be helpful in this setting.

## **Caffeine Consumption and Risk of Osteoporosis: A Cross Sectional Study of 3, 210 Patients from the National Health and Nutrition Examination Survey**

Nicola Berman<sup>1</sup>, Teresa Attina<sup>2</sup>, Bruce Cronstein<sup>1</sup>, Stephen Honig<sup>1</sup> and Michael Pillinger<sup>1</sup>, <sup>1</sup>Rheumatology, New York University School of Medicine, Division of Rheumatology, New York, NY, <sup>2</sup>Pediatrics, New York University School of Medicine, New York, NY

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Adenosine regulates bone metabolism. In vitro studies suggest that direct stimulation of the adenosine A2A receptor increases osteoblasts and diminishes osteoclasts, and thus inhibition of these receptors might promote osteoporosis. Caffeine is a regular part of many adult diets and acts in part by engaging adenosine receptors. However, the impact of caffeine consumption on bone metabolism remains incompletely elucidated. Previous population based studies have demonstrated that caffeine may be associated an increased risk of osteoporotic fractures in post-menopausal females. The National Health and Nutrition Examination Survey (NHANES) is an ongoing CDC assessment of the health and nutritional status of adults and children in the United States, with a particular emphasis on diet. In this study, we leveraged NHANES to assess whether caffeine intake is a risk factor for osteoporosis and resultant fractures.

### **Methods:**

We utilized NHANES for the 2013-14 cycle, which included a total of 10,175 subjects. All subjects underwent a 24-hour dietary recall interview to estimate intake of a specified panel of nutrients, caffeine included. Bone mineral density (BMD) was evaluated using Dual Energy X-ray Absorptiometry (DEXA) at the hip and spine. Subjects also answered surveys addressing history of prior fractures and risk factors for osteoporosis. Variables considered for analysis were downloaded from NHANES. Statistical analysis was conducted using STATA 14.2. We examined a subpopulation of patients over the age of 40 (N=3,210) and a further subset of Caucasian females over 50 (N=682). Sampling weights were accounted for unequal probabilities of selection. Univariate and multivariate analysis with logistic regression was used for data analyses. In the multivariate analysis, adjustments were made for age, body mass index, physical activity, prior corticosteroid use, smoking and alcohol.

### **Results:**

Baseline characteristics were similar in the two subpopulations. In the subpopulation of men and women over 40, caffeine intake was found to be associated with vertebral spine fractures in the univariate analysis ( $p=0.01$ ) and decrease in femoral neck BMD ( $p<0.001$ ) and spine fractures ( $p<0.001$ ) in the multivariate analysis. In the subpopulation of Caucasian women over 50, there was no significant associations from the univariate analysis, however caffeine intake was associated with both hip fractures ( $p=0.01$ ) and decreased femoral neck BMD ( $p=0.05$ ) on the multivariate analysis. Of note, in the subpopulation of Caucasian men over 50, there was no significant association between caffeine intake and decreased BMD or fractures.

### **Conclusion:**

In women over 50, caffeine intake is associated with a small but significant decrease in bone mineral density at the femoral neck and increased risk of hip fractures. Further, in a cohort of men and women over 40, we observed a significant association of caffeine intake with increased vertebral spine fractures and decreased femoral neck BMD.

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Most studies on sarcopenia and osteoporosis involve elderly populations. However, because postmenopausal hypoestrogenism is able to negatively modulate bone and muscle mass, it is important to understand the interplay between muscle and bone in early menopause. In addition, there is a paucity of studies investigating the potential influence of muscle mass and function upon bone quality (microarchitecture and strength), which could provide a more comprehensive view of fracture risk in this population. Therefore, the aim of this study was to assess the potential correlations between muscle parameters (mass, strength and function), and bone microarchitecture and strength using high-resolution peripheral computed tomography (HR-pQCT) in postmenopausal women.

**Methods:** A total of 248 healthy menopausal women (aged  $58.0 \pm 6.0$  years) were evaluated by clinical questionnaire, laboratory and body composition (DXA, Hologic, QDR-4500). Bone quality (density, microarchitecture, strength and cortical porosity) was analyzed by high resolution peripheral computed tomography (distal radius and tibia, XtremeCT, Scanco Medical, Brüttisellen, Switzerland). Functional mobility and muscle performance were measured by handgrip strength (JAMAR model dynamometer), Timed-Stand and Timed Up & Go tests. Balance was assessed by the Berg Balance Scale. The correlation between bone parameters (HR-pQCT) and muscle performance was analyzed by the Spearman test ( $p < 0.05$ ).

**Results:** At the radius, there were positive correlations between handgrip strength and trabecular bone HR-pQCT parameters (trabecular volumetric bone mineral density [Tb.vBMD]:  $r = 0.17$ ,  $p = 0.03$ ), trabecular thickness [Tb.Th]:  $r = 0.16$ ,  $p = 0.04$ ) and trabecular separation [Tb.Sp]:  $r = -0.15$ ,  $p = 0.02$ ), as well as between muscle strength and bone strength (Stiffness - S:  $r = 0.36$ ,  $p < 0.001$ ). At the tibia, the left leg muscle mass was positively correlated with number of trabeculae (Tb.N) ( $r = 0.16$ ,  $p < 0.001$ ), cortical thickness (Ct.Th) ( $r = 0.21$ ,  $p = 0.01$ ) and bone strength (S) ( $r = 0.37$ ,  $p < 0.001$ ). There were no significant correlations between HR-pQCT parameters and lower limb functional tests, except between the balance and tibial Tb.vBMD ( $r = 0.13$ ,  $p = 0.04$ ). There was a negative correlation between total body fat and muscle function (timed-stand test:  $r = -0.21$ ,  $p < 0.001$ , balance:  $r = -0.21$ ,  $p < 0.001$ ).

**Conclusion:** In postmenopausal women, muscle strength seems to play a more important role in the upper limb bone (radius) parameters, whereas muscle mass seems to exert a higher influence on the lower limb bone (tibia). These findings suggest a difference on relationship between muscle and bone according to distinct body segments. In addition, the negative correlation between body fat and balance/muscle function indicate that increased body fat mass might confer increased risk of falls in this population. Longitudinal studies are needed to test these assumptions.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Risk of osteoporotic fracture in type II Diabetes Mellitus is conflicting and possibly related to the anti-diabetic medication used. There is evidence to suggest protective effect of some medications (e.g. metformin and sulfonylureas) while others have been associated with increased risk for fractures (e.g. thiazolidinedione and DPP4-inhibitors). Thus, we examined the association of oral anti-diabetic medications with hip fractures risk in community-dwelling older adults with type 2 Diabetes Mellitus.

**Methods:** We conducted a nested case-control study in men and women  $\geq 40$  years old with incident (new-onset) type II Diabetes Mellitus, from The Health Improvement Network (THIN), an electronic medical records database from the United Kingdom. For each incident (new-onset) hip fracture case, we selected up to 4 controls matched by age and sex. We categorized the anti-diabetic medications into the following categories: 1) **Current use (last prescription within 1 year) of Metformin alone;** 2) **Current use of**

**Sulfonylureas alone; 3) Current use of Thiazolidinediones or DPP4 inhibitors alone; 4) Current use of combinations or others; 5) Current use of any drug with recent switch in category; 6) Remote use of any medications (last prescription >1 year ago) as the reference category.** In a multivariable conditional logistic model, we adjusted for alcoholism/heavy drinking, BMI, fall/high risk of falls, smoking and medications (ace inhibitors, anti-osteoporosis medications, anti-seizure drugs, beta-blockers, diuretics, estrogen, glucocorticoids).

**Results:** Among 2673 subjects (mean age 72y; 70% women; 447 incident hip fracture cases and 2226 controls), the hip fractures cases had lower BMI and were more likely to have alcoholism and falls. As shown in **Table**, compared to remote use of any oral anti-diabetic medications, the odds for hip fracture was reduced by 36% with current metformin use (OR 0.64, 95% CI 0.49- 0.84), no different with current use of sulfonylureas (OR 1.02, 95%CI 0.76-1.38) and slightly increased, although not statistically significant, with current Thiazolidinedione or DPP-4 inhibitors (OR 1.29, 95%CI 0.69-2.43) use.

**Conclusion:** We found protective effect of metformin use, no effect of sulfonylureas and possibly adverse effect of Thiazolidinedione and DPP-4 inhibitors on hip fracture risk in this large cohort of older diabetic patients. Clinicians caring for older diabetic patients need to consider fracture risk while selecting anti-diabetic medications.

<b>Table: Association of Anti-diabetic Medications with Odds of Hip Fracture</b>				
<b>Oral anti-diabetic medications use</b>	<b>Hip Fracture Cases</b>	<b>Controls</b>	<b>Crude OR</b>	<b>Adjusted OR</b>
<b>Current Metformin</b>	449	2246	0.57 (0.45, 0.74)	0.65 (0.50, 0.84)
<b>Current Sulfonylureas</b>	209	602	1.05 (0.79, 1.39)	1.05 (0.78, 1.40)
<b>Current Thiazolidinedione or DPP-4 inhibitors</b>	16	47	0.99 (0.54, 1.82)	1.24 (0.66, 2.31)
<b>Current</b>	12	34	1.01 (0.50, 2.03)	1.17 (0.57, 2.37)
<b>Current Mixed Use</b>	332	1252	0.76 (0.59, 0.99)	0.85 (0.65, 1.11)
<b>Remote use of any drug (Ref)</b>	99	287	1.0	1.0

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Prostate cancer is the most common male malignancy. It is hormone dependent and androgenic inhibition with LHRH agonists is one of the mainstays of treatment. There are different treatment scheme's options; continuous or intermittent in order to decrease secondary effects. As for bone effects, LHRH agonists therapy increase bone resorption, reduce bone mineral density (BMD), which leads to an increase in the risk of fracture. The influence of the different treatment schemes in bone metabolism has not been studied enough. The aim of this study is to evaluate the LHRH agonist treatment schemes effect in bone metabolism in prostate cancer patients and to evaluate whether antiresorptive treatment decreases the risk of osteoporosis according to different scheme of LHR agonists.

## Methods:

We recruited patients from the Prostate Cancer Protocol of Osteoporotic Risk Assessment. Patients were evaluated in a first visit (month 0) and at 6, 12, 18 and 24 months. We collected the following data: markers of bone turnover (serum BCTX and PINP), BMD of the lumbar spine, femoral neck, and total hip, LHRH agonists treatment scheme, PSA and testosterone levels, and antiresorptive treatment. Biostatistical analysis with R (3.3.2.) was performed.

## Results:

We selected 45 prostate cancer patients without bone metastasis with a minimum follow up of 12 months, 36 of them completed 24 months follow up. The mean age at prostate cancer diagnosis was 68.33 (9.02) years, with a mean Gleason score of 7 (1). 15 patients had intermittent LHRH agonists treatment scheme and 30 had continuous treatment scheme. 17 patients initiated antiresorptive treatment (mostly denosumab), 7 of them under intermittent LHRH agonist therapy. At baseline evaluation 16.7% of patients had osteoporosis and the 45.2% had osteopenia. 43.2% of patients had vitamin D values under 20ng/ml and 31.1% showed increased PTH values. Vitamin D and PTH levels were normalized, with supplementation, during the follow-up. Statistical analysis using a multivariable linear mixed model show that antiresorptive treatment had significant influence in femoral neck and total hip BMD ( $P<0.001$  and  $P<0.001$  respectively). Beta-CTX levels are related to the total hip BMD value ( $P=0.019$ ) in patients with no antiresorptive treatment. Furthermore, in patients receiving intermittent LHRH agonist scheme and without antiresorptive treatment there was an increase total hip and femoral neck BMD values, in comparison to patients receiving continuous LHRH agonist treatment without antiresorptive treatment who had a decrease of total hip and femoral neck BMD values (coef= 0.89; 95% CI 0.09-1.75 and coef= -0.28; 95% CI -0.99-0.46). No fractures have been detected during the follow up period.

## Conclusion:

In our patients cohort we detected a high prevalence of vitamin D deficiency. In patients without antiresorptive treatment, evolution of BMD values correlated to betaCTX levels during the follow-up. Moreover, patients without antiresorptive treatment under intermittent treatment with LHRH agonist display positive effects in total hip BMD values compared to patients receiving continuous LHRH regimen.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Bariatric surgery is used to treat severe obesity. We aimed to investigate the incidence of significant bone mineral density (BMD) loss at 6 and 12 months after bariatric surgery.

**Methods:** Observational study performed in a specialised centre for the treatment of obesity in a University Hospital in France. Surface BMD was measured by dual x-ray absorptiometry (DEXA). A reduction of  $>0.03\text{g/cm}^2$  was considered as significant.

**Results:** A total of 110 patients were included. A significant reduction in BMD was observed in 63.4% of patients at 6 months, and in 73.9% at 12 months after surgery. No case of osteoporosis was observed. There were 4 cases of osteopenia and one fracture post-surgery. BMD loss was related by univariate analysis to the reduction in Body Mass Index (BMI) ( $p<0.01$ ), weight loss ( $p<0.01$ ), fat mass ( $p<0.01$ ) and lean mass ( $p<0.01$ ). Multivariate analysis found a significant association between the reduction in BMD and the percent excess weight loss (odds ratio 1.11, 95% confidence interval (1.05-1.18),  $p<0.001$ ).

**Conclusion:** There is a significant reduction in BMD at 6 months after surgery in over 60% of patients undergoing bariatric surgery. BMD loss is persistent over time, and predominantly situated at the femoral level, and strongly associated with weight loss. Systematic vitamin and calcium supplementation, as well as follow-up by DEXA scan seems appropriate, with systematic DEXA scan pre- and post-surgery, and annually thereafter until weight has stabilized.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inflammatory bowel diseases (IBD), such as Crohn disease (CD) and ulcerative colitis (UC), are associated with a decreased bone mineral density caused by chronic inflammation and corticosteroid use. However, the increase of fracture risk is unknown and data are contradictory across studies.

The aim of our study was to assess the risks of fracture and presence of low bone mineral density (BMD) in patients with IBD compared to the general population.

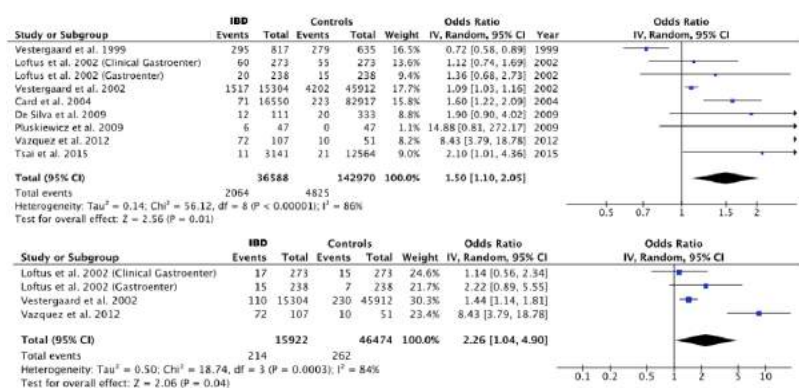

**Methods :** A systematic search of literature up to 1st February 2017 was conducted using databases including: MEDLINE (via PUBMED), EMBASE, the Cochrane library and abstracts from the ACR, ASBMR and EULAR congresses 2014-2016. Prospective and retrospective cohort studies were included if they reported the incidence of fractures and/or the measure of BMD by dual energy X-ray absorptiometry (DXA) (expressed in  $\text{g/cm}^2$ ) in IBD patients in comparison with healthy controls. Data was extracted by two

independent investigators. Meta-analysis was performed to assess odds-ratios (OR) for each outcome using the inverse variance approach to estimate pooled OR with their 95% confidence interval. Heterogeneity was assessed according to Cochran Q-test and  $I^2$  values. Calculations were made with the Cochrane RevMan 5.3 software. P-values less than 0.05 were considered significant.

**Results :** The literature search identified 1165 articles and no congress abstract; a manual search did not retrieve any additional article. Finally, 25 studies met the inclusion criteria. Nine of them reported 2065 fracture events among 42,615 IBD patients and 4825 fracture events among 203,240 healthy controls. Global risk of fracture was increased in IBD patients compared with controls with a pooled OR of 1.50 (95% CI 1.10-2.05;  $p=0.01$ ,  $I^2=86\%$ ). The pooled OR of vertebral fracture was 2.26 (95% CI 1.04-4.90;  $p < 0.001$ ,  $I^2=84\%$ ). Fracture risk was not significantly increased for any other site (arm, hip, wrist). The analysis of 17 studies concerning BMD showed a significant decrease of BMD and Z-score at three sites. At femoral neck, mean difference (MD) of BMD was -0.05 (95% CI -0.08 to -0.02;  $p=0.001$ ,  $I^2=60\%$ ) and MD of Z-score -0.48 (95% CI -0.64 to -0.33;  $p<0.00001$ ,  $I^2=0\%$ ). These values were respectively -0.08 (95% CI -0.11 to -0.05,  $p<0.00001$ ,  $I^2=46\%$ ) and -1.01 (95% CI -1.52 to -0.50;  $p=0.07$ ,  $I^2=69\%$ ) at total femur, and -0.06 (95% CI -0.10 to -0.03,  $p=0.0003$ ,  $I^2=87\%$ ) and -0.51 (95% CI -0.68 to -0.34;  $p<0.0001$ ,  $I^2=54\%$ ) at lumbar spine.

**Conclusion:** IBD patients have an increased risk of fractures, especially in the spine, and a decrease of BMD at all sites, suggesting the need for regular follow-up and preventing measures.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Osteoporosis is a frequent complication in patients with chronic liver diseases, mainly in advanced stages or with evidence of cholestasis. During the first few months after liver transplant (LT) it seems that there is an accelerated bone mass loss and greater fracture risk. The aim of the present study is to evaluate the antiresorptive treatment effect in bone metabolism in patients undergoing LT and to evaluate whether medical intervention prior to LT decreases the risk of osteoporosis.

**Methods:** We recruited patients from the LT Protocol of Osteoporotic Risk Assessment. The patients were evaluated 3-6 months before surgery, shortly after transplant (month 0) and 6-12-18-24 months after surgery. Data of bone metabolism biomarkers, densitometric values and antiresorptive treatment was collected. Biostatistical analysis with R (3.3.2.) was performed.

**Results:** We selected 163 LT patients of which 86 completed 24 months follow-up. From the total cohort, 77.8% were men and the mean age at transplantation  $54.53 \pm 9.4$  years old. 92.6% of patients were supplemented with vitamin D after surgery and 19.6% initiated antiresorptive treatment. We observed that 25-OH Vitamin D, PTH, beta-CTX and PINP levels were corrected through the follow-up. T-score during the first year of follow-up decreased slightly and at 24 months the tendency was towards increase. This pattern was stronger in lumbar spine (t-score  $-1.48 \pm 1.34$  after surgery and  $-1.28 \pm 1.06$  at 24 months). Statistical analysis showed that antiresorptive treatment significantly influence lumbar and hip densitometric values ( $P < 0.001$  and  $P < 0.001$  respectively) as well as PINP levels ( $P = 0.003$  and  $P = 0.012$  respectively). Moreover, obesity ( $P = 0.0004$ ), as well as beta-CTX ( $P = 0.029$ ) and 25-OH Vitamin D ( $P = 0.024$ ) standardization improved hip densitometric values. Finally, LT patients evaluated before surgery showed better lumbar densitometric values than those evaluated after the transplant ( $P = 0.007$ ).

**Conclusion:** We observed 25-OH Vitamin D levels and bone metabolism biomarkers correction during the first two years after LT. Medical intervention prior to LT as well as antiresorptive treatment seem to play a decisive role in bone mineral density improvement.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteopenia and osteoporosis (OP) have been described in patients with Gaucher disease (GD) but there are very few reports about bone mass in GD patients treated with imiglucerase. The aim of this study was to evaluate bone mineral density (BMD) and vertebral fractures (VF) in EG patients treated with imiglucerase.

**Methods:** We conducted a prospective, observational and descriptive study in 218 GD patients receiving enzyme replacement therapy (imiglucerase, mean dose of  $54 \pm 15$  U/kg [range: 11-120]) with a follow-up of 3 years. BMD was evaluated by DXA (Lunar Prodigy) to measure lumbar spine, total hip or femoral neck and total body according to age. The diagnosis of OP was performed according to WHO and ISCD criteria. The diagnosis of VF was performed with lumbar and dorsal spine by lateral Rx and by whole-body magnetic resonance. Data are expressed as mean  $\pm$  SD and differences were considered significant if  $p < 0.05$ .

**Results:** 126 women (57.8%) and 92 men (42.2%) were included, mean age 27.9±15.9 years (98% had splenomegaly, 49.2% hepatomegaly and 7.9% were splenectomized). The age at diagnosis was 153±154 months (range 4-702) and the mean age of initiation of treatment was 215±173 months (range 7-835). BMD was normal in 78.2%, 5.2% showed osteopenia/low bone mass (LBM) and 16.6% osteoporosis (OP). During 1 year follow-up (n=97), 10.3% were found with OP and 8.3% with LMB; at the second year (n=89) we found 6.7% OP and 7.9% LMB; while in the third year (n=53) only 3.8% showed OP and 5.6% LMB. This indicates a lower percentage of patients with OP during follow-up (chi2, p=0.0216). In the lumbar spine, a significant increase in BMD was found throughout the follow-up (percentage change: 1st year +2.48, 2nd year +4.00%, and 3rd year +6.95%). There was no significant difference in total hip or femoral neck and whole-body BMD. We excluded 25.14% of hip BMD due to the presence of avascular bone necrosis. The increase in BMD was found in <19 years old patients and in premenopausal women. 10 VF were found in females and 13 in males; 31.58% were located in low dorsal vertebrae, 21.05% lumbar, 15.79% dorsolumbar low and 31.58% high dorsal vertebrae without posterior wall compromise. High dorsal VF could only be detected by total body magnetic resonance. 45% of the fractures involved a single vertebra, 55% more than one. According to Genant classification, 13% were grade I and 87% grade II and III.

**Conclusion:** treatment with imiglucerase maintains and increases lumbar spine BMD in GD patients. VF findings in GD patients did not compromise the posterior wall and the whole-body magnetic resonance was useful for detecting high dorsal VF.

## **Association of Dorsal Flat Vertebra/Platyspondylia As a Form of Vertebral Dysplasia within Type II Collagen Disorders**

**Pilar Ahijado-Guzman**<sup>1</sup>, Raul Veiga<sup>2</sup>, Miguel Cantalejo<sup>1</sup>, Justo Ruiz<sup>3</sup> and Antonio Zapatero<sup>3</sup>, <sup>1</sup>Rheumatology Unit. Fuenlabrada's Hospital, Madrid, Madrid, Spain, <sup>2</sup>Rheumatology Unit. Fuenlabrada's Hospital, Madrid, Fuenlabrada, Spain, <sup>3</sup>Department of Internal Medicine. Fuenlabrada's Hospital, Madrid, Madrid, Spain

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Defects in the type II collagen gene are described. These predispose humans to various phenotypic combinations in families with skeletal dysplasia, and/or disease by causing deposits of microcrystals and/or early osteoarthritis and/or synovial osteochondromatosis. Flat vertebra is defined as the vertebrae with flattening of the vertebral body, also with irregular surface or with nodules of Schmorl (flat vertebra), in isolation or two a maximum of two vertebral bodies, to distinguish it from Scheuermann's disease.

The purpose of this is to demonstrate the possibility of "dorsal flat vertebra" in relation to pathologies associated with type II collagen disorders.

**Methods:** Patients attending physician since 1994, in whom Type II collagen disease or vertebral dysplasia was suspected, were selected for the study. Their medical history was taken. Also available radiographs, including dorsal lateral spine x-rays, were assessed for a flat vertebra, by triple-observer (two rheumatologists and one radiologist), according to the defined criteria. In all selected patients, a DEXA osteoporosis screening was performed, being both densitometric osteoporosis and chest trauma exclusion criteria.

**Results:** The 84 patients assessed included 43 women and 41 men, with a mean age of 47.1 years, mean weight of 84.6kg in men and 74.4kg in women, and mean height 168.8cm in men and 159cm in women.

From a radiological and clinical point of view it was obtained:

Atypical arthrosis: 64.3%

Synovial osteochondromatosis: 15.5%

Chondrocalcinosis: 7.1%

Lower Dorsal kyphotic apex: 38.1%,

Calcifying enthesopathies: 4.8%,

Exostoses: 4.8%,

Other calcifications: 20.2%,

Scoliosis: 33.3%,

Family history of flat vertebrae: 3.6%,

Dysplastic Peripheral traits: 27.4%,

Personal history of microcrystalline arthritis: 4.8%.

None developed T score suggesting osteoporosis by DEXA.

#### **Conclusion:**

The association of dorsal flat vertebra (according to the defined criteria) is seen as a form of vertebral dysplasia within type II collagen disorders.

All patients or their parents were born in small towns, leading to suspicion in endogamy.

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Women with breast cancer (BC) are at risk for the development of bone loss and osteoporosis (OP) mainly due to adjuvant therapies, as aromatase inhibitors (AI). Thus, it would be of special interest in this group of patients, to know at baseline which factors can predispose to develop fragility fractures (FF) during follow-up, in order to optimize vigilance and treatment.

The purpose of this study is to analyze which risk factors at baseline that can predict the appearance of a new FF in women with BC and OP.

#### **Methods:**

Retrospective analysis of consecutive female patients with recent breast cancer (BC) and low bone mineral density (BMD) referred to the osteoporosis outpatient clinic for assessment, as agreed with oncologists. For the purpose of this analysis, only patients with follow-up data (at least six months after baseline visit) were selected. FRAX tool-derived risk factors (age, BMI, DEXA, previous fracture, parent fractured hip, smoking, alcohol, glucocorticoids, rheumatoid arthritis, secondary OP) were taken as explicative variables. Student's t and chi-2 tests were used to perform comparisons based on the appearance of new FF in the study period.

## Results:

Results: A total number of 156 female patients have been assessed up to January 2017. Of the 107 patients in follow-up (68.5%; median time in follow-up 2.1 years p25-75 1.2-3.2). Median age was 62.07 years old (SD±10.35), being 89% of them postmenopausal. 73 (68.2%) were on AI therapy (10 anastrozole, 59 letrozole and 4 exemestane). At baseline, 29 patients (27.1%) showed a FF (15 vertebral; 10 non vertebral; 2 hip; 2 multiple fracture). Antiosteoporotic treatment was recommended in 95 patients (88.7%). During follow-up, 13 FF were seen (12.1%; CI95% 6-19); being 8 of them vertebral, 4 not vertebral, and one multiple fracture; no new hip FF was seen.

After comparison of the different risk factors according to the development of a new FF, no significant association was found (see table).

	New fragility fracture		p
	NO (n= 94)	YES (n=13)	
Age (years old), mean ±SD	62.0 ±10.7	62.1 ±9.9	0.956
BMI (kg/m2), mean ±SD	26.5 ±7.1	23.1 ±10.0	0.213
Follow-up duration (months) median ±SD	28.6 ±19.4	30.6 ±12.8	0.723
DEXA at lumbar spine (T-score) median ±SD	-2.7 ±0.8	-2.9 ±0.6	0.256
GFR (ml/min) mean ±SD	91.7 ±16.0	97.2 ±11.2	0.282
Menopause (%)	93.4	91.6	0.822
Previous fracture (%)	27.1	38.4	0.512
Parent fractured hip (%)	11.0	25.0	0.125
Smoking (%)	10.0	8.3	0.721
Glucocorticoids (%)	9.9	7.7	1.000
Rheumatoid arthritis (%)	3.2	0	1.000
Aromatase inhibitor (%)	70.9	69.2	0.897
Antiosteoporotic treatment (%)	88.4	92.3	0.676

## Conclusion:

In this study no relationship between FRAX-based risk factors and the development of new FF in women with OP and BC was found. As new FF occurred in 12% of cases, it highlights the need for special attention to this singular, secondary form of OP.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Postmenopausal women with breast cancer have higher osteoporosis risk due to declining estrogen levels and use of aromatase inhibitors (AIs). The American Society of Clinical Oncology (ASCO) update on bone health management in breast cancer elaborated on measures medical oncologists can undertake. Factors conferring high fracture risk are age  $\geq 65$ , women aged 60-64 with family history of fracture, weight  $< 70$ kg, prior fragility fracture, postmenopausal state on AIs, and chemotherapy (CT)-induced menopause. Recommendations include annual DXA, calcium and vitamin D for high risk patients, bisphosphonates for patients with T score  $\leq -2.5$ . Malignancies such as breast cancer are co-morbidities that rheumatic disease patients are at risk for. The purpose of this IRB-approved Loma Linda University study was to evaluate adherence of oncologists to ASCO guidelines, and to determine fracture rates in our cohort of breast cancer patients on AIs. This is a pilot study examining the practice of one of our breast cancer specialists.

**Methods:** Oncology clinic data from January-December 2016 was extracted using ICD10 codes related to breast cancer, osteoporosis, osteopenia, which identified 208 encounters. ICD10 code related to use of aromatase inhibitors was applied, resulting in a unique subset of 32 patients. Chart review collected patient demographics (age, sex), presence of metastases, estrogen receptor positivity (ER+), AI used, T-score (by DXA), frequency DXA ordered, anatomic fracture location, re-fracture events, bisphosphonate use, calcium/vitamin D use, current alcohol and tobacco, and thyroid disease.

**Results:** All 32 patients were ER+, postmenopausal females, with one having CT-induced menopause. Mean age was 70.2. Mean BMI was 26.5. 5 (16%) had thyroid disease. Twelve (39%) reported alcohol use; 1 (3%) was a smoker. Twelve (38%) of patients were on Anastrozole, 3 (9.4%) on Exemestane and 17 (53%) on Letrozole. Based on T-scores, 9 (28%) were osteopenic and 22 (69%) were osteoporotic. Twenty-nine (90%) patients were on appropriate doses of calcium/vitamin D. DXA was obtained annually in 15 (47%) patients. Of those with osteoporosis based on T-score, 17 (77%) were on a bisphosphonate, while 4 (18%) were on denosumab; 1 refused treatment. Overall, 9 fractures occurred; of these, 3 were re-fracture events. Mean age at time of first fracture was 69.3, while mean age at re-fracture was 76.3. Four (44%) occurred in the spine, with 1 due to metastases. Other sites of fracture were: hip (1), hand (1), rib (1), humerus (2). Re-fractures in the spine (2) and hand (1). Six fractures occurred while on bisphosphonates: alendronate (1), risedronate (3), ibandronate (2).

**Conclusion:** There was great adherence to ASCO bone health guidelines for breast cancer patients on AIs. It would be of interest if the same level of adherence applies to the entire oncology team. We also raise questions about the applicability of fracture risk calculators for this population. Postmenopausal breast cancer patients on AIs may need closer bone health monitoring given their high risk of fracture. Bone health issues related to malignancy should be of concern to all rheumatologists.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporosis-related fractures causes increased disability and morbidity and mortality. The FRAX algorithm quantifies the 10 year probability of a hip or major osteoporotic fracture. This study was initiated after observation of significant discrepancies between FRAX scores generated by the facility machine and those calculated using the online FRAX tool. We aimed to review a series of bone density scans to determine the reason for the discrepancy. Our hypothesis was that providers may not be using the correct measure to calculate the FRAX score.

**Methods:** This was a retrospective quality improvement study. 700 of 1200 DEXAs from 2013 to 2015 were randomly selected, 168 met the inclusion criteria of osteopenia. Data to calculate the score was obtained from the patient chart. The correct way to calculate the FRAX is to use the femoral neck bone mineral density (BMD) and to select the DEXA machine used. Selecting the femoral neck t-score gives the wrong DEXA result because the normative t-score values used by hologic differ from the FRAX. Selecting BMD without specifying the machine does not give an accurate score as it defaults to no bone mineral density result. Three separate FRAX scores were calculated: (1) FRAX by femoral neck T-score (T score FRAX), (2) FRAX by femoral neck BMD (No BMD FRAX), and (3) FRAX by BMD with hologic machine selected (BMD FRAX). The latter score was the gold standard. It was determined whether the patient was ultimately appropriately treated by chart review.

**Results:** Patients were primarily female (94%), age ranged from 40-89 years old, and race was primarily hispanic (54.7%) and black (31%). There was a difference when comparing BMD FRAX with the machine generated FRAX ( $p < .05$ ), and between the BMD FRAX with T-Score BMD ( $p = 0.001$ ). However, these differences were not clinically significant. There were clinically and statistically significant differences when comparing treatment of BMD FRAX with no BMD FRAX ( $P < .001$ ), all of whom would be over treated if using the latter. Four patients (2.4%) were over treated by FRAX guidelines, however, justification was given for each case. Four patients (2.4%) were undertreated. In 3 of these patients, no FRAX score was mentioned in patient notes and in 1 patient FRAX score was interpreted incorrectly.

**Conclusion:** Not selecting DEXA machine type can lead to significant overtreatment of patients. Many patients were undertreated due to lack of understanding of FRAX score by clinicians. Further education of clinicians regarding FRAX score use is needed. Modification of the FRAX score calculation may be required to ensure patients are not being over or under treated.

## Comparative Study of Frax® Score in Ecuadorian Population

Genessis Maldonado<sup>1</sup>, Carlos Paredes<sup>1</sup>, Roberto Guerrero<sup>1</sup>, Maricarmen Miele<sup>1</sup>, Maria Jose Intriago<sup>1</sup>, O Messina<sup>2</sup> and Carlos Ríos<sup>3</sup>,  
<sup>1</sup>Universidad Espiritu Santo, Guayaquil, Ecuador, <sup>2</sup>Hospital Argerich, Buenos Aires, Argentina, <sup>3</sup>Centro de Reumatología y Rehabilitación CERER, Guayaquil, Ecuador

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Osteoporosis and Metabolic Bone Disease – Clinical Aspects and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Osteoporosis is a systemic skeletal disease characterized by a decrease in bone mineral density with alterations in bone microarchitecture and an increased risk of fracture. The World Health Organization asserts that it is a major public health problem and increases morbidity and mortality in elderly patients. The FRAX® score is a tool that estimates the risk of fracture at 10 years. It was adapted to the Ecuadorian population in 2009. The purpose of this study was to identify the risk of fracture of the Ecuadorian population using the FRAX® Ecuador calculator and compare the results with FRAX® Colombia, Brazil and the United States (Hispanics).

**Methods:** A retrospective study that included the Ecuadorian population between 40-90 years old, who underwent bone densitometry between 2013-2015, and whose risk of fracture was assessed with FRAX® Ecuador, Colombia, Brazil and the United States (Hispanics). The DXA values considered were: Osteopenia: T Score -1.0 -2.5 and Osteoporosis: T Score  $\geq 2.5$ .

**Results:** We analyzed 1154 patients with a mean age of 61.39 [SD 11.07] (26-97). The predominant gender was female with 88.6% (1022) versus 11.4% (132) male. The mean age of menopause was 45.81 [SD 5.5]. The diagnoses according to bone densitometry were: 18.8% (217) normal, 32.3% (373) osteopenia and 48.9% (564) osteoporosis. The risk of major osteoporotic fracture of the population using FRAX® Ecuador was 1.5% (0.3-27%) and hip 0.5% (0-22%). For FRAX Colombia: 3.0% (0.2-40%) for major osteoporotic fracture and 0.8% (0-34%) for hip fracture. With FRAX® Brazil, 4.2% (1.2-56) was obtained for major osteoporotic fracture and 1.3% (0-49%) for a hip. Finally, FRAX® USA (Hispanic) had a risk of 5.1% (0.7-59%) for major osteoporotic fracture and 1.2% (0-50%) for hip fracture.

**Conclusion:** The risk of fracture for the Ecuadorian population according to the FRAX® Ecuador calculator was 1.5% for major osteoporotic fracture and 0.5% for hip fracture. Surprisingly, this population presents a low risk of fracture using the calculator of this country, in comparison to the scores obtained using the FRAX® of Colombia, Brazil and the United States (Hispanic). This may indicate that the risk of fracture may be underestimated with FRAX® Ecuador, although more specific studies are needed.

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Poor medication adherence attenuates optimal clinical benefits and reduces the overall effectiveness of health systems. A large number of interventions targeting medication adherence have been evaluated in randomized controlled trials (RCTs). However, there is no consensus on which adherence related outcomes should be used in these RCTs. We sought to assess the scope and consistency of adherence related outcome domains and measures in RCTs of medication adherence interventions.

**Methods:** Four reviewers independently extracted the adherence outcome domains and measures from RCTs included in the 2014 Cochrane review of interventions for enhancing medication adherence. Adherence as an outcome domain was classified into phases (using the ABC taxonomy these were divided into initiation, implementation, persistence or phase unclear). The time points, metric and method of aggregation of each outcome measure were also extracted. Contextual factors (any factor that may affect adherence but not measuring adherence itself) were also extracted.

**Results:** From 70 trials, the four adherence outcome domains (initiation, implementation, persistence and phase unclear) were measured using 68 different adherence measures, with a mean of 2 adherence measures per trial (range 1-5). For adherence outcome domains, implementation adherence was reported most frequently (61 trials [87%]), followed by persistence adherence (7 trials [10%]) and initiation adherence (2 trials [3%]). The phase of adherence being measured was unclear in 15 trials [21%]. There were 37 different contextual factors. The six most common contextual factors reported were disease knowledge (7 trials [10%]), medication knowledge (5 trials [7%]), lifestyle adherence (5 trials [7%]), medication satisfaction (4 trials [6%]), clinical care satisfaction (4 trials [6%]), and self efficacy (4 trials [6%]).

**Conclusion:** Implementation adherence is the primary type of adherence outcome domain reported. Adherence measures in RCTs are heterogeneous with a lack of uniformity. Many other factors that may be relevant to adherence are being reported in RCTs however their importance needs further evaluation. Additional work to ensure consistent reporting of robust outcome domains and measures that are relevant to all stakeholders, particularly patients, will improve the value of clinical trials in supporting evidence-based decision-making regarding medication adherence.

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Some studies point to a differential clinical expression between men and women with PsA, but the information on gender differences is very scarce in the earliest stages of the disease. We aimed to describe the baseline characteristics and impact of disease among men and women included in the REAPSER (Recent-Onset PsA Registry of the Spanish Society of Rheumatology) cohort.

## **Methods:**

REAPSER is an observational, multicenter study, with consecutive recruitment, that included adults of both sexes aged 18 yr or older that met CASPAR criteria for PsA, and had duration of less than two years since the appearance of symptoms attributed to PsA (recent-onset PsA). Annual follow-up visits will be carried out for 5 years. Measurements include socio-demographic data, employment status and impact of the disease, family history of PsA and other inflammatory diseases, comorbidities, lifestyle, use of health services, clinical status at disease presentation, anthropometric data, clinical evaluation of PsA manifestations, radiographic progression, analytical determinations, and treatment of the disease. The study has been approved by the ethical committees of the participating centers.

We have analyzed these aspects among men and women, with special emphasis on the perceived impact of the disease between both sexes. Descriptive statistic included central measures with dispersion values. Qualitative variables were compared by Chi-square and Fisher's exact test. The normal quantitative variables were compared by a Student's T test and the non-normal quantitative ones by non-parametric tests.

## **Results:**

<b>Parameter</b>	<b>Men. N: 142</b>	<b>Women. N: 68</b>	<b>p-values</b>
<b>Age (years)</b>	50.2 (13.8)	49.6 (14.1)	NS

Establishing and Maintaining a Volunteer Charity Rheumatology Clinic: One Clinic's Experience

**Background/Purpose:** In 2015, about 16% of adults under age 65 in Tennessee were uninsured. While there are options available for patients to receive primary care (health departments and faith-based benevolent clinics), there were limited options for rheumatology care, creating serious health risks for these patients. We set out to establish volunteer charity clinic to provide consultation and management for adult rheumatology patients who are uninsured.

**Methods:** The St. Sampson medical clinic was established as a 501c3 nonprofit organization, operating one Saturday per month since 2012. It's yearly budget of \$15,000, mostly for malpractice coverage, and clinic space was donated by the Lupus Foundation of America Mid-South Chapter, Tennessee Rheumatology Society, and Holy Trinity Greek Orthodox Church. The clinic has three Vanderbilt providers, two rheumatologists and a nurse practitioner, and other volunteers for intake. It uses an encrypted, password-protected electronic medical record designed for the clinic and HIPPA-compliant efax to communicate with referring providers. Clinic flow is shown in figure 1.

**Results:** As of May 2017, we have provided 1538 visits to 560 patients from 33 counties in Tennessee, Kentucky and Mississippi. The majority of diseases treated include rheumatoid arthritis/ other inflammatory arthritis (46%), lupus/ other connective tissue diseases (15%), fibromyalgia syndrome (11%), and psoriatic arthritis (7%). We have secured over \$500,000 in free medications, largely for biologic agents through patient assistance programs. We estimate we have donated \$186,703 in professional fees (consultations: \$94,080; return visits: \$92,623) to our patients.

**Conclusion:** We have been able to establish and maintain a successful volunteer charity rheumatology clinic with limited resources which has provided much needed care for rheumatology patients. Rheumatology is unique as a specialty as clinical history and physical examination play a majority role in diagnosis which was an important factor in being able to establish and sustain a volunteer charity clinic.

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A link between flares and physical activity would confirm the objective consequences of flares. In the ActConnect study of patients with RA or axSpA, the initial analyses made with traditional statistical tools on aggregated data found a low magnitude link between flares and physical activity(1). The objective of this reanalysis was to determine if applying Machine Learning technics (i.e., Big Data statistics) to this dataset, could lead to more accurate results about flares prediction.

**Methods:** In the ActConnect study, physical activity (steps) were collected through an activity tracker at the minute level, during 3 months for 170 patients, leading to 27 million information points that have been aggregated at the level of 24 hours (1). Patients also reported weekly their perceived flares. In this reanalysis, multi-class Bayesian classifications were performed to find a link between physical activity and flares / no flares states, using a Machine Learning software belonging to Orange (2). A normalization was performed to calibrate for each patient their pattern associated with no flares. As the data are sampled by minutes, models were designed using several aggregation intervals (24h, 12h, 4h, 1h) then trained randomly on 70% of data for each interval and tested on the remaining 30%. To evaluate the stability of the models, the complete analysis was done 10 times for each interval of aggregation. The performance of the models was evaluated using patient-reported flares (assessed weekly) as gold standard. Sensitivity, specificity and kappa were assessed.

**Results:** The modeling performance increased as the aggregation interval decreased. The best performance was evidenced for 1-hour interval (table 1). The increase in the agreement between the true classes and the predicted classes was also reflected in the substantial increase of the Kappa coefficient when the size of the aggregation intervals decreased (for 24 hours, kappa=0.51 [95% confidence interval 0.47, 0.56]; for 1 hour: kappa=0.90 [0.87, 0.92]).

**Conclusion:** Connected devices bring huge data-flows that cannot be handled with traditional statistical tools without data aggregation. Machine Learning techniques, which can compute raw datasets with minimal aggregation, bring more accurate predictions. These may contribute to a more precise quantification of existing links or to the identification of new links in rheumatological datasets.

## Perceived Stress and Fatigue in Systemic Lupus Erythematosus

**Patricia P. Katz**<sup>1</sup>, Desiree R Azizoddin<sup>2</sup> and Meenakshi Jolly<sup>3</sup>, <sup>1</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Department of Medicine and Behavioral Sciences, Rush University, Chicago, IL, <sup>3</sup>Rheumatology, Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fatigue is a common and often severe symptom among individuals with systemic lupus erythematosus (SLE). Yet, there is an incomplete understanding of the causes of fatigue. We examined perceived stress and depressive symptoms as potential predictors of fatigue in a large cohort of individuals with SLE.

**Methods:** Data from two years of the Lupus Outcomes Study (n = 650), obtained through annual structured telephone interviews, were used. All participants had physician-confirmed SLE. Fatigue was measured with the SF-36 Vitality scale (reversed); scores ranged from 0 – 100, with higher scores indicating greater fatigue. The following additional measures were also administered: 4-item Cohen Perceived Stress scale (PS), Centers for Epidemiological Studies Depression scale (CESD); Systemic Lupus Activity Questionnaire (SLAQ, self-reported disease activity), and Brief Index of Lupus Damage (BILD; self-reported lupus damage). Cross-sectional

multivariate linear regression analyses examined the association of CESD and PS on fatigue. Longitudinal analyses were then conducted to identify predictors of increases in fatigue. Three longitudinal regression models were constructed. The first examined the association of CESD at time 1 (T1) with fatigue at time 2 (T2), controlling for T1 fatigue, age, sex, disease duration, SLAQ, BILD, comorbid conditions, self-report of fibromyalgia, obesity, and pain (SF-36 Pain subscale). The second model then added PS at T1, and the third added decrease in PS from T1 to T2.

**Results:** Sample characteristics are shown in Table 1. In cross-sectional analyses, both CESD and PS were significantly associated with fatigue (Table 2). In longitudinal analyses, T1 CESD was a significant independent predictor of T2 fatigue (Table 2, Model 1). When T1 PS was added (Model 2), PS was a significant predictor of T2 fatigue but CESD was no longer significant. The further addition of T1-T2 decrease in PS increased the predictive power of the model (Model 3), and decline in PS was associated with a significant decrease in fatigue.

**Conclusion:** Both depressive symptoms and perceived stress were associated with concurrent fatigue. While depressive symptoms initially predicted subsequent increases in fatigue, the effects were mediated by perceived stress. Furthermore, a decrease in perceived stress was associated with a decrease in fatigue. These results suggest that perceived stress plays an important role in SLE fatigue and may be an important focus of interventions to reduce fatigue.

## The Influence of Testimonials on Patient Decision-Making

Changchuan Jiang<sup>1</sup>, Ellen Peters<sup>2</sup> and Liana Fraenkel<sup>3</sup>, <sup>1</sup>Yale University, New Haven, CT, <sup>2</sup>Decision Research, Eugene, OR, <sup>3</sup>Rheumatology, Rheumatology, Yale University School of Medicine, New Haven, CT, New Haven, CT

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Testimonials have been shown to have a strong influence on patient decision-making. Patients are increasingly accessing the Internet as a source of medical information. In this study, we sought to examine whether the presence and order of patients' testimonials influenced participant' willingness to take a medication, subjective knowledge, and risk perceptions.

**Methods:** We administered a survey to senior Mechanical workers ( $\geq 50$  years old; not on medication for osteoporosis or osteopenia) to examine the influence of online medication reviews on participants' stated willingness to take an osteoporosis medication. We first described osteoporosis and its complications and subsequently asked participants to imagine themselves as a patient with this disease in a clinical encounter during which a physician recommended treatment. Participants' received information describing outcomes using one of three randomly distributed versions: Icon arrays, icon arrays followed by narrative reviews, or narrative reviews followed by icon arrays. Numeracy was measured using the Rasch-based Numeracy Scale. Participant' willingness to take a medication, subjective knowledge, perceived benefit, riskiness, and worry related to the medication were measured on 10-point scales before and after reading the description of the medication presented in one of the three versions. We examined whether the presence and order of online testimonials influenced participant' willingness to take the described medication using a liner regression including age, sex, race, education, previous history of osteoporosis/fracture. Numeracy as a main effect and effect modifier were also included in the model. Similar models were used to examine the influence of online testimonials on participant' subjective knowledge, perceived benefit, riskiness, and worry.

**Results:** 499 valid responses were included in the analyses. The mean (SD) age was 59 (7), and the majority were female (61%), white (74%) and college graduate (56%). We found no significant differences in participant' willingness ( $p=0.21$ ), subjective knowledge ( $p=0.43$ ), perceived benefit ( $p=0.12$ ), riskiness ( $p=0.51$ ), and worry ( $p=0.06$ ) across the three groups. Participants with higher numeracy were significantly more willing take the medication ( $p=0.04$ ). Race was associated with riskiness and worry, with minority subjects having significantly higher scores on both scales. In contrast, participants with personal history of osteoporosis/low bone density were more likely to perceive greater benefit of the medication ( $p=0.04$ ).

**Conclusion:** In this study, we found no main effect of the presence or order of online testimonials on participants' decision-making. Interestingly, willingness and perceptions related to risks and benefits were each associated with different personal characteristics.

## Group Strength Training in Rheumatology Patients: Results of an Exercise Survey

**Kevin Rhie**<sup>1</sup>, Danielle Feger<sup>2</sup>, Sharon Banks<sup>2</sup>, Christopher Sciamanna<sup>3</sup> and Rayford R. June<sup>4</sup>, <sup>1</sup>Internal Medicine, Penn State Hershey Medical Center, Hershey, PA, <sup>2</sup>Medicine/Rheumatology, Penn State College of Medicine, Hershey, PA, <sup>3</sup>Medicine/Division of Population Health Research and Development, Penn State College of Medicine, Hershey, PA, <sup>4</sup>Rheumatology, Penn State Hershey Medical Center, Hershey, PA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Primary care (PC) patients have shown significant interest in a community based group strength training (GST) program, especially among those in poor health<sup>1</sup>. Exercise is known to reduce inflammation, improve symptoms such as fatigue and poor mental health, and has proven benefits in rheumatoid arthritis (RA), osteoarthritis (OA) and fibromyalgia (FMS). Group exercise program design improves adherence in PC patients but it is unknown the effect on exercise adherence in rheumatology patients. In this study, we examined the interest of rheumatology patients and the effect of comorbidities in pursuing an organized GST program. We hypothesized that rheumatology patients would be as interested in a GST program compared to a previous study of PC patients.

## **Methods:**

We conducted a cross-sectional survey of rheumatology patients from a rheumatology practice in central Pennsylvania in February and April 2017. This survey<sup>1</sup>, modified for rheumatology patients, assessed self-reported interest of patients in GST programs in addition to demographics, comorbidities, and quality of life measures. Logistic regression was used to quantify interest in a GST. PC data from the study by Sciamanna et al were used for comparative analysis for the primary outcome, interest in a GST program.

## **Results:**

A total of 397 of 656 patients returned surveys with a response rate of 61.6%. Patients had a mean age of 52, 80% were female, with RA (39.0%), FMS (21.4%), and OA (19.7%) as the most common rheumatology diagnoses. 50.1% of rheumatology patients were interested in a GST program and there was no difference of interest compared to the PC patients ( $X^2=2.04$ ,  $p=0.15$ ). Perceived health was worse in rheumatology patients (45.1%) compared to PC patients (18.8%). However, there was no difference in interest in a GST for rheumatology patients with poor health compared to patients with good health (OR=0.9,  $p=0.8$ , Table 1). Female rheumatology patients were more interested in GST than male patients (OR=3.7,  $p=0.001$ ). Patients with a BMI of 25-30 (OR=2.2,  $p=0.04$ ) or >30 (OR=1.7,  $p=0.12$ ) were also more interested compared to those with a normal BMI. There was no difference in interest in GST regardless of rheumatology disease or measured comorbidities.

## **Conclusion:**

Over 50% of rheumatology patients were interested in a GST exercise program design. While rheumatology patients have worse perceived health than published PC health perceptions, interest in GST remained the same. Our data suggests that rheumatologists can recommend GST for their patients regardless of disease, medical comorbidities, perceived mental or physical health or education level. Future studies should examine if a GST program design improves exercise adherence in rheumatology patients.

## The Development of the Lupus Foundation of America—Rapid Evaluation of Activity in Lupus (LFA-REAL™) Patient-Reported Outcome (PRO) to Evaluate Lupus Disease Activity

Anca Askanase<sup>1</sup>, Samantha Nguyen<sup>2</sup>, Miya Okado<sup>2</sup>, Nancy Leidy<sup>3</sup> and Joan T. Merrill<sup>4</sup>, <sup>1</sup>Rheumatology, Columbia University Medical Center, New York, NY, <sup>2</sup>Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY, <sup>3</sup>Evidera, Bethesda, MD, <sup>4</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The LFA REAL™ is designed as two complimentary disease activity measures in order to integrate clinician and patient input. The current report updates progress of the LFA REAL™ patient-reported outcome (PRO).

**Methods:** The PRO was developed in accordance with FDA guidance. After preliminary concept identification work, a qualitative study was performed with 25 adult participants with SLE, including 10 who participated in concept elicitation (Phase 1) and 15 for cognitive debriefing interviews (Phase 2). A semi-structured guide was employed by trained interviewers. Qualitative data were analyzed using ATLAS.ti software v7.5. A coding dictionary was developed based on the interview guide and concepts of interest. At the completion of the interviews, participants completed the draft PRO and measures to characterize the sample (SF-36, socio-demographic, clinical data questionnaires).

**Results:** Mean age of participants was 45.6 [22-69], 88% were female and all had SLE diagnosis confirmed by their rheumatologists. The mean SF-36 physical component score (PCS) for the sample was 29.8 (±9.1), and mental component scores MCS was 46.4 (±11.6). Phase 1 elicited symptom saturation (detailed in Table 1) and mapping of the draft PRO while Phase 2 debriefed instructions, items, response options for content clarity, comprehensiveness and content validity of the draft PRO. With a recall period of 4 weeks, the PRO asks patients to evaluate their overall progress and severity of symptoms associated with current lupus activity along a series of visual analogue scales. Instructions are brief and guide the patient to active as opposed to longstanding symptoms that are more likely due to damage. The PRO allows for global, organ-based or symptom specific disease assessments from the patient's perspective.

**Conclusion:** Results of this qualitative study address the content validity of the LFA-REAL PRO. As expected, fatigue or tiredness was spontaneously reported by 90% of patients. 100% of patients spontaneously brought up arthritis, which may be more important to this group than previously estimated and substantiates the approach to break down arthritis into joint pain, stiffness and swelling in this PRO. Shortness of breath and fever was also more common than expected. Quantitative validation of the PRO will be performed to characterize the psychometric properties of the PRO against other PROs used in lupus trials. After validation, the LFA-REAL system is

intended for clinical practice and clinical trial use.

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The major cause of mortality in patients with Rheumatoid Arthritis (RA) is cardiovascular disease (CVD). However traditionally, very few RA patients receive screening and treatment for modifiable CVD risk factors; rates as low as 27-45%. The primary objective was to (a) evaluate baseline cardiovascular risk awareness (CVRA) in patients with RA and to (b) compare CVRA among RA patients before, and immediately after, a web-based educational intervention (EI).

**Methods:** Consecutive patients at two academic centers with a diagnosis of RA of at least 3 months duration were enrolled. Patients completed questionnaires on demographics, RA and CVRA. CVRA was measured using the Heart Disease Knowledge Questionnaire (HDKQ; 30 items), and the Heart Disease Fact Questionnaire- RA (HDFQ-RA; 13 items); and were administered at baseline and immediately after EI. The EI consisted of a 28-minute educational video developed specifically to address CVRA in the context of RA. Experts in CVD prevention, educational intervention and RA were involved in developing the EI. The video also included RA patients' testimonials to normalize health behavior change and provide motivation. This short video focused primarily on CVD issues pertinent to RA patients. These included exercise in the context of RA, the control of RA, and medications. The EI and the questionnaires were pilot tested on set of RA patients. General linear model analyses for repeated measures were used to compare within person changes in CVRA. Effect size (ES) were calculated for observed improvements in CVRA.

**Results:** 86 RA patients participated. The average age was 55.2±14.3 years (mean ± SD); 90% were women. Self-reported CVD risks were: post-menopause (69%), smoking (20%), hypertension (41%), diabetes mellitus (DM; 28%), sedentary lifestyle (61%), poorly controlled RA (47%) and current steroid use (55%). Ninety-five percent were taking medications for RA; most commonly methotrexate (61%) and biologics (68%). Less than half of the participants correctly answered 8/30 HDKQ and 2/13 HDFQ-RA listed in Table 1. Average total scores for correct responses for HDKQ and HDFQ-RA at baseline were 63% and 78%; which improved to 67% (p=0.02, ES 0.25) and 89% (p <0.001, ES=0.71) respectively after EI. Improvements in CVRA after EI on specific questions of HDKQ and KDFA-RA are shown in Table 1. The largest improvements were noted for RA specific CVRA items.

**Conclusion:** General understanding of CVRA is poor among RA patients, specifically RA-specific CVD risks. However, a simple and short educational intervention resulted in large improvement in CVRA, specific to their RA. This EI may serve as a cost effective intervention that could potentially increase screening for CVD risks and behavior changes in RA. Further studies are ongoing to evaluate if the knowledge gains are retained over time and if they result in changes in health behaviors.

Table 1. Cardiovascular risk awareness in rheumatoid arthritis patients				
I.e. Baseline CVRA items with <50% correct responses				
Heart Disease Knowledge Questionnaire				
1	Having had children can increase the risk of getting heart disease.	36.30%

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The independency is one of the major concerns according to patients' perspective. For instance, independency is top ranking problem in psoriatic arthritis patients and it take part in PsA core set domain (1). The objectives of this study were to assess level of independency and its correlation with disease activity.

**Methods:** Patents with inflammatory arthritis were consecutively recruited. Age, sex, disease duration, education level, DMARD usage were recorded. Independency was assessed with visual activity scale (VAS)-independence (0-100 mm) according to patients' perspective. VAS - independence more than 40/100 mm were defined as "dependent patient". All patients were assessed with patient global assessment (PGA), physician global assessment (PhGA), pain VAS, fatigue VAS, swollen (66 joints), and tender joint counts (68 joints). Other measures were BASDAI, BASFI, ASDAS-CRP, DAS-28, SDAI, CDAI, and HAQ. Correlation of outcome measures with independence-VAS were calculated.

**Results:** Total 194 (66% female) patients (88 RA, 87 AS, 19 PsA) were enrolled to study. Mean age was 47.1±12 years-old and mean disease duration was 9.5 (7.8) years. 83 (42.8%) patients had less or equal than 5 years educational level and 104 (53.6%) patients had regular occupations. 88 (45.4%) patients were used biological DMARD. Independence-VAS score was zero in 141 (72.6%) patients and 28 patients (14.4%) had more or equal than 40 mm independence VAS score. Female patients were more frequently dependent than male patients (19.5% vs 4.5%, p=0.005). There was no difference at age, disease duration, incoming, occupation, disease type, biological DMARD usage according to dependence status. Dependent patients had worst disease activity and functional status (Table 1). Correlation of independence-VAS with other outcome measures were followed; HAQ (r=0.70), BASFI (r=0.64), BASDAI (r=0.58), PhGA (r=0.57), pain-VAS (0.57), PGA (r=0.52), CDAI (r=0.51), ASDAS-CRP (r=0.51), SDAI (r=0.48), fatigue-VAS (r=0.46), DAS-28 (r=0.42), TJC-68 joints (r=0.39), SJC-66 joints (r=0.27).

**Conclusion:** Being independent is a major goal according to patients' perspective. Independency is closely related with functional disability and disease activity. However, when assessed with VAS score, a floor effect can be seen. For inflammatory arthritis patients, we need a well-defined instruments for the assessment of independence.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Flare is an important, distinct feature of RA, often rendering patients immobile and contributing to a poor quality of life. Recently, there has been consensus on the domains that constitute a flare (OMERACT Flare Core Domains); however, variations in patients' definition of a flare continue to be observed. This study seeks to evaluate how demographic and clinical characteristics contribute to these differences.

**Methods:** Subjects enrolled in a prospective RA registry completed a qualitative flare survey which included the open ended question "What does a flare mean to you?" Responses were categorized into the OMERACT Core Domains (pain, function, swollen/tender joints, fatigue, stiffness, patient global, participation) and research domains (emotional distress, sleep disturbance). DAS28-CRP3 was collected at the same visit. Univariate analyses evaluated demographics such as age, gender and clinical characteristics, including a disease state variable that combined the DAS and flare status (yes/no in the past 6 months) into 4 groups (low DAS/no flare, low DAS/flare, moderate-high DAS/no flare, and moderate-high DAS/flare). Logistic regression analyses were used to model each of the above domains as the outcome with age, gender, and disease state as covariates.

**Results:** Among the 503 subjects, 84% were female, mean age (SD) was 61 years (13), and mean disease duration was 18 years (11.7). The mean DAS score was 2.3 (0.93). 55% reported at least 1 flare in the past 6 months. Of the 8 OMERACT Core Domains, this cohort reported on average 2.5 (1.3) domains when asked to define a flare. Pain (80%), physical function (44%), and painful joints (36%) were the most commonly recorded. 5 domains showed an association between flare definition and patient characteristics in individual logistic regression models (Table). When looking at DAS alone, we found no variations in patient reported domains to be statistically significant. Additional OR comparisons of DAS/flare status (moderate-high DAS/flare vs. moderate-high DAS/no flare) suggested high DAS influences a patient's definition to include participation regardless of flare status.

**Conclusion:** Patients reported at least one of 8 OMERACT Core domains when defining a flare, however, these domains vary by patients' demographic and clinical states. Furthermore, when a patient's current disease activity and experience of recent flare are evaluated together, differences in patients' descriptions of a flare are observed. Patients are more attuned to a flare as pain and fatigue when flaring in a low disease state. Considering a flare as a decrease in participation is influenced more by being in moderate-high disease activity. Variations in patients' flare definitions can lend insight into how physicians approach patients and potentially shed light on the reasoning behind discordance between patient-clinician flare definitions.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** We surveyed adult patients with a history of pediatric systemic lupus erythematosus (pSLE) regarding their process of transition from pediatric to adult care to determine if social and psychological constructs influence patients' perception of

transition preparedness.

**Methods** : Surveys were both mailed and administered in clinic to adult patients with pSLE seen in an adult SLE clinic. Demographics including sex, race, age, employment (full time, part time, not working) marital status (single, married, partnered, divorced) and education level (< high school, high school, college degree, graduate degree) were collected. Patients reported preparedness for transition as: completely prepared, mostly prepared, neutral, mostly unprepared or completely unprepared. The modified Medical Outcomes Study Social Support Survey (mMOS SS, range 8-40 points, higher scores indicate more support) and the Brief Illness Perception Questionnaire (IPQ, range 0-80 points, higher scores indicate increased perceptions of illness) were completed. We calculated Spearman rank correlations between variables and self-reported transition preparedness. Discrimination was assessed with the receiver-operating characteristic (area under the curve, AUC). Two multivariable logistic regression models, each including race, marital and employment status, educational level, and mMOS SS in one model and IPQ in the other, were analyzed to identify factors associated with transition preparedness.

**Results** : Of 258 surveys distributed, 30 patients (12%) responded. Average age was  $28 \pm 5$  years, (range 21-38), 27 (90%) were female. The cohort was 60% (n=18) white, 10% (n=3) black, 10% (n=3) Hispanic and 17% (n=5) Asian. Twenty subjects (67%) were single, 67% were employed full time and 67% had a college degree. Fourteen subjects (47%) reported feeling completely or mostly prepared, 9 (30%) were neutral and 6 (20%) felt mostly or completely unprepared for transition. Higher social support per the mMOS SS was positively correlated with preparedness (Spearman rho= 0.42, p=0.02). Prepared subjects (n=14) vs. unprepared subjects (n=6) had significantly higher mMOS SS scores ( $35 \pm 6$  vs.  $28 \pm 7$ , p=0.02); AUC =0.83. In a multivariable model, high mMOS SS scores were predictive of preparedness (p=0.03). In contrast, high IPQ were negatively correlated with preparedness (Spearman rho= -0.48, p<0.01). Mean IPQ scores were significantly lower in prepared vs. unprepared patients ( $32 \pm 13$  vs.  $47 \pm 12$ , p=0.02); AUC=0.76. Lower IPQ scores were predictive of preparedness in the multivariable model (p=0.02).

**Conclusion** : In an adult group of pSLE patients, self-reported lack of preparedness for transition was strongly associated with low social support and increased cognitive and emotional representations of illness. The transition from pediatric to adult care for SLE may be improved by implementing appropriate support systems.

**Pediatric SLE Patients Who Feel Unprepared to Transition Have Significantly Lower Social Support and Higher Perceived Illness Scores**

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The patient-specific experience of living with SLE is underreported. While there are data addressing factors influencing the quality of life of patients with SLE, these studies primarily derive from the perspective of the health care provider, not the patient. Changing to the patient perspective will likely improve our understanding of living with SLE, including reasons for medical noncompliance and socioeconomic differences in disease severity. Using an approach drawing from the sociological tool of ethnography, we performed extensive field observations and semi-structured interviews with a cohort (n=9) from the Lupus Clinic at Washington University School of Medicine to understand the patient perspective during the diagnosis of SLE and subsequent care.

**Methods:** Consented adult patients with SLE were recruited for this study during their scheduled clinic visits. We used a conventional ethnographic methodology to view the SLE experience from the patient perspective. Through long-form, semi-structured interviews (60-70 minutes) and field observations of interviewees, interviewees were encouraged to openly express their experience with SLE. 15 interviews across 9 individuals (6 individuals were interviewed twice) were performed. Interviews took place in a variety of locations including subject's homes, cafes, public libraries, and clinic office rooms. We determined a core list of questions for each round of interviews. The initial round was based from a review of existing literature on barriers in SLE care and the authors' clinical experience with perceived unmet needs among individuals with SLE. The second round centered on core themes which emerged from the first round of interview data and were often specific to the interviewee. Audio of interview data was recorded, transcribed, and analyzed using thematic analysis in NVivo 11.0 software.

**Results:** The dominant theme among patients with SLE is the deterioration of their social structure due to ambiguity and invisibility. Ambiguity derived from the protean nature of SLE disease activity, which disallowed individuals from complying with societal expectations of punctuality and reliability. Additionally, the common debilitating symptoms of SLE (e.g. chronic pain, fatigue, poor sleep quality) are largely invisible to others. Interviewees often attributed this invisibility to creating mistrust among non-SLE individuals in their social networks.

**Conclusion:** Ambiguity and invisibility contribute to poor quality of life in patients with SLE, with a particular negative effect on the patients' social networks. These data have the potential to alter how providers administer SLE care. For example, loss of social structure may lead to depression and anxiety, promoting a negative view of having SLE, and driving medication and office visit noncompliance, both of which are major barriers to appropriate SLE care. Awareness of the social implications of having SLE—which are largely underaddressed by clinicians—unlock a potential to vastly improve outcomes by rethinking the doctor-patient interaction and services the health care field offer for these patients.

## Are Chinese-American Rheumatology Patients Who Use Traditional Chinese Medicine Less Adherent to Prescribed Western Medications?

Kai Sun<sup>1</sup>, Jackie Szymonifka<sup>2</sup>, Henghe Tian<sup>3</sup>, Ya Ju Chang<sup>4</sup>, Jennifer Leng<sup>5</sup> and Lisa A. Mandl<sup>6</sup>, <sup>1</sup>Hospital for Special Surgery/Weill Cornell medicine, New York, NY, <sup>2</sup>Rheumatology, Hospital for Special Surgery, New York, NY, <sup>3</sup>Internal Medicine, New York University School of Medicine, New York, NY, <sup>4</sup>Mount Sinai Beth Israel, New York, NY, <sup>5</sup>Immigrant Health and Cancer Disparities laboratory, Memorial Sloan Kettering Cancer Center, New York, NY, <sup>6</sup>Rheumatology, Hospital for Special Surgery/Weill Cornell Medicine, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** High adherence is crucial for the management of rheumatic diseases. Nonadherence is more common among immigrants and minorities and may contribute to known outcome disparities. Chinese-American patients commonly use Traditional Chinese Medicine (TCM) and have worse outcomes in lupus and rheumatoid arthritis. Adherence among Chinese-American rheumatology patients has not been previously studied, and whether TCM use affects adherence to prescribed rheumatic disease medications is unknown.

**Methods:** Subjects were recruited from two rheumatology clinics that serve a predominantly Chinese-American immigrant population. Inclusion criteria were Chinese ethnicity, Mandarin or English fluency, and actively followed and prescribed  $\geq 1$  non-*pro re nata* (PRN), non-intravenous medication for a systemic rheumatic disease by rheumatologist. TCM use, adherence, Patient-Reported Outcomes Measurement Information System (PROMIS) domains, and other variables were assessed using validated instruments available in English and Chinese. Adherence was classified as high or medium/low based on the 8-item Morisky Medication Adherence Scale. Medication complexity was assessed using the Medication Regimen Complexity Index; higher score indicates more complexity. Chart review was performed to gather additional clinical data. Parametric and nonparametric statistics were performed as appropriate. Multivariable logistic regression using step-wise selection was used to assess factors independently associated with high adherence.

**Results:** 230 enrolled, median age 55 years (range 20-97), 65% female, 71%  $\leq$  high school education, 70% Medicaid, and 22% reported English fluency. 50% reported TCM use in the past year, most frequently *tuina* massage (47%), acupuncture (45%), and herbs (37%). The three most common diagnoses were RA (41%), SLE (17%), and spondyloarthritis (15%), with median time since diagnosis of 4.1 years (range 0.2-52). High adherence to western medicine was found in 28.3%, while 37.4% and 34.4% had medium and low adherence. Both herb and non-herb TCM users had better rates of high adherence to western medicine compared to TCM nonusers (33% and 39% vs. 20% respectively,  $p=0.02$ ). In multivariable analysis, high adherence was independently associated with TCM use (Odds Ratio [OR] 3.2, 95% confidence interval [CI] 1.6-6.7,  $p=0.002$ ), older age (OR 1.1, 95% CI 1.03-1.1,  $p<0.001$ ), unemployment (OR 4.1, 95% CI 1.5-11,  $p=0.005$ ), married/living with partner (OR 2.3, 95% CI 1.2-5.9,  $p=0.02$ ), more complex rheumatologic medication regimen (OR 1.1, 95% CI 1.02-1.2,  $p=0.02$ ), and lower levels of anxiety (OR 0.9, 95% CI 1.02-1.1,  $p=0.001$ ).

**Conclusion:** Among poorly integrated, low education, and low socioeconomic status Chinese-American rheumatology patients, high adherence rate was poor. TCM use was statistically significantly associated with high adherence to western medication. TCM use does not appear to represent an alternate but rather complementary approach to disease management. Future studies should evaluate whether TCM use is associated with disease activity and outcomes over time.

## Transition in Work Status and Quality of Life in People with Inflammatory Arthritis

Wiebke Bartels<sup>1</sup>, Eric C. Sayre<sup>2</sup>, Pam Rogers<sup>3</sup> and Diane Lacaille<sup>4</sup>, <sup>1</sup>Science, University of British Columbia, Vancouver, BC, Canada, <sup>2</sup>Arthritis Research Canada, Richmond, BC, Canada, <sup>3</sup>Rheumatology, Arthritis Research Canada, Richmond, BC, Canada, <sup>4</sup>University of British Columbia, Arthritis Research Canada, Richmond, BC, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** People with inflammatory arthritis (IA) frequently have to stop working due to their arthritis. It is assumed that economic and psychosocial consequences of premature work cessation lead to reduced well-being. Yet, patients who were struggling at

work could experience an improvement in quality of life. Our objective was to evaluate the association between transition in work status and changes in quality of life (QoL) in patients with inflammatory arthritis (IA).

**Methods:** We conducted a prospective study using data from the RCT of an employment intervention, the Making it Work program, aimed at helping people with IA stay employed. Participants were recruited from rheumatologist practices, consumer organization (Arthritis Consumer Experts), and advertisements. Eligibility criteria included: IA diagnosis, employed, age 19-59, and concerns about arthritis affecting ability to work. Surveys were administered online at baseline and every 6 mos for up to 3.5 years. Working status was defined as “Currently working” vs. “currently not working” if not working for any reason (incl. sick leave). Working status over two consecutive surveys was categorized as: 1) Remaining working; 2) Stopping work; 3) Remaining not working; or 4) Returning to work. QoL was measured using EQ5D-Index (0-1) and EQ5D-VAS (0-100). Linear GEE models were used to predict changes in EQ5D-Index and EQ5D-VAS scores between 2 consecutive surveys, acc. to work transitions, after controlling for potential confounders.

**Results:** The sample includes all RCT subjects with at least two consecutive surveys by 12/2016 (N= 367 people; 948 pairs of surveys; 77% females, mean age: 46yrs, 54% with RA, AS: 20%; PsA: 14%; SLE: 12%). Amongst people working at the first survey, stopping work (vs. remaining at work) was associated with worsening in QoL (EQ-index and EQ-VAS). Amongst those not working at the first survey, returning to work (vs. remaining off work) was associated with improvement in QoL (EQ-Index; not signif. for EQ-VAS) (Table 1). We observed little to no change in QoL when people remained in the same work status (data not shown).

A. Multivariable model predicting change in EQ-Index in people working at T1 (n=878)				
	N (%)	Parameter	95% Wald C.I.	P-value
Intercept		-0.015	-0.034, 0.003	<0.001

Living Situation, living with partner	40 (57.1%)	0.103	0.028, 0.178	0.007
Comorbidity, (>=1)	69 (98.6%)	0.093	0.022, 0.164	0.010
D. Multivariable model predicting change in EQ-VAS in people not working at T1 (n=70)				
	N (%)	Parameter	95% Wald C.I.	P-value
Intercept		14.982	6.236, 23.727	0.001
Work Transition, Remain not Working	50 (71.4%)		Ref.	
Work Transition, Return to Working	20 (28.6%)	4.061	-6.152, 14.273	0.436
Intervention, received MiW Program	36 (51.4%)	-9.476	-15.360, -3.591	0.002
Gender, Female	55 (78.6%)	-10.989	-19.175, -2.803	0.009
Arthritis Type, RA	22 (31.4%)	10.162	2.575, 17.751	0.009

**Conclusion:** Our results suggest that remaining employed or returning to work is beneficial for QoL in workers with IA. This provides useful information to guide people with arthritis in their decisions about continuing, stopping, or returning to work; and provides evidence in support of initiatives aimed at helping individuals with IA remain employed.

## Patient Preferences Associated with the Use of Treatments for Psoriatic Arthritis: Results of a Conjoint Analysis

**Yihua Xu<sup>1</sup>**, Lavanya Sudharshan<sup>1</sup>, Ming-Ann Hsu<sup>2</sup>, Andrew Koenig<sup>3</sup>, Joseph C Cappelleri<sup>4</sup>, Wen Liu<sup>5</sup>, Tim Smith<sup>6</sup> and Margaret Pasquale<sup>1</sup>, <sup>1</sup>Comprehensive Health Insights Inc., Louisville, KY, <sup>2</sup>Pfizer Inc, Groton, CT, <sup>3</sup>Pfizer Inc, Collegeville, PA, <sup>4</sup>Statistics, Pfizer Inc, New London, CT, <sup>5</sup>Humana Inc., Louisville, KY, <sup>6</sup>Pfizer Inc, New York, NY

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017  
**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II  
**Session Type:** ACR Poster Session B  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** As Psoriatic Arthritis (PsA) treatment choices continue to expand, it is important to consider patient preferences for treatment modalities for PsA. Involving patients in treatment decisions can influence adherence and outcomes of therapy, which has a large impact on treatment outcomes.

**Methods:** A choice-based conjoint survey was mailed to 2,800 randomly selected patients enrolled in Humana Inc. Medicare and commercial plans (1,400 patients each). Patients were 18-80 years old and had been diagnosed with PsA ( $\geq 2$  claims with a diagnosis code ICD-9-CM: 696.0 /ICD-10 CM: L40.5) between 1/1/2012 and 9/30/2016. Attributes for comparison included route of administration, frequency of administration, ability to reduce daily joint pain and swelling, likelihood of serious infections, improvement in the ability to perform daily tasks and activities, achieving clear or almost clear skin, and cost. Part-worth utilities (preference scores) and attribute importance scores (AIS) were estimated separately for patients enrolled in Medicare and commercial plans, using hierarchical Bayesian models after adjustment for demographic and clinical characteristics (age, sex, region, years since first PsA diagnosis, Deyo-Charlson comorbidity score, disease severity, and prior injectable/infusion experience). Mean AIS scores were used to rank order patient preferences for the attributes.

**Results:** A total of 468 patients (258 Medicare and 210 commercial; response rate of 16.7%) returned the survey (mean age  $\pm$  standard deviation Medicare: 66.7  $\pm$  7.6 years/Commercial: 51.4  $\pm$  10.7 years; proportion female Medicare: 58.1%/Commercial: 56.2%). The top three attributes of importance for patients enrolled in Medicare plans were (in order) route of administration, cost, and then improvement in the ability to perform daily tasks and activities. The top three attributes of importance for patients enrolled in commercial plans were (in order) cost, route of administration, followed by frequency of administration (Figure 1). For both health plans, oral formulation was preferred relative to self-injection and intravenous routes of administration, and lower cost was preferred. For the commercial plans, less frequency of administration was preferred; for Medicare plans, more improvement in ability to perform daily tasks and activities was preferred.

**Conclusion:** Route of administration and cost are among the most important and common considerations for patients diagnosed with PsA and surveyed in this study. Gaining a better understanding of the attributes considered important to patients may help inform payer policies and prescriber selections regarding therapy that may lead to higher patient satisfaction, improved medication adherence, and ultimately treatment outcomes.

**Figure 1.**

Data are represented as mean, standard deviation.

For each plan, the sum of the average importance scores across attributes equaled 100.

## Coexisting Fibromyalgia in Patients with Rheumatoid Arthritis Worsens Scores for Pain, Physical Function and Depression

Dylan Ruebeck<sup>1</sup>, Judith Baumhauer<sup>2</sup> and Allen P. Anandarajah<sup>3</sup>, <sup>1</sup>Internal Medicine, University of Rochester Medical Center, Rochester, NY, <sup>2</sup>Orthopedics, University of Rochester Medical Center, Rochester, NY, <sup>3</sup>Dept of Rheumatology, Univ of Rochester Medical Ctr, Rochester, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Quality of life (QOL) measures as assessed by Patient Reported Outcome Measurement Information System (PROMIS) can contribute essential information about the status of or a change in the physical, emotional, and social health outcomes of people living with chronic diseases compared with the general population. Rheumatoid arthritis (RA) is a chronic inflammatory disease that is associated with pain and progressive joint damage resulting in decreased function and changes in mood. The reliability of PROMIS in assessment of RA has been validated. Fibromyalgia (FMS) is a condition characterized by diffuse chronic pain associated with tenderness of joints and muscles along with fatigue, sleep disturbances and often poor mental health. FMS affects 10-20% of patients with RA and thus can negatively affect the pain and depression assessments. The impact of FMS on the quality of life measures as assessed by PROMIS in RA patients is not known.

**Purpose:** Compare pain, physical function and depression scores as assessed by PROMIS in patients with RA and FMS and assess the effect of coexisting fibromyalgia on these scores in RA patients.

**Methods:** This is a single center retrospective assessment of prospectively collected PROMIS data in all RA and FMS patients between January 2016 and April 2017 at an academic center RA clinic. The PROMIS t-scores are obtained as standard of care in all patients seen at the rheumatology clinic. ICD-10 diagnosis codes were used to identify patients with RA (M06.9 to M08.00) and FMS (M79.7). The t-scores for pain interference, physical function and depression during their rheumatology visits were retrieved and a mean calculated when more than one score was available. Age, gender, disease duration and medications were also recorded. The mean PROMIS scores were compared between patients with RA, FMS and FMS coexisting with RA.

**Results:** A total of 392 patients were identified with RA, FMS and coexisting FMS and RA but only 230 patients had complete PROMIS scores: 169 RA, 28 FMS and 33 with both. Mean age was similar between RA and FMS with RA groups, 56.7 (+/- 14.9) and 55.0 (+/- 9.3), respectively. The FMS cohort was slightly younger at 52.3 (+/- 10.7). A larger proportion of females were in the FMS (27/28; 96.4%) and FMS and RA group (31/33; 93.9%) compared with the RA patients (126/169; 74.6%). The scores for pain (63.7 +/- 5.9) and depression (54.8 +/- 9.6) were significantly ( $p < 0.05$ ) higher in patients with FMS coexisting with RA patients compared with RA only, (55.0 +/- 8.3) and (46.7 +/- 6.7), respectively. Additionally, the scores for physical function were significantly ( $p < 0.05$ ) lower among RA and FMS compared to RA only, (37.5 +/- 5.4) and (44.6 +/- 8.9), respectively. Interestingly, FMS patients had scores for pain (64.6 +/- 5.9), physical function (37.4 +/- 6.5) and depression (54.3 +/- 8.6) that were similar to patients with FMS and RA.

**Conclusion:** These results show that patients with RA have a worse quality of life as assessed by PROMIS than the average US population (t-score = 50) but coexistence of FMS in patients with RA negatively impacts PROMIS t-scores for pain, depression and physical function even further. This suggests that treatment aimed at FMS is needed to improve the QOL in these patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The UCLA SCTC GIT 2.0 and NIH PROMIS GI Symptoms Scales are validated in scleroderma to assess patient-reported gastrointestinal (GI) involvement. We sought to determine whether longitudinally administered reflux-specific domains of the UCLA GIT 2.0 and PROMIS are effective in capturing change in GI symptoms following therapeutic intervention in an international cohort of scleroderma patients with gastroesophageal reflux disease (GERD).

**Methods:** Six scleroderma centers participated in this longitudinal observational cohort study. Patients with active GERD, defined as symptoms for at least 3 of the last 7 days, were recruited during routine clinical visits. Patient-reported outcomes (PROs) were captured at baseline and again at 4 weeks follow-up. Effect size and standardized response mean (SRM) were calculated to assess the sensitivity to change and a range of 0.20-0.49 was interpreted as small magnitude, 0.50-0.79 as moderate magnitude, and  $\geq 0.80$  as large magnitude.

**Results:** 115 subjects with systemic sclerosis and active GERD were recruited. The average age was  $53.7 \pm 13.3$  years, with a mean disease duration of 12.7 years. Patients were more likely to be female (81%), and there was a similar distribution of patients with diffuse and limited cutaneous disease (43% vs. 48%, respectively). Mean body mass index was  $25.9 \pm 6.2$ . The mean UCLA GIT 2.0 Reflux score was  $0.98 \pm 0.63$  (N=112) and mean PROMIS score was  $53.5 \pm 8.1$  (0.3 SD above the US population; N=64). The UCLA GIT 2.0 and PROMIS had a significant correlation coefficient at baseline ( $-0.60$ ,  $p=0.000000219$ ). In patients where both the UCLA GIT 2.0 and PROMIS were available (N=57), the changes were associated with a small effect size and SRM during 4-week follow-up (Table 1). For subjects who reported improvement, the effect size and SRM were moderate ( $-0.62$  and  $-0.54$ ) for UCLA GIT 2.0, and large ( $-1.03$  and  $-1.02$ ) for NIH PROMIS.

Table 1. Effect size and standardized response means across patient groups				
	Whole Group	Whole Group	Improved group	Improved group
Patient-Reported Outcome Scales	Effect size	SRM	Effect size*	SRM*
UCLA SCTC GIT 2.0	0.25	0.22	-0.62	-0.54
NIH PROMIS	0.28	0.33	-1.03	-1.02

**Conclusion:** In this unique large international cohort, both the UCLA GIT 2.0 and PROMIS are sensitive to change. UCLA GIT 2.0 and PROMIS have a large correlation for the assessment of GERD in systemic sclerosis. Although the change was of small magnitude, statistical correlation was demonstrated.

## **What Factors Predict Good Patient Experiences of Switching from Reference Etanercept (Enbrel™) to an Etanercept Biosimilar (Benepali™) in a South West London General Hospital?**

Laura Attipoe, Samir Patel, Robin Birt, Jennifer Crooks and **Antigoni Grigoriou**, Rheumatology, Kingston Hospital, Kingston, London, England, Kingston, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The introduction of biological (BG) drugs in the last 20 years has revolutionised the treatment of patients with inflammatory arthritis (IA). The development of cheaper biosimilar (BS) drugs, analogous to existing licensed BG therapies, has significant cost benefits for the treatment of IA.

In 2016, our Hospital's Rheumatology Department switched all patients on reference etanercept (E) to an etanercept biosimilar (B). Patients were informed of their switch during a routine clinic appointment or by letter/phone.

In non privatised health settings it is inevitable that hospitals will continue switching patients from BG to their BS counterparts once efficacy, safety and licensing rights have been established. Little is known about how best to switch patients. We devised a questionnaire to investigate our patient's experiences of switching and gain feedback on factors that could be improved.

### **Methods:**

In May 2017, 355 anonymised questionnaires were sent to our patients with IA who had switched from E to B. We received 107 responses. Questions were semi-structured using Likert scales and focused on diagnosis, treatment history, how patients were informed of their switch and any effects they had from the switch itself.

### **Results:**

Rheumatoid arthritis represented 68% of patients, Psoriatic Arthritis 16% and Ankylosing Spondylitis 11%. 64% were female, 36% male. 20% were 18-49 years and 80% were  $\geq 50$  years. 29% of patients had a disease duration of 1-10 years and 71%  $> 10$  years. 44% were on monotherapy and 39% combined with Methotrexate.

65% of patients were informed of the switch by their rheumatology doctor, the remainder informed by their nurse/delivery company. 90% of patients were informed face to face in clinic with the remainder informed by phone/letter. 6% of patients were not given any information about B, the rest were given verbal or written information. 45% of patients found their switching experience excellent or very good, 44% was satisfactory. However 9% found their experience poor or very poor. From those patients 32% expressed that their experiences would have improved if they were given the option of switching and 21% if they were given more information about B. 39% experienced side effects (SE) whilst switching.

Factors significantly involved in patients' having a poor experience of switching were longer disease duration (p 0.042), not feeling sufficiently supported (p 0.00000079) and experiencing SE after switching (p 0.0018). There were no significant differences when looking at age, gender, the type of clinician informing the patient of the switch, whether patients were informed in person or by phone/letter or the type of information patients were given about the switch (verbal or written).

## Conclusion:

Switching onto BS is a phenomenon that is likely to continue with a need to improve patients' experience of switching. Longer disease duration, less support from clinicians and SE from switching contribute to poor experiences. Reducing SE in patients who have switched is fundamental, including those occurring via the placebo effect. Adequate information given in advance, having opportunities to ask questions and having a point of contact after switching are factors that patients express as important.

## Outcomes in Real-World Patients with Early Aggressive Rheumatoid Arthritis

**Keith Knapp**<sup>1,2</sup>, Eric Mueller<sup>1,2</sup> and Gary Craig<sup>1,2</sup>, <sup>1</sup>Arthritis Northwest PLLC., Spokane, WA, <sup>2</sup>Discus Analytics LLC., Spokane, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The window of opportunity to address early rheumatoid arthritis (RA) in patients (pts) is well documented. However early aggressive (agr) RA needs further study to identify optimal treatment patterns. This study compares outcomes of early agr RA to early non-agr patients on their first DMARD.

**Methods:** Pts >18 years and clinically diagnosed with RA in the JointMan database between 1 Jan 2009 and 31 Mar 2017 were included. Test pts had erosions on imaging and were positive for either anti-cyclic citrullinated peptide (ACPA) or rheumatoid factor (RF) within 6 months of their diagnosis. Controls had non-agr early RA with no erosions on imaging and were RF- and ACPA-.

Outcomes using composite disease activity metrics (DAM - DAS28, DAS28-CRP, SDAI, CDAI, and Rapid3) and 8 clinical metrics (tender & swollen joint counts, patient global, pain, physician global physician disease, ESR, and CRP) were tracked at baseline (first DMARD initiation), 6, 12, and 18 months follow up. Index date was the date of the first DMARD. Baseline was defined as the encounter immediately prior to the index date, but no greater than 12 months. Percentage change in each metric from baseline was calculated and differences between test and control (normally distributed) were compared with Welch's T-Test (significance level of 0.05).

**Results:** 618 patients were included in the analysis, 177 (28.6%) were test. Compared to controls, test pts were older (60 vs 53 years), but less likely female (71.8 vs 77.8%). There was significant difference between test and controls at baseline for ESR, CRP and all DAMs (p=0.034, 0.013, and <0.022 respectively) except Rapid3. The percentage change was significant between cohorts at 18 months for all DAMs (p<0.0001); DAS28-CRP had the greatest difference in percentage change (test -36.14 vs -28.94%), while the average swollen joint count was significantly different at all time points.

**Conclusion:** Early agr RA is distinct both at baseline and in its progression to that of non-agr RA. Close clinical monitoring may be necessary to ensure agr pts respond to therapy.

Disease Activity Metric	Baseline	6 Months	12 Months	18 Months
DAS28-CRP	0.002	0.027	0.525	0.0001
DAS28	0.002	0.168	0.415	0.0001
CDAI	0.022	0.066	0.979	0.0001
SDAI	0.003	0.224	0.902	0.0001
Rapid3	0.774	0.734	0.551	0.0001

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The use of patient reported outcomes(PROs) has become increasingly popular in the chronic disease management, disease monitoring and the assessment of drug efficacy. However, very few studies on rheumatoid arthritis (RA) have come down to PROs in China. We initiated CPRI-RA based on Chinese RA population, which include not only arthritis symptoms, physical function but also fatigue, appetite, emotional wellness and self-efficacy. We aimed to measure the reliability and the validity of CPRI-RA and evaluate the correlation and agreement with DAS28 and HAQ.

**Methods:** Nationwide multicenter cross-sectional and longitudinal studies were designed to recruit RA patients who fulfilled 1987 ACR classification criteria. Demographics, clinical and laboratory data were collected and CPRI-RA, DAS-28 and HAQ were recorded. Intensive treated patients with moderately to severely active RA were followed up regularly for 12-week and 24-week periods to track the changes of CPRI-RA, DAS-28 and HAQ scores. The reliability was measured using the Cronbach  $\alpha$  coefficient and the validity was analyzed by the construct validity using factor analysis method. Agreement between CPRI-RA and DAS28 was analyzed by the weighted kappa value. The correlation between CPRI-RA and DAS28, HAQ was analyzed by Pearson correlations. The linear mixed-effects model was adopted to analyze the dynamic correlation and consistency between the indices.

**Results:** A total of 1868 RA patients (83.08% women, mean $\pm$ SD age 54.79 $\pm$ 12.62 years, disease duration 6.18 $\pm$ 7.68 years, DAS28 5.56 $\pm$ 1.36) from 19 provinces and 23 hospitals completed the cross-sectional survey and 186 active RA patients(85.48% women, mean $\pm$ SD age 48.18 $\pm$ 10.61 years, disease duration 1.77 $\pm$ 1.52 years, DAS28 5.71 $\pm$ 1.06) participated in the longitudinal study. The overall Cronbach  $\alpha$  value was 0.756 and the Guttman spit-half coefficient was 0.733, indicating CPRI-RA had good internal consistency and stability. Three factors extracted by factor analysis (cumulative 53.199%) reflected the physical status, social and psychological properties of RA patients, which provided evidence for good construct validity. HAQ versus CPRI-RA scores were significantly correlated ( $r=0.581$ ,  $P<0.0001$ ), and DAS28 versus CPRI-RA scores were significantly correlated at higher levels ( $r=0.640$ ,  $P<0.0001$ ). The weighted kappa value was 0.4215 ( $P<0.0001$ ) for DAS28 versus CPRI-RA, indicating fair agreement of the indices. Dynamically, HAQ versus CPRI-RA scores and DAS28 versus CPRI-RA scores were both significantly correlated ( $r=0.4464$ ,  $r=0.4622$ ,  $P<0.0001$ ). The dynamic trends of the three indices were highly consistent.

**Conclusion:** CPRI-RA, a reliable, feasible and valid PRO scale, can provide similar quantitative information to DAS28 and HAQ. The results support the incorporating of CPRI-RA into the routine assessment and dynamic monitoring of RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** While weekly methotrexate (MTX) remains the gold standard treatment for patients with RA, studies suggest that MTX adherence may be sub-optimal and could be associated with side effects, poor outcomes, and unnecessary switching to other DMARDs. We set out to assess MTX adherence in patients with RA using electronic medication monitoring in a real-world non-clinical setting.

**Methods:** Patients were participants in the National Data Bank for Rheumatic Diseases (NDB) longitudinal survey-based study that reported oral MTX initiation independent of other treatments within a year of September 2016. Study patients used a Medication Event Monitoring System (MEMS®) to accurately record when they accessed their MTX pills and completed the Beliefs about Medications Questionnaire (BMQ). The BMQ assesses "General" beliefs about medications and also those taken for a "Specific" condition (RA). While validated in several chronic disease, the BMQ has never been studied in RA. After 24 weeks the MEMS data were retrieved and baseline patient characteristics were summarized by categorical adherence level.

**Results:** Of the 119 eligible patients invited, 62 enrolled and 32 had completed the study by May 2017. Mean (SD) MTX experience at the first time of MEMS use was 7.4 (5.0) months. Nine (28%) patients had perfect adherence, 7 (22%) had 1 interrupted week, 8 (25%) had  $\geq 2$  interrupted weeks, and 8 (25%) had major adherence deviations, including treatment discontinuation. On average, 80% of dosing intervals were between 6 and 8 days and MTX dose was taken in 77% of the monitored weeks. The table compares baseline characteristics between adherence categories. There was a significant difference in Non-Hispanic Caucasian and BMQ-General-Overuse response between patients with  $\leq 1$  interrupted weeks and  $\geq 2$  (94 vs. 63%,  $p=0.03$  and 11.1 vs. 9.4,  $p=0.02$ , respectively). There were also clinically significant differences in functional assessment (HAQ-II 0.7 vs. 1.2) and fatigue (VAS 2.9 vs. 4.9).

**Conclusion:** This study demonstrated the feasibility of using remote electronic medication monitoring in a participatory US RA population; yet, even with such participation biases, half had important adherence interruptions with MTX. Patients with beliefs that medicines are overused by doctors were most likely to be adherent while Non-Caucasian race and worse function and fatigue were less likely. Next steps include a larger and longer follow-up and investigating early intervention to improve MTX adherence.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis (RA) patients increasingly reach a state of absence of disease activity, or remission. However, the proportion of patients classified as in remission varies substantially between definitions and are often determined by disease activity score (DAS) of the joints. But, the importance of patients' perspective is increasingly recognized, which often result in discordance between patients and physician assessment.

### **Objectives:**

First, agreement between patient-perceived, physician-perceived remission and clinical response and remission definitions was determined in early RA patients. Second, the differences in clinical and patient-reported outcomes, in patients in physician-perceived remission, between patients in and not in self-perceived remission were assessed.

### **Methods:**

In early RA patients receiving COBRA-light treatment, DAS44, ACR/EULAR Boolean-based remission, EULAR good and ACR70 response were determined after 12 weeks. Agreement percentages and kappa values between patient-perceived, physician-perceived remission and clinical response and remission definitions were calculated. In patients in physician-perceived remission, improvement in clinical and patient-reported outcomes (RAID) were compared between patients in and not in self-perceived remission.

### **Results:**

Eighty-four consecutive patients were included (mean age 50 years, 67% female). Agreement between the assessed outcome measures differed enormously. The agreement between physician-perceived and patient-perceived remission was 64% (kappa 0.25,  $p < 0.01$ ). Physician-perceived remission (cut-off VAS  $\leq 20$  mm) had the best agreement with EULAR good response (86%, kappa 0.58,  $p < 0.01$ ). Agreement between patient-perceived remission was 69% for EULAR good and ACR70 response (kappa 0.36,  $p < 0.01$ ; kappa 0.40,  $p < 0.01$ , respectively). Patients not in self-perceived remission improved less on components of the RAID, especially on pain, sleep and emotional well-being.

### **Conclusion:**

One-third of the early RA patients disagreed with the physician on being in remission. Those patients had less improvement on components of the RAID, especially on pain, sleep and emotional well-being. Together with the variability in clinical response and remission definitions, these results highlight the need to increase patient involvement in their own health care decisions.

Table. Agreement between different definitions of response and remission.

	Physician-Physician- perceived remission (≤10 mm)	Patient- perceived remission (≤20 mm)	DAS44 remission	EULAR good response	ACR70 response	Boolean remission
Physician-x	86%	67%	74%	79%	60%	57%

## Eliciting the Research Priorities of Parents and Children with Juvenile Myositis

**Colleen K. Correll**<sup>1</sup>, Mitali Dave<sup>2</sup>, Anne Paul<sup>3</sup>, Vincent Del Gaizo<sup>4</sup> and Esi Morgan<sup>5</sup>, <sup>1</sup>Pediatrics, University of Minnesota, Minneapolis, MN, <sup>2</sup>Cure JM Foundation, Encinitas, CA, <sup>3</sup>Anderson Center for Health Systems Excellence, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>4</sup>Parent Partner, Whitehouse Station, NJ, <sup>5</sup>Cincinnati Children's Hospital, Cincinnati, OH  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Patient-Centered Outcomes Research Institute (PCORI) aims to improve the quality and relevance of research by conducting research that is of highest priority to patients and to engage patients at all phases of research. As a project of the PCORI-supported Patient Powered Research Network, PARTNERS (Patients, Advocates and Rheumatology Teams Network for Research and Service), we surveyed parents of children with juvenile myositis (JM) to identify what research questions are most important to them.

**Methods:** This research prioritization exercise was conducted through web-based surveys, a focus group, and a Delphi process. In November, 2016 a survey link, comprised of 3 open-ended questions to assess what concerns patients/families found most important, was emailed to members of the Cure JM Foundation listserv and posted on Cure JM social media sites. Parents, patients  $\geq 13$  years old and family/friends were included. Common themes on research areas of interest were identified from the survey and further characterized through a focus group consisting of parents of children with JM at the annual Cure JM conference in February, 2017. A final survey was created based upon these themes and emailed to the Cure JM listserv and posted to its social media sites in April, 2017. Survey respondents were asked to rank the themes most important to them. Responses were weighted and the 6 most important themes were identified.

**Results:** There were 138 respondents to the initial survey (77% parents, 11% patients, 12% family/friends). Response rate could not be calculated because the number of potential respondents from social media sites is unknown. From this survey, 23 concerns were identified. The 3 most common concerns were long-term effects of medications, long-term effects of juvenile myositis, and triggers for disease flare. The 23 concerns were further characterized into 20 research priorities during a 9-member focus group. The final ranking survey asked respondents to rank the 7 most important priorities from the 20 themes. There were 365 survey respondents (75% parents, 15% patients, 10% family/friends). The following were ranked in order as the most important research priorities: a cure, new treatments with less side effects, triggers for disease flare, treatment side effects (such as steroids), standards to measure disease activity/remission, genetic/environmental causes of the disease. These research priorities were formally presented at the Global Conference on Myositis and the Childhood Arthritis and Rheumatology Research Alliance annual meetings to help frame the juvenile myositis research agenda.

**Conclusion:** Patient centered research prioritization is increasingly recognized as a valuable tool in conducting high-quality research, yet there is a lack of publication describing patient/family preferences, especially in pediatrics. Here, we demonstrate a successful program from which we assessed patient/family research priorities in order to inform a joint research agenda process for the juvenile myositis research community.

Bingham III<sup>6</sup>, <sup>1</sup>Department of Medicine, Division of ClinEpi, Rheumatology, Respiriology, McGill University, Montreal, QC, Canada, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, <sup>3</sup>Johns Hopkins University School of Medicine, Baltimore, MD, <sup>4</sup>Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>5</sup>Rheumatology, Johns Hopkins School of Medicine, Baltimore, MD, <sup>6</sup>Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Although patient-reported outcomes (PROs) are routinely collected for research and quality purposes, they have not been routinely incorporated into the routine care of patients. Clinicians are best able to provide chronic disease care that is patient-centered when they have a better understanding of their patients' lived experiences. We hypothesized that having PRO results describing the range of symptoms and impacts of living with RA during clinic visits would provide insight into patient priorities, values, and preferences and facilitate SDM around treatment choices. Evidence for the impact of PROs on patient management from the clinician's perspective are presented.

**Methods:** Participants with RA in an observational study at an academic arthritis center completed PROMIS fatigue, pain, physical function, sleep, and participation on a tablet in the waiting room. Reports of results in numerical and graphical formats were available during the visit for review. Semi-structured interviews were used to query the experiences of rheumatologists and rheumatology fellows on the impact of PROs on RA patient management.

**Results:** Data are from interviews with 4 rheumatologists and 6 fellow trainees. Among rheumatologists, access to real-time PROMIS results that could be addressed during the visit was highly valued. All stated that completing questionnaires helped patient feel "heard" and discussing results made it clear that patients' experiences mattered. Several said reports prompted them to ask about symptoms they may have overlooked. There was concern that some symptoms (depression, anxiety) may have little to do with RA; identifying these without a clear pathway to resources was potentially problematic. All noted that how they used results differed depending on the needs of specific patients and the nature of the visit. While rheumatologists felt able to control the time spent discussing results, fellows expressed less certainty about their ability to control conversations, the value of additional PROs for RA care, or its impact on decision-making. Fellows also reported greater discomfort discussing results if they had not yet built a rapport with patients.

**Conclusion:** Expanded real-time assessments of RA symptom and impacts on day-to-day life as part of routine care appears to offer important new information to make RA care more patient-centered by informing discussions and facilitating shared decision-making around treatment. For trainees, the value of additional symptom information was balanced by concerns about greater time challenges, ways to integrate results into discussions and care plans, and availability of resources to address new problems that were identified. Results highlight opportunities to enhance broader communication skills training around potentially sensitive topics and quality of life in rheumatology training programs.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Inflammatory arthritides such as RA and PsA increase infection risk. The Centre for Disease Control and Prevention (CDC) recommends vaccination against i. influenza for all adults annually and ii. pneumococcus for all 'at-risk' adults (> 65 years, specific conditions or those taking certain immunosuppressants). The aim of this study was to examine patients' knowledge, uptake and attitudes to influenza and pneumococcal vaccination, and to assess opportunities to increase vaccination rates in our inflammatory arthritis clinic.

## Methods:

Patients attending the inflammatory arthritis clinic in St Vincent's University Hospital, Dublin completed an anonymous 23 question worksheet while awaiting their physician. Demographic details, medical history, medications, knowledge about vaccinations, vaccination status, reasons for lack of vaccination and attitudes regarding willingness to use a smart phone for healthcare record were recorded.

## Results:

125 patients responded, 79% were female and 71% were over 50 years of age. 83% had completed high school. Half of the patients had RA. 23% of patients were using methotrexate, 17% oral steroids and 34% an injectable biologic.

Awareness that rheumatological conditions increase risk of infection was reported by 51%, while 54% were aware that their medications can increase the infection risk. 67% were aware influenza vaccination was recommended, most commonly via their primary care physician (PCP) at 42%. 10% learnt of the need for vaccination through television or radio.

55% were up to date with their 'flu' vaccination, mainly (68%) via their PCP. 4% of patients received their last vaccine in hospital. Stated reasons for not being adequately vaccinated included lack of awareness (23%) and fear of side effects (15%).

66% were aware pneumococcal vaccination might be indicated, 42% were informed by their PCP. None were informed by television or radio. 47% of respondents were up to date with their pneumococcal vaccination, mainly (82%) via their PCP. 2% had been vaccinated in the hospital. 59% of those not adequately vaccinated cited lack of awareness as the reason.

75% of patients had access to a smart phone. 76% were willing to use their smart phone for their healthcare record and reminder re vaccinations.

## Conclusion:

Patient awareness of the risk of infection associated with disease and treatment was low. Although over two thirds were aware of influenza and pneumococcal vaccination recommendations, significantly fewer patients were up-to-date with their vaccinations. The majority of vaccinations took place in the community. The use of mass media and mobile technology may be an effective means of increasing vaccination uptake.

# A Scoping Review of Contextual Factors of Patient Decision Aids in Osteoarthritis

Alexa Meara<sup>1</sup>, Karine Toupin-April<sup>2</sup>, Bev Shea<sup>3</sup>, Liana Fraenkel<sup>4</sup>, Jennifer Barton<sup>5</sup>, Peter Brooks<sup>6</sup>, Maarten de Wit<sup>7</sup> and Peter Tugwell<sup>8</sup>, <sup>1</sup>Internal Medicine/Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH, <sup>2</sup>Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada, <sup>3</sup>University of Ottawa, Ottawa, ON, Canada, <sup>4</sup>Yale University, New Haven, CT, <sup>5</sup>Oregon Health and Science University, Portland, OR, <sup>6</sup>The University of Queensland, Sidney, Australia, <sup>7</sup>EULAR standing committee of PARE, Zurich, Switzerland, <sup>8</sup>Center For Global Health, Institute of Population Hlth, Ottawa, ON, Canada  
**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient decision aids (PDAs) have been developed to help patients make informed health care decisions that are consistent with their values and preferences. Patients diagnosed with osteoarthritis (OA) can choose from a wide array of treatments, such as physical therapy, exercise, medication, joint injections, and surgery (when indicated). OMERACT Filter 2.0 highlights the importance of measuring relevant contextual factors (*i.e.*, any factors that indirectly influence the process or outcomes of interventions) in clinical studies evaluating PDAs. However, very few studies have assessed these factors. A Cochrane Systemic Review published in 2017 performed an in-depth review of benefits of PDAs and performed subgroup analyses based on the timing of the use of PDAs (*i.e.*, before or during a consultation) but did not find any impact. The current study sought to systematically search the literature in order to appraise and summarize contextual factors that were assessed in randomized controlled trials (RCTs) of PDAs in OA.

**Methods:** We conducted a scoping literature review using Medline, Embase, AMED, PsycInfo and Cochrane Central from inception of the databases to June 14 2017. The search strategy was based on the Cochrane systematic review of PDAs and MeSh terms related to OA. Citations were included if they reported on RCTs evaluating PDAs compared to any control group in patients with OA.

**Results:** 235 citations were identified after removal of duplicates and six RCTs of PDA in OA were included. Of the six included trials, four were about the effectiveness of PDAs for knee arthroplasty and two others were for overall management of OA. Three RCTs measured PDA format as the main predictor of decision making outcomes (*i.e.*, internet vs. DVD PDAs, and paper-based educational booklet vs. video-booklet PDA). One of these RCTs also examined the impact of patient testimonials. A fourth trial measured the setting in which the PDA was used (*i.e.*, community or academic hospital setting) and another trial conducted subgroup analyses for patients' characteristics. Format and content of the PDA and patients' younger age (*i.e.*, 50-55 years old), sex (female) and willingness to undergo surgery at baseline were linked to better decision-making outcomes.

## Conclusion:

Contextual factors assessed in RCTs of PDAs in OA include format, content and setting of the PDA and patients' characteristics. There is a need for more research to assess contextual factors in PDA RCTs in rheumatology to fulfill the OMERACT filter 2.0. Potential contextual factors to consider include the timing in which PDAs are used and the interface between the PDA and patients (*e.g.*, tailoring to patients' health literacy, understanding, etc). Future work will be also be needed to assess contextual factors of PDAs in other prevalent rheumatic conditions.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Systemic sclerosis is a potentially life-threatening, clinically diverse, and rare condition. The prognosis and course of disease is difficult to predict and treatment is complex. This can be challenging to understand or explain, posing challenges for effective physician-patient communication. Our study explored communication between physicians and patients with SSc-ILD to assess communication and understanding and identify information gaps and needs.

### Methods:

23 20-minute consultations between physicians (rheumatologists, pulmonologists) and patients (19 real, 4 actors) with diagnosed SSc-ILD across 5 countries were directly observed and video/audio recorded. SSc-ILD (limited/diffuse) of all severities, with a range of other organ involvement, was represented. None of the discussants were known to one another. Consultations were analysed using linguistic techniques based on interactional sociolinguistic discourse analysis to understand the pattern and meaning of communication, whether the needs of both participants were met, and the level of understanding between participants.

### Results:

The following issues inhibited effective communication between patients and physicians:

- 1. Consultation pattern:** In most consultations, patients were given little opportunity to explain their concerns or ask questions. Physicians solicited the patient's story but quickly diverted it to extract clinical information. During effective consultations, patients were invited to tell their story, guided by physicians, who also gathered clinical information. Physicians used techniques to check and demonstrate understanding, express empathy and build rapport.
- 2. Use and meaning of language:** Physicians used plain language in their explanations but often reverted to medical terminology when the issue became complex. Patients often used medical terminology with limited understanding of the terms. Hence, some physicians mistakenly believed patients had a better understanding than they actually had.
- 3. Cognitive models:** Physicians and patients had different ways of understanding SSc-ILD based on their knowledge, experiences, expectations and beliefs. This determined what information patients shared and how they interpreted information from physicians. Differences in cognitive models between patients and physicians were responsible for misunderstandings.

### Conclusion:

Communication challenges between patients and physicians limit joint understanding of SSc-ILD and may result in both parties missing important information and patients being less aware of self-help management approaches. Strategies should be developed with physicians to facilitate effective communication and increase patient understanding and support.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Transition from pediatric to adult care is an important process for adolescents and young adults with Juvenile Idiopathic Arthritis (JIA). A seamless transition is critical for optimal health outcomes; however, young people are faced with obstacles at the patient, caregiver, and health care system levels. A "transition tool-kit" provides a standardized approach to the transition process and has the potential to overcome some of the existing barriers. A needs assessment was conducted to determine the most important features and tools that Canadian users would value in a transition tool-kit.

## Methods:

Participants were recruited from four Canadian rheumatology centres. In total, 22 individual interviews and 12 semi-structured focus groups (with approximately 4-7 participants in each) were conducted, including all user types (adolescents, young adults, caregivers, and pediatric and adult health care providers [HCPs]). Discussion focused on preparations, concerns and wishes regarding the transition process, and how these issues could be addressed using a transition tool-kit. The qualitative data were transcribed and analyzed by two coders using simple descriptive content analysis (NVivo 10). Demographic and disease-related data were analyzed using descriptive statistics.

## Results:

In total, 20 adolescents (60% female; mean age = 15.9±1.3 years), 12 young adults (58.3% female; mean age = 20.3± 1.8 years), 26 caregivers (88.5% female), 20 pediatric HCP (90% female; mean number of years practicing = 14.3±7.6), and 8 adult HCP (87.5% female; mean number of years practicing = 12.0±13.8) participated.

The main themes from the qualitative analysis include:

- (1) Preparation for transition: most participants expressed concerns about transition and felt that patients were not properly prepared; however, a small number of adolescent participants expressed no concerns.
- (2) Treatment decision making: most participants agreed that patients should be the ultimate decision makers following discussion with their caregivers and HCPs. Patients and caregivers identified the importance of access to accurate and comprehensive disease- and medication- related information from HCPs and online resources prior to making a treatment decision.
- (3) Transition tools: participants felt that a tool-kit would streamline the transition process and provided suggestions for potential components, such as a calendar feature to remind patients of appointments and to take medication, an online self-guided JIA resource website, a smartphone app for tracking and managing symptoms, and a resource to help manage JIA in college or university. Most participants thought that the tool-kit would be best suited as a website or mobile application.

## Conclusion:

Overall, participants felt that adolescents are not adequately prepared for transition, and had a positive response to the concept of a transition tool-kit. Key components of this tool-kit were identified by users, with a priority on resources for self-management and

shared decision-making. Next steps include the development of a standardized transition tool-kit, which will incorporate existing tools and development of new tools as necessary.

## **Lupus Diagnosis: Process and Patient Experience**

**Rossi Daly**, Roushanac Partovi and Patricia Davidson, Lupus Foundation of America, Washington, DC

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Delays in lupus diagnosis and misdiagnosis are sources of concern, as uncontrolled disease activity and early damage can increase mortality risk.<sup>1</sup> The purpose of this study is to analyze the diagnostic process through the patient perspective and provide insight into unmet needs in lupus diagnosis.

### **Methods:**

This cross-sectional study draws from a one-time online national survey conducted between December 2015 and January 2016 among 3,022 adults who self-reported a lupus diagnosis. To assess patient perspective on the diagnosis process, participants answered questions regarding symptoms pre-diagnosis, the provider(s) they discussed symptoms with, and the time frame to diagnosis. Descriptive statistics were conducted on demographic information and all diagnosis process measures.

### **Results:**

Respondent characteristics are described in Table 1.

This analysis provides a detailed look at the diagnostic process from the patient perspective. Beginning with the symptoms prompting a first visit, musculoskeletal symptoms and fatigue illustrate the non-specificity experienced by nearly half of the respondents (Table 2). Of importance, a majority of respondents (73.2%) specifically made an appointment to discuss these symptoms, 72% discussing them with a primary care provider. Of those who discussed symptoms with other types of providers, over 75% also discussed the symptoms with a rheumatologist. Leading up to respondents' diagnosis, more than half reported being told there was nothing wrong with them or that their symptoms were psychological (54.1%). Furthermore, 41% of respondents reported being told they had something other than lupus, and concurrently, nearly 40% of individuals waited more than one year from the onset of symptoms to receive an accurate diagnosis. At the time of diagnosis, over one third of respondents (34.5%) reported having severe symptoms.

### **Conclusion:**

The findings of this study suggest the need to provide ongoing education to both primary care and specialty providers in diagnosing lupus. Qualitative responses in this study, not reported here, also suggest that poor provider-patient communications may contribute to the delay in diagnosis. Lastly, describing the providers and care settings typically involved in diagnosis can be useful for creating a framework to identify future areas of intervention and/or research.

## The Effects of Disease Burden, Helplessness, and Pain on Depressive Symptoms in Rheumatoid Arthritis and Systemic Lupus Erythematosus

Sera Ramadan<sup>1</sup>, Perry M. Nicassio<sup>2</sup>, George Karpouzas<sup>3</sup> and Sarah Ormseth<sup>4</sup>, <sup>1</sup>Internal Medicine, Dignity Health St. Mary Medical Center, Long Beach, CA, <sup>2</sup>Cousins Center for PNI, UCLA, LA, CA, <sup>3</sup>Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, <sup>4</sup>Rheumatology, Harbor-UCLA Medical Center, Torrance, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Background/Purpose:** This research tested an integrated framework examining patient global assessment of disease activity (PtGA), maladaptive illness beliefs and pain as determinants of mood disturbance in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients.

**Methods:** The data of 232 patients (RA = 110, SLE = 122) were used to evaluate the hypothesized model in which PtGA (rated on a 10-cm visual analogue scale) directly and indirectly predicted mood disturbance (Center for Epidemiologic Studies Depression Scale and SF-36 Mental Health) through maladaptive illness beliefs (Arthritis Helplessness Index) and pain (SF-36 Pain and pain visual analog scale). Using EQS 6.1, multigroup structural equation modeling (SEM) was employed to test the model as well as the potential moderating role of diagnosis (RA compared to SLE).

**Results:** The model fit the data well for both patient groups [for RA: CFI = 1.00,  $\chi^2(6) = 1.93$ ,  $p = .926$ , RMSEA < .001; for SLE: CFI = 1.00,  $\chi^2(6) = 2.04$ ,  $p = .916$ , RMSEA < .001]. However, there were some differences in the significance and magnitude of paths between model variables, which were further assessed in multigroup analyses. As hypothesized, in both patient groups PtGA had direct positive effects on maladaptive illness beliefs and pain, and pain predicted greater mood disturbance. Moreover, illness beliefs were associated with mood disturbance for RA patients and SLE patients, though the nature of that relation was different for the two groups. Among RA patients, maladaptive illness beliefs directly predicted mood disturbance ( $\beta = .42$ ,  $p < .001$ ) whereas for SLE patients, the effect of illness beliefs on mood was indirect (mediated by pain;  $\beta_{\text{indirect}} = .39$ ,  $p < .001$ ). Multigroup SEM results further indicated that while illness beliefs predicted higher levels of pain in both patient groups, the effect of was significantly stronger for lupus patients (RA:  $\beta = .23$ ,  $p = .006$ ; SLE:  $\beta = .44$ ,  $p < .001$ ).

**Conclusion:** These findings suggest that maladaptive illness beliefs and pain may serve as mechanisms through which PtGA influences mood disturbance in both RA and SLE. Multigroup structural equation modeling elucidated differences between groups in the mediating pathways connecting PtGA to mood disturbance and have important implications for the development of targeted interventions to enhance mood regulation in RA and SLE patients.

**Figure 1.** Structural model with standardized path coefficients for Rheumatoid Arthritis (Lupus) subgroups. Note. \*pathway set to 1.0. Dashed line indicate significant between-group differences in the magnitude of the structural path. Pt = Patient; SF-36 = Short Form-36; VAS = visual analogue scale; CES-D = Center for Epidemiological Studies Depression scale.

## Stability of Two Short Medication Adherence Questionnaires over Time for Follow-up in Patients with Rheumatoid Arthritis

Raquel Sweezie<sup>1</sup>, Charles H. Goldsmith<sup>2</sup>, Imy Chiu<sup>3</sup>, Anna Gutlin<sup>3</sup>, Sharron Sandhu<sup>4</sup> and Mary J. Bell<sup>5</sup>, <sup>1</sup>Division of Rheumatology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, <sup>2</sup>Simon Fraser University, Vancouver, BC, Canada, <sup>3</sup>Rheumatology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, <sup>4</sup>Medicine, University of Toronto, Toronto, ON, Canada, <sup>5</sup>University of Toronto, Toronto, ON, Canada

**First publication:** September 18, 2017

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adherence to disease modifying anti-rheumatic drug (DMARD) therapy is suboptimal in patients with rheumatoid arthritis (RA). Efficient, low-cost measures are required for better monitoring of medication adherence in the rheumatology clinic. Self-report tools are the most efficient and cost-effective measures available. A 5-item version of the Compliance Questionnaire Rheumatology (CQR5) was developed from the original 19-item version to reduce patient burden. Long-term reliability (stability) of this questionnaire has not yet been evaluated over a period equivalent to RA patient follow-up (3 to 6 months). Therefore, we looked at stability of the CQR5 and the 9-item Medication Adherence Report Scale (MARS9), another short medication adherence tool that has been shown to be valid in a sample of RA patients.

**Methods:** RA patients (disease duration  $\geq 1$  year) taking at least one DMARD prescription were randomly selected from a rheumatology outpatient clinic database. Patients were assessed at baseline and three months. Demographic data were collected at baseline. At each visit, medication adherence was assessed with the CQR5 and MARS9. Each item on the CQR5 was scored on a four point Likert scale (1 = strongly disagree, 4 = strongly agree). Scores for each item were then summed into a total score which varied between 0 and 20. For the MARS9, each item was scored on a five point Likert scale (1 = always, 5 = never) and item scores were summed into a total score varying from 9 to 45. On both questionnaires, higher scores indicated greater adherence. Stability analysis was performed with the intraclass correlation coefficient (ICC) and the mean difference between measurements obtained at baseline and three months.

**Results:** 100 RA patients, ages [mean(SD)] 60.75(12.67) years, were recruited. 4 patients dropped out, therefore 96 were included in the analysis. In this sample, the CQR5 and MARS9 demonstrated good and fair stability, respectively [ $ICC_{CQR5} = 0.73(CI_{95\%} = 0.61 \text{ to } 0.81)$ ;  $ICC_{MARS9} = 0.43(CI_{95\%} = 0.24 \text{ to } 0.58)$ ]. One-sample t-tests showed that the differences in measurement from baseline to three months were not significantly different from zero ( $p > 0.05$ ) for both the CQR5 [mean(SD) = -0.22 (1.57)] and MARS9 [mean(SD) = -0.15 (4.18)]. The CQR5 and MARS9 had similar mean differences but variability for the MARS9 was larger than for the CQR5, indicating greater consistency across measurements for the CQR5.

**Conclusion:** We demonstrated stability of a short, rheumatology-specific adherence questionnaire in a time frame similar to RA patient follow-up. Our results also suggest that the CQR5 may be a more stable measure of medication adherence than the MARS9 when it is used in a rheumatology clinic setting.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The measurement of patient reported outcomes is a priority for patient-centered high value care. This is particularly true in chronic systemic diseases such as SLE, which can have a significant ongoing impact on quality of life. PROMIS instruments are precise, reliable, and valid measures of physical, mental, and social health, but their relevance and potential value in the clinical care of SLE patients has not been explored. The aims of this study were to evaluate SLE patient perspectives on the relevance and potential utility of PROMIS computerized adaptive tests (CATs) and PROMIS10.

**Methods:** Adult outpatients meeting 1997 ACR SLE classification criteria were recruited from an SLE Center of Excellence. Subjects completed 12 PROMIS CATs, the PROMIS10, and participated in focus groups (women) or structured interviews (men). Focus groups and interviews explored the relevance of PROMIS domains, the potential value of PROMIS instruments in routine medical care, and identified missing domains. Transcripts were analyzed for recurring themes and concepts using grounded theory.

**Results:** Twenty eight women and 4 men with SLE participated in 4 focus groups and structured interviews (table 1). Participants reported that PROMIS instruments, especially CATs, reflected their experience with lupus, with women prioritizing domains of fatigue, pain interference, physical function, sleep disturbance, and cognitive abilities as most relevant, and men selecting fatigue, sleep disturbance, anxiety, pain interference, and pain behavior. Subjects identified body image, intimate relationships, pregnancy, and relationships with providers as important areas not addressed by PROMIS. Participants were enthusiastic about using PROMIS in their medical care, citing utility in validating their experience, tracking symptoms and disease progression, facilitating communication with providers, and guiding treatment plans. A recurring theme in the focus groups and interviews was the importance of doctors reviewing the survey results.

**Conclusion:** SLE patients endorse PROMIS instruments as relevant, valuable, and potentially useful in improving clinical care. These data identify domains of importance to SLE patients, including men's greater emphasis on mental health, and areas where there is a need to develop PROMIS instruments. Further longitudinal studies are essential to explore how to most effectively integrate PROMIS measures in routine clinical care.

Table 1. Socio-Demographic Characteristics of Participants (n=32)

Characteristic	Value
Age, median (IQR) years	39 (33, 53.5)
Disease duration, median (IQR) years	11.6 (6.4, 24.2)
Female	28 (87.5%)
Race	
White	6 (21.4%)
Black or African American	14 (50.0%)
Asian	3 (10.7%)
Other	5 (17.9%)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Patient Outcomes, Preferences, and Attitudes Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** PROMIS CATs are precise measures of quality of life with construct validity in SLE. The longitudinal responsiveness (sensitivity to change) of PROMIS CATs in SLE patients is unknown. We aimed to evaluate the responsiveness of PROMIS CATs in SLE outpatients using patient and physician-derived anchors.

**Methods:** Adult SLE patients were recruited from an SLE Center of Excellence. Subjects completed 14 selected PROMIS CATs at two visits a minimum of one month apart. SLE disease activity was measured with a patient global assessment of change, a physician global assessment and the physician-derived SELENA-SLEDAI. Responsiveness of PROMIS scores was evaluated using known-groups validity. Changes in PROMIS scores from baseline to follow up were compared across groups of patients who differed in their patient global assessment of change, physician global assessment, and SELENA-SLEDAI using Wilcoxon rank-sum tests.

**Results:** A diverse cohort of 228 SLE patients completed baseline surveys (table 1), with 190 (83%) completing a follow up survey. Using the patient-based anchor, there was a trend towards responsiveness across 11 PROMIS CATs (table 2), with statistically significant changes in T-scores with improvement and worsening of health status in Physical Function (effect size 0.15, 0.01, and -0.14 [p <0.02] with “better”, “same”, and “worse” health status respectively), Pain Interference (0.0, 0.0, 0.25 [p <0.02]), and Anger (-0.37, -0.08, 0.0 [p <0.03]) CATs. Using the physician global assessment and SELENA-SLEDAI as anchors, there was no notable trend or statistically significant change in scores across groups, with the exception of the Applied Cognition-Abilities CAT (0.34, -0.01, 0.0 [p <0.01]) when the SELENA-SLEDAI was used as an anchor.

**Conclusion:** PROMIS CATs showed modest responsiveness to patient-reported, but generally not physician-derived changes in lupus health status. These data suggest that certain PROMIS CATs are precise and sensitive tools which may be used to measure and monitor important aspects of the patient experience of lupus not captured by physician-derived metrics. Further studies are needed to evaluate the role of PROMIS in optimizing longitudinal disease management in SLE.

Table 1. Baseline Characteristics of Participants (n = 228)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile MCTD (JMCTD) is a heterogenic autoimmune disease, with SLE-, SSc- and PM/DM and RA like manifestations. Cardiac involvement is known in juvenile SLE, SSc, JDM and JIA, but data is limited in JMCTD. Adult MCTD is more benign than other CTDs, and cardiac involvement is mainly subclinical. Mortality, however, is mostly related to cardiac causes. Aim of study was to compare cardiac function in JMCTD patients with controls, and explore associations between cardiac function and disease characteristics.

**Methods:** 50 patients and 50 matched controls were examined median 14.9 years after disease onset. Cardiac function was assessed by echocardiography; LV systolic function was assessed by biplane ejection fraction (EF) and normalized mitral annulus displacement (long axis strain (LAS)); LV diastolic function was assessed by early diastolic tissue velocity (E'), early diastolic transmitral flow (MV E), and early/ late diastolic transmitral flow ratio (MV E/A ratio). LV dysfunction was defined as EF≤61.6%, LAS≤15.3%, or E'≤9.3m/s, all defined by mean values -2 standard deviations in controls. Disease activity was assessed by SLEDAI, Juvenile Arthritis Disease Activity Score (JADAS), anti-RNP-levels and positive rheumatoid factor (RF). Patients were classified with SLE-like, SSc-like or PM-like findings.

**Results:** Table 1 shows characteristics and cardiovascular parameters in patients and controls. 86% were female; Mean age in patients was 27.4 years.

EF and LAS were lower in patients than controls ( $P \leq 0.001$  and  $P = 0.045$ ), but within normal range. MV E and MV E/A ratio were also impaired in patients ( $P \leq 0.029$ ). LV dysfunction was present in 16% patients versus 4% controls ( $P = 0.046$ ).

At follow-up, JADA was associated with lower EF (rsp= -0.283,  $p = 0.049$ ); Positive RF and higher SLEDAI at follow-up were associated with higher LAS (rsp=0.318,  $P = 0.026$  and rsp=0.281,  $P = 0.048$ ). Long duration of prednisolone treatment was associated with EF≤61.6% (rsp=0.340,  $P = 0.016$ ).

In final multivariable regression models (table 2), PM-like findings at diagnosis was an independent predictor of impaired EF ( $P = 0.001$ ), male sex was independent predictor of impaired LAS ( $P = 0.002$ ), and long disease duration was independent predictor of impaired E' ( $P \leq 0.001$ ).

**Conclusion:** LV cardiac function was impaired in JMCTD patients compared with controls. Subclinical LV dysfunction was present in 16% of the patients. PM-like manifestation at diagnosis, male sex and long disease duration predicted impaired cardiac function. Our results suggest that cardiac involvement in JMCTD varies among the different clinical phenotypes.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Child-onset systemic lupus erythematosus (SLE) is a chronic autoimmune condition with a high risk of organ damage. There are no guidelines on the use of echocardiography to detect cardiac manifestations. We aim to describe utilization of echocardiograms in youth with SLE, assess regional variation, and compare baseline echocardiogram use with subsequent rates of new cardiac diagnoses.

**Methods:** Using the Clinformatics<sup>TM</sup> DataMart (OptumInsight, Eden Prairie, MN) de-identified US administrative claims data from 2000-2013, we identified youth ages 10-24 years with an incident diagnosis of SLE ( $\geq 3$  ICD-9 SLE codes 710.0,  $>30$  days apart). Multivariable logistic regression with forward selection was used to identify factors associated with echocardiogram use during the baseline period from 1 year preceding to 6 months after SLE diagnosis. Linear regression was used to evaluate the association between echocardiogram use by census division and the proportion of imaged youth subsequently diagnosed with their first acute cardiac manifestation (pericarditis, myocarditis, endocarditis), at or after the baseline echocardiogram.

**Results:** Among 699 youth with new-onset SLE, 26% underwent echocardiogram at baseline. Youth hospitalized at diagnosis had the highest odds of baseline echocardiogram (OR 6.1, 95%CI 3.8-9.8), while youth with psychiatric diagnoses had lower odds (OR 0.5, 95%CI 0.3-0.7) (Table). There was significant geographic variability in echocardiogram use by census division after adjustment for other subject characteristics. The prevalence of acute cardiac manifestations at any time in the total cohort was 10%, ranging from 0-19% by division. There was a positive linear association between the proportion of youth in each division undergoing echocardiography and the proportion of those imaged who were subsequently diagnosed with new acute cardiac manifestations (Figure).

**Conclusion:** There is significant geographic variability in the use of peri-diagnostic echocardiograms in youth with SLE. Divisions with more widespread use of baseline echocardiograms diagnosed greater proportions of imaged youth with new acute cardiac manifestations following echocardiography. The results suggest the low frequency of cardiac diagnoses in divisions using few echocardiograms may partially reflect under detection. This underscores the need to obtain echocardiograms in large numbers of unselected youth with SLE to determine whether routine echocardiography is warranted to identify cardiac disease that would otherwise be missed or manifest in an acute clinical setting.

Table. Factors associated with use of baseline echocardiogram

	Univariable			Multivariable

## Blood Pressure Control over Time in Childhood-Onset Systemic Lupus Erythematosus

Pinar Ozge Avar Aydin<sup>1</sup>, Jian Shan<sup>2</sup>, Hermine I. Brunner<sup>1</sup> and Mark Mitsnefes<sup>3</sup>, <sup>1</sup>Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, <sup>2</sup>Peking Union Medical College Hospital, Peking, China, Peking, China, <sup>3</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular disease (CVD) is the leading cause of increased long-term morbidity and mortality in systemic lupus erythematosus (SLE). As an important modifiable risk factor for CVD, hypertension (HTN) is prevalent in patients with SLE and causes early cardiovascular aging and progression of the renal and cardiac disease. The aims of this longitudinal retrospective study were to determine the prevalence of HTN, evaluate longitudinal trend in blood pressure control, and assess risk factors for HTN in childhood-onset SLE (cSLE).

**Methods:** Between January 2012 and December 2016, demographic and clinical data of consecutive visits including sitting blood pressure, disease activity as measured by the SLE disease activity index (SLEDAI), presence of lupus nephritis, medication use, and results of the standard laboratory testing from cSLE diagnosis to the last visit were extracted from medical records of patients with cSLE admitted to the rheumatology clinic.

**Results:** 110 patients with cSLE were recruited: 79% female; 35% blacks; mean age at the baseline visit  $13.3 \pm 3.0$  years; median follow-up duration 29.5 months; 19% had lupus nephritis. Twenty-nine percent of patients had HTN and 23% had pre-hypertension at the baseline visit. Patients with HTN had higher disease activity, more frequent renal involvement, lower eGFR, and were more obese than patients without HTN. In the multivariate analysis, the presence of nephritis, obesity, and high extra-renal disease activity (SLEDAI score  $\geq 10$ ) were independent predictors of HTN at the baseline. No significant changes in blood pressure control were observed in patients without nephritis. Patients with nephritis had less stage 1 and 2 HTN, and more prehypertension at the last follow-up compared to the baseline.

**Conclusion:** While hypertension is known feature of lupus nephritis, our results indicate that hypertension is common and persistent in cSLE without kidney disease with about one third of patients having uncontrolled elevated BP almost 3 years after onset of lupus. In addition to renal disease, obesity and high overall disease activity were identified as independent predictors of HTN in these patients.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile-onset systemic lupus erythematosus (JoSLE) is associated with low bone mass for age and fractures, nevertheless risk factors and predictors of bone involvement are poorly understood in this condition. The aim of this study was to evaluate the risk factors for bone mass loss in patients with JoSLE analyzing clinical and laboratory data and bone microarchitecture parameters.

**Methods:** This study enrolled a sample of 49 female JoSLE patients, all of them with diagnosis, according to ACR classification criteria (2012 SLICC). All these patients were evaluated at baseline and after 3.5 years of follow-up in relation to: clinical data associated with the disease, lifestyle habits, treatment, laboratory tests including bone turnover markers (N-terminal propeptide of type 1 collagen - P1NP; C-terminal telopeptide of type 1 collagen - CTX), areal bone mineral density (aBMD) by dual X-ray absorptiometry (DXA) at lumbar spine and hip and parameters of bone microarchitecture by high-resolution peripheral quantitative computed tomography (HR-pQCT) at distal tibia and radius. Vertebral fractures were analyzed using DXA (VFA, Genant's method). aBMD changes above the least significant change were considered significant. Based on the difference between final and baseline aBMD value, the patients were divided into 3 groups: aBMD gain (BG), aBMD loss (BL) and aBMD no change (NC).

**Results:** The mean age of patients was  $18.7 \pm 3.3$  years and the mean disease duration was  $6.0 \pm 3.9$  years. Sixty-one percent of patients presented aBMD gain, 18.4% aBMD loss and 22.4% remained stable over this period of follow-up. Comparing the BL group with the BG group, there was a higher frequency of alcohol consumption (33.3 vs. 0%,  $p = 0.009$ ), a higher frequency of inadequate calcium intake (66.7 vs. 26.7%,  $p = 0.047$ ) and lower serum levels of baseline P1NP ( $52.42 \pm 33.56$  vs.  $119.72 \pm 85.78$  ng/mL,  $p = 0.036$ ) in the former group. Moreover, a worse evolution of HR-pQCT bone parameters: trabecular volumetric density at tibia ( $-16.36 \pm 15.71$  vs.  $-1.55 \pm 10.83$  mg/cm<sup>3</sup>,  $p = 0.003$ ) and cortical thickness at tibia ( $-0.025 \pm 0.09$  vs.  $0.054 \pm 0.07$  mm,  $p = 0.009$ ) was observed in the BL group. In addition, a higher frequency of renal activity was observed when the BL and NC groups were associated and compared to the BG group (52.6 vs. 23.3%,  $p = 0.036$ ). No significant differences were observed regarding other clinical, laboratorial and microarchitecture bone parameters and treatment.

**Conclusion:** This is the first longitudinal study in the literature that analyzed the risk factors of bone mass loss in JoSLE patients. The authors emphasize the importance of evaluating not only renal disease activity, but also lifestyle habits, mainly alcoholism and calcium intake in these young women. Furthermore, this study suggests that trabecular and cortical bone compartments were deteriorated in this disease and that low serum levels of P1NP may be a predictor of bone involvement in JoSLE.

## Investigating Time Trends in Incident Pediatric Lupus across Ethnic Groups in Toronto, Canada—a Large, Multiethnic Metropolitan Area

Laura Y Feldman<sup>1</sup>, Patrick Brown<sup>2</sup>, Linda T Hiraki<sup>1,3</sup> and Earl Silverman<sup>3</sup>, <sup>1</sup>Child Health Evaluative Sciences, The Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>Department of Statistical Sciences, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Division of Rheumatology, The Hospital for Sick Children, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Lupus incidence rates are known to differ by ethnicity among children and adults, with African ancestry as a risk factor for incident lupus, compared to those of European ancestry. Changes in a city's ethnic demographic over time make it challenging to determine if changes in lupus incidence rates over time reflect population ethnic groups changes. We aimed to investigate whether lupus incidence rates have increased over time and whether trends over time differed by ethnic groups in Toronto, Canada—a large, multiethnic metropolitan area served by a tertiary care, pediatric lupus clinic.

**Methods:** Demographic information, including sex, self-identified ethnicity, age at diagnosis and region of residence, were prospectively collected on all children aged <18 years who were diagnosed with lupus between 1994 and 2015 in the pediatric lupus clinic at the Hospital for Sick Children (SickKids), Toronto. Only children living in Toronto were included in this analysis; those travelling to SickKids from outside of Toronto were excluded. Overall lupus incidence rates and 95% confidence intervals (95%CI) were calculated using population denominators for Toronto that were obtained from the Census of Canada, which is conducted every

5 years. Rates by age, sex and ethnicity were also calculated. Poisson models were used to calculate incidence rate ratios (IRR) and 95%CI for the year of diagnosis, to investigate whether rates of lupus incidence changed over the study period. Interaction terms between the year and ethnicity were tested to determine whether time trends in the rates of incident lupus differed by ethnicity.

**Results:** From 1994 to 2015, 503 children living in Toronto were diagnosed with lupus at SickKids, corresponding to an overall lupus incidence rate of 1.92 per 100,000 person-years (95%CI 1.75–2.09). Overall lupus incidence rates were highest among Chinese (3.77, 95%CI 2.96–4.58) and Black (3.62, 95%CI 2.88–4.35) children and lowest among White children (0.74, 95%CI 0.59–0.88). After adjusting for sex and age at diagnosis, the lupus incidence rate was found to increase by 5% each year from 1994 to 2015 (IRR 1.05, 95%CI 1.03–1.06). Interaction terms between the year and ethnicity were not statistically significant.

**Conclusion:** Pediatric lupus incidence increased over time in Toronto. While lupus incidence rates were substantially higher among Black and Chinese children, compared to White children, trends in the increase of lupus incidence did not differ over time between ethnic groups, but may reflect the changing ethnic population in Toronto.

## Comparison of Clinical and Serological Features of Juvenile and Adult-Onset Neuropsychiatric Lupus in Spanish Patients

Sandra Garrote-Corral<sup>1</sup>, Alina Boteanu<sup>2</sup>, Walter A. Sifuentes-Giraldo<sup>1</sup>, Antía García-Fernández<sup>1</sup>, María Luz Gámir-Gámir<sup>1</sup> and Antonio Zea Mendoza<sup>1</sup>, <sup>1</sup>Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain, <sup>2</sup>Rheumatology, Hospital Universitario Ramon y Cajal, Madrid, Spain

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Neuropsychiatric (NP) manifestations are a main cause of morbidity and mortality in juvenile-onset systemic lupus erythematosus (jSLE). Some studies suggest that they are more frequent and severe in jSLE than in adult-onset SLE (aSLE). We performed a study to compare the clinical and serological profile of pediatric and adult patients with neuropsychiatric lupus (NPSLE) treated in a Spanish tertiary center.

**Methods:** A retrospective study of patients with jSLE (age of onset: 0-18y) and aSLE (age of onset: >18y) seen in our center during the period 1988-2016 was performed. Case definitions of the American College of Rheumatology were used to identify NPSLE manifestations. Demographics, clinical and serological data were obtained through a review of their medical records.

**Results:** A total of 69 patients with NPSLE were included, aSLE 41 (59%) and jSLE 28 (41%), the comparison of groups is presented in the table. Most of them were Caucasian (92%), mean age at diagnosis in adults was 36.4 years (range: 19-68) and 13.9 years (range: 8-18) in children. The proportion of males was higher in the latter group. The mean duration of the disease was significantly greater in adults, as well as the time from SLE diagnosis to NP manifestation onset, although without significant difference. Central NP manifestations were the most frequent in both groups (aSLE 93%, jSLE 96%) regarding to the peripheral manifestations (aSLE 12%, jSLE 11%). The most frequent manifestations in aSLE were headache (29%), cerebrovascular disease (27%), seizures (17%) and myelopathy (15%), whereas in jSLE were seizures (46%), headache (29%), mood disorder/depression (25%), psychosis (18%) and autonomic disorders (18%). A significant group of patients presented  $\geq 2$  central manifestation during their evolution (aSLE 32%, jSLE 41%), with the mean number of manifestations in adults being 1.36 (range: 1-3) and in children 1.44 (Range: 1-4). Patients with jSLE developed lupus nephritis (LN) with a significantly higher frequency, as well as higher titres of anti-DNA antibodies, erythrocyte sedimentation rate (ESR) and hypocomplementemia. During the study period there was mortality in 2 cases of aSLE and 2 jSLE (5% and 7%, respectively).

	Juvenile NPSLE	Adult NPSLE	p-value
N° of patients	28 (41%)	41 (59%)	-
Women:men	20:8	39:2	0.0060*
Time of disease (months)	19.8	232.5	0.0001*
NP manifestations at onset	7 (25%)	11 (27%)	0.8651
Time from diagnosis to NP manifestation (months)	42.4	87.1	0.1268
Lupus nephritis	16 (57%)	9 (22%)	0.0028*
Antiphospholipid syndrome	5 (18%)	10 (24%)	0.5182
ANA $\geq$ 1/1280	8 (29%)	11 (27%)	0.8736
Anti-DNA ab (IU/ml)	178.9	39.4	0.0005*
Anti-Ro/SSA ab	10 (36%)	17 (41%)	0.6308
Anticardiolipin ab	4 (14%)	10 (24%)	0.3054
Anti- $\beta$ 2 glycoprotein I ab	5 (18%)	7 (17%)	0.9328
Lupus anticoagulant	8 (29%)	10 (24%)	0.6977
Cryoglobulins	6 (21%)	3 (7%)	0.0874
ESR (mm/h)	53.8	35.7	0.0199*
CRP mg/l	4.6	4.7	0.9687
C3 low (< 80 mg/dl)	22 (79%)	16 (39%)	0.0012*
C4 low (< 16 mg/dl)	22 (79%)	13 (32%)	0.0001*

**Conclusion:** Our results corroborate that juvenile patients with NPSLE present higher disease activity compared to adults. There was no significant difference in the time from SLE diagnosis to NP manifestation onset, but tended to be shorter in jSLE. The spectrum of NPSLE was varied both groups and an important proportion developed  $\geq 2$  manifestation. Mortality continues to be important in NPSLE in both age groups.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Genome-wide association studies have identified nearly 60 susceptibility loci for systemic lupus erythematosus (SLE). However, few studies have investigated their influence on specific disease manifestations. Antiphospholipid

antibodies (aPL) are present in 30-40% of those with SLE and are major risk factors for thrombosis in childhood-onset SLE (cSLE). We hypothesized that SLE susceptibility loci are also associated with antiphospholipid antibody-positivity in cSLE.

**Methods:** We tested 41 SLE-related single nucleotide polymorphisms (SNPs) for association with lupus anticoagulant (LA) positivity and the presence of anti-cardiolipin (aCL) antibodies among cSLE patients diagnosed and followed at the Hospital for Sick Children, Toronto. Participants were genotyped on the Illumina Immunochip. Untyped SNPs were imputed from a 1000 genomes reference panel. Associations between SNPs and antibody status (positive/negative) were tested individually under the additive model and in a weighted genetic risk score.

**Results:** Among our sample of 348 cSLE patients, 56 were positive for LA and 144 were aCL-positive. The median age of SLE diagnosis was 13 (interquartile range: 11 – 15) and 19% were male. Of the 41 SNPs tested, 38 were genotyped or imputed with high quality. A one unit increase in SLE genetic risk score was associated with a 20% increase in odds of LA positivity (odds ratio (OR) 1.20; 95% CI: 0.88, 1.64) and a 13% increased odds of aCL (OR 1.13, 95% CI: 0.90 – 1.44) after adjustment for sex, age of SLE onset and ancestry. Though few were statistically significant, suggestive associations with antibody status were also seen for several of the individual SNPs included in the genetic risk score.

**Conclusion:** Our findings suggest that specific genetic variants related to SLE onset may underlie the development of aPL in cSLE patients.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is a chronic, heterogeneous, multisystem autoimmune disease characterized, in part, by the presence of autoantibodies. The spectrum of disease presents a challenge when discussing disease course, outcomes and treatment. While autoantibody clusters have been described in adult lupus, there is little data examining relationships among specific autoantibody clusters and disease manifestations in pediatric SLE (pSLE) patients. The objective of this study is to identify distinct autoantibody clusters and their role in the development of unique disease profiles within an exclusively pSLE cohort.

**Methods:** We conducted a cross-sectional analysis of pSLE patients in the CARRA legacy database (of N=989), ages 1-19 years. Patients without a complete autoantibody profile (including anti-dsDNA, anti-Smith, anti-RNP, anti-Ro, and anti-La antibodies) were excluded. A cohort of 198 patients were analyzed. Two-step cluster analysis was performed to identify subsets of patients with similar autoantibody patterns. Additional frequency analysis and logistic regression were completed to assess for cluster/disease manifestation associations.

**Results:** Demographic variables were similar between the entire pSLE cohort and the subset of 198 patients included in our analysis. Anti-dsDNA was the most prevalent autoantibody (66.2%), followed by anti-Smith (50%), Anti-RNP (47%), anti-RO (45%), and

anti-LA (23.2%). The most prevalent manifestations were immunologic disorder (86.9%), hematological disorder (65.7%), arthritis (64.1%), renal disorder (54%), and malar rash (45.5%). Four distinct antibody clusters were identified: Cluster 1 (all 5 antibodies present, n=53), Cluster 2 (anti-RNP, anti-Smith, anti-dsDNA, n=50), Cluster 3 (anti-dsDNA only, n=51), and Cluster 4 (anti-Ro, anti-La, anti-RNP and anti-dsDNA, n=44). The distribution of African American patients was statistically different across clusters, with the lowest percentage in cluster 3 ( $p=0.0067$ ). There were roughly twice as many white patients in cluster three as in the other three clusters with a  $p$ -value approaching significance ( $p=0.0634$ ). Patients in Cluster 1 were on average younger than patients in Cluster 2 at age of onset and at first visit to a rheumatologist. Clusters 2 and 3 had the highest frequency of neuropsychiatric manifestations (40% and 50%, respectively). The remaining clinical manifestations were equally distributed among clusters. For individual antibodies, patients with an anti-La antibody were 61% less likely to develop arthritis and 79% less likely to develop serositis. Patients were three times more likely to have hematological manifestations when anti-RNP antibodies were present, and 73% less likely if anti-Smith antibodies were present.

**Conclusion:** Our data suggests that autoantibodies in pSLE do tend to cluster, which could potentially represent subsets of disease. However, in our sample, there was not a robust correlation amongst clinical manifestations and clusters. Future research is needed to better define these clusters in larger populations.

## Patient Health Questionnaire-9 Utilization for the Detection of Depression in Adolescents and Young Adults with Lupus Nephritis

Peter Yorgin<sup>1</sup>, Eleanor Lazarow<sup>2</sup> and Robert Sheets<sup>3</sup>, <sup>1</sup>Pediatrics, Rady Children's Hospital/University of California San Diego, San Diego, CA, <sup>2</sup>Social Work, Rady Children's Hospital, San Diego, CA, <sup>3</sup>Pediatrics, Rady Children's Hospital/UCSD, San Diego, CA  
**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The PHQ-9 is a self-administered depression screening questionnaire. Patients with a PHQ-9 score of 0-4 have no depression, 5-9, mild; 10-14, moderate; 15-19, moderately severe; and 20-27, severe. A score  $\geq 10$  has a sensitivity of 88% and a specificity of 88% for major depression. Hypothesis: The PHQ-9 is a useful screening tool to identify depression in pediatric LN patients.

**Methods:** A retrospective study cohort was identified using Slicer Dicer, an electronic medical record tool. Between 11/30/14 and 5/30/16, out of 1,602,679 in the database, there were 94 patients with LN. 60 subjects remained after exclusion criteria were applied. Data from a hospital survey of all Nephrology and Rheumatology patients, after introduction of the PHQ-2 score (5/1/16 to 1/31/17), was analyzed.

**Results:** 50 subjects were female, 10 were male, with a mean age of  $17.4 \pm 3.4$  yrs. 39 subjects (65%) were Hispanic.

29 subjects (48% of all subjects) had a diagnosis of depression discoverable in EMR notes but only 14 subjects (23%) had a diagnosis of depression in their problem list. Only 2 of the 10 males had a diagnosis of depression.

Of the 45 of the 60 patients (75%) seen in the lupus multidisciplinary clinic, 27 of the 45 (60%) subjects had  $\geq 1$  PHQ-9 result. The 27 subjects (48%) who had discoverable PHQ-9 results, were not more likely to have a diagnosis of depression than those subjects who did not have PHQ-9 screening testing ( $p = 0.11$ ). Only 2 of 15 (13%) subjects not followed in lupus clinic had  $\geq 1$  PHQ-9 value ( $p=0.0024$ ). 2 the 7 subjects had PHQ-9 values recorded after referral to the Lupus Transition Clinic.

18 PHQ-9 values were  $\geq 10$  (14 moderate depression, 4 moderately severe depression, mean PHQ-9:  $5.1 \pm 5.1$ ). 8 patients were not previously known to be depressed and 2 patients were suicidal. There was dramatic PHQ-9 score variability over time.

The PHQ-9 was made available to other sub-specialty groups once the study was presented to the hospital EMR group. Patient demand quickly outstripped the supply of psychiatric resources. The PHQ-9 was removed and PHQ-2 was substituted (Table 1) while a behavioral referral pathway was created.

Study patients using the PHQ-9 were more likely to report depression than general Rheumatology ( $p < 0.01$ ) or Nephrology ( $p < 0.01$ ) patients using the PHQ-2.

**Conclusion:** Slicer Dicer is a quick and effective means to identify study populations of interest in EPIC.

30% of subjects had PHQ-9 scores  $\geq 10$  and cases of new depression were detected. Thus, the PHQ-9 was a useful tool to identify LN patients with depression.

The use of the PHQ-9 questionnaire was used more often in a multidisciplinary LN setting with social workers and a physician “champion” for PHQ-9 use.

Hospitals utilizing the PHQ-9 need to be ready with increased psychological services for the newly identified patients who are depressed.

It is unclear if the PHQ-2 is equally useful in identifying depressed LN patients.

Key study limitations include: the failure to utilize the PHQ-9 for all LN patients and visits, some PHQ-9 were completed by nurses or social workers acting as a scribe for the patient, there was no evaluation of relationship between PHQ-9 values and SLEDAI-2K values and corticosteroid doses.

## **Anti-MDA5 Autoantibodies Associated with Juvenile Dermatomyositis Constitute a Distinct Phenotype in North America**

Gulnara Mamyrova<sup>1</sup>, Takayuki Kishi<sup>2</sup>, Ira N Targoff<sup>3</sup>, Rodolfo V Curiel<sup>4</sup>, Frederick W Miller<sup>2</sup> and Lisa G Rider<sup>2</sup>, <sup>1</sup>Rheumatology, George Washington University School of Medicine and Health Sciences, Washington, DC, <sup>2</sup>Environmental Autoimmunity Group, National Institute of Environmental Health Sciences, National Institutes of Health, Bethesda, MD, <sup>3</sup>VA Medical Center, University of Oklahoma Health Sciences Center, and Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>4</sup>George Washington University School of Medicine and Health Sciences, Washington, DC

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-MDA5 autoantibodies (Abs) have been associated with clinically amyopathic and classic dermatomyositis (DM), with rapidly progressive interstitial lung disease (ILD) and poor prognosis in Japanese patients (pts). The aim of this study was to examine the frequency and characteristics of anti-MDA5 Abs associated with juvenile DM (JDM) in North America.

**Methods:** Demographic, clinical, laboratory and outcome features of 34 pts with anti-MDA5 Abs were compared to those of 60 Ab (MSA/MAA) negative, 164 anti-p155/140 Ab+ and 116 MJ Ab+ JDM and JCTM/DM pts meeting probable or definite Bohan and

Peter criteria. Differences were evaluated by Fisher’s exact and Mann-Whitney tests. Kaplan-Meier and Log-rank tests were used for time-to-event treatment analysis. Myositis Abs were tested by standard immunoprecipitation (IP) and MDA-5, p155/140 and MJ Abs tested by reverse IP-immunoblot. Significant univariable results were examined in multivariable logistic regression.

**Results:** Anti-MDA5 Abs were identified in 34 (7.5%) pts from a cohort of 453 JDM and JCTM/DM pts. Characteristics of MDA5 Ab+ compared to MSA/MAA-, anti-p155/140 Ab+ and anti-MJ Ab+ pts are shown in the Table. MDA5+ were older at diagnosis and had a slower disease onset compared to p155/140 + and MJ Ab+. Anti-MDA5 Ab+ had lower serum CK levels and more frequent fever, weight loss, adenopathy, arthralgia, arthritis, abnormal PFTs, dyspnea, ILD compared to MSA/MAA-, p155/140+ and MJ Ab+. The median skeletal, pulmonary, constitutional and overall total clinical system scores at diagnosis were higher in MDA5 Ab+ (p<0.0001). There were no differences in gender distribution, delay to diagnosis, and onset severity among the four groups. Total number of medications received was fewer (4.0 [IQR 3- 6] vs.5.0 [IQR 4- 8], p=0.04), treatment duration was shorter (23.2 mths [IQR 13- 54] vs. 38.2 [IQR 22- 66], p=0.04) in MDA5 Ab+ vs. p155/140 Ab+. MDA5 Ab+ had fewer flares (48% vs. 71%, p=0.035) and shorter time to discontinue steroid therapy (24.7 mths [IRQ 16-37] vs. 33.0 [IRQ 18-61], p=0.046) vs. p155/140 Ab+. Multivariable analysis revealed weight loss, arthritis and lower serum CK level as significantly associated with anti-MDA5 Ab+ vs Ab-, whereas weight loss, arthritis, arthralgia, ILD were significantly associated with anti-MDA5 Ab+ vs. p155/140 Ab+, and weight loss, arthritis, ILD, lower serum aldolase level, older age at diagnosis were significantly associated with anti-MDA5 Ab+ vs. MJ Ab+. There were no differences in disease course, status at most recent evaluation, and mortality of MDA5 Ab+ vs. other Ab groups.

**Conclusion:** Anti-MDA5 Abs are seen in a distinct subset of JDM with frequent arthritis, arthralgia, weight loss, adenopathy, and ILD, but lower serum CK and aldolase. MDA5+ have comparable outcomes, but with the ability to discontinue steroids more rapidly and less frequent flares compared to p155/140 Ab+ pts.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The impetus for this investigation was the specific questions from parents of JM patients pertaining to the physician's expectations about their child's disease course. The data in this study provides a window with which to study the anatomy of the first five years of response to current therapies available for JM children, classified by Myositis Specific Antibody (MSA).

**Methods:** Two groups: inception patients since diagnosis (n=36); referral patients (n=65) were assessed at diagnosis/referral and at 6, 12, 24, 36, 60 months. MSA was determined by immunoprecipitation and immunoblot (Oklahoma Research Lab). Nailfold capillary end row loops (ERL) were assayed using a Nikon Coolpix P6000 camera attached to a DermLite II ProHR (18x). TNF- $\alpha$ -308 (A/G) polymorphisms in the promoter region were determined as previously reported. Calcifications: Physician inspection identified the calcific deposits, or when clinically appropriate, they were located by radiographic study, and designated as mild, moderate or severe. Lunar Prodigy measured bone mineral density. Data Collection and Analysis: Study data was prospectively obtained and stored in a MEDLOG database. Statistical analysis was performed using R version 3.3.1 ([www.r-project.org](http://www.r-project.org)). For each clinical variable, a two sample t-test or the Wilcoxon Rank Sum test was performed as appropriate for the comparison between two defined patient groups. To test for the equality of more than two means, Tukey's HSD test in conjunction with ANOVA was performed for all pairwise comparisons among means

**Results:** The 2 groups were similar: myositis onset age, race, gender, duration of untreated disease, abnormal MRI and initial Disease Activity Scores (DAS). The inception group had higher values for SGOT (p=0.008), CPK (p=0.014), LDH (p=0.0014), aldolase (p=0.0076) and neopterin (p=0.0033) than the referred. By 60 months, the referral DAS total score > inception (p=0.05). Myositis specific antibody (MSA) frequencies for the 93 juvenile dermatomyositis (JDM): negative (33.3%); combination of anti p155/140 and anti-Mi-2 (positive or indeterminate) (6.5%); p155/140+ (40.9%), Mi-2 (6.5%); MJ (11.8%), MDA5 (1.1%). The eight U1RNP overlap myositis patients had a higher DAS muscle score at 60 months than MSA negative (p=0.008), and anti p155/140 (p=0.002). Disease/treatment related damage: cataracts (35%), lipodystrophy (30%), fractures (28%), abnormal pulmonary function (2/19 tested; 10.3%), and calcification (17%). At 60 months, chronic calcifications (n=7) were associated with decreased mean nailfold capillary end-row loop (ERL) count (p=0.002) and lipodystrophy (p=0.027).

## Conclusion:

Conclusion: 1) At 60 months, referral JDM and overlap patients each had a higher DAS, but all patients improved; 2) 21.7% had > 1 MSA; 3) cataracts and lipodystrophy were each present in 30% patients; 4) ERL count  $\leq 5$  was associated with calcinosis; 5) lipodystrophy was associated with calcinosis, but not ERL count.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile dermatomyositis (JDM) is a rare autoimmune disease of unknown origin, characterised primarily by cutaneous rashes and symmetrical weakness of the proximal skeletal muscles. Other organs can also be affected with characteristic changes in the involved tissues, in which local inflammation and impaired microcirculation probably have pathogenic role. Microvascular abnormalities are easily assessable in the nail folds by capillaroscopic examination (Nail Fold Capillaroscopy, NFC), and might mirror microvascular involvement in other organs. We aimed to examine the association between alterations in nailfold capillary network and pulmonary and cardiac involvement in JDM patients with medium- to long-term disease duration.

**Methods:** Fifty-nine JDM patients were examined after disease onset median 16.8 (2-38) years. Nailfold capillary density (NCD) was assessed by NFC and patients were divided into 'Low NCD' (<6.0 cap/mm) and 'Normal NCD' (≥6.0 cap/mm) groups. Pulmonary involvement was assessed by pulmonary function test (PFT; forced vital capacity, FVC; total lung capacity, TLC; diffusing capacity for carbon monoxide, DLCO) and high resolution CT imaging (interstitial lung disease, ILD; airway disease). PFT parameters are presented as predictive values. Additionally, the patients were also grouped by PFT values: a 'low' value was defined as less than the 5<sup>th</sup> percentile of the predicted value. Cardiac measures included echocardiography and conventional, as well as Holter ECG measures. Systolic cardiac function was assessed by long axis strain (LAS), diastolic function was measured by early diastolic tissue velocity (e'). Arrhythmias and heart rate variability were assessed by ECG.

**Results:** The low NCD group presented lower FVC and TLC without difference in FVC/DLCO ratio. Moreover, patients with low NCD presented more frequently low DLCO and abnormalities in PFT/HRCT than those patients with normal NCD. There were no significant association between NCD and cardiac measures.

**Conclusion:** Nail fold capillary alterations in JDM patients after median 16.8 years disease duration was associated with pulmonary involvement, and might be a useful tool to detect patients at risk for pulmonary complications. Further studies are needed to confirm the applicability of NCD as a biomarker for lung involvement in JDM after medium to long term disease duration.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Juvenile myositis (JM) is marked by skin rashes, proximal muscle weakness, and deconditioning causing potentially severe disability. Studies examining long-term physical function in JM remain scant. This study aims to define longitudinal predictors of physical function in JM.

### **Methods:**

JM patient data collected prospectively at routine clinic visits from January 2000 to June 2014 at Ann & Robert H. Lurie Children's Hospital of Chicago was used in this study. Only patient visits with documented Childhood Health Assessment Questionnaire (CHAQ) summary scores were included for analysis. Demographic/clinical variables were extracted, including: gender, race, duration of untreated disease, Disease Activity Score (DAS) - muscle/skin domains, Childhood Myositis Assessment Scale (CMAS), muscle enzymes (i.e. CPK, AST, LDH, aldolase), nailfold capillary end row loops (NFC-ERL), von Willebrand factor antigen (vWFag), calcinosis, lipodystrophy, possible markers of disease severity (i.e. NK cell absolute counts, TNFalpha-308A allele), and treatments. Descriptive statistics were calculated. CHAQ was dichotomized (0 vs. >0) as most scores equaled zero. Generalized estimating equations for binary data specifying logit link function were used to evaluate effects for each covariate with a main effect for time. Covariates were univariably analyzed at  $p < 0.10$ , with all univariably significant covariates entered into a multivariable model for CHAQ > 0 using a manual backward selection method.

### **Results:**

Table 1 describes the study sample (i.e.  $n = 187$  patients with 2293 study visits and median follow-up 3.58 years). The following univariably significant covariates (at  $p < 0.10$ ) were included in the multivariable model: time (years from visit 0) ( $p < 0.0001$ ), black race ( $p = 0.035$ ), DAS-skin ( $p = 0.006$ ), DAS-muscle ( $p < 0.0001$ ), CMAS ( $p < 0.0001$ ), LDH ( $p = 0.005$ ), aldolase ( $p = 0.013$ ), NFC-ERL ( $p = 0.002$ ), abnormal vWFag ( $p = 0.0001$ ), lipodystrophy ( $p < 0.0001$ ), cyclosporine ( $p = 0.0725$ ), and IV solumedrol ( $p = 0.0002$ ). Complete data for the multivariable model was available for 892 study visits from all 187 unique patients. Significant adjusted associations persisted in the multivariable model for CMAS (OR: 0.91,  $p < 0.0001$ ), aldolase (OR: 1.1,  $p = 0.0024$ ), and lipodystrophy (OR: 2.2,  $p = 0.0126$ ), with a trend towards significance for NFC-ERL (OR: 0.84,  $p = 0.0502$ ).

### **Conclusion:**

To our knowledge, this is the largest longitudinal study of prospectively collected physical function data yet reported in JM. Measures of muscle weakness/inflammation (i.e. CMAS, aldolase) predict long-term physical function. The relationships between lipodystrophy, vasculopathy (i.e. NFC-ERL), and physical function warrant closer attention and replication.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Children with juvenile dermatomyositis (JDM) are at risk of growth failure and delayed puberty because of inflammatory disease activity and side effects of corticosteroid treatment. Knowledge on growth and pubertal development in JDM is very limited. Our aim was to study growth and puberty in a multicenter longitudinal prospective cohort of juvenile dermatomyositis (JDM).

**Methods:** Anthropometric and pubertal data in children <sup>2</sup>18 years with recent onset or flare of JDM from 31 countries were studied. Growth failure was defined as parent-adjusted z-score < -1.5, and height deflection z-score < -0.25/year.

**Results:** Height and weight from four follow-up visits during two years in 196/275 (71.3 %) of the children included in the original JDM study were analyzed. There was a significant reduction in parent-adjusted height z score over time in females (p<0.0001) and males (p=0.001) with significant gender difference (p<0.05), but also catch-up growth at the final study visit were seen. Median BMI z score peaked at 6 months (p<0.0001) and was still significantly above baseline at the final study visit at a median of 26 months (p=0.007) with no gender difference. Females with a disease duration <sup>3</sup>12 months after onset had significantly lower parent-adjusted height z score (p=0.002) with no catch-up growth. Delayed pubertal onset, pubertal duration and delayed menarche was found in a substantial number of the participants as shown in the table. Growth failure at base line was the main determinant of growth failure at the final study visit (OR: 53.4).

**Conclusion:** Children with JDM of long duration are at high risk of having a lower than expected height and a delayed pubertal development.

**TABLE** Growth and pubertal characteristics at the final study visit of 196 participants in a longitudinal JDM cohort

	Girls (N=116)	Boys (N=80)
Growth failure	20/97 (20.6%)	11/73 (15.1%)
Height deflection	29/116 (25.0%)	25/80 (31.3%)
Age at B2 females(n=37)/ T2 males (n=23), mean (SD)	11.1 (1.9)	12.8 (1.6)
Menarche registered	31/55 (56.4%)	n.a.
Delayed menarche	7/31 (22.6%)	n.a.
Late pubertal onset	23/37 (62.2%)	15/23 (65.2%)
Delayed puberty	20/55 (36.4%)	11/27 (40.7%)

Numbers are frequencies (%) unless otherwise specified. Delayed menarche was defined as age of menarche >14 years, delayed pubertal onset was defined as age at Tanner B2 >12 years or age at Tanner T2 >13 years, delayed puberty was defined as a delay in pubertal onset, pubertal tempo or menarche.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile dermatomyositis (JDM) is the most common idiopathic inflammatory myopathy in children. Approximately one-third of JDM patients attain drug-free remission (DFR) without relapse; however, there exist patients who are refractory to glucocorticoid therapy with or without immunomodulating agents. The purpose of this study was to examine the risk factors for achieving DFR in patients with JDM.

**Patients and Methods:** JDM patients referred to the Kagoshima University Hospital between 1994 and 2015 were enrolled. Demographic, clinical and laboratory data were retrospectively collected from medical records. DFR was defined as a condition that patients maintained symptom-free status with normal laboratory test for at least 1 year after withdrawal of all medications. The following parameters were evaluated as the related factors for achieving DFR in JDM patients: sex, age at onset, disease duration and clinical manifestations at starting therapy, laboratory data such as creatine kinase (CK) and aldolase (ALD), and initial treatment (intravenous methylprednisolone pulse therapy and/or methotrexate). Episodes of disease relapse and development of subcutaneous calcinosis during the disease course was also analyzed. Mann-Whitney U test and Chi-square test were used for comparison of

continuous and categorical variables, respectively. Cumulative DFR rates were analyzed by Kaplan-Meier methods with log-rank test.

**Results:** A total of 40 JDM patients (18 male and 22 female patients) were involved. The mean age at onset was  $6.2 \pm 4.1$  years, and the mean disease duration at starting the therapy was  $0.6 \pm 0.8$  years. During the entire observation period, 22 patients had achieved sustained DFR (DFR group) while 18 patients were still on medication at the final visit (no-DFR group). Cumulative DFR rates of all patients were 21.6%, 35.6% and 58.6% at 3, 5 and 7 years after initiation of drug therapy, respectively. There were no significant differences between DFR group and no-DFR group with regard to sex, age at onset, disease duration by starting initial therapy, the presence or absence of skin ulcer and interstitial pneumonia. As to laboratory tests, the maximum serum levels of ALD (ALDmax) were significantly higher in no-DFR group than that in DFR group ( $p=0.0202$ ), though the serum CKmax showed no difference between the two groups. In addition, Kaplan-Meier analysis revealed that the cumulative DFR rates were significantly lower in patients with  $ALD_{max} \geq 20$  IU/L ( $p=0.0079$ , Figure 1) and patients with relapse ( $p<0.0001$ ) or subcutaneous calcinosis ( $p=0.0035$ ) during the disease course.

**Conclusion:**  $ALD_{max} \geq 20$  IU/L at starting therapy, and presence of episodes of relapse or subcutaneous calcinosis during the disease course may be predictors for a refractory disease course in JDM. Therefore, more prolonged and/or more aggressive therapies are needed to attain DFR in these patients.

**Figure 1. Cumulative drug-free remission rates and serum maximum aldolase levels.** Cumulative drug-free remission (DFR) rates were analyzed according to the serum maximum levels of aldolase ( $ALD_{max}$ ) at starting therapy. Less patients with  $ALD_{max} \geq 20$  IU/L attained DFR.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To analyze the clinical outcomes of TNF-inhibitors as a steroid-sparing agent in the treatment of juvenile dermatomyositis (JDM).

**Methods:** We performed a retrospective chart review on a total of 15 patients from 1997 to 2011 who were diagnosed with probable or definite JDM based on the Bohan and Peter criteria (1975). All patients were between the ages of 3-16 years at diagnosis and had exposure to TNF-inhibitor therapy. Patient demographic information, clinical history, medication history including dose, time between diagnosis and TNF-inhibitor use, and significant adverse events were reviewed. Outcome was defined based on medication changes, clinical history, and presence of adverse events.

**Results:** Infliximab was the most frequently administered TNF-inhibitor. Ten patients were treated with infliximab, four with etanercept, and one with adalimumab. Infliximab dose ranged from 3 to 15mg/kg/dose every 4 weeks. Twelve of 15 patients had at least a 50% reduction in oral steroid dose after TNF therapy and 20% of all patients were able to stop all medications. In the infliximab cohort, 60% were able to discontinue steroids and 30% were able to reduce the steroid dose by half. Among patients that improved, average time from diagnosis to initiation of TNF therapy was 12 ( $\pm$ 11.6) months. All patients received methotrexate and oral steroids prior to initiation of an anti-TNF agent. In addition, 10 patients were previously treated with IV methylprednisolone (IVMP), 10 with IV immunoglobulin, and 5 with hydroxychloroquine. Three patients were on IVMP at the start of TNF therapy and two discontinued the IVMP infusions while taking biologics. Three patients had infections that resulted in discontinuation of anti-TNF medications. Two patients, both taking infliximab, required hospitalization. There were no reported deaths or incidence of malignancy. In all patients, TNF therapy was held for infection and was not restarted due to baseline stability of disease.

**Conclusion:** JDM is the most common inflammatory myopathy in children. It is a multisystem disorder associated with significant morbidity and risk of long-term disability if untreated. In this cohort, TNF-inhibitors were typically used as a 3<sup>rd</sup> or 4<sup>th</sup> line therapy. The majority of infliximab-treated patients had a substantial decrease in overall steroid exposure and a significant percentage were able to stop steroids. Infection was the most common adverse event reported but this did not lead to any life-threatening morbidity and reversed after discontinuing the biologic. The use of TNF-inhibitors in JDM patients is still controversial. However, this data supports further investigation into the use of TNF-inhibitors, particularly infliximab, as a therapeutic option in children with refractory JDM.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile systemic sclerosis (jSSc) is a severe and heterogeneous autoimmune vasculopathy. Pulmonary fibrosis is the highest independent predictor of mortality, yet currently there are no known biomarkers associated with organ involvement, response to therapy, or prognosis in jSSc. CXCL4 is a chemoattractant for neutrophils and fibroblasts. Elevated peripheral levels of CXCL4 have been associated with pulmonary fibrosis, pulmonary hypertension, and overall disease progression in adult SSc. The purpose of this study was to evaluate whether CXCL4 levels are elevated in jSSc patients as compared to healthy pediatric controls and patients with other rheumatologic illnesses, and to determine whether there is an association with jSSc disease manifestations.

**Methods:** In this multi-center case-control study, plasma samples from 28 patients with jSSc, 26 with localized scleroderma (jLS), 36 with juvenile systemic lupus erythematosus (jSLE), and 35 age-matched healthy controls were tested for CXCL4. Testing was done on a Luminex 200 luminometer (Eve Technologies, Calgary, AB). CXCL4 plasma concentration was compared between diseases and controls. The CXCL4 level was then correlated with specific disease manifestations, including the presence of pulmonary hypertension and pulmonary fibrosis on HRCT.

**Results:** The mean ( $\pm$  95% CI) level of CXCL4 in jSSc patients was  $24,358 \pm 6047$  ng per milliliter, which was significantly higher than in controls ( $12,455 \pm 5032$  ng/mL;  $p=.001$ ). Mean CXCL4 in both jLS patients ( $20,692 \pm 4513$  ng/mL) and in jSLE ( $18,165 \pm 4360$  ng/mL) were also significantly higher than in controls, but to lesser extent ( $p=.01$  and  $p=.04$ , respectively). When the Bonferroni correction was applied, only the jSSc cohort was significantly different from controls. There was no significant difference in CXCL4 level between the sub-classifications of jSSc (diffuse versus limited cutaneous SSc). Within the jSSc cohort, there were three patients with PH and a mean CXCL4 level of  $41,768$  ng/mL (range  $3,472 - 79,585$ ), compared to  $24,565 \pm 19,731$  ng/mL for 17 patients with pulmonary fibrosis, and  $24,600 \pm 8,927$  ng/mL for patients without cardiopulmonary involvement.

**Conclusion:** Levels of plasma CXCL4 were elevated in patients with jSSc and, in a small number of patients, were higher with the presence of pulmonary hypertension. Levels did not correlate with HRCT-confirmed pulmonary fibrosis in this cohort. These findings suggest that CXCL4 may have value as a biomarker in jSSc, but further prospective studies of an inception cohort are needed.

## Assessing the Prevalence of Juvenile Systemic Sclerosis in Childhood Using Administrative Claims Data from the United States

Ivan Foeldvari<sup>1</sup>, Timothy Beukelman<sup>2</sup> and Fenglong Xie<sup>3</sup>, <sup>1</sup>Hamburg Center for Pediatric and Adolescent Rheumatology, Hamburg, Germany, <sup>2</sup>Pediatric Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Juvenile systemic Sclerosis (jSSc) is an orphan disease. There are some data regarding the incidence, but nearly no data exist regarding the prevalence of jSSc. To plan prospective trials, it is very important to gain data regarding the prevalence of jSSc.

### Methods:

We used Truven MarketScan® commercial insurance claims data from the United States for the years 2010 through 2014, inclusive. In each individual calendar year, we identified all persons in the claims data who were less than 16 years old. Among these persons, we identified all persons with at least 1 physician diagnosis code for systemic sclerosis (ICD-9 710.1) and then removed any person with a diagnosis code for localized scleroderma (ICD-9 701.0). From this remaining group of patients, we identified patients with at least one filled prescription or infusion claim for immunosuppressant medications often used to treat systemic sclerosis, namely methotrexate, mycophenolate mofetil, or cyclophosphamide. We assumed these children had jSSc and calculated the estimated prevalence and 95% confidence interval using a Poisson distribution.

## Results:

The results for each calendar year are shown in the Table. Very few children received diagnosis codes for systemic sclerosis. Approximately 70% of these patients did not have concurrent diagnoses of localized scleroderma, but only approximately 14% of those had treatment with immunosuppressant medications often used to treat systemic sclerosis. The prevalence estimates were approximately 3 per 1 million children and were relatively stable from year to year.

Year	N of Total Children	Diagnosis Code for Systemic Sclerosis	No Diagnosis Code for Localized Scleroderma	Use of Methotrexate, Mycophenolate Mofetil, or Cyclophosphamide	Estimated Prevalence per 1,000,000 Children [95% CI]
2010	5,888,868	254	186	23	3.9 [2.5-5.9]
2011	6,231,475	249	185	22	3.5 [2.2-5.3]
2012	6,278,116	217	170	26	4.1 [2.7-6.1]
2013	4,950,018	175	120	17	3.4 [2.0-5.5]
2014	4,933,522	138	91	14	2.8 [1.6-4.8]

## Conclusion:

Using diagnosis codes and medication usage from administrative claims, we estimated the prevalence of jSSc to be approximately 3 per 1 million children.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

In adult systemic scleroderma patients male have a more severe course. This issue was never evaluated in a larger juvenile scleroderma cohort.

## Methods:

Patients with jSSc were included worldwide to the jSScI cohort. We compared the demographics and clinical characteristics of male and female dcjSSc patients at the time of the enrollment into the jSScI.

## Results:

Sixty-two dcjSSc patients were enrolled Up till April 2016. 11/62 (18%) of the patients were male (M) and 51/62 female (F) (82%). The mean age of the onset of Raynaud symptoms was 8.0 in M and 9.4 years in the F patients and the non-Raynaud symptoms was 8.2 in M and 10.0 in F patients. At the time of the enrollment the mean MRSS was 24.3 in M and 17.3 in F patients. Anti-Scl 70 positivity was found in 4/11 (36.4%) in M and 14/49 (28.6%) in F patients. Anticentromere positivity occurred in 2/11 (18.2%) in M and 0/23 (0%) in F patients ( $p=0.035$ ). Capillary changes were present in 8/11 (73%) of the M and 30/51 (59%) of F patients, but 36% of M and F had already history of ulcerations. 7/11 (64%) of the M and 21/51 (41%) of the F patients had cardiopulmonary involvement. pulmonary hypertension occurred in F patients ( $n=6$ ). 7/11 (64%) of M and 11/51 (22%) of F patients had signs of interstitial lung disease ( $p=0.005$ ). No renal crisis was observed till enrollment. 37% in both sexes had gastrointestinal involvement. Patient global disease damage was on a VAS (0- 100) 56.9 in M and in 38.4 in F ( $p=0.014$ ) and patient global disease activity was 58.8 in M and 41.9 in M ( $p=0.024$ ). Physician global of disease activity on a VAS was 58.9 in M and 36.9 in F ( $p=0.004$ ) and physician global disease damage was 60.2 in M and 31.2 in F ( $p=0.001$ ).

## Conclusion:

Male patients had a significantly more severe disease course at time point of enrollment . This finding overlaps to the observation in adult cohorts.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

There is a current need to integrate health related quality of life (HRQoL) into outcomes for clinical trials (Chang & Reeve, 2005). For pediatric localized scleroderma (LS), large gaps continue to exist in regards to the impact of LS on QoL, and clinical trials have been limited by the lack of valid patient-reported outcomes (PROs). Our group developed the pediatric LS Quality of Life Instrument (LoSQI) to meet this need. The LoSQI includes 3 domains (skin sensations, physical functioning, body image and social support) and an optional subscale (systemic medication side effects). The goal of this project was to provide validity evidence for the LoSQI scores in children with LS.

## Methods:

The study had two phases (1) a pilot study and (2) a field test. The main purpose of the pilot study was to obtain input from pediatric LS patients regarding the under- and over- representation of the included content domains, understandability and readability of the survey items, and appropriateness of the recall period. Semi-structured interviews were used. The main goal of the field test was to provide quantitative validity evidence from multiple sources including patterns of missing or skipped items, reliability coefficients, and convergent and divergent validity. Patients were recruited from specialized scleroderma clinics at two sites: the Children's Hospital of Pittsburgh and the UT Southwestern Medical Center.

-

## Results:

Seventeen patients (ages 8-17) were enrolled into the pilot study and 74 patients aged 11-20 years were enrolled for the field test. Only 4% of the sample (3/74) had missing or skipped items. Internal consistency was excellent (all coefficients >0.8; Table 1) and test re-test reliability was >0.7 for the total score. The LoSQI had moderate to strong relationships with other PROs, but limited correlations with physician reported measures of disease activity and damage (Table 2).

## Conclusion:

Initial evidence supports the reliability and validity of the LoSQI to measures HRQoL in pediatric patients. Limited correlations to physician reported outcomes suggest that the LoSQI measures unique information and should be an additional outcome measured in future clinical trials. Additional examination into the responsiveness of the scale to change is needed.

Table 1. Reliability coefficients for LoSQI.

Scores	Number of items	Cronbach's alpha (n = 74)	Test re-test reliability (n= 30)
Domain 1: Skin sensations	4	0.88	0.60
Domain 2: Physical functioning	8	0.90	0.70
Domain 3: Body image and social support	7	0.93	0.66
LoSQI Total Score	21	0.94	0.72
Domain 4: Medication side effects (n = 41, 17)	11	0.82	0.77

Table 2. Relationships of the LoSQI total score to patient, parent, and physician reported outcomes.

Outcome Measure	n	Pearson's r	Spearman's rho
Patient Reported Outcomes			
CDLQI/DLQI	61	0.82	0.78
VAS-patient	47	0.56	0.54
Physician Reported Outcomes			
mLoSSI (activity)	56	-0.06	0.05
LoSDI (damage)	56	0.30	0.27
PGA-activity	34	-0.07	0.09
PGA-damage	34	0.34	0.48
PGA-severity	34	0.41	0.48
Parent Reported Outcomes			
VAS-parent	34	0.71	0.54
Peds QL Family Impact	45	-0.75	-0.59

CDLQI/DLQI = Children's Dermatology Life Quality Index; VAS = Visual Analogue scale; mLoSSI = Localized Scleroderma Skin Severity Index; LoSDI = Localized Scleroderma Damage Index; PGA= Physician Global Assessment.

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Juvenile localized scleroderma (jLS) is often associated with deep tissue and extracutaneous involvement (ECI), putting children at risk for severe morbidity such as hemiatrophy, arthritis, and seizures. Few studies have prospectively evaluated occurrence of ECI or its impact on jLS health related quality of life (HRQoL). Our multicenter, multidisciplinary group (LOCUS, Localized scleroderma Clinical and Ultrasound Study group) conducted a study to identify factors associated with ECI in jLS.

### Methods:

We conducted a prospective observational cohort study of active and inactive jLS patients. Inclusion criteria included diagnosis of jLS by a pediatric rheumatologist or dermatologist, onset < 16 years, and willingness to complete questionnaires. Ethical board approval was obtained at each site.

At each of the 3 study visits, physicians scored clinical disease features and Physician Global Assessments of activity and damage. Parents scored two global assessments (100 mm visual analog scales): 1) Impact of disease on their child's life at time of visit (Impact VAS, anchors No Impact, Very Large Impact), and 2) Disease activity (Activity VAS, anchors Not Active, Very Active). Parents also noted if specific symptoms or problems had occurred since the prior visit or in past 2 months. Physicians completed LS treatment and ECI forms. The ECI form was a checklist of specific problems for 8 organ systems, with option to list additional items.

Descriptive statistics, Spearman correlations, and least squares means were performed. Models were built by choosing variables that had a significant correlation with Impact VAS scores, followed by elimination of variables based on log-likelihood scores.

**Results:** Of the 90 subjects, 55.6% had ECI - mostly musculoskeletal including joint contracture (27), bone size difference (23), and myalgia (12). Factors associated with ECI included higher PGA-Damage and Impact VAS scores, mixed morphea subtype, limb involvement, RF positivity, and systemic treatment (Table). No association was found with gender, age of onset, disease duration, or ANA positivity. High impact VAS was associated with altered sensation at skin lesion site, joint problems, difficulty playing, and missing school ( $r = 0.209-0.322$ ). Modeling to identify variables associated with higher Impact VAS scores identified female sex (OR 10.7, 95% CI 3.9 to 29.5,  $p < 0.001$ ), active disease (OR 2.9, 95% CI 1.2 to 6.8,  $p = 0.014$ ), and ECI (OR 2.8, 95% CI 1.3 to 5.9,  $p = 0.008$ ).

**Conclusion:** Most jLS subjects had ECI, which occurred within a few years of disease onset. Several associated factors were identified, and subjects with EC were found to have higher physician rated damage and parent rated impact scores. The odds of higher impact scores were strongly associated with female sex. There is a need for more study to better evaluate variables associated with development of ECI and its impact on HRQoL.

Characteristics of Subjects with and without ECI

	All (90)	+ ECI (50)	No ECI (40)	P value (+ vs No ECI)

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Juvenile systemic sclerosis (jSSc) is a rare disease during childhood. Classification criteria for jSSc were published in 2007. They include a major criterion that is required and 20 minor criteria from which at least two are required for classification. The objective of this study was to investigate the distribution of the single minor classification criteria in patients with jSSc in relation to sex and the age at disease onset in a prospective cohort study.

## Methods:

Data from the prospective international inception cohort for jSSc was used to investigate the proportion of jSSc patients fulfilling the 20 minor criteria. 48 patients with a jSSc disease duration of less than 2.5 years were included in the analyses. Age at disease onset (AO) was categorized into two groups (<12 (AO G1) / ≥ 12 (AO G2) years). Latent class analysis (LCA) was used to identify distinct groups of patients which share a similar pattern of minor criteria for jSSc.

## Results:

The mean physician global on a visual analogue scale was 46 (sd=26) at enrolment, 37 (77.1%) were female, and 31 (64.6%) patients had diffuse subtype. Raynaud's phenomenon (90%), ANA positivity (87%), and nailfold capillary abnormalities (77%) were the most present minor criteria. Patients in group AO G1 met more often only 2 or 3 minor criteria (23% versus 11%), whereas almost 40% in AO G2 (versus 23% in AO G1) met more than 5 criteria. Patients in AO G2 had more often sclerodactyly (83%/47%), decreased DLCO (62%/38%) and were more often ANA positive (100%/72%) than in AO G1. LCA in patients of AO G2 resulted in two groups. In the first group, the leading minor criteria were sclerodactyly, Raynaud's phenomenon, nailfold capillary abnormalities and SCL-70 positivity. The second group was characterized by patients with nailfold capillary abnormalities, Raynaud's phenomenon, decreased DLCO, reflux and arthritis. Female patients fulfilled in mean significantly more minor criteria than boys (4.3 versus 5.1). Differences were highest in nailfold capillary abnormalities (84%/55%), gastro-esophageal reflux (30%/0%), and arthritis (35%/9%). No case with dysphagia, renal crisis, atrial hypertension, neuropathy and carpal tunnel syndrome was documented at enrolment.

## Conclusion:

Patients with a jSSc disease onset before the age of 12 and males met significantly less minor criteria than patients with a later onset and females. We could recognize 2 patterns of presentation of jSSc over the age at onset of 12, which was not described before. We have to observe in the long term follow up, how far to be part of a cluster present a prognostic factor for morbidity and mortality.

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Linear scleroderma of the face (LSF) is a very disabling condition and, to date, standardized and validated methods for assessing and monitoring the disease progression are lacking. The Cone Beam Computed Tomography (CBCT) is an imaging technique with good sensitivity for both soft and bony tissues, fast to be performed with no need for patient sedation. Of interest, the radiation exposure is 50 times lower than a traditional CT scan, being the ideal technique for a repeated use. We investigated whether CBCT may represent a reliable tool for assessing patients with LSF and monitoring their course over time.

**Methods:** Ten consecutive patients with LSF, aged 3-21 years, and 5 age-matched healthy controls underwent CBCT assessment. The transverse sections of CBCT scan, in digital format, were analyzed according with three arbitrarily selected anatomic levels: mandibular condyle (MC), floor of the maxillary sinus (MS) and mandibular foramen (MF). Measurements of both affected and unaffected side of the face were made by a standardized methodology. From the intersection axes, an origin point was generated and from this one, 30° and 60° lines, crossing bony and soft structures, were drawn. For each given degree, the soft tissue thickness and the total thickness (bony and soft tissues) of the right and left side were calculated by using the software Onis 2.4 free edition. Twenty-four measures for each subject (two for each side, right and left, of the three transverse sections) were therefore evaluated. Five raters, all physicians, after a two-hour training session, evaluated LSF patients' and controls' CBCTs twice and blindly one from the other. The intra-rater reliability was assessed by the repeatability coefficient and the inter-rater reliability by the Intraclass Correlation Coefficient (ICC) and interpreted as follows: ICC values range 0.75-1 excellent reliability, 0.4-0.74 good reliability, <0.4 poor reliability.

**Results:** CBCT was fast and well tolerated by the patients even the youngest. The intra-rater concordance resulted optimal as the repeatability coefficient ranged between 0.77 and 0.99. The inter-rater concordance for the total thickness, among the assessors, was also excellent with mean ICC value of 0.75 (SD 0.16) for patients and 0.89 (SD 0.09) for controls. The mean ICC for the soft tissue thickness was 0.49 (SD 0.24) for patients and 0.66 (SD 0.28) for controls, respectively. 58.3% of the measurements for patients and 91.2% of those for controls showed excellent ICC results (> 0.75). The best performances were obtained at the level of the MF and MC sections.

**Conclusion:** CBCT is a reliable method to assess and monitor skin and bone changes in patients with LSF. It is a fast, reproducible and reasonably safe technique. A prospective validation to confirm its relevance in evaluating the disease progression is ongoing.

## **Renal Disease Course in Pediatric Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis in the First 12-Months – a Pediatric Vasculitis Initiative (PedVas) Study**

**Kimberly Morishita**<sup>1</sup>, Audrea Chen<sup>2</sup>, Cherry Mammen<sup>1</sup>, Angelyne Rivera<sup>3</sup> and David Cabral<sup>1</sup>, <sup>1</sup>BC Children's Hospital and University of British Columbia, Vancouver, BC, Canada, <sup>2</sup>Medicine, University of British Columbia, Vancouver, BC, Canada, <sup>3</sup>Pediatrics, BC Children's Hospital and University of British Columbia, Vancouver, BC, Canada

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Renal disease is the most common manifestation of pediatric anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). Renal disease course and early trajectories have not been well studied. The aim of this project was to describe renal disease at time of diagnosis (TOD) and follow glomerular filtration rate (GFR) trajectories over 12-months.

### **Methods:**

PedVas is a multi-center international study that is currently collecting clinical and biological data from children with chronic vasculitis. The clinical data is stored in ARChive (A Registry for Childhood Vasculitis). Patients entered into ARChive with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA) and renal disease were included. Renal disease was defined as biopsy confirmed pauci-immune glomerulonephritis OR dialysis dependence at TOD. Patients had to be less than 18 years of age at TOD. GFR was estimated using the bedside Schwartz formula. GFR based outcomes were reported as proportion of children with normal GFR ( $>90$  ml/min/1.73m<sup>2</sup>), mildly reduced (MildR) (60-89 ml/min/1.73m<sup>2</sup>), moderately reduced (ModR) (30-59 ml/min/1.73m<sup>2</sup>), severely reduced (SR) (15-29 ml/min/1.73m<sup>2</sup>), and renal failure (RF) ( $<15$  ml/min/1.73m<sup>2</sup>, or requirement of dialysis).

### **Results:**

109 patients met inclusion criteria. 64% were female. 81% had GPA and 19% had MPA. No patients with EGPA had renal disease. Median age at diagnosis was 13.8 years (range 3.9 to 17.8 yrs). Ethnicity data was available for 83% of patients. Of those, 61% were Caucasian, 13% East Indian/South Asian, 9% Hispanic, and 17% other (Asian, Black, Aboriginal, Mixed, or Other). Renal manifestations at TOD included: hematuria (92%), proteinuria (84%), hypertension (29%), oliguria (20%), and nephrotic syndrome (14%). 29 patients (27%) required dialysis at TOD. Cyclophosphamide (CYC) and/or rituximab (RTX) were used as primary induction treatments in 93% of patients. 10% of patients received both CYC and RTX. 30% of patients also received plasmapheresis. All patients received corticosteroids.

At TOD, 36% of patients had a normal GFR. The remaining patients had reduced GFRs as follows: 6% MildR, 16% ModR, 12% SR, and 30% RF. By post-induction (4-6 months following diagnosis), 28% of patients had a normal GFR, 32% MildR, 17% ModR, 4% SR, and 19% RF. 71 patients had complete 12-month visit data. 21 patients (30%) had normal GFR, 34% MildR, 17% ModR, 3% SR, 14% RF, and 2 patients had been transplanted. Of the 21 patients with normal GFR, 17 (81%) had achieved a normal GFR by post-induction. Of patients requiring dialysis at TOD, 85% had ModR GFR or worse at 12-months, 50% remained on dialysis or were transplanted.

### **Conclusion:**

More than half of children with AAV associated renal disease have moderately reduced renal function or worse at diagnosis. In this cohort, only modest improvements in GFR were seen by post-induction, and minimal improvements were seen beyond that despite aggressive treatment. At 12-months, only 30% of children had normal GFRs. The majority of patients who required dialysis at TOD continued to have significantly reduced renal function at 12-months.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster II: Lupus and Related Disorders, Myositis, Scleroderma and Vasculitis

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Classification of chronic vasculitis to clinically or etiologically meaningful groups has been challenging. In 2008, the 1990 ACR classification criteria for GPA was adapted for children as the 2008 EULAR/PRINTO/PRES criteria. In 2017, ACR/EULAR proposed new criteria for classifying GPA using new knowledge, and based on data from 1500 adult patients in the Diagnosis and Classification Criteria in Vasculitis (DCVAS) initiative. We aimed to evaluate the 2017 criteria for GPA in a cohort of children and compare the 2008 criteria.

**Methods:** Time of diagnosis data was retrieved from the international Registry of Childhood Vasculitis (ARChiVe) in PedVAS. The 2017 Classification criteria and scoring system are shown in Table 1 with adaptations of criteria to align with the available ARChiVe dataset. All patients except Takayasu (TAK) were included. Classification of GPA versus not GPA patients by both the 2017 and 2008 criteria was computed from data, and sensitivity / specificity measured against Expert classification. Expert Opinion was determined as follows: If physician submitted diagnosis matched both 1990 and 2008 criteria for GPA, or not GPA, the diagnosis was considered as verified; an expert (KM or DC) evaluated clinical vignettes of remaining patients and verified the diagnosis if it matched submitted diagnosis. Both experts evaluated remaining patients and when consensus could not be reached patients were considered unclassifiable.

**Results:** After applying the 1990 and 2008 criteria for GPA in all 376 included patients (Table 2), those fulfilling both criteria matched submitted diagnosis of GPA in 163; and for those not fulfilling either criteria there was a matched submitted diagnosis that was not-GPA in 89. Clinical vignettes of the remaining 124 patients underwent expert review for classification. Ultimately 245 patients had GPA and 131 did not. The 2017 criteria for GPA and the 2008 criteria were each applied to all patients and sensitivity specificity respectively measured against Expert classification: 2017 criteria 93% and 72%, and 2009 criteria 95% and 70%. The 2017 criteria classified 6 additional patients.

**Conclusion:** Performance of the 2017 and 2008 classification criteria was similar but applicability of the 2017 criteria across the ages is valuable; low specificity may reflect relatively low non GPA numbers and exclusion of TAK. The value of criteria in both adults and children will be best assessed if classification to GPA is seen to be mutually exclusive of classification to other closely related diseases, when these criteria also become available from DCVAS.

**(a) ACR/EULAR Provisional 2017 Classification Criteria for Granulomatosis with Polyangiitis (GPA) showing adaptations of items for this pediatric study**

This criteria set is for use when a diagnosis of small or medium vessel vasculitis has been made, in order to classify the patient as having GPA

*\*(shows pediatric item modification)*

Clinical	1	Bloody nasal discharge, ulcers, crusting or sino-nasal congestion* <i>*(Chronic sinusitis substituted for sino-nasal congestion in ARChive)</i>	3
	2	Nasal polyps <i>*(Not collected in ARChive)</i>	- 4
	3	Hearing loss or reduction	1
	4	Cartilaginous involvement* <i>*(includes only nasal septal perforation &amp; saddle nose deformity in ARChive)</i>	2
	5	Red or painful eyes	1
Tests	6	cANCA or PR3- antibody positive	5
	7	Eosinophil count $\geq 1 (x10^9/L)$	- 3
	8	Nodules, mass or cavitation on chest imaging	2
	9	Granuloma on biopsy	3

Add scores in right column for all 9 items; a score of  $\geq 5$  is needed for classification of GPA

**(b) Assessing adapted ACR/EULAR Provisional Classification Criteria for GPA in 376 children with vasculitis against classification by expert opinion**

	2017 ACR/EULAR criteria		
	GPA	Not GPA	
Expert Opinion: GPA	200	45	245
Expert Opinion: not GPA	14	117	131
	214	162	

Sensitivity =  $(200/214) * 100 = 93.46\%$ ; Specificity =  $(117/162) * 100 = 72.22\%$

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Systemic autoimmune diseases expose patients to chronic inflammation, immune dysregulation, and vascular abnormalities; complications that can impact obstetric outcomes. The goal of this study was to investigate preterm birth (PTB) phenotypes in women with a variety of autoimmune diseases in large population-based data.

### **Methods:**

Maternally linked hospital and birth certificate records for all live singleton births in California between 2007 and 2011 were analyzed (n=2,481,516) using data provided by the California Office of Statewide Health Planning and

Development (OSHPD). Prevalent autoimmune disease at delivery was identified by ICD-9 codes for Systemic Lupus Erythematosus (SLE), Discoid Lupus Erythematosus (DLE), Systemic Sclerosis (SSc), Rheumatoid Arthritis (RA), Polymyositis/Dermatomyositis (DM/PM), and Juvenile Idiopathic Arthritis (JIA). Patients with more than one of these diagnoses were classified as “overlap”. PTB was assessed overall (20-36 weeks) and partitioned into phenotypes including pre-term premature rupture of membranes (PPROM), spontaneous, and medically induced PTB. Adjusted multivariable Poisson regression models estimated risk ratios (RR) and corresponding 95% confidence intervals for the above PTB outcomes (relative to term deliveries) for each autoimmune disease compared to the general obstetric population adjusting for maternal age, race/ethnicity, body mass index, smoking, education, payer, parity, and prenatal care.

### **Results:**

There were 4,458 births to 4,156 distinct mothers with autoimmune diseases (SLE n=2,419, RA n=1,649, SSc n=106, DLE n=114, JIA n=198, DM/PM n=43, Overlap n=164). Greater than 90% of women in all groups initiated prenatal care in the first five months of pregnancy and were nonsmokers. Compared to the general population, patients with systemic autoimmune diseases were more likely to deliver prematurely (Table). This increased risk persisted for all disease groups for spontaneous PTB and the majority of disease groups for both PPRM and medically indicated PTB at 32-36 weeks of gestation, with the exception of DLE.

### **Conclusion:**

These results indicate that women with systemic autoimmune diseases have an elevated risk of preterm delivery, both spontaneous and medically indicated. Therefore, preconception counseling and close monitoring during pregnancy is important. Despite the differences in these autoimmune conditions, the risks were consistently elevated for PTB outcomes, which may provide insight into the underlying mechanism of these obstetric complications.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Women with systemic lupus erythematosus (SLE) are at greater risk of preterm delivery compared to women without lupus. A significant proportion of SLE pregnancies are complicated by maternal factors and delivery is medically indicated (iatrogenic). For example, preeclampsia risk is increased in SLE pregnancies. We investigated the types of preterm deliveries in SLE (iatrogenic vs spontaneous), and estimated the proportion mediated by preeclampsia.

**Methods:** Women with and without SLE with singleton pregnancies were identified from SLINK, a Swedish register-based cohort, 2001-2013. Maternal SLE was defined as  $\geq 2$  SLE-coded discharge diagnoses from the National Patient Register and  $\geq 1$  SLE code from an appropriate specialist. Preterm delivery was defined as  $< 37$  weeks gestation, extremely and very preterm as  $< 32$  weeks. Spontaneous preterm birth was defined as due to preterm contractions or premature rupture of the membranes (PPROM). Iatrogenic was defined as planned C-section or induced labor. Maternal/fetal complications were stratified by maternal SLE, parity, and

gestational age (<32 weeks vs 32-37 weeks). Using Drug Register data (2006-2013), modified Poisson models estimated risk ratios of preterm delivery by maternal hydroxychloroquine (HCQ) use during pregnancy. Mediation analysis estimated the proportion of iatrogenic deliveries mediated via preeclampsia, using Poisson models accounting for maternal age/smoking. Autocorrelation of multiple births per women were accounted for using robust errors.

**Results:** There were 781 SLE-exposed and 11271 non-SLE-exposed pregnancies. Preterm delivery was more common in the SLE than non-SLE group for first (22% vs 6%) and subsequent (15% vs 4%) pregnancies. 27% of SLE-exposed first births delivered extremely or very preterm, 90% were iatrogenic (vs 47% of non-SLE first births). Among first and subsequent births, preterm deliveries were more frequently complicated by preeclampsia in SLE women. Preterm delivery was more common among those without HCQ use during pregnancy (RR=0.75, 95% CI (0.49 to 1.14)), but power was limited. For SLE pregnancies, preeclampsia mediated 12% of iatrogenic preterm births – as compared to spontaneous preterm births – among first pregnancies, and 11% among subsequent pregnancies.

**Conclusion:** Preterm delivery complicates a greater proportion of SLE compared to general population pregnancies, and a considerable proportion of risk is mediated through preeclampsia. This study is the largest to date to partition preterm delivery into spontaneous and iatrogenic, and the first to estimate the proportion of preterm birth mediated via preeclampsia. Our findings reinforce the importance of close monitoring for preeclampsia in lupus pregnancy, and suggest larger well-powered studies investigating the potential protective effect of HCQ on preterm delivery.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatic Diseases (RD) frequently affect women during reproductive age, therefore counseling on family planning is crucial for their quality of life. Children's outcome is a major topic, but no large studies are available. This study aimed at assessing the long-term health conditions of children born to women with RD.

**Methods:** 24 Italian Rheumatology Centers distributed the questionnaire (65 multiple-choice and 12 open-answer questions) to consecutive patients (aged 18-55) during September 2015. Data were analyzed subdividing children upon maternal diagnosis: Chronic Arthritides (CA) and Connective Tissue Diseases (CTD).

**Results:** Data were collected for 320 children (166 males, 52%) born to 184 mothers (63 CA and 121 CTD). At the time of interview, children had a mean age of  $17.1 \pm 9.6$  years. Pre-term delivery (<37 w) was observed in 72 cases (22.5%), including 13 (4%) cases born <34 w. The occurrence of an autoimmune/inflammatory disease (AIID) and/or neurodevelopmental disorders (ND)/learning disabilities (LD) is reported in Table 1. Twelve children (3.7%) were diagnosed with an AIID, mostly coeliac disease (8/12, 67%). Eleven children (3.4%) were diagnosed as having a ND and/or LD by a Pediatric Neuropsychiatrist. To rule out the possible effects of *in utero* exposure to maternal autoantibodies and/or anti-rheumatic drugs in the pathogenesis of ND, data on such exposures were retrieved for 280 children (87.5%) and a comparison was performed between affected (n=11) and not-affected children (n=258) as reported in Table 2.

**Conclusion:** The long-term follow-up of children born to mothers with RD in this large, multicenter study of randomly interviewed women did not raise particular concerns in terms of relevant health problems. In particular, each AIID did not display a significantly increased frequency as compared to the literature (e.g. 2.5% coeliac disease as compared to 1-2% in the general pediatric population, GPP). Children with ND/LD had a tendency to cluster in the group of mothers with CTD, especially after maternal diagnosis, with a higher frequency as compared to GPP (7.9% vs 3%). No particular association with the *in utero* exposure to either autoantibodies or drugs was found. Therefore, our data suggest that the development of ND/LD in children of patients with RD cannot be linked exclusively to maternal disease. The results of this study can be reassuring for patients with RD about problems in the offspring possibly related to their disease.

**Acknowledgements:** Statistical analysis supported by an unrestricted grant by UCB Pharma. The authors wish to thank Patients Associations and Participants to the survey.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pregnant SLE women are at increased risk of cesarean delivery compared to pregnant women from the general population. Yet, to date, no one has evaluated the indications for cesarean delivery in SLE pregnancies. Using the large population-based "QUALity of care, obstetrics RiSk Management, and mode of delivery (QUARISMA)" cohort, we assessed indications for cesarean delivery in SLE pregnancies versus unaffected pregnancies.

**Methods:** The QUARISMA cohort includes 184,952 pregnancies and was established as part of a cluster-randomized, controlled trial, which aimed to evaluate the effect of a 1.5-year intervention, involving audits of indications for cesarean delivery and feedback to healthcare professionals, at 32 hospitals in Quebec (2008-2011). The intervention had a small effect on the rate of cesarean delivery (Chaillet, *NEJM*, 2015). As part of the trial, in-hospital data, including maternal SLE status and information on indications for cesarean delivery, were abstracted by trained professionals from the medical records.

For the present study, we individually matched 4:1 SLE pregnancies to unexposed pregnancies on maternal age, parity, body mass index (BMI), hospital of delivery, QUARISMA intervention group, and intervention period. We identified cesarean deliveries in SLE and unexposed pregnancies, and ascertained their indications. We performed multivariate analyses to estimate the risk of cesarean delivery for any indications, as well as the risk of cesarean delivery for fetal distress (e.g. cardiac distress, prematurity, intra-uterine growth restriction, stillbirth), maternal disease, and/or preeclampsia in SLE pregnancies versus controls, adjusting for BMI and multiple births.

**Results:** We identified 122 SLE pregnancies and 488 unexposed pregnancies. Cesarean deliveries occurred in 35/122 (29%) of SLE pregnancies versus 132/488 (27%) of unexposed pregnancies. Among the 35 SLE cesarean deliveries, indications included (but were not limited to) cardiac distress in 34%, prematurity in 29%, maternal disease in 20%, and preeclampsia in 11%. Among the 132 unexposed cesarean deliveries, 28% were due to cardiac distress, 10% to prematurity, 4% to maternal disease, and 6% to preeclampsia. In multivariate analyses, there was a trend for an increased risk of cesarean delivery for any indications in SLE versus unexposed pregnancies (OR 1.6; 95% CI 0.9,2.9). Moreover, SLE pregnancies had a substantially increased risk of cesarean delivery for fetal distress, preeclampsia, and/or maternal disease versus unexposed pregnancies (OR 2.6; 95% CI 1.2,5.3).

**Conclusion:** Cesarean deliveries in SLE pregnancies are more often due to fetal distress, preeclampsia, and/or maternal disease than cesarean deliveries in pregnancies from the general population.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Women diagnosed with systemic lupus erythematosus (SLE) during the reproductive period have fewer children than unaffected women. Multiple disease-related factors might influence family size in SLE women, including impaired fertility. However, until now, no one has assessed if women with SLE have a prolonged time to pregnancy (TTP). Therefore, we aimed to measure TTP in women with SLE of reproductive age and compare the occurrence of delayed TTP (i.e.  $\geq 12$  months) to general population figures.

**Methods:** Female subjects with SLE from the Montreal General Hospital Lupus Clinic, aged 18-45 years, were enrolled between 2012 and 2017. SLE diagnosis was defined in accordance with the American College of Rheumatology classification criteria for SLE. At baseline and annual follow-up visits, the investigators administered a detailed reproductive questionnaire, wherein the TTP was measured. The TTP was assessed retrospectively for all pregnancies occurring prior to the baseline visit and prospectively for all pregnancies occurring over the follow-up period. Disease damage index [i.e. SLICC damage index (SDI) score] and the mean disease activity (i.e. SLEDAI score) over a maximum of 5 years were recorded, as well as previous cyclophosphamide (i.e. ever/never) and other relevant drug exposures. Descriptive statistics were calculated.

**Results:** A total of 333 women with SLE completed the questionnaire. Among these women, 135 never had a pregnancy and 198 conceived at least once. In women having  $\geq 1$  pregnancies, we identified 400 pregnancies for which the TTP was assessed. The TTP was measured retrospectively in 347 pregnancies, of which 226 and 121 respectively occurred prior and after SLE diagnosis. We observed a TTP  $\geq 12$  months in 4.9% (95% CI 2.6, 8.8) of pregnancies occurring prior to diagnosis and in 9.1% (95% CI 4.9, 16.0) of pregnancies after diagnosis.

43 pregnancies occurred over the study period and 11.6% (95% CI 4.4, 25.9) had a TTP  $\geq 12$  months. None of the women with prolonged TTP had prior cyclophosphamide exposure nor were exposed to steroids while attempting to conceive. However, they tended to be slightly older (median 33 vs 31 years) and more likely to have a SDI  $\geq 1$  [60% (95% CI 17, 92) vs 28% (95% CI 14, 47)] compared to women with TTP < 12 months.

**Conclusion:** Our findings suggest that the occurrence of delayed TTP after SLE diagnosis is similar to that of the general population, which has been consistently reported at approximately 10%. However, larger observational studies, including notably an unexposed group of women without SLE, are needed to confirm our results.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** SLE pregnancies are complicated due to risk for maternal disease exacerbation and potential for fetal and neonatal complications. With careful pre-pregnancy counseling and monitoring during pregnancy, most women with SLE can anticipate a successful pregnancy. Less is known about pregnancy courses in women with other connective tissue diseases (oCTD). Our purpose was to compare pregnancy outcomes in women with SLE with outcomes in women with oCTD and with other inflammatory rheumatic diseases.

**Methods:** The German pregnancy register Rhekiss is designed as nationwide, web-based longitudinal observational cohort study. Pregnant patients with confirmed diagnosis of inflammatory rheumatic disease are eligible to be enrolled until the 20<sup>th</sup> week of pregnancy. At baseline, sociodemographic parameters, disease severity, obstetric history, comorbidities and antibody status are reported. During each trimester, disease activity, flares, drug treatment and adverse pregnancy outcomes are documented. After birth, the outcome and child development during the first two years of life are collected

**Results:** Until April 2017, data from 455 patients were available (SLE [n=104]; other connective tissue diseases [oCTD, including UCTD, MCTD and Sjögren's Syndrome, n=77] and patients with other inflammatory rheumatic diseases [oIRD, including rheumatoid arthritis (RA), juvenile RA, psoriatic arthritis, and spondyloarthritis, n=271]. 192 women had already completed their pregnancy. Approximately 80 % of all pregnancies were planned. At enrolment, disease activity (physicians' global assessment, 0-10) was 1.6±1.5 [SLE] vs. 1.7±1.5 [oCTD] and 2.5±2.1 [oIRD]. HCQ was used in 63% [SLE] vs. 50% [oCTD] and 5% [oIRD]. Antiphospholipid-Syndrome was present in 14.2% [SLE] vs. 2.6% [oCTD] and 0.7 [oIRD]. The overall live birth rate was 93.7% [88.9% [SLE] vs 94.7% [oCTD] vs 95.4% [oIRD]]. Mean birth weight in singletons born at term was 3117 g [SLE] vs. 3131 g [oCTD] and 3477 g [oIRD]. Severe adverse pregnancy outcome included preterm birth [25% [SLE] vs 16.7% [oCTD] vs 16.3% [oIRD]] and preeclampsia [4.4% [SLE], 10.5% [oCTD], 0% [oIRD]]. Serious infections were documented in six preterm born newborns (all mothers had SLE or oCTD). Two neonatal deaths occurred (one in a baby born to a mother with SLE and APS who developed severe HELPP syndrome in her 23<sup>th</sup> week of pregnancy after inadvertent stopping of anticoagulation, the other death occurred in a preterm twin delivered in the 25<sup>th</sup> week of pregnancy by a mother with oCTD and triple aPl positivity.

**Conclusion:** Our real world data show that although most patients with SLE or oCTD have a successful outcome of pregnancy, compared to patients with oIRD, substantial more adverse pregnancy outcomes occurred in these women despite of a high rate of planned pregnancies. Prematurity is the main cause for serious complications.

Disclosures: Rhekiss is a collaborative project of the Rheumazentrum Rhein-Ruhr e.V. Düsseldorf and the DRFZ Berlin, jointly funded by both institutions.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Pregnancies in women with active rheumatic disease often result in poor neonatal outcomes. Prior data suggests that hydroxychloroquine (HCQ) can reduce disease activity and flares in pregnant women with systemic lupus. Due to significant increases in the volume of distribution and renal clearance, we hypothesize that HCQ levels decrease during pregnancy, thereby increasing the risk for worsened maternal disease activity and thus poor neonatal outcomes. We tested the relationship between HCQ levels and maternal/neonatal outcomes in a prospective pregnancy cohort.

**Methods:** We enrolled pregnant patients with rheumatic disease from a single center on a stable HCQ dose between 2013-2016 into an observational study. Frozen serum samples were sent to NMS laboratories and analyzed using high performance liquid chromatography/tandem mass spectrometry. HCQ levels were defined as non-therapeutic (<100 ng/mL) or therapeutic (≥100 ng/mL). Categorical outcomes were analyzed using Fisher's Exact Test and continuous outcomes were analyzed using linear regression models.

**Results:** 50 patients were enrolled in the study; 28 (56%) had systemic lupus, 7 (14%) had rheumatoid arthritis, and the remainder had undifferentiated connective tissue disease or other rheumatic diseases. Concomitant medications included corticosteroids in 14 (28%) and azathioprine in 9 (18%). Median HCQ levels for all patients at the most common dose (400 mg) trended down throughout pregnancy and returned near baseline post-partum ( $p=0.08$ ) (Figure 1, excluding levels <100 ng/mL). Of all patients, 24% had at least one visit with HCQ levels < 100 ng/mL (29% SLE and 18% non-SLE). Excluding one outlier, mean physician global assessment (PGA) scores in lupus patients decreased by 0.07 per 100 ng/mL increase in HCQ level ( $p=0.04$ ). There was no relationship between HCQ levels and C3, C4, or double-stranded DNA antibody in lupus patients. When analyzed by HCQ level closest to delivery, 100% of lupus patients with HCQ levels <100 ng/mL delivered premature ( $n=4$ ), whereas only 24% of individuals with levels ≥100 ng/mL delivered prematurely ( $n=21$ ), ( $p=0.01$ ). In non-lupus patients, there was no difference in prematurity by HCQ level category.

**Conclusion:** In this small cohort of patients, HCQ levels declined as pregnancy progressed, suggesting a physiologic effect of pregnancy on drug levels and the potential need to optimize dosing. Lupus PGA scores improved with increasing HCQ levels. All lupus patients with HCQ levels <100 ng/mL delivered prematurely, suggesting a role for therapeutic drug monitoring.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Our current knowledge about how to treat lupus in pregnancy derives from small prospective or retrospective cohorts, and how best to manage lupus nephritis remains unknown. The goal of this individual participant meta-analysis was to pool data from multiple prospective cohorts to answer the clinical question of whether hydroxychloroquine (HCQ) treatment is beneficial from the decision point of the first trimester.

**Methods:** PubMed, Embase, and the Cochrane Database of Systematic Reviews were searched for prospective cohorts of pregnancies among women with lupus. Data from each cohort were collected and analyzed individually. HCQ use was defined as use any time during pregnancy. Outcomes of interest included fetal loss, preterm birth (<37 weeks gestation), and high disease activity (PGA ever >1, SLEDAI ever >4, or a report of a flare, depending on available data). Logistic regression models estimated log odds ratios (OR) and standard errors individually in all cohorts. Pooled ORs were calculated by random-effect models using the generic inverse variance method in Review Manager. Primary analysis included only women with first trimester visits (5 cohorts). Sensitivity analyses included all women (6 cohorts), and subgroup analyses included patients with a history of nephritis.

**Results:** 46 potential cohorts were identified from 2811 manuscripts. Seven cohorts met inclusion criteria and agreed to participate. The current analysis included 811 pregnancies from six cohorts, of which 70% were exposed to HCQ during pregnancy.

**Fetal Loss:** When limited to only patients with a 1<sup>st</sup> trimester visit, a 52% decrease in fetal loss was observed (OR: 0.48; 95% CI: 0.24, 0.94; Table 1). Among all patients there was a modest decrease in fetal loss among HCQ users, but the association was stronger among women with a history of nephritis (Figure 1).

**Preterm Birth:** No association with HCQ use during pregnancy and preterm birth was observed among women with a 1<sup>st</sup> trimester visit (OR: 0.78; 95% CI: 0.47, 1.30), among all women, and among women with nephritis.

**Disease Activity:** Among patients with a 1<sup>st</sup> trimester visit, there was a decrease in high disease activity among HCQ users (OR: 0.62; 95% CI: 0.37, 1.05), particularly among women with a history of nephritis. Among all patients, there was no association of HCQ use and high disease activity during pregnancy.

**Conclusion:** Our results suggest that HCQ may decrease the risk of fetal loss, and the benefits are seen most among women with nephritis. The heterogeneity of data collection suggests a unified approach to identify larger cohorts of lupus pregnancies is needed.

Table 1. Summary of pooled odds ratios for the association of hydroxychloroquine and pregnancy outcomes among women with lupus.

	Overall Pooled OR (95% CI)	1 <sup>st</sup> Trimester Visits* Pooled OR (95% CI)
Fetal Loss		
Overall	0.61 (0.36, 1.04)	0.48 (0.24, 0.94)
LN History	0.20 (0.07, 0.55)	0.14 (0.03, 0.59)
No LN History	0.90 (0.42, 1.94)	0.70 (0.27, 1.84)
Preterm Birth		
Overall	1.03 (0.59, 1.80)	0.78 (0.47, 1.30)
LN History	0.69 (0.31, 1.53)	0.89 (0.37, 2.11)
No LN History	0.98 (0.48, 2.00)	0.81 (0.44, 1.50)
High Disease Activity		
Overall	0.81 (0.52, 1.27)	0.62 (0.37, 1.05)
LN History	0.51 (0.27, 0.95)	0.45 (0.19, 1.02)
No LN History	1.17 (0.62, 2.22)	0.94 (0.43, 2.04)

\*Includes only patients with a first trimester visit. Trimester-specific data unavailable in 1 cohort.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

With new data demonstrating medication compatibility in pregnancy and lactation, it is important to understand how this information can best reach patients. We sought to identify the decision-making process and gaps in knowledge for women of childbearing age regarding their use of rheumatic medication.

## Methods:

A cross-sectional study conducted in collaboration with an online arthritis community from March to June 2017. After an e-mail invitation members provided consent by clicking their unique link to the online survey. Participants were women aged 18-50 years with inflammatory arthritis.

## Results:

The majority of 250 women who took the survey were white (83%), not Hispanic (82%), college graduates (69%) and had rheumatoid arthritis (80%); average current age was 39.5yrs and age at diagnosis was 26yrs. Sixty eight (27%) women had pregnancies following their arthritis diagnosis and each reported about her most recent pregnancy. Of these, 31% stopped methotrexate (MTX) and 22% stopped TNF-inhibitor (TNFi) prior to pregnancy; 53% took prednisone, DMARDs or biologics during pregnancy. Fifteen percent had inadvertent MTX exposure during their most recent pregnancy. Prednisone was the most common medication in pregnancy and lactation, followed by NSAIDs and TNFi. Most women reported taking medications by physician instruction, but a minority stopped despite physician reassurances.

Of the 37 women who breastfed their last infant (76% of live born infants), 20 (54%) reported taking at least one anti-rheumatic medication (prednisone, DMARD, or biologic) beyond NSAIDs. Prednisone was by far the most common medication used in lactation (17) with only 5 women using a TNFi. Many avoided arthritis medications while breastfeeding: 86% reported either stopping breastfeeding to take medications or avoiding medications to breastfeed. This caused significant distress for some women: *"...I decided it would be better for my baby to be able to hold her, than to be breastfed"* and *"For the first 6 months I flared while breast feeding and... I would have my spouse hold the baby up to my breasts (to) breast feed. I was in bed for 6 months."*

Most women (69%) were very worried about the impact of their medications on a pregnancy. A majority of women talked to their doctor, most commonly a rheumatologist (89%) or obstetrician (OB) (78%), about the risks of medications on pregnancy, with fewer talking to a high-risk OB (39%). Women had the highest level of confidence in the high-risk OB (76% very confident) followed by their rheumatologist (58%) and OB (38%). Among women consulting more than one provider, most (75%) reported receiving a consistent message from their clinicians about medications in pregnancy and lactation. Many women (61%) also searched online for more information.

## Conclusion:

As many as half of women reported discontinuing arthritis medications during pregnancy and/or lactation, sometimes suffering with arthritis activity to avoid any perceived risk to the fetus or newborn. Clinical data suggests that many rheumatic medications may be compatible with pregnancy and lactation, but more education is necessary to support women's decision making about arthritis treatment.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Reproductive Issues in Rheumatic Disorders Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Patient-reported measures of disease activity may provide useful adjuncts to physician-reported measures in identifying pregnancies at greater risk for adverse pregnancy outcomes. Little is known about the utility of these measures in SLE patients, and most analyses in patients with RA use only a single measure of disease activity or disability.

**Methods:** Data on pregnancy outcomes were collected on 225 patients with SLE or RA enrolled in a prospective registry at a single academic center from 2008-2016. Disease activity was measured by physician global assessment (PGA) in SLE and RA, as well as joint counts in RA. The primary patient-reported measure used was the Health Assessment Questionnaire (HAQ); we also tested the utility of pain and general health visual-analog scales. Univariate and multivariable regression models adjusted for race, education, living status, and BMI were used to assess the relationship between patient and physician-reported measures of disease activity and adverse pregnancy outcomes.

**Results:** Among 145 women with SLE, the mean age was 30 and 50% were African American. Among the 80 women with RA, mean age was 33; nearly 80% were white. Women with RA were more likely to be living with a spouse or partner (85% vs 68%) and were more likely to have completed at least 4 years of college (75% vs 52%). Nearly 50% of women with lupus were Ro+, and 17% percent had a history of lupus nephritis.

In women with RA, patient-reported disease activity was associated with preterm birth (OR 5.9 (95% CI: 1.5-23.9)), and gestational age (*beta* -1.5 weeks (-2.6, -0.4)). In addition, physician assessment of disease activity predicted preterm (OR 2.1 (1.2-3.5)) and small for gestational age births (OR 1.8 (1.03-3.1), and gestational age in weeks (*beta* -0.6 weeks (-0.9, -0.02)). On the other hand, for women with SLE, patient-reported measures, including HAQ, pain and global health, were not associated with adverse pregnancy outcomes. However, physician's global assessment was associated with preterm birth (OR 2.9 (1.-6.3)), C-section delivery (OR 2.3 (1.0-5.3)), and preeclampsia (OR 2.8 (1.3-6.3)) in SLE patients. The results do not appear to be driven by nephritis or aPL syndrome.

**Conclusion:** Patient-reported measures of disease activity in RA patients may provide useful adjuncts for physicians to identify pregnancies at higher risk for adverse events. This suggests that increased activity on a patient-reported measure should prompt action during an RA pregnancy. In contrast, in SLE, while the physician-reported measures correlated with pregnancy outcome, the patient-reported measures did not. Our findings provide additional support for the use of patient-reported measures among women with inflammatory arthritis in pregnancy and impetus for the development of patient-reported measures that more accurately reflect lupus disease activity.

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Neonatal Lupus (NL) is a rare syndrome caused by placental transfer of maternal anti-Ro/SSA and anti-La/SSB autoantibodies to the fetus. Cardiac manifestations may comprise autoimmune congenital heart block (CHB) and dilated cardiomyopathy (DCM). The prevalence of CHB has been estimated as 1-2% in anti-Ro/SSA-positive women while the recurrence rate is 16-19%. The rarity of these conditions requires the establishment of collaborative registries in order to improve our knowledge on the management of CHB. Here we report the preliminary data of the Italian Registry of the autoimmune congenital heart block, which was created in the frame of the Italian Society for Rheumatology in 2016.

## **Methods:**

The aim was to collect retrospective and prospective pregnancies complicated with CHB in patients with anti-Ro/SSA and/or anti-La/SSB antibodies. The study was approved by the Ethic Committee of the Promoting Centre in July 2016 and it has been approved by other eight Italian Institutions. Data regarding demography, maternal treatment before and after CHB detection, neonatal outcome, maternal and neonatal follow-up were collected through an online electronic datasheet prepared in a Research Electronic Data Capture (REDCap) platform. Two-tailed Student's t-test for continuous variables, Fisher's exact test or Yates's Chi squared test for categorical variables were applied. The statistical software Stata/SE14.2 was used.

## **Results:**

Seventy-five pregnancies complicated with the detection of CHB were collected in 73 women. CHB was detected in utero in 68 cases (90.6%), 5(6.7%) neonatal cases, 2(2.7%) unknown. Demographic description of the cohort, degree of CHB and treatment are reported in the table. The death of the child was observed in 17 (23.2%) cases: 7 fetal-deaths, 5 termination of pregnancy and 5 postnatal death. Maternal and fetal risk factors for fetal mortality were analyzed for possible associations. At univariate analysis, factors associated with death were hydrops ( $p=0.065$ ) and pericardial effusion ( $p=0.025$ ).

## **Conclusion:**

The Lu.Ne registry is an ongoing project aiming at collecting all cases of CHB referred to Italian Rheumatology Centres. Our preliminary data confirmed that hydrops and pericardial effusion are risk factors for fetal death. Conversely, we found that the majority of the mothers (58%) whose pregnancy was affected by CHB had a formal diagnosis of systemic autoimmune disease. This is in contrast with other registries showing that usually CHB was incidentally detected in healthy women. Probably such discrepancy

is related to the recruiting Centres all belonging to Rheumatology Society. The collection of CHB cases from Gynecological and Pediatric Cardiology Centres, planned in the next months, will complete our analysis

<b>Maternal demography</b>	<b>(n=73)</b>
Caucasian ethnicity (n=73)	70 (%)
<b>Maternal Diagnosis at CHB detection</b>	
Undifferentiated Connective Tissue Disease	23 (31.5%)
Sjogren Syndrome	16 (22%)
Systemic Lupus Erythematosus	4 (5.4%)
Carriers Ro/SSA	17 (23.3%)
Carriers Ro/SSA+La/SSB	10 (13.7%)
Other	3 (4%)
<b>Pregnancies complicated by CHB</b>	<b>(n=75)</b>
Mean week of detection of CHB (±SD)	22.4±8.5
<b>CHB degree</b>	
II degree	15 (20%)
III degree	52 (69.3%)
Intermittent II-III degree	3 (4%)
Other/unknown	5 (6.6%)
<b>Therapy after CHB detection</b>	
Fluorinated steroids	18 (24%)
Intravenous Immunoglobulins	18 (24%)
Plasma-exchange	16 (21.3%)
<b>Pregnancy outcome</b>	<b>(n=75)</b>
Live birth	63 (84%)
Intrauterine fetal death/termination of pregnancy	12 (16%)
<b>Outcome of liveborns with CHB</b>	<b>(n=63)</b>
Pacemaker implantation	48 (76%)
Postnatal Mortality	5 (8%)
Neonatal mortality	3 (4.8%)
Later in life	2 (3.2%)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Transplacental passage of maternal anti-Ro IgG is thought to be critical in initiating inflammation leading to congenital heart block in neonatal lupus erythematosus (NLE). Congenital heart block is the most frequent manifestation of cardiac NLE. To date, the majority of studies have focused on babies born to mothers with systemic lupus erythematosus (SLE) or congenital heart block babies born to anti-Ro and/or anti-La mothers. In this large cohort study, we aimed to determine the proportion of babies born to anti-Ro and/or anti-La positive mothers with SLE, Sjögren syndrome or rheumatoid arthritis (RA), with congenital heart defects (CHD).

**Methods:** The Hospital for Sick Children offers serial fetal echocardiography for women with anti-Ro and/or anti-La antibodies. Babies born to anti-Ro and/or anti-La mothers are referred to the NLE clinic for follow-up. We performed an observational study of our large, single-centre NLE clinic cohort, on whom prospective data has been collected since 1984. We included all infants, seen in our clinic, born to mothers positive for anti-Ro and/or anti-La antibodies, with SLE, Sjögren syndrome or RA. Among them we identified infants with cardiac NLE disease diagnosed either prenatally or postnatally. We identified those babies with CHD, including septal defects, patent ductus arteriosus, and other rare structural heart defects. We compared the proportion of babies with CHD, with and without NLE congenital heart block using Fisher's exact test.

**Results:** A total of 451 children were included. Seven (1.6%) children had CHD. The most frequently observed CHD were ventricular septal defects and patent ductus arteriosus. Among cases with congenital heart block (N=28), the frequency of CHD was further increased, with 3 (10.7%) children diagnosed with at least one CHD. This was significantly higher when compared to the rate of CHD among babies without congenital heart block (0.9%,  $p < 0.006$ ).

**Conclusion:** In our NLE clinic cohort of children born to mothers with anti-Ro and/or anti-La antibodies and SLE, Sjögren syndrome or RA, we observed higher rates of CHD among those with congenital heart block when compared to our NLE clinic babies without congenital heart block. This suggests a common pathway in the development of congenital heart block and CHD. The precise role of maternal antibodies in the development of CHD requires further investigation and replication.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Juvenile idiopathic arthritis (JIA) may be active during reproductive age, therefore ovarian function and future fertility are relevant issues for its female population. Nonsteroidal antiinflammatory drugs (NSAIDs) may impair fertility inducing luteinized unruptured follicle syndrome (LUF) in adults rheumatoid arthritis patients however there is no study evaluating this condition in female adolescent and young adults with JIA. Thus, our objective was to assess LUF in three groups: JIA patients with NSAIDs vs. JIA without NSAIDs vs. healthy controls.

**Methods:** Twenty-three adolescent and young adult female JIA patients (ILAR criteria) and 11 healthy females were studied by pelvic ultrasound repeated 2 to 3 times monitoring for follicular development and ovulation in one menstrual cycle. Exclusion criteria included: presence of current gestation or lactation; hypothalamic-pituitary-ovarian axis dysfunction; end-stage renal disease; contraindication or refusal to suspend the use of hormonal contraceptives for at least 6 months; thyroid diseases; history of surgery or pelvic irradiation or neoplasia; use of gonadotrophin releasing hormone analogs; obesity in virgin patients due to the difficulty of performing the abdominal ultrasonography; polycystic ovarian syndrome; amenorrhea; and presence of another systemic autoimmune disease. JIA patients and healthy controls were systematically assessed for menstrual flow duration and cycle length. LUF syndrome

was defined by pelvic ultrasound with a dominant ovarian follicle without signs of follicular rupture, with elevation of progesterone in blood sample in the luteal phase of the menstrual cycle and LH detected in the urine.

**Results:** Comparison between JIA patients with (n=8) vs. JIA without NSAIDs (n=15) and healthy controls (n=11) revealed that the frequency of LUF syndrome was significantly higher in the former group [2(25%) vs. 0% vs. 0%,  $p=0.049$ ]. Of note, the two patients with LUF syndrome had normal menstrual cycles and used naproxen 500 mg bid. Further comparison between JIA patients with and without NSAIDs, and healthy controls showed similar mean in three groups regarding levels of Anti-Müllerian hormone (AMH) [3.4 (0.47-5.0) vs. 3.4 (0.6-13.9) vs. 3.3 (0.49-10.6) ng/mL,  $p=0.909$ ], estradiol [43 (32.7-160) vs. 47 (25.8-119) vs. 41.5 (18.9-61) pg/mL,  $p=0.436$ ], FSH [6.3 (5-10) vs. 6.4 (5-12) vs. 6.8 (4-10),  $p=0.662$ ], LH [8 (6.3-9.6) vs. 7.7 (4.1-28.7) vs. 7.6 (4.4-14.4) IU/L,  $p=0.686$ ], antral follicle count [15.5 (8-19) vs. 19 (6-40) vs. 22 (7-33),  $p=0.240$ ] and ovarian volume mL [6.1 (3.2-7.8) vs. 4.5 (2-15.8) vs. 4.6 (2.8-7.4),  $p=0.363$ ]. No differences were evidenced in three groups regarding white race, body mass index, duration and length of menstrual cycles ( $p>0.05$ ). The frequencies of prednisone, methotrexate and biological agents were similar in two JIA groups ( $p>0.05$ ).

**Conclusion:** The present study identified an increased incidence of LUF syndrome in JIA patients using NSAIDs. We further demonstrated that reduced ovarian reserve does not seem to contribute to this condition.

## Polycystic Ovarian Syndrome in Rheumatic Disease

Cuoghi Edens<sup>1</sup> and Maria Antonelli<sup>2</sup>, <sup>1</sup>Division of Pediatric Infectious Diseases and Rheumatology and Division of Rheumatology, Rainbow Babies and Children's Hospital and University Hospitals Cleveland Medical Center, Cleveland, OH, <sup>2</sup>Department of Medicine/Division of Rheumatology, Case Western Reserve University School of Medicine, MetroHealth Medical Center, Cleveland, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Polycystic ovarian syndrome (PCOS) is a common entity in the general population associated with polycystic ovaries, oligomenorrhea, difficulty conceiving, hormone abnormalities, metabolic comorbidities, and hirsutism. Prevalence ranges from 3-10%. Fertility issues, menstrual cycle irregularities, and metabolic conditions are common in those with rheumatic disease as well. The prevalence of PCOS in those with rheumatic disease is unknown.

**Methods:** Utilizing a secure cloud-based platform, Explorys, we conducted a retrospective cross-sectional study of females 10-50 years of age. The diagnosis of PCOS was determined if the subject had polycystic ovaries and 1/10 known findings associated with PCOS (Table 1). Our inclusion criteria was limited by the existence of Systematized Nomenclature for Medicine-Clinical Term (SNOMED-CT), as the Explorys database is ontology based. A SNOMED-CT does not exist for PCOS. Diseases of interest included: systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), dermatomyositis (DM), psoriasis (PsO), ankylosing spondylitis (AS), psoriatic arthritis (PsA), and juvenile idiopathic arthritis (JIA). Disease-specific searches excluded all other rheumatic diseases of interest in this study and endocrinopathies. Table 2 summarizes the findings of each patient population. Chi-squared testing was performed to compare prevalence of PCOS between rheumatic diseases.

**Results:** In our analysis, there was significant prevalence of PCOS between SLE and RA, PsO, PsA, and AS as well as RA and PsO and PsA with p-values <0.01. There was also significance between JIA and PsA, PsO, and AS. In our Explorys population, PCOS prevalence was found to be low, however recognized underreporting of PCOS and known lack of medical care for this diagnosis may account for this. In our data set, our disease specific prevalence was similar to reported values, validating our cohort.

**Conclusion:** PCOS prevalence in rheumatic diseases nears that of the general population. There is a significantly increased prevalence in those with PsA, PsO, and AS. It should be considered as a diagnosis in those who have oligomenorrhea, infertility, or signs of hyperandrogenization.

	Explorys	SLE	RA	DM	PsO	PsA	AS	JIA

## Lack of Uptake of Prophylactic Human Papilloma Virus (HPV) Vaccination Among Women with SLE in Saginaw Valley, a High Risk Population

**J. Patricia Dhar**<sup>1,2</sup>, Lynnette Essenmacher<sup>3</sup>, Renee Dhar<sup>4</sup>, Neli Ragina<sup>5</sup> and Robert Sokol<sup>6</sup>, <sup>1</sup>Internal Medicine, Wayne State University School of Medicine, Detroit, MI, <sup>2</sup>Internal Medicine, Central Michigan University College of Medicine, Saginaw, MI, <sup>3</sup>Wayne State University School of Medicine, Detroit, MI, <sup>4</sup>CMED medical student, Central Michigan University College of Medicine, Mt. Pleasant, MI, <sup>5</sup>Foundational Sciences, Central Michigan University College of Medicine, Mount Pleasant, MI, <sup>6</sup>Department of Obstetrics & Gynecology, Wayne State University School of Medicine, Detroit, MI

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Women with SLE are at increased risk for cervical neoplasia likely due to infection with high risk (HR) HPV and thus should be considered for HPV vaccination. We previously showed qHPV vaccine to be safe and immunogenic in women

with SLE. We sought to determine frequency of HRHPV infection and uptake of HPV vaccination in our regional female lupus population. The qHPV vaccine was approved for use in 2006 for women ages 9-26 years.

**Methods:** Data were analyzed from our electronic health records (EPIC) for women with ICD 10 or ICD 9 billing codes for SLE seen June 6, 2007 - May 1, 2017 at our regional medical center which services a large urban, suburban & rural population. This study was approved by the Central Michigan University/Covenant Medical Center institutional review board. Statistical analyses consisted of student's t-test, chi square, and Z test for proportions using SPSS v. 24 software.

**Results:** 1349 women with SLE were seen at our regional medical center, mean age=53 yrs., of which 70.8%=Caucasian, 20.8%=African American, and the rest other race/ethnicity, with 49% having exposure to cigarette smoke. HRHPV testing was performed in only 195 of these women (14.5%, mean age=50 years), of which 33 (16.9%) were positive. Those testing positive for HRHPV were slightly younger ( $P<0.05$ ) than those testing negative, with no statistical difference in smoking or race between the 2 groups (Table 1).

**Table 1: Comparison for Women HRHPV+ vs. HRHPV- (N=195 tested)**

	HPV + (n=33)	HPV - (n=162)	Significance
Age (mean, SD)	45.8 (11.2) yrs.	50.9 (12.8) yrs.	$p<0.05$
Race (n, %)			NS
White	22 (66.7%)	117 (72.2%)	
Black	8 (24.2%)	34 (21.0%)	
Other	3 (9.1%)	11 (6.8%)	
Smoke Exposure (n, %)			NS
Yes	17 (51.5%)	71 (43.8%)	
No	16 (48.5%)	91 (56.2%)	

Comparing our proportion testing positive for high risk HPV (0.169) vs. NHANES\* (0.088), we calculated a  $z=3.99$  ( $p<0.001$ ) indicating HPV infection is significantly higher (2X) in our regional female SLE population. Of the 238 women who were eligible to receive an HPV vaccine, only 16.0% (38/238) were tested for HRHPV with 9 being positive, and only 4.6% (11/238) were vaccinated. Of the 11 that were vaccinated, only one woman had testing for HRHPV and this female was positive for HR HPV.

**Conclusion:** HPV infection is 2 fold increased in our regional female lupus population compared to population controls. Despite the fact that HPV related cervical disease and neoplasia are increased in women with SLE, the frequency of testing for HRHPV testing is low (14.5%) and vaccination rate even lower (4.6%) in our region. This highlights the importance of the need for monitoring for HRHPV and including HPV vaccination as part of general health care in this vulnerable population. Promoting awareness of this problem with primary care doctors and the lupus community would improve uptake of prophylactic HPV vaccination and be beneficial to gynecologic health in women with SLE.

## Use of Estrogen-Containing Contraceptives Among SLE Women with and without Contraindications to Estrogen

Arielle Mendel<sup>1</sup>, Sasha Bernatsky<sup>2</sup>, Yvan St.Pierre<sup>3</sup>, Christian Pineau<sup>4</sup> and Evelyn Vinet<sup>5</sup>, <sup>1</sup>Rheumatology, McGill University, Montreal, QC, Canada, <sup>2</sup>Divisions of Rheumatology and Clinical Epidemiology, Research Institute of the McGill University Health Centre, Montreal, QC, Canada, <sup>3</sup>McGill University Health Centre, Montreal, QC, Canada, <sup>4</sup>Rheumatology, McGill University Health Center, Montreal, QC, Canada, <sup>5</sup>Divisions of Rheumatology and Clinical Epidemiology, McGill University Health Centre, Montreal, QC, Canada

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Estrogen-containing contraceptives may be contraindicated in specific medical conditions due to an increased risk of cardiovascular and thromboembolic events. Women with SLE are at increased risk of having medical contraindications to estrogen use. We assessed the prevalence of estrogen-containing contraceptives in reproductive-aged SLE women with and without possible contraindications.

**Methods:** Premenopausal women aged 18-45 enrolled in the Systemic Lupus International Collaborating Clinics (SLICC) Registry (2000-2017) were enrolled within 15 months of SLE onset and evaluated yearly to update drug use, including estrogen-containing contraceptives. We assessed the presence of World Health Organization (WHO) category 3 (theoretical or proven risks usually outweighing advantages of use) or category 4 (unacceptable health risk if used) contraindications to estrogen-containing contraceptives. Examples included smoking and age  $\geq 35$ , hypertension, migraine with aura, positive antiphospholipid antibodies (aPL), and stroke. High disease activity defined as a SLEDAI score  $>12$  or use of  $>0.5$  mg/kg/d of prednisone were also evaluated as relative contraindications since safety of estrogen in this population has not been established.

**Results :** We identified 1224 SLE women of reproductive age, who contributed 7756 visits. We observed  $\geq 1$  possible contraindications to estrogen in 648 (53%) subjects at enrolment and at 4376 (56%) visits over the study period. At baseline, 124 (10%) women were using estrogen-containing contraceptives and among these, 33 (27%) had  $\geq 1$  possible contraindication. Across all study visits, estrogen-containing contraceptives were used by 6% (95% CI 5-7) of women with  $\geq 1$  possible contraindication vs 12% (95% CI 11-13) of women without any contraindication. Among women using estrogen-containing contraceptives, the most frequently observed WHO category-3 or -4 contraindications were hypertension (44%), positive aPL (32%), and migraine with aura (27%).

**Conclusion:** In a large international prospective SLE cohort, more than half of SLE women of reproductive age had  $\geq 1$  possible contraindication to estrogen-containing contraceptives. Overall use of estrogen-containing contraceptives was low in SLE women (10%) compared to women of reproductive age in the general population (usually above 35%). Estrogen-containing contraceptives were used in 6% of women with possible contraindications. Further work is needed to explore prescribers' characteristics and prescription patterns over time, and to determine long-term outcomes associated with this exposure.

**Table 1.** Baseline characteristics of reproductive-aged SLE women, overall and among those using estrogen-containing contraceptives with and without 1 or more possible contraindications to estrogen

# Predictors of Contraceptive Use Among Reproductive-Age Women with Rheumatic Diseases

Mehret Birru Talabi<sup>1</sup> and Sonya Borrero<sup>2</sup>, <sup>1</sup>Rheumatology and Clinical Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA, <sup>2</sup>Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Contraception helps reproductive-age women with rheumatic diseases to avoid or plan pregnancies so that disease quiescence on safe medications may first be achieved. However, little is known about contraceptive usage among these women. This study examines the prevalence and predictors of prescription contraception among women receiving rheumatologic care from a large, multi-site health care system in Pittsburgh, Pennsylvania.

**Methods:** We examined administrative data for women aged 18-50 years with  $\geq 1$  of 18 rheumatic diagnoses based on ICD-9 codes, and  $\geq 2$  visits to a rheumatology outpatient clinic between years 2013 and 2014. Prescription contraceptive methods were identified and categorized by highest level of efficacy. Highly-effective contraceptive methods included female sterilization, intrauterine devices, and subdermal implants; records of these procedures were abstracted from years 2003-2014. Moderately-effective methods included pills, rings, patches, and injections. Patients' medications were categorized by FDA pregnancy risk classes (Class A/B/C medications: lower fetal risk, Class D/X medications: higher fetal risk). Logistic regression was used to evaluate associations of 1) any prescription contraception or 2) use of highest efficacy contraception, adjusting for frequency of visits to health care providers, medications by FDA pregnancy risk class, and demographic variables (age, race, marital status). Women with prior record of hysterectomies (n=97) were excluded from analyses.

**Results:** In our sample of 2631 women, most were married (52.6%) and White (82.2%), with mean age of 39.6 (S.D. 7.7). Antiphospholipid antibody syndrome (35.5%), rheumatoid arthritis (23.3%), systemic lupus erythematosus (19.4%), and Sjogren's Syndrome (18.8%) were the most common diagnoses. Women had a median of 3 rheumatology visits, but most had no documented visits with primary care providers (PCP) (59.8%) or gynecologists (68.3%) over the 2-year study timeframe. Contraception was prescribed to 32.6% of women, and 8.8% used highly-effective methods. Class D or X medications were prescribed to 71.2% of women. Younger age (aOR:0.9; 95%CI:0.92-0.96),  $\geq 1$  visits with a PCP (aOR:1.8; 95%CI:1.6-2.2) or gynecologist (aOR:3.6; 95%CI:3.0-4.3), or  $\geq 2$  rheumatology visits (aOR:1.2; 95%CI:1.0-1.4), were associated with prescription contraception. Fetotoxic versus safer medication prescription was not associated with overall prescription contraception, but was associated with prescription of highly-effective contraception (aOR:2.1; 95%CI:1.4-3.0), as was younger age (aOR:0.97; 95%CI:0.95-0.99), and at least 1 visit with a PCP (aOR:1.6; 95%CI:1.2-2.1) or gynecologist (aOR:3.6; 95%CI:2.7-4.8).

**Conclusion:** Overall prescription contraceptive prevalence was low in this sample. Care from PCPs or gynecologists enhanced the prescription of contraception-- particularly with highly-effective methods. Increasing referrals to these women's health providers is one approach to improving contraceptive care for reproductive-age women with rheumatic diseases.

## Contraceptive Use in Patients with Rheumatologic Disease on Teratogenic Medications: Rate of Use and Related Factors

Shanley O'Brien<sup>1</sup> and Megan Krause<sup>2</sup>, <sup>1</sup>Department of Internal Medicine, Division of Allergy, Clinical Immunology, & Rheumatology, Kansas University Medical Center, Kansas City, KS, <sup>2</sup>Division of Allergy, Clinical Immunology, and Rheumatology, Kansas University Medical Center, Kansas City, KS

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatologic diseases can affect females of reproductive age. Medications utilized for treatment of these diseases can be associated with harmful consequences in pregnancy. Unfortunately, not all women receive contraception despite this risk.

**Methods:** A retrospective chart review conducted at a single tertiary care center identified the most recent 500 women between ages 18-50 seen in outpatient rheumatology clinic with ICD codes for rheumatoid arthritis, systemic lupus erythematosus, vasculitis, and systemic sclerosis who had been prescribed methotrexate, leflunomide, mycophenolate mofetil, or cyclophosphamide between 06/01/2008-06/01/2016. Individuals were allowed to be included in multiple categories if they had received multiple diagnoses and different immunosuppressants over the time of follow-up. Additional data collected included: age at office visit, self-reported race, primary language, marital status, and type of contraception. Contraception was identified by searching medication lists, past medical/surgical history, and procedure codes. Fisher's exact test and chi-square were utilized.

**Results:** Of the 500 women, 62 (12%) were between ages 18-29, 127 (25%) were 30-39, and 311 (62%) were 40-50. Almost half were married (243, 49%). The vast majority were English speaking (478, 96%). Individuals who self reported as white represented 301 (60%), black 127 (25%), other 46 (9%), Asian 15 (3%), Native American 5 (1%), two races 4 (1%), Pacific Islander 1 (0.2%), and unknown 1 (0.2%). Rheumatoid arthritis was the most common diagnosis (338, 68%), followed by systemic lupus erythematosus (188, 38%), systemic sclerosis (69, 14%), and vasculitis (33, 7%). Methotrexate was the most common medication (342, 68%), followed by mycophenolate mofetil (191, 38%), leflunomide (76, 15%), and cyclophosphamide (25, 5%).

In total, 290 women (58%) received some form of contraception. The most common forms of contraception were hysterectomy (104, 21%) and combination hormone therapy (oral contraceptives and vaginal ring) (95, 19%). The following forms of contraception were also used with rates as follows: tubal ligation in 56 (11%), intrauterine devices in 34 (7%), medroxyprogesterone injections in 21 (4%), progesterone implant in 8 (2%), and progesterone only pill in 1 patient (0.2%).

Women who self-reported as white race were more likely to utilize contraception (63%) than non-white patients (50%) ( $p=0.003$ ). There was no statistically significant difference in the rates of contraception based on age, marital status, disease, or immunosuppressant utilized.

**Conclusion:** This study identifies that contraception is not being utilized in all patients when it would be recommended. Self-reported race/ethnicity was one factor associated with different rates of contraception. Understanding the magnitude of patients not receiving contraception and factors associated with this will better inform strategies to help improve rates of contraception in those exposed to teratogens.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Women with arthritis wonder whether they will be able to have the children they desire. They also worry that oral contraceptives may worsen their arthritis. Working with the Patient Governors of an inflammatory arthritis network, we developed a reproductive survey to answer these questions.

### Methods:

The survey was developed in a collaboration between the research and patient teams. The survey was distributed via email to the network's participant list and consent was implied the women clicked on the link to join the anonymous survey. This study is limited by selection and recall bias.

### Results:

From March to June 2017 14,711 invitations were sent with 250 female responses. Self-reported diagnoses of RA (80%) and SpA (24%) were hampered by many women reporting multiple diagnoses. The majority of respondents were white (83%), non-Hispanic (82%), with a college degree (69%).

Of all women, 59% had fewer children than they desired due to arthritis and 36% had the full number they wanted. Women who had fewer children had an earlier age of diagnosis compared to those did not (24.5yrs vs 31.6yrs,  $p<0.0001$ ). The most common fears limiting family size were 1.) being unable to care for a child (85%), 2.) arthritis medications would harm child (61%), and 3.) the child would get arthritis (52%).

Of the women who tried to conceive after their arthritis diagnosis, 44% reported infertility (23% with physician-diagnosed infertility and 42% taking  $>1$ yr to conceive). Unexplained infertility (39%) was the most common cause, followed by ovulation dysfunction (37%), endometriosis (26%), and uterine/tubal issues (26%). Women with physician-diagnosed infertility were younger at arthritis diagnosis than fertile women (24.6yrs vs 31.4yrs,  $p=0.007$ ). Half of the women with infertility used multiple forms of assisted reproductive technology, including oral (27) and injectable (16) medications and IVF (7).

Of the women not pregnant, trying to become pregnant, or in a same-sex relationship, 35% reported currently using highly effective, 32% effective, and 33% ineffective contraception; 28% of women taking methotrexate were using ineffective contraception.

Of the 135 of women who report ever using OCP, 70% report no impact of the pills on their arthritis; 9% had improved arthritis and 10% had worsened arthritis. At the time of the survey, 20% of women were currently taking OCPs: more prior OCP users noted worsening of arthritis with the drugs than current OCP users (16% prior vs 2% current users,  $p=0.02$ )

Half of women noticed an effect of their menstrual cycle on their arthritis disease activity with the vast majority reporting worsening just prior to (60%) or during menstruation (36%). Multiple women reported that taking OCPs continuously, and thus avoiding their monthly menses, seemed to decrease their pre-menstrual flares.

### Conclusion:

More than half of the women report having fewer children than they had ideally wanted, largely due to infertility and concerns about their medications and difficulty mothering. The frequency of ineffective contraceptive use among women on methotrexate remains unacceptably high. Fear of OCPs appears to be unfounded and continuous OCP use may provide relief for women with menses-related arthritis flares.

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

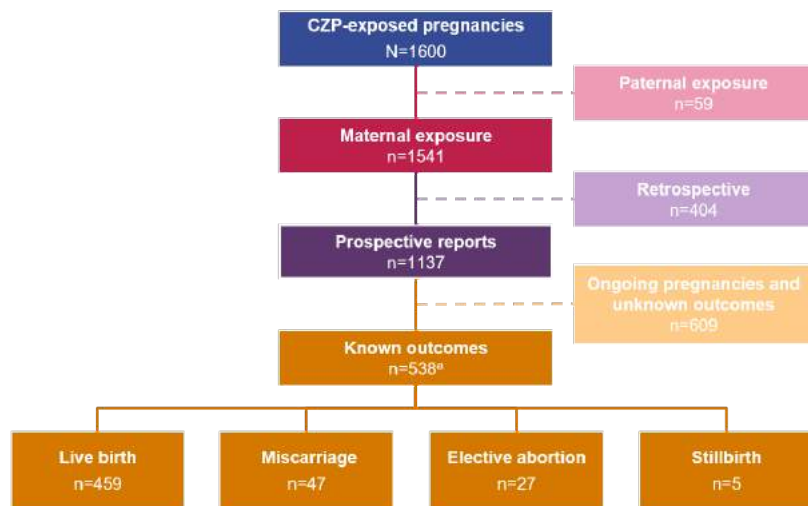

**Background/Purpose:** Anti-tumor necrosis factor medications (anti-TNFs) are effective in controlling chronic inflammatory diseases, but information about their use and safety in pregnancy is limited. Consequently, anti-TNFs are often discontinued early in gestation. Certolizumab pegol (CZP), a PEGylated, Fc-free anti-TNF approved for treatment of rheumatic diseases and/or Crohn's disease, has no active placental transfer. This project provides information on pregnancy outcomes in women receiving CZP, especially those with early pregnancy exposure.

**Methods:** Prospective and retrospective data on maternal CZP exposure, including timing and duration, outcomes, comorbidities, and major malformations were extracted from the UCB Pharma safety database through March 6, 2017. This analysis was limited to prospective reports to avoid bias associated with retrospective submissions. Numbers of live births, miscarriages, elective abortions, stillbirths, and major congenital malformations were ascertained.

**Results:** From a total of 1541 maternal CZP-exposed pregnancies, 1137 were reported prospectively, of which 528 pregnancies (including 10 twins) had 538 known outcomes: 459 live births (85%), 47 miscarriages (9%), 27 elective abortions (5%), and 5 stillbirths (1%) (Figure). Of the 459 live births, 8 (1.7%) cases of major congenital malformations were reported (vesicoureteral reflux, club foot, congenital heart disease, cerebral ventricle dilatation, polydactyly, anal fistula, accessory auricle, and hydronephrosis). Of the 528 prospective pregnancies with known outcomes, 436 (83%) were exposed during the 1<sup>st</sup> trimester, when most organogenesis occurs; 202 out of the 436 were exposed during the entire pregnancy.

**Conclusion:** This analysis represents the largest cohort of pregnant women exposed to an anti-TNF for management of chronic inflammatory diseases. Although these data should be interpreted with caution, there is no observed increased risk of major malformations or other adverse pregnancy outcomes with CZP use compared to baseline, as reported for the US general population by the Centers for Disease Control and Prevention (3%). The data are reassuring for women of childbearing age considering treatment with CZP.

## Maternal and Fetal Outcomes in a Cohort of Patients Exposed to Tumor Necrosis Factor Inhibitors throughout Pregnancy

Geneviève Genest<sup>1</sup>, Karen Spitzer<sup>2</sup> and Carl Laskin<sup>3</sup>, <sup>1</sup>Allergy-Immunology, McGill University and McGill University Health Center, Montreal, QC, Canada, <sup>2</sup>Trio Fertility, Toronto, ON, Canada, <sup>3</sup>Medicine, Rheumatology and Obstetrics and Gynecology, University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Tumor Necrosis Factor inhibitors (TNFi) are increasingly used during pregnancy but are frequently withheld in the second or third trimester to minimize transplacental transfer to the fetus. It is our practice to recommend uninterrupted TNFi treatment throughout pregnancy to avoid the risk of peri- or postpartum disease flare. We evaluated the maternal and fetal outcomes of women who continued their TNFi treatment throughout pregnancy compared to women who interrupted TNFi during pregnancy.

### Methods:

Women seen in our clinic from 11/2010-6/2017 with RA, PsA, JIA or AS having been exposed to TNFi during pregnancy were prospectively followed throughout pregnancy and during the postpartum period. Maternal age, medical comorbidities and medication was recorded at the initial visit and disease activity was assessed throughout the follow up period. Adverse pregnancy outcomes were

recorded as were the following fetal outcomes: birthweight, neonatal hospitalization and congenital anomalies. Pregnancies were divided into 2 groups: Group 1 included patients who stopped their TNFi at any time during pregnancy and Group 2 included patients who continued their TNFi throughout pregnancy.

## Results:

There were 36 women with 42 pregnancies in this cohort. Mean maternal age was 31.9 in Group 1 and 33.9 in Group 2. In Group 1, 11 women had 13 pregnancies and 11 live births. There were 2 first trimester losses (2/13, 15%) one in the setting of active RA. Four pregnancies (4/13, 30.7%) were complicated by a disease flare; one patient with RA miscarried; two patients, one with RA and the other with PsA resumed TNFi therapy. Another patient with AS and IBD failed to achieve disease control after resuming her TNFi and required switching to another TNFi peripartum. Six other patients (6/13, 46%) flared postpartum (4 patients with RA, 1 AS, 1 JIA). In total, 10/13 (77%) flared during or after pregnancy.

In Group 2, 25 women had 29 pregnancies and 31 live births. Three (3/28, 10.7%) adverse pregnancy outcomes were reported in 2 patients. One patient had a twin pregnancy and delivered at 33 weeks after developing PPROM at 32 weeks in the setting of a JIA flare. Her second pregnancy was complicated by active JIA before and throughout gestation and HELLP syndrome necessitating a C-section at 39 weeks. Another patient with comorbid APS underwent a C-section at 36 weeks for suspicion of HELLP syndrome. Three (3/29, 10.3%) postpartum flares occurred: one patient with IBD and AS developed anti-infliximab antibodies and responded to another TNFi; one patient with RA required treatment with a different class of biologics; and another was treated with a corticosteroid injection and hydroxychloroquine. There were no other adverse pregnancy outcomes. All offspring were born healthy, with no congenital abnormalities, and all were appropriate size for gestational age. No neonatal infections were reported. Therefore, a total of 4/29 (13.7%) pregnancies were associated with a flare during or after pregnancy.

## Conclusion:

Women who discontinued their TNFi during pregnancy, had a higher risk of peri- or post-partum flare compared to those that continued their TNFi throughout pregnancy. TNFi were not felt to be responsible for gestational complications in group 2.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

LEF is a first line DMARD. Due to the teratogenic effects in offspring of rats in preclinical study, the patients who plan to get pregnant are advised to withdraw the drug before pregnancy and take cholestyramine (CHL) simultaneously.

To evaluate the outcome of pregnancy of Chinese women with rheumatic disease treated by LEF in real world practice.

**Methods:** The patients with rheumatic disease treated by LEF who planned to get pregnant in the near future were included. The patients withdrew the LEF and were prescribed with CHL for drug clearance, 8 g, tid, for 11 days. The patients were followed up regularly. The medication and pregnancy outcome were recorded. The informed consent was obtained for all patients included.

## Results:

66 patients cared by 43 doctors from 34 hospitals across China were enrolled. The mean age of patients were  $31.54 \pm 4.63$  (23-46) years old, including 39 (59.09%) patients with RA, 21 (31.82%) patients with SLE, 3 (4.55%) patients with ctd, 1 (1.52%) patient with IgAN, 1 (1.52%) patient with takayasu arteritis, and 1 (1.52%) patient with Sjogren syndrome. The mean disease course was  $6.72 \pm 2.87$  (2-19) years. The mean medication time with Lef was  $34.20 \pm 23.86$  (2-94) months. The mean dose was  $16.15 \pm 4.90$  (10-20) mg. The drug combination during peripregnancy included glucocorticoid, CsA, HCQ, FK506.

There were 36 patients who had live birth: 33 patients with singleton and 3 with twins; 31 patients used CHL and 5 did not; 33 planned to get pregnant (using CHL after withdrawal of LEF) and 3 had accidental pregnancy. The mean interval between withdrawal of LEF and being pregnant was  $10.40 \pm 6.16$  (-3-25) months; the mean interval between administration of CHL and being pregnant was  $7.20 \pm 6.21$  (-4-21) months. The children were healthy: mean age of  $27.50 \pm 36.46$  (1-228) months; 31 children of full-term birth, 5 of premature delivery, mean gestational age of  $38.17 \pm 2.56$  (28-40) weeks, 18% being low birth weight, mean birthweight of  $2951.57 \pm 694.02$  (1100-4200) g; Apgar score of  $9.87 \pm 0.50$  (8-10). The physical, mental and intellectual developments of offsprings are normal.

There were 9 (13.64%) patients who had abnormal pregnancy: 8 patients used CHL and 1 did not; all planned to get pregnant. The mean interval between withdrawal of LEF and being pregnant was  $11.92 \pm 4.61$  (6-18) months; the mean interval between administration of CHL and being pregnant was  $8.86 \pm 5.692$  (3-18) months. Among them, 5 had embryo (56%) development ceasing, 2 (22%) had spontaneous abortion, 1 (11%) had Down's syndrome, and 1 (11%) had labor induction due to relapse.

Due to the relapse of rheumatic disease, 12 (18.18%) patients resumed using immunosuppressive drugs including MTX and LEF, resulting in terminating the preparation of pregnancy. 9 (13.64%) patients are successfully got pregnant and ongoing with good conditions so far.

## Conclusion:

To our knowledge, this is the largest study about pregnancy outcomes with the treatment of lef. The teratogenic effects was not found, however, the spontaneous abortion and embryo development ceasing are worthy of attention. For the sake of safety, the patients who plan to get pregnant are encouraged to use CHL for drug clearance.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

A significant part of patients with inflammatory arthritis are at their reproductive ages. Anti-tumor necrosis factor-alpha (Anti-TNF) agents are one of the relevant treatment options for inflammatory arthritis which may cause fetal morbidity and mortality. Anti-TNF studies for pregnancy outcomes are mostly related with maternal exposure. In male patients, there are limited studies related to the fetal risks associated with the use of anti-TNF alfa agents before preconception period.

The objective of this study was to assess fetal loss, who used to anti-TNF agents during preconception period in male patients with inflammatory arthritis.

### Methods:

A questionnaire was performed to 160 male patients admitted to our outpatient clinic between July 2015 and July 2016 who use anti-TNF alfa agents. Patients were asked whether their wife's had got pregnant after the start of anti-TNF agents. If their wife's had got pregnant we asked about pregnancy outcomes.

### Results:

Totally, 42 (39 AS, 2 RA, 1 PsA) male patients' wife had pregnancy during patients continue to anti-TNF agents. General characteristics of the patients whose wife had got pregnant was shown in the table. The mean age of patients was  $36.4 \pm 5.2$  years. Median disease duration was 10 (IQR=11) years. Thirty-eight (90.5%) patients had live births and all newborns were healthy. The median gestation week was 39 (IQR = 3) weeks. Four (10.5%) births were preterm (ended in <37 gestation week). Mean birth weight of newborns was 3229 gram (gr) (SD = 582). Thirty-one (81.6%) newborn had normal (2500-4000 gr) birth weights. Four had low and 3 had high birth weights.

One pregnancy of a RA patient using etanercept and methotrexate was terminated due to oligohydramnios at 37<sup>th</sup> gestation week. The birth weight was 2850 gr and newborn was healthy.

One pregnancy of 35-years-old male AS patient using Adalimumab was ended in live birth in normal gestational week and normal birth weight but newborn diagnosed as Angelman Syndrome in the following.

Three (7.9%) out of 38 live births hospitalized in intensive care unit after delivery. The indications of ICU admission were unknown.

On the other hand, 3 (7.1%) pregnancies were ended in spontaneous abortions and 1 (2.4%) pregnancy were terminated with curettage. No congenital malformations were found in connection to paternal exposure.

### Conclusion:

Our study is one of the most extensive studies which provides the male number of patients and the pregnancy outcomes related to men in the literature. Study results suggest that anti-TNF drugs could be safe following paternal exposure.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

There are limited data regarding gestational timing of oral corticosteroid (OCS) use during pregnancy and risk of preterm birth. The objective was to compare preterm birth risk in pregnant women with rheumatoid arthritis according to timing of OCS and disease modifying antirheumatic drug (DMARD) use.

### Methods:

This study included pregnant women (n=537) with rheumatoid arthritis who enrolled in the MotherToBaby Autoimmune Diseases in Pregnancy Study (2003-2014) before 20 weeks' gestation. Information on medication use and pregnancy characteristics was collected by telephone interview at up to 3 time points during pregnancy and once after delivery, plus by medical record review. Exposures were classified into mutually exclusive groups: neither OCS nor DMARD (reference) OCS only, DMARD only, and both OCS and DMARD according to any use during the 1st trimester, 2nd trimester, and 90 days prior to gestational week 37 or delivery date, whichever occurred first. Modified Poisson regression was used to estimate relative risks (RR) and 95% confidence intervals (CI) between exposure and preterm birth, with separate models for each exposure window. Models were adjusted for year, maternal age, race/ethnicity, socio-economic status, overweight, autoimmune comorbidities, multiple gestation, nonsteroidal anti-inflammatory drug use, Health Assessment Questionnaire (HAQ) score at enrollment, and gestational age at enrollment.

### Results:

During pregnancy, 55% of women used OCS (of which 98% used prednisone), 68% used biologics, and 31% used non-biologic DMARDs. Median HAQ score at enrollment was 0.25 for neither OCS nor DMARD, 0.38 for OCS only, 0.25 for DMARD only, and 0.5 for OCS and DMARD use in the 1<sup>st</sup> trimester. Preterm birth risk was 6% in women who did not use OCS or DMARD during the 1st trimester, and the adjusted RR was 3.3 (CI: 1.1-9.5) for 1<sup>st</sup> trimester OCS, 1.7 (CI: 0.6-4.7) for DMARD, and 3.1 (CI: 1.2-8.0) for DMARD and OCS. Preterm birth risk was 13% in women who did not use OCS or DMARD during the 2nd trimester, and the adjusted RR was 1.5 (CI: 0.9-2.5) for 2nd trimester OCS, 0.6 (CI: 0.3-1.2) for DMARD, and 1.5 (CI: 0.9-2.6) for DMARD and OCS. Preterm birth risk was 11% in women who did not use OCS or DMARD in the 90 days before delivery or gestational week 37, and the adjusted RR was 1.8 (CI: 1.1-3.1) for OCS, 0.8 (CI: 0.4-1.7) for DMARD, and 1.9 (CI: 1.1-3.4) for DMARD and OCS.

### Conclusion:

Early and late pregnancy OCS use with or without DMARD use was associated with an increased risk of preterm birth compared with women who did not use OCS or DMARD. DMARD use alone was not associated with an increased risk of preterm birth. The OCS and preterm birth association was strongest for 1st trimester use partly due to low preterm birth risk in the 1<sup>st</sup> trimester reference group. Results may reflect residual confounding by RA severity.

## Pregnancy Outcomes in Patients with Psoriasis: A Nationwide Population-Based Study

**Meng-Jiun Chiou**<sup>1</sup>, Yu-Hui Huang<sup>2</sup>, Chang-Fu Kuo<sup>1</sup>, Kuang-Hui Yu<sup>1</sup>, Shue-Fen Luo<sup>1</sup> and Yao-Fan Fang<sup>1</sup>, <sup>1</sup>Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, <sup>2</sup>Department of Dermatology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

The pregnancy outcomes in women with psoriasis have rarely been investigated. This nationwide population study aimed to estimate the risks of adverse maternal and neonatal outcomes in women with psoriasis compared with the general population.

#### **Methods:**

Among 2,350,339 singleton pregnancies identified using the Taiwan National Health Insurance and national birth registry between 2001 and 2012, 3,669 pregnancies were delivered by psoriasis patients. Odds ratios (ORs) and 95% confidence intervals (CIs) for maternal and Neonatal outcomes were estimated adjusted for age, sex, Charlson comorbidity score, birth year, maternal nationality and socioeconomic status using an adjusted generalized estimating equation model.

#### **Results:**

Pregnancies with psoriasis were associated with an adjusted OR (95% CIs) of 1.06 (1.01-1.12) for Cesarean delivery, 1.40 (1.09-1.81) for gestational hypertension, 1.53 (1.25-1.86) for preeclampsia, 1.47 (1.04-2.08) for antepartum hemorrhage, 1.59 (1.36-1.86) for severe postpartum hemorrhage, 1.13 (1.00-1.28) for gestational diabetes. Neonatal outcomes were also poorer, with an OR (95% CIs) of 1.51 (1.12-2.03) for stillbirth, 1.30 (1.16-1.45) for low birth weight, 1.11 (1.00-1.24) for prematurity, 1.12 (1.02-1.24) for small for gestational age, 1.49 (1.01-2.19) for an Apgar score <7 at 5 minutes.

#### **Conclusion:**

Both maternal and neonatal outcomes are worse in women with psoriasis than in the general population.

## **Influence of Rheumatoid Arthritis and Axial Spondyloarthritis on Pregnancy Complications, Pregnancy Outcome and Delivery Mode**

**Frauke Förger**<sup>1</sup>, Stephanie van den Brandt<sup>2</sup>, Astrid Zbinden<sup>3</sup>, Monika Ostensen<sup>3</sup> and Peter M. Villiger<sup>3</sup>, <sup>1</sup>Inselspital, University of Bern, Bern, Switzerland, <sup>2</sup>Clinical Immunology and Rheumatology, University of Amsterdam, Amsterdam, Netherlands, <sup>3</sup>Rheumatology, Immunology and Allergology, Inselspital, University of Bern, Bern, Switzerland

**First publication:** September 18, 2017

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To analyze pregnancy complications, pregnancy outcome and delivery mode in patients with rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA).

**Methods:** Patients with RA and axSpA were compared with those of matched healthy controls (HC) with respect to pregnancy complications, pregnancy outcome and delivery mode. Patients and controls were prospectively followed at the University of Bern once at each trimester and two months postpartum. To identify risk factors for adverse pregnancy outcomes and delivery modes, multivariable logistic regression analyses were performed. Differences in birth weight of neonates in patients and references were examined in multivariable linear regression analyses.

**Results:** We analyzed 244 pregnancies, of which 96 pregnancies occurred in 86 RA patients, 78 in 70 axSpA patients and 70 in 70 healthy women. Compared with healthy pregnant controls, pregnant women with RA and axSpA showed a higher risk for pregnancy complications (gestational diabetes, preeclampsia, infection, preterm premature rupture of membranes) as well as for small for gestational age infants and for preterm deliveries. Active disease in both RA and axSpA was a risk factor for preterm delivery. Compared to neonates born to healthy mothers, those born to women with RA showed a mean reduction in birth weight of 414.4 gm and those born to women with axSpA had a mean reduction in birth weight of 254.4 gm. Regarding delivery mode, most women had vaginal deliveries (RA: 51.0%, axSpA: 57.7%, HC: 72.9%). We found an increased risk of caesarean section (C section) in women with RA compared with healthy controls which was not seen in axSpA patients. The risk of elective C section and emergency C section was not increased in RA and axSpA patients compared to the healthy control group.

**Conclusion:** Autoimmune inflammatory diseases such as RA and axSpA are risk factors for adverse pregnancy outcome. Since maternal disease activity is a risk factor for preterm delivery, disease activity should be sufficiently controlled during pregnancy.

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Given the limited data on impacts of perinatal medication use, our objective was to investigate the association between conventional synthetic DMARD (csDMARD) use preconception and during pregnancy and risk of preterm deliveries.

**Methods:** We linked population-based health data in British Columbia, Canada from 2002 to 2012 on all physician visits, hospital admissions, and dispensed medications with a perinatal registry. Essential data from this registry included date of conception according to ultrasound-confirmed gestational age or last menstrual period. We created a pregnancy cohort of women with inflammatory arthritis using a case definition of 2 outpatient physician ICD9 codes for RA, ankylosing spondylitis, JIA, PsA, or connective tissue diseases and adult systemic vasculitides, <sup>3</sup> 2 months and <sup>2</sup> 2 years apart. We grouped csDMARDs according to accepted safety profiles - antimalarials, gold, CSA, and SSZ (Group 1); and MTX, LEF, AZA, CYC, chlorambucil, penicillamine, MMF, and minocycline (Group 2) – and determined perinatal exposure over two periods: as binary use (yes/no) during the 90 days preconception and as time-dependent use during pregnancy from date of conception until delivery. We used Cox proportional hazards models to evaluate the association between csDMARDs exposure preconception and/or during pregnancy and risk of preterm

delivery, defined as live births with gestational age (GA) < 37 weeks, while adjusting for baseline and time-dependent covariates. Subgroup analyses were conducted according to csDMARD groups.

**Results:** There were 610 pregnancies in 512 women and 5639 pregnancies in 4078 women with and without csDMARDs exposure, respectively (Table 1). There were 562 (10%) and 138 (23%) preterm deliveries in unexposed and exposed pregnancies, respectively, with mean GA at delivery at 38.5 weeks (SD 2.06) in unexposed pregnancies, 38.3 (2.46) in Group 1, and 37.1 (2.96) in Group 2. The adjusted hazard ratio (HR) for exposure to csDMARDs preconception and during pregnancy and risk of preterm delivery was 2.12 (95%CI 1.63-2.76) (Table 2). In subgroup analyses, the risk of preterm delivery was highest in those exposed to Group 2 csDMARDs during pregnancy (HR 3.92, 95%CI 1.45-10.62).

**Conclusion:** Our findings suggest a risk of preterm delivery associated with exposure to csDMARDs preconception and during pregnancy. This may have been impacted by disease activity and differences in inflammatory arthritis types between exposure groups. Nonetheless, with mean GA of neonates approximating term delivery, it is important to consider the risks and benefits of medication use during pregnancy.

<b>Table 1. Characteristics of pregnant women with inflammatory arthritis exposed and unexposed to csDMARDs preconception and during pregnancy</b>		
<b>Characteristics</b>	<b>Exposed to csDMARDs</b>	<b>Unexposed to csDMARDs</b>

<sup>#</sup>other medication use during 90 days preconception and/or during pregnancy

Table 2. Multivariable models of csDMARD use preconception and/or during pregnancy and risk of preterm deliveries			
Models*	Exposure groups	Hazard ratio	95% Confidence Interval
Model 1 All csDMARDs	Preconception only vs. unexposed	1.37	1.03-1.82
	During pregnancy only vs. unexposed	1.93	0.80-4.65
	Preconception AND during pregnancy vs. unexposed	2.12	1.63-2.76
Model 2 Group 1 csDMARDs	Preconception only vs. unexposed	1.40	1.02-1.90
	During pregnancy only vs. unexposed	1.86	0.77-4.48
	Preconception AND during pregnancy vs. unexposed	1.87	1.40-2.49
Model 3 Group 2 csDMARDs	Preconception only vs. unexposed	1.58	1.02-2.44
	During pregnancy only vs. unexposed	3.92	1.45-10.62
	Preconception AND during pregnancy vs. unexposed	2.64	1.75-3.98
*All models were adjusted for baseline covariates including maternal characteristics (maternal age, neighborhood income quintile, parity, number of visits to rheumatologist, hospitalizations, and maternal body mass index); obstetrical history (prior premature births, spontaneous abortions, low birth weight births, congenital anomalies, neonatal deaths, stillbirths, total prior hospital admissions, number of antenatal visits); use of medications (glucocorticoids, traditional NSAIDs, COX2 NSAIDs, biologic DMARDs, anxiolytics, antidepressants); and comorbidities (asthma, depression, anxiety). All models were also adjusted for time-dependent covariates during pregnancy, namely use of medications (traditional NSAIDs, COX2 NSAIDs, biologic DMARDs, anxiolytics, antidepressants)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fertility is reduced in patients with Rheumatoid Arthritis (RA) due to unknown cause. Few studies mostly involving single center cohorts have addressed pregnancy outcomes in RA. This study was undertaken to determine the frequency of complications occurring during pregnancy for women with RA and to compare these outcomes with the general obstetric population by using the largest inpatient care database.

**Methods:** By using the 2003-2011 Nationwide Inpatient Sample of Healthcare Cost and Utilization Project, we estimated the number of obstetric hospitalization, deliveries and caesarean deliveries in women between the age group 18-50 years. Patients hospitalized with RA as one of the top three diagnoses were identified. Demographic characteristics and in-hospital outcomes were recorded for both RA and control group. Then we compared maternal and pregnancy complications for all pregnancy-related admissions for women with and without RA. Multivariate logistic regression analysis was used to obtain adjusted odds ratio (OR).

**Results:** The total number of obstetric hospitalization was 42.32 million of which 31439 were women with diagnosis of RA. The maternal age of RA population was higher (30.5 years) than that in the control group (27 years) ( $p < 0.001$ ). After adjusting for potential confounders, maternal RA population had a significantly higher prevalence of hypertensive diseases, premature rupture of

membranes, antepartum hemorrhage, preterm delivery, intrauterine growth retardation and cesarean delivery. However, the prevalence of postpartum hemorrhage and the risk of inpatient mortality were not different between two groups. The frequencies of the above outcomes along with Odds Ratio are provided in Table 1.

**Conclusion:** Based on our study of national cohort, we conclude that women with RA have a higher risk of adverse outcomes of pregnancy than do pregnant women without RA and thus close antenatal and post delivery monitoring need to be performed in order to reduce complications. The mean maternal age of RA population is higher likely secondary to infertility. Further studies are needed to examine these findings in relation to severity of disease, medications used and the presence of other comorbidities.

**Session Title:** ARHP Reproductive Issues in Rheumatic Disorders Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Guidelines recommend screening for cervical cancer in women starting at age 21 but according to the American Congress of Obstetricians and Gynecologists, exceptions should be made for those with HIV and those with weakened immune systems. It is recommended that sexually active adolescents with weakened immune systems should be screened six months apart in the first year after they begin having sex and then continue with annual pap tests. Though studies are limited, it appears that the prevalence of an

abnormal Papanicolaou (Pap) smear is significantly increased in patients with SLE. The purpose of this study was to examine pap smear results among SLE adolescent patients at our institution.

#### **Methods:**

An IRB approved retrospective chart review was performed on SLE female patients < 21 years. Patients were identified using ICD-9 codes between the years 2000-2016. Sexually active patients with a history of a pap smear were included in the study. Data reviewed included demographics, menarchal status, age of coitarche, contraceptive use, human papillomavirus vaccine (HPV) status, use of immunosuppressive medication and pathology reports. Fisher exact test was used to determine statistical significance.

#### **Results:**

18 patients met inclusion criteria. Mean age of SLE diagnosis was  $13.6 \pm 3.4$  years while the average age of menarche was  $12.6 \pm 1.4$  years. All patients were sexually active and the mean age of onset of sexual activity of  $16.2 \pm 1.8$  years, mean age of initial pap smear was  $18.4 \pm 1.7$  years with 44% having a pap smear within the first year of coitarche. Majority were on immunosuppressive medication (94.4%) and 88.9% were on teratogenic medication. Although all utilized progestin-only contraception, only 39% used Long Acting Reversible Contraception and only 39% reported consistent condom use. 83.3% reported ever receiving HPV vaccine.

9/18 (50%) had abnormal pap smears, 4 were atypical squamous cells of undetermined significance (ASCUS) and 5 were Low-grade squamous intraepithelial lesion (LSIL). Plan of care was for repeat pap smear in 1 year in all but one patient with ASCUS pap who underwent a colposcopy with biopsy result of mild chronic endocervicitis and squamous metaplasia. Average age of coitarche was 16 years in both groups. Mean time frame between coitarche to the initial pap smear was 1.66 years and 2.77 years, HPV vaccination rate was 77.8% and 88.8% for those with normal and abnormal pap results respectively. Only 22.2% reported consistent condom use in the abnormal pap smear group compared to 55.6% in the normal pap smear group. Fisher exact test revealed no statistically significant difference (P value 0.1534).

#### **Conclusion:**

No high-grade dysplasia on pap smear was noted in this small retrospective study of sexually active adolescent SLE patient. 50% of our sample size had an abnormal pap smear. Despite its limitations and small sample size, this study provides further evidence that women with SLE are at increased risk of developing cervical changes. Larger studies with inclusion of a control group are needed to conclude pap-testing recommendations in the adolescent SLE population.

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Spleen tyrosine kinase (Syk) is a non-receptor cytoplasmic tyrosine kinase. B-cell receptor (BCR) and Fc receptor-mediated syk signaling pathways lead to activation of several immune cells, including B-cells, macrophages and osteoclast. In these cells, Syk plays an essential role in diverse cellular responses, such as production of inflammatory mediators and differentiation. These roles of Syk in immunologic processes make it an attractive target for the development of therapeutic drugs against autoimmune diseases. We

identified TAS05567 as a highly selective syk inhibitor and assessed its therapeutic potential in rheumatoid arthritis (RA) as well as in immune thrombocytopenic purpura (ITP).

#### **Methods:**

In vitro biochemical assay was performed with available kinase assay panels. Anti-IgM-induced phosphorylation of BLNK and PLC $\gamma$ 2 was detected by flow cytometry in B cells. TNF- $\alpha$  production from monocytes induced by IgG was measured by ELISA. Effect of TAS05667 on the intracellular calcium level of basophilic cells was evaluated with FLIPR Calcium assay. Mature osteoclasts were detected with TRAP staining.

Rat CIA model: Lewis rats were immunized with a bovine type II collagen emulsion on day -14 and -7. To evaluate the therapeutic efficacy of TAS05567 in a rat collagen-induced arthritis (CIA) model, TAS05567 was started to administer for 14 consecutive days when the overt clinical signs of disease were observed. Swelling in hind paws were measured by a plethysmometer. At the end of the treatment period, the hind paws were removed to analyze histopathological changes.

Mouse ITP model: C57BL/6 mice were injected with anti-CD41 antibody and bled the following day to measure platelets count by a hematology analyzer. IVIg used as a positive control was intravenously administered once and TAS05567 was orally administered for 2 days.

#### **Results:**

TAS05567 showed high potency against enzymatic activity of Syk ( $IC_{50}$  = 0.37 nM).and only inhibited 4 kinases with inhibitory activity of 191 off-target kinases tested (>70% within 135-fold of Syk  $IC_{50}$ ). TAS05567 also inhibited BCR-dependent phosphorylation of BLNK and PLC $\gamma$ 2 in B cells with  $IC_{50}$  of 1.8 nM and 23 nM, respectively. TAS05567 effectively inhibited Fc $\gamma$ R-mediated TNF- $\alpha$  production in monocytes ( $IC_{50}$  = 27 nM) and Fc $\epsilon$ R-mediated calcium flux in basophilic cells ( $IC_{50}$  = 52 nM). Furthermore, TAS05567 suppressed mature osteoclast differentiation from precursor cells in a dose-dependent manner.

In the established rat CIA model, TAS05567 dose-dependently suppressed paw swelling compared with vehicle. In the histological analysis, TAS05667-treated mice had a marked reduction in the severity of inflammation, pannus, cartilage destruction and bone destruction.

In the mouse ITP model, thrombocytopenia was induced by intravenous injection of anti-CD41 antibody. TAS05567 significantly protected symptoms of thrombocytopenia and exhibited more potent efficacy than IVIg in this model.

#### **Conclusion:**

Our study demonstrates a novel Syk inhibitor, TAS05567, showed potent efficacy in both RA and ITP models. These data suggest that TAS05567 would be an attractive therapeutic agent for autoimmune diseases including RA and ITP.

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Background/Purpose:**

The erosions of bone and cartilage are a cardinal feature of rheumatoid arthritis (RA) and associated with disease severity and poor functional outcome. Although several anti-inflammatory drugs improve symptoms of articular inflammation, they are less effective against bone erosion. The bone erosions in RA are associated with aberrant activations of osteoclasts induced by pro-inflammatory cytokines and receptor activator of nuclear factor  $\kappa$ B ligand (RANKL). Bruton's tyrosine kinase (BTK), which is expressed in immune cells and mature osteoclast, is reported to be a key molecule in inflammatory response and bone resorption. Thus, targeting BTK may be efficacious against not only inflammation but also bone erosion through direct regulation of activation of effector cells such as B cells, macrophages and osteoclasts in RA.

In this study, we evaluated the effect of TAS5315, a novel BTK inhibitor, on the expression of inflammatory factors from macrophages and osteoclasts activation compared with BTK inhibitor CC-292, and bone erosion by time-dependent micro-CT analysis in mouse collagen-induced arthritis (CIA).

**Methods:**

Kinase selectivity of TAS5315 was assessed by available kinase assay panels. The effects of TAS5315 on macrophages and osteoclasts were assessed by examining phosphorylation of BTK, expression of inflammatory factors, osteoclast *differentiation and bone resorptions compared with that of BTK inhibitor CC-292*. TAS5315 were orally administrated once a day for 21 consecutive days in an established mouse CIA model. Disease severity was evaluated by clinical score of paw swelling. Changes in bone mineral density (BMD) and bone erosion by TAS5315 were assessed using time-dependent micro-CT analysis.

**Results:**

TAS5315 selectively inhibited the enzyme activity of BTK and had less off target inhibition against other kinases. TAS5315 dose-dependently suppressed the expression of inflammatory factors (TNF $\alpha$  and IL-8) in macrophages. TAS5315 showed more potent efficacy against phosphorylation of BTK, osteoclastogenesis and bone resorbing activity in osteoclasts compared with CC-292. In established mouse CIA model, TAS5315 significantly ameliorated paw swelling in a dose-dependent manner and showed the anti-inflammatory effects in pathological analysis at a dose of 0.1 mg/kg. Most importantly, TAS5315 also showed repair of bone erosion and improvements of BMD from joint destruction in the initial treatment by micro-CT analysis.

These data suggests that TAS5315 indicated more potent efficacy on joint damage as well as inflammation, and also improved bone erosion in murine model for RA through direct inhibitory effects against osteoclasts function.

**Conclusion:**

Our study demonstrates that TAS5315 could be a promising RA therapeutic agent by improving bone erosion as well as inflammation.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of immature cells that increase in the pathological state such as tumor or inflammation and have the immunosuppressive ability. MDSCs have been reported to ameliorate arthritis in several mice models. The mechanistic target of rapamycin (mTOR) pathway and glutaminolysis are known to be activated in the differentiation from myeloid progenitors to mature myeloid cells such as dendritic cells, macrophages, or osteoclasts. The aim of this study is to evaluate the facilitative effects of the inhibition of mTOR pathway and glutaminolysis on MDSCs in a mouse model of rheumatoid arthritis.

**Methods:** Bone marrow (BM) cells from untreated Balb/c mice were cultured for 5 days under granulocyte-macrophage colony-stimulating factor (GM-CSF) stimulation with four patterns of drugs; 1) DMSO (control), 2) rapamycin, 3) 6-Diazo-5-oxo-L-norleucine (DON; a glutamine analogue), or 4) the combination of rapamycin and DON. Cultured BM cells were analyzed by flow cytometry. Cultured MDSCs were isolated by manual MACS and analyzed their immunosuppressive characters by co-culture with CFSE-dyed CD4<sup>+</sup> T cells. The four patterns of drugs described above were administered intraperitoneally to arthritic SKG mice induced by Zymosan A injection.

**Results:** We found that DON administration (separately or in combination) significantly suppressed the differentiation from BM cells to dendritic cells *in vitro*. Most DON-treated BM cells showed the phenotype of MDSCs, large part of which were Ly6G<sup>+</sup> cells (the phenotype of polymorphonuclear MDSCs; PMN-MDSCs). On the other hand, rapamycin administration (separately or in combination) significantly increased the TGF- $\beta$  expression and the inhibitory capacity of Ly6G<sup>+</sup> PMN-MDSCs. The combination of rapamycin and DON was the most effective to suppress arthritis in SKG mice among these four treatment patterns (see Fig 1).

**Conclusion:** The combination of rapamycin and DON facilitates the expansion of PMN-MDSCs *in vitro* and synergistically ameliorates arthritis in SKG mice *in vivo*.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Methotrexate (MTX) is an anti-metabolite inhibitor of folate-dependent biochemical pathways and is effective in reducing disease activity in autoimmune arthritis. This work seeks to investigate the relationship between dysregulation of folates and response to MTX in the collagen-induced arthritis (CIA) mouse model, with respect to biomarker identification and drug development.

**Methods:** Arthritis was induced in male DBA/1 mice at 7-9 weeks of age by intradermal injection of chicken-collagen in complete Freund's adjuvant (Day 0) with a booster injection at Day 19 (n=25) and compared to healthy controls (n=5). Subcutaneous MTX injections of 0, 2, 10, 20, and 50 mg/kg were given weekly beginning at Day 14 for a total of 6 weeks. Arthritis disease activity was assessed by paw volume measurement and a 16-point clinical disease score. Mice were sacrificed at Day 54 and tissue samples were collected. Erythrocyte and liver tissue samples were evaluated for folate content by ultra-performance liquid chromatography tandem mass spectrometry. Liver tissue samples were analyzed for folic acid (FA), tetrahydrofolate (THF), 5-methyl-THF (5mTHF) and formyl-THF (fTHF), and RBCs were analyzed for 5mTHF content.

**Results:** Induction of arthritis in mice had no significant effect on RBC 5mTHF levels, but caused a marked dysregulation of liver folate. Compared to healthy controls, untreated disease mice were found to have a 37% reduction in liver 5mTHF ( $8.89 \pm 1.84$  vs  $5.58 \pm 1.10$  pmol/mg,  $p=0.01$ ) and a 57% increase in liver fTHF ( $3.54 \pm 0.63$  vs  $5.57 \pm 0.68$  pmol/mg,  $p=0.003$ ), with no significant impact on liver THF or FA content. Treatment with MTX resulted in a dose-dependent reduction in RBC 5mTHF, with a 32% reduction in the 50 mg/mL treatment group ( $p<0.05$ ) that is similar to those observed in patients treated with low-dose MTX. Interestingly, MTX at 50 mg/mL also caused a 42% increase in liver 5mTHF ( $p=0.03$ ) and a 47% reduction in liver fTHF ( $p=0.003$ ), resulting in levels similar to those seen in the healthy control mice. Decreased paw volumes across the animals studied were associated with reduced RBC 5mTHF ( $r=0.63$ ,  $p=0.004$ ), increased liver 5mTHF ( $r=-0.62$ ,  $p=0.002$ ), and reduced liver fTHF ( $r=0.48$ ,  $p=0.03$ ). Similarly, reduced disease activity scores were associated with reduced RBC 5mTHF ( $r=0.59$ ,  $p=0.008$ ) and increased liver 5mTHF ( $r=-0.67$ ,  $p=0.0006$ ).

**Conclusion:** Together, this data suggests that induction of autoimmune arthritis is associated with the dysregulation of tissue folates in the CIA mouse model, and is at least partially reversed by treatment with MTX. The increased ratio of fTHF to 5mTHF is hypothesized to reflect increased oxidation of folates under pro-inflammatory conditions. The finding that measurements of disease activity are associated with the effect of MTX on folates supports the role of folates as a therapeutic target and biomarker of drug response in autoimmune arthritis.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Release and insufficient removal of endogenous nucleic acids may be involved in triggering harmful autoimmune reactions important in the initiation of systemic autoimmune diseases including rheumatoid arthritis (RA). Nucleic acid sensing molecules, such as the endosomal Toll-like receptors (TLRs) 3, 7 and 9, have been linked to pathogenic autoimmune processes, particularly in systemic lupus erythematosus, but their role in RA is less obvious. Data previously obtained in rats with pristane-induced arthritis (PIA) suggested involvement of TLR9 in the pathogenesis of this arthritis model (Hoffmann MH et al. J Autoimmun. 2011; 36:288). Interestingly, rats with PIA develop autoantibodies associated with RA including rheumatoid factor, anti-RA33 and antibodies to carbamylated proteins (Stoop JN et al. Ann Rheum Dis 2015; 74:949). It was therefore the aim of this study to gain more insight into the role of TLR9 in the pathogenesis of autoimmune arthritis by investigating the effects of TLR9 inhibition in rats with PIA.

**Methods:** Arthritis was induced in DA rats with the mineral oil pristane. Rats were treated with a TLR9 antagonist or a control oligonucleotide every other day, starting one before disease induction. Arthritis was scored using established scoring systems, inflammation and bone erosion were quantified by histological analysis. Expression of TLR9 and other nucleic acid sensing TLRs was quantified by RT-PCR and Western blotting; activation (phosphorylation) of various signal transduction molecules was determined by Western blotting. Furthermore, the role of TLR9 in osteoclast differentiation and activation was investigated *in vitro* using an established murine bone marrow culture system.

**Results:** Clinical signs of arthritis were significantly ( $p<0.05$ ) reduced by 30-50% in animals treated with the TLR9 antagonist. Histological analyses revealed significantly ( $p<0.05$ ) diminished inflammation, cartilage degradation, bone erosion and reduced numbers of osteoclasts in joints of animals treated with the TLR9 antagonist. Furthermore, serum levels of IL-6, AGP and RF were significantly decreased and expression and activation of NF- $\kappa$ B in lymph nodes appeared to be reduced. However, when treatment was started after onset of arthritis TLR9 inhibition had no effect on arthritis development and severity. Remarkably, mRNA levels of TLR7 and TLR9 strongly differed in the course of *in vitro* osteoclastogenesis. Whereas TLR7 expression did not change throughout osteoclastogenesis, expression of TLR9 was higher in precursor cells than in mature osteoclasts and partial inhibition of osteoclastogenesis was seen when cultures were exposed to the TLR9 antagonist, whereas a TLR7 antagonist was ineffective.

**Conclusion:** These results suggest a crucial role for TLR9 in the T cell-dependent initiation phase of PIA and thus important involvement of endogenous DNA presumably released during apoptosis and/or necrosis (induced by pristane in lymphoid organs) in the initiation of autoimmune arthritis and during osteoclastogenesis. The relevance of these findings for human RA needs to be further elucidated in future experiments.

Session Date: Monday, November 6, 2017

Session Title: Rheumatoid Arthritis – Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Angiotensin II (Ang II) is known to function on various organs including kidneys, adrenal glands as well as the nervous and cardiovascular systems through its specific receptors, called Ang II type I receptor (AT1R), type II receptor and Mas receptor. In addition, recent studies have revealed that Ang II affects the skeletal system as well. The presence and up-regulation of receptors for Ang II and angiotensin converting enzyme, a key enzyme for the generation of Ang II, have been previously shown in the synovial tissue in patients with rheumatoid arthritis, suggesting the potential involvement of Ang II in the disease process. However, the details are not yet clear. The purpose of this study is to determine whether and how Ang II exacerbates TNF-induced bone destruction using a murine arthritis model.

**Methods:** To investigate the effect of exogenous Ang II, Ang II (1 µg/kg/min) was infused by osmotic pumps from 12 to 16 weeks of age in wild-type and human TNF-transgenic (hTNF-tg) mice. As controls, H<sub>2</sub>O was infused by osmotic pumps in each genotype. The swelling of the paws was graded as arthritis score once per week until 16 weeks of age. The bone property of the talus of the hind paws was analyzed by micro-computed tomography (CT) to assess the extent of bone erosion. Inflammation, bone erosion, and osteoclast formation were evaluated by histological analysis. To examine the role of endogenous AT1R on the erosive bone destruction, AT1R deficient (AT1R-KO) mice were crossed with hTNF-tg. Inflammation and bone erosion were evaluated as described above.

**Results:** Micro-CT and histological analyses revealed that systemic administration of Ang II significantly augmented bone erosion on hind paws in hTNF-tg mice. Ang II increased the number of osteoclasts around the talus. The severity of clinical arthritis and the histological degree of inflammatory cell infiltration were not affected by Ang II infusion. Interestingly, genetic deletion of AT1R also resulted in more severe bone destruction in hTNF-tg mice without affecting the clinical severity of arthritis.

**Conclusion:** Both systemic administration of Ang II and genetic deletion of AT1R exacerbated bone destruction in hTNF-tg mice. These results suggest that Ang II is likely to be involved in the TNF-induced bone destruction, and the binding of Ang II to the receptors other than AT1R may be important in the process. Our findings have important implication for the present clinical use of AT1R blockers in patients with rheumatoid arthritis.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Antibodies to proteins/peptides containing citrulline (commonly measured using cyclic citrullinated peptide, CCP2) are hallmarks of Rheumatoid Arthritis (RA). These antibodies are strongly associated with the expression of the Shared Epitope (SE), a major risk factor for RA. RA patients also generate antibodies to homocitrulline-containing proteins/peptides. The latter antibodies are often referred to as anti-carbamylated protein antibodies (Anti-CarP). Citrulline and homocitrulline are structurally similar. There is evidence supporting an important role for immune responses to citrulline in the pathogenesis of RA. We hypothesize that immune responses to homocitrulline are related to citrulline (cross-reactive) and are also arthritogenic. We aimed to study: (1) the relationship between homocitrulline and citrulline immune responses using an established mouse model of RA: DR4-transgenic (DR4tg) mice that express human SE, (2) whether homocitrulline immune responses are dependent on the SE and (3) induce arthritis in this animal model.

## Methods:

We used DR4tg mice on a C57BL/6 (B6) background; these mice express the human SE, lack endogenous murine MHC class II and are known to develop immune responses to citrulline and arthritis when immunized with citrullinated fibrinogen. DR4tg and B6 mice were immunized subcutaneously with a homocitrullinated peptide (HomoCitJED). We examined immune responses to HomoCitJED and CitJED, which have an identical number of modified amino acids on the same peptide backbone. Splenic T cell proliferation was evaluated by <sup>3</sup>H-thymidine incorporation assay. IgG anti-HomoCitJED, anti-CitJED, and anti-CCP2 antibodies were screened by enzyme-linked immunosorbent assay (ELISA). Antibody cross-reactivity was examined by inhibition with CitJED and HomoCitJED. Some HomoCitJED immunized mice also received intra-articular injection (IA) of HomoCitJED and joint swelling was measured using calipers.

## Results:

HomoCitJED immunized DR4tg mice developed early T and B cell responses to HomoCitJED and late responses to CitJED. These mice also developed anti-CCP2 antibodies. In some mice, antibodies to HomoCitJED were also reactive to CitJED. B6 mice immunized with HomoCitJED developed late T and B cell responses to HomoCitJED, but did not generate responses to CitJED or anti-CCP2 antibodies. Unlike DR4tg mice, anti-HomoCitJED antibodies from B6 mice did not react to CitJED. DR4tg mice immunized with HomoCitJED developed knee swelling following IA injections of HomoCitJED.

**Conclusion:** DR4tg mice immunized with HomoCitJED developed immune responses to CitJED, indicating cross-reactivity. CitJED immune responses were dependent on the SE. HomoCitJED responses occurred in the absence of the SE (B6 mice); however, they developed earlier in DR4tg SE-expressing mice. HomoCitJED is immunogenic and its intra-articular presence is required for knee swelling in DR4tg mice.

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Acarbose, an alpha-glucosidase inhibitor anti-diabetic drug exhibited anti-arthritic effects. The mechanism that acarbose exerts its anti-arthritic effects is not fully understood. Since > 90% of acarbose is not absorbed, we hypothesized that acarbose influences the gut microbiota that affects the course of arthritis. We tested this hypothesis in a collagen-induced arthritis (CIA) model.

**Methods:** CIA was induced by intradermal injection of chicken collagen type II (CII) emulsified in complete Freund's adjuvant in male DBA/1 mice. Acarbose, miglitol (a control drug) in drinking water were administered daily at 500 mg/kg via oral gavage. In the prophylactic regimen, mice were treated 7 days prior to the induction of CIA, and in the therapeutic regimen, mice were treated on the day of immunization. All mice were euthanized on day 55 after immunization. Fecal pellets were collected before immunization, during onset of arthritis and after treatment for identification of bacteria using 16S rDNA sequencing. Intestines and spleen were harvested for isolation of lymphocytes and analysis for changes of Th17 and Treg cells. Serum was obtained for analysis of cytokines and autoantibodies to CII.

**Results:** Administration before induction of CIA, acarbose significantly reduced the incidence of arthritis and attenuated clinical severity of arthritis. This was accompanied by a significant reduction of levels of anti-CII antibodies compared to those of drinking water treated or miglitol treated groups of mice ( $P < 0.05$ ). The frequency of Th17 cells was significantly decreased in the intestinal lamina propria in both acarbose and miglitol prophylactic treatment ( $P < 0.001$ ). Prophylactically treated mice with acarbose showed significantly increased CD4<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>+</sup> Treg cells ( $P < 0.01$ ) with elevation of Helios<sup>+</sup> ( $P < 0.01$ ) and CCR6<sup>+</sup> ( $P < 0.05$ ). Mice prophylactically treated with miglitol also showed an increase of CD4<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>+</sup> Treg cells ( $P < 0.01$ ) with increased CCR6<sup>+</sup> ( $P < 0.05$ ) in the mucosal sites. Furthermore, a remarkable alteration in microbial community was observed in both acarbose and miglitol treated mice. Bacterial diversity and richness in mice with arthritis were significantly lower than those in acarbose treated groups ( $P < 0.05$ ). The frequency of *Firmicutes* was significantly reduced after arthritis onset but was restored after treatment with acarbose. The frequency of *Lactobacillus*, *Anaeroplasm*, *Adlercreutzia*, *RF39* and *Corynebacterium* was significantly higher in control groups than in acarbose or miglitol treated, while *Oscillospira*, *Desulfovibrio* and *Ruminococcus* enriched in acarbose or miglitol treated groups.

**Conclusion:** These data demonstrated that alpha-glucosidase inhibitors, in particular acarbose alleviated CIA. The therapeutic effect was through regulation of Th17/Treg cells in the intestinal mucosal immunity which might be resulted from impact of these drugs on gut microbial community. These inexpensive antidiabetic drugs with an excellent safety profile are potentially useful for management of rheumatoid arthritis.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Paraoxonase 1 (PON1) is an HDL-associated protein, which hydrolyzes biologically active oxidized phospholipids and prevents oxidation of lipids in LDL and HDL. Increased lipid peroxidation and oxidized LDL have been implicated in the pathogenesis of rheumatoid arthritis (RA), and we previously reported low PON1 activity in active RA patients. The current work evaluated the effects of PON1 gene overexpression in the collagen antibody induced arthritis (CAIA) and the K/BxN serum transfer induced arthritis (STIA) models of RA.

## Methods:

Mice homozygous for the PON1 human transgene [PON1Tg] and wild type littermate control mice [WT] were injected intraperitoneally (n = 10 per group) with either 5mg of collagen antibody cocktail (Chondrex) on day 0, and 50ug of LPS on day 3 (CAIA), or 200ul of pooled K/BxN serum on days 0 and 2 (STIA). Arthritis activity was assessed using caliper measurements of hind limbs and clinical scores 3 times weekly until sacrifice at 2 weeks. PON1 activity was assessed using paraoxon (paraoxonase), dihydrocumarin (lactonase), and phenylacetate (arylesterase) as substrates (*A&R* 2013; 65: 2765). Lipids were assessed by standard assays, and a luminex cytokine/chemokine panel analysis was performed for STIA group of mice.

## Results:

PON1Tg mice had significantly lower arthritis activity compared to WT mice in both CAIA and STIA models (Table). Arthritis activity was more severe in STIA. PON1 activity was strongly correlated with arthritis activity using all 3 assays of PON1 function ( $r$  values= -0.5 to -0.7; all  $p$  values<0.05); higher PON1 activity was associated with lower arthritis activity by joint scores. WT mice had significant increases in triglycerides (TG) and significant decreases in both total cholesterol (TC) and unesterified cholesterol (UC) post arthritis induction. In contrast, PON1Tg mice had no significant changes in TG, TC, or UC, but had significant increases in HDL cholesterol post arthritis induction in STIA. A trend was noted for lower serum IL-6 concentrations post arthritis in the PON1Tg mice (11±6 pg/ml) compared to WT mice (15±7 pg/ml), however no significant correlations of serum cytokine/chemokine levels with arthritis activity were noted.

## Conclusion:

Overexpression of the human PON1 transgene in two mouse models of RA was associated with reduction of inflammatory arthritis activity, which correlated strongly with serum PON1 activity. Further investigation of mechanisms behind these findings is warranted to evaluate potentially novel lipid pathways for treatment of RA.

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Our proprietary variant Ig domain (vIgD) platform creates novel, therapeutically-applicable protein domains with tailored specificity and affinity. These vIgDs are created through directed evolution of immunoglobulin superfamily (IgSF) proteins, which are key components of the immune system that include well-known family members such as PD-1, PD-L1, and CTLA-4. CD28 and Inducible T-cell Costimulator (ICOS) are two related costimulatory molecules within the IgSF which are expressed on T cells and interact with CD80/CD86 and ICOS ligand (ICOSL), respectively. Both play critical roles in T cell activation and adaptive immunity. We have used our vIgD platform to generate human ICOSL-Fc vIgDs capable of binding both ICOS and CD28, blocking the interaction of these costimulatory molecules with their respective receptors.

**Methods:** ICOSL-Fc molecules were evaluated *in vitro* in mixed lymphocyte reactions (MLR) generated using negatively-selected human pan T cells mixed with activated human monocyte-derived dendritic cells, and *in vivo* in standard mouse models of delayed type hypersensitivity (DTH), collagen-induced arthritis (CIA), and human-mouse xenograft PBMC-NSG<sup>TM</sup> graft versus host disease (GvHD).

**Results:** ICOSL-Fc fusion proteins containing variant ICOSL domains significantly attenuate T cell activation *in vitro* as assessed by suppressed proliferation and cytokine production in MLR. They also reduce mouse DTH reactions *in vivo*. ICOSL-Fc molecules mediate significant disease reduction, matching or exceeding CTLA-4-Ig comparators targeting only the CD28 pathway in mouse CIA, and in the human PBMC-NSG<sup>TM</sup> GvHD model. ICOSL-Fc suppresses the production of anti-collagen antibodies in CIA, likely reflecting the key roles CD28 and ICOS play in follicular helper T cell differentiation and T-dependent antibody responses.

**Conclusion:** Efficacy *in vitro* and *in vivo* of ICOSL-Fc is superior to wild-type ICOSL domains due to the induced alterations in affinity for cognate ligand (ICOS) and through specifically directed changes in ICOSL-Fc's ability to bind additional counter-structures (i.e. CD28). Thus, vIgDs like these ICOSL variants can be developed to acquire unique biochemical properties that can potentially significantly enhance their therapeutic utility as immunomodulatory agents. This vIgD therapeutic platform has broad potential to enhance the activity of biologics in treatment of autoimmune and other disorders driven or subject to modulation by IgSF proteins, such as cancer and infectious diseases. Preclinical development of ICOSL-Fc has been initiated to support clinical studies.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Filgotinib (FIL), a JAK1 inhibitor, and GS-9876, a SYK inhibitor, are currently being evaluated as once-daily monotherapy in subjects with rheumatoid arthritis (RA). A preclinical study was conducted to compare the efficacy of FIL + GS-9876 in combination versus monotherapy of each agent in a rat collagen-induced arthritis (CIA) model. A semi-mechanistic pharmacokinetic/pharmacodynamic (PK/PD) model was developed to 1) characterize the exposure (plasma concentration)-response

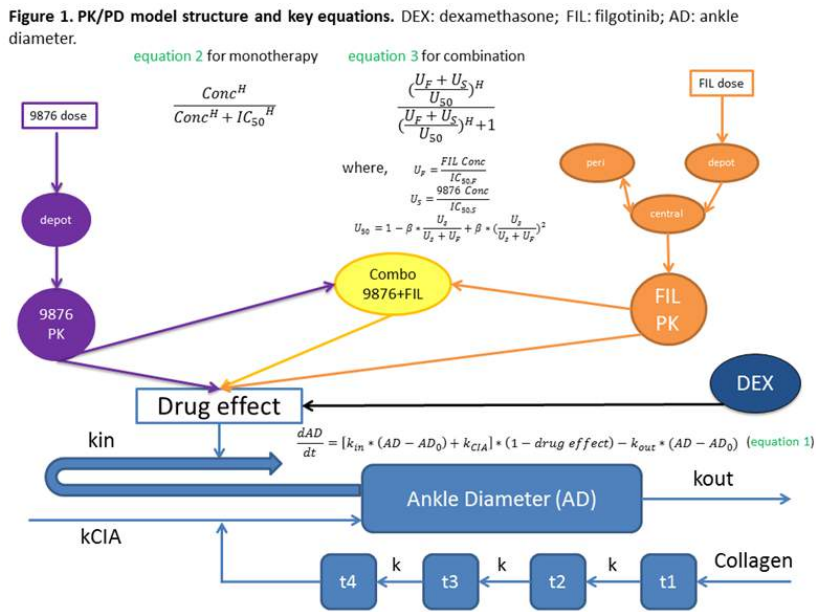

(ankle diameter) relationship following mono- and combination therapy, and 2) provide a quantitative assessment of PD interaction between the two drugs.

**Methods:** Monotherapy (FIL at 3 doses 1,3, or 5 mg/kg, QD or GS-9876 5 mg/kg BID) and the combination (FIL 1, 3 mg/kg QD and GS-9876 5mg/kg, BID) treatments were administered to CIA rats. FIL was co-administered with the active metabolite to reflect the PK profile in humans. Dexamethasone at 0.075 mg/kg QD was the positive control. Dosing was initiated at the peak of inflammation (day 17-20) and continued through the chronic disease phase until day 34. Population PK models were developed to characterize FIL and GS-9876 concentration versus time profiles. Disease progression, assessed as the change in ankle diameter over time, was described by equation 1 (indirect response model), and drug effect (monotherapy and combination) by equations 2 and 3 (Figure 1; **Ref: Minto et al., 2000**). The analysis was conducted using a nonlinear mixed-effects modeling approach (NONMEM 7.3) and R v3.3.2 was used for processing/visualizing data.

**Results:** The model adequately described the PK of FIL/GS-9876 and the exposure-response relationship, following monotherapy and combination therapy. The results indicated a dose/exposure dependent reduction in ankle paw diameter following FIL monotherapy. Furthermore, a synergistic effect on efficacy was observed (based on an estimated  $\beta$  value >1) following treatment with the combination compared with either agent alone. Simulations (of various dose levels) indicated an exposure dependent increase in efficacy following combination treatment, with a plateau at doses  $\geq$  FIL 3 mg/kg QD + GS-9876 5 mg/kg BID.

**Conclusion:** The PK/PD model demonstrated a synergistic interaction between FIL and GS-9876, thereby suggesting the utility of simultaneously targeting the JAK and SYK receptor pathways for RA. Furthermore, the model provides a quantitative framework for screening various drug combinations (of two or more drugs) in CIA rats and may help in selecting efficacious combinations for clinical assessment.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Theta ( $\theta$ ) defensins are the only known macrocyclic peptides found in the Animal kingdom and are exclusively expressed in Old World monkeys.  $\theta$ -defensins were discovered as antimicrobial effector molecules in rhesus macaque neutrophils, but later found to possess immune regulatory activity. Rhesus macaque theta defensin-1 (RTD-1), the prototype  $\theta$ -defensin, down-regulates expression of pro-inflammatory cytokines by macrophages stimulated with TLR agonists, reduces lethality in bacteremic and severely septic mice and also dose-dependently inhibits MAP kinase and NF- $\kappa$ B pathways in LPS-stimulated monocytes and macrophages. We recently showed that systemic administration of RTD-1 to rats with established pristane-induced arthritis (PIA), a model of rheumatoid arthritis (RA) rapidly arrests and induces resolution of arthritis. Pathogenesis of RA involves inflammation of the synovium, joint erosion and the dysregulation of immune signaling and cytokine gene expression pathways. We hypothesized that RTD-1 regulates the gene expression and signaling pathways in inflamed synovial tissues.

**Methods:** PIA was induced in DA rats and RNA-seq analysis was performed on synovial tissue RNA harvested from naïve and diseased rats, and from rats with PIA that were treated with vehicle or RTD-1. Bioinformatics analysis was used to investigate changes in gene expression in treated and untreated animals. These changes in gene expression were validated by quantitative real time PCR. Ingenuity Pathway Analysis (IPA) was used to identify signaling pathway targets of RTD-1.

**Results:** RNA-seq analysis revealed differential expression of 258 and 107 synovial tissue genes by 3 days and 5 days of RTD-1 treatment respectively (False Discovery Rate  $p < 0.05$ ; fold change  $> \pm 1.5$ -fold). qPCR analysis of 12 genes confirmed the RTD-1 regulation detected with RNA-seq. Bioinformatics analyses revealed that RTD-1 treatment modulates genes involved in leukocyte migration, extracellular matrix, rheumatoid arthritis, regulation of cytokine activity and in additional immune response pathways. Analysis of gene expression data by IPA identified, among others, inhibition of pathways stimulated by proinflammatory cytokines such as TNF $\alpha$ , IL-1 $\beta$ , IL-6 and activation of anti-inflammatory nuclear receptor pathways after 5 days of RTD-1 treatment, consistent with resolution of disease.

**Conclusion:** RTD-1 regulates genes and signaling pathways that are operative in RA and experimental arthritis and induces an anti-inflammatory gene signature in treated PIA rats. RTD-1 regulated genes and pathways include targets for FDA-approved treatments for RA underscoring the potential for RTD-1 as a future new treatment for RA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Periodontitis induced by oral pathogen *Porphyromonas gingivalis* (Pg) has been suggested to be associated with rheumatoid arthritis (RA). Pg peptidyl arginine deiminase -mediated citrullination and induction of anti-citrullinated protein antibodies seems to contribute to the development of RA, however, the exact mechanism remains unknown. We hypothesized that the fimbriae -flexible appendages on the bacterial cell surface- of Pg (FimA) play an important role in the link between Pg infection and RA development by serving as attachment pili and helping invasion into host cells of RA patients.

**Methods:** Collagen induced arthritis (CIA) induced mice were periodontally infected with Pg or Pg pre-incubated with anti FimA antibody (Ab). The number of oral anaerobic bacteria, and the degree of alveolar bone loss was determined to examine the severity of periodontitis. Joint inflammation and destruction was investigated by histological analysis and micro CT. Bacterial invasion into human gingival fibroblast (HGF) cell line or RA synovial fibroblast (RASf) was measured by electron microscopy and immunohistochemical analysis.

**Results:** Oral inoculation of Pg in CIA mice increased the number of total oral anaerobic bacteria, aggravated alveolar bone loss, and exacerbated synovitis and joint bone destruction. However, pre-incubation of Pg with anti-FimA Ab led to a significant reduction in the severity of both oral disease and arthritis. Moreover, FimA Ab pretreatment attenuated Pg attachment and aggregation on HGF and RASf. Pg was found in the joints of CIA mice, which suggests that orally inoculated Pg migrated to inflamed joints carried within the dendritic cells, macrophages, and neutrophils recruited to arthritic joints. However, FimA Ab treated-Pg was not found in the joints of CIA mice.

**Conclusion:** These results suggest that Pg fimbriae play a pathogenic role in Pg infection associated RA development. Disrupting Pg fimbriae suppresses the periodontitis and bacterial migration to the arthritic joints and thus, ameliorates joint inflammation in RA.

## Periostin Deficiency Exacerbates Joint Inflammation and Bone Destruction in Mouse Models of Rheumatoid Arthritis

**Yun-Hong Cheon**, Division of Rheumatology, Department of Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Periostin (POSTN), a matricellular protein, is involved in many fundamental biological processes such as bone metabolism, cell proliferation, cell invasion, and angiogenesis. Also, POSTN has been shown to be involved in many aspects of inflammation, wound fibrosis and recruitment several immune cells. Although POSTN expression has been reported to promote migration and invasion of fibroblast-like synoviocyte (FLS) in vitro, there is no study to investigate the role of POSTN in mouse models of rheumatoid arthritis (RA). This study was performed to assess the function of POSTN in 3 mouse models of arthritis, K/BxN serum transfer arthritis (STA), collagen-induced arthritis (CIA) and collagen-antibody induced arthritis (CAIA).

### Methods:

Periostin level in synovial fluid from RA and osteoarthritis (OA) patients were measured by ELISA. The expression of periostin FLS was stained by immunohistochemistry. STA, CIA and CAIA was induced in POSTN<sup>-/-</sup> and POSTN<sup>+/+</sup> mice. Arthritis was monitored in 3 mouse models of arthritis using defined criteria (clinical and histologic). Osteoclastogenesis was assessed using bone marrow monocytes (BMM) cultures from POSTN<sup>-/-</sup> and POSTN<sup>+/+</sup> mice.

#### Results:

POSTN level in synoviocyte tissue were increased in patient with RA compare to OA patient. In STA studies, the clinical score and hind paw thickness were significantly increased in POSTN<sup>-/-</sup> mice compared with POSTN<sup>+/+</sup> mice. Mean histologic severity scores including synovial inflammation, bone erosion and cartilage damage were increased in diseased joints from POSTN<sup>-/-</sup> mice compared with those from POSTN<sup>+/+</sup> mice. The IL-1 $\beta$  was increased in the serum, and TNF- $\alpha$ , IL-1 $\beta$ , and MMPs were increased in the ankle of POSTN<sup>-/-</sup> mice than wild type control. BMMs from POSTN<sup>-/-</sup> mice showed increased osteoclast formation compared with BMMs from POSTN<sup>+/+</sup> mice. Similarly, in CAIA and CIA model, both mean clinical severity scores and ankle joint swelling were significantly increased in POSTN<sup>-/-</sup> mice compared with POSTN<sup>+/+</sup> mice.

#### Conclusion:

This study suggests that POSTN contributes to pathogenesis of RA and might have a potential protective role in RA.

## Mortality of Tumor Necrosis Factor Transgenic Arthritic Mice with Interstitial Lung Disease Occurs with Pulmonary Arteriole Thickening and Right Ventricular Hypertrophy but Is Not Associated with Inducible Nitric Oxide Synthase Dependent Inflammatory Cell Infiltration

**Richard Bell**<sup>1</sup>, Emily Wu<sup>1,2</sup>, Homaira Rahimi<sup>3</sup> and Edward Schwarz<sup>1,4,5</sup>, <sup>1</sup>Center for Musculoskeletal Research, University of Rochester, Rochester, NY, <sup>2</sup>Department of Immunology, Microbiology, and Virology, University of Rochester, Rochester, NY, <sup>3</sup>Rheumatology, University of Rochester/Golisano Children's Hosp, Rochester, NY, <sup>4</sup>University of Rochester, Rochester, NY, <sup>5</sup>Univ of Rochester Med Ctr, University of Rochester School of Medicine and Dentistry, Rochester, NY

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis associated interstitial lung disease (RA-ILD) occurs in up to 15% of RA patients, whose median survival expectancy after diagnosis is only 2.6 years. The tumor necrosis factor-transgenic (TNF-Tg) mouse model of RA develops cellular ILD with increased mortality, which is presumed to be from lung and cardiac failure secondary to ILD. In the context of arthritis, inducible nitric oxide synthase (iNOS) is detrimental to clearance of immune cells from the joint, and selective iNOS inhibitors restore lymphatic flow. Thus, we hypothesize that ILD pathology is decreased in iNOS<sup>-/-</sup> x TNF-Tg mice.

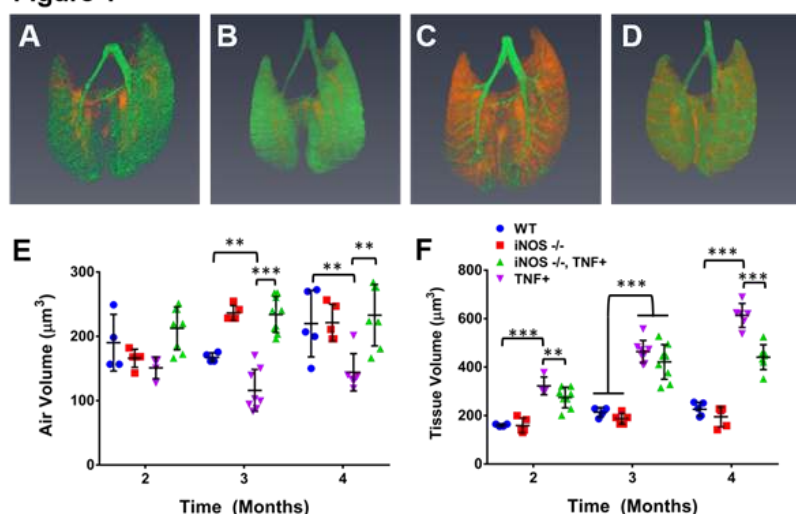

**Methods:** To test this, female TNF-Tg, iNOS<sup>-/-</sup>, iNOS<sup>-/-</sup> x TNF-Tg and WT littermates were weighed and scanned with  $\mu$ CT to investigate differences in ILD at 2, 3 and 4 months (Mixed Model with Tukey's Post-Hoc, \*\*\*p<0.001). The mice were euthanized at 4 months to perform histology on the hearts and lungs for histomorphometry (ANOVA, \*\*p<0.01). In a separate cohort, iNOS<sup>-/-</sup> x TNF-Tg, TNF-Tg and WT littermate were aged to investigate lifespan differences.

**Results:** There were no differences in weight or lifespan between the iNOS<sup>-/-</sup> x TNF-Tg and TNF-Tg, both failing to gain weight from 2mo and dying at 5mo. However,  $\mu$ CT 3D reconstructions of 4 months old WT (A), iNOS<sup>-/-</sup> (B), TNF-Tg (C) and iNOS x TNF-Tg (D) show preservation of air space and decrease in tissue volume in the iNOS<sup>-/-</sup> x TNF-Tg (**Fig 1, Air = Green, Tissue = Orange**). Quantification reveals a significant increase in air volume at 3 and 4 months in iNOS<sup>-/-</sup> x TNF-Tg compared to TNF-Tg (**E**, 3mo: 229 $\pm$ 26 $\mu$ m<sup>3</sup> vs 116 $\pm$ 32 $\mu$ m<sup>3</sup>, p<0.001; 4mo: 225 $\pm$ 48 $\mu$ m<sup>3</sup> vs 133 $\pm$ 42 $\mu$ m<sup>3</sup>, p<0.001), similar to WT and iNOS<sup>-/-</sup> (4mo: 219 $\pm$ 51 $\mu$ m<sup>3</sup> and 227 $\pm$ 28 $\mu$ m<sup>3</sup>). Furthermore, tissue volume was significantly decreased at 4mo in iNOS<sup>-/-</sup> x TNF-Tg compared to TNF-Tg (**F**, 438 $\pm$ 55 $\mu$ m<sup>3</sup> vs 606 $\pm$ 51 $\mu$ m<sup>3</sup>, p<0.001). Lung histomorphometry confirmed these  $\mu$ CT results finding more white area and less total cells in iNOS<sup>-/-</sup> x TNF-Tg compared to TNF-Tg. Interestingly, iNOS<sup>-/-</sup> x TNF-Tg and TNF-Tg had severe arteriole thickening (Green Arrows in **Fig 2, B and C**) in the lung (**Fig 2 D**, 0.01 $\pm$ 0.01mm<sup>2</sup> and 0.007 $\pm$ 0.005mm<sup>2</sup>) compared to WT (0.002 $\pm$ 0.001mm<sup>2</sup>, p<0.001). The right ventricle was also thicker in iNOS<sup>-/-</sup> x TNF-Tg and TNF-Tg than WT (**Fig 2 H**, 726 $\pm$ 108 $\mu$ m<sup>2</sup>, 664 $\pm$ 35 $\mu$ m<sup>2</sup> vs 359 $\pm$ 85 $\mu$ m<sup>2</sup>, p<0.01).

**Conclusion:** This study demonstrates for the first time that the cellularity of ILD in this model of RA is iNOS dependent, and is not associated with decreased lifespan. Moreover, lung arteriole thickening and right ventricular hypertrophy are consistent with pulmonary hypertension, likely causing cardiac failure and increased mortality in TNF-Tg mice.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Collagen-induced arthritis (CIA), a representative animal model of chronic inflammatory arthritis, follows phases of induction, peak of inflammation and resolution. This study aims to identify the key regulator genes that change with time course in animal models of rheumatoid arthritis through dynamics analysis.

**Methods:** We first investigated gene expression profiles in the synovial tissues of mice with CIA at early, peak, resolution phase of arthritis using microarray analysis and identified differentially expressed genes (DEGs) associated with arthritis resolution. We built a resolution-associated network model describing interactions among these DEGs and then selected three hub-like genes from the network model, which can significantly contribute to regulating function of the resolution-associated network. We examined the level of gene expression in the synovial tissues and the function of selected genes in resolution of CIA.

**Results:** From time-course gene expression profiles of CIA synovial tissues, we identified 2237 resolution-related genes, and found that these genes were significantly associated with Toll-like receptor and T and B cell receptor signaling pathways. Network analysis of these resolution-related genes further selected three hub genes, *Itgb1*, *RPS3* and *YwhaZ*, that can be predominantly responsible for arthritis resolution. These genes were highly expressed in independent synovial tissues at resolution phase. Particularly, the expression of *Itgb1*, *RPS3* and *YwhaZ* was elevated in regulatory T cells and alternatively-activated macrophages (M2) that are involved in restoration of chronic inflammation. Moreover, recombinant *Itgb1*, *RPS3*, and *YwhaZ* dose-dependently reduced pro-inflammatory cytokine expression in peritoneal macrophages and splenocytes. To test a potential application of proteins from selected genes for detecting the arthritis resolution, the levels of proteins from the selected genes also were analyzed in mice serum and urine of patients with rheumatoid arthritis (RA). As a result, serum *YwhaZ* concentration was higher at resolution phase than at peak phase among the three proteins from selected genes. Additionally, *YwhaZ* concentrations in the urine of patients with rheumatoid arthritis were associated with the degree of treatment response; *YwhaZ* levels increased significantly after treatment in good response group (n=23) while the protein level before and after treatment were not different in moderate (n=12) or none (n=25) response group.

**Conclusion:** Our comprehensive analysis of gene profile contributing to arthritis resolution reveals novel anti-arthritic genes, *tgb1*, *RPS3*, and *YwhaZ*. We anticipate that *tgb1*, *RPS3* and *YwhaZ* will be novel targets for predict the arthritis resolution and could be therapeutic targets for chronic inflammatory arthritis.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Rheumatoid arthritis (RA) is characterised by massive bone erosions leading to irreversible joint destructions. In this context, the multi-adaptor protein p62/SQSTM1 is of interest because apart from its involvement in autophagy, p62/SQSTM1 also interacts with TNFalpha signalling pathways and has the ability to bind directly to TRAF6 resulting in the stimulation of osteoclastogenesis. Here, we sought to investigate, whether based on these signalling characteristics, p62/SQSTM1 is functionally involved in human RA and in animal models of the disease.

## Methods:

Tissue samples of RA (n=30) and OA (n=9) patients were analysed to identify correlations between p62 expression and RA diagnosis, disease duration and medication. Furthermore, mice were generated that carry a shortened, but functional mutant of p62 with defective signal transduction domains (p62<sup>aaD69-251</sup>) for interbreeding studies with arthritic hTNFtg mice. The resulting genotypes (wt, hTNFtg, p62<sup>aaD69-251</sup> and hTNFtg/ p62<sup>aaD69-251/wt</sup>) were scored for clinical parameters (paw swelling, grip strength, weight) for 14 weeks. To quantify the extent of inflammation, cartilage degradation and number of osteoclasts, joints of 14 wks old mice were embedded into paraffin and stained with toluidine blue and TRAP. In addition, bone marrow derived monocytes (BMDMs) were isolated from all genotypes and osteoclastogenesis was studied using an established osteoclast formation assay. To investigate the underlying signalling pathways, cells were treated with TNFalpha at different time points, and MAPK activation was studied by Western blot analyses.

## Results:

A significant correlation of p62 expression with RA and prolonged disease duration and specific treatment was found (p<0.05). In our animal studies, histology revealed only minor changes in the number and size of osteoclasts between p62<sup>aaD69-251</sup> and wt animals suggesting that under physiological conditions, regulatory mechanisms compensate for the lack of the signal transduction domains of p62. Compared to wt cells, however, BMDMs of p62<sup>aaD69-251</sup> mice showed a significantly increased osteoclastogenic potential (+28,9% vs hTNFtg BMDMs), in particular when stimulated with TNFalpha *in vitro* (+30,6% vs hTNFtg BMDMs). Crossing of p62<sup>aaD69-251</sup> mice with hTNFtg animals resulted in a dramatic increase in the severity of joint damage in the hTNFtg/p62<sup>aaD69-251/wt</sup> mice as determined clinically and by histomorphometry, showing a significant increase of inflammation area (+113,9% vs hTNFtg) and the number and size of osteoclasts *in vivo* (+278,5% vs hTNFtg). Interestingly, MAPK activation studies only showed minor differences between wt and p62<sup>aaD69-251</sup> BMDMs.

## Conclusion:

In summary, our human expression data as well as the functional mouse data suggest that p62 is an important regulator of TNFalpha mediated joint damage. They indicate that the loss of the TRAF6 and aPKCs binding domains of p62 has important consequences for osteoclastogenesis under inflammatory conditions.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is characterized by inflammation and subsequent infiltration of peripheral blood monocytes (MNs) into the synovial tissue (ST). Micro (mi)RNAs are non-coding RNAs which regulate many physiological and pathological functions at the posttranscriptional level. We performed miRNA PCR array and found a panel of miRNAs, including miR429, were highly expressed in response to TNF- $\alpha$  in MNs. Hence we examined the contribution miR429 and one of its target genes, PAK2, in MN chemotaxis and acute inflammatory arthritis.

**Methods:** The expression of miR429 in RA and NL MNs was assessed via quantitative (q)PCR. RA MNs and RA fibroblast-like synoviocytes (FLS) were transfected with inhibitors and mimics of miR429 for 24 hours. Then these cells were stimulated with TNF- $\alpha$  for 25 minutes to determine phosphorylation of signaling molecules by Western blotting. We transfected U937 cells, a human leukemic MN lymphoma cell line, and NL MNs with miR429 mimics and inhibitors and performed chemotaxis. To investigate the role of miR429 in acute inflammation, miR429 shRNA or control shRNA were packaged into lentivirus and injected into mouse knees 30 minutes prior to administration of TNF- $\alpha$  or Zymosan. Mouse knee circumference was measured before injections and again 24 hours later. Following euthanasia, knees were harvested for immunofluorescence staining or homogenized for analysis of inflammatory cytokines.

**Results:** Non-stimulated RA MNs had a 2.6 fold increase in miR429 expression compared to non-stimulated Normal (NL) MNs by qPCR. We also found that miR429 is inducible, TNF- $\alpha$  induced significantly higher miR429 expression in NL MNs compared to non-stimulated MNs. With regards to MN migration, inhibition of miR429 decreased migration of U937 cells and MNs in response to MCP1/CCL2, suggesting a role for miR429 in MN migration. TNF- $\alpha$  upregulation of phospho-Erk, -JNK and -NFkB was decreased when RA MNs were transfected with miR429 inhibitor. Similarly, a decrease of TNF- $\alpha$  induced phospho-Erk, -JNK and -NFkB was observed in RA FLS. Furthermore we also determined that a miR429 target gene, PAK2, was downregulated when miR429 was inhibited in RA MNs and RA FLS. Additionally, TNF- $\alpha$  and Zymosan treated mouse knee swelling was significantly reduced in mice injected with miR429 inhibitor compared to control, indicating that miR429 is critical to arthritis development *in vivo*. We also found decreased ingress of leukocytes into mouse knee cryosections treated with miR429 inhibitor.

**Conclusion:** miR429 expression is increased with TNF- $\alpha$  stimulation and has higher levels in RA compared to NL MNs. miR429 plays an essential role in the migration of MNs and also regulates phosphorylation of signaling molecules and PAK2 transcription factor. Additionally mice treated with miR429 inhibitor showed decreased inflammation indicating the importance of miR429 in acute inflammation and MN recruitment. This data suggests that miR429 may be a therapeutic target in MN dependent diseases.

## ASN002, a Novel Dual SYK/JAK Inhibitor, Demonstrates Strong Efficacy in a Rat Model of Collagen-Induced Arthritis

**David Zammit**<sup>1</sup>, Sanjeeva Reddy<sup>1</sup>, Roger Smith<sup>1</sup>, Nitin Damle<sup>2</sup> and Sandeep Gupta<sup>1</sup>, <sup>1</sup>Asana BioSciences LLC, Lawrenceville, NJ, <sup>2</sup>Preclinical R&D, Sun Pharma Advanced Research Co. Ltd, Mumbai, India

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Spleen tyrosine kinase (SYK) and Janus kinase (JAK) mediate signaling in immune cells and hematopoietic cells important for the initiation and progression of rheumatoid arthritis (RA). JAK inhibitors have demonstrated clinical efficacy in RA and exert their biological activity principally by blockade of proinflammatory cytokine signaling. ASN002 is a novel potent dual inhibitor of SYK and JAK kinases, currently in clinical development for auto-immune (atopic dermatitis) and oncology indications. To date, more than 70 patients and subjects have received single or multiple oral, daily doses of ASN002. Here we demonstrate that ASN002 inhibits both SYK and JAK signaling pathways and cellular functions in both immune cells and osteoclasts; and is efficacious in both early and late stage rat models of collagen induced arthritis (CIA).

**Methods:** Cell lines, osteoclast progenitors, fresh human peripheral blood mononuclear cells (PBMCs) or isolated immune cells were cultured with various stimulating agents and inhibition of JAK or SYK mediated cell signaling or functions were measured by flow cytometry, proliferation assays or cytokine production. Osteoclast differentiation and bone resorption were assessed using the tartrate resistant acid phosphatase (TRAP) activity assay and collagen type 1c telopeptide (CTX) release by ELISA. ASN002, was tested for in vivo efficacy in an early and late stage rat CIA model. Dosing was initiated at either Day 14 (early model) or Day 18 (late model). Efficacy measures were arthritic scores, edema, and histopathology and radiographic assessments of the ankles.

**Results:** ASN002 is a potent inhibitor of SYK, JAK1, JAK2, JAK3 and TYK2 kinases with IC50 values of 5, 46, 4, 11, and 8 nM in biochemical assays respectively. In mechanistic cell-based studies, ASN002 strongly suppressed the SYK and JAK family kinase signaling pathways as measured by phosphorylation of LAT (a SYK substrate), and phosphorylation of signal transducers and activators of transcription (STAT). Cytokine induced phosphorylation of STAT in fresh human PBMCs was also suppressed. Human T and B cell proliferation and other cellular functions such as cytokine release were inhibited by ASN002 at nM levels. ASN002 also demonstrated nM level inhibition of osteoclast progenitor differentiation and bone resorption by osteoclasts. In the rat CIA model, ASN002 showed dose-dependent efficacy (3-30 mg/kg/day) and significantly reduced arthritic scores and paw edema in both early and late stage models. ASN002 showed a greater decrease in histopathology scores (82%) at 10 mg/kg, than either Tofacitinib (39%) or Fostamatinib (37%) alone.

**Conclusion:** ASN002 is an orally bioavailable, potent dual inhibitor of SYK and JAK kinases. It effectively inhibits SYK and JAK mediated cell signaling and functions. ASN002 significantly improved all efficacy measures in the rat CIA model, at lower exposures than those achieved in human studies to date. These data support the development of ASN002 for the treatment of autoimmune and inflammatory diseases, including rheumatoid arthritis and psoriatic arthritis. A Phase Ib study in patients with atopic dermatitis is in progress.

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Dendritic cells (DCs) are important antigen presenting cells (APCs) and therefore they play an important role in bridging the innate and the adaptive immune response. DCs can be divided in different subsets with specific functions. As powerful APCs, DCs are thought to play an important role in the induction of autoimmune diseases such as rheumatoid arthritis. However, the active role of DCs in joint inflammation is not known yet.

## Methods:

We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of CD11c+ cells by immunohistochemistry. We also performed synovial biopsies and analyzed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphtheria toxin receptor (DTR) transgenic mice, which express the human diphtheria- toxin receptor under the CD11c promoter, allowing for specific depletion of CD11c+ cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

## Results:

We show that Cd11c+ cells are present in significant numbers in the synovia of K/BxN and TNF driven arthritis. Both CD8+ CD11c+ and CD11b+CD11c+, can be found in synovial tissue. Upon depletion of CD11c+ cells clinical signs of K/BxN serum transfer arthritis were significantly reduced. Histological analysis found reduced synovial inflammation after the depletion of CD11c+ cells in K/BxN arthritis. In addition, local bone destruction and the number of osteoclasts was also significantly reduced. Analysis of K/BxN arthritis in wt mice and BATF3-/- mice, which lack a subset of DCs, namely CD8+CD11+ DCs, revealed no difference in arthritis severity between the two groups. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of CD11c+ cells led to a striking reduction of synovial inflammation and a complete depletion of osteoclasts.

**Conclusion:** These data show that in addition to initiating an adaptive immune response, CD11c+ dendritic cells, are also involved in innate effector mechanisms of inflammatory arthritis. Especially CD11b+CD11c+ and monocyte derived inflammatory seem to play a role in inflammatory arthritis, suggesting that they could be an important therapeutic target for patients suffering from inflammatory arthritis

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Animal Models Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recent studies indicate that fibroblast-like synoviocyte (FLS) glucose metabolism is altered in rheumatoid arthritis (RA). Hexokinases (HKs) catalyze the first step in glucose metabolism. HK2, which constitutes the principal HK inducible isoform, is mostly expressed in the lining of RA synovial tissue but not in OA tissue. Fibroblast-like synoviocytes (FLS) are a key component of RA hypertrophic and invasive synovium, and display unique aggressive features, including increased migration and invasion. We hypothesize that HK2 expression in FLS contributes to the synovial lining hypertrophy and plays a critical role in the arthritic joint bone and cartilage damage.

**Methods:** HK2 expression was determined in joints from wild-type (WT) and arthritic mice by immunohistochemistry (IHC). HK2 expression by qPCR in CD45<sup>neg</sup>PDPN<sup>pos</sup> subpopulation obtained after collagenase digestion and magnetic beads isolation was also performed. To study the effect of HK2 overexpression, we injected 10<sup>10</sup> particles of adenovirus (ad) carrying HK2 (ad-HK2) or GFP (ad-GFP) into the right or left knee respectively in WT mice. After 14 days, we collected the knees and H&E and safranin O staining was performed. Double color IHC was performed to confirm HK2 overexpression in FLS and to determine FLS activation with alpha-smooth muscle active (a-sma) staining. We also used HK2<sup>F/F</sup> mice, harboring Col1a1-Cre, in order to delete HK2 in non-hematopoietic cells including FLS. Serum transfer K/BxN arthritis was induced injecting intraperitoneally 150ml of serum. Clinical scores were assessed daily and histopathological studies were performed on joints harvested on day 12.

**Results:** HK2 was highly expressed by IHC in the synovial lining of arthritic joints from mice after serum transfer K/BxN arthritis. After CD45<sup>neg</sup> enrichment, PDPN<sup>pos</sup> cells had higher expression of HK2 in the arthritic joint ( $1.04 \pm 0.4$  in normal joints vs  $1.8 \pm 0.3$  in arthritic joints;  $p=0.03$ ). Over-expression of HK2 after intra-articular injection of ad-HK2 in normal knees dramatically increased synovial lining thickness ( $p=0.03$ ). Double color IHC confirmed HK2 expression in FLS after ad-HK2 injection and showed elevated a-sma expression in the hypertrophic lining. Safranin O staining revealed a higher proteoglycan loss in the cartilage from ad-HK2 injected knees compared with control knees. Finally, deletion of HK2 in Col1a1 expressing cells significantly decreased arthritis severity (clinical score at day 12 was  $9 \pm 2.5$  in WT mice vs.  $6.1 \pm 3.2$  in HK2<sup>F/F</sup>Col1a1-Cre;  $p=0.02$ ). Histopathological studies at day 12 showed significantly less synovial hypertrophy ( $p=0.04$ ), infiltration ( $p=0.05$ ); bone erosion ( $p=0.05$ ) and cartilage damage ( $p=0.03$ ).

**Conclusion:** HK2 expression is elevated in the synovial intimal lining of arthritic mice. Over-expression of HK2 in the synovial lining promotes hypertrophy of healthy synovium as well as FLS activation and cartilage damage. HK2 deletion in FLS ameliorates disease severity of arthritis. Taken together, the data suggest that HK2 is involved in FLS activation and synovial hypertrophy and could play a role in RA. HK2 inhibitors could serve as a new therapeutic option for the treatment of RA.

## Is Depression in Patients with Rheumatoid Arthritis Associated with Disease Activity? Comparative Study between Germany and Brazil

**Harriet Morf**<sup>1</sup>, Olga Seifert<sup>2</sup>, Geraldo Castelar-Pinheiro<sup>3</sup>, Ana Beatriz Vargas-Santos<sup>4</sup> and C Baerwald<sup>5</sup>, <sup>1</sup>Department of Internal Medicine, University Hospital, Erlangen, Germany, <sup>2</sup>University of Leipzig, Leipzig, Germany, <sup>3</sup>Universidade do Estado do Rio de Janeiro - UERJ, Rio de Janeiro, Brazil, <sup>4</sup>Internal Medicine - Rheumatology, State University of Rio de Janeiro, Rio de Janeiro, Brazil, <sup>5</sup>Department of Rheumatology, University of Leipzig, Germany, Leipzig, Germany

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid Arthritis (RA) can be associated with psychologic disorders and especially depression. About 13–20% of patients have clinical significant depression (Matcham F et al, 2013). Systemic inflammation could lead not only to inflammation in affected organs, but also mediates behavior abnormalities including depression symptoms.

**Purpose:** To characterise the inflammatory marker level and diseases activity in RA patients with depression.

### **Methods:**

176 german RA outpatients: age  $62.4 \pm 12.3$  years, mean duration of disease  $14.3 \pm 10.4$  years, DAS28  $3.3 \pm 1.3$ , HAQ  $1.0 \pm 0.75$ ; as well 91 brazilian RA outpatients: age  $56.3 \pm 12.6$  years, mean duration of disease  $15.9 \pm 8.5$  years, DAS28  $3.4 \pm 1.51$ , HAQ  $1.89 \pm 0.85$  could be included in this study. RA was diagnosed according to the ACR/EULAR Criteria 2010 and the following questionnaires were utilised: Beck depression inventory (BDI) (Beck et al., 1988), painDETECT (Freynhagen et al., 2006), visual analogue scale for pain (VAS), Short Form Health Survey (SF – 36) and Health Assessment Questionnaire (HAQ-DI). The participants were classified in 2 groups according to BDI I-II ( $BDI \leq 13$  – no signs of depression;  $BDI > 13$  signs of depression) (Beck et al, 1996). The cut-off of C-reactive protein (CrP) was 5mg/l.

### **Results:**

About 22.9 % of german RA patients were diagnosed with associated depression. It was divided into mild (64.1 %), moderate (28.2 %) and severe depression (7.7 %). Depressive patients had a higher level of CrP compare to patients without signs of depression ( $7.18 \pm 3.39$  vs  $5.25 \pm 1.41$ ,  $p = 0.001$ ). There was an association between CrP and clinical symptoms of depression (BDI:  $r = 0.226$ ,  $p = 0.003$ ), as well as pain (VAS:  $r = 0.184$ ,  $p = 0.017$ ), HAQ ( $r = 0.291$ ,  $p = 0.002$ ) and physical quality of life ( $r = -0.337$ ,  $p < 0.0001$ ). In depressive patients we found higher disease activity (DAS 28) ( $p < 0.001$ ). Depressive patients showed 25.8% with high disease activity and 45.2% with moderate disease activity. Only 12.9% were in remission and 16.1 % in low disease activity. In patients without depressive symptoms were 43.6% in remission and 17.8% showed low disease activity. Only 5% had a high disease activity and 33.7% with moderate disease activity. Concerning to brazilien population of RA patients it was found that 44 % of patients were diagnosed with associated depression. It was divided into mild (53.7 %), moderate (29.3 %) and severe depression (17.1 %). Brazilien RA patients with mild depression showed a higher CrP-level compare to patients with moderate depression ( $p < 0.05$ ). Depressive patients had higher levels of disease activity ( $p = 0.004$ ). 8.3% in remission and 75% in moderate disease activity. Only 16.7% had high disease activity. In patients without depression we found 16.7% in remission and 25.0% showed low disease activity. 41.7% had moderate disease activity and 16.7% with high disease activity.

### **Conclusion:**

The study indicates that RA-related depression could be associated with inflammatory markers and diseases activity. In RA-population with higher prevalence of depression we could find higher CRP- levels than in population with lower prevalence. It suggests the need for management strategies that specifically target depression as part of an overall RA- management program.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Little is known regarding the prevalence of erosive disease in a contemporary cohort of patients with RA and whether erosive disease prevalence differs by disease duration and seropositivity to anti-citrullinated protein antibodies (ACPA). The aim of this study was to characterize the proportion of patients with RA with erosive disease by disease duration category and stratified by positive and negative serological status (anti-cyclic citrullinated peptide [anti-CCP], a surrogate for ACPA). **Methods:** We identified patients with RA aged  $\geq 18$  years who were enrolled in the Corrona registry (October 2001–June 2016), with available disease duration, radiographic/MRI/ultrasound studies and serological status based on anti-CCP. Patients were grouped based on RA disease duration (0–2, 3–5, 6–10 and  $>10$  years from diagnosis). Unadjusted prevalence erosion rates were calculated based on the proportion of patients with reports of erosions present on joint radiographs/MRIs/ultrasounds. Seropositivity was based on laboratory results (anti-CCP  $\geq 20$  U/mL) at enrollment in the Corrona registry. Chi-squared tests were used to assess differences in prevalence rates.

**Results:** There were 9759 patients who met inclusion criteria. Most were women (76%), middle-aged (mean [SD] 57 years [14]), with moderate disease activity (mean [SD] CDAI 14.7 [13.4]). Prior use of at least one biologic or targeted synthetic DMARD had occurred in 41% of patients. Overall, the prevalence of erosive disease was 28.6%, with higher prevalence among anti-CCP+ (35.4%) vs anti-CCP– (20.1%) patients ( $p < 0.001$ , chi-squared test). The prevalence of erosions increased with increasing disease duration ( $p < 0.001$ ; Table). For each disease duration group, the prevalence of erosions was higher in patients who were anti-CCP+ compared with those who were anti-CCP–.

**Conclusion:** Erosions were common in this cohort of patients, and prevalence of erosions increased with longer disease duration. Patients who were anti-CCP+ had higher rates of prevalent erosions than those who were anti-CCP– with similar disease duration.

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Title:

Comprehensive provider judgment outweighs disease activity measures in the decision to not escalate therapy in patients with moderate to severe rheumatoid arthritis.

## Authors:

Stever, Sauer, Teng, Accortt, Collier, Cannon.

## Background/Purpose:

We evaluated US Veterans with RA in the Veterans Affairs Rheumatoid Arthritis (VARA) registry with moderate/severe disease activity (DAS28>3.2) and noted that of 941 patients with DAS>3.2, 559 (59%) did not have a change in RA therapy. We reviewed medical chart notes to determine provider reasoning for not modifying therapy despite documented moderate/severe RA disease activity.

## Methods:

US Veterans included in VARA had 1) moderate/severe disease activity (DAS28<sup>3</sup>>3.2) on the index date, 2) 18 months of VA data prior to the index date and 3) no major change to their medical therapy within 7 days before to 90 days after the index date. A major change was 1) initiation or escalation of DMARDs and/or prednisone and/or 2) 2 joint injections. There were 220 patients from 9 VARA registry sites randomly selected for chart review and the reasons documented in the patient record for continuing on therapy were recorded. In all patients, a Comprehensive provider judgment (CPJ) was made by the chart reviewer (JS) for each patient and categorized as mild or moderate/severe disease on the basis of text notes by the provider using these terms or similar comments on disease state. The CPJ was based on text notes and not physician global assessment by visual analog scale (VAS).

## Results:

The reasons for continuing current therapy despite DAS28>3.2 are listed in Table 1. A CPJ reported as mild was the predominant reason for no major change in therapy in 149 (68%) patients. CPJ mild patients had lower tender joint counts, swollen joint count, and physician global assessment. This CPJ of mild disease activity was not associated with other parameters evaluated including patient global assessment, ESR, CRP, and Health Assessment Questionnaire (HAQ) (Table 2).

## Conclusion:

The most common reason that RA patients remain on current therapy despite a documented DAS28>3.2 is a comprehensive provider judgment of acceptable disease activity. Many cases involved patients with a low numbers of tender and swollen joints. This observation suggests that a value of DAS28>3.2 may frequently occur in patients that most providers do not accept as having

moderate/severe disease with sufficient confidence to direct therapy. These data emphasize the need for a better understanding of factors in addition to disease activity measures directing therapy in clinical practice.

Table 2. Comparison of patients with mild disease activity by Comprehensive Provider Judgment (CPJ) to patients with moderate disease activity by CPJ. Mean (95% Confidence interval)			
Baseline Demographic and Clinical Data	Patients with No Change in Therapy at Index Date		
	All (N=220)	CPJ Mild (N=149)	CPJ Moderate (N=71)
Age (years)	66.6 (65.3-67.9)	67.1 (65.6-68.7)	65.4 (63.1-67.8)
Male Gender N (%) (95%CI)	194 (88.2%) (83.9-92.5)	133 (89.3%) (84.2-94.3)	61 (85.9%) (77.6-94.2)
Disease Duration (years)	14.8 (13.2-16.4)	14.7 (12.8-16.5)	15.2 (12.0-18.4)
Tender Joint Count (0-28)	4.0 (3.2-4.7)	3.3 (2.5-4.1)	5.4 (4.0-6.7)
Swollen Joint Count (0-28)	2.6 (2.2-3.1)	1.8 (1.4-2.2)	4.4 (3.3-5.4)
Patient Global Assessment (0-100)	46.6 (43.4-49.8)	45.6 (41.7-49.5)	48.7 (42.8-54.7)
Physician Global Assessment (0-100)	28.4 (25.6-31.3)	24.6 (21.4-27.8)	36.5 (30.9-42.0)
Visual Analog Pain Score (0-10)	5.0 (4.6-5.3)	4.7 (4.3-5.2)	5.4 (4.8-6.1)
HAQ (0 - 3.0)	1.0 (1.0-1.1)	1.0 (0.9-1.1)	1.1 (1.0-1.2)
ESR (mm/hr)	31.0 (28.2-33.7)	31.0 (27.6-34.4)	30.6 (26.0-35.3)
CRP (mg/dl)	1.1 (1.0-1.4)	1.1 (0.8-1.3)	1.3 (0.9-1.7)
DAS28 at index date	4.1 (4.0-4.2)	3.9 (3.8-4.0)	4.5 (4.2-4.7)
Average DAS28 before index date*	3.9 (3.8-4.0)	3.8 (3.6-3.9)	4.2 (3.9-4.4)

\* Average DAS 28 scores during 18 month observation period before index date as area under the curve calculation.

Table 1. Reason for continuing RA therapy without change despite moderate/severe disease activity (DAS≥3.2) (n=220)	
Comprehensive Provider judgment (CPJ) of RA as mild/remission	149 (68%)
Provider recommended continuing current therapy with anticipating improvement	13 (5.9%)
Patient with low adherence to prescribed therapy	13 (5.9%)
Patients disagreed with provider recommendation for major change	7 (3.0%)
Non-RA musculoskeletal disease activity explained symptoms	6 (3.0%)
No change in therapy recommend because of pending procedure.	2 (0.9%)
Patient requested additional time to consider therapy change before accepting change	2 (0.9%)
Provider waiting for imaging or laboratory results to decide on therapy changes	2 (0.9%)
Active Hepatitis C	1 (0.5%)
Change of Medication by non-VA provider	1 (0.5%)
Reason for persistence on therapy could not determine by chart review	24 (10.9%)
TOTAL	220 (100%)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Oral health is an important issue for patients with rheumatoid arthritis (RA) because periodontitis is a potential risk factor for RA and RA patients have been reported to have a significantly increased incidence of periodontitis compared to healthy individuals. We previously reported that 40% of Japanese RA patients disclosed receiving dental treatment in the previous 6 months (J Bone Miner Metab, 2017; 35: 344-350). Limited data exist in the literature concerning periodontitis in Japanese RA patients. This study aimed to evaluate periodontitis in our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort.

**Methods:** The IORRA cohort was established in 2000 as a single institute-based large cohort of Japanese RA patients. More than 122 publications have described various characteristics of Japanese RA patients using this cohort. Patients with RA enrolled in the IORRA cohort completed self-administered questionnaires as part of the 2016 October/November IORRA surveys, which included gingival bleeding during tooth brushing and periodontitis diagnosed by dentists in the previous 6 months (April to September 2016). Logistic regression analyses were used to evaluate associations between gingival bleeding during tooth brushing, periodontitis, and clinical variables.

**Results:** Among 5,660 Japanese patients with RA who participated in the cohort (median age, 62 years old; females, 86%), 31% and 18% reported having gingival bleeding during tooth brushing and periodontitis diagnosed by a dentist, respectively, in the previous 6 months. Among 1,211 patients with RA treated with anti-resorptive drugs (bisphosphonates and denosumab) (median age, 69 years old; females, 95%), 26% and 19% reported having gingival bleeding during tooth brushing and periodontitis diagnosed, respectively, in the previous 6 months. Among Japanese patients with RA, younger age, ever-smoker status, disease activity score (DAS) 28, and Japanese health assessment questionnaire disability index (JHAQ-DI) were significantly associated with gingival bleeding during tooth brushing, and older age, female sex, ever-smoker status, DAS28, and JHAQ-DI were significantly correlated with periodontitis (Table). Among Japanese RA patients treated with anti-resorptive drugs, younger age and patient general visual analogue scale (VAS) were significantly associated with gingival bleeding during tooth brushing, and older age was associated with periodontitis diagnosis in the previous 6 months.

**Conclusion:** In Japanese patients with RA, many patients experienced gingival bleeding during tooth brushing and were diagnosed with periodontitis by dentists. Age, female sex, ever-smoker status, general health status, disease activity, and disability may be associated with periodontitis in Japanese patients with RA.

**Table.** Factors associated with gingival bleeding during tooth brushing and periodontitis

Variables	Gingival bleeding during tooth brushing		Periodontitis diagnosis	
	All patients	Patients receiving anti-resorptive	All patients	Patients receiving anti-resorptive
		drugs		drugs
Age, per 10 years	0.70 (0.66-0.74)	0.66 (0.57-0.76)	1.26 (1.17-1.36)	1.23 (1.04-1.47)
Female sex	1.07 (0.87-1.33)	—	1.37 (1.04-1.80)	—
Ever smokers	1.17 (1.01-1.36)	—	1.34 (1.11-1.61)	—

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The composite scores DAS28, CDAI and SDAI all include number of tender and swollen joints (of 28). Rheumatoid arthritis (RA) patients with tender to swollen joint count difference (TSJD) >0 had reduced composite score remission and TSJD of ≥7 was shown to have ≥ 80% sensitivity and specificity to have “fibromyalgic RA” (FM-RA) (Pollard et al. Rheumatology 2010). Ultrasonography (US) is a sensitive imaging technique to detect synovitis including grey scale synovitis (GS) and power Doppler (PD) activity. The present purpose was to explore the impact of FM-RA on the composite scores in comparison to other clinical assessments including US in a longitudinal study of established RA patients initiating bDMARD therapy.

### **Methods:**

A total of 209 patients with RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were included when initiating bDMARDs and assessed at baseline and after 1, 2, 3, 6 and 12 months with joint pain VAS, patient's global VAS, RAID score, MHAQ, clinical examinations (performed by a study nurse; assessor's disease activity VAS, tender and swollen joint counts (of 28) and laboratory variables (ESR and CRP). All US examinations (semi-quantitative scoring (0-3)) of GS and PD (PIP 2-3, MCP 1-5, wrist (radiocarpal, intercarpal, radioulnar), elbow, knee, tibiotalar, MTP 1-5 and ext.carpi ulnaris/tib.post.tendons bilaterally) were performed by one rheumatologist (HBH) (Siemens Acuson Antares, excellence version, 5-13 MHz probe). To explore the impact of tender minus swollen joint count, patients were divided into three groups depending on TSJD at baseline; Gr.1=≤0 (n=125), Gr.2=1-6 (n=62), Gr.3=≥7 (n=22, FM-RA). Statistical calculations included frequency of DAS28(ESR), CDAI, SDAI and ACR/EULAR (Boolean) remission, one-way ANOVA and cross-tabs.

### **Results:**

There were significantly higher DAS28(ESR), CDAI, SDAI, joint pain VAS, patient's global VAS, RAID score and M-HAQ in the FM-RA group at all time points ( $p \leq 0.003$ ), while there were no differences between the groups regarding assessor's global VAS or ESR/CRP. On the other hand, sum scores GS and PD were higher in Gr.1 and 2 (figure 1). The table illustrates that the FM-RA group has a very low percentage of composite score remission both at 6 and 12 months follow-up.

### **Conclusion:**

In spite of having the lowest degree of US pathology, the 10.5% FM-RA patients had significantly higher levels of all the commonly used composite scores at all time points and they seldom reached remission. Thus, the small RA-FM group should be identified and other than composite scores should be used for assessing their disease activity.

Percentages of patients in composite score remission	6 months			12 months		
	Group 1; TSJD= $\leq 0$	Group 2; TSJD=1-6	Group 3; TSJD= $\geq 7$ , FM-RA	Group 1; TSJD= $\leq 0$	Group 2; TSJD=1-6	Group 3; TSJD= $\geq 7$ , FM-RA

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

## Background/Purpose:

In patients with rheumatoid arthritis (RA) the pain experience in joints with different degrees of joint inflammation is highly individual and dependent upon the pain threshold. The composite scores all include tender joints as an approximation of disease activity. Ultrasonography (US) is sensitive for assessment of joint inflammation (synovitis (grey scale, GS) and vascularization (power Doppler, PD)). The present objective was to cross-sectionally explore the associations at joint level between joint pain experienced by the patient, presence of pain by external pressure (tender joint), presence of joint swelling and the degree of US pathology.

## Methods:

174 patients with established RA (mean (SD) age 52 (13) years, disease duration 10 (8) years, 82% women, 79% anti-CCP positive, 80% on DMARDs (MTX in 74%) and 55.2% on prednisolone (mean (SD) dosage of 4.5 (5.8) mg) were assessed before initiating bDMARD treatment. The presence of patient reported joint pain (PRJP) was assessed at joint level by use of a manikin including 32 joints (bilateral wrist, MCP1-5, PIP2-3, elbow, knee, ankle, MTP1-5). Each joint was scored 0-3 reflecting the level of spontaneous joint pain the last day. The same 32 joints were scored 0-3 for US pathology (GS and PD). An experienced study nurse assessed the presence of tenderness and swelling (MTP1-5 scored as one joint). Correlations of sum scores (PRJP, GS, PD and tender/swollen joints) were assessed by use of Spearman. Associations at joint level was explored using Cohens kappa, with transforming semi-quantitative scores to categorical (PRJP: 0=0, 1-3=1; US GS 0-1=0 (as score 1 may also be seen in healthy joints), 2-3=1; US PD 0=0, 1-3=1).

## Results:

Correlations between sum scores showed moderate to high correlations between PRJP and tender joints as well as between swollen joints and US GS/PD (table1,  $*=p<0.05$ ,  $**=p<0.001$ ). At joint level, the associations between PRJP, tender and swollen joints were low, while US (GS/PD) had strong associations with swollen joints (table 2).

## Conclusion:

Sum scores of tender joints and PRJP were correlated, but they had low or none associations with sum scores of swollen joints and GS/PD. On the other hand, there were high correlations between sum scores of swollen joints and US. At joint level, there were surprisingly low association between tender joints and PRJP. In addition, tender joints had low associations with swollen joints and GS/PD US findings. However, also at joint level, swollen joints and US findings were associated. The present findings raise questions regarding the prominent role of tender joints in composite disease activity measures for RA.

Spearman correlations for sum scores	Sum score PRJP	Sum tender joints	Sum swollen joints	Sum US GS
Sum tender joints	0.54**			
Sum swollen joints	0.32**	0.21*		
Sum US GS	0.26**	0.03	0.69**	
Sum US PD	0.26**	-0.1	0.64**	0.88**

## Cohens kappa values on joint level (Standard error) (all joints, n=5568)

	Swollen	Tender	PRJP	US GS
Tender	0.32 (0.02)			
PRJP	0.25 (0.02)	0.34 (0.02)		
US GS	0.57 (0.02)	0.21 (0.02)	0.23 (0.02)	
US PD	0.56 (0.01)	0.20 (0.02)	0.25 (0.02)	0.74 (0.01)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Autoantibodies have long been recognized to be present in patients with RA, but it is more recent that autoantibodies against citrullinated proteins (anti-CCP) are emerging as contributors to Rheumatoid Arthritis (RA) pathogenesis. While depletion of CD20 B cells by rituximab clearly has a major beneficial effect in RA, it remains unclear whether this effect is associated with decreased autoantibody production. We recently reported that tocilizumab, a monoclonal antibody to the IL-6 receptor (IL-6R), specifically reduces the levels of IgG4 anti-CCP antibodies (Abs), but not IgG1 anti-CCP Abs, and that IL-6 promotes isotype switching to IgG4. No previous studies have examined whether rituximab treatment has an isotype-specific effect on autoantibody production. The objective of this study was to determine if rituximab has a specific effect on IgG4 versus IgG1 anti-CCP Abs in RA

**Methods:** RA patients who were starting a new biologic treatment or switching to a new biologic were consented to enter an accompanying laboratory study. Blood specimens were obtained prior to the first treatment (time 0), and 6-9 months later. Serum samples and peripheral blood mononuclear cells were collected. Levels of total anti-CCP antibodies (Abs), IgG1-anti-CCP and IgG4-anti-CCP Abs in serum were determined. Total levels of IgG1 and IgG4 in serum were also determined

**Results:** While some RA patients have no detectable IgG4 anti-CCP Abs, there is a fraction of RA patients with higher levels of IgG4 anti-CCP Abs than IgG1 anti-CCP Abs (about 40%). Rituximab treatment had no significant effect on IgG1 anti-CCP Abs levels, but it caused a marked reduction in the levels of IgG4 anti-CCP Abs. The total anti-CCP Abs levels were significantly reduced with rituximab, but the reduction was less pronounced due to the minimal effect on the IgG1 subclass antibodies. The reduction in IgG4 anti-CCP Ab levels by rituximab was not caused by a reduction in the total IgG4 serum immunoglobulin levels, as determined by spearman correlation

**Conclusion:** Rituximab specifically reduces the levels of IgG4 anti-CCP antibodies but has minimal effect on IgG1 levels and IgG1 anti-CCP antibodies. This effect on IgG4 could be masked if total Ig anti-CCP antibody levels are tested. The results from these studies reveal a novel effect of rituximab on autoantibody levels that has been questioned. Considering the emerging relevance of anti-CCP antibodies in the pathogenesis of RA, the specific effect of rituximab on IgG4 autoantibodies could be a novel mechanism for this biologic.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In the treatment of rheumatoid arthritis (RA), the early diagnosis and early medical treatment via tight control have become increasingly important with the advent of biological therapy. Ultrasonography (US) for the affected joints enables the evaluation of synovial hypertrophy, effusion and bone erosion in real time. US is a reliable method that can detect more erosive sites than radiography. US is now utilized widely and is a reliable tool among rheumatologists for diagnosing RA and evaluating the disease activity. However, many patients have swollen, deformed and painful joints due to overuse and advancing bone destruction. This study was conducted to clarify the relationship between the systemic disease activity, local disease activity using US and a synovial histopathological evaluation in RA patients in remission (Disease Activity Score [DAS] 28-ESR[4]<2.6).

**Methods:** Between March 2011 and April 2017, 176 joints were surgically treated among all RA patients in remission, and synovial biopsies were performed at the time of surgery. Among them, a total of 52 fingers, 32 wrists, 57 toes, 3 ankles, 12 elbows, 3 shoulders and 17 knees were investigated. Just before surgery, the US probe was placed on the joints to evaluate the activity of local synovitis. The maximum grade of power Doppler (PD) signal was determined, ranging from 0 to 3. The serum C reactive protein (CRP), matrix metalloproteinase-3 (MMP-3) and DAS28 values were also examined just before surgery. A histopathological examination of the gathered synovium at the surgical site was performed using the Rooney score (RS). Biological disease-modifying antirheumatic drugs (BIO) were used in 73 cases, namely infliximab in 8 cases, etanercept in 10, adalimumab in 10, tocilizumab in 28, abatacept in 5, certolizumab pegol in 2 and golimumab in 10.

**Results:** The PD score was grade 0 in 76 cases, 1 in 61 cases, 2 in 30 cases and 3 in 9 cases. The average CRP was 0.17 mg/dL, and MMP-3 was 94.6 ng/mL, both low values. The three items of lymphocytes in the RS score showed low values, while synovocyte hyperplasia and fibrosis showed high values due to a secondary reaction after inflammation at the joints. Group L consisted of 76 joints of grade 0, Group H included 61 joints of grade 1, 30 joints of grade 2 and 9 joints of grade 3. The values of MMP-3, synovium hyperplasia, lymphocyte infiltration and blood vessel hyperplasia were markedly low in Group L. Small Joints (SJ) consisted of 144 joints with fingers, wrists, feet and ankles. Large Joints (LJ) consisted of 32 joints with elbows, shoulders and knees. The values of MMP-3, synovium hyperplasia and high value were markedly low in SJ cases with blood vessel hyperplasia. Patients using BIO showed low values for CRP, synovium hyperplasia and lymphocyte infiltration.

**Conclusion:** The systemic disease activities, as indicated by DAS28, CRP and MMP-3, of RA patients in remission were low. However, synovitis was clearly present based on ultrasonography and histological findings of the surgical joints of PD-positive RA patients in remission.

## **Swollen Joint Count, but Not Inflammatory Cytokines, Differs By Frequency of Fish Consumption in a Cross-Sectional Rheumatoid Arthritis Cohort**

Sara K. Tedeschi<sup>1</sup>, Joan Bathon<sup>2</sup>, Jon T. Giles<sup>3</sup>, Tzu-Chieh Lin<sup>4</sup>, Kazuki Yoshida<sup>5</sup> and Daniel Solomon<sup>1</sup>, <sup>1</sup>Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, <sup>2</sup>Division of Rheumatology, Columbia University, College of Physicians & Surgeons, New York, NY, <sup>3</sup>Division of Rheumatology, Columbia University College of Physicians & Surgeons, New York, NY, <sup>4</sup>Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, <sup>5</sup>Brigham and Women's Hospital, Boston, MA

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Omega-3 fatty acids downregulate pro-inflammatory cytokines, thus have been of interest as adjunctive rheumatoid arthritis (RA) therapy for decades. We previously reported an inverse association between disease activity measured by DAS28-CRP and frequency of fish consumption in an RA cohort.<sup>1</sup> The present study tested whether individual components of DAS28-CRP or other inflammatory cytokines were related to frequency of fish intake.

**Methods:** We conducted a cross-sectional analysis using baseline data from participants in a prospective cohort study of cardiovascular disease in RA. Frequency of fish consumption was assessed by a baseline food frequency questionnaire assessing usual diet in the past year. DAS28-CRP was calculated using tender joint count (TJC), swollen joint count (SJC), and C-reactive protein (CRP) measured at baseline. Multivariable, total energy-adjusted linear regression models provided effect estimates and 95% confidence intervals (CI) for frequency of non-fried fish consumption (never to <1/month, 1/month to <1/week, 1/week, and  $\geq 2$ /week) on baseline TJC, SJC, and natural log (ln)-transformed cytokine levels. We also estimated the difference in each outcome associated with increasing fish consumption by one serving per week. A sensitivity analysis additionally adjusted for pack-years.

**Results:** Among 176 participants, 60% were female and median age was 59 years (interquartile range [IQR] 53-65). Seventy-nine percent were seropositive (RF or anti-CCP), median disease duration was 9 years (IQR 5-17), and median DAS28-CRP was 3.5 (IQR 2.9-4.3). Current medications taken as mono- or combination therapy included non-biologic disease modifying anti-rheumatic drugs (DMARDs) in 87%, biologic DMARDs in 46%, glucocorticoids in 39%, and fish oil supplements in 9%. Twenty percent ate fish never to <1/month and 18% ate fish  $\geq 2$  times/week. In adjusted linear regression models, subjects consuming fish  $\geq 2$  times/week had a significantly lower SJC compared with subjects who ate fish never to <1/month (difference -3.51 [95% CI -5.87, -1.16]) (**Table**). For each additional serving of fish per week, SJC was significantly reduced by 1.18 (95% CI -2.03, -0.33). We did not observe differences in TJC or ln-transformed cytokine levels based on frequency of fish consumption. Further adjustment for smoking produced similar results.

**Conclusion:** Differences in SJC according to frequency of fish consumption may explain our previous observation that higher intake of fish was associated with lower disease activity as measured by DAS28-CRP in RA patients.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

The 2015 ACR RA treatment guidelines focus on measuring disease activity and provide a guideline driven treat to target strategy. We hope to understand patients' personal choices of disease measures and treatment targets and how it compares to their physicians.

## Methods:

This is a cross sectional study of the first 120 RA patients defined by the 1987 or 2010 ACR criteria seen in our clinic from 1/16/17 to 3/13/17.

Before the routine care visit, each patient was given a questionnaire of traditional and personalized RA measures and asked which they prefer using to determine their treat to target goal. The patient was asked to rank each traditional (disease activity, functional status, patient global, physician global, joint pain/swelling) and personalized (ADLs, exercise, work, leisure, sleep) measure 1 to 5 (1 - most important and 5 - least important). Physicians completed the survey for each respective patient. Comparisons were made on both traditional and personalized physician and patients' ranking responses.

Percent agreement, Wilcoxon signed rank test and weighted kappa coefficients were used to understand the change in agreement between physicians and patients.

## Results:

Most patients (70%) and physicians (64%) believe a combination of traditional and personalized measures should be used to determine their RA treatment goal (Table 1).

<b>Table 1: Physician and Patient Preference for Traditional vs. Personalized Measures</b>		
	<b>Physicians</b>	<b>Patients</b>
Traditional	3 (27.3%)	17 (14.2%)
Personalized	1 (9.1%)	9 (7.5%)
Combination	<b>7 (63.6%)</b>	<b>84 (70.0%)</b>
Neither	0 (0%)	10 (8.3%)

As an overall group, both patients and physicians believe that functional status and disease activity are the most important traditional measures based on average ranking. Also, there is agreement in joint pain/swelling ( $p=0.36$ ). Being able to complete ADLs is the most important personalized measure based on average ranking (Table 2).

<b>Table 2: Overall Physician and Patient Preference Average Ranking (1 to 5)</b>		
(1 being most important, 5 being least important)		
<b>Traditional Measures</b>	Physician	Patient
Functional Status	<b>1.8</b>	<b>2.2</b>
Disease Activity	<b>2.1</b>	<b>2.9</b>
Tender/Swollen Count	<b>2.5</b>	<b>2.7</b>
Patient Global	4.0	3.2
Physician Global	4.6	4.1
<b>Personalized Measures</b>	Physician	Patient
ADLs	<b>1.2</b>	<b>1.5</b>
Work	3.2	3.5
Travel/Leisure	3.3	3.8
Sleep	3.4	2.8
Exercise	3.9	3.4

On an individual level, patient and physician level of agreement measured by weighted kappa coefficient is random (-0.024 to 0.283) and percent agreement showed a low of 20% (95% CI: 12.8%, 27.2%) for disease activity and high of 62% (95% CI: 53.0%, 70.4%) for ADLs.

## Conclusion:

To our knowledge, this is the first study to analyze patient preference in addition to a treat to target management of RA.

Using disease activity as a measure for a treat to target approach has improved RA patient care. However, this study shows that on an individual patient level, even physicians who know their patients well cannot predict what measure(s) are most important to them as an individual.

To provide population care that is patient-centered, we recommend setting a patient specific measure/goal (traditional or non-traditional) based on personal importance in addition to following guideline driven care (i.e. disease activity measure).

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ultrasound (US) has demonstrated subclinical synovitis in rheumatoid arthritis (RA) patients in clinical remission, but there is less information regarding US tenosynovitis. The aims of the present study were to evaluate prevalence of US detected tenosynovitis in RA patients in clinical remission, its association with other features of the disease and to assess whether US detected tenosynovitis could add to US synovitis in order to define US remission in these patients.

**Methods:** consecutive RA patients (2010 ACR/EULAR criteria) in clinical remission according to DAS28<2.6 were included. All patients underwent US examination by the same rheumatologist using a MyLab 70 machine (Esaote) provided with a linear probe (6-18 MHz). Synovitis and tenosynovitis were defined according to OMERACT preliminary definitions. Grayscale (GS) and Power Doppler US (PDUS) were graded for both tenosynovitis and synovitis from 0 to 3. The following tendons were bilaterally assessed: 1<sup>st</sup> to 6<sup>th</sup> extensor tendon compartments at wrist level, 2<sup>nd</sup> to 5<sup>th</sup> finger flexor tendons and posterior tibial and peroneal tendons. Joints assessed bilaterally were: wrist, 1<sup>st</sup> to 5<sup>th</sup> MCP and 2<sup>nd</sup> to 5<sup>th</sup> proximal IP. US remission was defined as the absence of both GSUS grade  $\geq 2$  and any PDUS signal at both joint and tendon level.

**Results:** 60 RA patients were included (table). GSUS tenosynovitis grade  $\geq 2$  and PDUS tenosynovitis were found in 14 (23%, CI95%:12-34) and in 13 (21.7%, CI95%:10-32) RA patients in clinical remission, respectively. The most frequent involved tendons were: 6<sup>th</sup> extensor wrist compartment, 3<sup>rd</sup> finger flexor and posterior tibial.

Mean erythrocyte sedimentation rate (ESR) and DAS28 values were higher in patients with US detected tenosynovitis than those without US tenosynovitis (19 vs 12.3,  $p=0.016$  and 2.2 vs 1.9,  $p=0.025$ , respectively). In multivariate analysis, the only feature associated with the presence of US tenosynovitis was ESR (OR:1.11, 95%CI: 1.02-1.22). ESR showed an area under the ROC curve for the detection of US tenosynovitis of 0.71.

Twenty-nine (48.3%, CI95%: 35-60) patients had US detected synovitis and were not classified as in US remission. Adding data of US detected tenosynovitis, 6 more patients would have been classified as not in US remission, giving a total of 35 (58.3%; CI95%: 45-70) (p=0.272).

**Conclusion:** about a quarter of RA patients in clinical remission had US detected tenosynovitis. The only feature associated with this US finding was the presence of higher levels of ESR. If US tenosynovitis is considered alongside with synovitis in the definition of US remission, a small number of patients would be added.

## Minimal Clinically Important Improvement (MCII) of RAPID3 (ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3), an INDEX of ONLY Patient Self-Report Scores in Rheumatoid Arthritis (RA): Similar Performance to DAS28 and CDAI

**Michael Ward**<sup>1</sup>, Isabel Castrejón<sup>2</sup>, Martin J. Bergman<sup>3</sup>, Lori C. Guthrie<sup>4</sup>, Maria I. Alba<sup>4</sup> and Theodore Pincus<sup>2</sup>, <sup>1</sup>NIH/NIAMS, Bethesda, MD, <sup>2</sup>Rheumatology, Rush University Medical Center, Chicago, IL, <sup>3</sup>Drexel University College of Medicine, Philadelphia, PA, <sup>4</sup>NIAMS/NIH, Bethesda, MD

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** No single “gold standard” measure is available to assess patients with rheumatoid arthritis (RA) in clinical trials and routine care, as in hypertension, diabetes, and other diseases. Therefore, an index of several measures, such as a DAS28 (Disease Activity Score-28) and CDAI (Clinical Disease Activity Index), based on 7 RA core data set measures, is needed. However, the only quantitative data collected in many (most) patients at routine rheumatology care visits are laboratory tests. RAPID3 (routine assessment of patient index data), which includes only patient self-report scores, is considerably more feasible than DAS28 or CDAI for routine care, distinguishes active from control treatments in RA clinical trials similarly and is correlated significantly with these indices. A minimal clinically important improvement (MCII) to aid in planning and interpretation of changes in disease activity/severity in clinical trials as well as in routine care has not been established for RAPID3, and is presented here.

**Methods:** Post hoc analyses were performed of a longitudinal study of 250 patients with active RA, in whom results of treatment escalation were assessed quantitatively, as described previously (1). All 7 RA core data set measures were collected at baseline and after treatment escalation. RAPID3 is the sum of 3 0-10 measures for a 0-10 (converted from 0-3) physical function scale and 0-10 visual analog scales (VAS) for pain and patient global assessment, total=0-30. DAS28-ESR and CDAI were computed as described in the literature. Patient judgment of improvement was recorded independently as “improved”, “the same” or “worsened”, and dichotomized as improved vs same/worsened to generate receiver operating characteristic (ROC) curves, to determine MCII as changes that had a specificity of 0.80 for improvement. Sensitivity to change was assessed as standardized response means (SRM).

**Results:** Among 250 patients, 167 (66.8%) reported improvement. Each composite index was sensitive to change, with SRMs ranging from -0.79 to -0.98 (Table). The mean ROC curve area ranged from 0.77 for DAS28-ESR to 0.80 for RAPID3 (Table). With a criterion of a specificity of 0.80, the MCII were -3.5 for RAPID3, -1.17 for DAS28-ESR, and -12.5 for CDAI. MCII were in a similar range of 11.6% to 16.8% of maximum score (Table).

**Table.** Changes in rheumatoid arthritis activity measures during the study.

Measure (range)	Baseline	Follow-up	Mean (%) change	SRM (95% CI)	ROC Curve Area (95% CI)	MCII (95% CI)	% of Total
<b>RAPID3</b> <b>(0 – 30)</b>	16.3 ± 6.3	11.1 ± 6.7	-5.2 ± 6.5 (32%)	-0.79 (-0.71, -0.88)	0.80 (0.74, 0.86)	-3.5 (-2.9, -4.3)	11.6%
<b>DAS28-ESR</b> <b>(0-9.4)</b>	6.16 ±1.2	4.8 ± 1.38	-1.31 ± 1.34 (21%)	-0.98 (-0.90, -1.07)	0.77 (0.71, 0.82)	-1.17 (-1.36, -0.87)	12.4%
<b>CDAI</b> <b>(0-76)</b>	36.8 ±13.5	23.0 ± 13.6	-13.7 ± 14.1 (37%)	-0.98 (-0.90, -1.08)	0.78 (0.73, 0.84)	-12.5 (-14.7, -10.5)	16.4%

\* SRM= standardized response mean; CI= confidence interval

**Conclusion:** MCII for RAPID3 were similar in ROC curve areas and SRM to DAS28 and CDAI. Knowledge concerning MCII thresholds can improve planning and interpretation of data from clinical trials and routine clinical care.

## The Relevance of Elevated CRP As an Inclusion Criterion in Clinical Trials in Patients with Rheumatoid Arthritis

**Craig Scoville**<sup>1</sup>, Jessica L. Suboticki<sup>2</sup>, Sheng Zhong<sup>3</sup> and Edward C. Keystone<sup>4</sup>, <sup>1</sup>Idaho Falls Arthritis Clinic, Idaho Falls, ID, <sup>2</sup>AbbVie Inc., Mettawa, IL, <sup>3</sup>AbbVie Inc., North Chicago, IL, <sup>4</sup>Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Elevated C-reactive protein (CRP) is often used as an entry criterion in clinical trials (CT) with rheumatoid arthritis (RA) patients (pts), resulting in the potential exclusion of pts with active disease and high screen failure rates<sup>1</sup>. This analysis assessed the relevance of requiring an elevated CRP ( $\geq 1$  mg/dL) as an inclusion criterion for clinical, functional, and radiographic outcomes.

### **Methods:**

This *post hoc* analysis used data from 2 randomized CTs in RA pts with an inadequate response to methotrexate (MTX). In DE019, pts on background MTX received adalimumab (ADA) or placebo (PBO)<sup>2</sup>; in MUSICA, pts received either 7.5 or 20 mg MTX, along with ADA<sup>3</sup>. MUSICA data were used to confirm observations from DE019. Pts were subgrouped by CRP level at entry (CRP <1 mg/dL,  $\geq 1$  mg/dL). Baseline (BL) demographics and disease characteristics were summarized for each group. Clinical efficacy was assessed through swollen/tender joint count (S/TJC) at 66/68 joints, pain, patient global assessment (PtGA), physician global assessment (PhGA), CRP, clinical disease activity index (CDAI), 28-joint disease activity score based on CRP (DAS28-CRP), and proportions of pts achieving ACR20/50/70. Functional outcomes were assessed by the disability index of the health assessment questionnaire (HAQ-DI), and radiographic outcomes by the modified total Sharp score (mTSS). Outcomes were assessed in pts with CRP <0.8 mg/dL in DE019, which included pts with CRP levels as low as 0.75 mg/dL. Observed data are reported at week 24.

### **Results:**

In DE019, 183 pts (89 and 94 in the ADA and PBO arms, respectively) had CRP <1 mg/dL and 224 pts (118 and 106, respectively) had CRP  $\geq 1$  mg/dL. Pts with elevated CRP had higher BL disease activity compared with those with CRP <1 mg/dL at entry (not shown). After 24 wks of treatment with ADA, pts in both CRP subgroups experienced significant improvements in most clinical and functional outcomes vs PBO (Table). In pts with CRP <0.8 mg/dL, the ACR20 response rate difference (30.4,  $p < .001$ ) and the difference in  $\Delta$ mTSS (-1.3,  $p < .05$ ) for ADA vs PBO treatment were still significant. Compared to pts with CRP <1 mg/dL, pts with elevated CRP experienced greater clinical and functional improvements. However, within the ADA subgroups, pts with elevated CRP had smaller differences vs PBO in mTSS, perhaps reflecting higher joint damage at BL. In general, similar trends were observed in MUSICA (not shown).

**Conclusion:** While pts with elevated CRP at entry experienced larger improvements from BL in clinical and functional outcomes upon treatment, significant improvements in most outcomes were also observed in those without elevated CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not be required to see differences between active and inactive treatment.

## Is Joint Damage Due to Secondary Osteoarthritis (OA) Clinically As Important As Inflammation in Contemporary Management of Rheumatoid Arthritis (RA)?

**Theodore Pincus**<sup>1</sup>, Isabel Castrejón<sup>2</sup>, Kathryn A. Gibson<sup>3</sup> and Joel A Block<sup>2</sup>, <sup>1</sup>Rheumatology, Rush University Medical Center, Chicago, IL, <sup>2</sup>Division of Rheumatology, Rush University Medical Center, Chicago, IL, <sup>3</sup>Liverpool Hospital, Sydney, Australia, Sydney, Australia

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Measures to assess patients with rheumatoid arthritis (RA) reflect primarily inflammatory activity in patients who meet inclusion criteria for selection into clinical trials. However, many patients seen in routine care (and some in clinical trials) have structural joint damage and/or patient distress in addition to inflammatory activity, which may affect RA indices. Thus, a patient with 0 swollen joints, an erythrocyte sedimentation rate of 15, 14 tender joints and patient global assessment of 80/100 (or 8/10) would have a DAS28 of 5.1 and CDAI of at least 22 (even if physician global assessment is 0), suggesting high disease activity, although the high score results from damage and/or distress. We have added to a physician global assessment (DOCGL) 0-10 visual analog scale (VAS) 3 three 0-10 VAS for inflammation, damage, and distress, as well as estimates of the proportion of clinical management decisions attributed to each (%inflammation+ %damage+%distress, total=100%). We hypothesized that a greater proportion of clinical decisions in RA may be attributed to structural damage than to inflammation as a result of modern therapeutics, by comparing scores in routine care patients.

**Methods:** At one academic center, all patients complete an MDHAQ/RAPID3 prior to seeing the rheumatologist. Physicians complete 4 0-10 VAS for DOCGL, inflammation (i.e., reversible disease) (DOCINF), damage (i.e., structural irreversible disease) (DOCDAM), and distress (i.e., fibromyalgia, depression, etc.) (DOCSTR). The rheumatologist also records estimates of the proportion of clinical management decisions attributed to %inflammation, %damage, and % distress, total=100%. Patients were classified in 5 groups for DOCINF and DOCDAM VAS as 0-2, 2.1-4, 4.1-6, 6.1-8, and 8.1-10, and for % of clinical decisions as 0-20%, 21-40%, 41-60%, 61-80%, and 81-100%, and compared using t tests and analysis of variance (ANOVA).

**Results:** In a cross-sectional analysis of a single random visit of 98 RA patients, mean physician DOCINF 0-10 VAS was 2.8, lower than 3.8 for DOCDAM (Table). The mean proportion of management decisions attributed to inflammation was 39%, lower than 52% for damage (Table) (9% for distress- data not shown). Minimal 0-2.0 VAS scores for DOCINF were seen in 48 patients vs 30 for DOCDAM, while 4.1-10 VAS were estimated in 20 patients for DOCINF (8+2+10) vs 29 for DOCDAM (12+15+2). More than 40% of management decisions was attributed to damage in 59 patients (24+20+15) (vs 22 for 0-20%), vs to inflammation in 42 patients (18+15+9) (same as 0-20%) (Table).

Measure	Inflammation	Damage
VAS		
Mean (SD)	2.8 (2.4)	3.8 (2.3)
0-2.0	48 (49%)	30 (31%)
2.1-4.0	30 (31%)	39 (41%)
4.1-6.0	8 (8%)	12 (12%)
6.1-8.0	10 (10%)	15 (15%)
8.1-10.0	2 (2%)	2 (2%)
% Decision		
Mean % of 100%	39% (29)	52% (30)
0-20%	42 (43%)	22 (22%)
21-40%	14 (14%)	17 (17%)
41-60%	18 (18%)	24 (24%)
61-80%	15 (15%)	20 (20%)
81-100%	9 (9%)	15 (15%)
Total	98	98

**Conclusion:** Structural joint damage appears more prominent than inflammatory activity in physician clinical management decisions in a cross-section of RA patients at this time. Quantitative physician estimates of damage as well as inflammation may clarify management decisions in patients with RA, as damage remains a significant challenge in routine clinical care.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Patient reported outcomes are recognized as increasingly important in defining the full burden of disease experienced by patients with rheumatic disease. Traditional measures of remission (DAS28, CDAI, SDAI, Rapid 3) are important in the treat-to-target paradigm as measures of response to treatment, but it is increasingly recognized that these measures cannot capture the full yoke that subjects with rheumatic disease endure. Furthermore, as modern rheumatology advances, it is increasingly difficult to capture the complete spectrum of the patient response to therapies using traditional measures. This primary objective of this study was to examine the relationship between DAS28CRP and fatigue, health, and mood using a novel electronic PRO delivery system.

### **Methods:**

We utilized the Optimising Patient Outcome in Australian rheumatology (OPAL) database employing a unique electronic questionnaire delivery system to obtain PRO information from rheumatology patients on a quarterly basis and/or prior to patient-physician consultation. The software enables an email to be delivered to the patient automatically, and the patient is invited to complete a validated PRO questionnaire by smartphone, tablet or desktop. Completed questionnaires are securely fed back into the patient's electronic health record (EHR) for discussion at the next consultation. PRO's collected included fatigue (FACIT-F), mood (PHQ-2), overall health (SF-1) and RAPID3 components. PROs were correlated with DAS28CRP using Pearson product-moment correlation coefficient.

### **Results:**

12,575 PROs have been returned from 1625 unique patients with a completion rate of approximately 70%. There was a weak correlation between fatigue and DAS28CRP ( $R^2 = -0.40$ ); CDAI ( $R^2 = -0.41$ ) HAQ-DI ( $-0.60$ ). However, a significant proportion of patients in low disease activity (LDA) and remission reported ongoing fatigue. Patient perception of their overall health was similar with 22% of patients in remission and 33% of patients in LDA reporting fair or poor health. Furthermore, 41% of patients in LDA and 31% of patients in remission reported feeling down in the previous 2 weeks.

### **Conclusion:**

Fatigue, mood disturbance, and poor health are reported by a considerable proportion of subjects in DAS28CRP LDA and remission. These results underline the importance of PROs in documenting the full impact of rheumatic disease and the patient response to therapy.

## 14-3-3 $\eta$ : Useful for More Than the Diagnosis of Rheumatoid Arthritis?

**Lisa Zickuhr**<sup>1</sup>, Maryam Pourpaki<sup>2</sup>, Martha M. Brooks<sup>3</sup> and Amy Joseph<sup>4</sup>, <sup>1</sup>Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, <sup>2</sup>Rheumatology, Advocate Christ Medical Center at Chicago, Oak Lawn, IL, <sup>3</sup>Rheumatology, St. Louis VA Medical Center, St. Louis, MO, <sup>4</sup>Rheumatology, Veterans Administration Central Office, St. Louis, MO

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Chronic hepatitis C virus (HCV) infection can masquerade as rheumatoid arthritis (RA). Distinguishing between the two is important because treatments differ. 14-3-3 $\eta$  has been explored in RA. When combined with traditional antibodies, high titers of 14-3-3 $\eta$  improve the accuracy of RA diagnosis. The utility of measuring 14-3-3 $\eta$  is not well understood in viral infections, such as HCV. We measure the incidence of 14-3-3 $\eta$  in patients with chronic HCV infection with long-standing arthralgias and compare it to the incidence in patients with long-standing RA to assess its utility in differentiating the two.

**Methods:** We recruited patients at the VA St. Louis Health Care System in St. Louis, MO, with an established diagnosis of either RA per 2010 ACR/EULAR Classification Criteria for RA or chronic HCV infection (defined as a detectable HCV viral load) with arthralgias of at least three joints. We obtained clinical information from chart review and physical exam at time of enrollment. We measured serum 14-3-3 $\eta$  titers with a quantitative sandwich ELISA (Quest Diagnostics Nichols Institute, San Juan Capistrano, CA), defining presence of 14-3-3 $\eta$  as a serum titer >0.19ng/mL. Chi-squared analysis compared the incidence of 14-3-3 $\eta$  in the two groups ( $\alpha = 0.05$ ).

**Results:**

	RA (N = 14)		HCV (N=21)	
	N (%)		N (%)	
Gender	2 (14.3%)		1 (4.8%)	
Female	12 (85.7%)		20 (95.2%)	
Male				
Age $\pm$ STD (years)	65.1 $\pm$ 8.8		63.7 $\pm$ 3.5	
Ethnicity	12 (85.7%)		7 (33.3%)	
Caucasian	2 (14.3%)		12 (57.1%)	
African American	--		1 (4.8%)	
Hispanic	--		1 (4.8%)	
Other (Asian, Native American)				
Duration of Joint Disease $\pm$ STD (years)	11.9 $\pm$ 12.2		18.7 $\pm$ 11.1	
Number of Joints Involved $\pm$ STD	14 $\pm$ 5		3.5 $\pm$ 0.5	
Active Disease, Synovitis at Time of Enrollment	2 (14.3%)		0 (0%)	
Treatment	1 (7.1%)		20 (95.2%)	
None	12 (85.7%)		1 (4.8%)	
DMARDs	2 (14.3%)		--	
Biologics				
Serologies	7 (50%)		7 (33.3%)	
Rheumatoid Factor (RF)	11 (78.6%)		0 (0%)	
Anti-Citrullinated Peptide (CCP)				
Presence of 14-3-3 $\eta$	2 (14.3%)		1 (4.8%)	
Erosions on X-ray	3 (21.4%)		0 (0%)	

Both groups had long-standing joint disease of more than ten years. All RA patients met 2010 ACR/EULAR Classification Criteria for RA, and all HCV patients had detectable viral loads. Only two (14.3%) RA patients and 1 (4.8%) HCV patient had elevated 14-3-3 $\eta$ . Chi-square showed no significant association between 14-3-3 $\eta$  positivity and diagnosis of either RA or HCV ( $X^2 = 0.73$ ,  $p=0.39$ ). Of the two RA patients with elevated 14-3-3 $\eta$ , both (100%) had RF and anti-CCP antibodies, and one (50%) had active disease, with synovitis at time of enrollment and radiographic erosions. The HCV patient with elevated 14-3-3 $\eta$  was RF positive.

**Conclusion:** We show a low incidence of 14-3-3 $\eta$  in a cohort of patients with long-standing RA or chronic HCV with arthralgias, lower than what was reported previously. In our cohort, 14-3-3 $\eta$  did not distinguish between joint pain from RA or chronic HCV infection. This suggests it is not useful in patients with long symptom duration. Most of our RA cohort's disease was controlled on therapy. Therefore, detection of 14-3-3 $\eta$  may be most useful early in the disease course and may be a good biomarker of disease activity. Additional studies correlating 14-3-3 $\eta$  positivity with disease activity and duration are warranted.

## Is ACPA-Positive RA Still a More Severe Disease Than ACPA-Negative RA? a Longitudinal Cohort Study in RA-Patients Treated from 2000 Onwards

Aleid C. Boer<sup>1</sup>, Annelies Boonen<sup>2</sup> and Annette H.M. van der Helm-van Mil<sup>3</sup>, <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre+, Maastricht, The Netherlands, Maastricht, Netherlands, <sup>3</sup>Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

***Background/Purpose:***

Anti-citrullinated-protein antibodies (ACPA)-positive rheumatoid arthritis (RA) is considered as more severe than ACPA-negative RA, because of its association with joint destruction. Clinically relevant joint destruction is now infrequent, thanks to adequate disease suppression. According to patients, important outcomes are pain, fatigue and independence. We evaluated if ACPA-positive RA-patients diagnosed  $\geq 2000$  have more severe self-reported limitations and impairments including restrictions at work than ACPA-negative RA-patients.

***Methods:***

492 ACPA-positive, 450 ACPA-negative 2010-criteria-positive RA-patients included in the Leiden Early Arthritis Clinic cohort  $\geq 2000$  were compared for self-reported pain, fatigue, disease activity, general wellbeing (measured by numerical rating scales) and physical function (measured by the health assessment questionnaire, HAQ) and also work restrictions including absenteeism at baseline and during 4-year follow-up. Linear mixed models were used.

***Results:***

At disease presentation, ACPA-negative patients had more severe pain, fatigue, self-reported disease activity-scores and functional disability ( $p < 0.05$ ), although absolute differences were small. During follow-up ACPA-negative patients remained somewhat more fatigued ( $p = 0.002$ ), whereas other patient-reported impairments and limitations were similar. 38% ACPA-negative and 48% ACPA-positive patients reported absenteeism ( $p = 0.30$ ), with median 4 days missed in both groups in the last 3 months. Also restrictions at work among employed patients and restrictions with household work were not statistically different at baseline and during follow-up.

***Conclusion:***

In current rheumatology practice, ACPA-positive RA is not more severe than ACPA-negative RA in terms of for patients relevant outcomes including physical functioning and restrictions at work. This implies that effort to further improve the disease course should not restrict to ACPA-positive patients.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Background/Purpose:** We have previously shown that rheumatoid arthritis (RA) patients with Post-Traumatic Stress Disorder (PTSD) have higher disease activity measures, due primarily to patient reported measures including higher tender joint counts, pain, and worse patient global scores. However, a recent systematic review and meta-analysis reported increased serum expression of IL-1, IL-6, and IFN- $\gamma$  in PTSD patients (Passos IC et. al., *Lancet Psychiatry*, 2015). The purpose of this study was to compare serum cytokine/chemokine expression in RA patients with and without PTSD.

**Methods:** Participants were enrollees in a multicenter, longitudinal observational cohort of US Veterans with RA categorized as having PTSD, other anxiety or depression, or neither based on administrative codes. Serum cytokines/chemokines were measured from banked serum at enrollment using a multiplex bead-based assay. Cytokines (CKs) were modeled using an overall cytokine (CK) score (log-transformed), the number of elevated cytokines ( $>2$  SD above mean), and by individual CKs (log-transformed). CK score and number of elevated CKs were compared between groups using ANOVA and  $X^2$ . The association of PTSD with CK parameters was assessed using multivariable least squares and negative binomial regression adjusted for age, sex, race, and smoking status. Analyses were additionally stratified by anti-CCP status.

**Results:** Of 1,460 RA subjects with mean (SD) age of 64 (11) years, RA duration 11 (11) years, were 91% male, 76% anti-CCP positive, and 80% current or former smokers, 9% had PTSD, 24% had other depression/anxiety, and 67% had neither psychiatric condition. In unadjusted comparisons, those with PTSD had higher CK scores ( $P=0.02$ ) and a greater number of elevated CKs ( $P=0.02$ , **Figure 1**). In multivariable least squares and negative binomial regression models, CK score and number of positive CKs were associated with PTSD, though this was limited to those who were anti-CCP positive (**Table 1**). Anxiety/depression subjects without PTSD had similar CK scores and number of elevated CKs as controls. PTSD was associated with heightened expression of several individual CKs (IL-1, IL-2, IL-6, IL-10, GM-CSF, IFN- $\gamma$ , MCP-1).

**Conclusion:** Anti-CCP positive RA patients with PTSD have a higher serum cytokine expression in comparison to those without PTSD. These findings support an objective measure of increased inflammation in RA patients with comorbid PTSD. Exploration of a potential mechanistic inflammatory link between RA and PTSD and contributions of specific cytokines will require future study.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures  
**Session Type:** ACR Poster Session B  
**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is a chronic autoimmune disease that primarily affects joints. There is still limited information of serum biomarkers suitable for effective monitoring of disease activity. To assess RA-associated serum protein signature using highly sensitive multiplex Proximity Extension ImmunoAssay (PEA) and its relationship with disease activity evaluated by activity score (DAS28).

**Methods:** We investigated the serum levels of 92 inflammation-related proteins in 78 Czech patients with RA and 38 age-matched healthy control (C) subjects using a highly sensitive innovative multiplex PEA (Proseek Multiplex, Olink Bioscience, Sweden). Statistical tests (Mann-Whitney U test, Benjamini-Hochberg correction, Spearman correlation) were performed using GenEx (Sweden),  $P$ -value  $\leq 0.05$  was considered as significant.

#### **Results:**

Top-ranked proteins distinguishing RA and C ( $P_{corr} < 0.0001$ ) were sTNFSF14, sulfotransferase 1A1, IL-6, axin 1, CCL7, caspase 8, oncostatin M, sirtuin 2, sTGF $\alpha$ , CCL3, sHGF, sCD40, STAMBP, FGF23, CXCL10, and sSLAMF1. Of them, upregulation of sulfotransferase 1A1, axin 1, and GDNF was not reported in RA yet. Disease activity positively correlated with CCL20 ( $r=0.495$ ,  $P=0.000004$ ), CCL7 ( $r=0.442$ ,  $P=0.00005$ ), CXCL1, CXCL9, IL-6, sCD40, GDNF, CXCL10 ( $r>0.30$ ,  $P<0.006$ ), and negatively correlated with IL-12B and sCD244 ( $r<-0.304$ ,  $P<0.007$ ). Subanalysis of protein pattern in patient phenotypes is ongoing.

**Conclusion:** Among the entire panel, the chemokines CCL20, CCL7, CXCL1, CXCL9, CXCL10 and GDNF appeared to be the most useful serum markers for evaluation of the disease activity of patients with RA. Further multivariate analysis is needed to identify pattern associated with high disease activity.

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibromyalgia has been reported in approximately 20% of Rheumatoid Arthritis (RA) patients. Several studies have shown that the presence of Fibromyalgia (FM) is associated with a significant increase in patient-reported outcomes (PROs). Therefore, traditional composite measures usually employed for the assessment of disease activity in RA, would not be able to discriminate between RA activity and FM symptoms. Baker et al. developed modified disease activity scores based on DAS28, SDAI and CDAI (M-DAS28, M-SDAI, M-CDAI). Interestingly, these scores of which all self-reported measures were excluded, showed a better correlation with synovitis detected on magnetic resonance imaging (MRI). By excluding the tender joint count and the patient's global assessment of disease activity, these new activity scores would represent a useful tool to better determine RA activity in patients with concomitant FM. The aim of this study was to evaluate the M-DAS28, M-SDAI and M-CDAI performance in a cohort of RA patients with and without concomitant FM. **Methods:** Cross-sectional observational study that included consecutive patients with diagnosis of RA (ACR/EULAR 2010 criteria) with and without concomitant FM (ACR 1990 and/or ACR 2010 criteria). Other connective tissue disorders (except secondary Sjögren's Syndrome) were excluded. Demographic and RA characteristics, and disease activity measures were collected. Patients were divided into 2 groups: RA and RA+FM. Statistical analysis: Mean differences between traditional and modified scores in RA patients with and without FM were analyzed. A linear regression model evaluating the effect of FM presence on score difference was performed, adjusting by covariates that proved significant on bivariate analysis. **Results:** A total of 130 patients were included, 90% women, mean age was 53 years (SD 12.3). Thirty-five patients had RA+FM (27%). Mean duration of RA was 66 months (IQR 23-120). The only difference between the groups with and without FM was the presence of nodular disease (11.4% vs 32.6%,  $p=0.01$ ). The difference between traditional and modified scores was higher and statistically significant in the RA+FM group (Table 1). This difference remained after adjusting for sex, age and nodular disease (Table 2). **Conclusion:** RA activity assessed by these new modified disease activity scores in patients with RA and concomitant FM was lower than that measured by traditional ones. Therefore, these new modified scores could avoid a disease activity overestimation in RA patients with FM, resulting in a better tool to achieve the "Treat to Target" premises.

**Table 1.** Difference between traditional and modified scores according to the presence or not of Fibromyalgia.

Score differences	Without Fibromyalgia, mean (SE)	With Fibromyalgia mean (SE)	<i>p</i> -value
DAS28ESR-MDAS28ESR (N= 128)	1.63 (0.17)	3.00 (0.57)	0.0023
DAS28CRP-MDAS28CRP (N= 119)	1.24 (0.16)	2.70 (0.61)	0.0015
SDAI – MSDAI (N= 119)	10.06 (1.56)	19.80 (4.56)	0.0103
CDAI - MCDAI (N= 130)	7.35 (1.46)	15.74 (4.06)	0.0158

SE= Standard error

**Table 2.** Effect of the presence of Fibromyalgia on the score difference between traditional and modified composite scores, adjusted by age, sex and nodular disease.

Score difference	Mean increment	CI95%	<i>p</i> -value
DAS28ESD-MDAS28ESD	1.50	(0.60-2.40)	0.001
DAS28CRP-MDAS28CRP	1.55	(0.63-2.48)	0.001
SDAI – MSDAI	10.78	(3.23-18.34)	0.006
CDAI - MCDAI	11.34	(3.80-18.89)	0.0158

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** HAQ is considered the gold standard for the evaluation of functional capacity in patients with RA, even though it doesn't focus in any particular anatomical region. With the objective of assessing functional incapacity of the hand in elderly patients with osteoarthritis, Baron et al. (1987) used a modified version of the HAQ which was calculated as the mean value for those categories involving mostly upper extremities and named it 'HAQUP'. This instrument has not been validated in patients with RA. Given the high prevalence of upper limb involvement in this disease and the lack of useful tools in daily clinical practice targeting the functional capacity of this anatomical sector, the aim of this study was to validate HAQUP in patients with RA.

**Methods:** Analytical, observational, prospective cross-sectional study. We included consecutive patients  $\geq 18$  years with diagnosis of RA (ACR/EULAR 2010). Socio-demographic data, characteristics of the disease, disease activity parameters and treatment were recorded. Patients completed the following self-administered questionnaires: HAQ-A (Argentine Spanish Version), HAQUP, Functional Index for Hand OsteoArthritis (FIHOA) and Quick Disabilities of the Arm, Shoulder and Hand (Quick DASH). In a subgroup of patients, an occupational therapist made an objective evaluation of the functional capacity of upper limbs using the Sequential Occupational Dexterity Assessment (SODA). The reproducibility of the questionnaire was assessed in 30 patients who completed HAQUP in a second visit, 10 to 15 days. *Statistical analysis:* Population characteristics were described. Reliability was assessed using the Cronbach test. Construct validity was analyzed through the correlation with other functional capacity questionnaires and disease activity parameters using the Spearman coefficient. Reproducibility was estimated using test-retest reliability. A linear regression model was constructed with HAQUP as the outcome variable and those variables that were statistically significant in bivariate analysis.

**Results:** We included 100 patients, 83% women, mean age 57.9 years (SD 11.6). The median HAQ-A was 0.88 (IQR 0.25-1.50). Cronbach's alpha test was 0.94. The intra-item correlation did not show redundant questions. HAQUP showed excellent correlation with HAQ-A ( $r = 0.93$ ); FIHOA ( $r = 0.89$ ); Quick DASH ( $r = 0.91$ ) and SODA ( $r = -0.84$ ). It also showed good correlation with DAS28 ( $r = 0.68$ ) and other composite disease activity indices as well as with other parameters of the disease [visual analog scale (VAS) for pain, patient and physician global, 28 tender joint count (TJC), 68 TJC, 28 swollen joint count (SJC) and 66 SJC]. There was no correlation between HAQUP and age or disease duration. The reproducibility of the questionnaire was 0.82. Multiple linear regression adjusted for age and sex showed patient global VAS as the main determinant of HAQUP, followed by the presence of morning stiffness and 66 SJC.

**Conclusion:** HAQUP was found to be reliable, valid and reproducible in patients with RA, representing a useful tool for the evaluation of the functional capacity of the upper limbs in these patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Prognostic factors facilitate decisions on treatment and follow-up of patients with rheumatoid arthritis (RA). Rheumatologists might use factors with poor link to evidence in clinical practice. The ProgresAR project aims to 1) benchmark the use of the most commonly known prognostic factors in RA in daily clinical practice, and 2) to contrast their use with the strength of association of these factors with poor outcome.

**Methods:** We performed an overview of systematic reviews of factors associated with disability, mortality, remission, and radiological progression in RA. Then, a panel of rheumatologists, removed and added factors to the selection. Following, a review in matrix was carried out for each factor and outcome. In parallel, a group of 42 rheumatologists randomly selected was surveyed. The use of each factor was recorded on a Likert scale from 1 (none) to 9 (always) generating 3 categories: 1-3 under use; 4-6 intermediate and 7-9 high use.

Prognostic factors	Use M (IQR)	Radiological progression	Disability	Mortality	Remission
<b>Sociodemographic data</b>					
Advanced age	5 (4)	C			C
Female gender	6 (4)	C	NN		C
Low educational level	5 (3)		N		C
Low sociocultural level	6 (4)	N	N		N

<b>Image data</b>					
Ultrasound synovitis with Doppler signal	7 (2)	NN			
Osteitis by magnetic resonance	4 (4)	NN			
Erosions by magnetic resonance	4 (4)	NNN			
Erosions by radiography	9 (1)	NNN	N		N
Erosions by ultrasound	7 (3)	N			

M: median; IQR: interquartile range; C: controversial; N/n: negative effect; P: positive effect. The number of letters indicates the strength of the association, from weak (N) to strong (NNNN). Lowercase (n) indicates an intermediate assessment.

**Results:** The reviews identified 36 prognostic factors that were further reduced to 28. The survey was completed by 42 rheumatologists. Table 1 shows, for each factor, the reported frequency of use and the strength of association with the various outcomes.

**Conclusion:** Rheumatoid factor, ACPA, and erosions by radiography are well recognized and strong predictors that are used frequently. Osteitis and erosions by magnetic resonance and shared epitope have good evidence but minor use. Disease duration and smoking are frequently used as prognostic factors despite weak association with outcome, similarly to activity and acute phase reactants at baseline. Subsequently, we will test whether displaying the evidence makes rheumatologists change opinions.

## **Assessing the Quality, Reliability and Readability of Online Health Information Regarding Rheumatoid Arthritis**

**Mathew Reynolds**<sup>1</sup>, David Ta<sup>1</sup> and Russell Buchanan<sup>2</sup>, <sup>1</sup>Department of Rheumatology, Austin Health, Heidelberg, Australia, <sup>2</sup>Department of Rheumatology, Austin Health, Melbourne, Australia

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis is a common autoimmune disease with complex pathophysiology and varied treatment options, which accounts for many visits to health care professionals. With increasing use of the internet, we assessed the quality, reliability and readability of online information relating to rheumatoid arthritis.

### **Methods:**

The search phrase ‘rheumatoid arthritis’ was used with the three most commonly accessed internet search engines (Googleä, Bingä and Yahooä) to identify websites. The first 25 ‘hits’ (excluding duplicates and excluded websites) for each search were assessed for quality using the DISCERN instrument (score 16-80 points), reliability using the four JAMA benchmarks (assessing authorship, attribution of references, currency (date of posted content) and disclosure of conflict of interest) and readability using the Gunning Fog Index (ideal score 7-8).

### **Results:**

There was significant concordance between the hits returned from each search engine with a total of 27 unique websites identified. The average DISCERN score was 44.9 (SD 10.7), and ranged from 29-62.

Websites that appeared earlier in searches did not have higher DISCERN scores (Pearson correlation -0.09).

The Top 5 websites by DISCERN score are seen in Table 1.

The mean number of JAMA benchmarks was 1.5 (SD 1.05), with currency present in 21/27 (77.8%), appropriate authorship in 8/27 (29.6%), attribution of references in 11/27 (40.7%) and disclosure of interest in only 1/27 (3.7%) of websites.

The average readability of the websites was 13.3 (SD 4.0) using the Gunning Fog Index.

### **Conclusion:**

The overall quality of online health information relating to rheumatoid arthritis, as assessed by the DISCERN instrument, is only fair.

Reliability, as measured by the JAMA benchmarks was of variable quality. Whilst the majority of websites provided dates of posted and updated content, references were available for less than half. The remaining benchmarks were poorly represented.

The readability of websites is higher than recommended for near-universal understanding, requiring an average of year 12 equivalent or higher education for understanding.

This assessment highlights the need for clinicians to provide patients with quality written information regarding rheumatoid arthritis or be able to direct them to websites with high quality information.

## **Disease Duration and Shared Epitope, but Not Smoking History, Are Associated with Peptidylarginine Deiminase 4-Antibody Development in Rheumatoid Arthritis**

**Laura Cappelli**<sup>1</sup>, Maximilian Konig<sup>1</sup>, Pooja Naik<sup>2</sup>, Arvin Saleh<sup>3</sup>, Allan C. Gelber<sup>3</sup>, Clifton O. Bingham III<sup>4</sup> and Erika Darrah<sup>5</sup>,

<sup>1</sup>Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>2</sup>Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Johns Hopkins University School of Medicine, Baltimore, MD, <sup>4</sup>Rheumatology, Johns Hopkins University, Baltimore, MD, <sup>5</sup>Department of Medicine/Division of Rheumatology, The Johns Hopkins University School of Medicine, Baltimore, MD

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Clinical characteristics and biomarkers help clinicians predict disease features in rheumatoid arthritis (RA). Both peptidylarginine deiminase 4 (PAD4) antibodies and smoking have been associated with common clinical characteristics in RA, namely erosive disease, anti-CCP positivity, and interstitial lung disease. Whether smoking is etiologically linked to developing PAD4 antibodies, however, is unknown. We evaluated whether smoking history was associated with PAD4 antibody development in RA.

**Methods:** Adults with physician-diagnosed RA were drawn from a longitudinal cohort followed at the Johns Hopkins Arthritis Center. PAD4 and PAD3/4 cross-reactive antibodies were measured by immunoprecipitation; anti-CCP levels were measured by ELISA. Genotyping for shared epitope (SE) alleles was performed. Clinical data were drawn from patient/physician reported and historical sources.

**Results:** Among the 274 patients with RA, demographics did not significantly differ in those with PAD4, PAD3/4 and without PAD4 antibodies (table 1). Disease duration was longer in PAD4 and PAD3/4 antibody positive groups compared with the PAD4 negative group, whereas presence of SE was higher in the PAD4 antibody group. Both PAD4 and PAD3/4 positive groups were more likely to be anti-CCP positive. There was no significant difference in smoking history between groups, but there was a trend toward lower frequency of current smokers among those with PAD4 antibodies. In subsequent analyses, all those with PAD4 antibodies were grouped (PAD4 only and PAD3/4). In stratified analyses (table 2), smoking history remained unassociated with PAD4 antibody status, and was inversely associated with having PAD4 antibodies in those with SE, although not statistically significant. In multivariable models adjusting for disease duration, SE, race and sex, smoking remained unassociated with PAD4 antibody presence, while longer disease duration and having SE were positively associated with PAD4 antibodies (table 3).

**Conclusion:** Smoking history was not associated with the development of PAD4 or PAD3/4 cross-reactive antibodies in this cohort with RA. The lack of association persisted in multivariable analyses accounting for potentially confounding features. Having shared epitope and longer disease duration, however, were associated with developing PAD4 antibodies.

Variable	PAD negative (P0) (n= 206)	PAD 4 Ab only (P4) (N= 34)	PAD 3/4 Ab (XR) (N = 34)	p-value XR vs P0	p-value P4 vs P0	p-value XR vs P4

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** First-degree relatives (FDRs) of patients with rheumatoid arthritis (RA) are at increased risk for developing RA compared to the general population. The purpose of the study reported herein was to evaluate the incidence rate of RA from a local cohort of FDRs that was initiated in 2004.

**Methods:** FDRs of patients with RA from Cedars-Sinai Medical Center (CSMC) enrolled in the Studies of the Etiology of RA (SERA, a multicenter prospective cohort of FDRs of probands with RA) were studied (Kolfenbach 2009). Participants were enrolled between 2004 and 2011, providing an average of 9.5 years of follow-up. FDRs who live in Southern California within approximately 150 miles of CSMC were contacted by phone and asked if they were given a diagnosis of RA by a rheumatologist or if they reported pain in one or more joints, and/or swelling or morning stiffness. If they had symptoms, but were not yet diagnosed with RA, they were evaluated in clinic by a rheumatologist and underwent testing for CCP antibodies (CCP 3.1).

**Results:** 250 FDRs enrolled in SERA between 2004 and 2011 and seen at CSMC who live in Southern California were contacted by telephone. 73 out of 250 subjects (29.2%) were reached to date. 2/73 FDRs (3%) reported a diagnosis of RA by a rheumatologist. Both FDRs diagnosed with RA were seronegative at the time of enrollment in the SERA cohort. One who was initially seronegative in 2007 seroconverted in 2011, with CCP2 and RF IgG positivity – she was diagnosed with RA in 2014. The second FDR diagnosed with RA remained seronegative for the duration of follow-up, even post-diagnosis. 9 of 73 FDRs (12.3%) had arthralgias defined as pain in one or more joints. Of these, 4 of the 9 have been evaluated to date by a rheumatologist in clinic without evidence of RA; none were CCP positive.

**Conclusion:** Our local cohort follow-up suggests that FDRs of patients with RA develop RA at a higher rate than the general population with an incidence rate of 3% in FDRs versus 0.4% in the general population over 10 years<sup>1</sup>. This is an ongoing effort to prospectively evaluate the risk of development of RA from a subgroup of FDRs established in the United States (SERA).

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The regular assessment of disease activity is necessary to implement a treat-to-target management approach in RA. The Multi-Biomarker Disease Activity (MBDA) Score is a novel tool developed to facilitate RA disease activity assessment, but there have been conflicting reports on the ability of the MBDA score to assess RA disease activity. Therefore, we performed a systemic review of MBDA in RA and meta-analysis of the correlation between the MBDA and composite RA disease activity measures.

**Methods:** We conducted a systematic review and meta-analysis of published manuscripts on the MBDA in RA (registered with PROSPERO) by searching MEDLINE, EMBASE, Scopus, Google Scholar, and the Cochrane Library from their inception to March 7, 2017, adhering to the PRISMA guidelines. We included studies reporting correlations of MBDA with composite RA disease activity measures and completed a meta-analysis to calculate a pooled estimate. Studies only assessing MBDA performance in separate cohorts or time points were modeled as separate studies. We performed a random-effects meta-analysis of correlation coefficients using the DerSimonian-Laird model for measures assessed in  $\geq 3$  cohorts. In sensitivity analyses, we allowed each study to only contribute one cohort and transformed correlation coefficients to Fisher’s Z scores prior to meta-analysis. Heterogeneity was assessed using the Cochran Q test.

**Results:** The systematic review identified 18 reports examining the MBDA in RA, with 6 of these (n=9 cohorts) reporting correlations with composite RA disease activity measures. Results from meta-analysis demonstrated a moderate to strong correlation of the MBDA with DAS28-CRP ( $r=0.53$ , 95% CI 0.40-0.67, **Figure 1**). Heterogeneity was marginally significant by Cochran Q ( $p = 0.07$ ). Results were similar following conversion of correlation coefficients to Fisher’s Z scores ( $r=0.54$ , 95% CI 0.40-0.66) and using only one cohort (baseline) per study ( $r=0.61$ , 95% CI 0.52-0.70). The MBDA demonstrated similar correlations with the Simple Disease Activity Index (SDAI) and a slightly less robust correlation with the Clinical Disease Activity Index (CDAI) with significant heterogeneity across relevant studies (**Table 1**). There was a moderate to strong correlation between  $\Delta$ -MBDA with  $\Delta$ -DAS28-CRP (**Table 1**).

**Conclusion:** The MBDA demonstrates moderate to strong correlations with DAS28-CRP and SDAI, but less robust correlations with CDAI. Since CRP is a common component of MBDA, DAS28-CRP, and SDAI, additional study is needed to assess whether MBDA correlates with RA disease activity measures lacking CRP.

Table 1. Random-effects meta-analysis of the correlation of MBDA with composite RA disease activity measures					
	N cohorts	Pooled $r$	95% CI	Cochrane Q	P value*
<i>MBDA</i>					
CDAI	4	0.38	0.19-0.56	12.36	0.006
SDAI	3	0.51	0.29-0.73	11.34	0.003
<i><math>\Delta</math>MBDA</i>					
$\Delta$ DAS28-CRP	3	0.51	0.38-0.64	1.67	0.44

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid arthritis (RA) is a chronic inflammatory disease that results in severe joint damage and physical disability, therefore, the discovery of new marker(s) for joint destruction is needed. Serum 14-3-3 $\eta$  protein is a novel diagnostic marker for RA, and also involved in joint damage (1, 2). 14-3-3 $\eta$  protein has been reported to be expressed at significantly higher levels in synovial fluid (SF) of RA patients when compared with matched serum by immunoblot analysis (1). Correlation of serum 14-3-3 $\eta$  protein with clinical variables, autoantibodies, inflammatory markers, and radiologic damage has been examined in RA (2). These associations have never been examined for RA synovial fluid (SF) 14-3-3 $\eta$  protein. In this study, we quantified SF 14-3-3 $\eta$  by ELISA and determined the association of serum and SF 14-3-3 $\eta$  protein with clinical, laboratory and radiographic damage in RA.

### **Methods:**

RA patients diagnosed according to 2010 ACR criteria were included. Serum and SF samples were obtained from all patients at the same day and 14-3-3 $\eta$  protein levels were measured using the quantitative 14-3-3 $\eta$  ELISA kit (Augurex Life Sciences Corp). A 14-3-3 $\eta$  cut-off of  $\geq 0.19$  ng/ml, the diagnostic cut-off was employed. Radiological damage was evaluated using Sharp/van der Heijde score (SHS). Spearman or Pearson correlations to compare relationships and Mann-Whitney U test for groups difference were used for statistical analysis.

## Results:

A total of 39 RA patients, mean age of 38 years, with 87.2% being female were included. Their mean disease duration was 9.3 years, and 48.7% of patients had moderate DAS28. Mean SF14-3-3 $\eta$  protein levels were 2 fold higher than mean serum protein levels (3.7 vs 1.7 ng/ ml). The prevalence of 14-3-3 $\eta$  protein positivity was higher in SF compared with serum from RA patients; 82.1% versus 69.2%, respectively. Although there was significant correlation between SF 14-3-3 $\eta$  protein levels and ESR ( $p=0.036$ ), no significant association was found between serum or SF 14-3-3 $\eta$  protein levels with DAS28 or autoantibodies in RA. There was significant correlation between serum and SF 14-3-3 $\eta$  protein levels ( $p<0.05$ ) in RA patients. Serum and SF 14-3-3 $\eta$  protein levels were positively correlated with SHS ( $p<0.001$ ). RA patients who were serum or SF 14-3-3 $\eta$  protein positive showed significant difference in SHS but not in clinical and laboratory features when compared with 14-3-3 $\eta$  negative patients.

## Conclusion:

14-3-3 $\eta$  levels are significantly higher in SF than in matched serum. Serum and SF14-3-3 $\eta$  protein levels correlate with radiographic damage. This study further substantiates 14-3-3 $\eta$  as a mechanistic joint damage marker for RA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Small RNAs (sRNAs), such as microRNAs, are important regulators of biological processes and serve as important biomarkers of disease. We found that approximately half of sRNAs in human plasma fail map to the human genome, but many map to microbial genomes. sRNAs, human and non-human alike, may alter cellular function. Thus, non-human plasma sRNAs may serve as an effector compartment of the human microbiome, an area of great interest in rheumatoid arthritis (RA). Our objective was to determine if sRNAs of microbial origin are altered in RA plasma.

**Methods:** RNA was extracted from plasma from 165 patients with RA and 91 controls frequency-matched for age, race and sex. Purified plasma RNA was used to prepare sRNA cDNA libraries. Sequencing was performed using Illumina NextSeq500. Using TIGER, an in-house sRNA-seq analysis pipeline, high quality reads were first aligned to the human genome allowing for 1 mismatch. Remaining reads were aligned to 57 genomes of bacteria previously found to be altered in RA. Separately, remaining reads were aligned to representative genomes of 207 human microbiome bacteria, 8 fungi, and 167 environmental bacteria. Differential expression analysis of sRNA and microbial genome counts were performed using DESeq2, adjusting for age, race, sex and batch, with 5% false discovery rate. Benjamini and Hochberg method was used for multiple test correction.

**Results:** Three microbial sRNAs, of variable length of the same sRNA were increased approximately 2-fold in the plasma of RA patients compared to control subjects ( $P=0.001$  to  $P=0.02$ ). These sRNAs mapped to multiple bacterial genomes of the human microbiome and environment. The three microbial sRNAs have an identical seed region, which in the case of miRNAs, is the region that binds with complementarity to target mRNAs to alter translation. This microbial sRNA seed region is predicted to target several human genes which are altered in RA including CARD8, IL17RA, and TRAF1. Comparing genome counts of RA-specific bacteria, *Lactobacillus salivarius* was significantly decreased in RA vs control ( $P=0.03$ ). Comparing genome counts of representative genomes of human microbiome, fungi and environmental bacteria, *Anaerobaculum hydrogeniformans* ( $P=0.01$ ), *Staphylococcus epidermidis* ( $P=0.04$ ), *Sphingobacterium spiritivorum* ( $P=0.04$ ), and *Staphylococcus aureus* ( $P=0.04$ ) were significantly decreased in RA compared to control subjects.

**Conclusion:** Microbial plasma small RNAs are altered in patients with RA. Three microbial plasma sRNAs were increased significantly in RA and are predicted to target genes associated with RA. Further studies will determine the role of these microbial sRNAs in RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Small noncoding RNAs (sRNAs), such as microRNAs (miRNAs), are regulators of biological processes and serve as important biomarkers of disease. Most previous plasma sRNA studies in inflammatory autoimmune diseases have relied on PCR or microarrays to quantify candidate miRNAs based on limited information about their function; however, unbiased sRNA sequencing could reveal new miRNA markers of disease. We hypothesized that plasma miRNAs are altered in patients with rheumatoid arthritis (RA) compared to control subjects and some may serve as markers of RA diagnosis.

**Methods:** This cross-sectional study included patients with 167 patients with RA, and 91 age, race and sex matched control subjects. Sequencing was done by Illumina NextSeq500. High quality reads were mapped to the human genome using Bowtie1. MiRBase21.0 was used to quantify miRNAs. miRNA reads were compared between RA and control subjects by DESeq2 with adjustment for age, race sex, and batch with 5% false discovery rate and multiple test correction by Benjamini and Hochberg method, and separately by random forest analysis. The top 12 differentially expressed miRNAs were validated by qPCR. A miRNA qPCR panel for RA diagnosis was developed using logistic regression, whose discrimination capacity was assessed by area under the receiver operative characteristic curve (AUC).

**Results:** Of 262 reliably mapped microRNAs, 107 were significantly altered >1.5-fold in patients with RA. Among the top 12 differentially expressed miRNAs identified by both DESeq2 and random forest analysis, miR-22-3p, miR-22-5p, miR-24-3p, miR-29c-3p, miR-30e-5p, miR-130a-3p, miR-140-3p, miR-221-3p, and miR-345-5p remained significantly altered and reliably detectable when validated by qPCR (Table). A panel including miR-22-3p, miR-24-3p, and miR-140-3p had AUC=0.81 for distinguishing between RA and control subjects. This panel remained robust distinguishing between control subjects and both seronegative RA (AUC=0.85) and seropositive RA (AUC=0.79).

**Conclusion:** Several plasma miRNAs identified by sRNA sequencing are altered in patients with RA compared to control subjects and may serve as novel diagnostic markers of RA. Further validation is necessary to confirm these findings.

Table. Top differentially expressed plasma miRNAs validated by qPCR.				
	RA (fM)	Control (fM)	Fold difference	P
miR-22-3p	58.10 [45.30, 74.50]	15.10 [10.80, 21.00]	3.85	8.45E-12
miR-22-5p	1.18 [0.89, 1.56]	0.39 [0.25, 0.61]	2.99	1.25E-07
miR-24-3p	3.98 [2.95, 5.37]	1.32 [0.85, 2.06]	3.01	1.19E-06
miR-29c-3p	1.46 [1.18, 1.80]	0.56 [0.41, 0.77]	2.59	5.32E-09
miR-30e-5p	4.23 [3.51, 5.11]	3.24 [2.49, 4.21]	1.31	2.39E-02
miR-130a-3p	5.00 [3.51, 7.12]	1.27 [0.81, 1.97]	3.94	8.56E-08
miR-140-3p	1.22 [1.00, 1.49]	0.25 [0.17, 0.37]	4.93	2.12E-13
miR-221-3p	9.96 [7.48, 13.20]	3.04 [2.15, 4.31]	3.27	6.78E-09
miR-345-5p	0.06 [0.04, 0.09]	0.02 [0.01, 0.03]	3.62	1.72E-04

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The purpose of this study is to explore new biomarkers for early diagnosis of rheumatoid arthritis (RA). For better discrimination power, we especially investigated the samples of early RA (eRA) patients with the onset of RA less than 2 year.

**Methods:** Gene expression profiles of peripheral mononuclear cells (PBMC) and CD4<sup>+</sup> T cells obtained patients with eRA, advanced RA (aRA, disease duration more than 2 year) and osteoarthritis (OA) were investigated using microarray. PBMC from 11 patients with eRA and CD4<sup>+</sup> T cells from 10 patients with eRA were analyzed compared to patients from aRA and OA. Quantitative real-time PCR (qRT-PCR) was performed to verify the results of microarray. The concentrations of representative cytokines were measured with enzyme-linked immunosorbent assay (ELISA) kits.

**Results:** We identified 52 differentially expressed genes (DEGs) with more than 1.5-fold higher expression values and 27 DEGs with lower expression on microarray of PBMC of eRA patients compared to OA ( $p < 0.05$ ). 29 genes were highly upregulated in CD4<sup>+</sup> T cells of patients with eRA compared to aRA and OA (3-fold,  $p < 0.05$ ). The top 10 genes were mainly interferon signature genes and related chemokine including CXCL10 (chemokine C-X-C motif ligand 10; 225-fold,  $p = 0.004$ ), IFIT3 (interferon-induced protein with tetratricopeptide repeats 3; 85-fold,  $p = 0.0002$ ), IFIT1 (interferon-induced protein with tetratricopeptide repeats 1; 33-fold,  $p = 0.002$ ), RSAD2 (radical S-adenosyl methionine domain containing 2; 23-fold,  $p = 0.001$ ), TNFAIP6 (tumor necrosis factor, alpha-induced protein 6; 15-fold,  $p = 0.005$ ), SLAMF7 (SLAM family member 7; 14-fold,  $p = 0.008$ ), IFI44 (interferon-induced protein 44; 14-fold,  $p = 0.0003$ ), IFIH1 (interferon induced with helicase C domain 1; 13-fold,  $p = 0.0002$ ), OASL (2-5-oligoadenylate synthetase-like; 11-fold,  $p = 0.0002$ ), HERC5 (HECT and RLD domain containing E3 ubiquitin protein ligase 5; 11-fold,  $p = 0.0003$ ). The differentially expressed genes were verified using qRT-PCR. Elevated levels of IFN- $\gamma$  and CXCL10 were demonstrated in patients with eRA. The concentration of IFN- $\gamma$  and CXCL10 was significantly higher in eRA than aRA (Table 1).

**Conclusion:** Our study defined that IFN- $\gamma$  signature genes in CD4<sup>+</sup> T cells and level of IFN- $\gamma$  in serum were highly presented in the early stages of rheumatoid arthritis. In addition, we found CXCL10, which supposed to be stimulated by IFN- $\gamma$ , was significantly increased not only in the gene level but also in the protein level of peripheral blood from eRA. IFN- $\gamma$  signature as well as CXCL10 could be useful as biomarkers in patients with the early stage of rheumatoid arthritis.

Table 1. The concentration of IFN- $\gamma$  and CXCL10 in eRA compared to aRA.

Protein Level	eRA	aRA	P value
IFN- $\gamma$ (pg/mL)			
n	14	21	
Mean $\pm$ SEM	39.8 $\pm$ 4.9	24.2 $\pm$ 6.7	<0.05
Median (range)	38.9 (10.2-72.5)	12.3 (5.5-141.9)	
CXCL10 (pg/mL)			
n	10	6	
Mean $\pm$ SEM	329.0 $\pm$ 104.8	67.9 $\pm$ 13.2	0.017
Median (range)	179.5 (63.7-1072.5)	57.3 (44.4-132.5)	

SEM ; the standard error of the mean

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Smoking is an important environmental risk factor for development of rheumatoid arthritis (RA). Smoking has been linked to lower rates of disease remission, incomplete response to DMARD therapy, and elevated serum levels of pro-inflammatory cytokines. Former smokers respond equally well to DMARD treatment as never smokers. In established RA patients, it is unknown if smoking cessation improves RA-associated outcomes. We aimed to investigate the association of tobacco use and disease activity in established RA patients. We hypothesized that current tobacco use in established RA is associated with increased DAS28-CRP and is affected by RA-associated comorbidities.

**Methods:** We performed a case control study on 95 patients with RA. Patients were consented and enrolled in the Penn State Investigation of Remission in Rheumatoid Arthritis cohort. Disease activity was measured by DAS28-CRP. Smoking was categorized as current, former or never status. Chi-square ( $X^2$ ) or Fisher's exact test were used to test for differences between categorical variables, and ANOVA or Kruskal-Wallis test were used for continuous variables. The primary outcome was the association of smoking status with DAS28-CRP. Multivariable linear regression was performed with covariates including age, education, pack years, disability as measured by the modified health assessment questionnaire (MHAQ), nodules, hypertension, periodontitis, and disease duration.

**Results:** RA subjects had an average age of 55.5 years, 74% were female and > 90% were Caucasian. Subjects had established RA with a mean disease duration of 10.9 years, 87% were seropositive, and mean DAS28-CRP was 3.36. 89.3% of patients met the 2010 ACR/EULAR classification criteria for RA. 19% percent were current smokers and 36% were former smokers, who were 10 years older than current smokers ( $p < 0.05$ ). Mean DAS28-CRP was significantly higher ( $p = 0.003$ ) in current smokers (4.40) compared to former (3.26) and never (2.95) smokers. Current smokers had a lower odds of being in remission than never smokers ( $OR = 0.14$ ,  $p = 0.02$ ). Rheumatoid nodules were more prevalent in current smokers ( $p = 0.06$ ). Level of education was inversely associated with DAS28-CRP ( $p = 0.008$ ). Median MHAQ scores were significantly higher in current smokers (0.75) than former smokers (0;  $p = 0.02$ ). MHAQ scores were strongly associated with DAS28-CRP ( $p < 0.0001$ ). There was no difference in DAS28-CRP scores between smoking groups when controlled for MHAQ score, education, and periodontitis.

**Conclusion:** Current smokers with established RA have higher disease activity and are significantly less likely to be in remission. Smoking status and RA disease activity are strongly associated with disability, education level, and periodontal scores, implying both a socioeconomic and pathophysiologic basis for this association. Effects of smoking cessation on RA outcomes would be of interest.

Table 1: Patient demographics, disease characteristics, and comorbidities.

	Overall (95)	Current Smoker (18)	Former Smoker (34)	Never Smoker(43)	P-value
Age, Mean (SD)	55.5 (13.54)	52.2 (12.91)	62.0 (11.70)	51.9 (13.53)	0.002

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The MBDA score, based on 12 serum proteins, is a validated tool for assessing disease activity in RA patients. MBDA biomarkers may be influenced by age, sex and adiposity. The objective of this study was to develop and validate an adjusted MBDA score that accounted for these three factors, using BMI or serum leptin as proxies for adiposity.

**Methods:** The MBDA score as a continuous variable was adjusted to account for age, sex and a proxy for adiposity (serum leptin) using data from 325,781 RA patients for whom MBDA tests had been ordered as part of routine care. Leptin values came from the MBDA test. As an alternative to using leptin to adjust for adiposity, a cohort of 1411 patients from 5 studies/registries (BRASS, CERTAIN, InFoRM, OPERA, RACER) was used to adjust for BMI, which was not available in the larger cohort, adding this BMI adjustment to that for age/sex from the larger cohort. Both types of adjusted MBDA score use the low, moderate, and high disease activity cutpoints of the original MBDA score. The two types of adjusted MBDA score and other variables were then evaluated for the prediction of radiographic progression (RP) in the 2 cohorts with available radiographic data (OPERA and BRASS) using univariate and multivariate linear regression analyses. Rate of RP was assessed as the change in modified total Sharp score ( $\Delta$ mTSS) per year after MBDA testing. Prediction of RP was evaluated using the original and adjusted MBDA scores and compared with conventional measures, as well as DAS28 without CRP or ESR (DAS28\*).

**Results:** The MBDA score increased with age, BMI and leptin concentration. In univariate analysis of the combined OPERA and BRASS cohorts (n = 555), the significant variables predicting  $\Delta$ mTSS were leptin-adjusted MBDA score, seropositivity for RF or anti-CCP, BMI-adjusted MBDA score, MBDA score, BMI, CRP, baseline mTSS, disease duration, DAS28-CRP, SDAI, CDAI and DAS28\* (Table 1). The leptin-adjusted and BMI-adjusted MBDA scores were the first and third most significant univariate predictors of  $\Delta$ mTSS. To compare them directly, DAS28-CRP, MBDA score, BMI-adjusted MBDA score and leptin-adjusted MBDA score were combined in pairs in regression analyses of  $\Delta$ mTSS; the BMI-adjusted (p = 0.0027) and leptin-adjusted MBDA score were significant (p = 0.00063) after adjusting for DAS28-CRP (p = 0.87 and 0.74, respectively) and the leptin-adjusted MBDA score was significant (p = 0.024 and 0.020, respectively) after adjusting for either the MBDA (p = 0.32) or BMI-adjusted MBDA scores (p = 0.094).

**Conclusion:** We developed two adjusted MBDA scores that combine molecular and biometric variables to account for age, sex, and adiposity. One of them, the leptin-adjusted MBDA score, significantly outperformed DAS28-CRP and the original MBDA score in predicting radiographic progression in RA patients. These results suggest that the leptin-adjusted MBDA score may offer improved clinical utility for the personalized management of patients with RA.

**Table 1. Univariate Linear Regression Analysis of the Association of Clinical and Laboratory Variables with  $\Delta$ mTSS in the OPERA and BRASS Combined Cohort**

Variable	n	F-statistic	p-value
Leptin-adjusted MBDA Score	555	17.1	0.000040
RF or Anti-CCP Status	555	14.8	0.00013
BMI-adjusted MBDA Score	555	14.4	0.00016
MBDA Score	555	12.9	0.00036
BMI	555	10.9	0.001
$\log_2$ (CRP)	555	6.8	0.0093
Baseline mTSS	555	5.3	0.022
$\log_2$ (Disease duration + 1)	401	4.8	0.030
DAS28-CRP	536	4.6	0.032
SDAI	533	4.3	0.040
CDAI	533	3.9	0.049
DAS28*	536	3.1	0.079
Gender	555	1.5	0.23
Smoking Status	478	0.8 (2 df)	0.46
Age	555	0.1	0.76

DAS28\* = DAS28 with no CRP or ESR component, i.e.,  $0.56(\text{TJC28})^{1/2} + 0.28(\text{SJC28})^{1/2} + 0.014(\text{GH})$ .

## **A Single Immunosignature Test Accurately Discriminates RA from Related Autoimmune and Inflammatory Disorders**

**Theodore M. Tarasow**<sup>1</sup>, Robert Gerwien<sup>1</sup>, Jonathan Melnick<sup>1</sup>, Scott A. Melville<sup>1</sup> and Chaim Putterman<sup>2</sup>, <sup>1</sup>HealthTell, Inc., San Ramon, CA, <sup>2</sup>Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY, USA, Bronx, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Rheumatoid Arthritis (RA) is a chronic inflammatory autoimmune disease primarily targeting the synovium. RA is B-cell driven, and is associated with autoantibody production. The clinical heterogeneity in RA and overlapping symptoms with other diseases can pose diagnostic challenges, especially in early disease. An accurate diagnostic tool or a means to further stratify patients could have a significant impact on patient care.

Immunosignature (IS) technology permits differential diagnosis of related autoimmune diseases based on distinct serum autoantibody profiles, as determined by binding to a microarray containing 126K distinct peptides with an average length of 9 amino acids. Our unique approach to peptide microarray fabrication, combining photolithography with optimized peptide chemistry and MALDI-based quality control, enables low-cost, rapid, and reproducible testing.

Here, the IS technology was applied to the serological differentiation of RA from other rheumatic diseases (inflammatory and non-inflammatory) and healthy controls.

### **Methods:**

379 serum samples were prospectively collected, including RA (n=95), systemic lupus erythematosus (SLE) (n=75), Sjögren's syndrome (SS) (n=20), osteoarthritis (OA) (n=24), fibromyalgia (n=22), other disease (OD) (n=76) and healthy controls (HC) (n=59). Subjects with rheumatological diseases were diagnosed based on ACR criteria. There were no significant differences in gender, race, or ethnicity across all groups. Antibody(IgG)-peptide binding was quantified and peptides with significant intensity differences between contrasting groups were identified by Bonferroni adjusted t-test. Support vector machine classifiers were trained using the most distinguishing peptides between contrasts. Classifier performance was evaluated by a cross-validation routine that included feature selection, model training, and model testing.

## Results:

The number of significant peptides that discriminate RA from other groups and classification cross-validated area under the curve (cvAUC) values are summarized in the table below.

Contrast	Samples	Significant Peptides	cvAUC (95% CI)
RA vs. HC	154	3,062	0.80 (0.78-0.83)
RA vs. other rheumatic diseases*	239	328	0.70 (0.66-0.74)
RA vs. SLE	170	201	0.80 (0.76-0.85)
RA vs. OA	119	130	0.73 (0.67-0.78)
RA vs. Fibromyalgia	117	753	0.78 (0.73-0.83)
RA vs. SS	115	20	0.66 (0.60-0.73)
*Other rheumatic diseases = SLE, SS, OA, psoriatic arthritis (11), gout (9), seronegative spondyloarthropathy (2), pseudogout (1)			

## Conclusion:

Using IS technology, RA is best discriminated from patients with SLE and HC. Nevertheless, RA can also be differentiated from closely-related conditions such as SS with modest cvAUCs. The results presented represent a step toward creating a single test using a small serum sample capable of multi-classification across a range of symptomatically related diseases and in patients with conditions referred to rheumatologic evaluation. Whether diagnostic accuracy would be improved by combining results from standard serological tests is being studied. Verification in cohorts from other sites and validation in blinded studies would allow for further model refinement to create a robust diagnostic assay.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the intra- and interobserver reliability of the ultrasonographic (US) assessment of subtalar joint (STJ) synovitis in patients with rheumatoid arthritis (RA).

**Methods:** Following a 2-round Delphi consensus process on US-defined STJ synovitis in patients with RA, twelve sonographers conducted an US reliability exercise on 10 RA patients with ankle/rearfoot pain using a 16-8 MHz linear probe. The anteromedial, posteromedial, and posterolateral STJ was assessed ultrasonographically using B-mode and power Doppler (PD) techniques according to an agreed US protocol and using a 4-grade semiquantitative grading score for synovitis (synovial hypertrophy (SH) and power Doppler (PD) signal) and a dichotomous score for the presence of joint effusion (JE). Intraobserver reliability was calculated by Cohen's kappa. Interobserver reliability was computed by Light's kappa. Weighted k coefficients with absolute weighting were computed for B-mode and PD signal.

**Results:** Overall intra- and interobserver agreement for the STJ was 83% and 69%; overall intra- and interobserver agreement for SH, PD signal and JE, was 81(51-100)%, 88 (67-100) %, and 80 (72-88)%, respectively, and 69 (60-74)%, 76 (66-83)%, and 60 (54-65)% respectively. Mean weighted Cohen's kappa for SH, PD, and JE, was 0.80 (0.62-0.98), 0.61 (0.48-0.73), and 0.52 (0.36-0.67), respectively. Weighted Cohen's kappa for SH, PD, and JE in the anteromedial, posteromedial and posterolateral STJ was -0.04-0.79, 0.42-0.95, and 0.28-0.77; 0.31-1, -0.05-0.65, and -0.2-0.69; 0.66-1, 0.52-1, and 0.42-0.88, respectively. Weighted Light kappa for SH was 0.67 (95%CI 0.58-0.74), 0.46 (0.35-0.59) for PD, and 0.16 (0.08-0.27) for JE. Weighted Light kappa for SH, PD, and JE was 0.63 (0.45-0.82), 0.33 (0.19-0.42) and 0.09 (-0.01-0.19), for the anteromedial STJ; 0.49 (0.27-0.64), 0.35 (0.27-0.4), and 0.04 (-0.06-0.1) for posteromedial STJ, and 0.82 (0.75-0.89), 0.66 (0.56-0.8), and 0.18 (0.04-0.34) for posterolateral STJ, respectively.

**Conclusion:** Ultrasound is a reliable imaging technique for assessing synovitis of the STJ in patients with RA. The most reliable site to assess STJ synovitis in patients with RA is the posterolateral probe position.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disease flares in RA are associated with radiographic progression<sup>1</sup> and functional deterioration<sup>2</sup>. Predicting flare is of direct relevance to clinical practice, particularly in patients with low disease activity (LDA) in whom treatment tapering may be considered. The aim of this study was to investigate various biomarkers as predictors of flare in patients with LDA and to evaluate the impact of flare on 12-months clinical outcomes.

**Methods:** The REMIRA study was a prospective cohort study in which adult RA patients on stable DMARD treatment with a DAS28 < 3.2 for > 1 month were included.<sup>3</sup> At baseline and during every 3 months for 1 year, clinical (DAS28), functional (HAQ-DI, EQ-5D, SF36), serum (MBDA, calprotectin, CXCL10) and imaging (ultrasound) data were collected. Flare was defined as an increase in DAS28 >1.2 or >0.6 if concurrent DAS28 <sup>3</sup>3.2 compared to baseline. Univariate Cox regression analyses were used to identify baseline predictors of flare. Subsequently, multivariate analyses were used to calculate HR for flare, adjusted for age, gender, DAS28, CRP, ESR, ultrasound and MBDA score. Linear regression analyses were performed to compare 12-months clinical outcomes between patients with and without a flare.

**Results:** In total 152 patients were included of whom 46 (30%) patients experienced a flare. Several baseline characteristics were associated with flare in univariate analyses (DAS28, ESR, CRP, PGA, HAQ-DI and EQ-5D) (Figure 1). The strongest magnitude of association was seen with HAQ-DI and EQ-5D. Baseline MBDA score, calprotectin, CXCL10 and ultrasound were not predictive of flare. A sensitivity analysis limited to flares with a rise in MBDA score to >44 (high disease activity) did show a relationship between baseline MBDA value and flare risk (1.07, 95% CI 1.02 to 1.11; p=0.005). In the multivariate analysis only HAQ-DI remained a significant independent predictor of flare (adjusted HR 1.76, 95% CI 1.05-2.93). Adjusting for baseline values, patients who flared had significantly worse clinical outcomes at month 12 (Table 1).

**Conclusion:** Flares occur frequently in RA patients with LDA and are associated with worse clinical outcomes after 1 year. However we found no strong predictors of flare, which may highlight a challenge in attempting to reduce flare rates or in considering patients for treatment tapering.

## Foot Arthritis : Poor Prognosis Factor in RA

**Sung-Hae Chang**<sup>1</sup>, Sung Won Lee<sup>2</sup>, Mi-Il Kang<sup>3</sup> and Seong Yong Kim<sup>4</sup>, <sup>1</sup>Soonchunhyang University Cheonan Hospital, Cheonan, Korea, Republic of (South), <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Department of Rheumatology, Soonchunhyang University Cheonan Hospital, Cheonan, Korea, Republic of (South), <sup>3</sup>Dankuk University Hospital, Cheonan, Korea, Republic of (South), <sup>4</sup>Application Statistics, Hoseo University, Cheonan, Korea, Republic of (South)

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The objective of the current study is to evaluate the clinical importance of foot and ankle joint arthritis.

**Methods:** Data from Korean Biologic Registry (KoBio) data were analyzed. Foot and/or ankle arthritis defined as one or more swollen and/or tender joint among 1st-5th metatarsal or ankle joints. A chi-square analysis was employed to calculate the relative risk (RR) of remission for patients with foot and/or ankle arthritis among. Marginal model was applied to assess prognostic effect of foot and/or ankle arthritis adjusting positive rheumatoid factor, anti-CCP antibody and radiographic abnormalities

**Results:** A total of 2026 patients (biologic disease modifying anti-rheumatic drugs, R, n=1400 non-biologic DAMRDs treatment group, C, n=626) at baseline, 1554 patients (R, n=1046, C, n=508) at 1 year follow-up, 1068 patients (R, n=712, C, n=356) at 2 year follow-up, and 472 patients (R, n=327, C, n=145) were enrolled. At baseline evaluation, prevalence of foot synovitis was 29.4% of total patients (595 of 2026). Patients with foot or ankle arthritis (Group 1) were less likely to achieve clinical remission (using Disease Activity Score 28 ESR, DAS-28 ESR) compared to patients without foot and ankle arthritis (Group 2); remission rate of Group 1 vs Group 2 was 11.7 % vs 39.7% (p<0.001) at 1 year, 18.1 % vs 40.1 % (p<0.001) at 2 year, and 23.1 % vs 44.5 % (p<0.001) at 3 year follow-up. They were also tend to have functional impairment (using Routine Assessment of Patients Index Data, RAPID3); remission rate of Group 1 vs Group 2 was 5.0 % vs 20.4% (p<0.001) at 1 year, 9,0 % vs 18.5 % (p<0.001) at 2 year, and 3.1 % vs 20.3 % (p<0.05) at 3 year follow-up. Even among patients without radiographic abnormalities (joint space narrowing or erosion) in baseline foot x-ray, Group 1 patients showed significantly low clinical remission rate; remission rate of Group 1 vs Group 2 was 12.9 % vs 40.7 % (p<0.001) at 1 year, 15.3 % vs 41.3 % (p<0.001) at 2 year, and 26.2 % vs 47.7 % (p<0.001) at 3 year follow-up. Presence of foot and/or ankle arthritis at baseline or at any time point of observation period was associated with poor prognosis (Table 1, 2).

**Conclusion:** Foot and/or ankle arthritis is associated with less achievement of clinical remission.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The clinical diagnosis of rheumatoid arthritis (RA) remains a challenge, making serological markers most interesting. The 2010 ACR/EULAR classification criteria for RA take into account two serological markers: anti-cyclic citrullinated peptide (ACPA) and rheumatoid factor (RF).

The objective of this study is to evaluate the diagnostic performance of 6 RF and 7 ACPA assays in a secondary care hospital

### Methods:

From January 2014 to June 2015, all unique patients who for the first time underwent laboratory testing for a rheumatologic disease at the OLV hospital Aalst were included. Review of the medical records was done and the diagnosis was registered and reviewed by the consulting rheumatologist. Patients were categorized into three groups: RA, rheumatologic disease control group (RDCG) and disease control group (DCG). For all RA patients the fulfillment of the ACR classification criteria (1987 and 2010) was checked. Six commercial RF assays (Zenit, Phadia, Inova, Roche, Abbott, Euroimmun (EI)) and 7 commercial ACPA assays (Zenit, Phadia, BIOFlash Inova (BF), Roche, Abbott, EuroDiagnostica (ED), EI) were tested and diagnostic performance (sensitivity, specificity, receiver operating characteristics (ROC) curve analysis, likelihood ratio (LR)) evaluated.

### Results:

We included 594 patients: 44 (7,4%) RA, 247 (41,6%) RDGC and 225 (37,9%) DCG. For 78 (13,1%) the diagnosis remained undifferentiated. Most of the included RA patients fulfilled the ACR classification criteria (94,3% 1987; 78.56% 2010).

Sensitivities for RF range from 35,7-44,3% and for ACPA from 35,7-41,4% (Table 1), lower than normally described. Demographic patient features, like older patients, could be partly responsible for this low RF/ACPA positivity. The low false positive reactivities in the control patient cohorts are also quite remarkable for RF, as RF is historically known as a more aspecific serological RA marker. Since the control group consists of a primary diagnostic, consecutive rheumatological population, they represent the real life setting in this secondary care hospital, reflecting the true diagnostic usefulness of the RF/ACPA analyses. A negative serological test result will not exclude RA. For RF the importance of a weak positive result (1-3 times cut-off value) depends on the assay used. For ACPA a weak positive result is of diagnostic importance. Strong positive RF or ACPA results can aid in the diagnosis of RA as they have a high LR for RA (>10 for all assays), except for two RF assays (from Inova and Euroimmun).

### Conclusion:

The aid of the serological reactivities in the diagnosis of RA is dependent on the choice of the RF (especially) or ACPA assay used due to the lack of harmonization. Demographic features of the patient population and the possible low serological positive RA pretest probability will also influence the usefulness of these serological tests.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Progranulin (PGRN) and semaphorins (sema) are known to be involved in immune responses as well as bone remodeling process. The aim of this study was to investigate the clinical significance of serum levels of PGRN, sema3A, and sema4D in patients with RA.

**Methods:** Blood samples were collected from 85 RA patients who satisfied 2010 ACR/EULAR classification criteria for RA and 43 age- and gender-matched healthy controls. The serum levels of PGRN and sema3A/4D were determined using ELISA. Additionally, TNF- $\alpha$ , IL-6, IL-23, RANK ligand, osteoprotegerin, and osteopontin were measured using magnetic bead-based multiplex assays. RA disease activity was assessed by DAS28 and structural joint damage was assessed by plain radiographs using the modified Sharp/van der Heijder score (SHS) at baseline and after an average 2-year follow-up period.  $\Delta$  SHS  $\geq$  1 unit/year was defined as having radiographic progression.

**Results:** Serum levels of PGRN were significantly increased in patients with RA, compared with healthy controls (31.0 [24.5-39.1] vs 25.9 [21.1-31.0] ng/mL,  $p=0.001$ ), while those of sema4D did not differ between two groups. Although the serum levels of sema3A were below the detection range in most samples, the serum sema3A level in RA patients was significantly elevated in comparison with the level in the controls (0.44 [0-1.90] vs 0 [0-0.19] ng/mL,  $p<0.001$ ). In RA patients, serum concentrations of sema4D were found to be correlated with those of IL-6 ( $r=0.514$ ,  $p<0.001$ ) and IL-23 ( $r=0.234$ ,  $p=0.031$ ) and PGRN was negatively correlated with osteopontin. Serum sema4D levels showed positive correlations with ESR ( $r=0.336$ ,  $p=0.002$ ), CRP ( $r=0.337$ ,  $p=0.002$ ), DAS28 ( $r=0.240$ ,  $p=0.029$ ) and  $\Delta$  SHS/year ( $r=0.244$ ,  $p=0.025$ ). However, the levels of PGRN and sema3A were not associated with disease activity or joint damage. RA patients with radiographic progression had significantly higher serum sema4D levels than those without progression (127.5 [66.4-230.2] vs 81.9 [52.1-106.9] ng/mL,  $p=0.018$ ).

**Conclusion:** Serum sema4D levels were associated with disease activity as well as radiographic progression in RA patients, although its levels were comparable between RA patients and controls. These findings suggest that sema4D might play a role in RA-related joint damage and is a possible biomarker reflecting inflammatory burden and radiographic progression in patients with RA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In contrast to high evidence of HDL inflammatory function in cardiovascular risk in rheumatoid arthritis (RA) patients, there is scarce data about the total HDL levels as a marker of RA disease activity.

**Methods:** A cross-sectional study in Rheumatology department of Hospital Almenara EsSalud. Lima Perú. Subjects were recruited consecutively from our RA cohort. RA was defined with ACR 87/ACR EULAR 2010 RA criteria, without overlap syndromes except Sjögren, current infections or pregnancy. For these analyses hospitalized patients, with recent medical/surgical procedures or severe anemia (less than 7 g/dL) were excluded. Clinical interview, chart review, physical examination (included 28 joint count), health questionnaires, Visual analogue scales and laboratory sampling including a complete lipid profile were performed in the same day. A univariable and multivariable linear regression models were performed in order to determine if HDL levels were associated with disease activity (DAS 28 or CDAI) independently of disease duration, gender, age at diagnosis, socioeconomic status, use of conventional DMARDs, biologics, current corticosteroid dose, CRP, anti CCP, RF, and metabolic syndrome.

#### **Results:**

Results: Two hundred and seventy-eight patients were included, all Mestizos, 92.8% were female, disease duration was 15.16 (11.92) and age at diagnosis 44.08 (13.92) years. The most frequent socioeconomic statuses were low: 30.9%, middle 33.1% and high 33.8%. Current prednisone dose was 4.50 mg/d (3.30). Patients with current conventional DMARD use were 97.1 % and 6.1 % with biologic agent; RF level was 290.39 (474, 17) UI/ml and anti CCP 544, 98 (132.37) U/ml. Level of HDL was 56.98 (1326, 37) mg/dL and LDL 120.76 (33.00) mg/L. One hundred and three patients (37.1 %) had metabolic syndrome. DAS 28 media score was 4.69 (1.22) and CRP level 11.76 (21.41) mg/dL. In the multivariate analysis HDL cholesterol level was associated with DAS 28 score (B= -0.016; CI: -0.26 - -0.01; p=0.04) independently of other variables. HDL cholesterol level was also independently associated with CDAI score (B -0.14 CI -0.24 - -0.04 p= 0.009)

**Conclusion:** Low HDL cholesterol level was associated with higher disease activity in RA patients, independently of other known classical factors. A more careful evaluation of active disease could be performed in patients with this potential marker, in clinical practice.

#### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It is known that the chemokine molecule CXCL5 (C-X-C motif chemokine 5 or epithelial neutrophil activating peptide 78 -ENA78-) is a link between obesity, inflammation, and insulin resistance (IR) in general population. Similarly, chronic inflammation has been found to deteriorate IR and impair pancreatic beta cell function in rheumatoid arthritis (RA) patients. The aim of this study was to explore the role of CXCL5 in the IR of RA patients.

**Methods:** Cross-sectional study that encompassed 141 non-diabetic patients with RA. IR by homeostatic model assessment (HOMA2), insulin and C-peptide serum levels and lipid profile, and CXCL5 serum levels were assessed in patients. A multivariable regression analysis, adjusted for IR related factors, was performed to evaluate how CXCL5 is related to IR, disease activity and disease characteristics in RA patients.

**Results:** Insulin and C peptide serum levels did strongly correlated between them ( $r^2=0.913$ ,  $p<0.001$ ) but not with CXCL5 (insulin  $r^2=-0.034$ ,  $p=0.69$ ; C peptide  $r^2=-0.050$ ,  $p=0.56$ ). Interestingly, while glucocorticoids were related with insulin (beta coef. 2.56 [95%CI 0.31-5.42],  $p=0.080$ ), C-peptide serum levels (beta coef. 1.69 [95%CI 1.09-2.28],  $p=0.000$ ), and HOMA2-IR (beta coef. 0.34 [95%CI -0.02-0.70],  $p=0.06$ ) and HOMA2-%B-C peptide (beta coef. 51 [95%CI 31-70],  $p=0.000$ ), the use of prednisone was not associated with CXCL5 serum levels (beta coef. -6 [95%CI -74-63],  $p=0.87$ ). C reactive protein (beta coef. 0.2 [95%CI -1.4-1.9],  $p=0.80$ ) and disease activity through DAS28 (beta coef. 13 [95%CI -14-41],  $p=0.34$ ) also disclosed no relation with CXCL5. Other disease characteristics like disease duration, presence of rheumatoid factor or anti-citrullinated protein antibodies, or use of methotrexate or anti-TNF alpha therapies were not related with CXCL5 serum levels. Additionally, CXCL5 did neither explained HOMA2-IR (beta coef. -0.00 [95%CI -0.00-0.00],  $p=0.21$ ) nor beta cell production, using HOMA2-%B-C peptide (beta coef. -0.05 [95%CI -0.12-0.02],  $p=0.17$ ), through multivariable regression analysis.

**Conclusion:** CXCL5 is not related to RA disease characteristics or IR in RA patients. This could imply that the mechanisms that lead to IR of RA patients are different from those from general population.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Rheumatoid arthritis (RA) is associated with significant cardiovascular disease (CVD), sarcopenic obesity, and mortality. Galectin-3 is a biomarker associated with inflammation, fibrosis, and increased risk of CVD and all-cause mortality. We aimed to: 1) explore clinical relationships between RA and galectin-3; and 2) investigate changes in galectin-3 in patients with RA and prediabetes mellitus (PD) before and after a novel high-intensity interval training (HIIT) program.

### Methods:

All RA patients in this study satisfied 1987 ACR criteria. Serum galectin-3 was measured in 47 persons with RA; concentrations were compared among older RA (age>55yrs; n=24), younger RA (<55 y, n=23), and older, age, sex and BMI-matched healthy controls (>55 y, n=12). In a second study, we compared galectin-3 in older RA (age<50; n=12) to older PD (age<50; n=9), before and after 10 weeks of HIIT. Student's t-tests and Wilcoxin signed rank tests were used to compare outcome variables. Correlations were compared using Spearman's rho.

## Results:

As compared to both the younger RA group (7.85±4.0(SD) ng/mL, p=0.390) and older healthy controls (6.89±1.9, p=0.042), the older RA group had higher concentrations of galectin-3 plasma concentrations (8.80±3.5). In the total RA group (n=47), galectin-3 was significantly and positively correlated with age (r=0.39), BMI (r=0.32), prednisone use (r=0.42), plasma IL-6 (r=0.29), and thigh cross-sectional area (r=0.46); it was negatively correlated with thigh muscle density (r=-0.44; p<0.05 for all). In the HIIT study, as compared to the PD group, the RA group was younger (63.9±7.2 vs 71.4±4.9, p<0.05) and thinner (27.4±9.3 vs 29.4±3.0, p<0.05). After HIIT, galectin-3 did not change in either group, but both baseline and post-HIIT galectin-3 were greater in the RA group compared to the PD group (pre: 12.21±6.7 vs 8.73±2.3, p=0.118; post: 11.99±4.2 vs 8.71±2.3, p=0.056). A decrease in galectin-3 was also correlated with an increase in absolute peak VO<sub>2</sub> in the total group (r=-0.47, p=0.03) and in RA (r=-0.57, p=0.05).

## Conclusion:

In RA, greater galectin-3 plasma concentrations associate with traditional cardiovascular risk factors including age and adiposity, as well as with RA-specific risk factors, including prednisone use and IL-6. The importance of RA-specific risks is emphasized by greater galectin-3 in RA even when comparing to an older, heavier, prediabetic cohort. While HIIT did not change mean galectin-3 concentrations, reductions in galectin-3 were associated with cardiorespiratory fitness improvements in RA. These findings suggest that galectin-3 may represent a novel risk factor for CVD in RA, and that CVD risk in RA may be modulated by exercise training.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Sarcopenic obesity and the associated risk of cardiovascular disease (CVD) and mortality in rheumatoid arthritis (RA) may be related to dysregulated skeletal muscle remodeling (Huffman et al. Arthritis Research & Therapy (2017); 19:12). Skeletal muscle remodeling relies on coordinated signaling through cytokines and myokines. We hypothesized that exercise training-induced alterations in muscle cytokines and myokines would reprogram muscle remodeling differently in (RA) versus those with prediabetes (PD). In this study, we investigated relationships between skeletal muscle cytokines and myostatin in patients with RA and PD before and after a high-intensity interval-based training (HIIT) program.

## Methods:

All RA patients in this study satisfied 1987 ACR criteria. Body composition was assessed with Bod Pod<sup>®</sup>. Using *vastus lateralis* biopsies, muscle (m) cytokines, mL-1 $\beta$ , mL-6, mL-8, mTNF- $\alpha$ , mL-10, and myostatin were quantified in RA (n=12) and pre-DM (n=9) before and after a 10-week supervised HIIT program. Continuous variables were compared using Students t-tests and Wilcoxon signed rank tests, dependent on normality. Correlations between muscle cytokines and clinical variables were compared using Spearmans rho.

## Results:

The RA group was younger (age 63.9 vs 71.4 y;  $p < 0.05$ ) and thinner (BMI 27.4 vs 29.4 kg/m<sup>2</sup>;  $p < 0.05$ ) with similar cytokine yet lower muscle myostatin concentrations (Table 1). For both groups after HIIT training, there were no significant responses in cytokines or myostatin concentrations. While overall body composition changes were small in RA, an increase in lean mass correlated with decreases in mL-6, mL-1  $\beta$ , and mTNF- $\alpha$ . A decrease in body fat percentage was correlated with a decrease in mTNF- $\alpha$ .

## Conclusion:

While muscle cytokines in RA were comparable to an older, heavier, prediabetic group, RA myostatin was lower. As a potent negative regulator of skeletal muscle growth and hypertrophy, lower muscle myostatin suggests that in RA, sarcopenic obesity may be related to impaired myostatin signaling. Although 10 weeks of HIIT did not significantly alter mean group cytokine or myostatin concentrations, reductions in RA muscle cytokines were associated with improved body composition (greater lean mass and less body fat percentage). Thus, HIIT may improve coordination of cytokines and myokines critical for skeletal muscle remodeling.

Table 1

Skeletal Muscle Concentrations (pg/mL/ $\mu$ g)	All participants (n=21)		Rheumatoid arthritis (n=12)		Pre-diabetes mellitus (n=9)

## Characteristics of Patients with Rheumatoid Arthritis and Atlanto-Axial Pannus

**Jessica Williams**<sup>1</sup>, Andrew Joyce<sup>2</sup>, Glenn Gaviola<sup>1</sup>, Zacharia Isaac<sup>1,2</sup> and Joerg Ermann<sup>3</sup>, <sup>1</sup>Brigham and Women's Hospital, Harvard Medical School, Boston, MA, <sup>2</sup>Spaulding Rehabilitation Hospital, Harvard Medical School, Boston, MA, <sup>3</sup>Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Formation of pannus, an inflammatory tissue mass, in the atlanto-axial joint of the cervical spine is an important sequela of rheumatoid arthritis (RA). Atlanto-axial pannus may result in spinal cord injury if not recognized in a timely manner. The purpose of this study was to further characterize patients with RA and atlanto-axial pannus in order to more accurately identify these patients in clinical practice.

## **Methods:**

Subjects were identified by free text searching the Partners HealthCare Research Patient Data Registry for the terms ‘atlanto-axial’ and ‘pannus’ in cervical spine magnetic resonance imaging (MRI) reports between January 1, 2001 and December 31, 2015. RA diagnoses were verified by chart review conducted by 2 reviewers. Data were extracted regarding demographics, prior cervical spine surgery, years since RA diagnosis, clinical presentation, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels, presence of rheumatoid factor or anti-cyclic citrullinated peptide (CCP) antibody, and surgery or medication change after MRI demonstrating pannus.

## **Results:**

Seventy-four patients were identified with pannus in the atlanto-axial joint, and 27 of these patients had a confirmed diagnosis of RA, including 5 with juvenile rheumatoid arthritis (JRA). At the time of MRI, the mean age of patients with pannus and RA was 58 years. The median number of years since RA diagnosis was 21 years (range 5-69 years). Most patients were female (85%) and white (78%). Fifteen percent of patients had undergone cervical spine surgery prior to the identification of atlanto-axial pannus. The most common specialty to provide referral for cervical spine MRI was rheumatology (59%). The vast majority of patients reported neck pain (85%), and only 11% reported associated traumatic injury. Only 41% had an abnormal neurologic exam, most commonly an abnormal sensory exam (15%). Eighty-one percent of patients had ESR or CRP checked within 3 months of MRI (mean ESR  $39 \pm 33$  millimeters per hour, median CRP 6.4 milligrams per liter (interquartile range 13.0)). Sixty-seven percent of patients were seropositive, and 67% had been treated with biologic therapy prior to MRI. Only 15% of patients underwent cervical spine surgery after MRI, but all of these patients reported improvement in their symptoms post-operatively. The majority of patients had no change in their RA medications after MRI demonstrating pannus (81%).

## **Conclusion:**

The majority of patients with atlanto-axial pannus had long-standing RA, but pannus was also reported as soon as 5 years after RA diagnosis. A traumatic neck pain in a patient with RA should prompt consideration of atlanto-axial pannus, and clinicians should not be dissuaded by a normal neurologic exam. Interestingly, the proportion of patients with seronegative RA and pannus formation in our study was similar to the frequency of seronegative disease in the general RA population. Most of the patients in our study were diagnosed in the pre-biologics era. It needs to be shown whether treatment of RA with biologics will result in a lower incidence of atlanto-axial pannus in the future.

# IMPACT of Smoking in the Expression of Periodontitis and Anticitrullinated Protein Antibodies in Rheumatoid Arthritis

**Jerián González Febles**<sup>1</sup>, Jorge Luis Garnier Rodríguez<sup>2</sup>, Fernando Sánchez-Alonso<sup>3</sup>, Sagrario Bustabad<sup>4</sup>, Federico Díaz-González<sup>5</sup>, Mariano Sanz Alonso<sup>1</sup> and Beatriz Rodríguez Lozano<sup>6</sup>, <sup>1</sup>Periodontology, Universidad Complutense de Madrid, Madrid, Spain, <sup>2</sup>Odontology, Dental Clinic Garnier, S/C Tenerife, Spain, <sup>3</sup>Unidad de Investigación, Spanish Society of Rheumatology, Madrid, Spain, <sup>4</sup>Rheumatology, Servicio de Reumatología. Hospital Universitario de Canarias, La Laguna, Tenerife, Spain, <sup>5</sup>Servicio de Reumatología. Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, <sup>6</sup>Rheumatology, Hospital de Canarias, S/C Tenerife, Spain

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Environmental, genetic and epigenetic factors can induce citrullination of structural peptides by the enzyme PAD, which induce anti-citrullinated protein antibodies (ACPA) preceding RA. Among the environmental factors are cigarette smoke, infections, such as *P. gingivalis* and *A. actinomycetemcomitans* in periodontitis (PD) and *Prevotella copri* of intestinal microflora, and silica dust. Given the implication of these two exogenous factors, tobacco and PD in citrullination, and tobacco enhancer factor in PD, we studied: 1. The risk of smoking for developing advanced PD in patients with RA. 2. Possible influence of smoking on the expression of severe PD and ACPA in RA patients.

**Methods:** Observational, cross-sectional study in RA patients older than 18yo (ACR/EULAR 2010), with  $\geq 4$  teeth, without tooth cleaning nor antibiotic intake 6 months previously. Socio-demographic and anthropometric variables included smoking status, social indicators such as Graffar scale, stress level, and co-morbidities such as diabetes mellitus, dyslipidemia, ischemic cardiovascular disease. Serum ACPA detection: semiquantification Ab IgG against citrullinated peptides (ELISA) with Immunoscan CCPlus® test kit. Euro Diagnostica: positive  $>25$  U/mL; ACPA title stratification: Low (25–75), moderate (76–300) and high ( $>300$ ). Periodontal parameters: plaque index (PI), Bleeding on probing (Bop), probing pocket depth, recession, clinical attachment level (CAL). CAL loss was categorized according to European Workshop 2005 (Tonetti): T level 0 (absence), TL1 (mild), TL2 (severe). Statistical analysis: t-student, Kruskal Wallis, Chi-cuadrado by Stata program 13.1.

**Results:** We studied 187 patients, F/M 78.6%/21.4%, mean age 54.4 yo Follow-up time 8.8 yo Rheumatoid Factor positive 74.2%, ACPA positive in 114/168 patients (67.86%). Smoking habit: Current smoker (19.25%), former smoker (24.6%); low socioeconomic status (36.4%)/ relative poverty (33.7%). PD was observed in 97.3%: TL1 52.4%, TL2 44.9%. A “risk gradient” was observed for PD related to smoking habit: former smoker OR 1.62 (95% CI 0.81–3.27),  $p=0.174$ ; smokers, OR 2.27 (95% CI 1.05–4.91),  $p=0.037$ . When analyzing the influence of smoking on PD development according to ACPA profile, a gradient effect of developing severe PD was observed from former smokers OR 2.37 (IC95% 0.52–7.64) to current smokers OR 6.99 (IC95% 1.53–32.07) ( $p=0.029$ ) in ACPA(-) patients. This relationship was not observed in ACPA (+) patients ( $p=0.383$ ).

**Conclusion:** 1. There is a “risk gradient” to develop PD in RA in relation to past or current exposure to tobacco, so that, although not significant, former smokers are at greater risk than non-smokers, and current smokers have a significant risk 2.3 times higher. 2. This risk gradient is shown in ACPA (-) patients, but not in ACPA (+) patients, which suggests an independent relationship between PD and ACPA (+) RA.

## Physician Global Assessments for Disease Activity in Rheumatoid Arthritis Are All over the Map!

**Matthew Turk**<sup>1</sup> and Janet E. Pope<sup>2</sup>, <sup>1</sup>Biochemistry, Schulich School of Medicine & Dentistry, University of Western Ontario, London, ON, Canada, <sup>2</sup>Department of Medicine, Division of Rheumatology, University of Western Ontario, St Joseph's Health Care, London, ON, Canada

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Assessments of disease activity in rheumatoid arthritis (RA) determine the course of treatment. Physician global assessments of disease activity (MD globals) are important outcomes in trials as they are part of the CDAI (Clinical Disease Activity Index) and SDAI (Simple Disease Activity Index) composite scores. MD globals may vary between physicians based on their age, sex, practice setting, experience (number of patients seen per year), and years in practice. Our research goal was to determine which factors contribute to the variability of MD globals. We expected assessments to be lower as physician experience increased (i.e. once you have been in practice a long time, you have seen the worst, so this would reset the global assessments for less active patients to a lower value relative to less experienced rheumatologists).

**Methods:** After obtaining ethics approval, we surveyed rheumatologists who were members of the Canadian Rheumatology Association with RA patient scenarios where each was rated as a MD global for disease activity from 0 – 10. The cases covered a range of disease activity; to determine extreme cases and cases in between. There were some scenarios where a change in status was given (i.e. a rating with one disease state and then the patient returned and another rating was given by each participant when the patient was obviously better or worse). Means, t tests, and correlations were used to analyze the responses.

**Results:** We received 145 responses from eligible physicians spanning the above categories (approximately 40% response rate). Contrary to our original hypothesis, MD global assessments were not significantly different between physicians in any category (number of RA patients seen per year, years of experience, age, sex, type of practice [community vs. university], and self-reported expertise in RA). Moreover, the range of answers for the same scenario was as high as 7.6 out of a possible 10, indicating vast discrepancies between physicians. We checked to ensure the questions were not answered backwards by individuals using the scenarios where a patient changed disease activity over time. The agreement was highest in the extreme scenarios (very low and very high disease activity, but in the spectrum in between agreement was extremely poor). Some scenarios outlined changes in individual patients, however physicians surveyed were often in disagreement as to how well the patient recovered or worsened. The change in MD globals between one time and the next in the cases had better agreement than the actual scores (i.e. most agreed that a patient had worsened or improved).

**Conclusion:** This research emphasizes the need to establish stringent evaluation criteria of disease activity as rated by the physician in RA; particularly if remission and low disease activity is used clinically by CDAI or SDAI. Perhaps a catalogue examples of patient scenarios of MD globals that range from 0 to 10 should be developed, standardized and agreed upon; to decrease the wide variability of ranking by rheumatologists.

## Decisional Conflict in Doctor – Patient Discussions about Disease Modifying Anti-Rheumatic Drugs

**Rohit Nallani**<sup>1</sup> and Richard W Martin<sup>2</sup>, <sup>1</sup>Michigan State University, College of Human Medicine, Grand Rapids, MI, <sup>2</sup>Medicine, Rheumatology, Michigan State University, College of Human Medicine, Grand Rapids, MI

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are few published studies describing patient-physician discussions about initiating new rheumatoid arthritis (RA) medications in real world settings. The purpose of this study is to describe the incidence of these discussions, levels of decisional conflict and its correlation with primary adherence.

**Methods:** We conducted a prospective observational study of consecutive RA patients attending a routine rheumatology clinic visits. Immediately after the visit, we identified all patients whom had a discussion about starting a new medication. We conducted immediate written and 30-day post-visit telephone surveys. This assessed patient preference, actions and decisional conflict about starting the proposed medication.

**Results:** Of 580 RA patients seen during the observation period, 104 (17.9%) patients confirmed discussing a new medication. 91 (87.5%) completed the follow up survey. Demographics: mean age = 55.4 years, 79.8% female, 7.7% minority, 3.8% with inadequate health literacy RA duration 7.5 years, and mean CDAI 20 (range 0-50). 65.4 % of discussions involved adding or changing disease modifying drug therapy (DMARD). Mean post-visit Decisional Conflict Scale score (DCS)<sup>1</sup> was 18.3 (SD: 18.8), with 11.8% demonstrating high<sup>2</sup> DCS. Mean 30 day DCS was 16.1 (SD: 18.4). There was no difference between immediate post-visit and 30 day DCS (p=.47). While 97.1% of patients intended to start the discussed medication, primary adherence was 68.3% at 30 days. Most patients identified “Too Risky” as the reason for primary non-adherence. There was no significance difference in decisional conflict between patients considering DMARD vs. non-DMARD therapy.

**Conclusion:** Discussions to start or change medications occurred daily in community rheumatology practice. Despite short times of deliberation after visits, patients reported high levels of feeling informed about benefits and harms and had relatively low levels of decisional conflict. This raises questions about the depth and quality of patient deliberation following physician - patient discussions about initiating new DMARD therapy.

## Tenosynovitis in the Forefoot at Disease Presentation Is Specific for RA: Results from a Cross-Sectional MRI Study in Early Arthritis

**Yousra J. Dakkak**<sup>1</sup>, Debbie M. Boeters<sup>2</sup>, Annette H.M. van der Helm-van Mil<sup>2</sup> and M. Reijnders<sup>3</sup>, <sup>1</sup>Rheumatology, Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>3</sup>Department of Radiology, Leiden University Medical Center, Leiden, Netherlands

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

The foot is a preferential location for rheumatoid arthritis (RA)-manifestation, but physical examination of the metatarsophalangeal (MTP) joints is difficult. Magnetic Resonance Imaging (MRI) is sensitive in depicting inflammation at an early stage; it detects synovitis, bone marrow edema (BME) and tenosynovitis. MRI detected inflammation in the MTP joints has not been studied thoroughly in an early arthritis setting, but may increase our understanding of forefoot inflammation. This cross-sectional MRI study thoroughly examined the forefoot to identify inflammatory findings that are specific for RA compared to other arthritides.

#### **Methods:**

218 patients presenting with early arthritis (93 RA, 125 other arthritides) underwent contrast-enhanced 1.5T MRI of unilateral MTP 1-5-joints. BME, synovitis and tenosynovitis were scored by two readers according to OMERACT rheumatoid arthritis MRI scoring system (RAMRIS), and Haavardsholm et al. Comparisons between RA and other arthritides were made at joint level.

#### **Results:**

1090 MTP-joints were studied. RA-patients more often had MRI-detected inflammation in any of the MTP-joints than other arthritides (74 vs 61%,  $p=0.038$ ). Tenosynovitis was associated with RA; the association was strongest for MTP 5 (OR 12.8, 95% CI 2.9-57.1), followed by MTP 1 (OR 3.1, 95% CI 1.3-7.3). Inflammation in RA was present at both the flexor and extensor tendons. The specificity of tenosynovitis was high, ranging between 89-98% at the different MTPs. The sensitivity for RA ranged 16-19%.

In addition, BME in MTP 3-5 was associated with RA, as well as synovitis in MTP 3-5. Of these joints, MTP 5 showed the strongest associations (BME: OR 5.2, 95% CI 2.1-12.9, synovitis: OR 6.0, 95% CI 2.8-13.1).

#### **Conclusion:**

MRI detected inflammation including BME, synovitis and tenosynovitis was increased at the level of MTP 5 joints of RA patients, this is in line with MTP 5 being a preferential location for erosion development. Previous studies have shown that tenosynovitis in wrist and MCP joints is associated with RA; the present study is the first demonstrating in an early arthritis setting that tenosynovitis in MTP joints is also specific for RA.

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

#### **Background/Purpose:**

Microwave Radiometry (MR) is an easy-to-perform, rapid, non-invasive, objective method, able to measure in-depth tissue temperature. In a proof-of-concept study using joint ultrasound as reference method, we showed that an increased in-depth knee joint temperature detected by MR in the absence of relevant clinical signs reflects the presence of subclinical synovial inflammation in rheumatoid arthritis (RA) (1).

We aimed to test the hypothesis that a ‘thermo-score’ constructed as the sum of MR-derived temperatures of small and large joints reflects global disease activity levels in RA.

## Methods:

Consecutive RA patients (N=61) underwent clinical, laboratory and MR (RTM 01 RES microwave computer based system, Bolton, UK) assessments, as well as joint ultrasound. Unselected patients with active disease (N=19) were re-examined 2 months after treatment initiation. Age- and sex-matched healthy individuals (N=23) and patients with osteoarthritis (N=23) served as controls. We created a ‘thermo-score’ by summing the relative temperatures (Dt) of 7 small joints (wrist, 2<sup>nd</sup>-3<sup>rd</sup> metacarpophalangeal, 2<sup>nd</sup>-3<sup>rd</sup> proximal interphalangeal, 2<sup>nd</sup> and 5<sup>th</sup> metatarsophalangeal) of the clinically dominant hand and foot, based on the German US7 ultrasound score (2), as well as of 3 large joints (elbow, knee, lower leg) of the clinically dominant arm and leg. The relative temperature (Dt) was calculated as the difference between the reference and a control point for each joint, thus, resulting in lower Dt values in inflamed versus healthy joints. Among healthy individuals examined 2 months apart ‘thermo-score’ values were repeatable (ICC=0.714).

## Results:

The baseline ‘thermo-score’ could discriminate RA patients in high [mean (SD)=7.36 (1.68)], moderate [mean (SD)=9.71 (1.70)], low disease activity [mean (SD)=10.74 (1.37)] and remission [mean (SD)=11.63 (1.71)] ( $p<0.001$  by Kruskal-Wallis test). Healthy subjects [mean (SD)=11.84 (2.42)] and patients with osteoarthritis [mean (SD)=10.99 (3.05)] had comparable values with RA patients in remission and low activity, respectively. Among RA patients, the ‘thermo-score’ correlated inversely to the DAS28 disease activity score ( $p<0.001$ ), tender joint count ( $p<0.001$ ), swollen joint count ( $p=0.028$ ), patient’s visual analogue scale ( $p<0.001$ ), CRP ( $p=0.014$ ), ESR ( $p=0.013$ ), as well as the standard Ultrasound Scores of 7 joints (2) (all  $p<0.05$ ). Notably, individual ‘thermo-score’ changes from baseline to follow-up mirrored the corresponding DAS28 changes in 15/19 patients.

## Conclusion:

In-depth temperatures of small and large joints detected by MR allow the construction of a ‘thermo-score’ that reflects the global disease activity levels in RA and may serve as an additional biomarker. Optimization of MR equipment and technique may result in an objective measurement of RA disease activity in clinical practice.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fatigue is a common complaint in patients with rheumatoid arthritis (RA)<sup>1</sup>. However, its impact on disease activity and clinical remission in patients with RA has not been explored thoroughly in daily clinical practice<sup>2</sup>. The aim of this study was to investigate how fatigue is related to disease activity and clinical remission in patients with RA.

**Methods:** Among Japanese patients with RA in the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort study in April 2015, fatigue was measured based on the checklist of individual strength (CIS) 8R (normal, CIS 8R≤26; heightened fatigue, 27≤CIS 8R≤34; severe fatigue, CIS 8R≥35). We performed a cross-sectional investigation of the association between fatigue severity and the 28-joint disease activity score (DAS28) and its components (swollen joint counts, tender joint counts, erythrocyte sedimentation rate and patient global assessment [PtGA]) with an ordered logistic regression analysis. We also analyzed the contribution of patient demographic and clinical factors to fatigue severity among the variables with significance in an ordered logistic regression analysis by analysis of variance (ANOVA).

**Results:** Among 5,679 RA patients (mean age, 61.4 years; female, 85.8%; mean DAS28 score, 2.62; mean CIS 8R, 28.3), fatigue severity was normal in 2,152 patients (37.9%, [mean age, 61.0 years; female, 82.0%]), heightened in 1,489 patients (26.2%, [mean age, 61.0 years; female, 86.7%]) and severe in 1,383 patients (24.4%, [mean age, 57.5 years; female, 90.4%]). The proportion of corticosteroid use (normal fatigue, 22.0%; heightened fatigue, 30.3%; and severe fatigue, 40.3%) and non-steroidal anti-inflammatory drug [NSAID] use (normal fatigue, 38.8%; heightened fatigue, 52.0%; and severe fatigue, 62.7%) was significantly higher with fatigue severity ( $P = 0.0010$  and  $0.0327$ , respectively). The DAS28 score was significantly associated with fatigue severity (mean DAS28 score: normal fatigue, 2.30; heightened fatigue, 2.63; and severe fatigue, 2.98;  $P = 0.0443$ ). The DAS28 remission rate significantly decreased with fatigue severity (normal, 65.5%; heightened, 51.5%; and severe, 40.0%;  $P < 0.0001$ ). Of the four components of the DAS28 score, only PtGA had a significant association with fatigue severity (mean PtGA [mm]: normal fatigue, 11.7; heightened fatigue, 24.7; and severe fatigue, 40.2;  $P < 0.0001$ ). Among the six variables with significance in an ordered logistic regression analysis (gender, PtGA, pain, the Japanese version of the Health Assessment Questionnaire [J-HAQ] score, corticosteroid use and NSAID use), PtGA had the strongest contribution to fatigue severity (81.0%), followed by the J-HAQ score (9.4%), gender (3.2%) and NSAID use (3.1%).

**Conclusion:** Fatigue was strongly associated with PtGA and affected the evaluation of disease activity and clinical remission in patients with RA, suggesting that evaluating fatigue may be important for controlling disease activity in patients with RA in daily practice.

## Serum Progranulin Antibodies (PGRN-abs) in Rheumatoid Arthritis Patients Being Negative for RF-IgM and ACCP-IgG

Gunter Assmann<sup>1</sup>, Silke Zinke<sup>2</sup>, Moritz Gerling<sup>3</sup>, Natalie Fadle<sup>3</sup>, Klaus Dieter Preuss<sup>3</sup>, Michael Pfreundschuh<sup>3</sup> and Lorenz Thurner<sup>3</sup>, <sup>1</sup>Medicine I, University Medical School of Saarland, 66424, Germany, <sup>2</sup>Rheumaprxaxis, Rheumatology Center Berlin - Lichtenberg, Berlin, Germany, <sup>3</sup>Medicine I, Jose Carreras Center, University of Saarland, Homburg, Germany

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Until recently, most research on progranulin (PGRN) had been focused on its role in neurodegenerative diseases as frontotemporal dementia. After the detection of elevated PGRN serum levels in patients with autoimmune arthritis we discovered antibodies against PGRN in a protein array-based screening of serum from various different rheumatic diseases. Furthermore, serum PGRN antibodies (PGRN-abs) have been proved to have neutralizing effect on PGRN serum levels; in addition, serum PGRN presented preferentially in a phosphorylated stage in PGRN-abs positive patients. Here we conducted the study to evaluate the prevalence of PGRN-abs in sera of rheumatoid arthritis patients being seronegative according to RF and ACCP.

**Methods:** PGRN-abs were determined in sera of 257 RA patients with positivity for RF-IgM and/or ACCP-IgG and in sera of 224 seronegative RA patients, which were prospectively included in the study from 2013-2015. Healthy serum donors n=97 served as control cohort. All RA patients have fulfilled the revised ACR/EULAR classification criteria for RA from 2011. The ELISA detecting PGRN-abs as well as the phosphorylated stage of PGRN were applied as previously described. Subgroup analyses has stratified the RA cohort into diseases duration (less or more than 2 years) as well as gender, age of diagnoses, erosive course of diseases and the occurrence of tumor necrosis factor inhibitor failure (TNFi-failure). The statistics were performed with Mann-Whitney-U test evaluating the differences between seronegative, seropositive RA, and healthy controls; using the chi2 test differences between different RA subgroups were investigated. p-value of < 0.05 were considered significant.

**Results:** PGRN-abs were detected in 24.5% of seropositive RA and in 22.3% of RF/ACCP negative RA (OR 1.43, CI 0.93-2.21, p=0.106), Figure 1. In healthy controls (n=97) one serum was positive for PGRN-abs. Phosphorylated stage of PGRN were tested positive in sera of 33 of 36 PGRN-abs positive RA patients and negative in all 158 RA without PGRN-abs. Patients (n=107 out of 481) could be retrospectively stratified into early RA defined by diseases duration less than 2 years; early RA patients showed in 18.7% PGRN-abs compared to not-early RA patients (n=201; data missing) with 22.7% (OR 0.82; CI 0.52-1.30, p=0.397). Erosive disease as well as TNFi failure patients were significantly more frequently PGRN-abs positive (28.4%, 29.9%, respectively).

**Conclusion:** Here we present the first study evaluating the PGRN-abs in sera of patients with seropositive and seronegative RA. Testing PGRN-abs in sera of RA patients seems to reduce the fraction of seronegative status in RA patients by more than 20%. In what way PGRN-abs can be used as diagnostic biomarker has to be further demonstrated in larger cohort of RA patients.

## Agreement between the DAS28-ESR and the DAS28-CRP and Factors Related to the Discrepancies between Disease Activity Levels According to These 2 Scores in Patients with Early Rheumatoid Arthritis

Cécile Gaujoux-Viala<sup>1</sup>, Mohamed Belkacemi<sup>2</sup>, Alain Cantagrel<sup>3</sup>, Bruno Fautrel<sup>4</sup> and Bernard Combe<sup>5</sup>, <sup>1</sup>Rheumatology, Nîmes University Hospital and EA2415 Montpellier University, Nîmes, France, <sup>2</sup>EA2415 Montpellier University, Montpellier, France, <sup>3</sup>Rheumatology, Toulouse University Hospital and Toulouse University, Toulouse, France, <sup>4</sup>UPMC University Paris 06, Pitié-Salpêtrière Hospital, Paris, France, <sup>5</sup>Rheumatology, CHU Lapeyronie and Montpellier University, Montpellier, France

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** DAS28 is often used as a treatment decision tool in patients with rheumatoid arthritis (RA) in the daily clinic. Although different versions of DAS28 have previously been validated, and although disease activity thresholds are the same, it is not clear whether DAS28-ESR and DAS28-CRP can be used interchangeably in individual patients.

**Objectives:** The aims of our study were to examine the agreement between these two DAS28 versions in individual early RA patients in the daily clinic and to identify factors related to the discrepancies between disease activity levels according to these 2 scores.

**Methods:** Baseline and 6 months data from 677 patients with early RA (ACR EULAR 2010) were extracted from the French cohort of early arthritis ESPOIR (at least 2 swollen joints for less than 6 months, DMARD naïve) and were used to calculate DAS28-ESR and DAS28-CRP. Disease activity levels according to the DAS thresholds and EULAR responses were assessed.

Intraclass correlation coefficient [ICC] and weighted kappa (k) were calculated. The Bland-Altman method was used to examine the bias between the DAS scores and the 95% limits of agreement (LoA).

Multivariate logistic regression was used to determine the patient and RA features independently associated with discrepancies between disease activity levels according to DAS28-ESR and DAS28-CRP.

**Results:** The mean value of DAS28-CRP ( $5.04 \pm 1.16$  at M0 and  $3.38 \pm 1.33$  at M6) was smaller than that of mean DAS28-ESR ( $5.33 \pm 1.24$  at M0 and  $3.51 \pm 1.42$  at M6).

Agreement between the scores was excellent: ICC=0.93 at M0 and M6. Agreement between disease activity levels according to the 2 scores was good: k=0.70 at M0 and 0.75 at M6. Agreement between EULAR responses at M6 according to the 2 scores was good: k=0.78. At M0, the bias of DAS28-CRP was -0.28 (LoA -1.16, 0.59) and -0.14 (LoA -1.17, 0.89) at M6.

There were discrepancies between disease activity levels according to the 2 scores in 122 (18.6%) patients at M0 with clear difference in moderate (88 patients for DAS28-CRP vs 29 for DAS28-ESR) and high disease activity (18 patients for DAS28-CRP vs 80 for DAS28-ESR), and in 171 (28.1%) patients at M6 with clear difference in remission (42 patients for DAS28-CRP vs 29 for DAS28-ESR) and high disease activity (9 patients for DAS28-CRP vs 32 for DAS28-ESR).

At M0, presence of erosion (OR 95%CI=1.76 [1.07-2.90]), better mental component of the SF36 (OR 95%CI=2.14 [1.38-3.31]), fewer tender joint counts (TJC) and better physical component of the SF36 (PCS) (with significant interaction between TJC and PCS) were associated with discrepancies between disease activity levels according to the 2 scores. At M6, only being male (OR 95%CI=1.62 [1.09-2.41]) was associated with discrepancies.

**Conclusion:** DAS28-CRP significantly underestimated disease activity compared to DAS28-ESR. Agreement was high between the 2 scores, good for disease activity levels and EULAR responses. In the individual patient, however, the two scores may differ considerably. The scores should not be used interchangeably in the daily clinic without caution.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid Arthritis (RA) disease activity outcomes are used for treatment decisions (ie. DAS28-ESR). Surgically operated joints (SOJ) are assumed not to respond to therapy and are often not included in standard trials. This analysis examines whether a therapeutic benefit is conferred to SOJ over six months, as measured by grey-scale synovial hypertrophy (GSUS) and power Doppler (PDUS) synovitis scores.

**Methods:** 20 RA patients with SOJ enrolled in an open-label 24-week tocilizumab study. Participants' joints were identified as SOJ (replaced, fusion, arthroscopy, tendon) or as a non-operated joint (NOJ). Joint assessments occurred at baseline, 1-mos, 3-mos, and 6-mos for: tender joint (0/1), swollen joint (0/1), GSUS (0-3), and PDUS (0-3). GSUS and PDUS images were captured for 32 joints including bilateral MCPs, PIPs, wrist, medial/lateral parapatellar knee recesses, and MTP 2-5. Maximum GSUS and PDUS scores across the views for each joint were calculated. Mean GSUS and PDUS scores from SOJ were compared to NOJ over time by mixed effects linear models analysis. GSUS and PDUS compared baseline to 6months using mixed effects models, while TJ and SJ used McNemar test.

**Results:** A significant difference between NOJ and SOJ over 6mos was seen for GSUS and PDUS (both  $p < 0.0001$ ) (Figure 1). There was a significant improvement in TJ for NOJ ( $p = 0.02$ ), however no difference seen in SOJ for SJ or TJ (Table 1). Of 37 SOJ joints assessed by ultrasound, 78% of joints had PDUS > 1 and 86% of joints had GSUS > 1 at baseline, while NOJ had 43% and 64% respectively. There was a significant GSUS response seen for the overall set of SOJ from baseline to 6-months ( $p = 0.03$ ), and a trend for PDUS ( $p = 0.07$ ).

**Conclusion:** RA activity measures such as DAS28-ESR require strict parameters to provide patient prognosis and treatment efficacy. Traditional trials exclude operated joints from measurement and analysis. This study suggests that SOJ joints exhibit significant synovitis. Response to tocilizumab over six months, by GSUS. Further research is needed to validate these findings, and this study suggests that ultrasound RA clinical studies should assess response in both SOJ and NOJ.

**Table 1: Therapeutic response over Six Months in NOJ and SOJ**

Non-Operated Joints (NOJ)					
	Baseline		Month 6		p-value
	N	% / Mean (SD)	N	% / Mean (SD)	
Tender Joint (Y)	944	41.8%	799	33.5%	0.02
Swollen Joint (Y)		32.6%		17.1%	0.17
PDUS (0-3)	413	0.83 (1.10)	357	0.59 (0.98)	0.002
GSUS (0-3)		1.23 (1.11)		1.06 (1.03)	0.02
Surgically Operated Joints (SOJ)					
	Baseline		Month 6		p-value
	N	% / Mean (SD)	N	% / Mean (SD)	
Tender Joint (Y)	59	20.3%	53	18.9%	0.99
Swollen Joint (Y)		27.1%		11.3%	0.20
PDUS (0-3)	37	2.12 (0.98)	33	1.60 (1.22)	0.07
GSUS (0-3)		2.24 (0.82)		1.70 (1.06)	0.03

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Currently there are several outcome metrics used for the assessment and quantification of musculoskeletal (MSK) ultrasound inflammatory burden in rheumatoid arthritis (RA). This study compares the effect sizes of MSK ultrasound metrics in RA. Effect size is an important factor that judges the robustness of response in a standardized fashion and impacts power and sample size calculations in clinical trials.

## Methods:

This study was an open-label 24 week trial of 54 RA patients starting tocilizumab IV recruited from two rheumatology clinic sites. Inclusion criteria required DAS28-ESR > 4.4 and power Doppler (PDUS) > 10. At baseline patients started 4mg/kg dosing and were dose escalated to 8mg/kg at 12 weeks if the DAS28-ESR > 3.2. Joints examined by ultrasound included bilateral MCPs, PIPs, wrist midline/radioulnar, medial/lateral parapatellar knee recesses, and MTP 2-5. Joint images of PDUS and grey-scale synovial hypertrophy (GSUS) were assessed based on a semiquantitative scale (0-3). Ultrasound measure means were calculated: maximum PDUS by joint, PDUS by view, German US7 PDUS (wrist, MCP/PIP 2/3, MTP2/5), modified Global OMERACT-EULAR Synovitis Score (GLOESS) 22 (all except shoulder, elbow, ankle, hindfoot), modified GLOESS 9 (excludes elbow, shoulder), GLOESS 4 (MCP2-5), PDUS dichotomous (0 vs 1,2,3), PDUS dichotomous (0,1 vs 2,3), GSUS US7, GSUS max joint, and GSUS by view. Cohen's *d* effect sizes were computed as the mean change in the measure from baseline to 4, 12, and 24 weeks of the study divided by the standard deviation of the changes.

**Results:** 54 RA patients enrolled in the trial and 44 patients completed the study. Of all the MSK ultrasound measures calculated, the PDUS dichotomous 0 vs 1,2,3 had the largest effect size of 0.92 at 24 weeks and the GLOESS 4 demonstrated the smallest effect size at 0.55 (Figure 1). The US7 PDUS measure also performed well with the second best effect size of 0.85 at 24 weeks.

**Conclusion:** Effect sizes are important in clinical trials to judge if the response was robust and meaningful. It has important implications for calculating the power and sample size in randomized clinical trials. For MSK ultrasound outcome measures, the PDUS dichotomous measure of 0 vs 1,2,3 had a large effect size and GLOESS measures had moderate effects sizes. Based on this study, a simple PDUS dichotomous measure of 34 joints will decrease the sample size by approximately 60% compared to utilizing the GLOESS 4.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Outcomes in ERA are largely thought to reflect individual prognostic factors and treatment strategy employed. We hypothesize that an additional factor may be the provider, who could influence outcomes through their educational and practice experience, approach to patient interactions, and practice resources. We have undertaken an analysis of remission outcomes across 11 ERA clinics, demonstrating significant variation in rates of remission. In this analysis, we incorporate patient characteristics, treatment strategy and investigator effect in understanding this variation.

**Methods:** Data were analyzed for ERA patients with >1 year of follow-up, enrolled at sites with >40 patients at baseline and >30 patients with 2 years of follow-up data. Multiple linear regression was applied to predict DAS28 remission at 12 months, with all continuous variables centered at the mean prior to entry in the models. Covariates in the model were patient characteristics (age, sex, symptom duration at initiation of treatment, education, comorbidities, smoking status, seropositive status and baseline DAS28 and HAQ scores); treatment strategy (oral methotrexate monotherapy, subcutaneous methotrexate monotherapy, methotrexate-based combinations, triple therapy, biologic therapy and steroid); and investigative site characteristics (volume of recruitment; academic or community practice; solo vs group; allied health resources available; teaching site; and the proportion of investigators at that site by sex, age cohort, location of training, training years and practice type (rheumatology alone or also providing internal medicine services)).

### Results:

1,633 participants with mean age 54 years, 73% female, and mean DAS28 4.9 (SD 1.4) were included. At 12 months, 49% of patients across all sites had achieved DAS28 remission (site range 22%-80%) and the frequency of sustained DAS28 remission over all follow-ups was 52% (site range 29-71%). There were significant differences between centers in the means of patient characteristics and frequency of use of treatment strategies (oral methotrexate monotherapy 8%, subcutaneous methotrexate monotherapy 6%, methotrexate-based combination therapy 36%, triple therapy 11%, and biologics 14%). 27% of sites were community-based practices, 45% systematically incorporated allied health professionals in the care plan, 82% were a teaching site, 64% were group recruitment sites with a mean of 5 investigators per site, and 62% of the investigators were female. In the model, investigator age, location of training, training year and practice type were excluded due to collinearity with the other characteristics. Patient characteristics of age, sex, comorbidities, smoking status, seropositive status, baseline DAS28 scores were significant factors in remission (all  $p < 0.04$ ). The specific treatment strategy had no significant effect, except for use of oral steroids. The presence of learners had a negative impact on remission (coefficient -0.50, 95%CI -0.76 to -0.24).

**Conclusion:** Patient prognostic factors contribute greatly to the variation in remission outcomes, with treatment strategy and investigator/investigative site factors having lesser contributory roles.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** RA is estimated to affect approximately 1.3 million adults in the US and accounts for a significant proportion of US health care spend with direct medical costs of over \$70 billion a year. The primary driver of cost in RA are the specialty drug classes. Given the cost differential between available RA treatments, it is critical to ensure that patients are receiving optimal therapy at the optimal time. We compared improvements in disease activity between biologic DMARD classes, in a large cohort of patients with RA, under conditions of routine clinical practice.

**Methods:** The OM1 platform collects, links, and leverages, structured and unstructured data from electronic medical records (EMR) and other sources in an ongoing and continuously updating manner. The OM1 RA Cohort includes data on >75,000 patients treated by rheumatologists. Disease activity measures (measured and identified using advanced natural language processing) were available in 59,326 patients and established American College of Rheumatology cutpoints were used to define disease severity. There were an average of 9.1 (imputed + observed) disease activity measures per patient. The analysis included patients who were treated with the same biologic disease modifying anti-rheumatic drug (bDMARD) for a 6-month period and had disease activity measures at baseline and at 6 months.

**Results:** The mean±SD age was 60±14 years, 76% of the cohort was female, and 71% Caucasian.

At baseline, 23% of patients were in remission, and 36%, 24% and 17% had low, moderate and high disease activity, respectively. Total and swollen joint counts were available in ~40% of the cohort and erythrocyte sedimentation rate was available in 70%. During the study period, 44% of the cohort received nonbiologic DMARD and 45% bDMARD; tumor necrosis factor inhibitor (TNF-inhibitor) accounted for 77% of bDMARD. The figure presents proportion of patients treated with bDMARD (categorized as TNF-inhibitor, n=9,574, 18% [95% CI: 17%-18%], and other bDMARD, n=5,877, 14% [13%-15%] for naive and non-naive patients combined), with moderate to severe disease at baseline, who achieved low or remission status within the subsequent 6 months. Analysis was stratified by whether they had documented prior treatment with biologics.

## Conclusion:

Using a data driven platform that enables large scale assessment (patient characteristics, treatment patterns, clinical outcomes) of patients, we found that naive patients treated with TNF-inhibitors showed the most improvement in disease activity overall. Among non-naive patients the TNF-inhibitor group had the highest proportion of patients achieving remission or low disease activity over a 6-month treatment period.

Safford<sup>1</sup> and Jeffrey R. Curtis<sup>2</sup>, <sup>1</sup>Weill Cornell Medical College, New York, NY, <sup>2</sup>Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, AL, <sup>4</sup>Rheumatology, Rheumatology, Yale University School of Medicine, New Haven, CT, New Haven, CT

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Quantifiable measures of patients' symptoms such as patient reported outcomes (PROs) provides the physician with quantifiable information of subjective symptoms experienced by patients with rheumatoid arthritis (RA). Electronic tools that include instruments that physicians value to inform their treatment recommendations are limited since collection of this type of data can be time consuming and requires personnel to administer them. To determine which PRO domain, are most commonly used by rheumatologists when treating RA patients and best ways to administered them at the point of care.

**Methods:** We developed a survey following qualitative data of 4 nominal groups and 25 rheumatologists. Items were aggregated into topic groups and categorized by themes. We used the items/responses generated in the nominal groups to develop the questions and responses of the survey. The survey included multiple choice questions and others included a scale where participants graded specific items into: 1) very important; 2) Important; 3) Somewhat important; 4) Not important; 5) do not assess. Rheumatologists who are a part of the American College of Rheumatology membership were invited to participate. The survey was deployed via Qualtrics. We used proportions to describe the results of this survey.

**Results:** We invited 600 rheumatologists and 56 responded to the survey (ongoing survey). The majority of the respondents were between 35 and 54 years of age; 64% male. The aspects that physicians graded as very important are shown in figure 1. The majority of them valued medication compliance, aspects related to physical function, and quality of life were. While the Patient-Reported Outcomes Measurement Information System (PROMIS) was known by 16 respondents, only 1 rheumatologist was using it regularly in practice. There were 16 and 25 respondents who collect MDHAQ and RAPID3 on most of all office visits, respectively. The majority of the respondents were interested in having PRO data collected electronically and synchronized with the electronic health record (64%).

**Conclusion:** Electronic collection of PROs that incorporates medication compliance, patient function and that it has an interface with the electronic health record will make the collection of PROs more feasible for physicians. While PROMIS instruments was known by a small number of respondents only 1 was using it. Educating physicians about these questionnaires can increase its use in clinical

practice, which is limited according to these results.

## Can 3 0-10 Physician Visual Analog Scales (VAS) to Assess Levels of Inflammation, Damage and Distress Offer Comprehensive Quantitative Data That May be As Informative As Detailed, Formal Swollen and Tender Joint Counts?

**MJ Bergman**<sup>1</sup> and Theodore Pincus<sup>2</sup>, <sup>1</sup>Drexel University College of Medicine, Philadelphia, PA, <sup>2</sup>Rheumatology, Rush University Medical Center, Chicago, IL

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Management of patients with rheumatoid arthritis (RA) remains primarily according to a patient history and physical examination, unlike in many other chronic diseases, in which a “gold standard” biomarker, such as a laboratory test provides the primary basis for clinical management. A need for quantitative measures has led to a count of tender and swollen joints. A formal joint count is standard in clinical trials and clinical research, but not at most patient visits. Perhaps this phenomenon suggests that a joint examination without a formal quantitative joint count may be adequate, e.g., it matters considerably whether a patient has, say, 2 vs 12 swollen joints, but not necessarily whether the patient has 1 vs 2 or 11 vs 12 swollen joints. Furthermore, joint counts have relatively poor test-retest reliability, and can be affected by phenomena other than inflammatory activity, such as joint damage and/or distress. An alternative approach to quantitate a clinical encounter involves 3 physician visual analog scales (VAS) for inflammation, damage and distress to supplement a physician global assessment, as analyzed here.

**Methods:** At one private practice rheumatology site, all patients complete a patient self-report MDHAQ/RAPID3 at each visit. The rheumatologist performs a formal 28-joint count of tender (TJC) and swollen (SJC) joints, and then completes four 0-10 VAS, for overall global assessment, inflammation, damage, and distress. A random visit of 259 RA patients was studied for mean values, and correlations of the 4 physician VASs with SJC and TJC. Because correlations may be artefactually elevated if many patients have a value for a zero for the two variables compared, correlations also were calculated of patients whose SJC was >1.

**Results:** Mean values for the 0-10 VASs were 2.09 for physician global assessment, 2.50 for inflammation, 1.47 for damage and 0.74 for distress, as well as 4.17 for patient global assessment (Table). Mean SJC 28 was 5.15, and TJC 28 2.54. SJC was correlated at significantly higher levels with the inflammation VAS,  $r=0.766$  than the damage VAS,  $r=0.235$ , or distress VAS,  $r=0.030$ . In patients only with SJC >1, the correlation of SJC with the inflammation VAS was somewhat lower,  $r=0.688$ , but remained significantly higher

than other correlations with physician VAS. The correlation of TJC was similar for overall global, inflammation and distress. The 4 VAS required about 15 seconds to complete vs about 90 seconds for a 28 joint count.

Measure	Mean value±SD	Correlation with SJC	Correlation with TJC	Correlation with SJC>1	Correlation with TJC>1
Physician global assessment VAS	2.09±2.18	0.415	0.372	0.333	0.338
Inflammation VAS	2.50±2.04	0.766	0.389	0.688	0.344
Damage VAS	1.47±1.81	0.235	0.062	0.174	0.016
Distress VAS	0.74±1.55	0.030	0.345	0.017	0.272
SJC28	5.15±5.32	-----	0.386	-----	0.411
TJC28	2.54±4.95	0.386	-----	0.411	-----
Patient global assessment VAS	4.17±2.83	0.312	0.369	0.241	0.350

VAS=visual analog scale, SJC= swollen joint count, TJC= tender joint count

**Conclusion:** 3 physician VAS for inflammation, damage and distress may provide a useful tool to document a physician assessment of patient status and the rationale for clinical decisions, e.g., not escalating anti-inflammatory therapy in a patient with high RA index score who does not have high scores for inflammation but rather high scores for damage and/or distress.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Clinical Aspects Poster II: Pathophysiology, Autoantibodies, and Disease Activity Measures

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). In a clinical trial setting, standard criteria for measuring the effectiveness of treatments in patients with RA include American College of Rheumatology (ACR) response rates (defined as the proportion of patients with an improvement of 20/50/70%, respectively, in tender and swollen joint counts and 20/50/70% improvement in 3 of the 5 core components [patient and physician global assessments, pain, disability, and an acute phase reactant] between time points).<sup>1</sup> Tender and swollen joint counts are typically assessed by counting 68 and 66 joints, respectively.<sup>2</sup> However, the use of a 28 joint count is considered a valid and reliable way to determine ACR response rates,<sup>3</sup> and a 28 joint count has been used to determine ACR response rates in the recently completed ORAL Strategy (NCT02187055) Phase 3b/4 study of tofacitinib. The current post-hoc analysis was conducted to determine whether ACR response rates in six Phase 3 studies of tofacitinib varied when a 28 joint count vs a 68/66 joint count was used.

**Methods:** Data from patients with active RA who received tofacitinib 5 or 10 mg twice daily (BID) in six randomized, double-blind Phase 3 studies (ORAL Step [NCT00960440], ORAL Solo [NCT00814307]; ORAL Scan [NCT00847613], ORAL Sync [NCT00856544], ORAL Standard [NCT00853385], and ORAL Start [NCT01039688]) were included in this analysis. ACR20/50/70 response rates were determined using 28 joint counts and compared with ACR20/50/70 response rates obtained in the respective study using the full joint count (68/66 joints). ACR response rates were assessed at the time of the primary endpoints of the studies (Month 3 in ORAL Step and ORAL Solo; Month 6 in all other studies). All analyses were based on the full analysis set; missing data were imputed using non-responder imputation.

**Results:** Overall, the ACR20/50/70 response rates of 3141 tofacitinib-treated patients were determined; 1558 (49.6%) and 1583 (50.4%) patients were randomized to receive tofacitinib 5 and 10 mg BID, respectively. At the primary endpoint, ACR20/50/70 response rates measured using the 28 joint count were generally similar to those determined using the full joint count within each study (Table). ACR20/50/70 response rates of placebo-treated patients were also generally similar when measured using the 28 and 68/66 joint counts (data not shown).

**Conclusion:** The results of this post-hoc analysis suggest that the use of a 28 joint count in tofacitinib-treated patients with RA provides similar ACR response rates as the use of a full joint count (68/66 joint count).

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Rheumatoid Arthritis – Clinical Aspects Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Regular physical activity is important for people with rheumatoid arthritis (RA). Sleep requirements for adults should be on a 'sleep needs spectrum' of between 7 to 9 hours per day. Poor sleep is a common complaint among people with RA, which may have an effect on their activity levels and well-being. There is evidence that physical activity and exercise can impact sleep quality and disturbances in other chronic disease populations therefore, examining how they could affect sleep in people with RA is important. There is a lack of objective information regarding total sleep time (TST) and its relationship with physical activity and disease related variables in people with RA.

**Methods:** Aim of the study was to objectively measure sleep and energy expenditure in people with RA and to determine if relationships exist between sleep, physical activity and related disease variables among people with RA. A cross-sectional study design was used to recruit people with RA attending rheumatology outpatient clinics. Participants had to have a confirmed diagnosis of RA according to the American College of Rheumatology (ACR) classification criteria to be included in the study. A SenseWear<sup>(R)</sup>TM armband was applied to the right upper arm and participants were encouraged to wear same for 24 hours a day for 8 days. Subjects were contacted 3 times during the week to remind them to continue to wear the monitor. Four valid days with 95% wear time was determined as the measurement criteria.

**Results:** Seventy five (75) participants completed period of monitoring, with 32 subjects having the required wear time. The mean TST was 5.7 (SD 1.11) hours per night, with a median 1.25 (IQR 1.88) hours of daily physical activity. Sleep time had a positive significant relationship with physical activity ( $p=0.018$ ); physical activity also demonstrated a negative significant relationship with functional limitation ( $p=0.009$ ); physical activity energy expenditure further demonstrated a significant negative correlation with disease activity ( $p=0.011$ ) and low disease activity was strongly correlated with improved global health ( $p<0.001$ ). Therefore, those who were more active had the longest TST, with reduced functional limitations. Those who expended more energy had lower disease activity with improved global health. Physical activity correlated with lower CRP levels and CRP levels had in turn a significant relationship to global health ( $p=0.034$ ).

**Conclusion:** This study has demonstrated that people with RA who are more physically active have longer TST. Disease related factors and function variables also correlate with sleep, with lower CRP, lower DAS, lower HAQ and increased global health in those with higher physical activity levels and longer TST. These findings are significant given recent information that sleep is commonly reduced in people with RA and that people with RA have lower physical activity profiles.

People with RA have varied sleep patterns and fall below the required 'sleep needs spectrum'. Future research should specifically investigate the effect of physical activity and exercise on sleep and from this, the most effective exercise prescription, the ideal approach to exercise delivery and how compliance can be promoted.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The response to any treatment in rheumatoid arthritis (RA) is assessed by symptomatic changes, such as swollen joint count and DAS28. However, such assessments does not provide information regarding the effect of the treatment at the tissue level. Chronic inflammation has a detrimental effect resulting in elevated levels of tissue remodeling and the release of extracellular matrix (ECM) metabolites into the circulation. The tissues consist mainly of interstitial matrix, basement membrane and cells, which are all affected by auto-immune disorders. Tissue metabolites can be measured in serum as biomarkers of tissue remodeling and may give insight to effect at the tissue level of different interventions. The purpose was to investigate if tissue remodeling is differently modulated by tocilizumab (TCZ) and methotrexate (MTX). This was conducted by measurement of tissue metabolites in serum of the RA patients participating in the phase III clinical trial.

**Methods:** The AMBITION study, a phase III RCT with tocilizumab vs. Methotrexate in which TCZ monotherapy (8 mg/kg every 4 weeks) was compared to methotrexate monotherapy over 24 weeks in patients with moderate-severe RA (AMBITION, NCT00109408). TCZ is a compound that inhibits the IL-6 receptor. Tissue metabolites were measured in baseline and 8-weeks sera (n=319) by ECM specific ELISAs: Connective tissue remodeling was measured by C3M (type III collagen degradation), basement membrane remodeling by C4M (type IV collagen), inflammation by C-reactive protein (CRP) and its metabolite CRPM. Comparison between groups were done by ANCOVA adjusting for age, gender, BMI and disease duration.

**Results:** Tissue remodeling was increased by 10% in the placebo group. The connective tissue remodeling was significantly ( $p<0.001$ ) inhibited by both MTX and TCZ compared to placebo. The inhibition with TCZ was 14% greater than that of MTX ( $P=0.0005$ ). Basement membrane remodeling was likewise inhibited by both MTX and TCZ; the effect of TCZ was 20% greater than MTX ( $p<0.0001$ ). In contrast, MTX had no or limited effect on CRP and its metabolite CRPM compared to placebo or baseline. TCZ reduced the level to 27% and 73% of baseline, respectively. Although the effect of TCZ was much greater when assessing CRP, this was the least significant response marker, due to the huge placebo modulation, as well as the general high variation in response. Only changes in CRP was correlated to 8-week changes in DAS ( $\rho=0.27$ ,  $p=0.001$ ) in the TCZ group. In the MTX group all changes in markers were correlated to change in DAS ( $\rho=0.28$  to  $0.41$ ,  $p<0.001$ ). In contrast, only changes in C4M and CRP were significantly correlated with DAS changes ( $\rho=0.31$ ,  $p<0.05$ ).

**Conclusion:** Chronic inflammation results in an increased amount of tissue remodeling. There was a significant difference in the magnitude of effect MTX and TCZ on tissue remodeling. In addition there was a disconnect between tissue remodeling and change in disease activity, which was treatment dependent.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic inflammation, insulin resistance, and endothelial dysfunction were implicated in the development of cardiovascular disease in rheumatoid arthritis (RA) [1-3]. Since insulin resistance can promote endothelial dysfunction and IL-6 blockade yields a rapid improvement of endothelial function [4], we aimed to assess whether IL-6 blockade may also result in a reduction of insulin serum levels and improvement of insulin resistance in patients with RA.

**Methods:** 50 Spanish patients on treatment with anti-IL-6 monoclonal antibody-Tocilizumab who fulfilled the 2010 classification criteria for RA [5] were recruited. Patients with diabetes mellitus or plasma glucose > 110 mg/dl were excluded. Fasting blood samples were taken for determination of plasma glucose and serum insulin levels immediately prior to (time 0) and after (time 60 minutes) Tocilizumab infusion. Insulin resistance was assessed by the homeostasis model assessment for insulin resistance (HOMA) and insulin sensitivity was evaluated by the quantitative insulin sensitivity check index (QUICKI).

**Results:** A marked reduction in the serum insulin levels was observed following Tocilizumab infusion (mean  $\pm$  standard deviation (SD):  $10.60 \pm 5.80$   $\mu$ U/ml *versus*  $7.61 \pm 5.08$   $\mu$ U/ml,  $p < 0.0001$ ). In addition, a decrease in the insulin/glucose index was observed in patients with RA after Tocilizumab dose (mean  $\pm$  SD:  $0.12 \pm 0.06$  *versus*  $0.08 \pm 0.05$ ,  $p < 0.0001$ ). Furthermore, a significant improvement of insulin resistance (HOMA: mean  $\pm$  SD:  $2.61 \pm 2.05$  *versus*  $1.65 \pm 1.14$ ,  $p = 0.0003$ ) and insulin sensitivity (QUICKI: mean  $\pm$  SD:  $0.34 \pm 0.003$  *versus*  $0.37 \pm 0.04$ ,  $p < 0.0001$ ) was found following Tocilizumab infusion.

**Conclusion:** Our study confirms a rapid beneficial effect of Tocilizumab on insulin resistance and insulin sensitivity in RA patients treated with this drug. It may support the long-term use of drugs that act blocking IL-6 function to reduce the mechanisms implicated in the development of atherosclerosis in patients with RA.

## **Persistence of Mast Cell-Rich Synovitis Is Associated with Lack of Response to Synthetic Disease Modifying Anti-Rheumatic Drugs in Patients with Early Rheumatoid Arthritis**

Felice Rivellesse, Frances Humby, Sara Pagani, Alessandra Nerviani and Costantino Pitzalis, Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and The London, School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Mast cells (MCs) are immune cells infiltrating the synovial membrane and implicated in the pathogenesis of Rheumatoid Arthritis, but their strict contribution to disease development and progression is still unclear. We have previously shown an association between synovial MCs and disease severity in early RA patients. Aim of this study was to analyse the presence of MCs in the synovia of RA patients at baseline and 6 months after treatment with synthetic DMARDs in relationship with disease parameters and response to treatment.

**Methods:** DMARD-naïve patients with early (<12 months) RA (n=20) fulfilling the 2010 ACR/EULAR criteria were recruited as part of the Pathobiology of Early Arthritis Cohort at Barts Health NHS Trust. Synovial tissue was obtained by ultrasound-guided synovial biopsy at baseline and 6 months after treatment with synthetic DMARDs. Sequentially cut sections were stained by IHC for CD117+ MCs and immune cells (CD20+ B cells, CD3+ T cells, CD68+ macrophages and CD138+ plasma cells). Patients were classified according to the presence or absence of MCs, and MC density (n/mm<sup>2</sup>) was calculated by automated cell counting (cellSens, Olympus). Upon SQ scoring (0-4), sections were stratified into synovial pathotypes according to the degree of immune cell infiltration: (i) Lymphoid- grade 2/3 B cell aggregates, CD20≥ 2 and/or CD138>2 ii) Myeloid- CD68 SL≥ 2, CD20≤1 and/or CD3≥1, CD138≤2 and iii) Fibroid- CD68 SL<2 and CD3, CD20, CD138<1.

**Results:** At baseline, the presence of synovial MCs was significantly associated with synovial inflammation (high synovitis score 60.7% in MC+ vs 16% in MC-, p<0.05) and lymphoid aggregates (lymphoid pathotype 64.4% in MC+ Vs 16.1% in MC-). Additionally, MCs were associated with systemic inflammation and disease activity (e.g. DAS-28 5.96 in MC+ vs 5.18 in MC-, p<0.05). Treatment with synthetic DMARDs induced a partial reduction in MC numbers (mean MC at baseline 14.2/mm<sup>2</sup>; at 6 months 8.2/mm<sup>2</sup>, p=0.094). Accordingly, synovial MCs were still present at 6 months in 45% of patients (9/20), in association with synovitis and lymphoid aggregates (high synovitis score and lymphoid pathotype 44.4% in MC+ vs 0% in MC-, p<0.05). Additionally, the presence of MCs at 6 months was associated with a higher DAS28 (4.08 in MC+ vs 2.41 in MC-, p<0.05) and a lower rate of remission (DAS28<2.6 22.2% in MC+ vs 72.7% in MC-, p<0.05).

**Conclusion:** Here we show that treatment with synthetic DMARDs in early RA patients partially reduces the number of synovial mast cells and their persistence (MC-rich synovitis) is associated with lack of response to DMARDs. This exploratory study confirms the relevance of MCs as part of the inflammatory infiltrate in the synovia of RA patients, warranting further investigations to clarify their role in disease progression and response to treatment.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with RA harbor autoantibodies of various isotypes and directed against several post-translational modifications. Baseline seropositivity is a poor prognostic factor for sustained drug-free remission (SDFR). However, autoantibody levels may change and patients may become seronegative under treatment. It is unknown how often this happens, and whether decreasing levels or becoming seronegative early in disease, indicating disappearance of serological autoimmunity, improves chances

of SDFR. To investigate this, we measured a large variety of autoantibodies, including isotypes, in RA patients over time and investigated whether changes in their levels and/or presence associated with SDFR.

**Methods:** In sera of 381 seropositive RA patients in the IMPROVED study<sup>1</sup>, we measured, at 4 month intervals over the first year of treatment: IgG, IgM, and IgA isotypes for anti-cyclic citrullinated peptide-2, rheumatoid factor, anti-carbamylated protein antibodies, and autoantibodies against 4 citrullinated and 2 acetylated peptides. We investigated whether changes in antibody levels and seroconversion from positive to negative for each individual antibody was favorable for SDFR (drug-free DAS44<1.6 lasting ≥1 year until last follow-up).

**Results:** For all 14 antibodies, median levels decreased significantly between baseline and 4 months and then stabilized. The prevalence of seroconversion from positive to negative between 0-12 months varied substantially depending on the autoantibody and occurred in 3% (anti-CCP2 IgG) to 66% (anti-CarP IgA) of patients positive at baseline. We hypothesized that greater level decreases and seroconversion, reflecting disappearance of the underlying immunopathology, might be favorable for the long-term outcome SDFR, an outcome approximating disease curation. Surprisingly, greater median decreases in levels were not associated with higher chance of SDFR. Furthermore, we found no evidence that rates of SDFR were higher in patients who seroconverted compared those who stayed seropositive, for all antibodies analyzed (see Figure).

**Conclusion:** Autoantibody levels decrease and seroconversion from positive to negative occurs under treatment, but these changes do not seem to translate to apparent clinical long-term benefits with regard to SDFR. This suggests that in these patients, despite the disappearance of measurable serological autoimmunity, other immunopathological processes sustain the disease.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The Mediterranean Diet has been associated with lower mortality and risk of cardiovascular diseases and cancer. Although its components have been analyzed in several studies, only two studies have investigated the association between Mediterranean diet and risk of rheumatoid arthritis (RA) and reported no association.

**Methods:** Data on 1726 incident cases and 3683 controls, matched on age, gender and residential area, from the Epidemiological Investigation of RA (EIRA), a population-based case-control study, was used to estimate the association between the Mediterranean dietary score and the risk of RA. The score, ranging from 0 to 9, was calculated using a 124-item food frequency questionnaire. Odds ratios (ORs) and their 95% confidence intervals (CIs) were calculated using conditional logistic regressions, and multivariable models were adjusted for body mass index, educational level, physical activity, use of dietary supplements, energy intake, and smoking.

**Results:** In the EIRA study (median age 53), 23.5% of the cases and 27.9% of the controls had a high adherence to the Mediterranean diet (a score between 6 and 9). An high adherence reduced the odds of developing RA by 23% (OR 0.76; 95% CI, 0.62-0.92) as compared to low adherence (a score between 0 and 2). The odds ratio was even lower among men (OR 0.49; 95% CI, 0.33-0.72), but no association was found among women (OR 0.89; 95% CI, 0.71-1.11). The inverse association was observed for rheumatoid factor (RF) positive (OR 0.66; 95% CI, 0.52-0.84), but not negative RA (OR 0.93; 95% CI, 0.66-1.30), and for antibodies to citrullinated peptides (ACPA) positive, but not ACPA-negative RA (Table 1).

**Conclusion:** In this large population-based case-control study, the Mediterranean diet score was inversely associated with risk of RA. The association was stronger among men than among women and no significant association was observed for seronegative RA.

**Acknowledgments:** This study was supported by grant from Forte (grant registration number 2015–00689).

**Conflict of interest:** The authors declare that they have not conflict of interest.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Hydrogen sulfide (H<sub>2</sub>S) is an endogenous gasotransmitter known to play a role in inflammation. While levels of hydrogen sulfide have been studied in patient populations with cardiovascular disease, there has been little research of H<sub>2</sub>S levels in plasma of subjects with autoimmune diseases such as rheumatoid arthritis (RA). H<sub>2</sub>S bioavailability is regulated through its conversion into different biochemical forms. Past H<sub>2</sub>S studies concerning rheumatoid arthritis have not employed analytical biochemistry to measure biochemical forms of H<sub>2</sub>S, specifically the free H<sub>2</sub>S, acid-labile sulfide, and bound sulfane sulfur. Thus, the aim of this study was to measure these metabolites of H<sub>2</sub>S in rheumatoid arthritis subjects and compare them to non-RA individuals over time.

### Methods:

Thirty control non-RA and thirty RA subjects were selected based on specific criteria and consented in the University Health Rheumatology Clinic. Subjects with diabetes were excluded from the study. Following consent, 10 ml of venous blood was collected into a BD microtainer plasma separator tube with heparin. Samples were prepared for detecting H<sub>2</sub>S pools. Hydrogen sulfide can be

released from acid-labile sulfide form in 100 mM phosphate buffer (pH 2.6) with or without the reductant TCEP. Sulfide levels were measured by derivatization of hydrogen sulfide with excess monobromobimane (MBB) in 50 mM Tris-HCl buffer. The fluorescent product sulfide-dibimane was then measured by RP-HPLC with a fluorescence detector. An F test was performed on the data to check for a significant difference in variances. Because the variances differed significantly with some populations, the Mann-Whitney test was performed.

## Results:

Subjects with RA had significantly higher levels of acid labile sulfur ( $p=0.009$ ) and total sulfide ( $p=0.04$ ) at the one month blood draw. Additionally, acid labile sulfide levels ( $p=0.04$ ) and total sulfide levels ( $p=0.01$ ) were greater in control males as compared to females at the 6-month blood draw. White male control's H<sub>2</sub>S levels were found to have an upward trend over the 6 months.

## Conclusion:

This research serves as a pilot study comparing the different biochemical forms of H<sub>2</sub>S (free, acid-labile, and bound) in the plasma of RA subjects versus control subjects. The method used in this study is unique, validated and quantitative because, unlike any prior studies on H<sub>2</sub>S, the MBB method analytically measures different forms of H<sub>2</sub>S in the plasma. Our findings show that acid labile and total H<sub>2</sub>S levels are higher in RA subjects than controls at the one month visit. Further studies are needed to determine the relationship of medications, disease activity, and diet during various time points of disease progression.

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Discovery and application of new therapies for rheumatoid arthritis (RA) has been hampered by multiple factors, including disease heterogeneity and the lack of well established approaches to analyze the synovial target tissue. The goal of the Accelerating Medicines Partnership (AMP) program is to deconstruct RA through cellular and molecular profiling of synovial tissue and matched peripheral blood from individuals with RA. During phase 1 of the AMP – RA program, we tested the feasibility of applying cytometric and transcriptomic analyses to synovial tissues from RA patients recruited from clinical sites across the network.

## **Methods:**

**Patient Enrollment.** A multicenter cross-sectional study of individuals undergoing elective surgical procedures and a prospective observational study of synovial biopsy from RA  $\geq$  age 18 with at least one inflamed joint were recruited from 10 contributing sites in the network.

**Tissue Processing.** Synovial tissues were cryopreserved on site then shipped to a central processing site for tissue disaggregation, cell sorting, mass cytometry and RNA-seq. Synovial tissue quality and grading of synovitis were evaluated via histologic analysis (H and E staining).

**Analytic Pipelines.** Cellular composition of RA and osteoarthritic (OA) synovial tissue was determined by flow cytometry and mass cytometry. RNA-seq was performed in parallel.

## **Results:**

58 synovial tissues acquired from 22 synovial biopsies and 36 elective surgical procedures (20 RA and 16 OA) were analyzed by combination of flow cytometry, mass cytometry, and RNA-seq. Synovial cellular composition determined by flow cytometry and mass cytometry were highly consistent in T cells ( $r=0.98$ ), B cells ( $r=0.96$ ), myeloid cells ( $r=0.64$ ), endothelial cells ( $r=0.81$ ) and synovial fibroblasts ( $r=0.93$ ), validating synovial analysis by mass cytometry of synovial tissue. Whereas RA synovial tissue obtained from elective surgical procedures exhibited varied degrees of inflammation with mean Krenn inflammation score (0-3) of 0.94 (S.D.=0.51), synovial tissues obtained from biopsies revealed significantly higher Krenn inflammation score than OA (1.68 vs 0.73;  $p=0.02$ ) and higher abundance of lymphocytes by flow cytometry (67% vs 8%;  $p<0.001$ ). Lymphocytic infiltration assessed by

cytometry was significantly correlated with histologic inflammation score ( $p<0.001$ ,  $r=0.58$ ), further supporting the fidelity of flow cytometric assessment of cryopreserved synovial tissue. Principle component analysis of synovial cell flow cytometry data identified 3 RA arthroplasty samples with inflammatory features resembling that seen in RA biopsies. Consistent with this analysis, these arthroplasty samples also showed higher inflammation score of inflammation by histology (2.0 vs 0.77,  $p<0.001$ ). Ongoing transcriptomic profiling of sorted synovial cells demonstrate molecular heterogeneity in RA synovium.

## Conclusion:

In Phase 1 of the AMP-RA program, robust cell yield from synovial tissue enables mass and flow cytometric data. These results lay the ground work for the larger phase 2 of the Accelerating Medicines Partnership (AMP) – RA network, which will utilize >100 independent samples.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Detailed analyses of cells from rheumatoid arthritis (RA) synovium may identify cell phenotypes and functions that drive tissue pathology and joint damage. The AMP RA/SLE network aims to deconstruct RA pathology using multiple high-dimensional analyses of cells obtained from rheumatoid synovium. These studies hold the potential to identify novel therapeutic strategies to counteract pathologic inflammatory responses in RA.

**Methods:** We developed a method to cryopreserve intact synovial tissue for downstream analyses of viable cells. Synovial tissue fragments were cryopreserved in a 10% DMSO-containing solution, then thawed and disaggregated. Synovial cells were analyzed using a 35-marker mass cytometry panel. In parallel, synovial cell populations, including fibroblasts, T cells, B cells, and macrophages, were flow-cytometrically sorted for low-input and plate-based single cell RNAseq transcriptomics.

**Results:** Intact cryopreserved synovial tissue yielded high numbers of viable cells after a thawing protocol followed by tissue dissociation. Cells isolated from cryopreserved tissue demonstrated intact expression of lineage markers by flow cytometry, comparable to freshly processed tissues. Optimization of synovial tissue dissociation performed across 6 sites, utilizing >30 arthroplasty and >20 synovial biopsy samples, yielded a consensus dissociation protocol of tissue digestion with 100ug/mL of liberase TL enzyme, which provided high cell yields, preserved surface markers, and minimized variability in RNAseq transcriptomes across replicates.

Arthroplasty samples were mechanically dissociated after enzymatic digestion by gentleMACS. To reduce cell losses when using smaller synovial biopsies, biopsy samples were mechanically dissociated by rapid, continuous magnetic stirring during enzymatic digestion and passage through an 18-gauge syringe. Cryopreserved tissue dissociated by these methods could be analyzed by multiple high-dimensional analyses. Mass cytometry revealed 1) diverse fibroblast phenotypes, 2) clear separation of memory B cells from antibody-secreting cells, and 3) multiple phenotypes of activated CD4+ and CD8+ T cells. To complement mass cytometry analysis, a flow cytometric sorting strategy was developed to collect fibroblasts, macrophages, T cells, B cells for bulk and single cell RNAseq transcriptomics. RNAseq of total synovial cells revealed a transcriptomic effect of tissue dissociation, compared to intact synovial tissue. Nonetheless, RNAseq of sorted cell populations demonstrated robust separation of synovial lymphocytes, fibroblasts, and macrophages. Single cell RNAseq by CelSeq2 yielded transcriptomes of over 1000 genes/cell and demonstrated characteristic lineage markers in the expected cell populations.

**Conclusion:** We propose that this method of acquisition of viable cells from cryopreserved tissue can serve as a model for centralized generation of multiple, robust high-dimensional analyses of synovial samples acquired in multi-site studies. Integrated analysis of these datasets in a large patient cohort may help define the molecular heterogeneity of RA pathology and identify new therapeutic targets and biomarkers.

# Huntingtin Interactin Protein 1 (HIP1) Regulates Invasiveness, Actin Filament and Lamellipodia Formation in Rheumatoid Arthritis Fibroblast-like Synoviocytes (FLS)

**Teresina Laragione**, Carolyn Harris, Erjing Gao and Percio S. Gulko, Medicine/Rheumatology, Icahn School of Medicine at Mount Sinai, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Huntingtin-interacting protein 1 (Hip1) is an arthritis severity and joint damage gene recently discovered in rodent models of arthritis. Hip1 regulates fibroblast-like synoviocytes (FLS) invasiveness, and FLS invasiveness strongly correlates with joint damage. Previous studies suggested that Hip1 regulates PDGFR signaling in rodent cells. In the present study we aimed at determining whether Hip1 mediates PDGF $\beta$  and EGF-induced invasion in RA-derived FLS.

**Methods:** FLS cell lines from RA patients were transfected with siRNA targeting Hip1 or controls. Knock-down was confirmed with qPCR and western blot. Invasion was studied in a well-established two-chamber assay through Matrigel, where lower chamber contained either PDGF $\beta$  (50ng/ml), EGF (1ug/ml) in SFM. Cells were also treated with PDGF $\beta$  for 5, 15 and 30 minutes and analyzed by immunofluorescence for pFAK localization and actin cytoskeleton. Total cell lysates from RA FLS stimulated with PDGF were used to quantify matrix metalloproteases (MMP1-3, 8-10, 12, 13), as well as total and phospho-FAK.

**Results:** siRNA Hip1 knock down in RA FLS (n=6) significantly reduced invasiveness induced by PDGF $\beta$  (40% reduction; p=0.03) and EGF (50%; p=0.005) compared with siRNA control cells. Hip1 knock-down cells had fewer thick actin filaments and developed an unusual star-like morphology unable to take the polarized shape typically required for movement and invasion, with impaired formation of lamellipodia. Total levels of phospho-FAK did not differ between Hip1 knock-down and control FLS. However, in Hip1 knock-down FLS phospho-FAK distribution was significantly different from controls and distant from the cell periphery. Levels of MMPs were not affected by siRNA Hip1.

**Conclusion:** We describe a new role for Hip1 in the regulation of EGF and PDGF-induced invasiveness of RA FLS, and show that in the absence of Hip1 the cells take an unusual and non-invading morphology without lamellipodia. These new findings provide new understanding of events regulating FLS behavior in RA and have the potential to generate new prognostic biomarkers and a new intra-cellular target for therapies aimed at reducing joint damage.

## The Cation Channel TRPV2 Decreases Rheumatoid Arthritis Fibroblast-like Synoviocyte Invasiveness By Inhibiting RhoA Activation, Cell Adhesion and Actin Cytoskeleton Changes

**Teresina Laragione**, Carolyn Harris, Erjing Gao and Percio S. Gulko, Medicine/Rheumatology, Icahn School of Medicine at Mount Sinai, New York, NY

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have recently identified the non-selective cation channel TRPV2 (transient receptor potential vanilloid subfamily, type 2 channel) as a new central mediator of arthritis and fibroblast-like synoviocyte (FLS) invasiveness. TRPV2 activation by the synthetic agonists O1821 and LER13 suppressed invasiveness of FLS from DA rats, B6 mice and RA FLS and reduced disease severity and joint damage in collagen induced arthritis (CIA) and KRN serum-induced arthritis. However, the mechanism of action of TRPV2 agonists was incompletely understood. In this study we characterized the cell signaling events and mechanisms mediating the TRPV2 suppressive activity in FLS.

**Methods:** FLS cell lines developed from RA patients were pre-treated with O1821 (or vehicle) for 30 minutes, followed by either a) adhesion to multiple substrates (collagen I/II/IV, fibronectin, laminin, tenascin, vitronectin or BSA), b) cell lysis for Milliplex MAPK pathway analyses or RhoA/Rac1/Cdc42 activation assay, or c) for quantification of total matrix metalloproteases (MMPs). The active form of MMP2 was quantified on a Zymogram using supernatants from FLS cultured on Matrigel. Actin filaments and pFAK localization on FLS were analyzed by immunofluorescence.

**Results:** O1821 significantly reduced FLS adhesion to laminin, tenascin, vitronectin, and type IV collagen suggesting an inhibitory effect on different integrins. O1821 decreased pFAK (tyr397) levels and prevented pFAK co-localization with lamellipodia. Additionally, O1821 reduced actin filament thickness inducing a disorganized filament distribution and keeping the cells in a round and non-polarized shape. O1821 prevented the formation of lamellipodia and reduced levels of activated RhoA, while the activator CN03 bypassed that effect. We detected no significant effect of O1821 on MMPs, Cdc42, Rac1, MAPK pathway phosphorylated members p38, Jnk, Erk, CREB, Akt, Stat3, Stat5, p70S6K or NFκB.

**Conclusion:** We describe new cellular and signaling processes regulated by TRPV2 suggesting that it suppresses RhoA activation to prevent actin filament changes required for cell mobility and invasion, including adhesion, polarization of cell morphology and the formation of lamellipodia. These observations provide new understanding into the mechanism of action of arthritis and invasion suppressive TRPV2 agonists that are being developed toward therapeutic use.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In our previous study, we discovered that ursolic acid (UA), a pentacyclic triterpenoid with anti-inflammatory properties, induces apoptosis in synovial fibroblasts from rheumatoid arthritis patients (RASFs) by upregulating Noxa and downregulating Mcl-1. To examine the molecular mechanism of UA-mediated apoptosis, we tested early signaling pathways that may activate Noxa expression as well as potential mechanisms of Noxa-mediated proteasomal degradation of Mcl-1 in human RASFs.

**Methods:** Human RASFs were treated with UA (5-10 μM) to determine the activated signaling pathways by Western blotting and qRT-PCR methods. The spatial association of Noxa with Mcl-1 and other E3 ligases was studied using immunoprecipitation (IP), immunofluorescence (IF), and proximal ligation assay (PLA) methods. The ubiquitination of Mcl-1 was studied using denatured IP.

**Results:** Treatment of RASFs with UA (5-10  $\mu$ M) resulted in a time- and dose-dependent increase in Noxa, but decrease in Mcl-1 expression. Addition of proteasome inhibitor (MG132) showed no further increase in Noxa expression, suggesting transcriptional activation as a potential mechanism behind UA-induced Noxa expression. Evaluation of the signaling pathways showed that UA induced temporal expression of hypoxia-inducible factor-1  $\alpha$  (HIF-1 $\alpha$ ) in RASFs. Furthermore, our results showed that UA utilizes Akt, p38-MAPK, and JNK/SAPK signaling pathways to activate Noxa expression in RASFs. Utilizing inhibitors of JNK/SAPK (SP600125), p38-MAPK (SB203580), Akt (LY294002), and HIF-1 $\alpha$  (HIF-1 $\alpha$  inhibitor) pathways, we showed that inhibition of JNK/SAPK pathway significantly reduced UA-mediated upregulation of Noxa. In addition, the results from PLA and IF studies in UA-treated RASFs showed that Noxa co-localizes with Mcl-1 predominantly in the non-nuclear compartment of the cell, suggesting its association with Mcl-1 in 'priming' Mcl-1 for proteasomal degradation. Interestingly, the IP of Mcl-1 under denatured condition after UA treatment and subsequent Western blot analysis showed an increase in K48-linked, but not K63-linked, ubiquitin chains tagged to Mcl-1. This K48 polyubiquitylation of Mcl-1 appears to be mediated by Mule, a HECT domain containing E3 ubiquitin-protein ligase, since UA treatment of RASFs preferentially induced the recruitment of Mule rather than SCF $^{\beta}$ -TrCP to Noxa/Mcl-1 complex to facilitate Mcl-1 degradation.

**Conclusion:** Taken together, these results suggest that UA induces Noxa expression via JNK pathway and facilitates Mcl-1 association with E3 ubiquitin ligase Mule to activate Mcl-1 degradation that sensitizes RASFs to apoptosis. These findings not only unveil a novel mechanism of UA in inducing apoptosis of RASFs, but also a potential new approach to treat RA.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Emerging evidence highlighted the role of Tyro3, Axl and Mer Tyrosine Kinase receptors (TAMs) and their ligands Gas6 and ProteinS in the pathogenesis of autoimmunity; however, little is known about their expression and function in Rheumatoid Arthritis (RA). Axl is able to inhibit the pro-inflammatory cascade in Antigen-Presenting-Cells. Its soluble form (sAxl) behaves as a potent decoy receptor for the ligand Gas6, thus playing an essential role in regulating TAMs functions. Given the crucial role of Axl receptor and its ligand Gas6 in controlling inflammation, we aimed to characterise their expression and function in RA.

### **Methods:**

Biologic samples were collected from patients with early inflammatory arthritis (disease duration <12 months) DMARDs and steroids-naïve; all patients underwent an US-guided synovial biopsy of the most inflamed accessible joint before starting treatment. Only patients diagnosed with RA according to ACR/EULAR 2010 criteria were included in this study. Axl/Gas6 expression was evaluated: i) in synovial tissue at gene expression level by next generation sequencing (81 patients); ii) in synovial tissue at protein

level through immunohistochemistry (30 patients); iii) in synovial fluid by ELISA (18 patients); iv) in supernatants of RA-fibroblasts-like-cells (FLS) by ELISA.

## Results:

Axl mRNA levels, but not GAS6, were significantly down regulated in highly inflamed synovial tissues containing B/T cells ectopic structures compared to non-lymphoid synovitis ( $p < 0.001$ ) and negatively correlated with the synovitis score ( $r = -0.48$ ). Axl gene expression showed a significant strong negative correlation with indexes of disease activity, including ESR, CRP, swollen joint count and DAS28. At protein level, Axl was predominantly detected in cells forming the lining layer or in close association with blood vessels, independently of the synovial pathotype. In RA synovial fluids, sAxl was significantly more abundant in patients characterised by high-inflamed lymphoid synovitis compared to non-lymphoid ( $28.55 \pm 12.99$  ng/ml *versus*  $4.86 \pm 2.18$  ng/ml,  $p < 0.05$ ); moreover, synovial fluid levels of sAxl positively correlated with the synovitis score ( $r = 0.55$ ) and with systemic inflammation (sAxl/ESR  $r = 0.56$ ). In an *in vitro* system of cultured RA FLS, sAxl shedding and release in the supernatant was significantly increased upon treatment with TNF $\alpha$  in comparison with untreated synovial fibroblasts.

## Conclusion:

Axl is down regulated in highly inflamed RA synovial tissues and negatively correlates with multiple markers of disease activity. It can be shed and released into the synovial fluid and its levels are higher in presence of high-inflamed synovitis and positively correlate with systemic inflammation. TNF $\alpha$  is able to enhance Axl proteolytic cleavage from RA synovial fibroblasts. In conclusion, the dysregulation of the TAM system could provide a novel mechanistic explanation of the persistent inflammation characterizing the RA joints but could also be potentially exploited for therapeutic strategies in order to regain tissue homeostasis.

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Protein tyrosine phosphatase non-receptor 22 (PTPN22) binds to C-Src tyrosine kinase (CSK) forming a key regulator complex in autoimmunity<sup>1</sup>. In this regard, *PTPN22* is the main non-HLA genetic risk factor involved in rheumatoid arthritis (RA) susceptibility<sup>2</sup> and several *PTPN22* single-nucleotide polymorphisms (SNPs) have been significantly related with RA<sup>3</sup>. Moreover, *PTPN22* expression profiles have been proposed as biomarkers of RA<sup>4</sup>. Nevertheless, the potential influence of *PTPN22* SNPs on *PTPN22* expression in RA has not been elucidated and there is no information of the role of CSK in RA. Accordingly, we

determined if the most relevant *PTPN22* (rs2488457, rs2476601 and rs33996649) and *CSK* (rs34933034 and rs1378942) polymorphisms may influence on *PTPN22* and *CSK* expression in peripheral blood of RA patients when compared to healthy controls.

## Methods:

*PTPN22* and *CSK* mRNA expression was assessed by quantitative real-time PCR in peripheral blood samples from 89 patients with RA, who met the 1987 ACR and the 2010 ACR/European League Against Rheumatism criteria for RA<sup>5-6</sup>, and 43 healthy controls recruited from Hospital Universitario Marqués de Valdecilla (Santander, Spain) and Hospital Universitario La Princesa (Madrid, Spain). *PTPN22* (rs2488457, rs2476601 and rs33996649) and *CSK* (rs34933034 and rs1378942) were genotyped by TaqMan SNP genotyping assays. Differences in *PTPN22* and *CSK* expression between patients and controls stratified according to their genotype for each SNP were analyzed by Student's t test. All the results were adjusted by sex, age at time of study and cardiovascular risk factors.

**Results:** A significant down-regulation of *PTPN22* expression in patients with RA carrying *PTPN22* rs2488457 and rs2476601 mutant alleles compared to controls was observed ( $p=0.009$  and  $p=0.008$ , respectively). Furthermore, patients with RA carrying *CSK* rs1378942 mutant allele showed a significantly lower *CSK* expression than healthy individuals ( $p<0.0001$ ).

**Conclusion:** Our study shows for the first time that the mutant allele of *PTPN22* rs2488457, *PTPN22* rs2476601 and *CSK* rs1378942 influences on the down-regulation of *PTPN22* and *CSK*, respectively, in RA. The transcriptional suppression of this *PTPN22/CSK* complex, may have a noteworthy clinical relevance in patients with RA, playing an important role in disease diagnosis and progression.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid arthritis (RA) is characterized by hyperplastic synovial pannus tissue, which mediates destruction of cartilage and bone. Fibroblast-like synoviocyte (FLS) are a key component of the invasive pannus and have a major role in the initiation and perpetuation of destructive joint inflammation. *Stauntonia hexaphylla* (Lardizabalaceae) is widely distributed in Korea, Japan and China, and is a popular herbal supplement in Korean and Chinese folk medicine owing to its analgesic, sedative, and diuretic properties. However, the exact pharmacological effects of *S. hexaphylla* extract, particularly its effect on inflammation, are not known. We investigated the suppressive effects of *S. hexaphylla* extract, YRA-1909 on the aggressiveness of lipopolysaccharide (LPS) - induced RA-FLS.

**Methods:** RA-FLS were cultured from synovial specimens obtained from RA patients undergoing joint replacement therapy. Inflammatory cytokines/chemokines level was measured by multiplex cytokine ELISA. Matrix metalloproteinase-2 (MMP-2) activity was measured using gelatin zymography. The expression of p-ERK1/2, p-p38, p-JNK and p-Akt was detected by Western blot analysis. The location of NF- $\kappa$ B p65 and expression of pro-inflammatory mediators in RA-FLS was detected by immunofluorescence microscope.

**Results:** YRA-1909 inhibited the production of pro-inflammatory cytokines, chemokines and matrix metalloproteinases (MMPs) including tumor necrosis factor- $\alpha$ , interleukin-6 (IL-6), IL-17A, CXCL8, CXCL10, MMP-1, 2, 3, 9 and 13 in RA-FLSs. Moreover, YRA-1909 suppressed LPS-induced MMP-2 enzyme activity and expression of MMP-2 and MMP-9 in RA-FLSs. YRA-1909 inhibited LPS-induced nuclear factor kappa B (NF- $\kappa$ B) activation by reducing the phosphorylation of p65 at Ser468 and Ser536. YRA-1909 also suppressed nucleus translocation of p65. Furthermore, YRA-1909 suppressed LPS-induced phosphorylation Akt and mitogen-activated protein kinases (MAPKs), including JNK1/2, and p38 signaling.

**Conclusion:** YRA-1909 reduces production of inflammatory cytokines/chemokines via inhibition of MMP-2 activity and MAPKs-NF- $\kappa$ B signaling pathway in activated RA-FLS. These observations suggest that YRA-1909 might be useful for the development of new anti-inflammatory agents.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** AIRE is a transcriptional regulator of tissue specific antigens in medullary thymic epithelial cells (mTEC). AIRE orchestrates the negative selection of self-reactive T cells as well as the induction of regulatory T cells in the thymus. *AIRE* was recently identified as a risk gene in rheumatoid arthritis (RA) by GWAS. Integrative analysis using omics data on fibroblast-like synoviocytes (FLS) from RA patients and controls points to a role of AIRE in RA-FLS. Activated FLS are key effector cells in RA, mediating persistent inflammation and tissue destruction. In addition, MHC class II is induced on FLS in the RA joint suggesting a

role in antigen presentation. Our aim was to investigate if AIRE is expressed and can regulate gene transcription in primary RA-FLS and if AIRE is present in synovial tissue in RA.

#### Methods:

Primary FLS were stimulated by proinflammatory cytokines for 12-24 hours before qPCR, confocal microscopy and ImageStreamX flow cytometry for AIRE expression. Stimulated or unstimulated control or AIRE-silenced RA-FLS samples were subjected to RNA seq. Differential gene expression and pathway analyses were performed. Synovial tissues from RA and control osteoarthritis (OA) patients were subjected to confocal microscopy.

**Results:** No *AIRE* expression was detected in unstimulated FLS. However, *AIRE* mRNA expression was induced up to  $222 \pm 102$  fold by IL-1 $\beta$  in RA-FLS compared with unstimulated ( $p=0.009$ ,  $n=3$ ). In OA-FLS *AIRE* was induced  $39 \pm 9$  fold ( $p<0.0001$ ,  $n=6$ ) by IL-1 $\beta$  and  $10 \pm 5$  fold ( $p=0.011$ ) by TNF compared with unstimulated. A synergistic effect was seen using IL-1 $\beta$  + TNF ( $66 \pm 33$  fold,  $p=0.009$ ). The *AIRE* induction was significantly higher in RA than OA-FLS ( $p=0.035$ ). AIRE protein expression was detected in stimulated RA-FLS. RNAseq analysis identified 55 (adjP-value<0.05) genes regulated by AIRE in RA-FLS of which 33 are annotated as interferon- $\gamma$  response genes. The top-ranked network by pathway analysis was "Dermatological diseases and conditions, organismal injury and abnormalities, connective tissue disorders" with a score of 38. AIRE expressing cells were present in lining and sublining in RA but not in OA synovium.

#### Conclusion:

AIRE is induced by TNF and IL-1 $\beta$  in primary RA-FLS and regulates the expression of interferon- $\gamma$  response genes suggesting an immune-modulatory role in these cells. AIRE is expressed in the RA synovium supporting a role of AIRE in arthritis.

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adipose tissue synthesizes and releases physiologically active molecules that are known as adipokines. Resistin, an adipokine, has been widely studied the regulation of glucose homeostasis and insulin sensitivity. Moreover, resistin also plays an important role of inflammation. We previously reported that serum level of resistin correlated with the disease activity of rheumatoid arthritis (RA). However, the pathogenic role of resistin has not been elucidated. In this study, we examined the stimulatory effect of resistin on fibroblast-like synoviocytes (FLSs) from RA patients.

**Methods:** Expression of resistin and the receptor, adenylyl cyclase-associated protein 1 (CAP1), in the synovial tissue from RA and osteoarthritis (OA) was examined by immunohistochemistry. FLSs were incubated with resistin for 18 hours. Then, total RNA was extracted, and the gene expression profile was analyzed by RNA sequencing. Concentration of chemokines in the culture supernatant was determined by enzyme-linked immunosorbent assay (ELISA). Expression of CAP1 was examined by RT-PCR and Western blotting. To verify signaling of resistin, we pretreated FLSs with a PKA inhibitor, KT5720, or transfected siRNA for CAP1 before stimulation with resistin.

**Results:** Resistin and CAP1 was abundantly expressed in the RA synovial tissue. Resistin expression was minimal in the OA synovium. Double immunofluorescence staining revealed that CD68-positive macrophages expressed resistin in RA synovium. CAP1 was expressed by cadherin-11-positive FLSs in RA. RT-PCR and Western blotting showed that *in vitro* cultured FLSs also expressed CAP1. RNA sequencing revealed that expressions of 18 genes, including 7 chemokines (CXCL1, CXCL2, CXCL3, CXCL5, CXCL6, CXCL8 and CCL2), from RA FLSs were increased more than 2 folds by stimulation with resistin. Production of CXCL8 and CCL2 in the culture supernatant of FLSs was increased by resistin. Pretreatment with KT5720 or transfection with CAP1 siRNA suppressed resistin-induced CXCL8 production by FLSs.

**Conclusion:** Resistin might play an important role in the pathogenesis of RA via upregulation of chemokine production in the synovial tissue.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Fibroblast-like synoviocytes (FLS) are increasingly recognised as major pathogenic cells in synovial inflammation of patients with Rheumatoid Arthritis (RA). In response to pro-inflammatory stimuli, such as TNF, FLS produce vast amounts of cytokines and chemokines that help to recruit and activate immune cells and drive the local inflammatory process. The pathways and transcription factors that determine the inflammatory response in FLS are, however, largely unexplored. Here, we investigated the potential contribution of the transcription-factor IRF1 to the inflammatory gene expression in FLS.

**Methods:** Expression of IRF1 in synovial tissue samples (12 RA and 8 osteoarthritis (OA) patients) was assessed by immunohistochemistry (IHC). Moreover, FLS were isolated according to established protocols and cultured using 2-D or 3-D culture techniques. IRF1 expression in response to TNF was determined by western blots, qPCR, immunofluorescence microscopy or IHC. FLS were also stimulated with TNF in the presence or absence of IRF1 siRNA pools. Expression of pro-inflammatory cytokines and chemokines was measured by qPCR.

**Results:** IRF1 expression was significantly increased in rheumatoid synovial tissues as compared to patients with OA on protein level. RA-FLS stimulation with TNF *ex vivo* caused rapid upregulation of IRF1 and proved the involvement of TNF in the regulation of IRF1. Immunofluorescence analysis further revealed that IRF1 was mainly localized in the nucleus of TNF-stimulated FLS. Moreover, also chronic TNF exposure of FLS grown in a 3-D synovial tissue culture system promoted the expression of IRF1. SiRNA-mediated knockdown of IRF1 in FLS significantly reduced the TNF-induced expression of pro-inflammatory cytokines and chemokines, such as IL6, CCL7, CXCL11 and TNFSF13B, which confirmed the role of IRF1 as a critical regulator of proinflammatory genes in RA FLS.

**Conclusion:** Our data reveal that IRF1 is crucial for the inflammatory response of FLS and support the idea that IRF1 might be an exciting therapeutic target in patients with RA.

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Undifferentiated Arthritis (UA) is defined as an inflammatory oligo/poly arthritis that does not fulfil criteria for a definitive diagnosis. Delay in diagnosis and treatment leads to poor prognosis. The aim is to identify synovial biomarkers that may be useful to diagnose patients with early UA

**Methods:** Retrospective longitudinal study. Patients with UA followed in our Arthritis Unit, who underwent arthroscopy between 2000 and 2014. Synovial biopsy were stained by immunohistochemistry (IHC) with the following antibodies: antiCD3 (T cells), antiCD20 (B cells), antiCD79 (preplasma cells), antiCD138 (plasma cells), antiCD31 (vessels), antiCD68 (macrophages), antiCD15 (neutrophils), antiCD117 (mast cells), antihs47 (fibroblasts), and quantified by Digital Image Analysis (Olympus). The same antibodies were evaluated in RA and PsA control groups. A transcriptomic analysis was performed to study different pathways of inflammation; only the Type 1 Interferon pathway shown differences between RA and PsA, IHC with MxA (one of the gene of Type 1 IFN signature) was performed.

**Results:** 54 UA and 78 controls were included. Table 1 shows the clinical, serological and demographic characteristics at time of synovial biopsy. Among patients with UA, 24 (44%) patients met criteria for RA and 30 (56%) for PsA during follow-up. Synovitis of patients with UA had higher macrophage (CD68+) density in total tissue ( $p=0.008$ ) and sublining (SL) ( $p=0.012$ ) than the control group. The UA that evolved to RA had a higher density of CD3 T lymphocytes than the control RA group ( $p=0.014$ ). No differences were observed in cells of adaptive immunity (CD20 B lymphocytes, CD138 plasma cells), innate immunity (CD117 mast cells, CD15 neutrophils), vessels (CD31) between the 4 groups. The area (%) stained by anti-hsp47 (synovial fibroblasts) in SL was higher in the RA control group than in the PsA ( $p=0.003$ ). The expression of MxA was increased in pre-RA Group compare to RA control ( $p=0.036$ ) especially in patients with synovial lymphoid neogenesis

**Conclusion:** This is the first immunohistological study of synovitis in a significant group of patients with UA who developed AR or PsA during follow-up. Although there are some differences between the UA and control groups in the density of CD68+

macrophages and lymphocytes T CD3+, these do not appear to be useful for an early diagnosis of UA. On the other hand, unlike the results of some previous studies, we not found differences between the cellular infiltrate (adaptive immunity, innate immunity or vessels) in patients with RA and PsA. The Type 1 Interferon pathway could be a biomarker in patients with UA who develop RA, but a prospective study would be necessary to validate this results. The fact that some patients with UA were undergoing treatment prior to synovial biopsy and its retrospective character limit the results of this study.

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Human Etiology and Pathogenesis Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Fibroblast-like synoviocytes (FLS) in the synovial intimal lining produce pro-inflammatory cytokines resulting in increase of joint inflammation. Recent studies about the cellular metabolism in FLS offered novel approaches to understand the inflammation in rheumatoid arthritis (RA). However, it has been unknown about mitochondrial dysfunction and metabolic change in RA. Mitochondria are very dynamic organelle and dysfunctional mitochondria are removed by mitophagy for cellular homeostasis. In addition, it was reported that mitochondrial dysfunction may be induced by mitophagy defect and that treatment with pyruvate protects fibroblast senescence induced by mitochondrial dysfunction. In this study, we show that RA FLS has mitophagy defect which was improved by treatment with pyruvate.

### Methods:

To analyze mitochondrial function in RA FLS, we determined mitochondria membrane potential by TMRM staining and FACS analysis. Mitochondrial respiration and glycolysis were measured using a Seahorse Bioscience Extracellular Flux Analyzer (XF24). Defective mitochondria are degraded by autophagy. We analyzed LC3b and p62 protein levels by Western-blotting. Cells were transfected with GFP-tagged LC3 expression vector. Mitochondria were stained by MitoTracker Deep Red and analyzed by confocal microscopy. Mitophagy was evaluated by transmission electron microscopy (TEM). The pyruvate effect on mitophagy process was

analyzed by the change of fluorescence of mitochondria-targeted mKeima (mt-mKeima) using confocal microscopy. Pro-inflammatory cytokines were measured by qRT-PCR and ELISA.

## Results:

Mitochondrial membrane potential (MMP), oxygen consumption rate (OCR) and the extracellular acidification rate (ECAR) were significantly increased in RA FLS compared with OA FLS. We also found that the abundance of LC3-b protein and p62 protein in RA FLS and the increase of colocalization of GFP-LC3 puncta with mitochondria in RA FLS. In addition, TEM and mt-mKeima confocal analysis revealed the accumulation of abnormal mitochondria and the dysregulation of mitophagy in RA FLS compared with OA FLS. Interestingly, these mitophagy defect and metabolic change such as increase of OCR, ECAR and MMP in RA FLS recovered by treatment with pyruvate. In addition, pyruvate decreased IL-6 and IL-8 production in RA-FLS.

## Conclusion:

Pyruvate improved mitophagy defect and suppressed proinflammatory cytokine production in RA FLS.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low trough levels of the tumor necrosis factor inhibitor, adalimumab (ADL), and anti-ADL antibodies (AAA) were reported to be correlated with lack of response at later time points in patients (pts) with rheumatoid arthritis (RA).<sup>1</sup>

**Objective:** To assess the ability of ADL trough levels and clinical assessments at Week 12 to predict clinical remission (REM) after 24 weeks (wks) of treatment with ADL +/- methotrexate (MTX) in established RA pts.

**Methods:** Data from MTX inadequate responders (MTX-IR) pts with established RA with available measurement of ADL trough levels and clinical assessments at Wks 12 and 24 from several clinical trials were pooled: for pts who received ADL+MTX combination therapy from DE009, DE019, M10-261 and M13-390; for pts who received ADL monotherapy from DE011, M10-261 and M13-390. Efficacy endpoints at Wk 24 were DAS28-CRP <2.6 and DAS28-CRP low disease activity (LDA, <3.2), remission (REM) and LDA by simplified disease activity index (SDAI, ≤3.3 and ≤11 respectively); REM and LDA by clinical disease activity index (CDAI, ≤2.8 and ≤10 respectively). Each of the pooled datasets was randomly and equally split into training and testing sets. Predictive modeling was performed on the training set, and the best-performing model was selected and validated in the testing set. The performance of the final model was reported based on the testing set.

**Results:** Based on the cutoffs selected by the predictive model, ADL concentrations at Wk 12 were only slightly predictive for Wk 24 clinical assessment in the ADL monotherapy group, but not in the ADL+MTX group (Table 1). However, based on achievement of the specified CDAI, SDAI or DAS28-CRP score at Wk 12 (selected by the model), pts were correctly predicted to reach Wk 24 REM or LDA with an accuracy of 80-90% and area under the receiver operating characteristic curve (AUC) of 75-90% (Table 2). As an example, pts on ADL monotherapy with DAS28 < 3.3 at Wk 12 had 60% and 70% chance of reaching Wk 24 DAS28-CRP<2.6 and LDA respectively, whereas pts with DAS28 ≥ 3.3 had 0% and 7% chance of achieving Wk 24 DAS28-CRP<2.6 and LDA, respectively (Table 2). Pts on ADL+MTX with Wk 12 SDAI <12.5 had a 25% and 77% chance of achieving SDAI REM and LDA at Wk 24, respectively.

**Conclusion:** The ADL concentrations at Week 12 selected by the prediction model were weak predictors of disease control at 6 months, especially for pts on ADL+MTX combination therapy. However, using the model-selected cutoffs of composite clinical endpoints at Wk 12, disease control after 6 months of ADL +/- MTX treatment could be correctly predicted in 70-80% of pts.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In patients (pts) with rheumatoid arthritis (RA), treat-to-target recommendations call for adjustment of treatment if a target is not met within 3-6 months (mths) of initiation. While some pts continue therapy beyond 3-6 mths despite not achieving the target, it's unclear if they still can achieve the target, and how the timing of target attainment impacts long-term outcomes.

**Objective:** To evaluate clinical, functional, and radiographic outcomes based on initial time to low disease activity (LDA) attainment among early RA pts who are naïve to MTX, or are MTX-insufficient responders (MTX-IR).

**Methods:** This post hoc analysis included pts receiving MTX in monotherapy or in combination with adalimumab (ADA) in 2 randomized, controlled trials (RCTs) of MTX-naïve pts with early RA: PREMIER included a 104-week (wk) RCT<sup>1</sup>; OPTIMA included a 26 wk RCT followed by treatment adjustments based on a target of LDA at wks 22 and 26<sup>2</sup>. Pts not achieving stable LDA received open-label (OL) ADA+MTX for an additional 52 wks (MTX-IR). Pts were subgrouped by treatment and time to first LDA event [SDAI  $\leq 11$ : 0-<3 mths, 3-≤6 mths, >6-≤12 mths]. The following were summarized for each subgroup: mean values and change from baseline ( $\Delta$ ) in SDAI, HAQ-DI and modified total Sharp score (mTSS). The proportions of pts achieving SDAI remission (REM) at 1 year (yr) were assessed.

**Results:** Roughly equal proportions of pts on MTX alone experienced their first LDA response between 0-<3 mths (21%), 3-≤6 mths (21%), and >6-≤12 mths (17%). More pts on ADA+MTX experienced LDA within 3 mths (0-<3: 45% and 56% for MTX-naïve and MTX-IR backgrounds, respectively), with smaller proportions in the 3-≤6 mths (19% for both MTX-naïve and -IR backgrounds), and >6-≤12 mths groups (14% and 4% for MTX-naïve and MTX-IR backgrounds). Approximately 50% of the 0-<3 mth group across treatments achieved SDAI REM at 1 yr. Interestingly, 10%, 14%, and 8% of the MTX, ADA+MTX (MTX-naïve), and ADA+MTX (MTX-IR) pts who first experienced LDA after 6 mths were in SDAI REM at 1yr.

Among MTX-naïve pts, pts on ADA+MTX had greater  $\Delta$ HAQ and smaller  $\Delta$ mTSS than pts on MTX alone at Wks 26 and 52 (**Table 1**). Regardless of their time to first SDAI LDA response, pts on MTX monotherapy or ADA+MTX experienced comparable improvements in SDAI, HAQ-DI and comparable  $\Delta$ mTSS at Wks 26 and 52.

**Conclusion:** Pts on ADA+MTX achieved a first SDAI LDA response earlier than pts on MTX monotherapy, regardless of whether they were MTX-naïve or MTX-IR. More pts with a very early response went on to achieve SDAI REM at 1 yr. However, pts with a longer time (>6 mths) to their first SDAI LDA response had comparable clinical, functional and radiographic outcomes compared to pts who responded earlier (within 3 or 6 mths). Therefore, achieving a clinical response in the direction of the treatment target, even if not yet achieving it, may be sufficient to continue therapy in appropriate pts.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Low dose glucocorticoids (GCs) are recommended in combination with  $\geq 1$  synthetic DMARDs as part of the initial treatment strategy in rheumatoid arthritis (RA), with taper recommended as quickly as is clinically feasible<sup>1</sup>. The purpose of this analysis was to evaluate the ability of patients (pts) with early RA receiving MTX monotherapy or adalimumab (ADA)+MTX to taper and discontinue low-dose GCs and associated impact on outcomes.

**Methods:** This post hoc analysis included MTX naïve pts receiving PBO+MTX or ADA+MTX in the double-period OPTIMA trial. Pts achieving stable low disease activity (sLDA; DAS28 <3.2 at wks 22 and 26) during the first 26 wks (P1) continued blinded therapy (MTX, ADA continuation) for an additional 52 wks (P2). PBO+MTX pts not achieving sLDA were offered open-label (OL) ADA+MTX in P2 (OL ADA rescue). Pts receiving GCs ( $\leq 10$  mg/d) at baseline (BL) continued a stable dose through P1; tapering  $\leq 1$ mg/EOW was permitted in P2. Pts were categorized by GC use in each treatment group. The proportions of pts discontinuing GC were summarized. Outcomes were assessed as change from wk 26 to wk 78. Adverse events (AEs) were summarized.

**Results:** Of the 926 pts who entered P2 (RA disease duration ~4 months), 207/460 (45%) and 188/466 (40%) in the initial PBO+MTX and ADA+MTX groups, respectively, had GC treatment at BL. BL characteristics appeared similar between pts receiving and not receiving GCs. In P1, the proportions of pts achieving sLDA between those receiving and not receiving GCs in the PBO+MTX group were similar (51% without and 49% with GCs), while in the ADA+MTX group a higher proportion of pts achieved sLDA without GCs (58% without vs 42% with GCs). At the beginning of P2, 54/112 (48%) and 45/105 (43%) pts in the MTX and ADA continuation groups, respectively, were on GCs; 145/348 (42%) pts in the OL ADA rescue group received GCs. Of these pts, equal proportions [57% (n=31), 56% (n=25), and 57% (n=83) from the MTX continuation, ADA continuation, and OL ADA rescue groups, respectively] discontinued GCs during P2. Although slight increases in disease activity were observed, GC discontinuation across the different groups did not result in clinically meaningful changes through wk 78 (**Table**). Within the 3 P2 treatment groups, the AE profile appeared similar between those receiving and not receiving GCs.

**Conclusion:** Approximately 60% of early RA pts receiving PBO+MTX or ADA+MTX along with GCs whose treatment was modified based on attainment of sLDA were able to discontinue their GC use without clinically meaningful worsening in disease activity, structural damage or decreases in function. As the current analysis is limited by its retrospective, uncontrolled nature, further studies are needed to prospectively evaluate the ability of pts with early RA to taper or discontinue GCs.

## Tofacitinib Monotherapy Improves Arterial Stiffness in Conventional Dmards Active Rheumatoid Arthritis Patients. a Cohort Study

**Kensuke Kume**<sup>1</sup>, Kanzo Amano<sup>2</sup>, Susumu Yamada<sup>1</sup>, Toshikatsu Kanazawa<sup>3</sup> and Kazuhiko Hatta<sup>4</sup>, <sup>1</sup>Rheumatology, Hiroshima Clinic, Hiroshima, Japan, <sup>2</sup>rheumatology., hiroshima clinic, Hiroshima, Japan, <sup>3</sup>rheumatology, hiroshima clinic, hiroshima, Japan, <sup>4</sup>Rheumatology, Hatta Clinic, Kure, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with rheumatoid arthritis (RA) have an increased cardiovascular (CV) risk. We should have strategies for primary cardiovascular prevention in RA. We reported Tofacitinib(Tofa) plus methotrexate improve arterial stiffness in RA. How about Tofa monotherapy. To examine the effect of Tofa monotherapy on arterial stiffness with CV disease in conventional DMARDs resistant RA patients in a cohort study design.

**Methods:** 16 RA patients with moderate to severe active disease despite conventional DMARDs treatment (disease activity score: DAS28>3.2) were received Tofa monotherapy. Arterial stiffness was assessed with cardio-ankle vascular index (CAVI) and augmentation index corrected for a heart rate of 75 beats per minute (Aix@75) at baseline and 24 weeks follow-up. Clinical data were collected at regular visits. CAVI is very similar to pulse wave velocity (PWV), and CAVI measures arterial wall stiffness independent of blood pressure and it is superior to brachial ankle PWV as an index of arterial stiffness.No new all treatments(statin, low lipids drug, and etc.) were allowed.

**Results:** Treatment with Tofa monotherapy attenuated the CAVI significantly from baseline to 24 weeks follow up( $13.62 \pm 1.96$  and  $11.44 \pm 1.65\%$ ;  $p = 0.021$ ). Treatment with Tofa monotherapy attenuated the Aix@75 significantly from baseline to 24 weeks follow up( $38.7 \pm 11.6$ ,  $35.2 \pm 8.6\%$ ;  $p = 0.024$ ). DAS 28-ESR score improved significantly from baseline to 24 weeks( $5.56 \pm 1.29$ ,  $2.61 \pm 1.45$ ;  $p = 0.01$ ). On the other hand, fasting serum total cholesterol TC was significantly increased from baseline to follow-up at 24 weeks ( $187 \pm 28.2$ mg/dL,  $209 \pm 19.8$ mg/dL,  $p = 0.021$ ). No patients suffered from new CV disease.

**Conclusion:** These findings suggest that Tofa monotherapy not only reduced RA disease activity but also limited vascular damage despite up-regulating cholesterol in patients conventional DMARDs resistant active RA, as well as Tofa plus methotrexate.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Background/Purpose:** Steroids are used to reduce inflammation and pain among rheumatoid arthritis (RA) patients, but they can cause harmful side effects, and in some patients, difficulty to discontinue/taper the dose. Adalimumab (ADA) has been shown to be effective in treating RA patients with a well-established safety profile. The objective of this study was to determine if patients on ADA treatment were able to discontinue or lower the dose of steroids post-ADA initiation.

**Methods:** Biologic naïve RA patients who initiated ADA after 2008, and with at least 6 months of continuous therapy were included in the study. The difference in mean steroid dose from ADA initiation (baseline) to 6 months was evaluated for all ADA initiators and by type of therapy (monotherapy/combination therapy with methotrexate). Paired t-tests were used to compare changes. The distribution of steroid dose categories (0 mg, >0 to 5 mg, >5 to 10 mg, >10 to 15 mg and >15 mg) at baseline and 6 months was also described and stratified by ADA monotherapy and combination therapy. Descriptive characteristics at baseline were examined; appropriate tests of comparisons (1-way ANOVA/chi-square/Kruskal-Wallis) were used to compare across type of therapy.

**Results:** Among 713 biologic naïve ADA initiators who were eligible to participate in the study, 239 (34%) used steroids during the 6 month follow up period: 109 at initiation only, 94 at initiation and follow-up, and 38 at follow-up only. The mean (SD) age of the study population was 55.4 (12.3) years, 73% were female, and the mean (SD) disease duration was 5.1 (7.4) years. Mean (SD) clinical disease activity index at baseline was 20.1 (14.9), with ~70% in moderate/severe disease activity (CDAI>10) and a mean (SD) functional disability index score of 0.5 (0.5) as measured by the modified health assessment questionnaire. Mean steroid dose at baseline was 6.1 mg (6.1) and over the 6 months of therapy, the steroid dose reduced to a mean (SD) dose of 3.6 mg (5.0), with a mean (SD) change of 2.5 mg (8.0) (p<0.0001). Similar dose reductions were seen in ADA monotherapy and combination therapy groups (data not shown). As seen in the table below, approximately 53% of the 201 patients who were on steroids at ADA initiation were able to discontinue the steroid by 6 months.

**Conclusion:** In this real world study of ADA initiators, approximately half of the patients who received concomitant steroids at initiation were able to discontinue the steroid by 6 months. For those who continued steroids at 6 months, patients were on average able to significantly reduce their dose.

**Figure. Distribution of steroid dose at ADA initiation vs steroid dose at the 6-month follow-up visit for all initiators (N=239)**

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are limited data regarding the impact of tocilizumab (TCZ) treatment on prednisone use in patients with rheumatoid arthritis (RA). The objective of this study was to examine prednisone use among US patients with RA who initiated TCZ in routine clinical practice, overall and stratified by initiation of TCZ as monotherapy (TCZ mono) or in combination with a conventional synthetic DMARD (csDMARD; TCZ combo).

**Methods:** TCZ-naïve patients enrolled in the Corrona RA registry (NCT01402661) who initiated TCZ on or after January 1, 2010; had a 12-month follow-up visit without discontinuation of TCZ and had prednisone dose information available at the time of TCZ initiation (baseline) and follow-up were included. Outcomes included the proportion of patients with changes in prednisone use (initiation, discontinuation, dose escalation or reduction  $\geq 5$  mg) and change in Clinical Disease Activity Index (CDAI) score at 12 months. Outcomes were assessed in the overall population and stratified by initiation of TCZ mono or TCZ combo. Baseline patient characteristics were compared between the TCZ mono and TCZ combo groups using 2-sample *t* tests or Wilcoxon rank-sum tests for continuous variables and chi-square or Fisher exact tests for categorical variables.

**Results:** Of the 648 eligible patients, 29% initiated TCZ mono and 71% initiated TCZ combo. Patients who initiated TCZ mono were older (mean age, 60.5 vs 57.9 years;  $P = 0.01$ ), weighed less (mean weight, 174.0 vs 184.4 pounds;  $P = 0.01$ ), were less likely to have private insurance (71.8% vs 79.3%;  $P = 0.04$ ) and had used fewer csDMARDs ( $P < 0.001$ ) and tumor necrosis factor inhibitors ( $P = 0.03$ ) compared with TCZ combo. At baseline, 222 patients (34.3%) were receiving prednisone and 426 (65.7%) were not. Changes in prednisone use, including discontinuation and dose reduction  $\geq 5$  mg, were observed within 6 months after TCZ initiation. Of the patients on prednisone at baseline, 30.6% had discontinued prednisone and 13.1% had decreased the dose after 12 months of TCZ therapy (**Table 1**). Of those not on prednisone at baseline, only 8.5% initiated prednisone over 12 months of TCZ therapy (**Table 1**). Changes in prednisone use were not different between TCZ mono and TCZ combo, and there were no differences in CDAI improvement between patients using prednisone vs not using prednisone at baseline, overall or stratified by TCZ mono vs TCZ combo (**Table 1**).

**Conclusion:** A considerable proportion of patients initiating TCZ were able to discontinue or lower the dose of prednisone over 12 months. Changes in prednisone use were observed within 6 months after TCZ initiation, were similar regardless of whether TCZ was administered as monotherapy or in combination with csDMARDs and did not result in differences in the observed decrease in disease activity.

**Table 1.** Distribution of Prednisone Use and Change in CDAI Score at 12 Months in Patients With RA Who Initiated TCZ as Monotherapy or With a csDMARD

Baseline Prednisone Use	Prednisone Use				Disease Activity
	No Change, n (%) <sup>*</sup>	Increased Dose by ≥ 5 mg, n (%)	Decreased Dose by ≥ 5 mg, n (%)	Discontinued, n (%)	Change in CDAI Score, mean (SD)
<b>All TCZ initiators (N = 648)</b>					
Not on prednisone (n = 426; 65.8%)	390 (91.5)	36 (8.5)	N/A	N/A	-9.9 (13.5)
On prednisone (n = 222; 34.2%)	115 (51.8)	10 (4.5)	29 (13.1)	68 (30.6)	-10.3 (14.7)
<b>TCZ monotherapy initiators (n = 188; 29.0%)</b>					
Not on prednisone (n = 124; 66.0%)	105 (84.7)	19 (15.3)	N/A	N/A	-11.0 (12.9)
On prednisone (n = 64; 34%)	30 (46.9)	1 (1.6)	9 (14.1)	24 (37.5)	-11.3 (12.6)
<b>TCZ + csDMARD initiators (n = 460; 71.0%)</b>					
Not on prednisone (n = 302; 65.7%)	285 (94.4)	17 (5.6)	N/A	N/A	-9.4 (13.8)
On prednisone (n = 158; 34.3%)	85 (53.8)	9 (5.7)	20 (12.7)	44 (27.8)	-9.8 (15.5)

CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic disease-modifying antirheumatic drug; N/A, not applicable; RA, rheumatoid arthritis; TCZ, tocilizumab.

<sup>\*</sup>Includes patients with changes in dose of < 5 mg.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In patients with RA, low-dose glucocorticoids (GCs) have been shown to increase clinical, functional and radiographic efficacy when combined with conventional synthetic DMARDs;<sup>1</sup> however, evidence for potentiation of bDMARD efficacy is lacking. The objective was to assess the impact of low-dose GCs on the efficacy of SC abatacept or adalimumab in biologic-naïve patients with active RA and inadequate response to MTX enrolled in the AMPLE trial (NCT00929864).<sup>2,3</sup> **Methods:** In this *post hoc* analysis, efficacy outcomes were compared based on GC therapy at baseline (≤10 mg/day vs no GC) in patients receiving abatacept or adalimumab. Outcomes assessed were: mean change from baseline in DAS28 (CRP), HAQ-DI and modified total Sharp score (mTSS) over time; CDAI and SDAI remission rates, proportion of patients with DAS28 (CRP) <2.6 and with improvement in HAQ-DI score ≥0.3, and radiographic non-progression rates (TSS ≤ SDC [2.2 points]) at Years 1 and 2. **Results:** The analysis included 317/318 patients treated with abatacept + MTX (161 GC, 156 no GC) and 326/328 treated with adalimumab +

MTX (162 GC, 164 no GC). Baseline demographics and adverse events during follow-up were similar across groups. At baseline, patients treated with GC had more severe radiographic disease (mean [SD] TSS: abatacept/GC 23.9 [37.9] vs abatacept/no GC 15.8 [26.9], adalimumab/GC 22.8 [32.6] vs adalimumab/no GC 15.6 [23.7]). Baseline disease activity (mean [SD] DAS28 [CRP]) was similar across groups: abatacept/GC 5.7 (1.1) vs abatacept/no GC 5.3 (1.2), adalimumab/GC 5.6 (1.1) vs adalimumab/no-GC 5.5 (1.1). Mean change (95% CI) from baseline in DAS28 (CRP) was significantly greater in the abatacept/GC than in the abatacept/no-GC subgroup at Month 6 (−2.24 [−2.45, −2.04] vs −1.94 [−2.14, 1.74];  $p=0.0293$ ), but not at Year 1 or 2, and did not differ significantly by GC treatment in adalimumab-treated patients. The proportions of patients in CDAI or SDAI remission or with DAS28 (CRP) <2.6 were similar in GC and no GC subgroups for both treatments (Figure). Radiographic progression rates at Years 1 and 2 and mean change from baseline in mTSS over 2 years were the same regardless of GC use. The proportion of patients with improvement in HAQ-DI score  $\geq 0.3$  was higher in the abatacept/GC subgroup than the abatacept/no GC subgroup at 6 months (70.47 vs 57.64%;  $p=0.0289$ ) but not at later time points and was not seen in adalimumab-treated patients.

**Conclusion:** The use of low-dose GC with abatacept or adalimumab in RA patients with inadequate response to MTX has no impact on short-term and medium-term outcomes. This finding could be because patients who entered this trial had active disease despite background GC use and they responded to the addition of an active medication.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many treatment options are currently available to patients with rheumatoid arthritis (RA), including tumor necrosis factor inhibitors (TNFi's). While combination therapy of TNFi's or other biologics with a conventional synthetic disease-modifying antirheumatic drug (csDMARD; commonly methotrexate, leflunomide, sulfasalazine, or hydroxychloroquine) is thought to be the most effective treatment option, few studies have examined changes in treatment initiation over time. This study describes RA treatment patterns among patients newly initiated on biologic and non-biologic therapy over time.

**Methods:** This retrospective, cohort study included adult patients with RA enrolled in the Corrona RA registry who initiated monotherapy with a biologic or csDMARD or combination therapy between January 1, 2004, and December 31, 2015. Patients were required to have  $\geq 6$  months of follow-up time after initiation of therapy, with at least one follow-up visit. Patients could belong to one of five cohorts: TNFi monotherapy, other biologic monotherapy, csDMARD monotherapy, combination therapy with TNFi + csDMARD, or combination therapy with other biologic + csDMARD. Cohorts were defined by the first treatment initiation after enrollment into Corrona and were mutually exclusive. The primary outcome of interest was time on therapy. Time periods of interest were 2004-2007, 2008-2011, and 2012-2015; these were based on the year of enrollment into Corrona. Data were analyzed descriptively by cohort.

**Results:** There were 8,027 patients in this analysis. Overall, the majority of patients were female (77%), white (82%), and biologic-naïve (60%), with mean (SD) duration of RA 7.9 (9.2) years. 9.6%, 4.6%, 37.2%, 37.6%, and 11.0% of patients initiated TNFi monotherapy, other biologic monotherapy, csDMARD monotherapy, combination therapy with TNFi + csDMARD, and combination therapy with other biologic + csDMARD, respectively. Over time, treatment initiation between monotherapy and combination therapy has not changed: about half of patients initiated monotherapy and half combination therapy, mostly TNFi + csDMARD (Table). Mean CDAI at treatment initiation has remained similar within the TNFi monotherapy cohort over the three time periods. Patients who initiated csDMARD monotherapy had the lowest CDAI at treatment initiation, while TNFi and other biologic monotherapy and both combination therapy cohorts had comparable CDAI. Time on drug has remained stable for TNFi monotherapy and decreased for all other cohorts; in the most recent time period, time on drug was similar among all cohorts.

**Conclusion:** In the Corrona registry, over time, treatment initiation between monotherapy and combination therapy has changed little. Mean time on drug has decreased over time, likely due to the availability of more treatment options and/or the emphasis on achievement of treat-to-target goals.

**Table. Disease Activity, RA Duration, and Persistence Among Different Therapy Cohorts Over Time**

		Monotherapy						Combination therapy						Total
Time period		TNFi		Other biologic		csDMARD		TNFi/csDMARD		Other biologic/csDMARD		n

## Higher Levels of Interleukin-6 As Well As Soluble Interleukin-6 Receptor Leads to Worse Clinical and Radiographic Prognosis in Rheumatoid Arthritis Patients Treated with Tocilizumab

Naoshi Nishina, Yuko Kaneko, Keiko Yoshimoto and Tsutomu Takeuchi, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** We have already reported that baseline levels of soluble interleukin-6 receptor (sIL-6R), target of tocilizumab, predicted response to tocilizumab treatment in rheumatoid arthritis (RA) patients. However, there is a report that interleukin (IL)-6 is also one of predictors. The aim of this study is to investigate the association of baseline levels of both IL-6 and sIL-6R with clinical and radiographic response to tocilizumab in patients with RA.

**Methods:** Consecutive RA patients at our institution who received tocilizumab as the first biologic agent from April 2010 to April 2013 were included. Serum levels of sIL-6R and IL-6 were measured by electrochemiluminescence assay at week 0, 4, 24, and 52. According to baseline levels of sIL-6R and IL-6, patients were divided into 3 groups using K-means clustering. Clinical response and radiographic progression were compared among the 3 groups. Differences among 3 groups were analyzed by analysis of variance (ANOVA)

**Results:** Fifty six patients were enrolled. Distribution of sIL-6R and IL-6 at week 0 is shown in Figure 1 and the clusters were named as Group 1, 2 and 3. Mean levels of sIL-6R and IL-6 of Group 1 (n=29) were 46.2 ng/mL and 3.9 pg/mL; Group 2 (n=7), 65.4 ng/mL and 32.8 pg/mL; and Group 3 (n=20), 100.4 ng/mL and 5.6 pg/mL, respectively. Baseline characteristics were comparable among the groups except for RA activity. Mean disease activity score (DAS28-ESR) was higher in Group 2 compared to Group 1 and 3 (4.9 vs 6.2 vs 5.0 for Group 1, 2, and 3, respectively;  $p=0.02$  by ANOVA). Time course of mean DAS28-ESR is shown in Figure 2. Although significant difference was observed only at week 24, mean DAS28-ESR of Group 2 tended to be higher than those of Group 1 and Group 3 ( $p=0.21$ ,  $0.02$ , and  $0.08$ , respectively at week 4, 24, and 52). Mean yearly progression of van der Heijde modified total Sharp score was worse in Group 2 but without statistical significance ( $0.2$  vs  $2.1$  vs  $0.2$ , for Group 1, 2, and 3, respectively;  $p=0.07$ ) as shown in Figure 3.

**Conclusion:** Despite lower levels of sIL-6R, patients with very high levels of IL-6 showed worse clinical and radiographic response to tocilizumab in RA. IL-6 as well as sIL-6R could be strong indicators for the effectiveness of tocilizumab.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Lymphopenia is a frequent feature of RA,<sup>1</sup> and RA medications may also affect absolute lymphocyte count (ALC). Previous analyses showed an increased rate of serious infection (SI) in tofacitinib-treated patients (pts) whose ALCs were <500 cells/mm<sup>3</sup>, which was the basis for the recommendation to adopt the ALC <500 cells/mm<sup>3</sup> threshold for treatment discontinuation. Here we describe the association between ALC and infection events in the tofacitinib RA clinical development program.

**Methods:** Data were pooled from pts in 19 RA studies (2 Phase [P] 1; 9 P2; 6 P3; 2 long-term extension [LTE] studies [1 LTE ongoing at time of analysis; database not locked at March 2015 cut-off]) across all tofacitinib doses (1, 3, 5, 10, 15, 30 mg twice daily and 20 mg once daily). Exposure-adjusted incidence rates (IRs; pts with event/100 pt-years) and 95% confidence intervals (CIs) for SIs, opportunistic infections (OIs), and herpes zoster (HZ; all reported cases, both serious and non-serious) were calculated for ALC categories: ≥2000, ≥1500–<2000 (normal reference range), ≥1000–<1500, ≥750–<1000, ≥500–<750, and <500 cells/mm<sup>3</sup>. Numbers needed to harm (NNH) were calculated as reciprocals of the differences in IRs relative to the ALC ≥1500–<2000 category.

**Results:** Of the 6194 pts (tofacitinib exposure: 19,229 pt-years) in this analysis, 527 (8.5%) reported SIs (IR 2.74 [95% CI: 2.51, 2.98]). The IR for SI in pts with normal ALC (≥1500–<2000 cells/mm<sup>3</sup>) was 2.49 (2.06, 2.98). IRs were similar in pts with ALC ≥750–<1500 cells/mm<sup>3</sup>, but increased by 75% to 4.36 (3.10, 5.96) and by 234% to 8.31 (3.05, 18.10) for ALCs ≥500–<750 and <500 cells/mm<sup>3</sup>, respectively, relative to pts with normal ALC (Figure); however, CIs were wider in the ≥500–<750 and <500 cells/mm<sup>3</sup> ALC categories due to smaller pt numbers. For all ALC categories except <500 cells/mm<sup>3</sup>, IRs for SI with tofacitinib were within the range of published rates for biologic DMARDs (3.04–5.45).<sup>2</sup> For NNH, 179 and 53 more pts in the ≥750–<1000 and ≥500–<750 cells/mm<sup>3</sup> categories, respectively, would need to be treated to experience 1 additional SI event compared with pts with ALC ≥1500 cells/mm<sup>3</sup>. A similar pattern was observed with IRs for OI (0.21 [0.10, 0.38] for normal ALC vs 0.89 [0.38, 1.76] and 1.39 [0.04, 7.75] for ALCs ≥500–<750 and <500 cells/mm<sup>3</sup>, respectively). There was a trend for increased HZ risk with decreased ALC; IR differences between ALC categories were <2-fold with overlapping CIs and did not inform the selection of an appropriate ALC threshold.

**Conclusion:** These findings support the recommendation to discontinue tofacitinib in pts with ALC <500 cells/mm<sup>3</sup> to decrease the risk of SI. Discontinuation at higher thresholds results in further decreases in SI incidence but also excludes a larger number of pts who will not develop a SI.

## Discovery and Characterization of JNJ-61178104, a Bispecific Antibody Against Human Tumor Necrosis Factor (TNF) Alpha and Interleukin (IL)-17A

Fang Shen<sup>1</sup>, Jennifer F. Nemeth<sup>2</sup>, Brian Jones<sup>1</sup>, Ann Cai<sup>1</sup>, Shannon Hitchcock<sup>3</sup>, Thai Dinh<sup>2</sup>, Ravi Malaviya<sup>1</sup> and Tatiana Ort<sup>1</sup>,

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Tumor necrosis factor alpha (TNFα) and interleukin (IL)-17A are pleiotropic cytokines implicated in the pathogenesis of several autoimmune diseases including Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA). It has been suggested that TNFα and IL-17A drive independent actions on cellular inflammatory responses resulting in significantly increased proinflammatory mediator

output. Targeting both TNF $\alpha$  and IL-17A has been proposed to have potential to achieve better and long lasting efficacy with a favorable safety profile in RA and PsA.

#### Methods:

JNJ-61178104 is a novel human anti-TNF- $\alpha$  and anti-IL-17A bispecific antibody. The affinities of JNJ-61178104 binding to TNF $\alpha$  and IL-17A were assessed by surface plasmon resonance. The functional activity of JNJ 61178104 was evaluated in several preclinical cell based assays to characterize neutralization in the conditions where only one or both cytokines were present. Given the bispecific nature of JNJ-61178104, the ability to neutralize both TNF $\alpha$  and IL-17A simultaneously was assessed in a co-culture model. To evaluate pharmacodynamics (PD) activity of JNJ-61178104 *in vivo*, Balb/c mice were treated with intranasal instillation of TNF $\alpha$  and IL-17A to induced acute lung inflammation. Proinflammatory cytokine production was assessed by ELISA and cellular influx was enumerated in lung lavage.

#### Results:

JNJ-61178104 binds to both TNF $\alpha$  (KD= 1.88~2.11 x 10<sup>-11</sup> M) and IL-17A (KD= 2.20~4.53 x 10<sup>-11</sup> M) with high affinity and inhibits binding of human TNF $\alpha$  to its receptors (IC<sub>50</sub> = 0.92~1.96 nM) or human IL-17A to IL-17RA receptor (IC<sub>50</sub> = 1.18 nM). JNJ-61178104 also potently neutralizes soluble TNF $\alpha$  (IC<sub>50</sub> = 0.22~1.33 nM), transmembrane TNF $\alpha$  (IC<sub>50</sub> = 0.74 nM), IL-17A- and IL 17A/F heterodimer (IC<sub>50</sub> = 0.32~3.06 nM) -mediated responses in multiple cell based assays.

In a co-culture system consisting of human synovial-like-fibroblast cells isolated from an RA donor and activated human Th1/Th17 cells, either parental anti-TNF $\alpha$  antibody or parental anti-IL-17A antibody only partially inhibit cytokines production, while JNJ-61178104 inhibited IL-6 and GRO $\alpha$  production in a dose dependent manner similarly to the combination of parental antibodies.

In the acute pharmacodynamics model, while the parental anti-TNF $\alpha$  antibody or parental anti-IL-17A antibody dosed at 10 mg/kg partially attenuated cell accumulation in the lung, treatment with the JNJ 61178104 at 1 mg/kg, 3 mg/kg, and 10 mg/kg resulted in a significant, dose dependent inhibition of cell influx, with a near complete ablation of total cells/neutrophils in the lung with the highest dose of 10 mg/kg.

#### Conclusion:

Overall, JNJ-61178104 demonstrated potent functional neutralization of both TNF $\alpha$  and IL-17A driven inflammatory responses *in vitro* and *in vivo* preclinical models. Favorable pharmacological profile of JNJ-61178104, i.e., along with significant clinical experience with both TNF $\alpha$  and IL-17A pathways in RA and PsA subjects support the clinical investigation of JNJ-61178104 in autoimmune and inflammatory disease.

## Incidence Rates of Adverse Events with Death As an Outcome during Abatacept Treatment in RA: Results from an Integrated Data Analysis from 16 Clinical Trials

D Fleming<sup>1</sup>, TA Simon<sup>1</sup>, A Torbeyns<sup>2</sup>, U Meier-Kriesche<sup>1</sup> and A Johnsen<sup>1</sup>, <sup>1</sup>Bristol-Myers Squibb, Princeton, NJ, <sup>2</sup>Bristol-Myers Squibb, Braine l'Alleud, Belgium

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with RA have a 1.5–2-fold increased risk of mortality compared with the general population. The association between mortality rates and different RA treatments has been investigated: increased (glucocorticoids),<sup>1</sup> decreased (MTX),<sup>2</sup> and no impact of treatment on mortality (TNF inhibitors)<sup>3</sup> have been reported. To date, the impact of treatment with the selective T-cell co-stimulation modulator abatacept on mortality across clinical trials have not been comprehensively reported.

**Methods:** The risk of mortality in adult patients with RA treated with abatacept was investigated using an integrated safety database, which included 16 short- and long-term clinical trials of both SC and IV abatacept (N=7044). Of the 16 trials in this analysis, 9 were double-blind (DB), placebo-controlled studies (n=4138; non-biologic DMARD was a background therapy for all patients). Incidence rates (IRs) (95% CI) per 100 person-years (p-y) of deaths were calculated as the number of patients experiencing an event with death as the outcome divided by the total number of p-y of exposure. The p-y of exposure was censored at the time of onset of the first event with an outcome of death, discontinuation, or end of study. **Results:** Most patients were women; mean duration of RA was 8 years and <10% had a history of a prior biologic therapy (Table 1). During the DB, controlled period, IRs for overall deaths were 0.5 and 1.0 in the abatacept and placebo groups, respectively, with overlapping 95% CIs (Table 2). The most frequent causes of death were in the cardiovascular and infection System Organ Classes. In the cumulative population on abatacept, the most frequent causes of death were pneumonia (IR [95% CI]: 0.09 [0.05, 0.14]) and cardiac arrest (0.05 [0.03, 0.09]). IRs were similar with overlapping 95% CIs within each age group, with the highest IR in patients aged >65 years (1.73 [1.3, 2.3]), as expected. These rates are within the ranges reported in the literature.

**Conclusion:** The data from this ongoing assessment of abatacept safety are consistent with the current known benefit–risk profile of abatacept. In the DB phases, the overall IRs of death (95% CI) were 0.5 (0.3, 0.9) on abatacept and 1.0 (0.5, 1.6) on placebo. In the cumulative abatacept population, IR was 0.7 (0.5, 0.8), similar to both the DB population and published literature.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A recent US-study suggests considerable underuse of MTX and too early switches to biologic (b)DMARDs<sup>1</sup> before using a high MTX dose or changing the route of administration. We investigated doses of MTX, route of administration and time to treatment escalation with bDMARDs in Germany.

**Methods:** The biologics register RABBIT (*R*heumatoid *A*rthritis: *O*bservation of *bi*ologic *th*erapy) comprises a control group of patients who were enrolled when starting csDMARDs after failure of at least one csDMARD therapy (mostly MTX monotherapy). We selected n=1,608 patients starting either with MTX monotherapy, MTX + another csDMARD or triple therapy (MTX plus hydroxychloroquine and sulfasalazin). In a sub-cohort of patients recruited between 2009 and 2013 (n=1,151) information about the route of administration was available.

**Results:** 1,210 patients (75.2%) were enrolled at start of MTX plus another csDMARD, 356 patients (22.1%) starting MTX monotherapy and 42 patients (2.6%) with triple therapy. The proportions of male and seropositive patients were higher in MTX combination and triple therapy (p<0.05). Disease severity (DAS28) at baseline and physical function were not significantly different. Larger differences were found in the sub-cohort: patients treated with subcutaneous (sc) MTX were significantly younger, had a higher DAS28, higher doses of glucocorticoids (GC) and less physical function at baseline (p<0.01).

Overall, 266 (16.5%) patients were escalated to a bDMARD within the 1<sup>st</sup> year of observation. Only 53 patients (3.3%) switched to a bDMARD within 3 months after enrollment; without an impact of calendar time (p=0.23). In recent years, escalation to bDMARD therapy occurred earlier (Fig. 1). The median time to a bDMARD was highest (p<0.01) in MTX monotherapy (366d) compared to MTX combination (266d) and triple therapy (150d).

In year one, the average doses of MTX did not vary between the treatment regimens: MTX mono (15.2mg), combination (15.6mg), triple (15.0mg). In patients who switched to a bDMARD, 28.2% 95%CI [23.0; 34.1] had prior high doses (>20 mg) of MTX and 54.1% [47.9; 60.2] had GC doses ≥5 mg/d which was significantly higher than in patients who maintained csDMARD therapy (MTX >20mg: 17.7% [15.7;19.9], GC ≥5mg: 32.3% [29.8; 34.9]). Stratified by route of administration, doses were significantly higher with sc MTX (16.8mg [16.4; 17.1]) vs. oral (14.8mg [14.5; 15.1]) but more patients (p<0.01) with sc MTX (21.6%) were switched to a bDMARD compared to oral MTX (10.9%).

### Conclusion:

Our data suggest that German rheumatologists use different strategies after insufficient response to MTX before switching to a bDMARD: MTX dose increase, change to sc MTX, combination with other csDMARDs or increase in GC dose. The results of the US-study<sup>1</sup> could not be confirmed.

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Targeted blockade of TNF has been a major advance in the treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). However, many patients lose response to a TNF inhibitor. One possible mechanism for this is development of anti-drug antibodies (ADAb).

However, there is no standardised assay for detection of ADAb. It can be difficult to determine if ADAb have *in vivo* neutralising ability. Serum trough drug levels may be a more robust biomarker. We sought to determine if serum trough levels of adalimumab (ADL) correlated with disease activity in patients with RA, PsA and AS.

### Methods:

## Methods:

This was a prospective observational cohort study in bDMARD-naïve patients aged 18-80 yo with RA, PsA and AS commencing ADL. Serum samples were collected 24 hours before a dose of ADL at baseline and months 4, 10 and 16. GRIFOLS Proteomika – Promonitor™ ELISA assays were used to determine serum trough drug levels. These were correlated with the following measures: DAS28, SDAI, RAPID3, CRP, ESR for RA and PsA; and BASDAI, ASDAS, CRP, ESR for AS. Samples with a serum trough ADL level <0.01 µg/ml were assayed for ADAb.

Spearman correlation coefficients (rho values) and multiple regression analysis were used to assess relationship between variables. The significance threshold was set at  $p < 0.05$  (2-tailed).

## Results:

There was a negative correlation between serum trough ADL levels and DAS28 ( $r =$

$-0.73$ ,  $p = 0.001$ ) and SDAI ( $r = -0.50$ ,  $p = 0.05$ ) in RA patients ( $n = 7$ ). Disease remission ( $\text{DAS28} < 2.6$ ) was associated with a serum trough ADL  $> 5$  µg/ml. A negative correlation was found between serum trough ADL levels and BASDAI

( $r = -0.52$ ,  $p < 0.001$ ), ASDAS-ESR ( $r = -0.47$ ,  $p < 0.001$ ) and ASDAS-CRP ( $r = -0.48$ ,  $p < 0.001$ ) in patients with AS ( $n = 22$ ). A serum trough ADL level of 5-8 µg/ml was associated with lower ASDAS-ESR and ASDAS-CRP scores. Of the 32 blinded samples with a serum trough ADL  $< 0.01$  µg/ml, 26 were found to be baseline samples (ie, prior to ADL exposure). Of the remaining (non-baseline) samples, 5 had ADAb (mean  $\pm$  sem:  $386 \pm 158$  IU/ml) while 1 had no detectable ADAb ( $< 10$  IU/ml).

## Conclusion:

There was a moderately strong negative correlation between serum trough ADL levels and markers of disease activity in RA (DAS28, SDAI) and AS (ASDAS-ESR, ASDAS-CRP, BASDAI). A serum trough ADL level of  $> 5$  mcg/ml was associated with DAS28 remission in RA. A serum trough ADL level of 5-8 mcg/ml was associated with lower ASDAS-ESR and ASDAS-CRP scores. ADAb were present in almost all samples with undetectable serum trough ADL levels. Serum trough drug levels may be useful in dose titration of, or choice of bDMARD.

## The Prognostic Value of IgA Subtypes of Rheumatoid Factor and Anti-Citrullinated Protein Antibodies (ACPA) for Prediction of Therapeutic Responses to TNF Inhibitory Therapy in Patients with Rheumatoid Arthritis

Daniela Sieghart<sup>1</sup>, Farideh Alasti<sup>2</sup>, Paul Studenic<sup>1</sup> and Günter Steiner<sup>2</sup>, <sup>1</sup>Medical University Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria, <sup>2</sup>Rheumatology, Medical University of Vienna, Vienna, Austria

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Rheumatoid factor (RF) and Anti-Citrullinated Protein antibodies (ACPA) are the most specific diagnostic markers of rheumatoid arthritis (RA). These antibodies are predominantly of the IgM (RF) or IgG (ACPA) isotype. The presence of IgA subtypes was reported but their added diagnostic and prognostic value has still not been fully elucidated. It was therefore the

objective of this study to (i) determine the prevalence of IgA-RF and IgA-ACPA in patients with RA and (ii) to investigate their potential predictive value regarding response to treatment with methotrexate (MTX) and TNF inhibitors.

## Methods:

To determine the diagnostic sensitivity and specificity sera from 255 RA patients, 258 disease controls and 100 healthy subjects were tested for the presence of IgA-RF and IgA-ACPA by EliA (Thermo Fisher Scientific). IgM-RF and IgG-ACPA were routinely measured by nephelometry and the anti-CCP EliA, respectively. Therapeutic responses to MTX and TNF inhibitors (TNFi) were analyzed in an inception cohort (n=104) who had started their DMARD therapy at our clinic. To define therapeutic responses simplified disease activity score (SDAI) and American College of Rheumatology (ACR) responses were calculated.

## Results:

Diagnostic specificity was 95% for IgA-RF and 98% for IgA-ACPA, respectively. Among the 255 RA patients, 49% had at least one type of IgA antibody: 45% were IgA-RF positive (as compared to 61% IgM-RF positivity) and 31% were IgA-ACPA positive (56% IgG-ACPA positivity). Importantly, 10.5% of IgA-RF positive patients (i.e. 5% of the total cohort) were negative for IgM-RF (and half of also them for IgG-ACPA) while - apart from two exceptions- all IgA-ACPA positive patients had also IgG-ACPA. Thus, the added diagnostic value of IgA-RF was approximately 5% whereas IgA-ACPA only marginally increased the sensitivity of ACPA testing. Remarkably, the percentage of patients showing a SDAI50 response to TNFi was significantly lower in patients positive for IgA-RF and/or IgA-ACPA ( $p<0.0001$ ) compared to IgA negative patients: while 58% of IgA negative (but IgM-RF and/or IgG-ACPA positive) patients showed a SDAI50 response only 25% of the IgA positive ones were responders. Interestingly, IgA-ACPA positive/IgA-RF negative patients were the poorest responders with only one out of nine patients showing a SDAI50 response whereas 4/13 IgA-RF positive/IgA-ACPA negative patients were responders. Seronegative patients also showed a significantly decreased SDAI50 response ( $p<0.001$ ) to TNFi compared to IgM-RF/IgG-ACPA positive patients without IgA antibodies. Similar results were obtained when ACR20 was used as primary response criteria. Interestingly, no difference between the various groups was seen with respect to treatment with MTX.

**Conclusion:** Apart from a moderate added diagnostic value of IgA-RF, IgA subtypes and particularly IgA-ACPA appear to be strongly associated with a diminished therapeutic response to TNF blocking biological drugs, irrespectively of IgM-RF and IgG-ACPA. Therefore their determination may help in further stratification of RA patients and therapeutic decision making.

## Tailoring Second-Line Biologic Therapy in Rheumatoid Arthritis: New Findings on the Usefulness of Antibody Status to Optimise Drug Selection

**Muhammad Shipa**<sup>1</sup>, Maria Di Cicco<sup>2</sup>, Emese Balogh<sup>2</sup>, Aneela Mian<sup>3</sup>, Dev Mukerjee<sup>4</sup> and Euthalia Roussou<sup>2</sup>, <sup>1</sup>Rheumatology and General internal Medicine, North Middlesex University Hospital NHS trust, London, United Kingdom, <sup>2</sup>Barking Havering and Redbridge University hospitals NHS Trust, London, United Kingdom, <sup>3</sup>Rheumatology, King's College London, London, United Kingdom, <sup>4</sup>Rheumatology, North Middlesex University Trust, London, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Treatment of rheumatoid arthritis (RA) has been revolutionized by the introduction of Tumour Necrosis Factor alpha inhibitors (TNFi). However a significant proportion of patients fails to respond (primary failure) or may lose the initial response over time (secondary failure). Whether a second TNFi or Biologics with Different Mode of Action [ BDMA; Rituximab (RTX), Abatacept (ABT), Tocilizumab (TCZ)] should be used, who had secondary failure still needs to be defined. The aim was to retrospectively compare the efficacy of second TNFi versus BDMA after secondary failure and to investigate whether there was an association between response and antibody status [Rheumatoid Factor (RF) and Anti CCP].

## Methods:

This was a retrospective observational real life data analysis from two hospitals of North-East London serving diverse ethnic population. The list of the RA patients (defined by 2010 ACR/EULAR criteria), who had secondary failure to first line TNFi from 2010 to 2016, was obtained. The study population were randomly selected using 'RESEARCH RANDOMIZER' software. Response to treatment was defined as the achievement of at least moderate response at six months according to EULAR response criteria.

## Results:

A total of 422 patients were included in the analysis: 211 in each group (TNFi and BDMA). Male/female ratio was 1:3 and the mean age was of 61.4 years (SD  $\pm$  12.1). Baseline DAS28 (SD) scores were higher in BDMA group than in the TNFi group: [5.90(0.6) vs 5.20(0.8);  $p < 0.01$ ].

Table 1 describes response rates according to biologic subcategories and autoantibody status. This reflects 74 patients responded to second TNFi (35%) compared to 148 patients who responded in the BDMA group (70%) ( $p < 0.01$ ); Number need to treat (NNT) was 2.9. The response rates were better in seropositive if receiving RTX (85%) or TCZ (68%), while poorer on ABT (46%),  $p < 0.01$ . In contrast, for seronegative patients RTX response was poor (35%), but markedly better response observed on ABT or TCZ (83% and 74% respectively).

Table 1: Comparison between TNFi and different BDMA according antibody status [Rheumatoid Factor (RF) and Anti CCP]

Total (N=422)	TNFi (N=211)	BDMA (N=211)	p Value	RTX (N=99)	ABT (N=55)	TCZ (N=57)	p Value
Responders (%)	74(35%)	148 (70%)	<0.01	74 (75%)	36 (65%)	40 (70%)	0.90
Sero (+) (%) : Sero (-) (%)	134(63%) :77(37%)	130(62%) :81(38%)	0.80	73 (74%) : 26 (26%)	26 (47%) : 29 (53%)	31 (54%) : 26 (46%)	0.01
Sero (+) Responders (%)	48 (36%)	98(75%)	<0.01	62(85%)	12(46%)	21(68%)	<0.01
Sero (-) Responders (%)	26 (34%)	50 (61%)	0.01	9 (35%)	24(83%)	17 (74%)	<0.01

Footnote: Sero (+) = seropositive, Sero (-) = seronegative, N= number.

## Conclusion:

RA patients who had secondary failure to the initial TNFi, had greater response rate (nearly 3:1), if treated with a BDMA instead of another TNFi. Our findings suggest that seropositive patients may be benefitted from switching to RTX or TCZ, meanwhile seronegative patients may do better with ABT or TCZ.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recently, the possibilities that autophagy regulates apoptosis resistance and hyperplasia of fibroblast-like synoviocytes (FLS) were also presented. The aim of this study is to investigate the influence of COX-2 inhibitor on viability of rheumatoid arthritis (RA) FLS and to reveal how COX-2 inhibitor affects the viability of RAFLS.

**Methods:** RA synovial tissue was obtained from patients during total knee replacement surgery or arthroscopy. FLS was cultured with COX-2 inhibitor, caspase inhibitor (z-VAD-fmk), autophagy inhibitor (3-methyladenine; 3-MA), knockdown of si-autophagy protein 5 (Atg5) or si-Bec1. Cell viability was measured by MTS assay and by cell count using trypan blue staining. The expression of autophagy flux was analyzed by western blot and apoptosis activation was measured caspase3/7 activity assay.

**Results:** Synoviocyte from RA patients showed that COX-2 inhibitor attenuated cell proliferation and promoted apoptosis. A kind of COX-2 inhibitor dose-dependently decreased cell viability (IC<sub>50</sub> of 120  $\mu$ M) of RAFLS. COX-2 inhibitor also increased the expression of conversion of LC3-I to LC3-II, Atg5, Beclin1, p62 and decreased expression of lysosomal associated membrane protein 1 (LAMP1) in RAFLS. Combination of autophagy by 3-MA, si-Atg5 or si-Bec1 restored viability of RAFLS by COX-2 inhibitor. COX-2 inhibitor decreased expression of phosphorylation-AKT signaling pathway. And, COX-2 inhibitor-induced autophagic cell death via ROS-dependent effect in RAFLS.

**Conclusion:** Taken together, this study indicated that COX-2 inhibitor induced apoptosis, inhibiting RA-FLS proliferation while promoting autophagic cell death by the PI3K/AKT/mTOR signaling pathway. Then, autophagy regulation may be an effective therapeutic strategy in inflammatory autoimmune disease such as RA.

## Background/Purpose:

Denosumab is a fully human monoclonal antibody (IgG<sub>2</sub> subclass) that inhibits bone resorption by blocking RANKL. Phase 2 (DRIVE) and phase 3 (DESIRABLE) studies demonstrated that denosumab inhibited progression of joint destruction in Japanese patients with rheumatoid arthritis (RA). The results of subgroup analyses of DRIVE study have already been reported in ACR 2014. The subgroup analyses of DRIVE and DESIRABLE studies were undertaken to understand whether denosumab was broadly effective upon progression of the joint destruction in RA patients.

## Methods:

These analyses used pooled data from two randomized, multicenter, double-blind placebo control trials in RA patients treated with denosumab [60 mg every 6 months (Q6M) or 60 mg every 3 months (Q3M)] or placebo. All patients continued conventional synthetic DMARDs (including MTX) and a supplement of calcium and vitamin D throughout the study. The modified total Sharp score (mTSS), the bone erosion score (ES) and the joint space narrowing score (JSN) were assessed by the modified Sharp van der Heijde method. Subgroup analyses were conducted according to risk factors for radiographic damage.

## Results:

A total of 909 patients were included (306 in placebo, 302 in Q6M and 301 in Q3M). Denosumab significantly inhibited the progression of mTSS and ES from baseline to 12 months compared to placebo, whereas denosumab didn't have an effect on JSN. The incidence of adverse events (AEs), serious AEs and AEs leading to discontinuation of study drug were similar among treatment groups. Each subgroup with a specific risk factor for radiographic damage showed consistent results for the mTSS in total group.

Change from baseline in modified total Sharp score at 12 months by subgroups

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Tocilizumab (TCZ) is an effective treatment for rheumatoid arthritis (RA). There is great variability in intravenous (iv) TCZ serum concentrations among individuals. Moreover, initial drug dosage approved by Regulatory Agencies (FDA and EMA) differs. Empirical dose de-escalation strategies are being fostered in patients with disease remission.

The purpose of the study was to examine TCZ serum concentrations at the different prescribed doses in RA. Secondary objectives were to evaluate the relationship between drug serum concentrations and laboratory parameters of disease activity.

## Methods:

Prospective, observational, single-center study conducted in a university tertiary hospital. Enrolled RA patients received iv TCZ at a dose range from 4 to 8 mg/kg every 28 days. Demographic characteristics and clinical laboratory data were obtained at study entry. Blood samples for drug concentration testing were collected from the third TCZ dose onwards, just before TCZ infusion and, when possible, once a week until the next drug administration.

## Results:

A total of 35 patients (88.6% women, 80% Caucasian) were included. Mean age  $\pm$  SD was  $54.1 \pm 12.3$  and the median [range] of disease duration was 11.1 [2.9-48.5]. Median [range] treatment duration with iv TCZ was 36.5 [3-68] months. 54% of patients received the standard dose of 8 mg/kg whereas the rest received reduced doses (23% were on 6 mg/kg and 23% on 4 mg/kg) due to persistent remission/low disease activity. 20 patients (57.1%) were being treated with low steroid dose and 24 (68.6%) were on concomitant DMARD, mainly methotrexate.

Regarding drug concentration testing, a total of 109 samples were obtained. Nineteen patients participated to multiple drug sampling between two drug administrations and in the 17 remaining patients, a pre-dose sample was drawn. Mean TCZ concentrations are displayed in table 1. No significant differences were observed in median pre-dose TCZ concentration values (54 samples) between patients on 8 and 6 mg/kg whereas significant lower drug levels were observed in those taking 4 mg/kg.

According to inflammatory parameters, mean C-reactive protein (CRP) concentration was significantly lower in those patients with trough TCZ concentrations  $>1 \mu\text{g/mL}$  compared to those  $<1 \mu\text{g/mL}$  (0.066 mg/dL vs 0.689 mg/dL, respectively;  $p<0.001$ ). This difference was not observed with calprotectin serum concentrations (2.260  $\mu\text{g/mL}$  vs 2.143  $\mu\text{g/mL}$ ).

## Conclusion:

Trough TCZ serum concentrations do not differ between patients on an 8 and 6 mg/kg regimen. Therefore, according to the pharmacokinetics observed in our study, a maintenance dose of iv TCZ 6 mg/kg would be appropriate for most RA patients. Although CRP levels are significantly higher in patients with trough iv TCZ concentrations  $<1 \mu\text{g/mL}$ , serum calprotectin did not show the same tendency.

Table 1. Mean ( $\pm$  standard deviation) intravenous tocilizumab serum concentrations at different prescribed doses within time.

Time (days)	TCZ 8 mg/kg	TCZ 6 mg/kg	TCZ 4 mg/kg
Pre-infusion (C <sub>trough</sub> )	8.91 $\pm$ 6.0	5.68 $\pm$ 9.1	0.79 $\pm$ 1.2
T7	84.82 $\pm$ 33.9	48.88 $\pm$ 18.6	26.06 $\pm$ 6.4
T14	46.40 $\pm$ 19.8	30.98 $\pm$ 11.5	15.16 $\pm$ 5.3
T21	21.63 $\pm$ 9.5	19.65 $\pm$ 10.5	7.11 $\pm$ 4.4
T28 (C <sub>trough</sub> )	10.63 $\pm$ 7.3	10.29 $\pm$ 10.8	1.32 $\pm$ 2.3

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). We examined high sensitivity C-reactive protein (hsCRP) levels in relation to structural progression in patients with RA receiving tofacitinib or methotrexate (MTX).

**Methods:** This was a post-hoc analysis of data from a Phase 3, randomized, double-blind controlled trial of tofacitinib monotherapy vs MTX (ORAL Start [NCT01039688]) in patients with early RA who were naïve to therapeutic doses of MTX. Patients were randomized to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or MTX titrated up to 20 mg/week. hsCRP levels through Month (M) 24 were analyzed descriptively for patients with structural progression at M12 (change from baseline in modified Total Sharp Score [mTSS] >0.5; mTSS progressors) and those without structural progression at M12 (mTSS non-progressors). The proportions of patients who were mTSS non-progressors at M6, M12, and M24 were summarized for patients with baseline hsCRP level  $\leq 7$  mg/L and  $> 7$  mg/L.

**Results:** A total of 885 patients who had mTSS assessments at M12 were included in this analysis, of whom 345 received tofacitinib 5 mg BID, 371 received tofacitinib 10 mg BID and 169 received MTX. Mean baseline hsCRP levels were similar across treatment groups, but M12 mTSS progressors appeared to have a higher mean baseline hsCRP vs non-progressors in all treatment groups (Figure). On a group level, patients who were mTSS progressors at M12 generally had numerically higher mean hsCRP levels vs mTSS non-progressors over 24 months (Figure); effect was generally greater with MTX vs tofacitinib groups. At M24, mean changes from baseline in hsCRP appeared higher for M12 progressors (-21.5 to -27.8 mg/L across groups) vs non-progressors (-12.6 to -16.7 mg/L across groups). Rates of mTSS non-progression appeared to be numerically higher at M6, M12, and M24 in patients with baseline hsCRP  $\leq 7$  mg/L vs those with baseline hsCRP  $> 7$  mg/L (Table). At M24, among patients with baseline hsCRP  $> 7$  mg/L, 59.5% of patients treated with MTX and 77.0% and 79.6% treated with tofacitinib 5 mg and 10 mg BID, respectively, were mTSS non-progressors, compared with 77.1%, 85.6% and 90.8%, respectively, among patients with baseline CRP  $\leq 7$  mg/L (Table).

**Conclusion:** Patients with RA receiving tofacitinib 5 mg or 10 mg BID or MTX who showed structural progression at M12 generally had numerically higher mean hsCRP levels through M24. Numerically higher rates of non-progression were observed over time in patients with baseline hsCRP  $\leq 7$  mg/L vs  $> 7$  mg/L. At M24, structural progression was lower with tofacitinib vs MTX, regardless of baseline hsCRP level.

Figure. Mean hsCRP levels over 24 months according to mTSS progression at M12 in patients receiving A) tofacitinib 5 mg BID, B) tofacitinib 10 mg BID, or C) MTX

A) Tofacitinib 5 mg BID

B) Tofacitinib 10 mg BID

C) MTX

Progressors were defined as those patients with change from baseline in mTSS score >0.5 at M12  
BID, twice daily; CI, confidence interval; hsCRP, high sensitivity C-reactive protein; M, Month; mTSS, modified Total Sharp Score; MTX, methotrexate

**Table. Rates of mTSS non-progression at M6, M12, and M24, according to hsCRP level at baseline in patients receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, or MTX**

n/N % (95% CI)	Tofacitinib 5 mg BID	Tofacitinib 10 mg BID	MTX
<b>M6</b>

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** In inflammatory rheumatic diseases, pharmacokinetics of MTX may be modified by patients' weight [1]. The rheumatologists are though reluctant to prescribe a high dosage to patients with a low weight. On the other hand, international guidelines (ACR and EULAR [2, 3]) do not recommend any weight adaptation concerning MTX dose. Following which, rheumatologists generally do not increase MTX dosage above 25 mg/wk for patients with high weight. Our goal was to evaluate the MTX dosage used in routine practice to treat RA as compared the patients' weight.

**Methods:** We used the baseline data of SELFi study. This phase III trial included patients treated by MTX ( $\geq 3$  months, oral or SC) randomized in two arms: MTX in prefilled syringes or MTX autoinjector. The primary objective of the study was to compare the arms in terms of HAQ and treatment adherence at 6 months. In this preliminary post-hoc analysis, we evaluated in four groups  $<50$  kg, 50-74,9 kg, 75-99,9 kg, and  $>100$  kg the mean dosage of MTX in mg/kg, the proportion of patient receiving  $<10$ , 10 to 14.9, 15 to 19.9,  $\geq 20$  mg/wk, and the proportion of patients receiving  $<$  or  $\geq 0.3$  mg/kg/wk. We also evaluated the factors associated to the use of  $\geq 0.3$  mg/kg/wk using univariate or multivariate analyses.

**Results:** Between Sept 2015 and Sept 2016 SELFi study recruited 264 patients (192 women and 72 men); mean age:  $58.4 \pm 13.2$  years. Mean weight of women/men was  $67.3 \pm 13.5$  kg and  $81.5 \pm 13.7$  kg respectively ( $p < 0.0001$ ). The difference of BMI between men and women was statistically significant:  $25.8 \pm 5.3$  for women and  $26.9 \pm 3.9$  for men ( $p = 0.014$ ). Absolute value of MTX dosage was the same for both genders: 15.4 mg/wk in women vs 15.9 in men ( $p = 0.36$ ). Although, the proportion of women and men receiving  $\geq 15$  mg/wk dosage is not statistically different (75.5% vs 84.7%,  $p = 0.11$ ), 17.7% of women vs only 2.9% of men received  $\geq 0.3$  mg/kg/wk ( $p = 0.002$ ). While the patients  $<50$  kg receive 0.29 mg/kg/wk for the other groups this parameter is decreased to 0.24, 0.19 et 0.16 mg/kg/wk for the tree other groups. Results of the univariate analysis show that the prescription of MTX  $\geq 0.3$  mg/kg/wk is associated with the female gender ( $p < 0.002$ ), the height ( $p < 0.001$ ) and the weight ( $p < 0.0001$ ). In multivariate analysis, only the weight remains associated ( $p < 0.0001$ ). However, the MTX dosage  $< 0.3$  mg/kg/wk was not associated with higher disease activity, but the study was designed to consider patients with low disease activity.

**Conclusion:** Weight does not seem to influence the MTX dosage in RA patients. Although the dosage of MTX in mg/wk seems slightly higher in men vs women, it is significantly lower in mg/kg/wk. These results raise the question of the utilization of mg/kg/wk MTX dosage rather than the absolute value in mg/wk. On this basis, it would be interesting to design a randomized controlled trial to further explore these findings.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Tocilizumab (TCZ) as monotherapy (Mono) is nowadays a standard treatment in rheumatoid arthritis (RA) for patients in whom methotrexate (MTX) gives an inadequate response<sup>1</sup>.

The objective was to describe factors influencing the use of TCZ in Mono or in combination with DMARDs (Combo) in real-life practice in RA patients (pts).

## Methods:

**Analysis:** pooled data of 2 prospective, multicentre, observational studies (Spare-1 n=307, Act-solo n=577). **Patients:** RA pts requiring TCZ treatment according to their physician. **Treatment:** TCZ as prescribed in real life. **Endpoint:** Evaluation of factors influencing the use of TCZ in Mono or in Combo. **Data collected:** demographic characteristics, past medical history, RA characteristics and history including previous RA treatments, TCZ treatment strategy (in Mono or Combo). **Statistical analysis:** Pts fulfilling inclusion and non-inclusion criteria and with  $\geq 1$  TCZ infusion were analyzed. 1- descriptive analysis 2- Univariate and multivariate analysis to determine factors influencing the use of TCZ in Mono. 3.-A propensity score was built to balance baseline characteristics.

## Results:

884 pts were analysed at inclusion. Pts' characteristics: 57% of the pts were  $>55$  years old, 78.4% female, mean RA duration  $10.7 \pm 9.1$  years, 84.3% positive for RF and/or ACPA, 77.5 % with erosive disease, CRP  $19.4 \pm 26.2$  mg/l, mean DAS28-ESR  $5.14 \pm 1.27$ . Comorbidities were: diabetes 8%, high blood pressure (HBP) 28%, dyslipidemia 20%, osteoporosis 21%, others 56%. Past RA treatment included csDMARDs in 98.2% and biologics in 73.8% (median=2 [1-6]). TCZ was initiated as Mono in 39% of pts and in Combo in 61%, with MTX in 78.5% of Combo pts (mean dose  $16.1 \pm 4.5$ mg). Steroids were used in 78.5% of pts (mean dose  $11 \pm 6.8$ mg). In the multivariate analysis variables associated with a TCZ prescription in Mono were: number of previous bDMARD (1 bDMARD, OR=1.30 [0.88-1.93], 2 bDMARD OR=2.32 [1.55-3.45],  $\geq 3$  bDMARD, OR=1.21 [0.78-1.90]) p<.001, HBP OR=1.45 [1.05-2.00], p=0.025, osteoporosis OR=1.63 [1.14-2.33], p=0.007, CRP  $\geq 10$ mg/l OR=1.61 [1.21-2.15], p=0.001. At 12 months, mean DAS28-ESR was  $2.41 \pm 1.28$  and  $2.29 \pm 1.23$  with 74.7% and 77% of pts in DAS28 LDA in Mono and Combo respectively. No differences were observed between Mono and Combo groups on other efficacy data. This remains true when weighting by the propensity score.

## Conclusion:

This pooled analysis suggests that TCZ in monotherapy is used more often in previously heavily treated, with higher inflammatory markers and with comorbidities such as HBP or osteoporosis.

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Background/Purpose:** RA patients (pts) are at increased risk of herpes zoster (HZ), and ACR guidelines recommend vaccination in pts aged  $\geq 50$  years prior to starting biologic DMARDs or tofacitinib.<sup>1</sup> Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Live zoster vaccine (LZV) has shown 70% efficacy in immunocompetent adults aged 50–59 years, and 51% efficacy in those aged  $\geq 60$  years.<sup>2</sup> We previously reported that RA pts on background methotrexate who started 3 months of treatment with tofacitinib after LZV had similar varicella zoster virus (VZV)-specific immunity to placebo (PBO) pts, and that their VZV immunity at Week (Wk) 6 post-vaccination was comparable with healthy individuals aged  $\geq 50$  years.<sup>3</sup> The objective of this study was to evaluate the long-term effectiveness of LZV in pts with RA, via the incidence of HZ after treatment with tofacitinib for up to 27 months.

**Methods:** The initial study involved 112 RA pts given LZV and randomized 2–3 wks later to tofacitinib 5 mg twice daily (BID) or PBO for 12 wks (A3921237 [NCT02147587]). At 14 wks post-vaccination, pts joining the long-term extension ORAL Sequel study (NCT00413699) initiated open-label treatment with tofacitinib 5 or 10 mg BID. The incidence of post-vaccination HZ after tofacitinib exposure up to 27 months (based on an extended follow-up beyond the January 2016 data snapshot) was evaluated. Among HZ cases, we analyzed measures of VZV-specific immunity with average immunity after LZV.

**Results:** 112 pts were randomized to PBO (n=57) or tofacitinib 5 mg BID (n=55). 100 pts continued to receive tofacitinib in ORAL Sequel. Five cases (not adjudicated) of HZ occurred, with an incidence rate (pts with events per 100 pt-years) of 3.60 (95% confidence interval 1.17, 8.39) (#1: 202 days [219 days post-LZV], #2: 267 days [281], #3: 702 days [748], #4: 699 days [741], #5: 446 days [544] after initiation of tofacitinib). Cases #1–#4 were monodermatomal; case #5 involved 5 dermatomes. All cases resolved with treatment. Cases #1, #4, and #5 had undetectable ELISPOT measures at baseline and at Wk 6 post-vaccination, indicating a lack of VZV-specific immunity. Cases #2 and #3 responded adequately to vaccination by both immunoglobulin G (IgG) and ELISPOT measures, but had lower-than-average VZV IgG levels, both at baseline and at Wk 6 (Table).

**Conclusion:** LZV prior to treatment with tofacitinib is effective at boosting IgG levels and cell-mediated immunity towards VZV. Of the 5 pts who developed HZ, 3 did not have any measurable cell-mediated response, and 2 had a low humoral response.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** We have been prospectively investigating therapeutic efficacy of biologic or targeted synthetic DMARDs in patients with rheumatoid arthritis (RA) by ultrasound (US) in Kyushu region, Japan from June 2013. In this study, we have investigated efficacy of abatacept (ABT) by US indices and tried to find the correlations of those with serum cytokines, chemokines and bone-related biomarkers.

**Methods:** Forty-seven RA patients, registered and completed ABT therapy for 6 months, were enrolled from the Kyushu multicenter RA US prospective observational cohort study. They gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of each center. We evaluated clinical disease activity, US synovitis score [22 joints including bilateral 1<sup>st</sup>-5<sup>th</sup> metacarpophalangeal (MCP) joints, proximal interphalangeal (PIP) joints and wrist joints semi-quantitatively examined by grey-scale (GS) and power Doppler (PD) from 0 to 3] and serum levels of 38 kinds of cytokine and chemokine biomarkers (multi-suspension array), bone-related biomarkers[TRACP-5b (EIA), sRANKL (ELISA), multi-suspension array; DKK-1, osteocalcin (OC), osteoprotegerin (OPG), osteopontin (OPN) and sclerostin (SOST)], rheumatoid factor (RF), anti-cyclic citrullinated peptide antibodies (ACPA), matrix metalloproteinase-3 (MMP-3) at baseline, 3 and 6 months. Variables predicting PD non-responder defined that sum of PD score from 22 joints did not improve at 6 months were assessed.

**Results:** The median of disease duration was 82 months and that of DAS28-CRP was 4.49 at baseline. Clinical disease activity, US synovitis score, RF titer and MMP-3 significantly improved at 3 and 6 months from baseline ( $p < 0.001$ ). In addition, most of cytokines, chemokines and bone-related biomarkers were down- or up-regulated by ABT therapy. A multivariate logistic regression analysis revealed that longer disease duration (OR 1.01, 95%CI 1.01-1.03,  $p = 0.0003$ ), low PDUS synovitis score (OR 0.75, 95%CI 0.54-0.92,  $p = 0.0010$ ) and high DKK-1 (OR 1.11, 95%CI 1.01-1.25,  $p = 0.027$ ) at baseline was predictive of PD non-responder (Table 1).

**Conclusion:** Cytokines, chemokines and bone-related biomarker differently changed after introduction of ABT therapy. Therapeutic response of ABT evaluated by US indices may be predicted by baseline bone-related biomarkers such as DKK-1.

Table 1. Multivariate regression analysis to predict power Doppler non-responder at 6 months

	Comparison	OR	95% CI		p-value
Disease duration	1 increase	1.01	1.01	1.03	0.0003
PDUS synovitis score	1 increase	0.75	0.54	0.92	0.0010
DKK-1	100 increase	1.11	1.01	1.25	0.027

Variables with a *p* value less than 0.02 in univariate analysis were used in multivariate models.

### Background/Purpose:

Little is known regarding the corticosteroid sparing effect of non-TNF biologics in rheumatoid arthritis (RA).

**Objectives :** To compare the corticosteroid sparing effect of non-TNF biologics in daily practice in RA.

## Methods:

Autoimmunity and Rituximab (AIR), Oencia and Rheumatoid arthritis (ORA) and REGistry–RoAcTEmra (REGATE) are three prospective registries promoted by the French Society of Rheumatology for patients who initiate rituximab (RTX), abatacept (ABA), or tocilizumab (TCZ), as intravenous drugs.

The observational data were used to emulate a target trial with 3 groups: patients receiving rituximab, abatacept and tocilizumab. A propensity-score approach was used to adjust for differences in observed factors that might affect both treatment assignment and outcome and to emulate randomization.

Change in oral corticosteroid dosage was analyzed by 3 different approaches regardless of drug discontinuation: delta decrease  $\geq 5$  mg/d compared to baseline dose, final daily dose  $\leq 5$  mg/d, and total discontinuation of corticosteroids in patients receiving the drug at baseline. To compare these outcomes, we used logistic regression with weighted GEEs, with drug as the only covariate.

## Results:

At enrollment, 77.7, 74.4 and 66.5% of patients treated with RTX (n= 1619), ABA (n= 623) and TCZ (n= 941) had daily oral corticosteroid (mean (SD dose): 11.8 (8.8), 11.2 (8.3), 10.3 (7.2) mg/ day, respectively).

- Delta decrease  $\geq 5$  mg of the daily dose compared to enrollment

At 6 months, such a decrease was observed in 31.6, 41.6 and 48.4% of RTX, ABA and TCZ-treated patients respectively (p=0.003 for the comparison between TCZ and RTX, no significant difference between ABA and TCZ). At 12 months, such a decrease was observed in 43.1, 51.9 and 62.2% of RTX, ABA and TCZ-treated patients respectively (p< 0.001 between TCZ and RTX). At 24 months, it was observed in 58.3, 62 and 71% of patients, respectively.

- Daily dose  $\leq 5$  mg/d

At 6 months, a daily dose  $\leq 5$  mg/d was observed in 26.4, 37.8 and 52.9% of patients, treated with RTX, ABA and TCZ respectively (p< 0.001 between TCZ and RTX). At 12 months, it was observed in 44.7, 53.5 and 72.2% of patients, respectively (p< 0.001 between TCZ and RTX). At 24 months, a daily dose  $\leq 5$  mg/d was observed in 66.1, 67.1% and 75.8% of patients, respectively (p=0.001 between TCZ and RTX).

- Discontinuation of oral corticosteroids

At 6 months, in patients initially treated with steroids, oral corticosteroids were discontinued in 9.7, 13.7 and 15.6% of patients respectively treated with RTX, ABA and TCZ. At 12 months, they were discontinued in 11.5, 23.4 and 24.9% of patients, respectively (p= 0.003 between ABA and RTX, p< 0.001 between TCZ and RTX). At 24 months, steroids were discontinued in 20.5, 31.5 and 38% of patients, respectively.

## Conclusion:

These results demonstrate a corticosteroid-sparing effect for all 3 of the non-TNF targeted biologics in around half of the patients at 12 months. However, only 21% to 38% of patients with baseline oral corticosteroids use could discontinue corticosteroids at 24 months, which emphasizes the need to continue to enlarge the armamentarium of new biologic and targeted DMARDs in RA.

## Adverse Drug Reactions Due to Disease Modifying Drugs in a Cohort of Patients with Incident Rheumatoid Arthritis

**Zulema Rosales Rosado**<sup>1,2</sup>, Dalifer Freites Núñez<sup>2</sup>, Cristina Lajas Petisco<sup>1</sup>, Esperanza Pato Cour<sup>1</sup>, Leticia Leon<sup>2</sup>, Judit Font Urgelles<sup>1</sup>, Juan A Jover Jover<sup>1</sup> and Lydia A Alcazar<sup>2</sup>, <sup>1</sup>Rheumatology, Hospital Clínico San Carlos, Madrid, Spain, <sup>2</sup>Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There is a well-known risk of developing adverse drug reactions (ADR) in rheumatology due, mainly, to the Disease Modifying Drugs (DMARD) used. After more than twenty years using DMARD, there is no doubt about their efficacy in rheumatoid arthritis (RA), but it is necessary to increase our knowledge of their ADR, especially those that lead to discontinuation in real life. Purpose: to describe the incidence and characteristics of ADR to DMARD in patients with incident RA as well as the factors related to their development.

**Methods:** An observational longitudinal study was conducted. Patients: all recent onset RA patients diagnosed between April 15<sup>th</sup> 2007 and 31<sup>st</sup> June 2011 followed in outpatient clinic at Hospital Clinico San Carlos until December 31<sup>st</sup> 2016, which used any DMARD (synthetic and biologic). Primary outcome: development of an ADR that required discontinuation of the DMARD (moderate: discontinuation; severe: discontinuation and hospitalization or death as a result of the ADR). Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. Comparisons between associated factors were run by Cox bivariate and multivariate regression models. **Results** were expressed by hazard ratio (HR) and [CI].

**Results:** We included 1054 courses of DMARD treatment in 405 patients (2277.9 patient-years). 78.3% were women with a mean age at diagnosis of 57±15 years. Median time to the first DMARD was 0.3 [±0.6] days. 16.3% of patients were taking biological DMARD, 73.3% were using monotherapy and 89% were taking corticoids. There were 369 ADR in 212 patients, 88.9% of them moderate. Gastrointestinal was the most frequent cause of ADR (26.3%), followed by infections (12.2%). Incidence rates are shown in table 1. In the multivariate analysis (table 2) after adjusting by age and sex, number of concomitant DMARD was directly related to more risk. Regarding type of DMARD, Abatacept had the highest risk of ADR development (HR: 4.9[2.1-11.2]) compared to the other drugs followed by Gold (HR: 1.6[1-2.6]) and Leflunomide (HR: 1.4[1.1-1.9]). Methotrexate was the safest drug compared with the others (0.6[0.5-0.8]).

**Conclusion:** The IR of ADR estimated was 16.2%, being gastrointestinal the main cause followed by infections. We have found differences in discontinuation rates among DMARD due to ADR, being Abatacept, Gold and Leflunomide the drugs with the highest risk. Methotrexate is a protective factor for the development of ADR. Caution should be taken in patients receiving combined therapy and with certain comorbidities.

## Targeted Therapeutic Delivery to Cartilage with Knottin Proteins

**Emily Girard**, Michelle Cook Sangar, Gene Hopping, Fiona Pakiam and James Olson, Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Arthritic diseases affect more than 50 million Americans and, although there are many etiologies, the common manifestation of the disease is pain and limited mobility (1). Delivery of therapeutics to alleviate symptoms and perturb disease progression is limited by the risk of systemic toxicity (2). Intra-articular therapeutic administration is limited to accessible joints and cannot address disseminated disease (3). We have identified a panel of cysteine-knot peptides that target to cartilage in rodents following systemic administration. This work characterizes the *in vivo* pharmacokinetics of cartilage-targeting knottins and assesses the potential for translation to arthritis therapeutics in the clinic.

**Methods:** Whole body autoradiography (WBA) was used to evaluate biodistribution of knottin peptides in rodents. Radioactive signal of  $^{14}\text{C}$ -KNT-17R (100 nmol, IV) was quantified in the knee and intervertebral disc (IVD) between 5 min and 96hr. Delivery of a cargo was assessed after KNT-17R conjugation to the fluorophore Cy5.5 (10nmol IV, 3hr) or Dexamethasone (100nmol IV, 3 and 24hr). Accumulation in knee and IVD were assessed by fluorescent microscopy and WBA. Binding to human cartilage explants was assessed by microscopy or liquid scintillation counting after overnight incubation with 10mM  $^{14}\text{C}$  or Cy5.5 labeled peptide.

**Results:** Two independent time course experiments show that peptide KNT-17R distributes rapidly and persists in all types of cartilage in the mouse. The peak signal intensity of 60 $\pm$ 14 % injected dose/g (knee) and 34 $\pm$  8 % injected dose/g (IVD) was observed 30 min after administration. Peak signal did not significantly decline until after 3 hours (knee) or 8 hours (IVD). Fluorescent microscopy further demonstrated that Cy5.5-KNT-17R accumulated in cartilage of the knee and IVD. Dexamethasone-KNT-17R accumulated in the knee at 41 $\pm$ 14 % injected dose/g and in the IVD at 20 $\pm$ 3 % injected dose/g after 3 hours. Signal intensity in cartilage was too low to measure in mice treated with  $^{14}\text{C}$ -Dexamethasone. KNT-17R was found to bind to human cartilage with significantly greater intensity than negative control peptide KNT-15R by fluorescence microscopy and liquid scintillation counting.

**Conclusion:** This work demonstrates cartilage accumulation by a systemically administered knottin peptide. The peptide is able to deliver a steroid payload to cartilage in multiple clinically relevant joints. Binding to human cartilage explants establishes evidence that a knottin peptide may have promise in the treatment of arthritis in humans.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** NLRP3 inflammasome is an intracellular protein complex involved in the production of pro-inflammatory cytokines as IL-1 $\beta$  and IL-18, which has been reported to have a role in the pathogenesis of RA. Since CCH is a potent inhibitor of NLRP3, we hypothesized that it may significantly modify the expression and function of this molecular complex, reducing the inflammatory phenomenon in RA. Accordingly, the aim of this study was to evaluate the possible effect of CCH administration on the expression and activity of NLRP3 in patients with early RA.

**Methods:** We selected consecutive patients with RA according to the ACR/EULAR 2010 criteria with  $\leq 12$  months of evolution and were randomly assigned to 2 groups: MTX (15 mg/week); or MTX (15 mg/week) plus CCH (1.5 mg/day). Inflammasome expression by monocytes was assessed by two-color flow cytometry (CD14<sup>+</sup>NLRP3<sup>+</sup> cells), and its function was estimated through the analysis of Caspase-1 activity (colorimetric assay). Clinical activity was assessed by HAQ-DI, CDAI, SDAI and DAS28-ESR at 0, 1 and 3 months.

**Results :** Twenty DMARD naive patients have been recruited, their main characteristics are shown in table 1. In a preliminary analysis of 7 patients in the MTX group and 6 patients in the MTX+CCH group after 1 month of treatment, and 3 patients in the MTX group and 4 patients in the MTX+CCH group after 3 months of treatment, all patients had increased levels of caspase-1 activity and NLRP3; patients in the MTX group had a significant change in its expression at 1 month (Table 2), however that difference was not subsequently detected at month 3. In contrast, patients in the MTX+CCH group showed a significant decrease in the expression and activity of NLRP3 at 1 and 3 months ( $p < 0.05$ ). Moreover, a significant improvement in clinical parameters was observed in both at months 1 and 3. We will present follow-up all patients.

**Conclusion:** Our preliminary data suggest that CCH administration is associated with sustained decrease in the expression and activity of the NLRP3 inflammasome. This phenomenon might contribute to decrease inflammation and may help to achieve low disease activity.

## Clinical Significance of Serum Levels of ROM (reactive oxygen metabolites) at 12 Weeks during Treatment with Biologic Agents As a Predictor for the 52-Week Remission

Arata Nakajima<sup>1</sup>, Masato Sonobe<sup>1</sup>, Shinji Taniguchi<sup>1</sup> and Koichi Nakagawa<sup>2</sup>, <sup>1</sup>Orthopaedics, Toho University Sakura Medical Center, Sakura-city, Chiba, Japan, <sup>2</sup>Toho University Sakura Medical Center, Sakura-city, Chiba, Japan

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Oxidative stress induced by reactive oxygen species is thought to be an important mechanism that underlies joint destruction and synovial proliferation. We have shown that serum levels of reactive oxygen metabolites (ROM) at 12 weeks during treatment with biologic agents (BAs) are predictive for the DAS28-remission at 52 weeks. However, it has not been elucidated whether ROM is also a predictor for the CDAI-, SDAI- or Boolean-remission at 52 weeks.

**Methods:** Fifty-four BAs-naïve RA patients (mean age: 59.8}13.6 y, disease duration: 7.26}10.8 y) were included in this study. Association between ROM, CRP, MMP-3, DAS28, CDAI, SDAI, and HAQ at 12 weeks and the CDAI-, SDAI-, and Boolean-remission at 52 weeks was investigated. To measure ROM, the d-ROM test was performed using the FRAS4 analyzer (Wismarl, Italy). In order to identify predictor(s) for the 52-week remission, a multivariate logistic regression analysis was performed and an ROC analysis was also performed to determine their cut-off values.

**Results:** CDAI and SDAI at baseline was 17.8}11.6 and 20.4}13.0, respectively but decreased to 5.54}11.6 and 6.21}13.1 at 52 weeks and the remission rate for CDAI, SDAI and Boolean was 54, 57 and 56%, respectively. Significant factors at 12 weeks between the remission and non-remission group at 52 weeks were (1) ROM, DAS28, CDAI, and HAQ for the CDAI-remission, (2) ROM, DAS28, CDAI, SDAI, and HAQ for the SDAI-remission, (3) ROM, DAS28, and HAQ for the Boolean-remission (Table 1). A multivariate logistic regression analysis revealed that ROM at 12 weeks was associated with the CDAI- (p=0.032, OR: 0.991, 95%CI: 0.983-0.999), SDAI- and Boolean-remission (p=0.006, OR: 0.988, 95%CI: 0.980-0.997) at 52 weeks. ROC analyses demonstrated that AUC for the CDAI-remission was 0.702 and the cut-off value was 389.5 U.Carr (sensitivity: 52.4%, specificity: 91.7%). AUC for the SDAI- and Boolean-remission was 0.746 and the cut-off value was 389.5 U.Carr (sensitivity: 55.0%, specificity: 92.3%, Figure 1).

**Conclusion:** These results suggest that neither CRP nor MMP-3 can be a predictor for the remission during early stage of treatment with BAs. Instead, ROM at 12 weeks was a predictor for the CDAI-, SDAI-, and Boolean-remission at 52 weeks. Serum levels of

ROM will be a useful biomarker in the current treatment strategy aiming at the early remission of RA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Biologics (Bio) have shown outstanding efficacy and became one of the most effective drugs in the treatment of RA. However, several issues remain, including adverse effect (AE), therapeutic failure (Failure), and expensiveness. On the other hand, cumulative evidence has suggested that some genetic and environmental factors affect responsiveness of anti-rheumatic drugs including Bio. Smoking is thought to be one of crucial environmental factors. The purpose of this study is to investigate the influence of smoking on Bio treatment in RA.

**Methods:** The association between smoking habit and discontinuation of Bio treatment was analyzed on Japanese RA patient cohort (11940 patients). Smoking habit was assessed by questionnaire and the patients were divided into three groups as current smoker, never smoker, ever smoker. The total percentages of discontinuation were analyzed according to four categories: Failure, adverse effect (AE), Remission, and others. The association between the causes of discontinuation of Bio and smoking habit was analyzed statistically.

**Results:** 3,187 (26.7%) of the total registered patients were treated with one or more Bio during 6 years. Among them, 584, 1,321, 397, 589, 223, and 73 patients were treated with IFX, ETN, ADA, TCZ, ABT and GLM respectively. Failure in the current smoker group was significantly more frequent than never smoker and ever smoker groups (OR=0.678, 95%CI:0.482~0.967, OR=0.577, 95%CI:0.357~0.869, respectively). Among therapeutic targets, patients treated with TNF inhibitors (IFX, ETN, ADA, GLM) showed more significant association between smoking habit and Failure than those treated with either IL-6 inhibitor (TCZ) or T cell inhibitor (ABT).

**Conclusion:** Smoking reduced responsiveness of treatment by Bio in RA, especially when treated with TNF inhibitors. Smoking cessation may reduce failure of treatment by Bio in RA.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adalimumab (ADL) tapering based on clinical assessment is an usual practice, especially in patients in remission. The objective of INGEBIO was to analyze how personalized management guided by Therapeutic Drug Monitoring (TDM) in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients impacts the annual direct costs to the

Health System and the quality-adjusted life year (QALY) gained with respect to conventional practice in Spain. Second, to evaluate the effectiveness of TDM in the reduction of the number of days with high disease activity compared with conventional practice.

**Methods:** In a pragmatic, non-randomized, non-inferiority trial, adult patients treated with ADL (40 mg sc) who remained clinically stable for at least 6 months were recruited in 3 sites. Patients were grouped in Control (CG) and Intervention groups (IG) according to the site. ADL frequency was adjusted based on physician criteria. Patients are assessed at 8 visits for up to 18 months. Trough ADL and anti-ADL antibodies levels are measured with Promonitor-ADL and Promonitor-ANTI-ADL (Progenika). TDM data were released only to the IG, and blinded to the CG. Physicians in the IG were not obliged to follow any therapeutic algorithm based on TDM results but could use tests to alter doses based on their clinical judgement. Endpoints include DAS28, BASDAI, BASFI and HAQ-DI scores at every time point. Cost-effectiveness is evaluated according to associated costs and QALY.

**Results:** A total of 169 patients were recruited, but 19 were lost to follow-up (disease, N IG, N CG, %) (RA, 25, 29, 36.0%; PsA, 30, 18, 32.0%; and AS, 43, 5, 32.0%). Median disease duration was 124.0, 105.5 and 129.0 months for RA, PsA and AS, respectively. At baseline, 9 (17.3%) and 28 (28.6%) patients had low disease activity, 43 (82.7%) and 70 (71.4%) patients were in remission, and median trough ADL levels were 5.76 and 5.04 mg/L in the CG and IG, respectively. Mean follow-up (FU) was 544.6 and 530.8 days in the CG and IG, respectively. ADL doses were tapered in 18/52 (34.6%) and 35/98 (35.7%) patients in the CG and IG, respectively. Patients were in remission/low activity an average of 475.2 vs 460.2 days in the CG and IG, respectively. The number of flares in the CG and IG was 47 and 66, respectively. The rate of flares per patient-year of FU is 0.639 vs 0.463 in the CG and IG, respectively (a difference of -0.176; CI95%: -0.379 to 0.0289). The risk of flare is 27.5% lower in the IG (IRR= 0.7252; CI95%: 0.4997 to 1.0578). Median time to first flare was 136,5 and 145 days in the CG and IG, respectively. Quality of life (EQ-5D-5L) was significantly better in the IG at visits 2 (p=0.001) and 3 (p=0.035); EQ-5D-5L was higher (although not statistically significant) in the IG in the remaining visits. Mean QALY were 1.145 and 1.076 during FU per intervention and control patient, respectively (gain of 0.069). Average cost of Humira per patient-year was 10,664.54€ vs 9,856.45€ (-808.08€, 8% savings) in the CG and IG, respectively.

**Conclusion:** BDM-guided management is not inferior to clinically based management for maintaining remission after 18 months and is associated with fewer flares, better quality of life and lower treatment costs during the course of treatment.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Tapering trials confirmed the feasibility of TNF inhibitors (TNFi) tapering for a relevant proportion of patients in remission and/or low disease activity. However, there are no consensual predictors of a good response to therapeutic spacing among patients with

rheumatoid arthritis (RA) in remission. We aimed to develop a predictive score of successful TNFi tapering.

## Methods:

Post-hoc analysis of a controlled trial of a tapering strategy in RA patients, fulfilling ACR 1987 criteria, treated with subcutaneous TNFi with sustained remission, randomized to either spacing or maintaining TNFi. We used the data of the Spacing arm.

Performances of several variables (DAS28, SDAI, CDAI, CRP, ACPA status, HAQ, patient/physician global assessment, and boolean remission criteria) were assessed for the prediction of successful TNFi tapering, defined as reaching at least 25% tapering of the full regimen during at least 6 months, using sensitivity (Se) and specificity (Spe) for dichotomous variables, or the area under the ROC curve (AUC) and its 95% confidence interval for continuous variables.

A predictive score of successful tapering was constructed using LASSO regression modeling to avoid overfitting (R software version 3.2.1).

## Results:

The main characteristic of the 64 patients of the Spacing arm were the following (mean  $\pm$  SD): age  $54.3 \pm 10.7$  years, disease duration  $8.3 \pm 5.4$  years, and DAS 28  $1.9 \pm 0.6$ .

The baseline variables were similar between patients who failed or succeeded at TNFi spacing, except for the HAQ score (0.30 in the group success and 0.89 in the failure group,  $p = 0.01$ ) and the CRP (2.35 mg/l versus 3.48 mg/l, respectively,  $p=0.02$ ).

Baseline variable performance in predicting successful TNFi spacing: None of the tested variables was able to predict successful TNFi spacing, except the HAQ score and the CRP. A HAQ threshold  $\geq 1.125$  had a Spe of 93% and an AUC: 0.713 (CI95%: 0.540-0.886). A CRP threshold  $\geq 6.8$  mg/l had a Spe of 0.97 and an AUC: 0.689 (CI95%: 0.547-0.831).

Predicting score: A composite score able to predict successful TNFi spacing has been elaborated, including ACPA status, Boolean criteria, SDAI, CRP and HAQ. A 0.5 threshold predicted successful TNFi spacing with Spe = 100% and Se = 54% (AUC: 0.829; CI95%: 0.671 - 0.986).

## Conclusion:

The remission maintenance in rheumatoid arthritis after TNFi spacing is possible. Our results showed that in a population of RA patients in remission with TNFi, baseline HAQ and CRP are independent predictor factors of successful tapering. We have developed a composite index able to predict successful TNFi spacing, with an AUC of 0.829 and a 100% Spe. A validation study will be needed to confirm its ability to select patients for treatment decrease.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Background/Purpose:** There is currently no consensus on selecting a therapeutic target in patients (pts) non-responsive to their first TNF inhibitors (TNFi). The development of anti-drug antibodies (ADA) is a frequent cause of secondary inefficacy in our pts with TNFi and there is evidence that those who develop ADA at their 1st TNFi achieve a higher degree of response to the second one, compared to ADA- pts. Thus ADA measurement can help in choosing a therapeutic target in pts who failed to respond to their 1st TNFi. The objective of this study was to assess if development of ADA to the 1st TNFi determines better response when switching to a 2nd TNFi versus a nonTNFi. As secondary objective, it was analyzed whether the presence or absence of ADA to a 1st TNFi influences the efficacy of a 2nd TNFi

**Methods:** Of a total of 110 pts that switched from infliximab or Adalimumab to a 2nd biologic agent (Etanercept, Rituximab, Tocilizumab, Adalimumab, Abatacept, Certolizumab and Infliximab), only 60, who had measured drug levels (DL)/ADA at discontinuation of the 1st TNFi, were included. Clinical response was evaluated with DAS28, Delta-DAS28 ( $\Delta$ DAS28) and EULAR response (E-resp) at 6 (v-6) and 12 (v-12) months after initiating 2nd biologic agent and at the last visit prior to drug discontinuation or ending of the study for those who did not interrupt the biological therapy (v-end). DL/ADA levels were measured by ELISA. T tests and Fisher's exact test were used to test statistical differences. Analysis was performed using SPSS version 20.0

**Results:** Within the 60 pts who had measured DL/ADA at suspension of the 1st TNFi, 26 (43%) were ADA-. In this ADA-subpopulation, 50% changed to a 2nd TNFi; at v-6 there were no differences between switchers to a 2nd TNFi and switchers to a nonTNFi in DAS28 ( $3.7 \pm 2.1$  TNFi vs  $4.2 \pm 1.1$  nonTNFi,  $p=0.286$ ),  $\Delta$ DAS28 ( $1.4 \pm 2$  TNFi,  $1 \pm 1.2$  nonTNFi,  $p=0.374$ ) and resp-E (75% good/moderate resp in TNFi, 40% in nonTNFi,  $p=0.064$ ). At v-12, switchers to a 2nd TNFi showed a lower DAS28 ( $2.5 \pm 0.6$  TNFi,  $3.9 \pm 0.9$  nonTNFi,  $p=0.009$ ) and a higher good E-resp rate with a marginally significant difference (80% in TNFi, 22% in nonTNFi,  $p=0.071$ ). However, at v-end, pts with a 2nd nonTNFi had better response (DAS28  $> 5.1$  in 50% of TNFi pts, 0% of nonTNFi,  $p=0.044$ ). Likewise  $\Delta$ DAS28 at v-end was higher in the nonTNFi group ( $0.7 \pm 1.7$  TNFi,  $1.7 \pm 0.8$  nonTNFi,  $p=0.06$ ). Along these lines, the good/moderate E-resp rate was higher in switchers to a nonTNFi (30% in TNFi, 92% in nonTNFi,  $p=0.006$ ). In ADA+ subpopulation ( $n=34$ ), no differences were found at v-end in DAS28 ( $3.7 \pm 1.2$  TNFi,  $3.9 \pm 1.1$  nonTNFi,  $p=0.64$ ),  $\Delta$ DAS28 ( $0.63 \pm 1.6$  in TNFi,  $1.4 \pm 1.4$  in nonTNFi,  $p=0.35$ ) and good/moderate E-resp rate (65% in TNFi, 75% in nonTNFi,  $p=0.703$ ). In pts who changed to a 2nd TNFi, those with ADA to 1st TNFi had a higher good response rate than ADA- pts (65% in ADA+, 30% in ADA-,  $p=0.07$ ).

**Conclusion:** The development of ADA to the first TNFi entails a better response when switching to a 2nd TNFi, with a similar efficacy to the pts who switched to a nonTNFi. In those pts who did not develop immunogenicity to the 1st TNFi, there is a better response when changing therapeutic target. The ADA measurement can help to select the pts who can benefit from a 2nd TNFi.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

RA is a burdensome for most of the patients, comorbidities usually provide additional disadvantages the course of RA. The possible effects of comorbidities on selection of biological DMARDs in RA patients were not frequently assessed.

Objectives: The objective of this study was to assess effects of comorbidities and multimorbidities on biological DMARDs choose, timing of biological DMARDs and response of biological DMARDs.

## Methods:

Hacettepe University Biologic Registry (HUR-BIO) is single center biological DMARD registry. After 2012, all known comorbidities reported by patients were evaluated by a standard questionnaire. HUR-BIO included 1235 patients with RA and 998 patients were assessed for comorbidities. Assessed comorbidities were obesity, diabetes, hypertension, hyperlipidemia, osteoporosis, coronary heart disease, cerebrovascular event, chronic kidney disease, hepatitis B, tuberculosis, amyloidosis, and cancer. Multimorbidity defined as more than 1 comorbidity. Disease duration, initial date of biological DMARDs, initial and overall biological DMARD choose were recorded. DAS-28 responses were compared to comorbidity presence and multimorbidity.

## Results:

Totally, 998 RA patients were enrolled. The mean age was 53.1 (12.5) and mean disease duration (SD) was 11.7 (7.5) years. At least one comorbidity was detected in 689 (69.1%) patients, 375 (37.9%) patients had multimorbidity. Patients had mean  $1.36 \pm 1.32$  comorbidity. Patients with comorbidity were older ( $56.2 \pm 11.3$  vs  $46.1 \pm 12.4$ ,  $p < 0.001$ ), more frequently female (83% vs 74%,  $p = 0.01$ ), worst functional disability (HAQ score 1.0 (0-2.9), vs 0.77 (0-2.5),  $p < 0.001$ ) and highest baseline patient global assessment score (70 (0-100) vs 60 (10-100),  $p = 0.004$ ). The median duration of first biological DMARDs prescription were 60 (3-552) months after RA diagnosis. For multimorbidity patients, the median first biological prescription duration were longer than patients without multimorbidity patients (72 (3-552) vs 60 (3-396) months,  $p < 0.001$ ). The physicians prescribe anti-TNF biological drugs less frequently than other biologic DMARDs in patients with at least one comorbidity (66.2% vs 74.5%,  $p = 0.007$ ) or multimorbidity (34.6% vs. 43.5%,  $p = 0.006$ ). Patients with comorbidities and multimorbidity achieved to DAS-28 remission less frequently than patients without comorbidity (31.6% vs 42.6%,  $p = 0.012$  and 27.2% vs 39.7%,  $p = 0.001$ , respectively).

## Conclusion:

Physicians were postpone to prescribe biological DMARDs in patients with multimorbidity. Furthermore, comorbidity may have a negative effect on the treatment response. This situation may rise from both late start of the efficient treatment and additional burden effect of the comorbidities on the course of RA disease.

## Handling of Missing Data, Protocol Violation and Performance of Intention-to-Treat Analysis in the Randomized Controlled Trials of Drug Therapy of Rheumatoid Arthritis

Fawad Aslam<sup>1</sup>, Karina Torralba<sup>2</sup> and Nasim A. Khan<sup>3</sup>, <sup>1</sup>Rheumatology, Mayo Clinic, Scottsdale, AZ, <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Loma Linda University, Loma Linda, CA, <sup>3</sup>Rheumatology, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Background/Purpose:** Intention-to-treat (ITT) method is recommended to analyze Randomized Controlled Trials (RCTs). It requires analyzing all participants per the assigned intervention group at randomization to prevent treatment effect estimation bias. In practice, RCTs have subjects with protocol deviations and/or missing outcomes. Incorrect analysis of these subjects may give biased results<sup>1,2</sup>. Single imputation methods like “last observation carried forward (LOCF)” are discouraged as they may bring bias, and don’t adjust for the uncertainty of imputation<sup>3</sup>. We studied the ITT principle application, protocol deviations and missing outcome data handling in RCTs of rheumatoid arthritis (RA) drug therapy.

**Methods:** MEDLINE and Cochrane Central Register of Controlled Trials database were searched to identify parallel-design, English language, original RCT reports of drug therapy for RA with clinical primary and efficacy outcome(s) published in 2002-3, 2006-7 and 2010-11. Two reviewers assessed each RCT for the primary outcome(s) analysis and handling of missing data.

**Results:** 134 RCTs were eligible and enrolled a median (interquartile range, IQR) of 160 (59-381) patients. A median (IQR) of 83 (70-90) % remained enrolled until trial completion. 92 (67%) RCTs lost >10% to follow-up for the primary outcome. 84 (62.7%) reported using ITT analysis, 10 (7.5%) reported modified ITT analysis, and 40 (29.9%) mentioned no such term. 63 (47%) RCTs actually performed true ITT analysis (analyzed all patients as randomized, although 7 RCTs had missing data with undefined approach to imputation). 32 (23.9%) performed a modified ITT analysis [percent analyzed: 97 (95-99)%] with exclusion of following categories: those without post-baseline assessment (17); no intervention received (12), and non-eligibility (1). 20 RCTs analyzed only those completing the trial per the study protocol [percent analyzed: 89 (86-97)%], while for 19 RCTs patients exclusion reason was unclear [percent analyzed: 91 (69-93)%]. Only 5 RCTs had all subjects complete the trials. Only 92 of the 129 (71%) RCTs with a missing final outcome described missing primary outcome handling which included: LOCF (51), non-responder assignment to those with missing data (29), calculation by interpolation (5). Only 2 RCTs did sensitivity analyses with different missing data assumptions. Experimental intervention efficacy could be assessed for 124 RCTs. The percentage of positive RCTs (statistical significance favoring experiment intervention) according to analytic method were: ITT (66%), modified ITT (87%), per-protocol (67%) and unclear (50%) [p = 0.056, Likelihood Ratio test].

**Conclusion:** A considerable variation in reporting and application of ITT principle in the RCTs exists. In about 30% RCTs, per-protocol or unclear analytic methods were used. Similar number of RCTs with missing data did not address handling of such data. Vast majority of RCTs used the non-recommended single imputation methods for missing data. A better description of subjects selected for final statistical analysis and approaches to deal with missing outcomes are needed.

## **Impact of Biological and Targeted Synthetic Dmards on Work in Patients with Chronic Inflammatory Arthritides : A Meta Analysis of Randomized Controlled Trials and Controlled Cohorts**

**Charlotte Traverson**<sup>1</sup>, Amandine Tubery<sup>1</sup>, Charlotte Hua<sup>2</sup>, Françoise Barchechath-Flaisler<sup>1</sup>, Cédric Lukas<sup>3</sup>, Bernard Combe<sup>2</sup>, Jacques Morel<sup>2</sup> and Cécile Gaujoux-Viala<sup>4</sup>, <sup>1</sup>Rheumatology, Nîmes University Hospital, Nîmes, France, <sup>2</sup>Rheumatology, CHU Lapeyronie and Montpellier University, Montpellier, France, <sup>3</sup>Rheumatology, CHU Lapeyronie and EA2415, Montpellier University, University of Montpellier, France, <sup>4</sup>Rheumatology, Nîmes University Hospital and EA2415 Montpellier University, Nîmes, France  
**First publication:** September 18, 2017

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The addition of biological (b) and new targeted synthetic (ts) DMARDs agents in chronic inflammatory arthritides (CIAs) therapeutic strategies has improved the possibility of controlling disease activity and slowing the progression of joint damage. However their impact on work participation is unclear.

**Objective:** to assess the effect of biological and tsDMARDs versus conventional treatments in patients with CIAs on work outcomes : employment, presenteeism and absenteeism.

**Methods:** A systematic review of the literature using Pubmed-Medline and the Cochrane library was performed until January 2017. All randomized controlled trials (RCT) and controlled cohorts (CC) comparing work outcomes in patients with rheumatic diseases such as rheumatic arthritis (RA), ankylosing spondylarthritis (AS) and psoriatic arthritis (PsA) treated with biological or tsDMARDs versus conventional therapies were selected. Statistical analysis determined in each study effect size (ES) or odds-ratios (OR) as appropriate to assess the magnitude of treatment effect. Pooled ES and OR were computed by meta-analysis. A random effect model was used in case of heterogeneity.

### **Results:**

Thirty three RCTs and 8 CCs were analyzed ie 12306 patients with conventional treatment and 21328 patients with bDMARD or tsDMARD (6610 Infliximab, 5613 Etanercept, 3820 Adalimumab, 672 Golimumab, 2935 Certolizumab, 691 Abatacept, 444 Sirukumab, 351 Baricitinib); 26 studies included 29592 patients with RA, 10 studies included 2226 patients with AS and 5 studies included 1816 patients with PsA.

This meta-analysis showed in patients treated by bDMARD vs conventional treatment:

- a significant decrease of accumulated missed workdays at week 24: ES -0.34 IC95%[-0.6; -0.08] and at week 52: ES -0.04 IC95% [-0.29; 0.2],
- a significant decrease of patients losing hours due to CIAs: RR 0.63 IC95%[0.48; 0.83],
- a significant improvement in VAS productivity: ES -1.81 IC95%[-2.61; -1.01] and in activity impairment (WPAI): ES -10,57 IC95% [-13,99; -7,14].
- For the employment loss, the positive effect of bDMARDs was nearly significant: OR 0.60 IC95% [0.33; 1.09].

**Conclusion:** Despite the heterogeneity of the data, this meta-analysis showed the beneficial effect of bDMARDs on both absenteeism and presenteeism in CIAs. Thus the high cost of biologic agents could be partly balanced with savings in indirect costs.

## **Association of Poor Prognostic Factors with Medication Persistence Among Adult RA Patients within a Community of Rheumatology Clinics**

**Damemarie Paul**<sup>1</sup>, Laura McDonald<sup>2</sup>, Aarti Rao<sup>3</sup>, Ruthwik Anupindi<sup>4</sup> and Keith Knapp<sup>5,6</sup>, <sup>1</sup>HEOR, Bristol Myers Squibb, Lawrence Township, NJ, <sup>2</sup>CORDS, Bristol Myers Squibb, Uxbridge, United Kingdom, <sup>3</sup>Analytics, Mu-Sigma, Bengaluru, India,

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A fixed treatment paradigm often exists for Rheumatoid Arthritis(RA) patient(pts)<sup>1</sup>. However, RA is a heterogeneous disease and differences in pts' serostatus affect disease progression. For pts receiving targeted disease modifying antirheumatic drug (tDMARD) (biologics and JAK inhibitors), this study compares the differences in treatment factors such as persistence, adherence and medication effectiveness for pts with versus those without poor prognostics factors (PPF).

**Methods:** Pts  $\geq 18$  years and satisfying either ACR 1987 or 2010 criteria in the JointMan database between 1 Jan 2009 and 31 Mar 2017 were included. Pts were required to have at least one record for either anti-citrullinated protein antibodies(ACPA) or rheumatoid factor (RF) at baseline (study period start date to index treatment initiation + 30 days). Pts who were ACPA positive (+) only, RF+ only or dual+ were considered PPF positive (PPF+) and pts who were both ACPA and RF negative (-) were controls (PPF-). First tDMARD prescription date was considered as the index date.

Persistence, measured as number of days from index date to first switch from, or discontinuation of the index tDMARD or end of study period, whichever came first, was reported for the two cohorts. Persistence was stratified by cohort and PPF+ subgroups. Kruskal-Wallis test compared median persistence with a significance level of 0.05. Comparisons for all treatment factors will be conducted in the same way.

**Results:** 797(71 %) out of the 1,122 pts included in the analysis were PPF+. Compared to controls, PPF+ pts were older (59 vs 56 yrs) and less likely to be females (73 vs 81%). Overall, median persistence was greater for the PPF+ cohort (420 vs 379 days) but not significant. Comparison of the PPF+ subgroups to controls showed significant differences in persistence between ACPA+ and dual+ pts versus controls. Intragroup comparison of PPF+ subgroups also showed that dual+ pts had substantially lower persistence compared to ACPA+ and RF+ subgroups. ACPA+ pts remained on tDMARD therapy the longest. (ACPA+: 577, RF+: 484, dual+: 344 days)

Table1: Persistence (days) by subgroups of PPF

Descriptive Statistics	Cohort Subgroups			
	PPF+			PPF- (controls)
	ACPA+ (N=163)	RF+ (N=369)	ACPA+ and RF+ (N=265)	ACPA- and RF- (N=325)
Median(IQR)	577(217-1533)	484(174-1108)	344(152-640)	379(161-890)
p-value	0.0016	0.0823	0.0434	Reference
	<.0001	<.0001	Reference	N/A

## Conclusion:

In this study, tDMARD persistence varied based on PPF status. Scientific evidence also demonstrates a correlation between serostatus and RA disease progression. PPF status may need to be considered in tDMARD assignment decisions. Further analysis to evaluate the effect of PPF status on other treatment factors is needed.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** TURKBIO is the Turkish version of Danish DANBIO rheumatologic database which has been established in 2011. In 2016, the EULAR RA management guideline recommended assessment of certain prognostic factors while deciding the treatment strategy after the first csDMARD failure. However, it is unknown how frequent these factors are in bDMARD and tsDMARD initiators and how they affect the treatment response in RA patients. We examined the frequency and influence of these poor prognostic factors on treatment response in bDMARD and tsDMARD initiating RA patients enrolled in TURKBIO. **Methods:** Seven poor prognostic factors were investigated in 898 RA patients started bDMARD and tsDMARD in TURKBIO: (1) Moderate to high disease activity (2) Elevated acute phase reactants (3) High swollen joint counts ( $\geq 4$ ) (4) High RF/ACPA titers (5) Combinations of the above (6) Erosions (7) Failure of  $\geq 2$  csDMARDs. The frequencies of these factors at treatment initiation and influence of these on achievement of DAS28-CRP remission/remission+low disease activity (LDA) at the 6<sup>th</sup> month of treatment were evaluated in overall any bDMARD and tsDMARD-receiving RA patients and in subgroups of individual drugs including TNFi inhibitors (TNFi), abatacept (ABA), rituximab (RTX), tocilizumab (TCZ) and tofacitinib (TOFA). The presence of these factors in patients who stayed on or were withdrawn from the bDMARDs and tsDMARD were also determined. **Results:** Among the seven prognostic factors; factors 1, 2, 4, 6 and 7 were found in over 60% of patients while factors 3 and 5 were present in about 30% of the patients. Factors 1 and 3 were more frequent in patients who were in moderate/high disease activity compared to those in remission+low disease activity at the 6<sup>th</sup> month of treatment (Table). Similarly factors 1 and 3 were determined at higher percentage in non-remission than remission group (Factor 1: 93.4% vs. 82.2%,  $p < 0.001$ ; factor 3: 43% vs. 30.7%,  $p = 0.002$ ). These two factors were also significantly more frequent in patients withdrawn from the treatment than in patients who stayed on treatment (Factor 1: 93% vs. 85%,  $p < 0.001$ ; factor 3: 41% vs. 34%,  $p = 0.038$ ). In TNFi group besides factors 1 and 3, factors 5 and 7 were also significantly more frequent in non-remission group than in remission group whereas, in the RTX group, only factor 1 was significantly more frequent in remission group compared to in non-remission group. For the other bDMARDs and tsDMARD we did not find any difference in poor prognostic factors among patients who did achieve remission and did not. **Conclusion:** Five of the seven poor prognostic factors were detected more than half of the RA patients at bDMARD and tsDMARD initiation in TURKBIO. Patients with poor prognostic factors especially factors 1 and 3 achieved remission less frequently. Additionally, there was a relationship between bDMARDs and tsDMARD withdrawal and factors 1 and 3. The influence of these factors was mainly observed in TNFi receiving group.

**Table. Frequencies of poor prognostic factors in RA patients initiating bDMARDs and tsDMARD.**

<b>Factors</b>	<b>Remission+low disease activity, %</b>	<b>Moderate+high disease activity, %</b>	<b>P value</b>
<b>Factor 1:</b> Moderate to high disease activity	95.9	83.6	<b>&lt;0.001</b>
<b>Factor 2:</b> Elevated acute phase reactants	100	99.5	=
<b>Factor 3:</b> High swollen joint counts (≥4)	47.1	31.7	<b>&lt;0.001</b>
<b>Factor 4:</b> High RF/ACPA titers	68.3	71.9	0.465
<b>Factor 5:</b> Combinations of the factors 1, 2, 3, 4	31.3	25.9	0.284
<b>Factor 6:</b> Erosions	56.5	65.6	0.332
<b>Factor 7:</b> Failure of ≥2 csDMARDs	69.4	69	0.918

*\* Disease activity was assessed by using DAS28-CRP at the 6<sup>th</sup> month of treatment*

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Despite the availability of immunosuppressive disease-modifying anti-rheumatic agents (DMARDs), many rheumatoid arthritis (RA) patients still fail to achieve remission. Fibroblast-like synoviocytes (FLS) are non-immunological joint-lining cells that become invasive during RA. Non-immunosuppressive agents targeting FLS in combination with DMARDs have the potential to improve control of RA without enhancing the risk of infections. We recently reported that disrupting the interaction between the receptor protein tyrosine phosphatase sigma (RPTP $\sigma$ ) and the proteoglycan syndecan-4 using an RPTP $\sigma$  decoy biologic (RPTP $\sigma$ -Ig1&2) reduces FLS cartilage invasion. Here we examined the therapeutic potential of RPTP $\sigma$ -Ig1&2 in combination with tumor necrosis factor- $\alpha$  (TNF) inhibition.

**Methods:**

The relationship between RPTP $\sigma$  and TNF was evaluated in RA FLS, murine FLS and collagen-induced arthritis (CIA) mice by qPCR. The anti-rheumatic effect of RPTP $\sigma$ -Ig1&2 was assessed in spontaneous KBxN (sKBxN) and collagen antibody induced arthritis (CAIA). Also, RPTP $\sigma$ -Ig1&2 was administered to CIA mice either alone or in combination with a mouse anti-TNF receptor agent.

**Results:**

TNF was found to negatively regulate the expression of RPTP $\sigma$  in RA FLS ( $P<0.0001$ ). Anti-TNF treatment of CIA mice increased the joint expression of RPTP $\sigma$  ( $P=0.031$ ). RPTP $\sigma$ -Ig1&2 administration attenuated arthritis in multiple mouse models (sKBxN  $P<0.001$ ; CAIA  $P<0.001$ , CIA  $P=0.0079$ ). Combining RPTP $\sigma$ -Ig1&2 with anti-TNF receptor treatment enhanced the reversal of CIA ( $P<0.0001$ ).

**Conclusion:**

Our study provides the first evidence that an FLS-targeting therapy is efficacious in multiple mouse models of RA and enhances TNF blockade in experimental arthritis.

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Rheumatoid arthritis (RA) patients have a higher frequency of requiring surgical procedures and worse surgical outcome. However, literature regarding post-surgical infectious outcome associated with combination of modifying anti-rheumatic drugs (DMARDs) and biologics is scarce. The aim of the study is to assess whether the risk of post-operative infectious complications among RA patients is affected by discontinued methotrexate (MTX) and Tumor Necrosis Factor Inhibitor (TNFi) prior to surgery during perioperative period.

## Methods:

Using the United States Veterans Affairs (VA) databases, we identified surgical procedures in a 18-year cohort of RA patients, who were on at least 1 DMARDs or 1 biologic agent in the perioperative period. Surgeries were divided into the following groups: patients treated with methotrexate (MTX) and etanercept (ETA) combination therapy, and those treated MTX and adalimumab (ADA) combination therapy. MTX is continued throughout the surgery. The risk of infection is compared among groups that continue vs discontinue within 90 days, 60 days and 30 days of the surgery. Infection includes pneumonia, urinary tract infection and wound infection. Primary endpoints are total infectious complication. Unconditional multilevel mixed effect logistic regression model was used for analysis. Covariates include chronic steroid use status and modified Charlson score. Statistical significance is defined as  $p < 0.05$ .

## Results:

Table 1. Post-operative infection with MTX continued and TNFi discontinued within 90 days

Continue methotrexate		Odds ratio	95% CI	P value	Observations
Continue (reference) vs discontinue					
Discontinue >90 days	etanercept	0.64	0.28~1.47	0.29	811
	adalimumab	0.53	0.21~1.34	0.18	685
Discontinue <90 days	etanercept	1.04	0.26~4.17	0.96	811
	adalimumab	1.74	0.51~5.98	0.38	685

Table 2. Post-operative infection with MTX continued and TNFi discontinued within 60 days

Continue methotrexate		Odds ratio	95% CI	P value	Observations
Continue (reference) vs discontinue					
Discontinue >60 days	etanercept	0.68	0.30~1.51	0.34	820
	adalimumab	0.50	0.20~1.28	0.15	691
Discontinue <60 days	etanercept	0.76	0.15~3.77	0.73	820
	adalimumab	2.64	0.75~9.27	0.13	691

Table 3. Post-operative infection with MTX continued and TNFi discontinued within 30 days

Continue methotrexate		Odds ratio	95% CI	P value	Observations
Continue (reference) vs discontinue					
Discontinue >30 days	etanercept	0.65	0.29~1.45	0.29	830
	adalimumab	0.59	0.24~1.45	0.25	702
Discontinue <30 days	etanercept	1.11	0.21~5.82	0.90	830
	adalimumab	2.09	0.41~10.53	0.37	702

## Conclusion:

When MTX is continued through surgery for patients with RA, there is a trend towards lower risk of post-operative infection when TNFi was discontinued before surgery. Sensitivity analyses of TNFi discontinuation at 30-60-90 days before surgery yielded similar results. However, the reduced infection risks did not reach statistical significance. This could be because of the heterogeneity of surgeries in our study. Further analyses looking at specific types of surgeries may help to ascertain this.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The JAK1 selective inhibitor filgotinib (GLPG0634, GS-6034) was efficacious as both add-on to methotrexate (MTX) and monotherapy in two 24-week phase 2B studies in active rheumatoid arthritis (RA) patients with inadequate response to MTX (DARWIN 1 and 2)<sup>1</sup>. We evaluated the utility of a Multi Biomarker Disease Activity (MBDA) score in relation to clinical disease activity assessments in patients treated with filgotinib.

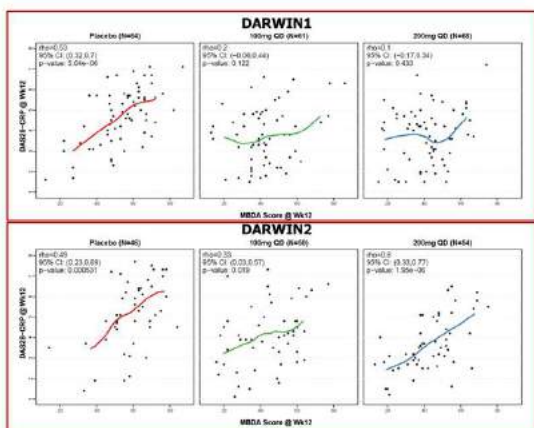

**Methods:** Serum samples from RA patients receiving either a stable dose of MTX and PBO, filgotinib 100mg or 200mg QD (DARWIN 1), or placebo (PBO) or filgotinib monotherapy at 100mg or 200mg once daily (QD, DARWIN 2), were collected and analyzed at baseline and week 12 with the MBDA test (Crescendo Biosciences, CA, US). Spearman's rank correlations between MBDA score and clinical measures (*e.g.* DAS28-CRP, SJC28, TJC28) were estimated at baseline and week 12 and for their changes from baseline to week 12.

**Results:** At baseline, median MBDA scores were the same for both DARWIN 1 and 2 studies (58) with statistically significant correlation observed between MBDA score and DAS28-CRP ( $r=0.43$ ,  $r=0.48$ , respectively, both  $p<0.001$ ). There was weak correlation of MBDA score with SJC28 and TJC28 for DARWIN 1 ( $r=0.2$ ,  $0.11$ ;  $p<0.01$ , ns) and DARWIN 2 ( $r=0.19$ ,  $0.17$ ; both  $p<0.05$ ). At week 12, statistically significant correlations were observed in 200mg filgotinib monotherapy cohort between MBDA score and DAS28, SJC28, and TJC28 ( $r=0.6$ ,  $0.36$ ,  $0.46$ ;  $p<0.001$ ,  $<0.01$ ,  $<0.001$ ) that were less so in 100mg ( $r=0.33$ ,  $0.16$ ,  $0.15$ ;  $p<0.05$ , ns, ns) and PBO ( $r=0.49$ ,  $0.40$ ,  $0.22$ ;  $p<0.001$ ,  $<0.01$ , ns) treatment groups. When comparing change from baseline at week 12, the MBDA only correlated to DAS28-CRP for 200mg filgotinib monotherapy and PBO groups ( $r=0.36$ ,  $0.39$ ;  $p<0.01$ ). There was no statistically significant correlation between MBDA and clinical measures (or between their changes from baseline) for filgotinib on a background of MTX at week 12.

**Conclusion:** The MBDA score significantly correlated with disease activity measures in subjects treated with filgotinib as monotherapy for 12 weeks. Despite similar baseline associations and treatment efficacy no correlation was observed between MBDA score and DAS28-CRP for filgotinib with MTX add-on.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Filgotinib is a potent and selective JAK1 inhibitor in clinical development for treatment of inflammatory diseases, including rheumatoid arthritis and inflammatory bowel diseases. Filgotinib does not inhibit or induce CYP or UGT metabolic enzymes in vitro, and did not alter the pharmacokinetics (PK) of midazolam, a sensitive CYP3A substrate, in healthy subjects. In order to support the use of filgotinib in fertile women, this Phase I study was conducted to rule out unanticipated interactions of filgotinib on the PK of a representative oral contraceptive (OC), levonorgestrel (LEVO)/ethinyl estradiol (EE).

### Methods:

This was an open-label, randomized, two-way crossover study in healthy female subjects. Subjects received a single dose of LEVO (150 ug)/EE (30 ug) alone (Treatment A; reference), or in combination with multiple-dose filgotinib (200 mg once daily; 15 days; Treatment B; test). PK sampling was performed for 120 hours following administration of the OC, and safety was assessed throughout the study. An analysis of variance using a mixed-effects model was applied to the natural logarithmic transformation of PK parameters (AUC and  $C_{max}$ ) for EE and LEVO. Geometric-least squares means (GLSM) ratios and 90% confidence intervals (90%CI) of PK parameters were estimated for the test vs reference treatments, and were compared against pre-specified lack of PK alteration boundaries of 70 to 143%. The PK of filgotinib was evaluated as well, and compared against historical values.

## Results:

The study enrolled 24 subjects. All subjects completed study treatments; 1 subject discontinued after the last PK draw, due to withdrawal of consent. The mean (range) age of subjects was 37 (21-45) years, 21 (87.5%) were white, and 24 (100%) were of Hispanic or Latino ethnicity.

Coadministration of OC with filgotinib resulted in comparable exposures of LEVO and EE. The GLSM ratios (90%CI) for  $AUC_{inf}$ ,  $AUC_{last}$  and  $C_{max}$  of LEVO were 94.9 (90.2, 99.8), 94.2 (89.1, 99.6) and 105 (94.8, 117), respectively; corresponding values for EE were 114 (109, 118), 113 (109, 117) and 114 (106, 122). The GLSM ratios (90%CI) were contained within the pre-specified lack of interaction bounds (70-143%), indicating a lack of interaction of filgotinib on OC. Exposures of filgotinib were consistent with historical data.

Study treatments were generally well tolerated; 3 (12.5%) and 6 (25.0%) of subjects experienced an adverse event (AE) during Treatments A and B, respectively. No serious or severe AEs occurred; all AEs reported were Grade 1 (mild). Of the AEs reported only one (headache) was recorded as related to study drug (during Treatment B), and it was not distinctly attributed to LEVO/EE versus filgotinib. All laboratory abnormalities were Grade 1, and there were no clinically significant trends in laboratory abnormalities, vital sign measurements, or ECG recordings.

## Conclusion:

Co-administration with filgotinib did not alter the PK of levonorgestrel/ethinyl estradiol. Hormonal contraceptives can be allowed as an effective contraception method for subjects on filgotinib treatment.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Randomized clinical trials have shown that if a patient is in sustained remission, biological disease-modifying anti rheumatic drugs (bDMARDs) therapy can be tapered in rheumatoid arthritis (RA). However, little is known about down-titration of bDMARDs in the real world. We retrospectively analyzed our cohort to determine the frequency and predictive factors associated with the successful down-titration of bDMARD in RA patients in our two university hospitals.

**Methods:** This study included consecutive RA patients who fulfilled 1987 ACR and/or 2010 ACR/EULAR classification criteria and treated with bDMARD (infliximab, adalimumab, etanercept, golimumab, certolizumab-pegol, tocilizumab, and abatacept) for longer than 6 months. The patients receiving stable and standard dose treatment were defined as SD group, while the patients receiving down-titration were defined as DT group. We retrospectively reviewed clinical charts and compared the route of administration, concomitant medication use, laboratory data, X-ray findings and patient characteristics at the beginning of bDMARD between SD group and DT group. Statistical analyses were performed using univariate and multivariate analysis.

**Results:** A total of 347 patients (age  $62.5 \pm 13.8$  years old, female 83.6%, disease duration  $12.3 \pm 8.5$  years) were included in this analysis, 255 (73.5%) and 92 (26.5%) patients belonged to SD and DT groups, respectively. Five (1.4%) patients experienced disease flare after down-titration of bDMARD after  $8.4 \pm 5.7$  months. There was no significant difference between SD group and DT group in disease duration, route of administration, prevalence of the anti-citrullinated protein antibody and the rheumatoid factor, TJC, SJC, PGA, DAS28-ESR, and X-ray at baseline. In the univariate analyses of baseline data, there were statistically significant differences in the rates of bDMARD naïve patients, age at onset, age at the beginning of bDMARD, concomitant oral corticosteroid use, and CRP levels between SD group and DT group (57.1% vs 76.4%,  $p = 0.001$ ,  $51.0 \pm 14.6$  vs  $47.1 \pm 14.9$ ,  $p = 0.03$ ,  $59.6 \pm 13.7$  vs  $55.5 \pm 14.6$ ,  $p = 0.02$ , 43.1% vs 34.8%,  $p = 0.04$ , and  $1.9 \pm 2.5$  vs  $1.1 \pm 1.3$ ,  $p = 0.03$ , respectively). Multivariate statistical analysis revealed the low level of serum CRP at baseline were associated with successful down-titration ( $p = 0.03$ , odds ratio = 0.81, 95% CI: 0.663-0.990).

**Conclusion:** Down-titration of biologics might be achieved in RA patients who have the following factors at the beginning of bDMARD: bDMARD naïve, younger age, no concomitant use of corticosteroid, and low level of serum CRP.

The relationship between serum IL-37 and disease activity in patients with rheumatoid arthritis: post-hoc analysis of PLANETRA study.

### Background/Purpose:

Rheumatoid Arthritis (RA) is a chronic inflammatory disorder affecting synovial joints. Multiple pro- and anti-inflammatory cytokine are thought to play a major role in the development of the disease. IL-37 is an anti-inflammatory cytokine which belongs to IL-1 family superfamily and regulates inflammation. We investigated the association of IL-37 with disease activity in RA patients, who were treated with infliximab for 30 weeks.

### Methods:

Patients were recruited from the PLANETRA study (NCT01217086). Patients with active RA were treated with CT-P13 or infliximab originator (INX). We measured the serum levels of IL-37 at week 0 (baseline) and at 30 weeks after treatment. Other demographic, laboratory and clinical variables were evaluated simultaneously. Mann-Whitney or Wilcoxon signed rank test was performed to determine the difference between two groups and Spearman's correlation coefficient was used to test for correlations between variables. The values described are the median values.

### Results:

66 patients with active RA (53 females and 13 males, 54 White and 12 Asians) were analyzed and median age of patients was 50 years. Compared to baseline, all measured clinical and laboratory parameters and serum IL-37 (from 46.1 to 25.2 pg/ml,  $p=0.011$ ) were significantly reduced. There was a correlation between IL-37 and CRP at the time of screening, and IL37 correlated with ESR, CRP, DAS28-ESR, DAS28-CRP and PGAD at week 30. IL-37 levels at 30 weeks after treatment, were lower in patients with  $\text{DAS28} \leq 3.2$  than in patients with  $\text{DAS28} > 3.2$  (DAS28-ESR; 0.0 in  $\text{DAS28} \leq 3.2$ , 30.6 in  $\text{DAS28} > 3.2$ ,  $p=0.002$ , DAS28-CRP; 0.0 in  $\text{DAS28} \leq 3.2$ , 34.3 in  $\text{DAS28} > 3.2$ ,  $p=0.010$ ). IL-37 levels decreased significantly in the EULAR good & moderate response group (DAS28-ESR; 42.2 at week 0, 0.0 at week 30,  $p=0.006$ , DAS28-CRP; 44.8 at week 0, 18.5 at week 30,  $p=0.001$ ), but not in non-responder group. According to the median level of IL-37, CRP was higher in the high group ( $n=29$ ) at screening, and CRP, ESR, DAS28-ESR, DAS28-CRP, HAQ and PAP were higher in high group at week 30.

### Conclusion:

Serum levels of IL-37 is elevated in active RA patients and is associated with disease activity measures of RA.

Table1. Laboratory and clinical parameters at baseline and 30 weeks after treatment

	screening	30 weeks	P-value
Anti-CCP Ab-positive, no(%)	55 (83.3)	52 (78.8)	0.261

## Induction of Immune Tolerance through an Epitope-Specific Vaccine Induces Clinical Amelioration in Patients with Rheumatoid Arthritis

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

The manipulation of immune tolerance using immune checkpoints such as PD-1 is gaining progressive attraction in diseases such as cancer where such manipulation would be clinically relevant. In our previous studies, we have identified an antigenic epitope which contributes to autoimmune inflammation in rheumatoid arthritis. Using dnaJP1, a peptide derived from the pro-inflammatory dnaJ proteins, we have concluded Phase I and II clinical trials<sup>1,2</sup> in which clinical amelioration was associated with the induction of immune tolerance to dnaJP1. Here, we hypothesize that clinical amelioration relies on immunomodulatory mechanisms of immune tolerance involving the reactivation of immune checkpoints.

### Methods:

PBMCs obtained at the end of the Phase II trial (Day168), from clinical responders treated with dnaJP1 (n=6) and clinical non-responders treated with placebo (n=10) were studied for gene expression by quantitative PCR and multi-coloured flow cytometry with antibody panels designed to investigate the T cell immunomes. Flow cytometry results were analysed by clustering with Multi-Dimensional Automated Reduction and Visualization (MARVis), an in-house customised machine learning software.

### Results:

Analysis of PBMCs with the MARVis software employed in this study allowed for the identification of immune subsets and the dissection of complex interactions between immune cell populations at a level which was unachievable before. Examination of the T cell immunomes of dnaJP1 responders and placebo non-responders revealed that clinical amelioration is an outcome of an active process of tolerization. More specifically, the induction of immune tolerance appears to depend on the generation of a population of CD4<sup>+</sup>FoxP3<sup>+</sup> regulatory T (Treg) cells in which PD-1 plays an active role in enhancing the production of anti-inflammatory cytokines such as TGF $\beta$ . This vital observation is complemented by the reshaping of the effector T (Teff) cell compartment which is accompanied by a significant decline in the expression of pro-inflammatory cytokines such as IL-17A and IFN $\gamma$  between the start and

the end of epitope-specific immunotherapy. In parallel, epitope-specific immunotherapy also elicited a subset of antigen-experienced memory T cells (CD4<sup>+</sup>CD45RO<sup>+</sup>CD69<sup>+</sup>TGFβ<sup>+</sup>) which are reliant on tolerogenic pathways.

#### **Conclusion:**

We have taken a holistic approach in identifying the mechanisms dictating the induction of immune tolerance. Our data paves the way for a vaccine-like approach for epitope-specific immunotherapy in rheumatoid arthritis. This novel approach relies on the restoration of the balance amongst various immune checkpoints and will contribute significantly to the development of clinically effective therapies in RA.

#### **Background/Purpose:**

TNFα inhibitors (TNFi) can be immunogenic in patients with autoimmune diseases. B-cell activating factor transgenic mice (BAFFtg) are a model of autoimmune disease since they present with lupus and Sjögren-like manifestations. Prolonged treatment with TNFi in this model leads to anti-drug antibodies (ADA). In humans, low dose Methotrexate (MTX) diminishes immunization against TNFi. MTX favors the release of adenosine monophosphate (AMP), which, via the CD73 ectoenzyme will be transformed in adenosine, a powerful immune-regulatory mediator. We thus sought to investigate the role of MTX in BAFFtg mice to identify the mechanism of action involved in this tolerance.

#### **Methods:**

BAFFtg mice treated with adalimumab or etanercept for 52 weeks with or without MTX for 3 consecutive days starting the day of TNFi, were studied. Drug concentration and ADA were monitored with Theradiag® assays. WT and BAFFtg mice splenocytes and B1 peritoneal cells were compared for surface markers either involved in MTX-related purinergic metabolism (CD73 CD39) or B-

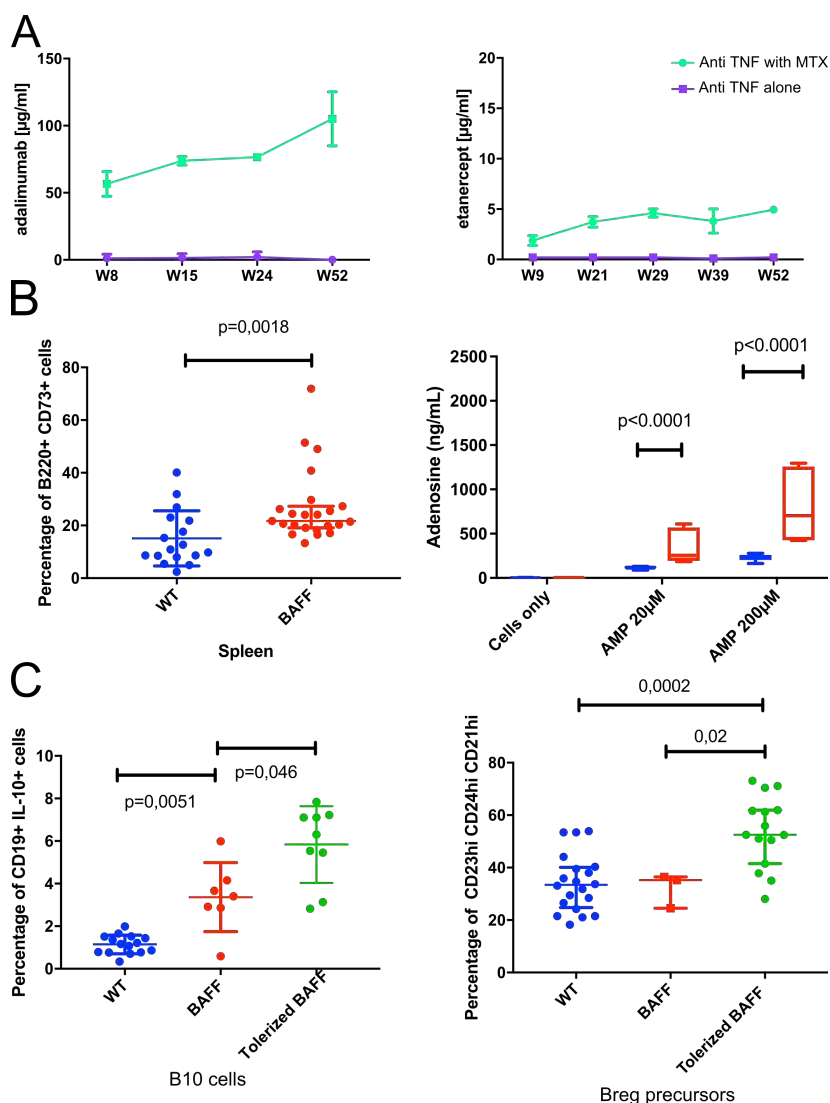

cell regulatory function (IL-10 or Breg precursors: CD21hi CD24hi CD23+ cells). Detection of adenosine on sorted B-cells was performed using mass spectrometry-coupled with HPLC.

## Results:

In BAFFtg mice, a short course of MTX treatment starting the day of the TNFi administration prevented immunization against TNFi and maintained drug concentration over 52 weeks (Fig A). The same experiments made in WT mice led to controversial results. BAFFtg mice splenic B-cells expressed more CD73 (median: 21.7% vs 10.9% for WT) (FigB) leading to more adenosine production (Fig B) when exposed to AMP known to be released by cells upon MTX exposure. BAFFtg splenocytes also expressed more IL-10 (B10 cells) and B1 peritoneal cells express more CD73. Tolerization with MTX further increased B10 and Breg precursors (Fig C).

## Conclusion:

In BAFFtg mice, immunization against TNFi can be prevented for a year by a single course of MTX if administered concomitantly with the first TNFi injection. This supports an interaction between MTX and BAFF to prevent ADA formation. The mechanism of this specific tolerance could involve interaction between extracellular release of AMP induced by MTX and increase of CD73 in BAFFtg mice, which in turn may increase adenosine and IL-10 regulatory B cells.

# Relation of HLA-DRB1 Genotype to the Efficacies of Abatacept and Tocilizumab in Patients with Rheumatoid Arthritis

**Kensuke Oryoji**, The Center for Rheumatology, Matsuyama Red Cross Hospital, Ehime, Japan

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate whether clinical efficacy of abatacept (ABT) and tocilizumab (TCZ) differs depending on whether or not HLA-DRB1 Shared Epitope (SE) is present in patients with rheumatoid arthritis.

**Methods:** HLA-DRB1 genotype of patients treated with ABT (n=78) and TCZ (n=78) was identified. HLA-DRB1 0101,0102,0401,0404,0405,0408,1001 was defined as SE. Retention rate and clinical efficacy were assessed by Cox proportional hazard model and multiple regression analysis.

**Results:** The patients with SE positive were 51 in ABT (65%) and 53 in TCZ (68%). The retention rate of ABT was significantly higher in SE positive patients than in SE negatives. ( $p < 0.0001$ , log rank), and the retention rate of TCZ was not significantly different in both group.

Average CDAI at 24 week was 3.5/10.7 in SE positive/negative group with ABT ( $p < 0.0001$ , ANOVA), and 6.3/5.8 with TCZ ( $p = 0.87$ ). Multivariable Cox hazard regression model, in which age, sex, disease duration, ACPA titer, RF titer, MHAQ, prior use of biological agents, MTX dose, oral steroid dose, and SDAI and CRP at baseline were adjusted, revealed that, compared with SE-positive, SE-negative had a higher abatacept discontinuation due to lack of efficacy (adjusted HR=9.2, 95% CI: 2.8-30.4), but was not significant in TCZ ( $p = 0.41$ ). In addition, the predictor of CDAI at 24 week by multiple regression analysis was SE ( $p < 0.0001$ ) in ABT but SE was not predictive in TCZ.

**Conclusion:** ABT is effective in SE positive group, but TCZ is not relevant for SE.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Background/Purpose:** RA is a chronic, inflammatory disorder leading to disability and reduced quality of life. Effective treatment with biologic DMARDs poses a significant economic burden. The Abatacept versus adalimumab comparison in biologic-naïve RA subjects with background methotrexate (AMPLE) trial was a head-to-head, randomized study comparing SC abatacept with SC adalimumab.<sup>1</sup> A recent *post hoc* analysis showed improved efficacy for abatacept in patients with seropositive, erosive early RA (defined as: disease duration  $\leq 6$  months, RF or anti-citrullinated protein antibody seropositivity and  $>1$  radiographic erosion) compared with adalimumab.<sup>2</sup> **Methods:** A previously published decision tree<sup>3</sup> was used to compare the cost per response of abatacept and adalimumab in a cohort of 1000 patients over a 2-year time horizon. Clinical inputs were based on a *post hoc* analysis of the AMPLE trial in patients with or without seropositive, erosive early RA. Response was based on ACR20/50/70/90 and HAQ-DI. Unit costs for direct medical costs of AEs were based on local tariffs for disease-related groups and the ex-manufacturer price, including mandatory reductions, pay-back and transparent discounts for drugs. **Results:** The cost per response in patients with seropositive, erosive early RA favored SC abatacept compared with SC adalimumab for ACR20, ACR50, ACR70, ACR90 and HAQ-DI across all countries (Table). Cost per ACR90 and HAQ-DI response consistently favored SC abatacept in patients with or without seropositive, erosive early RA in all countries. The cost per CDAI and SDAI remission also favored SC abatacept in patients with seropositive, erosive early RA in all countries; however, the cost per DAS28 remission favored SC adalimumab in the US and Canada. Results in patients without seropositive, erosive early RA were less consistent for SC abatacept, except in Germany and Spain where the cost of abatacept is lower than the cost of adalimumab.

**Conclusion:** The cost per responder favored SC abatacept in patients with seropositive, erosive early RA. Cost savings can be achieved through the use of abatacept over adalimumab in patients with early, rapidly progressing RA in the US, Germany, Spain and Canada. 1. ## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Cardiovascular disease (CVD) constitutes a relevant cause of morbidity and mortality in Rheumatoid Arthritis (RA) patients. Rituximab (RTX) has been proved to be effective in the treatment of RA, indicating that B-cells play a crucial role in the pathogenesis of the disease, not only through the production of autoantibodies. Moreover, B-cells seem to be important in the development of CVD. However, the effect of RTX in the context of CVD in RA patients has not been fully elucidated yet. Therefore, the aims of this study were to evaluate the mechanism of action of RTX on immune and endothelial cells and to investigate the effect of B-cells depletion in the context of CVD in RA patients.

**Methods:** The analysis includes 10 RA patients with moderate-high disease activity based on Disease Activity Score using 28 joints. To evaluate the influence of B-cells depletion on the inflammatory profile of T-cells, purified lymphocytes from 6 RA patients were treated with RTX (1 µg/ml) for 24 hours. B-cells depletion was assessed by flow cytometry and the changes in the inflammatory profile were analyzed by RT-PCR. Following, to identify changes in the activity of crucial mediators in the production of pro-inflammatory cytokines, a western blot was performed on extracted proteins from purified lymphocytes of the 6 RA patients treated with RTX. In a second set of experiments, supernatant from cultured lymphocytes of 6 RA patients, in the presence or in the absence of RTX, was added to cultured endothelial cells (HUVECs) and monocytes isolated from Healthy Donors (HDs) and the response was analyzed by RT-PCR. Finally, serum from 4 RA patients at baseline and after 3 months of therapy with RTX, was added to HUVECs and monocytes isolated from HDs and the response was analyzed by RT-PCR.

**Results:** In parallel to a significant depletion of B-cells, we observed a downregulation of the pro-inflammatory profile of T-lymphocytes, as shown by a significant drop of IL1, IL6, IL17, IFN $\gamma$ , and TNF $\alpha$  genes expression levels. We also found a decrease in the phosphorylation and protein expression of STAT-3 and p38 in lymphocytes treated with RTX, compared to non-treated T-cells. HUVECs and monocytes cultured with supernatant of RA-lymphocytes treated with RTX, showed a decrease in the expression levels of various pro-thrombotic factors (i.e. TF, IL8, and VEGF) as well as cell-adhesion molecules (i.e. V-CAM, I-CAM and e-Selectin). Both HUVECs and monocytes, treated with serum of RA patients after 3 months of therapy with RTX, showed a reduced expression of genes related to their pro-thrombotic and pro-inflammatory profile.

**Conclusion:** Overall, RTX showed a beneficial effect in the context of CVD in RA patients, through the modulation of the inflammatory and pro-thrombotic profile of distinct leukocytes subtypes and vascular endothelial cells. Supported by CTS-794, ISCIII (PI15/01333; RIER RD16/0012/0015)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Tocilizumab, a humanized anti-human IL-6 receptor antibody that blocks the signaling of IL-6/IL-6R complex, is an effective treatment in chronic inflammatory rheumatoid arthritis (RA). Although IL-6 contributes significantly to RA pathology, it is unknown how tocilizumab regulates the immune response of these patients.

**Methods:** Heparinized blood and clinical data from 47 RA patients were collected before treatment (t0) and after 12 months (t12m). Plasmatic cytokines were measured by ELISAs and phenotyping of circulating T CD4<sup>+</sup> lymphocytes (memory, naïve, Tregs and Th subsets) was analyzed by flow cytometry.

## Results:

Clinical and disease characteristics of the patients are shown in table 1. At t0 and at t12m, the concentrations of IL-6 and IL-10 and the concentrations of IL-17, VEGF and IL-22 correlated. After 12m with tocilizumab, the concentrations of sIL-6R and IL-10 significantly increased. Despite the decrease of CD4<sup>+</sup> T lymphocytes, the percentages of Tregs and the Treg subset CD45RA<sup>+</sup> significantly increased. No differences were observed in the percentages of Th1, Th2 and Th17 between t0 and t12m. However, the percentages of Th9 and Th9 CD45RO<sup>+</sup> significantly decreased (Table 2). When patients were segregated according to EULAR response to tocilizumab (NR= no responders, R= responders), sIL6R (at t12m, NR=652±83 vs. R=1731±160 ng/ml, p=0.02) and monocytes/ul (at t12m, NR=840±40 vs. R=610±30, p=0.02) decreased and the ratio t12m/t0 of TregCD45RO<sup>+</sup> increased (NR=0.49±0.15 vs. R=0.91±0.005, p=0.01) only in those patients with good or moderate response.

**Conclusion:** Despite the blocking of IL-6/IL-6R in all RA patients, changes in soluble mediators and T cell subsets were different between EULAR responders and non-responders to tocilizumab. Further information would be necessary to understand the immunological mechanisms operating in the different groups of patients.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

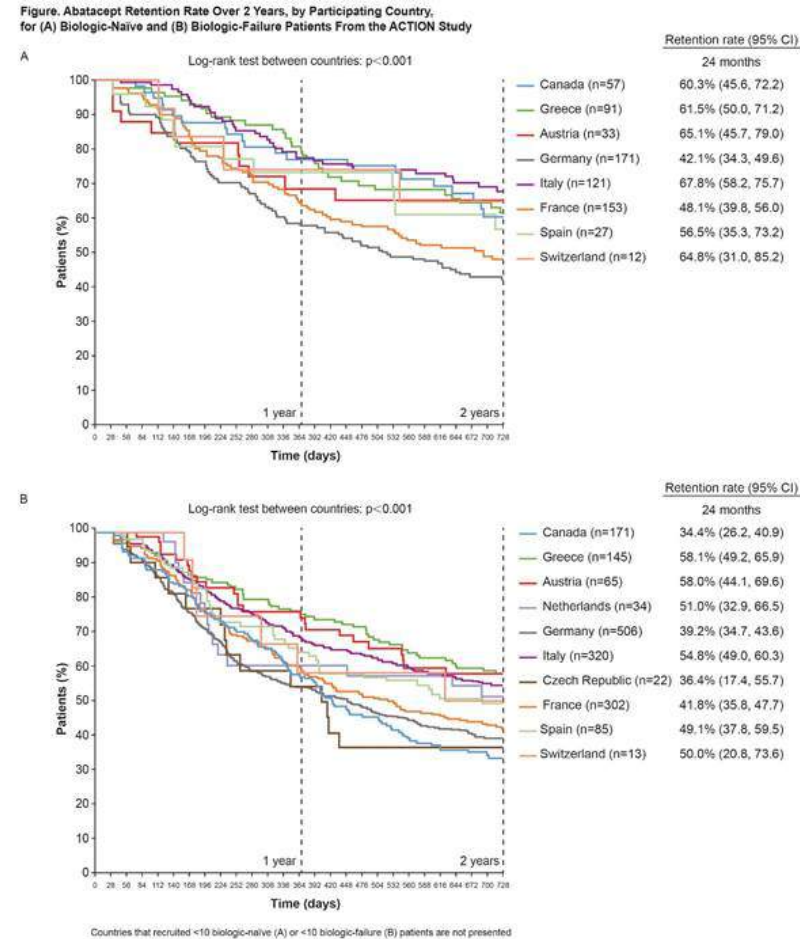

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** ACTION (NCT02109666) was the first prospective international non-interventional study designed to provide long-term real-world data on abatacept retention in patients (pts) with RA. The 1-y interim analyses of ACTION were reported previously.<sup>1</sup>

**Methods:** ACTION is a 2-y observational study of pts with moderate-to-severe RA who initiated IV abatacept as first- or second/further-line biologic therapy in routine clinical practice in Europe and Canada (May 2008–Dec 2013). Here we report the primary outcome of the study, ie 2-y crude abatacept retention rate with 95% CI (overall and by treatment line), estimated by Kaplan–Meier analysis. Additional study outcomes were crude retention rates by participating country, prognostic factors of retention, identified by backward selection method in multivariate models, and EULAR response by treatment line and RF/anti-citrullinated protein antibody (ACPA) seropositivity, compared by Fisher’s exact test.

**Results:** In total, 2350/2364 enrolled pts were evaluable for analysis: 673 (28.6%) biologic naïve and 1677 (71.4%) biologic failures. Some expected differences in baseline characteristics were seen between groups and were reported previously.<sup>2</sup> The 2-y retention rate was 47.9% (95% CI 45.7, 50.0) in the overall population, and was higher in biologic-naïve (54.5% [50.4, 58.3]) vs -failure pts (45.2% [42.7, 47.7]; p<0.001); main reasons for abatacept discontinuation were lack of efficacy (61.4 vs 67.7%) and safety (21.3 vs 21.2%).<sup>2</sup> By country, overall retention rates were 37.5–66.7%; rates were highest in Belgium (66.7%) and Austria (60.5%). Retention rates were higher in biologic-naïve vs -failure pts (Figure). Predictors of higher abatacept retention<sup>2</sup> included: RF/ ACPA seropositivity (p=0.030 biologic naïve; p=0.028 biologic failure); diabetes (p=0.044 biologic naïve); geographic location, Canada, Spain and Italy vs Germany (p<0.001 biologic naïve); and abatacept combination therapy (p<0.001 biologic failure). Only high Patient Global Assessment, ie ≥70, (p=0.009 biologic failure) predicted lower retention. At 2 y, a greater proportion of biologic-naïve vs -failure pts had good/moderate EULAR response (p=0.005); RF and/or ACPA seropositivity was associated with a significantly better response (p=0.007)].<sup>2</sup> **Conclusion:** In a real-world setting, higher abatacept retention rates were achieved by biologic-naïve vs -failure pts. Consistent with other reports,<sup>3</sup> geographic location impacted 2-y abatacept retention even in analyses adjusted for patients’ baseline characteristics. RF and ACPA seropositivity were predictors of higher retention and better outcomes independent of treatment line. These results are consistent with the 1-y ACTION data.<sup>1</sup> 1. ### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** ACTION is a 2-year, observational study of patients (pts) with moderate-to-severe RA who initiated IV abatacept in Canada and Europe (NCT02109666). The objective was to determine pt biologic (b)DMARD use prior to initiation and after discontinuation of abatacept overall and by treatment line in ACTION. **Methods:** Pts with RA initiated IV abatacept as first- or second-/further-line therapy. Biologic-naïve and biologic-failure pts were enrolled during three periods between May 2008 and December 2013. Pts could switch administration routes (IV to SC) during treatment. Crude retention rates (Kaplan–Meier) were compared by log-rank test.

**Results:** Of the 2364 pts enrolled, 2350 were evaluable for analysis: 673 (28.6%) were biologic naïve and 1677 (71.4%) biologic failures. Baseline characteristics differed: biologic-failure pts had longer RA duration, higher CRP levels and prevalence of radiographic erosions, and lower rates of chronic obstructive pulmonary disease and neoplasms vs biologic-naïve pts. Most biologic-failure pts (96.7%) had previously received  $\geq 1$  TNF inhibitor (TNFi): 48.7% had received 1 and 48.0%  $\geq 2$  TNFi; 56.6% had received  $\geq 2$  bDMARDs. The overall 2-year retention rate was 47.9% and was higher for biologic-naïve vs biologic-failure pts (54.5 vs 45.2%;  $p < 0.001$ ); the most common reasons for abatacept discontinuation were inefficacy (61.4 vs 67.7%) and safety (21.3 vs 21.2%). In pts who discontinued abatacept, 83.0% started a bDMARD  $\leq 6$  months after discontinuation (Table), most commonly abatacept IV. Mean (SD) days from stopping abatacept to starting a bDMARD was similar for biologic-naïve (93.4 [51.3]) and biologic-failure pts (93.6 [48.0]). Among pts who restarted abatacept, 62 (80.5%) biologic-naïve and 158 (85.0%) biologic-failure pts were considered to have discontinued as the time from last dose was  $> 84$  (IV) or  $> 28$  (SC) days, and thus were no longer temporary discontinuations, as predefined in the protocol. Three pts discontinued for bad compliance, 3 for lack of efficacy, 3 for remission/major improvement, 12 for safety and 15 for surgery. A good/moderate EULAR response was achieved by 76.7% of pts at the last follow-up before abatacept discontinuation and 58.3% at abatacept restart; mean (SD) DAS28 (CRP) was 3.2 (1.1) and 3.8 (1.4), respectively.

**Conclusion:** Prior to abatacept treatment, over half of biologic-failure pts had received  $\geq 2$  bDMARDs and most had received a TNFi. After initial discontinuation (protocol defined), over one-third of pts restarted abatacept.

SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** SB4 is approved by the European Commission as a biosimilar of the reference etanercept (ETN). The phase III clinical study results have been reported previously.<sup>1,2</sup> Data to date shows no correlation between the development of anti-drug antibody (ADA) and clinical response or adverse events with etanercept treatment. The objective of this study was to investigate the impact of the presence of ADA or injection site reaction (ISR) on efficacy in patients with rheumatoid arthritis (RA) treated with SB4 or ETN up to week 24.

**Methods :** In this phase III randomized, double blind study, patients with moderate to severe RA received 50 mg/week of either SB4 or ETN with background methotrexate (MTX) for 52 weeks. Efficacy, safety and immunogenicity were assessed.

**Results :** Up to week 24, the incidence of ADA (2 patients [0.4%] in SB4 vs 39 patients [13.1%] in ETN,  $p < 0.001$ ) and the incidence of ISR (9 patients [3.0%] in SB4 vs 48 patients [16.2%] in ETN,  $p < 0.001$ ) were significantly lower in SB4 compared to ETN. Due to the low incidence of ADA in the SB4 treatment group, the impact of ADA on efficacy could not be evaluated. Within the ETN treatment group at week 24, there was a trend towards increased efficacy (ACR20, ACR-N, change in DAS28, remission and low disease activity based on DAS28, SDAI, or CDAI) in patients without detectable ADA compared to patients with ADA (Table). In regards to ISR, efficacy tended to be higher in patients who did not experience ISR compared to those who did within each treatment group.

There was no correlation between the presence of ADA and incidence of ISR. In patients without detectable ADA and patients with ADA, respectively, 3.0% (9/297) vs. 0.0% (0/2) of patients from SB4 group and 16.3% (42/248) vs. 15.4% (6/39) of patients from the ETN group experienced ISR.

**Conclusion :** Significantly fewer patients from SB4 developed ADA or experienced ISR compared to ETN, however the efficacy was still comparable between SB4 and ETN in patients without detectable ADA and in patients who did not experience ISR. Within the ETN group, there was a trend towards increased efficacy in patients without detectable ADA compared to patients with ADA. In both SB4 and ETN group, patients without ISR tended to have higher efficacy than patients with ISR. There was no correlation between the presence of ADA and ISR.

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-TNF has drastically changed the prognostic of the RA, carrying an important healthcare expense. This is why, optimisation seems a successful strategy that should not be linked to a worse outcome of our patients' clinical evolution.

**Methods:** Observational study of the prospective cohort RA-Paz. Aim of the study: describe a population of patients with RA under optimised treatment with Adalimumab (Ada) or Infliximab (Ifx). Study the incidence of flares and establish predictive factors of flares at baseline and pre-optimization. All the patients diagnosed of RA under treatment with Ifx or Ada between Jan. 2000 and Dec. 2016 of the day-care unit, were included. Demographic data, clinical activity and blood sample results were collected at baseline, pre-optimization (pre-op) and at 3, 6, 9, 12, 18 and 24 months. Drug serum trough levels were measured under ELISA in each visit. Optimal range for Ifx was described as drug concentration between 1000- 4000 ng/ml and 1500- 5000 ng/ml for Ada. Optimisation was defined as drug use below standard dose. Flares were collected from the pre-op visit. Flare was described as clinical worsening which led to a therapeutic change or a DAS28 > 3.2 and Delta DAS28 > 0.6. Predictive factors of flare at baseline and pre-op were evaluated with a uni and multivariate analysis.

**Results:** Of the 271 patients diagnosed of RA, 74 patients were optimised (44 under Ada and 30 under Ifx). During the 24 months after the pre-op visit, 55.4% (41) of the patients presented at least one flare, with an average of 1.38 flares [1-5]. 53.7% of the patients, (22/41), were controlled with the adjustment of non biological treatment. Only 39.0% (16) of the patients, had to go back to the previous optimised dose and 7.3% (3) to the standard dose. 88% (39/41) were controlled after the dose modification. 104 flares were collected, 33% (34) happened at the 3rd month and 20% (21) at 24th. In the population who presented flares, we observed a persistent higher DAS Vs the patients who never presented flares (DAS pre-op 3.20±1.16 Vs 2.26±0.59; DAS 24month 3.61±1.13 Vs 2.10±0.65; p=0.007). A least proportion of patients with flares were in supra-optimal range (13.3% with flares vs 26% without, p=0.007). At baseline, no clinical factors were predictive of flare. Nor were blood sample results. In contrast, a higher disease activity, measured by DAS pre-op (p=0.004), a worst EULAR answer (p=0.027) and not being in supra-optimal range (p=0.032), were statistically correlated with flares development at the univariate analysis. Time to the optimisation tended to the significance (OR=1.152; p=0.08). In the multivariate analysis, only a higher DAS pre-op (OR: 2.00, [1.08-3.73]) and being in optimal (OR: 5.90, [1.38-25.2]) and sub-optimal range (OR=6.05 [1.28-28.7]), were independently correlated.

**Conclusion:** We noted a high proportion of flares in our cohort of optimised patients. However, flares were controlled with dosage readjustment without needing a change of the treatment. Independently correlated predictive factors for flares were a higher disease activity measured by DAS and not being in therapeutic range in the pre-optimisation visit.

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Adipose tissue produces several inflammatory mediators. Thus, obesity affects the disease course and the responses to the anti-rheumatic agents in inflammatory diseases. Several previous reports have documented that obesity decrease the response rate to anti-TNF- $\alpha$  agents in rheumatoid arthritis (RA). The aim of the study was to determine whether body mass index (BMI) is involved in the response to rituximab in RA.

**Methods:** Data on patient characteristics, diagnosis, previous treatment and outcomes have been collected since 2011 in Turkish Biologic (TURKBIO) Registry. By the end of May 2017, 206 RA patients, received rituximab from the TURKBIO registry, were included in the analysis. Demographic and clinical data including age, sex, disease type, disease duration, and previous or current treatment with DMARDs and biological drug durations are stored in the database. Kaplan-Meier survival analysis was performed to estimate the drug survival. Subgroups were compared by log-rank.

**Results:** 32.5% patients were normal/underweight, 67.5% were overweight and 28.6% were obese. Mean age, female percentage, DAS28-CRP and VAS were higher in obese patients than non-obese ones (Table 1). Rituximab treatment was ongoing 71.2% in obese and 63.3% in non-obese patients ( $p=0.279$ ). Median drug survival duration was 77 months in obese patients and 62 months in non-obese ones ( $p=0.053$ ). Estimated drug survival rates for rituximab were not statistically significantly different in the obese and non-obese patients (Fig. 1).

**Table 1.** Clinical and laboratory data in obese an non-obese patients

	Obese patients	Non-obese patients	p

**Conclusion:** It is known that adipose tissue increases TNF- $\alpha$  level and enhances cellular immunity. Since its act on humoral immunity may be limited, obesity does not affect the response to rituximab.

## **Golimumab Improves Work Productivity and Activity Impairment in Patients with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA): Interim Results from a Non-Interventional Trial in Germany**

Klaus Krüger<sup>1</sup>, Sven Remstedt<sup>2</sup>, Astrid Thiele<sup>3</sup> and Ines Klaudius<sup>4</sup>, <sup>1</sup>Praxiszentrum St. Bonifatius München, München, Germany, <sup>2</sup>Rheuma Praxis Berlin, Berlin, Germany, <sup>3</sup>Krankenhaus St. Josef Wuppertal, Wuppertal, Germany, <sup>4</sup>MSD Sharp & Dohme GmbH, Haar, Germany

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

In Germany no prospective data are available for Golimumab (GLM) in patients with RA, AS and PsA regarding outcomes evaluating work productivity and activity in daily life.

It is the aim of this study to show the benefit of GLM in work productivity and activity for RA, AS and PsA pts in Germany. The analysis was performed by the validated WPAI (**W**ork **P**roductivity **A**ctivity **I**mpairment) as primary endpoint. WPAI is rated to be the most psychometrically validated and frequently used instrument for measuring of health-related work-productivity. **Methods:**

As primary endpoint the change of work productivity impairment and ability for daily activities in month 3 (V1) versus baseline visit (V0) was evaluated.

All 4 subscores of the WPAI were analyzed: disease related absence from work (absenteeism), working while sick (presenteeism), total work productivity impairment (TWPI) and activity impairment with TWPI as primary score.

In addition an evaluation of the activity impairment in the mITT population (**m**odified-**I**ntention-**T**o-**T**reat) was performed. **Results:**

749 pts were included in the study (all patients who started with GLM); thereof 664 pts formed the mITT population (at least V0 and V1 documented). 469 (RA=150, AS=168, PsA=151) of 664 pts were included in the analysis of the primary efficacy endpoint, as they were employed at V0.

Figure 1: Overview of WPAI scores including relevant standard deviations of RA pts; for all  $p < 0.05$  (mean difference of TWPI is based on 76 / 150 pts, due to the fact that for 74 pts entries for the WPAI questionnaire were missing).

Figure 2: Overview of WPAI scores including relevant standard deviations of AS pts; for all  $p < 0.05$  (mean difference of TWPI is based on 104 / 168 pts, due to the fact that for 64 pts entries for the WPAI questionnaire were missing).

Figure 3: Overview of WPAI scores including relevant standard deviations of PsA pts; for all  $p < 0.05$  (mean difference of TWPI is based on 80 / 151 pts, due to the fact that for 71 pts entries for the WPAI questionnaire were missing). **Conclusion:**

GLM s.c. 1 x monthly is an effective treatment in pts. with RA, AS and PsA.

All scores of the WPAI showed a significant ( $p < 0.05$ ) reduction in mean score values in each indication. GLM leads to an improvement of work productivity and daily activities in all pts. already within the first 3 months of treatment.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Response prediction of certain biologic agents for the treatment of rheumatoid arthritis (RA) is still an unmet need in real-world clinical practice. To reduce trial and error, discovering easily-accessible predictive markers for treatment response would be beneficial both for patients and healthcare systems. The patient-reported components tender joint count (TJC) and visual analogue score (VAS-GH) of the 28-joint disease activity score (DAS28) has been termed DAS28P and investigated as a predictor to the response to biologic agents, mostly TNF inhibitors (1, 2). We aimed to evaluate DAS28P as a predictor of EULAR response to abatacept in patients with RA.

**Methods:** The study population was a prospective cohort of Korean patients with RA who were followed up for a nationwide post-marketing survey of abatacept. By applying 6 month last observation carried forward method, 341 patients were involved in the analysis stratified upon the EULAR response criteria (3). Univariate analysis including chi-square test or Kruskal Wallis test were conducted for demographic factors, medical history, and clinical indices. Correlation of DAS28P with DAS28-ESR, change of DAS28-ESR, and EULAR response group were evaluated by Pearson's coefficient (PC) or Student t-test. Logistic regression analysis was used to predict good to moderate EULAR response to abatacept in the study population.

**Results:** Presence of comorbidities, previous exposure to biologic agents, baseline DAS28-ESR, three of its components (tender joint counts, VAS global health, and ESR) and baseline DAS28P were significantly associated with EULAR response of abatacept at 6 months. Baseline DAS28P had positive correlation with baseline DAS28-ESR (PC=0.529,  $p < 0.001$ ) (Fig 1A) and negative correlation with interval change of DAS28-ESR (PC=-0.275,  $p < 0.001$ ) (Fig 1B). Stratified upon EULAR response, a group with good or moderate response had higher baseline DAS28P and lower interval change (Fig 1C, 1D). ROC curve of DAS28P and EULAR response revealed significant association (AUC=0.590,  $p = 0.014$ ). Logistic regression analysis showed that a DAS28P cutoff of  $> 0.44$  had the strongest association (OR=4.84,  $p = 0.001$ ) with good to moderate EULAR response (Table 1).

**Conclusion:** The subjective proportion of baseline DAS28, the DAS28P, is predictive of response to abatacept with a higher baseline DAS28P associated with a favorable therapeutic response of abatacept at 6 months after treatment initiation.

## Collection of Anti-Rheumatic Medication Data from Both Patients and Rheumatologists Shows Strong Agreement in a Real World Clinical Cohort

**Mohammad Movahedi**, Angela Cesta, Xiuying Li and Claire Bombardier, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Collection of Anti-Rheumatic Medication (ARM) information from both patients and rheumatologists is considered a strength for Rheumatoid Arthritis (RA) registries and cohorts. However, it is important to assess the agreement between these two data sources. We aimed to examine the agreement between patient and rheumatologist reported ARM use, their administration routes, and start and stop dates in the Ontario Best Practices Research Initiative (OBRI).

### **Methods:**

Adult Patients enrolled in the OBRI who consented to both patient interviews and rheumatologist evaluations were included. Patients in the OBRI are interviewed every six months, while rheumatologist assessments are conducted as per routine care. For this analysis, we included patients who enrolled in OBRI on or after Sep 1<sup>st</sup> 2010 and compared ARM use reports where rheumatologist visits and interviews occurred within 60 days of each other. ARM included conventional synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs) and biologic DMARDs (bDMARDs). Cohens' Kappa statistics of agreement between the two data sources were calculated for ARM use and administration route. Kappa values 0.61-0.80 were considered to represent good and 0.81-1.00 as very good agreement. To examine factors associated with agreement, a multivariate backward stepwise logistic regression was used to model the odds of agreement for ARM use. The absolute time gap (days) for starts and stops dates between patient reports and rheumatologist reports were also assessed and presented by median and interquartile range (IQR) in a subset analysis.

### **Results:**

2,154 patients (78.7% female) were included with a mean (SD) age at OBRI enrolment of 57.8 (12.6) year. Mean (SD) disease parameters were: disease duration: 8.4 years (9.9); DAS28: 4.2 (1.6); physician global: 4.0 (2.5); and health assessment questionnaire (HAQ) disability Index: 1.1 (0.8). For csDMARDs use, the prevalence was 74.2% based on patient reports and 76.6% based on rheumatologist reports. The prevalence of bDMARDs use was approximately 20.0% based on both reports.

Overall agreement for ARM use between patient and rheumatologist reports was good. In the regression model, increased HAQ-pain index (OR: 0.66; 95% CI: 0.60-0.73) and physician global (OR: 0.95; 95% CI: 0.92-0.98) were significantly associated with lower agreement. By contrast, post-secondary education (OR: 1.20; 95% CI: 1.02-1.40), and seeing an academic rheumatologist (OR: 1.47; 95% CI: 1.25-1.73) were significantly associated with higher agreement between the two data sources.

There was good and very good agreement for reported administration route of bDMARDs and csDMARDs, respectively. The median absolute time gap (IQR) of start dates and stop dates for ARM use reported by the two data sources was 7 days (1-27) and 19 days (5-48), respectively.

### **Conclusion:**

The results of this analysis suggest that ARM reports from the two data sources have strong agreement in the OBRI. This agreement is even better for patients who have post-secondary education and are being treated by an academic rheumatologist.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patient-reported outcomes are, in addition to other efficacy and safety related outcomes, important reflections of effectiveness and adverse effects of a therapy. The Outcomes Measures in Rheumatology Clinical Trials (OMERACT) initiative therefore strongly endorses to monitor also health-related quality of life (HRQoL) in rheumatoid arthritis (RA) studies. In the U-Act-Early strategy trial, initiation of tocilizumab (TCZ) has been proven more efficacious for reducing disease activity when compared to a step-up methotrexate strategy in disease modifying anti-rheumatic drugs (DMARD)-naïve patients with early RA. Here we report the effect of the strategies in this treat-to-target trial on HRQoL, as measured by the five dimensional EuroQol (EQ-5D) questionnaire.

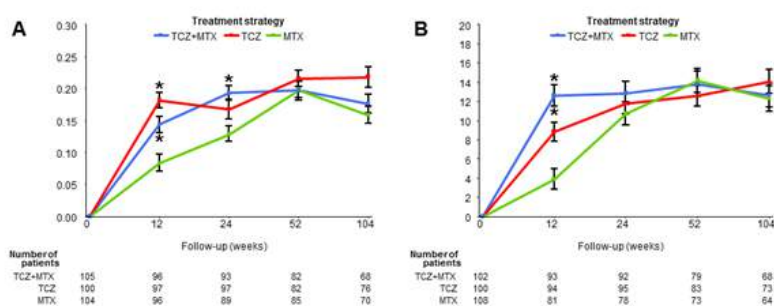

**Methods:** In U-Act-Early, 317 early RA patients were randomized (1:1:1) to initiate methotrexate (MTX), TCZ or TCZ+MTX therapy and were treated to target until sustained remission (disease activity score assessing 28 joints (DAS28) <2.6 with ≤4 swollen joints for ≥24 weeks) was achieved. Hydroxychloroquine, as part of the initial treatment regimen, was added if remission was not achieved. If after 12 additional weeks the target still was not reached, patients switched to a subsequent treatment regimen: those in the TCZ arm or in the MTX arm switched to TCZ+MTX therapy; patients who started with TCZ+MTX switched to standard of care. We used a linear mixed model to analyze the differences between groups in change from baseline over time in EQ-5D utility scores (anchored at “0” (dead) and “1” (perfect health)) and the corresponding visual analogue scale (EQ-VAS, range 0-100). ANCOVA was used for between-group comparisons of scores at week 12, 24, 52 and 104.

**Results:** Significant greater improvements over time were found in EQ-5D scores in patients in the TCZ+MTX arm, compared to the MTX arm ( $p=0.02$ ), but not compared to the TCZ arm ( $p=0.09$ , Fig. 1). No significant differences were found over time between the strategies in EQ-VAS scores ( $p\geq 0.14$ ). When evaluating between-group differences at specific time-points, improvements were significantly greater at week 12 in both TCZ strategies in EQ-5D (TCZ+MTX vs MTX,  $p=0.04$ ; TCZ vs MTX,  $p=0.01$ ) and EQ-VAS scores (TCZ+MTX vs MTX,  $p<0.01$ ; TCZ vs MTX,  $p=0.04$ ), when compared to the MTX strategy. After 24 weeks, significance only remained in the EQ-5D score in favor of the TCZ+MTX strategy (TCZ+MTX vs MTX,  $p<0.01$ ).

## Conclusion:

Initiating a treat-to-target TCZ-based strategy in DMARD-naïve patients with early RA resulted in significant improvements in HRQoL when compared to initiation of step-up MTX therapy, in line with current standards.

**Fig. 1:** Mean (SE) improvements from baseline (y-axis) in (A) EQ-5D (range 0-1) and (B) EQ-VAS (range 0-100) scores.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sirukumab, a selective, high-affinity, human anti-IL-6 monoclonal antibody, is in development for rheumatoid arthritis (RA) and other diseases. Effects of sirukumab on RA symptoms and disease activity and health-related physical and emotional well-being were evaluated in 2 phase 3 randomized controlled trials (RCTs) in RA pts with inadequate responses to conventional DMARDs (SIRROUND-D) or TNF inhibitors (TNFi; SIRROUND-T). Across both RCTs, significant improvements were observed in all 8 SF-36 domains with both evaluated sirukumab doses (50 mg q4w and 100 mg q2w) versus placebo (PBO;  $P < 0.001$ ).

**Methods:** In both RCTs, eligible pts were randomized (1:1:1) to treatment with SC sirukumab 50 mg q4w, sirukumab 100 mg q2w, or PBO. Durations of PBO treatment were 52 and 24 wks, respectively, in SIRROUND-D and SIRROUND-T. Efficacy of sirukumab was evaluated using traditional RA endpoints. This analysis included SDAI and CDAI scores and the following patient-reported outcomes (PROs): pt global assessment of disease activity, pain (0-10 VAS), HAQ-DI, FACIT-Fatigue, and SF-36 health survey. In this post-hoc analysis, correlations between changes from baseline (BL; at Wks 16 [primary endpoint] or 24) in disease activity, symptoms, and SF-36 domain scores were evaluated. Last observation carried forward was used for imputing missing data.

**Results:** For changes from BL to Wk 16 in SIRROUND-T, correlation coefficients ( $r$ ) were low to moderate between all 8 SF-36 domains and SDAI ( $r$  ranging from  $-0.535$  to  $-0.208$ ) and CDAI ( $-0.526$  to  $-0.209$ ; **Table**). Low to moderate correlations were also observed between changes from BL to Wk 16 in 7 of 8 SF-36 domains and pt global assessment scores ( $r$  ranging from  $-0.461$  to  $-0.267$ ) in SIRROUND-T, and a high correlation was observed for the remaining domain, bodily pain ( $-0.665$  to  $-0.619$ ). Moderate correlations were observed between changes from BL to Wk 16 in the SF-36 bodily pain, physical function, social function, and role-physical domains and changes in HAQ-DI ( $r$  ranging from  $-0.560$  to  $-0.310$ ). Moderate to high correlations were observed for changes from BL to Wk 16 in 7 of 8 SF-36 domains and FACIT-Fatigue scores ( $r$  ranging from  $0.392$  to  $0.627$ ; **Table**). As anticipated, changes from BL to Wk 16 in VAS pain and SF-36 bodily pain domain were highly correlated ( $r$  ranging from  $-0.672$  to  $-0.661$ ; **Table**). Correlations were generally higher with sirukumab than placebo. Similar correlations were observed in changes from BL to Wk 16 in SIRROUND-D. These correlations were maintained at Week 24 in both RCTs.

**Conclusion:** Results of these analyses highlight the importance of PROs, including SF-36 and FACIT-Fatigue, as independent measures of treatment success. Although some SF-36 domains are moderately correlated with clinical responses, these findings indicate that SF-36 captures aspects of patient well-being not covered by standard measures of RA symptoms and disease activity.

SF-36, Short Form-36; HAQ-DI, Health Assessment Questionnaire-Disability Index; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; CDAI, clinical disease activity index; SDAI, simple disease activity index.

\*Correlations were defined by the following categories: low =  $\geq -0.3$  to  $\leq 0.3$ ; moderate =  $> -0.6$  to  $< -0.3$  or  $> 0.3$  to  $< 0.6$ ; or high =  $-1.0$  to  $\leq -0.6$  or  $\geq 0.6$  to  $1.0$ .

<sup>b</sup>For FACIT-Fatigue scores, a more positive correlation coefficient indicated a stronger correlation.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy Poster II: Prognostic Factors, Imaging and Miscellaneous Reports

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Response to therapy in rheumatoid arthritis (RA) is heterogeneous. Early identification of patients (pts) who are unlikely to achieve a meaningful clinical response may inform decisions to stop treatment in individual pts (Wijbrandts and Tak;

Mayo Clin Proc; in press). This would improve benefit:risk ratio in pts who continue treatment, and allows earlier cycling to alternate treatments for those who do not respond. Sirukumab (SIR) is a human monoclonal antibody that selectively binds to the cytokine IL-6 with high affinity, and has demonstrated efficacy in Phase 3 RA studies. This post hoc analysis explored whether lack of change in Clinical Disease Activity Index (CDAI) after a single dose of SIR could be used to identify pts with a low likelihood of clinical response after continued treatment.

**Methods:** We evaluated clinical response to SIR in two Phase 3 clinical trials in anti-TNF inadequate responders (IRs; SIRROUND-T; Aletaha D, et al. Lancet. 2017;389(10075):1206-1217) and DMARD IRs (SIRROUND-D) using CDAI - a simple composite measure of disease activity which does not include measurement of inflammatory markers. In both studies pts were randomized 1:1:1 to placebo, SIR 50 mg every 4 weeks (q4w), or SIR 100 mg every 2 weeks (q2w). We evaluated whether a change from baseline in CDAI  $>0$  (representing worsening) at Week 4 could predict clinical outcomes including ACR20 (primary endpoint) and DAS28 (CRP)  $\leq 3.2$  at Week 16 in pts receiving SIR 50mg q4w in SIRROUND-T. Analyses were repeated for Week 24 outcomes, SIR 100 mg q2w and in SIRROUND-D.

**Results:** A significantly greater proportion of pts achieved the primary endpoint of Week 16 ACR20 response on both doses of SIR compared to placebo in SIRROUND-T and -D ( $p < 0.001$ ). Worsening in CDAI at Week 4 after a single dose of SIR 50mg q4w was predictive of non-response at Week 16 in SIRROUND-T: 22% (65/291) of pts had CDAI worsening at Week 4; of these pts more than 85% did not achieve ACR20 or DAS28 (CRP)  $\leq 3.2$  at Week 16 (NPV in Table 1). The 22% of pts with CDAI worsening at Week 4 could consider stopping SIR at Week 4 based on predicted non-response. In the remaining subgroup of pts, there was an approximate 20% relative increase in ACR response rates compared to the overall population rates. Results were comparable for the SIR 100 mg q2w dose, Week 24 outcomes, and for both doses in SIRROUND-D (Table 1).

**Conclusion:** SIR has demonstrated robust efficacy in RA. Lack of clinical efficacy at 16 weeks can be predicted using worsening from baseline in CDAI after a single dose of SIR 50mg. This approach can be further refined using different cut-offs and methods of prediction. It can also be extended to determine probabilities of achieving other outcomes, e.g. remission, which may be specific to the individual pt. These results have the potential to enable early treatment discontinuation decisions for individuals who are unlikely to respond to continued therapy.

**Table 1. Predictive values of ACR20 and DAS28 (CRP)  $\leq 3.2$  after 16 and 24 weeks of treatment with sirukumab 50mg q4w and 100 mg q2w based on change from baseline to Week 4 in CDAI.**

	ACR20		DAS28 (CRP) $\leq 3.2$	
	Week 16	Week 24	Week 16	Week 24
Week 4 CDAI change from baseline	SIRROUND-T (anti-TNF inadequate responders)			
Sirukumab 50 mg q4w N=292 CDAI change > 0 (NPV) $\leq$ 0 (PPV)	56/65 (86.2%) 108/226 (47.8%)	54/65 (83.1%) 114/226 (50.4%)	57/65 (87.7%) 91/226 (40.3%)	58/65 (89.2%) 94/226 (41.6%)
Sirukumab 100 mg q2w N=292 CDAI change > 0 (NPV) $\leq$ 0 (PPV)	43/50 (86.0%) 125/242 (51.7%)	39/50 (78.0%) 114/242 (47.1%)	43/50 (86.0%) 96/242 (39.7%)	40/50 (80.0%) 97/242 (40.1%)
	SIRROUND-D (DMARD inadequate responders)			
Sirukumab 50 mg q4w N=556 CDAI change > 0 (NPV) $\leq$ 0 (PPV)	64/80 (80.0%) 288/476 (60.5%)	61/80 (76.3%) 279/476 (58.6%)	62/80 (77.5%) 192/476 (40.3%)	62/80 (77.5%) 213/476 (44.7%)
Sirukumab 100 mg q2w N=558 CDAI change > 0 (NPV) $\leq$ 0 (PPV)	67/88 (76.1%) 278/470 (59.1%)	61/88 (69.3%) 286/470 (60.9%)	67/88 (76.1%) 212/470 (45.1%)	71/88 (80.7%) 247/470 (52.6%)

Data presented are n/N (%) of patients not achieving (NPV) or achieving (PPV) clinical outcome of interest  
CDAI – Clinical Disease Activity Index, ACR20 - American College of Rheumatology response 20%, DAS28 (CRP) – Disease Activity Score analyzed using C-reactive protein, TNF – Tumor Necrosis Factor, DMARD – Disease Modifying Anti-Rheumatic Drug, NPV – Negative Predictive Value, PPV – Positive Predictive Value  
CDAI change from baseline >0 is considered worsening; CDAI change from baseline  $\leq$ 0 is considered maintenance or improvement of response.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Despite men being less prone to develop autoimmune diseases, male sex has been associated with a more severe disease course in several systemic autoimmune diseases. In the present study, we aimed to identify differences in clinical presentation between the sexes at the time of diagnosis and during long-term follow-up of primary Sjögren's syndrome (pSS), and to establish whether male sex is associated with a more severe form of pSS.

## **Methods:**

Incident, treatment naïve patients (n=199, 186 females and 13 males) from Stockholm, Sweden were prospectively included during a 5-year period and examined for items of classification criteria for pSS as well as extraglandular manifestations (EGM). Serum was sampled at the time of diagnosis and anti-Ro52/SSA levels measured by ELISA. Replication of significant findings was confirmed in an independent cohort of incident pSS patients from Pisa, Italy (n=377, 368 females and 9 males), and meta-analysis performed.

We further studied a cohort of 967 patients with prevalent pSS (899 females and 68 males) from Scandinavian clinical centers. The mean follow-up time (years) was  $8.8 \pm 7.6$  for women and  $8.5 \pm 6.2$  for men (ns). Clinical data including serological and hematological parameters, glandular, EGM and comorbidities were compared between men and women.

## **Results:**

An increased frequency of EGM in men at diagnosis was observed and replicated ( $p=0.05$ ,  $p=0.0003$ , and  $p_{\text{meta}}=0.002$ , respectively). This related to pulmonary involvement, vasculitis and lymphadenopathy being more common in men, for whom a lower age at diagnosis was observed in the exploratory cohort. Additionally, SSA positive male patients had significantly higher levels of anti-Ro52 levels than their female counterparts ( $p=0.02$ ).

After long-term follow-up, male patient serology was characterized by more frequent positivity for anti-SSA and anti-SSB ( $p=0.02$ ), and ANA ( $p=0.02$ ). Also, men with pSS were more frequently diagnosed with interstitial lung disease ( $p=0.008$ ), lymphadenopathy ( $p=0.04$ ) and lymphoma ( $p=0.007$ ). Conversely, concomitant hypothyroidism was more common among female patients ( $p=0.009$ ).

## **Conclusion:**

Our analysis of two independent cohorts of incident pSS and a large cohort of prevalent pSS demonstrates significant differences between women and men with pSS. Notably, men present with more EGM, enhanced serological profile and a higher frequency of lymphoma development.

## Risk of Ischemic Stroke in Sjögren's Syndrome Patients: A Systematic Review and Meta-Analysis

**Jirapat Teerakanok**<sup>1</sup>, Daniel Cordoba<sup>2</sup>, Sakolwan Suchartlikitwong<sup>3</sup> and Kenneth Nugent<sup>4</sup>, <sup>1</sup>Internal medicine, Texas Tech University health and sciences center, Lubbock, TX, <sup>2</sup>Internal Medicine, Texas Tech University Health and Sciences Center, Lubbock, TX, <sup>3</sup>Internal medicine, Texas Tech University Health Sciences Center, Lubbock, TX, <sup>4</sup>Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary Sjögren's syndrome (SS) is an autoimmune disease of the exocrine glands with lymphocytic infiltration into lacrimal and salivary glands. Autoimmune diseases increase cardiovascular risk by premature vascular damage. There were observational studies on the risk of ischemic stroke in primary SS patients, but results have been inconclusive. We conducted a meta-analysis to compare incidence of ischemic stroke in SS and normal populations.

**Methods:** Two investigators searched published articles in EMBASE and PubMed database from 1980 to the end of February 2017 using the terms "Sjögren's syndrome", "ischemic stroke", "stroke", "cerebrovascular accident", "cerebrovascular disease", "cerebrovascular disorder", "cerebral infarction", "cerebral ischemia", "brain infarction" and "brain ischemia". Manual searching in the conferences abstract database from 2002-2016 was performed. Inclusion criteria were 1) observational studies (cohort, case control, cross sectional studies), 2) studies comparing incidence of ischemic stroke in SS and normal population, 3) studies providing relative risk (RR), odds ratio (OR), or standardized incidence ratio (SIR) with 95% confidence interval (CI). Quality assessment of studies was performed using Newcastle-Ottawa quality assessment scale. Review Manager 5.3 software was used to perform data analysis. Studies were combined by the generic inverse variance method described by Dersimonian and Laird. We used a random-effect model because of the variance in the studies. Cochran's Q test was used to calculate  $I^2$  to measure heterogeneity across studies. A funnel plot was used to assess for publication bias.

**Results:** Five studies (3 cohort studies, 1 case control study, and 1 cross sectional study) were met our criteria with 9,514 patients with primary SS. The pooled risk ratio for ischemic stroke in primary SS patients compared to control populations was 1.21 (95% CI 0.97-1.50), heterogeneity was moderate with  $I^2$  of 60%, there was no evidence of publication bias from funnel plot.

**Conclusion :** We found no statistically significant increased risk for ischemic stroke in primary SS patients compared to the normal population, but more studies are needed to clarify the association between these two conditions.

**Disclosure:** J. Teerakanok, None; D. Cordoba, None; S. Suchartlikitwong, None; K. Nugent, None.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Sjögren's Syndrome Poster II: Clinical Research

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are associated with an increased risk of ischemic heart disease (IHD). The risk of IHD in patients with Sjögren's syndrome (SS) from previous observational studies has been inconclusive. Therefore, we conducted a meta-analysis to compare incidence of IHD in SS patients to normal populations.

**Methods:** Two investigators (J.T. and S.S.) searched published articles in EMBASE and PubMed database from 1980 to the end of May 2017 using the terms "Sjögren's syndrome" and terms of ischemic heart disease. The diagnosis of Sjögren's syndrome was made by physicians (primary care, rheumatologist) or retrieved from medical records using ICD-9-CM code 710.2. A manual search in the conferences abstract database from 2002-2017 was performed. Inclusion criteria were 1) observational studies (cohort, case control, cross sectional studies), 2) studies comparing incidence of IHD in SS and normal populations. Exclusion criteria were pediatric patients and non English-language articles. Quality assessment of studies was performed using Newcastle-Ottawa quality assessment scale. Review Manager 5.3 software was used to perform data analysis. We used a random-effect model because of the variance in the studies. Cochran's Q test was used to calculate  $I^2$  to measure heterogeneity across studies. A funnel plot was used to assess for publication bias.

**Results:** We identified 243 studies from the search. Five studies met our criteria (3 cohort studies, one case-controlled study and one cross-sectional study) with total 21,261 SJS patients. The pooled risk ratio for IHD in SJS patients compared to control populations was 1.27 (95% CI 0.91-1.79).

**Conclusion:** This meta-analysis did not find statistically significant increased risk of IHD in SJS patients compared to the general population.

**Disclosure:** J. Teerakanok, None; S. Suchartlikitwong, None; T. Mingbunjerdasuk, None; P. Ratanasrimetha, None; Y. Vorakunthada, None; J. S. Pixley, None.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The extant epidemiologic data of Primary Sjögren's Syndrome (pSS) remains limited with few published estimates for the general population and little data regarding racial/ethnic populations in the U.S. The Manhattan Lupus Surveillance Program (MLSP) is a population-based registry comprised of patients with Systemic Lupus Erythematosus (SLE) and related diseases including pSS treated in New York County (Manhattan) that was developed to determine the incidence and prevalence of SLE among Manhattan residents. Leveraging MLSP data we provide estimates of the prevalence and incidence of pSS during 2007 and 2007-09, respectively, in Manhattan across the major racial/ethnic populations (black, Hispanic, Asian, white).

**Methods:** MLSP cases were identified from hospitals, rheumatologists, and state population databases. Case screening was performed using ICD-9 codes, including 710.2 for SS. Charts were abstracted and final diagnosis was coded for Manhattan residents with one of the screening ICD-9 codes. pSS was defined using three case definitions: 1) a physician (regardless of specialty for cases hospitalized and not seen by a Rheumatologist) stating the diagnosis of pSS; 2) a rheumatologist's diagnosis of pSS 3) a diagnosis of pSS with documentation of patient complaints of dry eyes and/or dry mouth and autoantibodies defined as a positive anti-SSA and/or anti-SSB antibody or a positive rheumatoid factor and antinuclear antibody titer >1:320.

**Results:** Based on the diagnosis of pSS found in the medical chart, the preliminary age-adjusted overall prevalence and incidence rates of pSS in Manhattan were 9.8 and 2.6 per 100,000, respectively, Table 1. The overall prevalence and incidence rates were 6 times higher among women than men, and rates among women were also higher within racial/ethnic groups. The prevalence of pSS was 17.4 among Asian women, 17.2 among white women 10.2 among Hispanic women, and 8.5 among black women, though confidence intervals overlapped, Table 1. The incidence of pSS was 7.1 among Asian women, 4.2 among white women, 2.2 among black women, and 2.0 among Hispanic women. Restricting the case definition to a rheumatologist diagnosis or to cases with symptoms and autoantibodies reduced both the prevalence and incidence of pSS, though there were similar trends in gender and racial/ethnic differences, Table 1. The average age  $\pm$ SD at diagnosis among incident cases was 52.4  $\pm$ 18.4 years among women and 58.1  $\pm$ 17.3 years among men. The average age  $\pm$ SD at diagnosis among incident cases was 48.6  $\pm$ 18.2 years among Asians, 55.0  $\pm$ 19.2 years among whites, 48.0  $\pm$ 12.5 years among blacks, and 57.3  $\pm$ 19.7 years among Hispanics.

**Conclusion:** Using data from a large population-based registry revealed substantial gender disparities in pSS among Manhattan residents. These data also provided epidemiologic estimates for the major racial/ethnic populations in the U.S.

Rates are per 100,000 Manhattan residents. Denominator data is based on 2007 intercensal population estimates from the NYC DOHMH Bureau of Epi Services (2000-2014 files).

Data are age adjusted to the US 2000 Standard Population.

Cases were assigned to one of five mutually exclusive race/ethnicity categories: non-Hispanic white, non-Hispanic black, non-Hispanic Asian, Hispanic, and non-Hispanic other. Non-Hispanic cases identified with more than one race were categorized as non-Hispanic other.

## Incidence of Cancer in a Cohort of Patients with Primary Sjögren Syndrome

**Martin Brom**<sup>1</sup>, Sebastian Moyano<sup>1</sup>, Marina Scolnik<sup>2</sup> and Enrique R. Soriano<sup>3</sup>, <sup>1</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina, <sup>2</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, CABA, Argentina, <sup>3</sup>Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several neoplasia have been associated with Sjögren Syndrome (SS), being non-Hodgkin lymphoma the most frequent one. Our objective was to evaluate the incidence of all type of cancer in a cohort of patients with primary SS.

**Methods:** A retrospective descriptive study was performed in a university hospital with its own health insurance and captive population. Electronic medical records of SS patients were reviewed between 01/01/2000 and 12/31/2015. We included patients fulfilling ACR 2012 or American-European Consensus Group (AECG) 2002 SS criteria, or patients diagnosed as Primary SS by the treating rheumatologist. We registered and analyzed demographic, clinical and histopathologic information available on their medical records.

Incidence rate of cancer with their 95% CI was calculated. Patients were followed up until the end of study, death, loss of follow up, or when a diagnosis of cancer was performed. Incidence was compared with statistics on general population from United Kingdom (UK) as there is no full data available in the country where the study was performed.

**Results:** One hundred fifty-seven patients with Primary SS were included, and followed for 1158 patient/years. Table 1 shows patients' characteristics. 15 patients developed a neoplasia during follow up: 3 lymphomas (two MALT lymphomas of the parotid and one disseminated non-Hodgkin lymphoma), 1 Multiple Myeloma, 4 Skin (non – melanoma) neoplasia and 7 solid organ cancer (4 Breast, 1 Lung, 1 Uterus, 1 Tongue). Table 2 shows the cohort cancer incidence rates and comparison with statistics from general population. Non- Hodgkin Lymphomas showed an increased incidence in SS patients. All 3 patients with lymphoma were females, with anemia, leukopenia, thrombocytopenia and high erythrocyte sedimentation rate. In multivariate logistic regression analysis only thrombocytopenia was associated with an increased risk of cancer in general (OR 7, CI 95% 1.9-25.7).

**Conclusion:** We only found an increased rate of non- Hodgkin lymphomas in this cohort of SS patients. Other types of cancer incidence rates were in ranges expected for general population

Table 1. SS patients' characteristics

	SS patients (n=157)
Females, n (%)	150 (95.5)
Mean age at diagnosis, years (SD)	49.4 (19)
Dry eyes, n (%)	152 (96.8)
Dry mouth, n (%)	139 (89.1)

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Abstract**

**Background/Purpose:** In rheumatoid arthritis and systemic lupus erythematosus, cardiovascular disease is frequently a major cause of mortality or morbidity. Studies have shown that acute systemic inflammation and chronic systemic vasculitis are associated with endothelial dysfunction and atherosclerotic plaque formation, subsequently leading to cardiovascular disease. The studies of atherosclerosis in primary Sjogren syndrome (PSS) are still inconclusive to date. This meta-analysis aimed to explore the association of subclinical atherosclerosis and arterial stiffness in PSS.

**Methods:** A comprehensive search of the CENTRAL, MEDLINE and Embase databases was performed from 2000 through January 2017. The inclusion criterion was observational studies evaluating the association between primary Sjogren syndrome, subclinical atherosclerosis and arterial stiffness by measuring pulse wave velocity (PWV) and intima media thickness (IMT). Definitions of PSS and methods to assess PWV and IMT were recorded for each study. Different locations of IMT were assessed including common carotid, internal carotid, and femoral arteries. Pooled mean difference (MD) of PWV and IMT and 95% confidence interval (CI) were calculated using a random-effect meta-analysis. The between-study heterogeneity of effect size was quantified using the  $Q$  statistic and  $I^2$ .

**Results:** Data were extracted from 10 observational studies involving 789 subjects. Pooled result demonstrated a significant increase in PWV in patients who have PSS compared with controls (MD=1.30 m/s; 95% CI: 0.45 – 2.15, p-value=0.003,  $I^2$  = 82%). Patients with PSS also have higher IMT (MD=0.10 mm; 95% CI: 0.07-0.14, p-value<0.01,  $I^2$  = 49%).

**Conclusion:** Our study suggests that PSS is associated with arterial stiffness and subclinical atherosclerosis. Further studies need to be conducted in order to find the correlation of subclinical atherosclerosis in PSS with cardiovascular event, the pathophysiologic changes of arterial stiffness in PSS, and the benefit of statins, because controlling cardiovascular risk factors or disease activity could potentially help avoid progression of atherosclerosis to an overt cardiovascular disease.

**Session Time:** 9:00AM-11:00AM

### Abstract

**Background/Purpose:** Studies have demonstrated that acute systemic inflammation and chronic systemic vasculitis are associated with endothelial dysfunction and atherosclerotic plaque formation, subsequently leading to cardiovascular or cerebrovascular disease. In rheumatoid arthritis and systemic lupus erythematosus, the tendency of atherosclerosis is a major cause of mortality. Patients with primary Sjogren syndrome (PSS) may have a higher frequency of subclinical atherosclerosis, but studies on cardiovascular or cerebrovascular events in this population are limited with conflicting results. This meta-analysis aimed to explore the risk of cardiovascular and cerebrovascular event in PSS.

**Methods:** A comprehensive search in the CENTRAL, MEDLINE and Embase databases was performed from 1990 through January 2017. The inclusion criterion was observational studies evaluating the association between PSS and cardiovascular disease or cerebrovascular event. PSS is defined using American College of Rheumatology or American European Consensus criteria. Outcomes are diagnosis of ischemic heart disease, myocardial infarction, ischemic stroke or hemorrhagic stroke. Pooled odds ratio (OR) of cerebrovascular event or cardiovascular disease and their 95% confidence interval (CI) were calculated using a random-effect meta-analysis to compare risk between those who have PSS and controls. The between-study heterogeneity of effect-size was quantified using the  $Q$  statistic and  $I^2$ .

**Results:** Data were extracted from five observational studies involving 94,426 subjects. Pooled result demonstrated no significant difference in risk of having cardiovascular disease or cerebrovascular event in patients who have PSS compared with controls (OR=1.24; 95% CI: 0.96-1.61, p-value=0.10,  $I^2$  = 67%). Subgroup analyses showed no difference in risk for cerebrovascular event

(OR=1.26; 95% CI: 0.93-1.69, p-value=0.13,  $I^2 = 72\%$ ), and cardiovascular disease (OR=1.30; 95% CI: 0.67-2.53, p-value=0.43,  $I^2 = 72\%$ ).

**Conclusion:** Our study has not shown an increased risk of cardiovascular or cerebrovascular event in patient with PSS. Further studies need to be conducted in order to find the correlation of subclinical atherosclerosis in PSS with cardiovascular or cerebrovascular event.

### SESSION INFORMATION

Session Date: Monday, November 6, 2017

Session Title: Sjögren's Syndrome Poster II: Clinical Research

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

**Background/Purpose:** Interstitial lung disease (ILD) is a rare but potentially severe manifestation of primary Sjögren's syndrome (pSS). The aims of this study were to: 1) analyze clinical presentation, characteristics and outcome of ILD in pSS; 2) evaluate predictive factors associated with ILD onset and evolution; 3) explore whether the inflammatory chemokines RANTES, IL-8 and MCP-1 may be associated to pSS-related ILD.

**Methods:** Patients with a diagnosis of pSS (AECG 2002) were included in this single center study. Demographic, clinical and radiological data were collected retrospectively. Serum levels of RANTES, MCP-1 and IL-8 were measured by commercial ELISA kits in a subgroup of pSS patients with and without ILD.

**Results:** We included in this study 285 (12 M:273 F) patients with pSS. Eighteen out of 285 (6.3%) presented ILD: 12/18 NSIP and 6/18 UIP pattern. Patients with ILD were more frequently males (4/18 (22%) vs 8/267 (3%),  $p=0.004$ ) and older at the diagnosis with respect to non-ILD pSS patients ( $62\pm13$  vs  $50\pm13$  yrs,  $p=0.000$ ). The clinical presentation of ILD was acute-subacute in 8 cases, slow progressive in 3 and subclinical in 7 patients. ILD diagnosis preceded pSS diagnosis in 8/18 cases. These patients presented more often a UIP pattern (5/8 vs 1/10,  $p=0.04$ ). Patients were treated with steroids in monotherapy (7/18) or in association with immunosuppressive drugs (11/18) including cyclophosphamide ( $n=4$ ), azathioprine ( $n=5$ ), mycophenolate mofetil ( $n=1$ ) and rituximab ( $n=1$ ). During the disease course 5 patients improved, 11 were stabilized and 2 worsened. Patients that at the end of the follow-up presented a DLCO  $<60\%$ , were more frequently positive for anti-Ro/SSA antibodies ( $p=0.04$ ) and all presented a UIP pattern ( $p=0.000$ ). Finally, circulating levels of RANTES, but not of IL-8 and MCP-1 were significantly able to discriminate pSS-ILD from non-ILD pSS patients ( $620.4\pm318.4$  vs  $280.2\pm180.9$ ,  $p=0.02$ ).

**Conclusion:** This study showed that, despite rare, ILD can be a presenting feature of pSS especially in males and older patients. The inflammatory chemokine RANTES, promoting lymphocyte infiltration, may play a role in the pathophysiology of pSS-related ILD and may have a role as diagnostic biomarker for ILD especially in less symptomatic pSS patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Salivary gland ultrasonography (SGUS) has recently appeared as a promising tool for the diagnosis and the early stratification of patients affected by primary Sjögren's syndrome (pSS). In particular, the SGUS score has been reported as correlated with the ESSDAI score, suggesting that patients with more prominent pathological findings at the SGUS may have a higher disease activity. In this study, we aimed at correlating the SGUS score with the single domains of the ESSDAI and of the ClinESSDAI in order to better investigate any eventual association and correlation between SGUS abnormalities and pSS clinical and biological features.

**Methods:** Patients with pSS (AECG 2002) were prospectively enrolled in this study. All subjects had a standardized evaluation which included laboratory testing and a complete rheumatologic evaluation. SGUS was carried out by the same radiologist blinded to the diagnosis and the following US parameters were recorded: size, parenchymal echogenicity and inhomogeneity in the parotid and submandibular glands on both sides. A modified version of the De Vita score was used to grade the echostructure alterations of the salivary glands.

**Results:** One hundred and forty consecutive pSS patients (137 F: 3 M, age = 56.7±13 yrs) were enrolled in this study. Out of them 59/140 patients showed no pathological findings at the SGUS examination and 81/140 presented at least some mild alterations. The mean SGUS score was 1.97± 2.20 (range 0-8). The mean ESSDAI was 3.10±4.33 (range 0-33). The total SGUS score significantly correlated with both the ESSDAI ( $r=0.340$ ,  $p=0.000$ ) and the ClinESSDAI ( $r=0.263$ ,  $p=0.002$ ). In particular the biological domain of the ESSDAI were significantly correlated to both partial parotid scores ( $r=0.379$ ,  $p=0.000$ ) and submandibular scores ( $r=0.200$ ,  $p=0.02$ ). By contrast, only partial parotid scores (but not the partial submandibular scores) significantly correlated with the ClinESSDAI ( $r=0.253$ ,  $p=0.03$ ) and, particularly with glandular ( $r=0.279$ ,  $p=0.001$ ), hematological ( $r=0.185$ ,  $p=0.03$ ) and skin domains ( $r=0.188$ ,  $p=0.03$ ). Total and partial parotid SGUS scores inversely correlated with the age of the patients at pSS diagnosis ( $r=-0.168$ ,  $p=0.04$  and  $r=-0.208$ ,  $p=0.01$ ).

**Conclusion:** This study demonstrated that patients with US pathological findings in their parotid glands, also in the absence of evident glandular swelling, presented a more aggressive disease phenotype. SGUS may therefore be useful in clinical practice to identify patients with subclinical parotid involvement who may deserve a closer monitoring and a more aggressive treatment.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Recently, pleural irregularity (PI), a new lung ultrasound (US) sign, has been proposed as an emerging tool for the diagnosis of interstitial lung disease (ILD) in connective tissue diseases. However, few data are available regarding its role in the evaluation of ILD associated to primary Sjögren's syndrome (pSS). Aim of this study was to assess the accuracy of PI-US in detecting pSS-associated ILD by correlating PI-US findings with chest high-resolution computed tomography (HRCT) and pulmonary function tests.

**Methods:** Eighteen patients with pSS-associated ILD were included in the study. HRCT and tests of pulmonary function were performed in each patient. PI-US was performed by a single operator using a MyLab-25 (Esaote), 10 MHz, 5 cm linear probe. PI was defined as the loss of the normal hyperechoic linear pleural contour (score 0-2: normal, minimal and major changes at each intercostal space). PI US total score represented the sum of partial scores assigned to 6 lung fields (2 for the anterior, 2 for postero-superior and 2 for postero-inferior chest surface). Abnormal findings at HRCT were quantified by an expert radiologist according to the Warrick score.

**Results:** We included in this study 18 patients with pSS-related associated ILD (14 F:4 M, mean age =68.8 ±9.9 yrs). The median PI-US score was 45 (range 25.5-73.5). Both PI-US total score and partial postero-inferior PI-US score strongly correlated with the Warrick HRCT score ( $r=0.813$ ,  $p=0.000$  and  $r=0.914$ ,  $p=0.000$ ). Regarding pulmonary function tests, the Warrick HRCT score correlated with FVC ( $r=-0.753$ ,  $p=0.001$ ), TLC ( $r=-0.853$ ,  $p=0.000$ ), and DLCO ( $r=-0.834$ ,  $p=0.000$ ). Similarly, PI-US total score and partial PI-US postero-inferior score correlated inversely with FVC ( $r=-0.849$ ,  $p=0.000$  and  $r=-0.836$ ,  $p=0.000$ ), TLC ( $r=-0.895$ ,  $p=0.000$  and  $r=-0.829$ ,  $p=0.000$ ), and DLCO ( $r=-0.953$ ,  $p=0.000$  and  $r=-0.883$ ,  $p=0.001$ ). Finally, both PI-US score and PI-US of the infero-posterior field (but not Warrick HRCT score) directly correlated with FEV1/SVC ( $r=0.701$ ,  $p=0.004$  and  $r=0.619$ ,  $p=0.01$ ) and with FEV1/FVC ( $r=0.600$ ,  $p=0.02$  and  $r=0.501$ ,  $p=0.05$ ).

**Conclusion:** This study demonstrated a high correlation between PI-US, HRCT findings and pulmonary function tests, supporting the use of lung ultrasonography in clinical practice for the assessment of pSS-associated ILD. The exclusive correlation between PI-US scores and both FEV1/SVC and FEV1/FVC seemed to indicate a higher sensitivity of PI-US with respect to HRCT in ILD assessment. Further studies are warranted to clarify the role of PI-US for the early diagnosis of ILD.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The geographic variation in healthcare service utilization and quality across and within countries is well documented. Part of this geographic variation is linked to differences in population health and needs. However, some of the variation may be unwarranted and driven by factors other than health needs, such as provider discretion, the availability and distribution of resources, financing and reimbursement models (Wennberg 2011). In this study, we identified the need for instruments to collect comparable data in Europe to establish practice profiles in the treatment and management of patients with Primary Sjögren's Syndrome (pSS).

**Methods:** We describe the development and preliminary validation of a questionnaire to pSS to collect information on access to and intensity of treatments and services (e.g. diagnostic testing, hospitalizations, specialist visits), patients' satisfaction with the care received and socio-demographic data (e.g. age, sex, education level). A short questionnaire is also administered to specialists treating the selected pSS to collect data on the organization of the clinical centers and involvement and relations with other healthcare professionals besides clinical information of the selected patients.

**Results:** The pilot version of the questionnaire was administered to 50 pSS in the clinical centre of Pisa (Italy) and counted 22 closed-ended questions. Three questionnaires out of 50 were returned incomplete. Mean (SD) age was 60 (12.2) years and 96% of the sample was female. The majority of the respondents had a primary or secondary school (59%). Construct validity was supported by the questionnaire's ability to discriminate between groups with different levels of activity of the disease and socio-demographic characteristics. Disease activity was significantly associated with frequency of rheumatologic visits and diagnostic tests ( $p<0.001$ ). The total number of specialists involved in the care other than the rheumatologist varies significantly among patients. As expected, the most frequently involved were the ophthalmologist (90%) and the dentist (58%). Additionally, patients with lower education have attended on average less specialists than those with a high school or university degree ( $p<0.001$ ).

**Conclusion:** Preliminary results confirm that the questionnaire is a valid instrument to assess patterns of care for pSS in terms of access and utilization and in relation to clinical and socio-demographic characteristics of patients. Further analysis will be conducted in other clinical centers within the European Horizon 2020 project "HarmonicSS" to verify the generalizability and additional psychometric properties of the instrument.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** It is well documented that patients with immune-mediated inflammatory diseases (IMID) like rheumatoid arthritis are exposed at an increased risk of cardiovascular disease. Primary Sjögren syndrome (PJS) is a progressive autoimmune disease characterized by a chronic inflammation of exocrine glands and a functional deficit of the salivary and lacrimal glands, biological inflammation being infrequent. The purpose of this article was to investigate the association between PJS and an increase of the cardiovascular morbidity and mortality.

**Methods:** We performed a systematic review of available articles on the databases of MEDLINE and the COCHRANE library from their dates of inception to January 2017 and recent abstracts from ACR and EULAR meetings, searching for studies reporting observed cardiovascular morbidity and cardiovascular mortality in PJS and having a comparison group. The relative risks of cardiovascular morbidity and mortality associated with PJS were collected and pooled in meta-analysis using Review Manager Software (Cochrane collaboration). Random effects meta-analyses were conducted, and forest plots were constructed to summarize the risk ratio estimates and their 95% confidence intervals. The heterogeneity between studies was assessed using the Cochran's Q-test and the I<sup>2</sup> value.

**Results:** 457 studies were retrieved, among which 26 involving 61254 PJS patients met the inclusion criteria and were analyzed after the selection procedure was applied. Ten studies involving 32 907 PJS patients were included in the meta-analysis. The studies showed that patients with PJS had a significantly increased prevalence of coronary morbidity (relative risk (RR)= 1.75, 95%CI : 1.36-2.25; p<0.0001), cerebrovascular morbidity (RR= 1.46, 95%CI : 1.43-1.49, p<0.00001), heart failure rate (odd ratio (OR)=2.54, 95%CI: 1.30 – 4.97, p<0.007), thromboembolic morbidity (RR= 1.78, 95% confidence interval (CI) :1.41- 2.25, p<0.00001), and a trend to increased cardiovascular mortality ((RR)= 1.48, 95%CI : 0.77-2.85, p=0.24) compared to the control population without IMID.

**Conclusion:** This meta-analysis demonstrates that PJS is associated with an increased cardiovascular morbidity suggesting that these patients should also been proposed for a screening of cardiovascular comorbidities and specific preventive interventions.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

A seasonal effect was reported on fatigue and pain in rheumatoid arthritis. We speculated that fall and winter could be associated with increased fatigue and pain and that spring and summer could be associated with increased dryness. If a seasonal effect plays a role on patients's symptoms, it has to be taken into account in clinical trials and also in daily practice.

Our objective was to assess a seasonal effect on fatigue, pain and dryness.

## Methods:

The data (date, VAS pain, fatigue, dryness) were extracted from three negative placebo-controlled randomized controlled trials (infliximab (n= 103 patients), hydroxychloroquine (JOQUER, n= 120 patients) and rituximab (TEARS n=120)) and from the ASSESS prospective cohort (n= 395 patients). VAS pain, fatigue and dryness were analyzed at each visit for each patient, according to the day of the year, the month of the year, and the season. Linear mixed models were fitted with a fixed time effect (month, with or without cosinus transformation, or season effect, in distinct models) with a random subject effect used to take into account the repeated structure of the data and analyze a potential cyclic effect. Statistical analyses were performed using R3.3.1 with the LME4 and HGLM libraries.

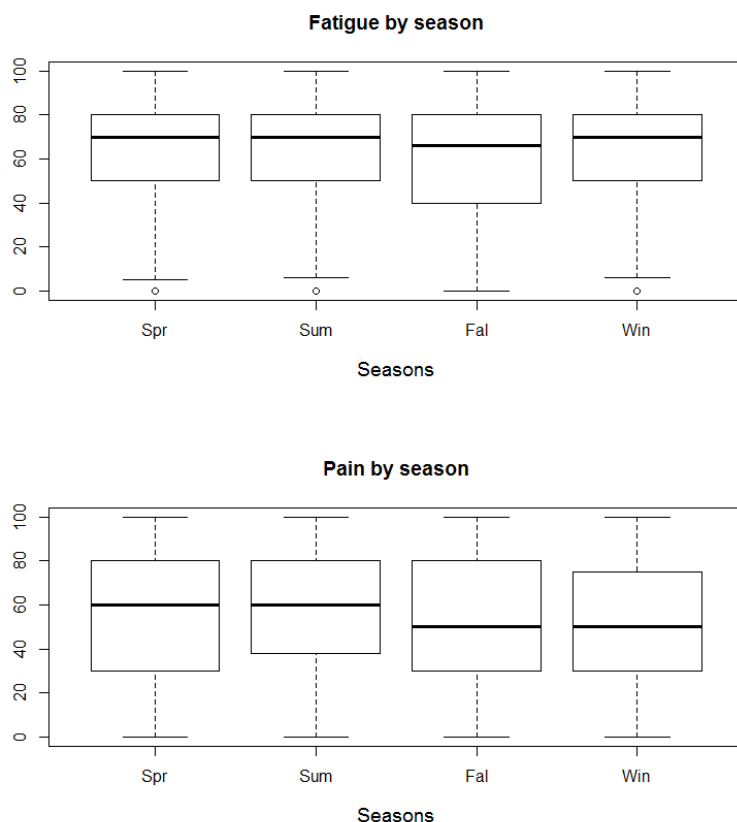

## Results:

744, 584, 848 and 682 pain, fatigue and dryness VAS were collected on 632 subjects in spring, summer, fall and winter, respectively. Mean (SD) pain VAS was 52.2 (27.9), 55.1 (28.1), 51.0 (28.7) and 51.7 (28.4) in spring, summer, fall and winter, respectively. Mean (SD) fatigue was 61.9 (23.2), 62.2 (25.2), 60.0 (25.5), 61.9 (24.2), respectively. Mean (SD) dryness was 58.9 (21.8), 61.2 (22.9), 56.9 (22.8), and 57.9 (23.8), respectively (Figure 1). No significant difference was observed in pain, fatigue and dryness, according to the day of the year, the month or the season (all p-values >0.05). Variations from month to month or season to season of mean pain, fatigue and dryness were mild (maximum between-months variation for pain was 7.22 on a 100-unit scale). All observed fluctuations were well lower than MCII for fatigue, dryness and pain (20, 10 and 10 point on a 100-point scale, respectively, ref 1).

## Conclusion:

Intensity of perceived dryness, pain and fatigue do not seem to have meaningful fluctuations according to seasons or months. Therefore, the impact on the main symptoms of the disease in randomized trial is not biased by a seasonal effect.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Patients with primary Sjögren's syndrome (PSS) suffer from severe alterations in both the quality and quantity of saliva and tears. Body water represents around 50-55% of the body weight. Tears contain 98% of water and saliva 99.5%. We evaluated the percentage of total body water (TBW) among patients with PSS assessed its correlation with the severity of sicca symptoms.

**Methods:** We included 85 patients with PSS and 85 non-diabetic controls matched by gender, age ( $\pm 3$  years) and body mass index ( $\pm 1 \text{ kg/m}^2$ ) (BMI). We assessed the Schirmer-I test, non-stimulated whole salivary flow (NSWSF) and ocular staining. We evaluated ocular as well as oral symptoms during the past 15 days, using for each symptom, a VAS scale (0-10, a higher score implies worst symptoms). We obtained the TBW percentage with a bioelectric impedance analysis (BIA-SECA-514, Hamburgo).

**Results:** 80% were women, mean age  $54.8 \pm 13.7$  years and mean disease duration  $11.5 \pm 7.52$  years. The percentage of TBW was similar among patients and controls (PSS  $46.85 \pm 4.6$  vs.  $46.9 \pm 4.5$ ,  $p=0.88$ ). However among the patients, the TBW negatively correlated with age ( $\rho=-0.25$ ,  $p=0.02$ ), disease duration ( $\rho=-0.30$ ,  $p=0.005$ ), BMI ( $\rho=-0.78$ ,  $p=0.001$ ) and the ocular VAS scale ( $\rho=-0.28$ ,  $p=0.01$ ), but not with the NSWSF or the oral VAS scale. When we compared the patients in the 25% percentile (group with the lowest % of water) vs. the remaining patients, the former group was older ( $56.6 \pm 8.1$  vs.  $54 \pm 14.2$ ,  $p=0.02$ ), with longer disease duration ( $12.4 \pm 5.9$  vs.  $10.8 \pm 7.12$ ,  $p=0.03$ ), lower scores at the Schirmer test (1 (range 0-8) vs. 2 (range 0-9),  $p=0.01$ ), higher BMI ( $31.1 \pm 5.1$  vs.  $23.7 \pm 2.9$ ,  $p=0.001$ ) as well as with higher ocular VAS scores ( $8.3 \pm 1.4$  vs.  $6.7 \pm 2.5$ ,  $p=0.007$ ). At the linear regression analysis, the variables that remained associated with the TBW were disease duration ( $b -0.22$ ,  $p=0.001$ ), BMI ( $b -0.76$ ,  $p<0.001$ ) and the ocular VAS scale ( $b -0.15$ ,  $p<0.001$ ).

**Conclusion:** Patients with PSS had similar TBW percentages than controls. However among PSS patients, the TBW had a negative correlation with the intensity of ocular symptoms independently of disease duration, age and BMI.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The objective of this study is to introduce the clinical and laboratory characteristics of Korean primary Sjögren's syndrome (pSS) patients enrolled in Korean Initiative of Sjögren's Syndrome (KISS). We also sought to compare the performance of newly proposed 2016 American College of Rheumatology (ACR)/European League-Against Rheumatism (EULAR) criteria to 2002 American-European Consensus Group (AECG) and 2012 ACR classification criteria for primary pSS in a well characterized registry.

**Methods:** Patients with pSS from 12 university affiliated hospitals in Korea were enrolled from Oct 2013 to JAN 2017. The patients were diagnosed with pSS by either fulfilling 2002 AECG or 2012 ACR classification criteria. Data of clinical manifestations and various laboratory findings were obtained.

**Results:** Data at inclusion were available in 458 patients. The mean age was  $51.9 \pm 11.8$  years. Four hundred fifty patients (98.3%) were female. Mean disease duration was  $33.9 \pm 46.7$  months. Most common extraglandular manifestation was arthralgia (47.8%) followed by Raynaud's phenomenon (15.7%) and lymphadenopathy (13.5%). Median [interquartile range] ESSDAI and ESSPRI was 2 [0-5], 5 [4-6.7], respectively. Among 458 patients, 328 patients had sufficient data to determine the fulfillment of each criteria. All three criteria were met by 307 patients. Among 3 patients by whom 2016 ACR/EULAR criteria were not met, one 2002 AECG- 2012 ACR+ had negative anti Ro or La while positive antinuclear antibody and rheumatoid factor with more than 3 ocular staining score. Two 2002 AECG+ 2012 ACR- showed no ocular sign and negative anti Ro or La while had positive focus score. Ninety-six patients had results of all items in 2016 criteria, 95 met the criteria.

**Conclusion:** We successfully established a nationwide pSS registry in Korea, which represents the characteristics of Korean pSS patients. The newly proposed 2016 ACR/EULAR criteria were met by most of the patients diagnosed with pSS according to previous criteria.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Sjögren's syndrome (SS) has been thought rare during pediatric age. Because patients in this age group lack sicca symptoms, the diagnosis of SS is often difficult by currently available diagnostic or classification criteria, and accordingly needs new criteria. Japanese Pediatric Sjögren's syndrome Study Group has developed new criteria for diagnosis of SS in pediatric patients (Table 1,2). This criteria has been approved by both the board of the Pediatric Rheumatology Association of Japan and the board of the Japanese Society for Sjögren's syndrome. In this criteria, patients are classified into 5 groups: definite, probable, possible, need follow-up or non-SS. In the present study, we compared the sensitivity of our criteria with 4 major criteria, and evaluated which criteria is most suitable for identifying SS patients in the early stage.

**Methods:** We enrolled 41 pediatric patients who were diagnosed as having SS with unanimity by 10 pediatric rheumatologists. They were categorized into primary SS (pSS), secondary SS (sSS) and primary to secondary SS (psSS), which was diagnosed as primary SS at diagnosis but developed other collagen diseases during follow-up. We classified those patients into 5 groups according to our criteria, and examined whether each patient fulfilled the major criteria: revised American-European Consensus Group classification criteria (AECG), the revised Japanese diagnostic criteria (JPN), ACR classification criteria (ACR), American College of Rheumatology/European League Against Rheumatism Classification Criteria for primary Sjögren's syndrome (A/E).

**Results:** The numbers of patients were as follows: pSS 25, sSS 11 and psSS 5. According to our criteria, patients were classified into definite 33, probable 2 or possible 6 at the first visit, and 38, 3 or 0 at the last visit. No patient was diagnosed as non-SS. In the other 4 criteria, the most sensitive was JPN, followed by A/E and ACR among all patients group (Table 3). However, even by using JPN criteria, there was 12% of pSS patients diagnosed as non-SS at the last visit.

**Conclusion:** Our new criteria is useful for diagnosis of pediatric SS, and make it possible to recognize SS-associated complications at an early stage.

Table 1: Scoring

		Score	
Serological score	serum IgG	1 ( $\geq 97.5$ th percentile for age)	
	anti-nuclear antibody	1 (1:40~1:80), 2 (1:160), 3 ( $\geq 1: 320$ )	
	Rheumatoid factor	3 ( $\geq 15$ U/ml)	
	anti-SSA/Ro or SSB/La antibody	6 (positive)	
Glandular score	Salivary gland	Labial salivary gland biopsy	1 ( $< 1$ focus / $4\text{mm}^2$ ), 2 ( $\geq 1$ focus / $4\text{mm}^2$ )
		Solography (conventional or MRI)	2 (Rubin-Holt stage $\geq 1$ )
		Salivary scintigraphy	1 (Decreased in uptake or secretion)
		Decreased salivary flow (counted if at least one other test is positive)	1 (Saxon test $\leq 2.0\text{g} / 2\text{min}$ , or Salivary flow rate $\leq 1.5\text{ml} / 15\text{min}$ , or Gum test $\leq 10\text{ml} / 10\text{min}$ )
	Lacrimal gland	2 (Schirmer test $< 5\text{mm}/5\text{min}$ and Rose-Bengal test van Bijsterveld score $\geq 3$ , or Schirmer test $< 5\text{mm}/5\text{min}$ and fluorescein test (+), or ACR score $\geq 3$ )	

Table 2: Classification

Serological score	Glandular score		
	$\geq 2$	1	0
$\geq 6$	Definite	Probable	Possible
5	Probable	Probable	Possible
4	Probable	Probable	Possible
3	Probable	Possible	Need follow-up
2	Probable	Possible	Need follow-up
1	Possible	Possible	Need follow-up
0	Need follow-up	Need follow-up	Possibly non-SS

Table 3: Sensitivity of each criteria

		1st visit			Last visit		
		pSS	sSS	psSS	pSS	sSS	psSS
AECG fulfilled		20 (%)	18.2	20	36	36.4	20

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** This study aimed to investigate the longitudinal changes in EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and to study clinical features associated with favorable ESSPRI changes in Korean patients with primary Sjögren's syndrome (pSS).

### Methods:

At baseline and after a median 6.6 [interquartile range, 4.9~8.4] years, 41 pSS patients were evaluated through ESSPRI, EULAR Sjögren's syndrome disease activity index (ESSDAI), EULAR Sicca Score (ESS), health-related quality of life (HRQOL) questionnaires (SF-36), Xerostomia Inventory (XI), and visual analog scale (VAS) for exocrine and extra-exocrine symptoms. Also, we collected data for used medications and laboratory results. Favorable outcome (F) group was defined as patients who had improved ESSPRI (from baseline ESSPRI  $\geq 5$  to follow-up ESSPRI  $< 5$ ) or the maintenance of satisfactory symptom state (ESSPRI  $< 5$ ) and unfavorable (UF) group was those with worsening of ESSPRI (from baseline ESSPRI  $< 5$  to follow-up ESSPRI  $\geq 5$ ) or the maintenance of unsatisfactory symptom state (ESSPRI  $\geq 5$ ).

**Results:** During the follow-up period, ESSPRI was significantly increased from 4.11 [3.22~5.56] to 5.33 [3.50~6.67] ( $p < 0.05$ ) and SF-36 scores were not changed in pSS patients even though XI scores ( $p=0.01$ ) and oral dryness ( $p<0.05$ ) were significantly

decreased in the total enrolled patients. Hyper-gamma-globulinemia ( $p<0.001$ ) and anemia ( $p<0.05$ ) were improved but ESSDAI was not changed. When compared between F ( $n=17$ ) and UF ( $n=24$ ) group, F group exhibited significantly lower VAS levels of oral or eye dryness (both  $p<0.05$ ), XI scores ( $p<0.05$ ), and ESS scores ( $p<0.00$ ) than UF group at baseline. Also, F group had more patients with Raynaud's phenomenon (19.5% versus 9.8%,  $p<0.05$ ). In spite that baseline physical component summary (PCS) scores were comparable and F group was less likely to take cholinergic (12.2% versus 46.3%,  $p=0.001$ ) or immuno-modulatory (7.3% versus 31.7%,  $p<0.05$ ) drugs, F group showed significantly better PCS scores at final follow-up than UF group ( $p<0.001$ ).

#### Conclusion:

In routine clinical practice, most values for subjective or objective assessments including ESSPRI and HRQOL were not significantly improved during the follow up periods in pSS patients. pSS patients with less severe sicca symptom are more likely to have a favorable course, based on ESSPRI status.

#### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Many classification criteria sets have for primary Sjögren's Syndrome (pSS). We aimed to compare the performance of 3 classification criteria sets for pSS, to determine the agreement between each other and expert opinion and to investigate diagnostic contribution with any combined use of these criteria. For those assessments, American-European Consensus Criteria (AECG), American Collage of Rheumatology (ACR) / Sjögren International Clinical Alliance (SICCA) criteria and L.S. Martin et.al. criteria named Mathematical model (M.model) had chosen.

**Methods:** 86 patients (F:96%, mean age: 51.7±11.8) with the diagnosis of pSS were enrolled to the study. Expert opinion had been taken as gold standard for pSS diagnosis. Patients were questioned for eye/mouth dryness. Antinuclear antibody, complement, anti-Ro-La, serum protein electrophoresis, rheumatoid factor, break-up time (BUT) and Schirmer, minor salivary gland biopsy results were analysed cautiously. The aforementioned criteria sets, were implemented to assess the classification. The percentage of exact agreement and Kappa test was calculated.

**Results:** Number of patients classified as pSS according to ACR/SICCA, AECG and M.model criteria were 75 (87%), 63 (73%) and 58 (67%) respectively. 9 patients (10%) did not fulfill any of these 3 criteria but they were diagnosed as pSS according to expert opinion (Figure 1). The Kappa test was moderate between the ACR/SICCA and AECG criteria and slightly low between the M.model with the AECG and ACR/SICCA criteria (Table 1). According to our proposed combination model, number of patients classified as pSS, either AECG or M.model was 74; either AECG or ACR/SICCA model was 76; either ACR/SICCA or M.model was 77 (Table 2). In the triple combination of our model, if all 3 criteria used concomitantly, only 46 of patients fulfill the criteria simultaneously; however if any of 3 criteria sets used 77 patients fulfill as pSS.

**Conclusion:** In this study, ACR/SICCA classification criteria for pSS was found the most compatible criteria set with expert opinion.

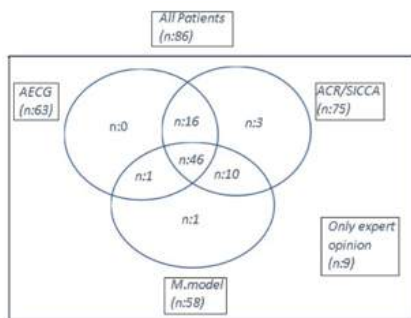

Table 1. The agreement between three pSS classification criteria sets.(%, Kappa test)

	AECG	ACR/SICCA	M.MODEL
AECG		%83 K:0.50	%68 K:0.25
ACR/SICCA	%83 K:0.50		%75 K:0.34
M.MODEL	%68 K:0.25	%75 K:0.34	

Table 2. Number of patients fulfilling classification criteria

	Classsification criteria (n) (%)	
According to 1 criteria	ACR/SICCA	75 87,2
	AECG	63 73,2
	M.model	58 67,4
According to either of 2 criteria	ACR/SICCA or M.model	77 89,5
	AECG or ACR/SICCA	76 88,3
	AECG or M. model	74 86
According to either of 3 criteria	AECG or ACR/SICCA or M.model	77 89,5

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Focal lymphocytic sialadenitis (FLS) on minor salivary gland biopsy (MSGB) is one of the classification criteria for Sjögren's syndrome (SS). As no diagnostic criteria exist, there is a need for timely diagnosis of seronegative patients (SSA and SSB antibody negative), to allow earlier intervention and prevent end-organ damage. There are only a few studies on how seronegative patients with FLS on MSGB differ clinically from seropositive patients (SSA and/or SSB antibody positive). Therefore, the objective of our study was to compare the clinical and laboratory features of patients with and without autoantibodies (anti-SSA and/or anti-SSB) among those with FLS on MSGB. As a secondary objective, we compared the clinical and laboratory features of those with and without FLS on MSGB among the seronegative patients only.

**Methods:** Cases > 18 years old with a MSGB performed at the University of Iowa Hospital and Clinics between 1/1/2000-12/31/2016 were identified, excluded patients with incomplete clinical and laboratory data. Then data was extracted by retrospective chart review. Fisher's exact test or chi-square test was used to compare categorical variables between the groups; student's t-test was used for comparison of continuous variables.

**Results:** During the study period 230 patients had MSGB done for sicca symptoms, 51 patients were excluded due to incomplete clinical data. FLS on MSGB was found in 133 patients, 27% (37/133) were seropositive and 72% (96/133) were seronegative. Dry eyes, dry mouth, fibromyalgia and depression, predominated as statistically significant clinical features in the seronegative group compared to the seropositive group (Table1– Among all MSGB positive patients, comparison of the clinical and laboratory features of those with and without SSA antibody and/or SSB antibody). Symptomatic seronegative patients who underwent MSGB were 137, and no FLS on MSGB was found in 41 patients. Smoking predominated as a statistically significant variable ( $p=0.0003$ ) in the seronegative patients with no FLS on biopsy, whereas seronegative patients with a positive biopsy tended to be older and have more sicca symptoms.

**Conclusion:** Identifying the subset of symptomatic SS patients, who are seronegative is challenging. When patients have sicca symptoms, associated with other clinical features like fatigue, inflammatory arthritis, peripheral nervous system clinical symptoms; with no serological markers, these patients should be considered for a further evaluation by MSGB. Smoking can also cause sicca symptoms with no FLS on MSGB, this should be considered while evaluating the patients with sicca symptoms.

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There have been three classification proposals for Sjögren's Syndrome (SS) over the past 15 years (1-3). The 2016 criteria require a diagnostic work-up which includes at least evaluation of focus score (FS) in minor salivary gland (MSG) biopsy, anti-SSA antibodies, Schirmer's test, unstimulated whole salivary flow (UWS), and ocular staining score (OSS), the last two tests being unavailable at our centre. Patients have to score  $\geq 4$  points to fulfill the ACR-EULAR criteria for SS (3 points for FS  $\geq 1$  and antiSSA positivity, 1 point for UWS  $\leq 0.1$  ml/min, Schirmer  $\leq 5$  mm/5min and OSS  $\geq 5$ ). In some of our longstanding patients, MSG biopsies performed at disease onset scored negative and have not been repeated, either because they are judged to be unnecessary by the attending physician or due to patient refusal. While ESSDAI reflects SS biological activity, ESSPRI is claimed to be disease-specific for SS (4) and both scores have been validated (5). The aim of this study was to investigate EULAR Sjögren Syndrome Disease Activity Index (ESSDAI) and EULAR Sjögren Syndrome Patient Reported Outcome (ESSPRI) in a monocentric sicca syndrome cohort, all of whom have a working clinical diagnosis of SS.

**Methods:** Cross sectional study carried out at our AID Unit from January to December 2016. Inclusion criteria: 1) sicca syndrome symptoms as main complaint and clinical diagnosis of SS; 2) absence of any other known autoimmune disease (AID) at inclusion time; 3) follow up in AID Unit of at least 1 year. Demographic and clinical features, previous diagnostic investigation, ongoing therapeutics and fulfillment of sequential classification criteria were recorded. ESSDAI activity (Low  $< 5$ , moderate 5 – 13, high  $\geq 14$ ) and ESSPRI-Patient acceptable symptom state (PASS  $< 5$  points) (5) were performed once in each patient. Parameters were analyzed according to disease duration. Univariate statistical analysis was performed using the Wilcoxon Mann-Whitney test for non-parametric distributed data.

**Results:** Overall, between January and May 2017, 45 consecutive patients were included, of which 18 (40%) met 2002; 7 (16%) 2012; and 15 (33%) the 2016 SS classification criteria. Median age was 63 years (y), IQR 57-72, range 29-83; 100% female; median disease duration was 12 y, IQR 8-19; range 2-36; median ESSDAI and ESSPRI were, respectively 0, IQR 0-2; range 0-17 and 5, IQR 3,7-7, range 0 – 10. Two patients were diagnosed with lymphoma, one prior to enrolling time. Disease duration was greater than 10 y in 29 (64%) and smaller or equal to 10 y in 16 (35%) patients. Approximately half of the patients in each group were on hydroxychloroquine (200 mg/day) and  $\leq 5$  mg/day of prednisolone. Both groups presented low biological activity (only 2 patients had a score above 14, one due to renal and another due to lung involvement). There were no statistically significant demographic or clinical differences according to disease duration.

**Conclusion:** Regardless of disease duration, patients presented low biological activity but remained symptomatic with a PASS  $\geq 5$ . ESSDAI and ESSPRI provide important information and therapeutic stratification, particularly as regards the need for new therapies that provide symptomatic relief.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Adding major salivary gland ultrasonography (SGUS) improves the diagnostics of primary Sjögren's syndrome (pSS). Juvenile Sjögren's syndrome (jSS) is a rare, poorly defined disease. With regard to the late onset of sicca-symptoms and current lack of diagnostic criteria, a non-invasive diagnostic method is warranted for jSS. The aim of this study was to evaluate SGUS bed-side scoring (realtime) and still/2D-image scoring, and to investigate whether imaging findings differ in the parotid and the submandibular glands.

## Methods:

Patients were recruited from Brazil (n=40), Norway (n=11), and Spain (n=5) in the period 2016-2017. SGUS of the parotid and submandibular glands had been performed bed-side in all patients, using linear high-frequency transducers (6-15 MHz), and glands characterized as normal or SS-like. Still/2D-images from 26 patients were available for re-evaluation by the same experts (DSH and MVJ).

## Results:

Mean age at diagnosis was 12.1 years (range 4-17), with first symptoms at 10.1 years (range 3-17). Time from onset of symptoms until diagnosis was 1.8 years (range -2-8). Oral and ocular symptoms were reported by 16/26 and 18/26 patients, respectively. Reduced tear-production was detected in 9/25 patients, and hyposalivation in 11/26 patients. Focus score was available in 19/20 cases. Anti-Ro/SSA-titer was elevated in 23/26, and anti-La/SSB in 12/26. AECG and ACR/EULAR diagnostic criteria was fulfilled by 21/26 patients. The female:male ratio was 23:3.

When comparing the total SGUS score, pathological changes were noted in 18/26 patients using realtime images, as compared to 24/26 using still/2D-images ( $p=0.027$ ,  $\kappa=0.316$ ).

In the realtime images SGUS pathological changes were detected in 16/26 parotid glands (15/16 in both right and left gland,  $p<0.001$ ,  $\kappa=0.920$ ), and 15/26 submandibular glands (14/15 in both right and left gland,  $p<0.001$ ,  $\kappa=0.842$ ). In four cases, pathological changes were detected only in the parotid glands (n=2) or only in the submandibular glands (n=2).

In the still/2D-images pathological changes were detected in 19/26 parotid glands (17/19 in both right and left gland,  $p<0.001$ ,  $\kappa=0.821$ ), and 21/26 submandibular glands (18/21 in both right and left gland,  $p=0.029$ ,  $\kappa=0.425$ ).

When comparing the glands separately, pathological changes were reported in 2D/still images of glands that had been diagnosed as normal using realtime images; 3/10 cases in the right parotid ( $p0.001$ ,  $\kappa=0.742$ ), 2/11 cases in the left parotid ( $p0.001$ ,  $\kappa=0.839$ ), 6/11 cases in the right submandibular ( $p=0.004$ ,  $\kappa=0.490$ ) and 5/11 cases in the left submandibular ( $p=0.001$ ,  $\kappa=0.581$ ).

## Conclusion:

Although containing a limited number of patients, our study highlights important challenges in the clinical applications of SGUS. Notable differences were observed when comparing still/2D-images to realtime evaluation, especially in cases with normal-appearing

glands or early pathological changes, and the submandibular glands as compared to the parotid glands. We speculate that bed-side or video scoring to evaluate the whole gland should be the preferred method, and SGUS evaluation using only one slide/gland should be performed with caution.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune rheumatic disease characterised by sicca features and systemic manifestations such as pain and fatigue. The classic therapeutic approach for pSS is based upon symptomatic treatment of sicca manifestations with immunosuppression for more severe disease. To date, there has been no longitudinal analysis of medication use for patients with pSS.

**Methods:** We used data from the United Kingdom Primary Sjögren's Syndrome Registry to identify patients with sufficient follow-up data including their current medications. Patients who were not on medication at visit 1 but who were on medication at visit 2 were included. Those patients who were not on medication at visit 1 or visit 2 were included for comparison. The medication regimes were group into four categories: Hydroxychloroquine (HCQ), Immunosuppression, NSAIDs and Analgesics. The differences in characteristics and patient-reported scores between each group were evaluated by analysis of variance. Paired data between the two visits was evaluated by a paired t-test.

**Results:** 98 patients had sufficient data to be included. The median time between visits was 4 years and was not different between groups (p=0.48). Patient-reported scores at visit 1 revealed significant differences in physical fatigue (p=0.017) and pain (p=0.049)

between the groups. Patients treated with HCQ, Immunosuppression, NSAIDs or Analgesia (N=87) showed a worsening of physical and mental fatigue, pain and dryness whereas the inverse was true for those patients not treated (N=11). In particular, patients who were started on analgesics reported higher physical fatigue (p=0.03), mental fatigue (p=0.005) and pain (p=0.16) at visit 2. Haematological analysis reveal that patients treated with HCQ had a lower ESR (p=0.045), IgG (p=0.0044) and IgM (p=0.0031) whereas those treated with other immunosuppressives only had a lower IgM (p=0.0035).

**Conclusion:** Whilst HCQ appears to reduce the clinical parameters associated with active disease in patients with pSS, it was not accompanied by improvement in patient-reported symptoms at visit 2. Symptomatic treatments in the form of NSAIDs or analgesics appear to be associated with worsening patient-reported scores whereas those not treated with any medication seem to improve at visit 2. Despite the limitations with this analysis our data suggest that HCQ, immunosuppressive therapies and symptomatic medications are ineffective in improving patients' symptoms.

Regime	Visit 1 (Mean)	Visit 2 (Mean)	P-value

# Sexual Dysfunction and Vaginal Dryness Are Common in Female Patients with Early, Active Primary Sjögren's Syndrome

**Jolien F. van Nimwegen**, Greetje S. van Zuiden, Frans G.M. Kroese, Suzanne Arends and Hendrika Bootsma, Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** The objective of this study was to evaluate the prevalence of sexual dysfunction and vaginal dryness in female patients with early, active primary Sjögren's syndrome (pSS), and to explore the association with patient characteristics, symptoms, disease activity, and exocrine gland function.

**Methods :** Between September 2015 and May 2017, 52 female pSS patients were included in an RCT studying the efficacy and safety of abatacept (NCT02067910). Inclusion criteria were fulfilment of the AECG criteria, EULAR Sjögren Syndrome Disease Activity Index (ESSDAI)  $\geq 5$ , disease duration  $\leq 7$  years and positive salivary gland biopsy. The present analysis concerns data from the baseline visit. ESSDAI, unstimulated whole salivary flow (UWS), stimulated whole salivary flow (SWS), Schirmer's test, ocular staining score (OSS), immunoglobulin G, and rheumatoid factor were determined. Patients completed a questionnaire including the Female Sexual Function Index (FSFI), EULAR Sjögren Syndrome Patient Reported Index (ESSPRI), numeric rating scale (NRS, range 0-10) for vaginal, ocular and oral dryness, and EuroQol five dimensions questionnaire (EQ-5D). Patients who did not have intercourse due to lack of a sexual partner were excluded from analyses involving the FSFI, as this may cause low FSFI scores while no sexual dysfunctioning is present. Sexual dysfunction was defined as FSFI  $< 26.55$ <sup>1</sup>. Associations between FSFI, vaginal dryness and other clinical parameters were explored using Spearman's correlation coefficient.

**Results:** Of the 52 included patients, 26 (50%) were premenopausal. Median vaginal dryness score was 6.0. 32 patients (62%) did not have intercourse in the past four weeks. Reasons for not having intercourse were low sexual desire (n=10), dyspareunia (n=7), lack of a sexual partner (n=7), vaginal dryness (n=4) and other (n=4). Median FSFI score was 14.4. Sexual dysfunction was present in 40 patients (89%). Sexual dysfunction was associated with age, vaginal dryness, and ESSPRI total and pain subdomain (table 1). Vaginal dryness was associated with age, ESSPRI total and dryness subdomain scores, and with ocular and oral dryness. In premenopausal patients, sexual dysfunction was associated with ESSPRI fatigue subdomain ( $\rho = -0.450$ ,  $p = 0.036$ ) and MFI reduced activity ( $\rho = -0.520$ ,  $p = 0.013$ ). In postmenopausal patients, sexual dysfunction was associated with ESSPRI total ( $\rho = -0.426$ ,  $p = 0.043$ ) and pain subdomain scores ( $\rho = -0.459$ ,  $p = 0.027$ ), EQ-5D score ( $\rho = -0.500$ ,  $p = 0.015$ ), and MFI reduced motivation ( $\rho = -0.611$ ,  $p = 0.002$ ).

**Conclusion:** Sexual dysfunction and vaginal dryness are highly prevalent in female patients with early, active pSS, and should be included in the outcome measures of clinical trials. Sexual dysfunction and vaginal dryness are associated with symptoms of pSS in pre- and postmenopausal women, but not with systemic disease activity or salivary and tear gland function.

<sup>1</sup> Wiegel et al. J Sex Marital Ther 2005;31:1-20.

# **Comparison of Classification Criteria for Sjögren's Syndrome from 2002 and 2016 in an Incident Cohort Diagnosed 2007 to 2011 from Stockholm County Sweden**

**Marika Kvarnstrom**<sup>1</sup> and Marie Wahren-Herlenius<sup>2</sup>, <sup>1</sup>Unit of Rheumatology, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden, <sup>2</sup>Unit of Experimental Rheumatology, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Sjögren's Syndrome Poster II: Clinical Research

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Comparison of classification criteria for Sjögren's syndrome from 2002 and 2016 in a 5 year cohort of incident patients diagnosed 2007 to 2011 from Karolinska University Hospital, Stockholm County, Sweden.

The current American-European Consensus Criteria (AECC) from 2002 has been the most widely used and applied all over the world. New classification criteria for Sjögren's Syndrome was published in 2016, designed in collaboration between ACR and EULAR. They are made up of a scoring system in which 4 points are required for classification. The weight/score is as follows:

- Labial salivary gland biopsy (?) with focal lymphocytic sialadenitis and focus score of  $\geq 1$  foci/4 mm<sup>2</sup> – 3
- Anti-SSA/Ro positive – 3
- Ocular Staining Score  $\geq 5$  (or van Bijsterveld score  $\geq 4$ ) in at least 1 eye – 1
- Schirmer's test  $\leq 5$  mm/5 minutes in at least 1 eye – 1
- Unstimulated whole saliva flow rate  $\leq 0.1$  ml/minute – 1

We wanted to examine the consistency between the different classification criteria.

## **Methods:**

We compared a cohort of all diagnosed patients with primary Sjögren's syndrome between the years 2007 to 2011 at the Dep. of Rheumatology at Karolinska University Hospital in Stockholm Sweden. Data on the item Ocular Staining Score  $\geq 5$  was not available since it is not included in AECC. The cohort consisted of 199 patients all fulfilling the 2002 AECC. Another eight patients did not fulfill the criteria but were regarded as possible Sjögren syndrome under development by the rheumatologist investigating them.

## **Results:**

196 of the 199 pSS patients also fulfilled the new criteria from 2016. The three patients who did not, only had SSB autoantibodies and no positive biopsy. Of eight patients with suspicion of Sjögren under development, three fulfilled

the new criteria.

## Conclusion:

The classification criteria for Sjögren's syndrome from 2002 and 2016 are consistent. This study indicates a possibility that the new criteria may be more sensitive early in the disease development, as long as the classification is not based on autoantibody positivity against SSB.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The concept of axial Spondyloarthritis (SpA) as defined by the ASAS criteria is relatively new. While the prevalence of Ankylosing spondylitis is around 0.5%, the exact prevalence of axial SpA in the general population is unknown. To evaluate the prevalence of axial SpA according to the ASAS classification criteria among the Israeli population of Jewish origin.

**Methods:** The study composed of 3 steps: 1) preliminary screening of the general population based on an internet screening survey of 4000 Israelis of Jewish origin, aged 18-45, which form a representative sample of the general population. Those answering positively to the question of suffering from lower back pain (LBP) for more than 3 months continued to the second step questionnaire. 2) step 2 comprised of 11 questions pertaining to inflammatory back pain (IBP) and other SpA features such as arthritis, enthesitis, uveitis, dactylitis, psoriasis, Crohn's disease or colitis, and family history of SpA. Those who answered positively to at least one of the questions were invited to undergo further evaluation by a rheumatologist. Those who agreed moved to the 3rd step and were invited to the department of rheumatology. 3) the evaluation included a clinical form comprising the SpA features as specified in the ASAS criteria, imaging (X-RAY and MRI of the sacroiliac joints) and laboratory evaluation (CRP and HLA-B27).

**Results:** A total of 4012 people were screened via the internet survey. Of these, 1440 (36%) suffered from LBP for more than 3 months. 467 fulfilled the ASAS criteria for inflammatory back pain (32%) while 30-60% described at least one characteristic of inflammatory back pain, 11% arthralgia/arthritis, 12% dactylitis and 13% enthesitis. Four percent reported uveitis, 3.5% on psoriasis and 2% on Crohn's disease or colitis. 1389 (35%) of them continued to step 2 and 981 (70%) answered positively to at least one of the SpA feature questions and were invited to be examined by a rheumatologist. 417 agreed and 60 kept their appointment. 3 patients were further excluded based on the exclusion criteria. HLA-B27 returned negative in all but one patient. The MRI showed findings compatible with sacroiliitis in 20 patients (active and/or chronic). Fifteen patients complied with the ASAS classification criteria for axial SpA resulting in an estimated prevalence of at least 0.4%.

**Conclusion:** The estimated prevalence of axial SpA is at least 0.4%. Taking into consideration the proportion of patients with IBP (6%), the prevalence is probably much higher and is between 0.4 and at least 1%. Internet screening for IBP may be a useful tool for detection of axial SpA.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** only scarce data are available regarding the diagnostic value of pelvic Xrays abnormalities suggestive of axial spondyloarthritis (axSpA) in patients with recent onset back pain to distinguish mechanical chronic back pain (CBP) and axSpA.

**Objective:**To evaluate the prevalence of sacroiliac abnormalities suggestive of axSpA in a non-axSpA CBP population and to compare its prevalence to an recent onset axSpA cohort.

## Methods:

*Study design:* Observational cross-sectional national multicentre study. *Patients:* a) Recent onset axSpA patients: first, a sample of 100 patients representative in terms of imaging abnormalities of the global DESIR<sup>(1)</sup> axSpA cohort (> 3 months but <3 years), based on the results of the previously published central reading of baseline films of DESIR<sup>(2)</sup> were selected (e.g. 21% of patients fulfilling the modified NY criteria (mNY)). b) CBP patients: consecutive in- and outpatients consulting for recent (>3months but <5years) mechanical CBP, initiating before the age of 45y and with a maximum age of 50y, in four tertiary care Hospitals were included in the study. *Imaging:* Pelvic Xrays were performed in both groups with an identical protocol. *Central reading:* an experienced reader (AM) centrally read X-ray films, blinded for clinical diagnosis.

*Statistical analysis:* prevalence of lesions suggestive of axSpA and the fulfilment of the mNY criteria for radiographic sacroiliitis were compared in both groups. Sensitivity, specificity and positive likelihood ratio of each lesion for the diagnosis of axSpA were calculated.

## Results:

A total of 98 patients with CBP were included, and compared to 100 axSpA patients. Age and gender were comparable (mean (SD) 36.2 (9.9) vs. 32.2 (8.7)y, and 41.8% and 45% males, in the CBP vs. axSpA groups, respectively).

Patients with axSpA had consistently more lesions suggestive of axSpA than CBP patients (Table), and presence of erosions showed the best positive likelihood ratio. The fulfilment of mNY criteria presented also a high positive likelihood ratio (LR+).

LESIONS	CBP n=98	axSpA n=100	p	Sensitivity	Specificity	LR+
• Erosion	9/97 (9.3%)	35 (35.0 %)	<0.001	0.4 (0.3, 0.5)	0.9 (0.8, 0.9)	3.8 (1.9, 7.4)
• Sclerosis	21/97 (21.6%)	50 (50.0%)	<0.001	0.5 (0.4, 0.6)	0.8 (0.7, 0.9)	2.3 (1.5, 3.5)
• Joint widening	13/97 (13.4%)	25 (25.0%)	0.06	0.3 (0.2, 0.4)	0.9 (0.8, 0.9)	1.9 (1.0, 3.4)

\* NA = not applicable, since one of the categories is 0, Specificity can not be calculated.

## Conclusion:

Prevalence of sacroiliac lesions suggestive of axSpA in pelvic Xrays of patients with recent onset CBP is high, but significantly lower when compared to recent onset axSpA. Presence of erosions and fulfilment of mNY criteria were the best performing features for axSpA recognition even in an early disease stage.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

There are few studies of the heritability of ankylosing spondylitis (AS) in families, a disease where hereditary factors play a dominant role in disease pathogenesis. One study (Calin et al, Lancet 1999; 354: 1687-90) showed that in families with affected parent: offspring pairs, the mother was more likely to be affected compared to the father. This study aims to better understand the pattern of inheritance of this disease in familial AS and to determine whether exists gender bias in disease inheritance in parent: offspring pairs in familial AS.

### Methods:

Two cohorts were examined comprising 105 affected parent:offspring pairs, including one taken from 865 AS patients meeting modified New York Criteria enrolled in a longitudinal study of outcome who were administered a questionnaire querying spondyloarthritis symptoms in their first degree relatives (the proband recall cohort) and a second from 210 AS probands enrolled in a study of familial AS genetics, where the diagnoses were confirmed by either review of pelvic radiographs of affected family members or by radiographic reports thereof (the radiographic cohort). We tested whether the proportion of affected fathers was same as that of affected mothers and also evaluated the gender association between affected parents and offspring by conducting a test of one sample proportion and Chi-square test, respectively, at a 5% level of significance. All parent:offspring pairs were HLA-B27 positive.

**Results:** Overall, in 105 parent:offspring pairs, the father was the more likely affected parent after combining the parent: offspring pairs from the proband recall and the radiographic cohorts ( $p = 0.003$ ). In the proband recall cohort there were 54 parent:offspring pairs and the father was more likely to be the affected parent compared to the mother ( $p = 0.007$ ). In the radiographic cohort there were 51 affected parent: offspring pairs. Here a trend was also seen for greater paternal involvement, although the results were not statistically significant ( $p = 0.12$ ).

Next it was tested whether affected parents are more likely to transmit the disease to their same or opposite gender offspring. In the radiographic cohort, the father and son were affected in 26 of 55 (47%) of father:offspring pairs whereas there in an affected mother:son pair in 12 of 24 (50%) of mother:offspring pairs ( $p = 0.40$ ). Similar results were seen in the proband recall cohort-28/36 (77%) father:son versus 12/17 (71%) affected mother:son pairs, or in the combined cohorts ( $p = 0.07$ ). Overall, sons were more likely to be affected than daughters ( $p = 0.0003$ ) in the proband recall and combined cohorts.

**Conclusion:** In affected parent:offspring pairs with AS, the father is more likely to be affected than the mother, and there is greater likelihood for transmission to male versus female offspring, perhaps reflecting the male gender bias known to exist in this disease. There were no significant differences in parental transmission AS to same gender versus opposite gender offspring.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Traditionally, patients with spondyloarthritis (SpA) were classified in five subgroups: ankylosing spondylitis (AS), psoriatic arthritis, arthritis associated with inflammatory bowel disease, reactive arthritis and undifferentiated SpA (uSpA). Nowadays, the ASAS criteria classify patients in peripheral SpA and axial SpA (axSpA), being the latest classified in two groups: classical AS and non-radiographic axSpA (nr-axSpA). Whether or not patients with nr-axSpA represent the same group of patients that used to be classified as uSpA remains unclear. The purpose is to evaluate the similarities and differences between patients with predominant axial disease classified currently as nr-axSpA versus those traditionally classified as uSpA.

## Methods:

Baseline data from the ESPeranza program (a multicenter national initiative to early diagnose SpA between 2008 and 2011) was used. Inclusion criteria for this program were: age <45 years, symptoms duration 3-24 months and with inflammatory back pain -IBP- or asymmetrical arthritis or spinal/joint pain plus  $\geq 1$  SpA features). For this study, only patients with predominant axial manifestation were selected. Demographic, clinic, laboratory and image results were compared between two groups: i) 182 patients with nr-axSpA according to ASAS criteria, and ii) 166 patients classified as uSpA defined as fulfilling ESSG/Amor criteria in absence of sacroiliitis (mNY), psoriasis, inflammatory bowel disease and reactive arthritis. In order to get a deeper knowledge of the differences between nr-axSpA and uSpA, we also compared: i) 88 patients only classified as nr-axSpA, ii) 72 patients only classified as uSpA; iii) 94 patients fulfilling both criteria.

## Results:

Results are shown in table 1 and table 2. Compared to patients classified as uSpA patients with nr-axSpA were younger, had HLA-B27 positive more frequently and higher values of CRP. On the other hand, they had history of SpA less frequently and lower values for BASDAI, BASFI and ASQoL.

**Table 1: Results are presented in mean  $\pm$  standard deviation for continuous variables and n (%) for categorical variables.**

	nr-axSpA N (%)= 182	Undifferentiated SpA N (%) = 166
Age (years)	31.5 $\pm$ 7.1	32.8 $\pm$ 7.4
Male	108 (61)	95 (57.2)
HLA-B27	142 (80.2)	87 (52.4)
Dactylitis	11 (6.2)	12 (7.2)
Enthesitis	46 (26.0)	51 (30.7)

ASQoL	5.9 ± 4.7	5.2 ± 4.5	7.4 ± 5.2	0.01
CRP (mg/L)	10.7 ± 14.3	9.8 ± 16.5	5.1 ± 9.1	<0.05

\*p value for differences between nr-axSpA and undifferentiated SpA (Student-t test for continuous variables and Pearson Chi-square test for categorical variables)

### Conclusion:

Compared with patients traditionally classified as uSpA, patients who are currently classified as nr-axSpA are diagnosed earlier, are more frequently HLA-B27 carriers and have higher disease activity according to objective parameters. On the other hand, they report lower values for patient reported outcomes.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Assessment of SpondyloArthritis international Society (ASAS) recommendations for use of TNF inhibitors (TNFi) in axial SpA include active disease and a positive expert opinion, which includes consideration of serum acute phase reactant and/or imaging results that indicate active inflammation and/or risk of radiographic progression. Little is known about the characteristics of patients (pts) with non-radiographic axial SpA (nr-axSpA) who fulfill criteria for TNFi use. Here we characterize the clinical phenotype of nr-axSpA pts enrolled in the ABILITY-3 adalimumab study in terms of ASAS classification criteria and parameters of objective inflammation at baseline.

**Methods:** ABILITY-3 enrolled adult pts with nr-axSpA defined as fulfilling ASAS classification criteria but not modified New York radiologic criteria for ankylosing spondylitis (AS). Pts were required to have a minimum baseline disease activity (defined as *Ankylosing Spondylitis Disease Activity Score*  $\geq 2.1$ , BASDAI  $\geq 4$ , and total back pain score  $\geq 4$ ), objective evidence of inflammation (in  $\geq 1$  of the following: MRI of the SI joints, MRI of spine, and/or elevated high-sensitivity CRP [each centrally evaluated]), and an inadequate response to  $\geq 2$  NSAIDs. Pts received open-label adalimumab 40 mg every other wk for 28 wks during period 1. Pts achieving sustained remission (wks 16–28) were randomized into the double-blind period 2. Here, we analyzed whether enrolled patients fulfilled the imaging arm of the ASAS classification criteria (sacroiliitis on imaging plus  $\geq 1$  SpA feature), the clinical arm (presence of HLA-B27 plus  $\geq 2$  SpA features), or both arms, and which objective parameters of inflammation were present.

**Results:** 673 of 1506 screened pts were enrolled; screen failures were commonly due to pelvic x-ray consistent with AS (24.7%), not fulfilling ASAS classification criteria (29.3%), or lack of objective evidence of inflammation (22.1%). Overall, 664 pts (98.7%) fulfilled the ASAS criteria, of which 447 (67.6%) fulfilled the imaging arm, 513 (77.4%) the clinical arm, and 296 (44.0%) both arms. At baseline, 662 (98.4%) pts had objective evidence of active inflammation. Most pts (74.0%) had evidence of MRI inflammation, 31.4% had MRI inflammation only, 42.6% were MRI positive and had elevated hsCRP, and 24.1% had elevated hsCRP only (**Table**).

<b>Table. Baseline Characteristics and Parameters of Objective Evidence of Inflammation</b>	
<b>Characteristic, n (% of total population)</b>	<b>Total Population (n=673)</b>
Age, mean $\pm$ SD, y	37.3 $\pm$ 11.1
Male	330 (49.0)
White	651 (96.7)
Symptom duration, mean $\pm$ SD, y	7.7 $\pm$ 7.7
Positive HLA-B27 status <sup>a</sup>	515 (76.6)
Elevated hsCRP	451 (67.0)
MRI evidence of inflammation <sup>b</sup>	
SI joint and/or spine	498 (74.0)
+ Elevated hsCRP	287 (42.6); 57.6% of MRI+
+ Normal hsCRP	211 (31.4); 42.4% of MRI+
SI joint only	316 (47.0)
Spine only	50 (7.4)
SI joint AND spine	130 (19.3)
Elevated hsCRP only (MRI normal) <sup>c</sup>	162 (24.1)
Positive MRI for SI joint AND spine AND elevated hsCRP	90 (13.4)
Negative MRI for SI joint AND spine AND normal hsCRP	11 (1.6)
HLA-B27, human leukocyte antigen-B27; hsCRP, high-sensitivity C-reactive protein; MRI, magnetic resonance imaging; SI, sacroiliac.  <sup>a</sup> 1 pt had missing HLA-B27 data from the central laboratory.  <sup>b</sup> 4 pts had missing MRI imaging (spine only, n=1; SI joint only, n=2; SI joint and spine, n=1).  <sup>c</sup> Elevated hsCRP = greater than the upper limit of normal for the lab.	

**Conclusion:** An important proportion of screened nr-axSpA pts with clinically active disease did not present with objective measures of inflammation, and would not be candidates for biologics per ASAS recommendation. Many pts fulfilled both imaging and clinical arms of the ASAS criteria with more fulfilling the clinical vs imaging arm. Nearly 60% of pts who presented with MRI inflammation also had elevated hsCRP, suggesting hsCRP assessment as the first step in evaluating pts for objective inflammation due to low cost and ease of obtainment, unless MRI is required for diagnosis.

## **Validation of Self-Reported Inflammatory Back Pain Score Compared to Rheumatology Consultation in University Students**

**Nelly Ziade**<sup>1</sup>, **Fouad Fayad**<sup>1</sup> and **Lea el-Khoury**<sup>2</sup>, <sup>1</sup>Rheumatology, Hotel Dieu de France Hospital and Saint Joseph University, Beirut, Lebanon, <sup>2</sup>Saint-Joseph University, Beirut, Lebanon

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Validation of self-reported inflammatory back pain score compared to rheumatology consultation in university students**

**Background/Purpose:** Low Back Pain (LBP) is a major public health problem affecting all ages, mostly young adults. University students may be vulnerable due to sedentary lifestyle and high stress levels. LBP is usually self-limited but a small proportion may have inflammatory back pain (IBP), a cornerstone symptom of axial spondyloarthritis, often overlooked. The objective of the study is to test an auto-questionnaire for IBP screening in educated young individuals, compared with the rheumatologist consultation as gold standard.

**Methods:** University students of three faculties (Medicine, Engineering and Sciences at Saint-Joseph University) were invited to respond to an auto-questionnaire about the presence and characteristics of LBP. Items related to IBP from the ASAS, Calin and Berlin criteria were collected. The students were then invited to a rheumatology consultation. Correlations between IBP score according to ASAS, Calin and Berlin criteria were studied between the auto-questionnaire and the rheumatology consultation.

**Results:** 611 students completed the auto-questionnaire (66.5%). 154 (25.2%) gave their consent to be contacted, 85 (55.2%) could be reached for consultation at the time of this report. Responders differed from non-responders by LBP (presence), age (older), BMI (higher), year of study (higher), habits such as smoking, alcohol consumption, caffeine consumption and sports activities (higher). 44% of students reported having at least one LBP episode during the past year (59.5% in medicine vs 25.5% in others,  $p < 0.001$ ). LBP correlated with specialty, caffeine consumption, sleep hours, walking when studying and anxiety in multivariate analysis. 8.6% of LBP were chronic, 84.8% were recurrent ( $>2$ /year) and 31.6% were highly recurrent ( $>4$ /year). IBP was found in 17.5% (ASAS), 12.3% (Calin) and 8.8% (Berlin) of interviewed LBP. The correlation with the medical interview was acceptable, with agreement ranging from 73.68 to 85.96%.

**Conclusion:** LBP is more frequent in medical university students compared to others. The correlation between the auto-questionnaire and the rheumatology consultation was acceptable, which makes the auto-questionnaire a suitable screening tool in educated individuals.

## Similarities and Differences between Non-Radiographic and Radiographic Axial Spondyloarthritis

**Denis Poddubnyy**<sup>1</sup>, Robert D Inman<sup>2</sup>, Joachim Sieper<sup>1</sup>, Servet Akar<sup>3</sup>, Santiago Muñoz-Fernández<sup>4</sup> and Maja Hojnik<sup>5</sup>, <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Toronto Western Hospital, Toronto, ON, Canada, <sup>3</sup>Rheumatology, Izmir Katip Celebi University, School of Medicine, Rheumatology, Izmir, Turkey, <sup>4</sup>Hospital Universitario Infanta Sofía, Universidad Europea, Madrid, Spain, <sup>5</sup>AbbVie, Ljubljana, Slovenia

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Differences between non-radiographic and radiographic axial spondyloarthritis (axSpA) – such as a higher prevalence of females and lower level of acute phase reactants in non-radiographic axSpA (nr-axSpA) – have been reported in national observational studies, mostly from Europe. This analysis compared demographic and clinical characteristics of patients (pts) with nr-axSpA and radiographic axSpA (ankylosing spondylitis, AS) in a large multinational cohort of pts with recently diagnosed axSpA.

**Methods:** PROOF is a prospective observational study evaluating clinical and radiographic outcomes in axSpA pts in rheumatology clinical practice in 29 countries. Pts with axSpA fulfilling ASAS classification criteria were eligible if diagnosed  $\leq 1$  year prior to study enrolment. Investigator's confidence with the axSpA diagnosis was ascertained on a numeric rating scale (NRS 0-10) at enrolment and end of follow-up. At baseline, demographic and clinical data related to the diagnosis, disease activity, quality of life and work productivity, as well as conventional radiographs of the sacroiliac joints were collected. Classification as nr-axSpA or AS was based on results of the assessment of sacroiliac radiographs. Available radiographs were assessed by a local reader and then by a central reader according to grading system of modified New York criteria. In the case of a disagreement in classification (nr-axSpA or AS), the radiograph was evaluated by the 2<sup>nd</sup> central reader, who was blinded to previous assessments and final classification was made based on the decision of 2 out of 3 readers.

**Results:** Of the 2126 pts enrolled in PROOF, 1281 (60.3%) pts were classified as AS and 845 (39.7%) as nr-axSpA according to investigators. Confidence with the diagnosis of axSpA was  $8.7 \pm 1.8$ . Final classification according to central assessment of sacroiliac radiographs was confirmed in 1583 pts included in this analysis. A total of 987 pts (62.3%) were classified as AS and 596 (37.7%) as nr-axSpA. AS pts expectedly had longer symptom duration, more frequently had elevated and higher CRP and were more often male and treated with TNF inhibitors (**Table**). In addition, HLA-B27 positivity was more frequent among AS pts, while pts with nr-axSpA had a significantly higher prevalence of enthesitis, psoriasis, and inflammatory bowel disease (IBD). Prevalence of other SpA features was comparable between the two subgroups of axSpA. Mostly, pt-reported outcomes reflecting burden of disease were comparable between the two subgroups, but BASDAI was significantly higher in the nr-axSpA subgroup (**Table**).

**Conclusion:** There were a few differences between nr-axSpA and AS pts in the PROOF cohort. Clinical constellation of female sex, low CRP, enthesitis, psoriasis, and IBD in nr-axSpA pts appears to reflect a phenotype less prone to structural damage in the sacroiliac joints. However, clinical burden of disease was comparable between the two subgroups of axSpA.

**Table. Baseline demographic and clinical characteristics of patients from PROOF cohort.**

## **Similarities and Differences between Osteitis Condensans Ilii and Axial Spondyloarthritis Patients Presenting with Chronic Back Pain in a Rheumatology Setting**

Henning Weineck<sup>1</sup>, Joachim Listing<sup>2</sup>, Torsten Diekhoff<sup>1</sup>, Kay-Geert Hermann<sup>1</sup>, Joachim Sieper<sup>1</sup> and **Denis Poddubnyy**<sup>1,2</sup>, <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>German Rheumatism Research Centre, Berlin, Germany

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Osteitis condensans ilii (OCI) is regarded as a non-inflammatory disorder, which is considered to be induced by mechanical stress (e.g., by pregnancy and delivery). An extended sclerosis of the sacroiliac joints without erosions or ankyloses is the most characteristic imaging feature. More recently, paraarticular bone marrow edema has been described on magnetic resonance imaging, which can occur early but also intermittently later in the course of the disease. The clinical characteristics of OCI patients have not been well described. To date, there are no published systematic data on the characteristics of OCI as compared to axial spondyloarthritis (axSpA).

The objective of this matched case-control study was to investigate demographic, clinical, and lab characteristics of OCI as compared to axSpA.

### **Methods:**

Using medical database search we have identified n=103 patients aged ≥18 years who were diagnosed with OCI upon presentation with chronic back pain in the Early Spondyloarthritis Clinic of the rheumatology department in the Charité University Hospital between January 2010 and May 2015. These patients were contacted in order to obtain an informed consent and to complete a survey on the disease-related history. N=60 OCI patients who

provided an informed consent and completed the survey were included in the final analysis. These patients were matched with a 1:2 ratio according to the back pain duration to patients with definite axSpA diagnosed in the same setting in order to compare demographic, clinical and lab characteristics.

## **Results:**

The main characteristics of the two groups are presented in the table. Most importantly, all but 2 patients with OCI were females and had a significantly lower prevalence of inflammatory back pain, lower level of CRP stressing a rather non-inflammatory nature of this condition. All patients were referred because of possible axSpA, therefore SpA features, although being lower than in axSpA patients (table), were higher than can generally be expected in chronic back pain patients. This is probably the reason why a statistical significance in comparison to axSpA was observed for uveitis only. There was no difference in age of back pain onset. Signs of sacroiliitis at physical examination were only slightly more frequent in axSpA; there were no differences in spinal mobility. The level of symptoms (BASDAI) and the perceived level of functional disability (BASFI) were comparable between groups. 83% of female patients with OCI reported a history of at least one pregnancy with a mean number of pregnancies of 3 (median=3, range 1-8).

## **Conclusion:**

OCI manifesting with chronic back pain starting before 45 years of age represents an important differential diagnosis for axSpA. A constellation of a female sex (with a history of pregnancies), negative HLA-B27 and negative CRP seems to be of differential diagnostic value as compared to axSpA.

**Table.** Demographic, clinical and lab characteristics of OCI as compared to axSpA in the rheumatology setting.

## Real-Life Performance of the ASAS Health Index in Routine Care of Patients with Spondyloarthritis

**Uta Kiltz**, Thomas Wiatr, Xenofon Baraliakos, Kirill Fedorov and Jürgen Braun, Rheumazentrum Ruhrgebiet, Herne, Germany

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The ASAS Health Index (ASAS HI) have been developed to measure health and impairment in functioning in patients with spondyloarthritis (SpA). Its measurement properties have already been evaluated in a cohort study. So far, its association with structural damage has not been examined. The purpose is to investigate the relationship between clinical data, function and health as assessed by the ASAS HI and to investigate the influence of structural spinal damage in patients with axial SpA (axSpA) on the ASAS HI.

**Methods:** Patients fulfilling ASAS classification criteria for axial SpA (axSpA) were recruited prospectively. Information was collected on clinical assessments (ASAS HI, NRS pain, BASDAI, ASDAS, BASFI, BASMI), laboratory parameters and spinal x-rays. Imaging were scored using mSASSS by two independent readers. The relationship between ASAS HI and other health outcomes was evaluated by Spearman correlation.

**Results:** A total of 150 patients (57 nr-axSpA and 93 AS patients) were included: 68.7% male, mean (SD) age 46.4 (14.1), symptom duration 18.7 (13.5) and diagnosis since 11.4 (11.8) years, and HLA-B27 positive in 82.0%. Values of clinical assessments were ASAS HI 7.4 (4.1), BASDAI 4.7 (2.3), ASDAS 2.7 (1.1), BASMI 3.3 (1.8), pain 5.7 (2.7), and BASFI 4.7 (2.6). An elevated CRP level was found in 34.8% of the patients. Radiographs of the sacroiliac (SI) joint and the spine were available in 138 patients, 38.0% of which had syndesmophytes and 7.5% a bamboo spine. The median (IQR) mSASSS value was 4.3 (IQR 1.0-22.1) in AS und 0.2 (IQR 0.0-1.4) in nr-axSpA patients. Patients received a treatment with NSAIDs (62.7%), DMARDs (20.9%) and/or biologics (49.4%). Significant correlation of ASAS HI was noted for BASMI (0.5), BASDAI (0.7), ASDAS (0.5) and BASFI (0.8). No correlations were found for ASAS HI and any of the results for radiographic damage (mSASSS 0.2, syndesmophytes 0.01, bamboo spine 0.2) and CRP level (0.07). Stratifying patient population by symptom duration (cut-off 3 years) does not change the results.

**Conclusion:** Measures of function and spinal mobility correlate well with the ASAS HI in patients with SpA. Probably due to relatively low mSASSS scores at baseline, the influence of structural changes as measured by mSASSS on the ASAS HI was rather limited in this study. Further study in more severely affected patients is needed to study the association of physical activity, spinal mobility, function and radiographic damage.

## Is Sacroiliac Imaging the All-Decisive Factor in the Diagnosis of Early Axial Spondyloarthritis? Data from the Spondyloarthritis Caught Early (SPACE) Cohort

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Imaging of the sacroiliac joints plays a pivotal role in the recognition of axSpA. However, interpretation of imaging is challenging and has led to concerns of overreliance on imaging possibly leading to incorrect diagnoses of axSpA. Given these controversies, surprisingly little is known about how rheumatologists actually integrate sacroiliac imaging results in the diagnostic work-up of patients suspected of axSpA. Therefore, we evaluated the influence of sacroiliac imaging on diagnosis and rheumatologists' confidence in diagnosis of patients with chronic back pain (CBP) suspected of early axSpA.

### **Methods:**

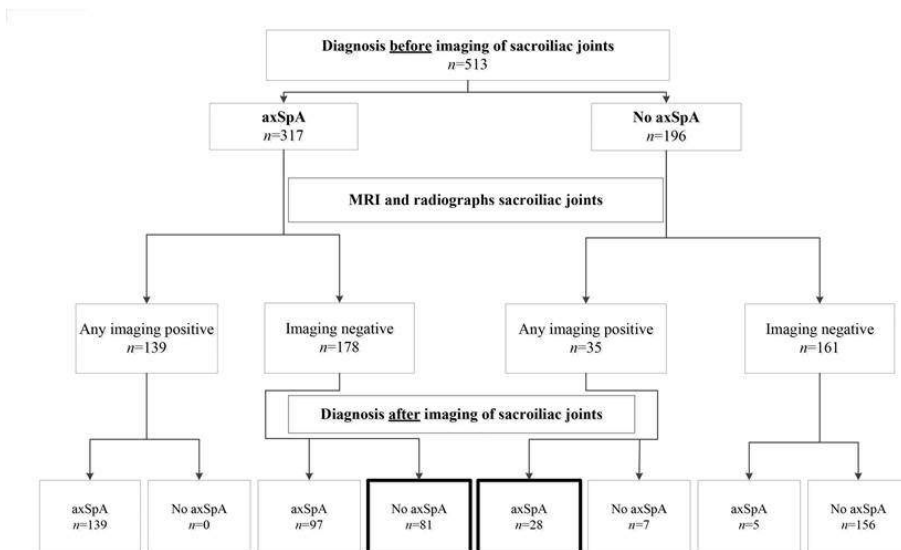

Baseline data from 513 patients from the SPACE cohort which includes patients with CBP ( $\geq 3$  months,  $\leq 2$  years, onset  $< 45$  years) were analysed. All patients underwent a full work-up including MRI and radiography of the sacroiliac joints. Rheumatologists were asked to provide a diagnosis before and after taking imaging into account. Also, a level of confidence (LoC) regarding the diagnosis on an 11-point numerical scale (0: not confident at all to 10: very confident) was documented.

### **Results:**

Before imaging, 317/513 (62%) CBP patients were diagnosed with axSpA. Of these patients, 178/317 (56%) did not have sacroiliitis on MRI or radiography, and after imaging rheumatologists changed diagnosis to 'no axSpA' in 81/178 (46%) patients. Of the patients without axSpA before imaging, 35/196 (18%) had sacroiliitis on imaging. After imaging, 28/35 (80%) patients were diagnosed with axSpA and in 7/35 (20%) patients the diagnosis remained 'no axSpA'. In general, diagnostic confidence increased significantly following imaging (all patients' average LoC 6.2 to 7.4,  $p < 0.001$ ). Overall, imaging results not in line with the diagnosis ( $n=213$ ) before imaging led to a change in diagnosis in 109 (51%) patients.

### **Conclusion:**

In CBP patients suspected of axSpA sacroiliac imaging increases diagnostic confidence. However, the number of changes in diagnosis suggests that imaging is an important but not the all-decisive factor in axSpA diagnosis.

**Figure 1** Rheumatologist's diagnosis before and after considering imaging of sacroiliac joints in CBP patients from the SPACE cohort, n=513. axSpA, axial spondyloarthritis; MRI, magnetic resonance imaging; any positive imaging defined as sacroiliitis on MRI and/or radiographic sacroiliitis; imaging negative defined as no abnormalities on MRI and radiographs of sacroiliac joints. Boxes in bold represent the patients with imaging results not in line with the diagnosis before imaging.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Timely identification of nr-axSpA may lead to earlier intervention to reduce symptoms, improve function, and reduce disease burden. The purpose of this study was to compare the clinical characteristics that are present at the time of diagnosis of nr-axSpA patients in the US and EU.

**Methods:** Nr-axSpA patients from the 2015 SpA Disease Specific Programme, a cross-sectional, multi-national survey of patients and rheumatologists conducted in France, Germany, Italy, Spain, United Kingdom, and the United States were analyzed. Rheumatologists completed patient record forms containing patient demographics, clinical measurements and symptomology at diagnosis.

**Results:** Data from 391 rheumatologists (299 EU/92 US) and 1,995 patients with nr-axSpA (1513 EU/482 US) were included in this analysis. In the US and EU, at the time of diagnosis patients had similar rates of IBP, back pain for more than 3 months, and a family history of SpA (Table 1). Patients in the US were significantly more likely to have peripheral joint involvement at diagnosis than patients in the EU. In the US, patients that had peripheral joint involvement at diagnosis were significantly more likely to have had IBP that was previously diagnosed as mechanical back pain ( $p=0.002$ ) and have back pain for greater than 3 months ( $p=0.035$ ) at diagnosis when compared to patients that did not have peripheral joint involvement at diagnosis. In the EU, patients that had peripheral joint involvement at diagnosis were significantly more likely to have elevated ESR ( $p<0.001$ ) and alternating buttock pain ( $p=0.002$ ) when compared to patients that did not have peripheral joint involvement at diagnosis. In the US and EU, patients that had peripheral joint involvement at diagnosis were significantly more likely to have elevated CRP, morning stiffness for more than 30 minutes, dactylitis, enthesitis, tendonitis, synovitis, and arthritis at diagnosis when compared patients that did not have peripheral joint involvement at diagnosis (Table 2).

**Conclusion:** Nr-axSpA patients in the US and EU share a range of clinical features at diagnosis. However, patients in the US were more likely to have peripheral joint involvement at diagnosis than patients in the EU. Furthermore, nr-axSpA patients in the US and EU with peripheral joint involvement at diagnosis were associated with a worse symptom profile versus patients without peripheral joint involvement.

**Table 1.** Comparison of symptoms of nr-axSpA patients at diagnosis in the US vs. EU

Symptoms at Diagnosis	USA	EU	p-value
	% with symptom	% with symptom	
Peripheral joint involvement	50.8	23.3	<0.0001
IBP or spinal pain	69.3	67.6	0.5016
Age of onset of IBP less than 45 years	48.5	48.2	0.9167
Back pain for more than 3 months	56.0	54.9	0.7128
IBP that was previously diagnosed as mechanical back pain	27.4	27.3	1.0000
Family history of spondyloarthritis	20.7	20.9	1.0000
Morning stiffness for more than 30 minutes	57.9	51.8	0.0210
Elevated CRP	37.1	37.1	1.0000
Elevated ESR	37.3	25.4	<0.0001
HLA-B27 positive	46.5	49.5	0.2293

**Table 2.** Comparison of symptoms of nr-axSpA patients with peripheral joint involvement at diagnosis vs. nr-axSpA patients without peripheral joint involvement at diagnosis

Symptoms at Diagnosis	USA		EU	
	% With Symptoms	p-value	% With symptoms	p-value
Back pain for < 3 months	60.8	0.0348	59.1	0.0764
IBP previously diagnosed as mechanical back pain	33.9	0.0015	30.1	0.1943
Morning stiffness for more than 30 minutes	63.3	0.0165	61.6	<0.0001

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

The association of *HLA-B\*27* and ankylosing spondylitis (AS) is relatively weak in some populations. The aim of this study is to compare the clinical manifestations between *HLA-B\*27*<sup>+</sup> and *HLA-B\*27*<sup>-</sup> patients in a Turkish AS population, which has been reported to have a low *HLA-B\*27* prevalence.

## Methods:

A total of 881 AS patients and 900 healthy controls were included in the analysis. All patients fulfilled the modified New York criteria for AS. Clinical and demographic parameters were compared between the *HLA-B\*27*<sup>+</sup> and *HLA-B\*27*<sup>-</sup> patients. Group comparisons were performed using t-tests for continuous measures that were normally distributed and x<sup>2</sup> tests were used for categorical measures.

## Results:

*HLA-B\*27* was positive in 64% of patients (n=561) and 6.3% of controls (n=57). All results are summarized in Table 1. Seventy-four percent of the *HLA-B\*27*<sup>+</sup> patients and 60% of *HLA-B\*27*<sup>-</sup> patients were male (<0.001). *HLA-B\*27*<sup>+</sup> patients had a younger age at symptom onset, as well as a shorter delay in diagnosis. Moreover, uveitis and a family history for AS were significantly more frequent among *HLA-B\*27*<sup>+</sup> AS patients, whereas co-existent psoriasis and inflammatory bowel disease (IBD) were more frequent among *HLA-B\*27*<sup>-</sup> patients. Further, *HLA-B\*27*<sup>+</sup> patients had a 22% higher CRP (P<0.05) and 13% higher ESR (P=0.06) than *HLA-B\*27*<sup>-</sup> patients. Prevalence of peripheral arthritis, dactylitis, biologic use, hip replacement surgery, family history for psoriasis or IBD or uveitis were not different between the two groups. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Metrology Index (BASMI) were also similar in both groups.

## Conclusion:

The results of this study conducted in an AS population with a relatively low prevalence of *HLA-B\*27* are in line with those of other studies performed in other populations. *HLA-B\*27*<sup>+</sup> AS patients are more likely to be males and have an earlier age of symptom onset, and a shorter delay in diagnosis as compared to AS patients lacking *HLA-B\*27*. Moreover, *HLA-B\*27*<sup>+</sup> AS patients show a greater risk for occurrence of acute anterior uveitis, a greater familial occurrence, and an elevated CRP/ESR, the latter suggesting that *HLA-B\*27* carriage influences degree of inflammation in AS.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Axial spondyloarthritis (axSpA), characterized by spinal inflammation, is also associated with extra-spinal manifestations including inflammation of the entheses (enthesitis). Enthesitis is equally prevalent throughout the axSpA disease spectrum and can severely reduce patients' (pts) quality of life. RAPID-axSpA (NCT01087762) was a long-term, phase 3 study in axSpA pts with/without radiographic sacroiliitis treated with certolizumab pegol (CZP). Here we report improvements in tenderness at enthesal sites in males and females with axSpA treated with CZP for <4 years.

**Methods:** RAPID-axSpA was double-blind and placebo (PBO)-controlled to Wk24, dose-blind to Wk48 and open-label to Wk204. Pts fulfilled ASAS axSpA classification criteria with/without radiographic sacroiliitis (AS/nr-

axSpA) and had active disease. Enthesitis was assessed by the Maastricht Ankylosing Spondylitis Enthesitis Score (MASES; count of 0–13 tender sites)<sup>1</sup> at baseline (BL) and through to study completion/early withdrawal. Data are shown for all pts randomized to CZP (200 mg Q2W/400 mg Q4W) at BL, or where noted, for those reporting tenderness at BL. Observed case (OC) data are reported, with last observation carried forward (LOCF) imputation used where noted. Model-based analyses were run to evaluate effects independently associated with MASES outcomes (data not shown).

**Results:** Of 218 pts (83 female, 135 male) randomized to CZP at Wk0, 148 (67.9%) exhibited  $\geq 1$  tender site (MASES  $\geq 1$ ) at BL (AS: 78/121 [64.5%]; nr-axSpA: 70/97 [72.2%]). AxSpA females had mean (SD) MASES of 4.8 (4.0) at BL, with 84.3% reporting  $\geq 1$  tender site, compared to 57.8% for axSpA males whose mean (SD) was 2.7 (3.3). BL data were similar for AS and nr-axSpA females: 28/33 (84.8%) AS pts and 42/50 (84.0%) nr-axSpA pts reported  $\geq 1$  tender site and mean MASES = 4.6 and 4.9, respectively. At Wk204, mean MASES (OC/LOCF) was reduced to 1.0/1.1 (AS) and 2.0/2.5 (nr-axSpA). In males, mean MASES at BL = 2.4 (AS), 3.1 (nr-axSpA); Wk204 = 0.7/0.8 (AS), 0.6/0.7 (nr-axSpA). No notable differences were observed between enthesal sites in the resolution of tenderness at Wks24 and 204, with resolution in 70.5–83.6% sites affected at BL by Wk204 (Table). New onset of tenderness was rare: 1/107 pts (0.9%) without Achilles tenderness at BL reported tenderness at Wk204 (observed data).

**Conclusion:** In CZP-treated males and females across the broad axSpA spectrum with enthesal tenderness, improvements were maintained in all MASES sites. Females reported higher BL MASES than males. Improvements in MASES at Wk204 were greater for AS females than AS males, and were similar in both genders for nr-axSpA pts. A high percentage of pts with positive BL MASES at a particular site achieved total resolution in the affected area by Wk24, which was maintained to Wk204.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Uveitis is a common extra-articular manifestation in patients with spondyloarthritis (SpA) requiring, in most severe cases, the use of biological therapy, especially tumour necrosis factors inhibitors (TNFi). Currently, the most frequently TNFi used are infliximab and adalimumab. However, in cases of failure or adverse events related to these drugs, other TNFi (with indication for SpA patients) such as certolizumab pegol (CZP) could be an effective option

for both uveitis and SpA control, as we have previously reported (1). Our purpose is to analyze the effectiveness and safety profile of CZP in patients with SpA-associated- uveitis refractory to previous immunosuppressive or biological therapy.

## Methods:

Observational, multicentric, retrospective study. Inclusion criteria were: patients with SpA and with a diagnosis of uveitis (confirmed by an Ophthalmologist) as main extra-articular SpA manifestation, refractory to previous immunosuppressive or biological agents and who received CZP for at least 6 months. Variables analyzed: age, sex, diagnosis, type of uveitis, duration since the first uveitis episode and number of eyes affected; previous treatment (NSAID, disease-modifying anti-rheumatic drugs (DMARDs), immunosuppressive, biological therapy); outcome and time to follow-up.

## Results:

Twenty-two eyes of 13 patients (10 men); age  $50.4 \pm 11.7$  (range 29-71 years) were included in the study. Diagnosis were: ankylosing spondylitis (n=7), psoriatic arthritis (n=4), non-radiographic axial SpA (n=1) and SpA associated to inflammatory bowel disease (n=1). Type of uveitis: 14 anterior (63.6%), 6 panuveitis (27.2%), and 2 intermediate uveitis (9.1%). Mean disease duration was  $161.7 \pm 138.5$  months (range 5-420). 84.6% patients had previously received biological therapy (53.8% > 2 biological agents). 69.2% received CZP in monotherapy and 5 patients received concomitant treatment: 4 methotrexate and 1 azathioprine. In all cases CZP was started due to inefficacy to previous treatment except for 2 cases whose primary reason was the concurrence of adverse events or intolerance. After a follow-up of  $17.8 \pm 9.9$  months (range 6-39), 8 patients are still on CZP treatment. Thirteen eyes showed improvement of visual acuity (59.1%), 7 remained stable and 2 worsened. During the follow-up no serious adverse events were reported. Five cases withdrew CZP treatment: 2 due to worsening of articular symptoms but with no uveitis activity; 1 due to persistence of macular edema and 2 due to uveitis activity. Two patients switched to infliximab, one to golimumab, one to adalimumab and one required switch to tocilizumab due to persistence of macular edema. In all 13 patients except 2, CZP achieved a good control of SpA activity.

## Conclusion:

CZP demonstrates moderate effectiveness in patients with SpA-associated-uveitis refractory to previous TNFi treatment, with a good safety profile.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Certolizumab pegol (CZP) is available for patients with spondyloarthritis (SpA), including ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axialSpA). CZP has a different molecular structure, the only Fc free PEGylated antiTNF and monovalent. Thus, CZP represents an alternative for solution NSAIDs refractory patients suffering with SpA.

**Objective:** To evaluate the effectiveness and safety of CZP in a real word setting in SpA patients.

**Methods:** Multicentric cohort of SpA patients treated with CZP according to routine clinical practice. The study was approved by the local Ethics Committee. Maximum follow-up was 12 months. Clinical response was evaluated through BASDAI, ASDAS, BASFI and MASES scores. Safety variables: discontinuation rate.

**Results:** 336 patients with axSpA were included: 56.5% male, mean age 45.8 ( $\pm 12.1$ ) years, median disease time 4.3 (range 0, 49.5) years, 68.5% HLAB27 positive, never smokers 64.7%. Prior bDMARD exposure: (27.2% none; 37.9% 1, 35%  $\geq 2$ ). At baseline, 36.8% had concomitant csDMARDs. Mean duration on treatment with CZP was 10.3 months. 31.8% of patients had peripheral arthritis and 42.7% enthesitis at baseline.

Statistically significant differences in BASDAI, BASFI, ASDAS and MASES were observed at the last visit comparing with baseline (Table 1). In the last observation, 41.0% of the patients achieved BASDAI50, 34% were in ASDAS remission ( $ASDAS < 1.3$ ) and 49% presented a minimal clinical response ( $\Delta ASDAS \geq 1.1$ ). Percentage of patients with enthesitis at baseline (42.9%) was reduced to 16.8% at the end of the observation. Finally, 46.3% had resolution of the enthesitis ( $MASES = 0$ )

Table 1. Evolution of the disease activity variables.

	Baseline	Last visit
BASDAI evolution (mean $\pm$ SD)	6,2 $\pm$ 1.6	3,9 $\pm$ 2.2 *
BASFI evolution (mean $\pm$ SD)	5,6 $\pm$ 2.1	3,7 $\pm$ 2.3 *
ASDAS evolution (mean $\pm$ SD)	3.7 $\pm$ 2.7	2,4 $\pm$ 2.2 *
MASES score (mean $\pm$ SD)	3,9 $\pm$ 2.7	1,2 $\pm$ 1.8 *

\*p<0,001, Wilcoxon's test

According to Kaplan-Meier analysis, the drug survival of CZP is 83.3% (Figure1), and similar retention rates were observed independently if CZP were used as monotherapy (82.9%) or in combination with csDMARDs (82.6%).

Figure 1.

56/336 (16.7%) withdrawn CZP treatment: 34/336 (10.1%) due to lack of efficacy, 16/336 (4.8%) due to adverse event and 6/336 (1.8%) for other reason. Serious adverse event was found in 23/336 (6.8%) patients.

**Conclusion:** Real life experience from this nationwide rheumatology study, demonstrated the effectiveness and safety of CZP in patients with SpA, with a significant reduction of BASDAI, BASFI, ASDAS and MASES scores.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate the effectiveness and safety of Certolizumab Pegol (CZP) in a real word setting in Psoriatic Arthritis (PsA) patients.

**Methods:** Multicentric cohort of PsA patients treated with CZP according to routine clinical practice. Study approved by local Ethics Committee. Maximum time of observation is 12 months. Effectiveness variables: SJC, TJC, PtGA, PhGA and DAS28-CRP. Safety variables: discontinuation rate.

**Results:** 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 ( $\pm 11.9$ ) years, median disease duration 5.0 (0, 40.2) years, 14.9% of patients were HLAB27 positive, BMI ( $\text{kg}/\text{m}^2$ ) 26.9 ( $\pm 4.7$ ) and never smokers 70.3%. Regarding extra-articular manifestations ever: Psoriasis (90%; PASI $\geq 10$  4.9%), enthesitis (44.4%), dactylitis (41.9%), nail disease (32%), inflammatory bowel diseases (4.9%). 37.3% of the PsA patients had erosions and a 3% arthritis mutilans (N=8). 48.9% patients received 1 prior csDMARDs and 52.1% at least 2 csDMARDs. Prior bDMARD received (28.4% none; 38.1% 1, 33.5%  $\geq 2$ ). 29.6% of PsA patients received CZP in monotherapy. Mean duration on treatment with CZP 10 m (78.2%).

Statistically significant differences in SJC, TJC and DAS28[CRP] were observed at the last visit comparing with baseline (Table 1). In the last observation, 47.1% of the patients had a DAS28 response (reduction of  $\geq 1.2$  from baseline). The percentage of patients with enthesitis at baseline (25.4%) was reduced to 9.5% at the end of the observation; 73.2% of the patients had a total resolution of the enthesitis (MASES=0). The percentage of patients with dactylitis at baseline (29.1%) decreased to 8.6% in the last observation; 82.5% of these patients had a total resolution of the dactylitis.

Table 1. Evolution of clinical variables of activity

	Baseline	Last observation
DAS28-crp; mean $\pm$ SD	4.6 $\pm$ 0.9 (N=210)	3.8 $\pm$ 1.0 (N=132)*
TJC evolution; mean $\pm$ SD	7.2 $\pm$ 5.1 (N=228)	4.0 $\pm$ 4.0 (N=188)*
SJC evolution; mean $\pm$ SD	5.0 $\pm$ 3.7 (N=212)	2.8 $\pm$ 2.8 (N=137)*

\*p<0,001, Wilcoxon's test

The drug survival of CZP is 78.2% (Figure1), and similar retention rates were observed independently if CZP were used as monotherapy (79.2%) or in combination with DMARDs (78.9%).

Figure 1.

262 patients were included in the safety analysis, 21.8% withdrawn treatment: 12.6% due to lack of efficacy, 5.3% due to intolerance and 3.8% other reasons.

**Conclusion:** Real life experience from this nationwide study, demonstrated the effectiveness and safety of CZP in PsA patients (bionactive only: 28.4%), with a significant reduction of DAS28, enthesitis and dactylitis. CZP survival seems to be similar regardless of csDMARDs concomitant use.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Certolizumab pegol (CZP) is a PEGylated Fab' fragment of a humanized anti-TNF antibody with high affinity to TNF. RAPID-axSpA trial investigated the efficacy and safety of CZP in patients with axSpA, including ankylosing spondylitis (AS) and non-radiographic (nr)-axSpA, and has shown CZP to improve the signs and symptoms of axSpA over 4 years.

**Objective:** To investigate the effectiveness of CZP in a real word setting in axSpA patients including AS and nr-axSpA.

**Methods:** Multicentric cohort of axial spondyloarthritis patients treated with CZP according with the clinical practice. Study was approved by local Ethics Committee. Maximum time of observation is 12 months. Clinical response was assessed by BASDAI and ASDAS.

**Results:**

336 patients with axSpA were included and 333 were classified: 228 (68.5%) patients with AS, 95 (28,5%) patients with nr-axSpA and 10 (3%) patients with peripheral SpA. The baseline characteristics of the patients are shown in Table 1.

Table 1. Baseline demographic and clinical characteristics of the patients with ankylosing spondyloarthritis and patients with non-radiographic axial SpA.

	AS	nr-axSpA
Age (mean, yr)	46.4±11.9 (N=207)	43.8±12.1 (N=77)
Male sex	63.2% (N=228)	45.3% (N=95)
Evolution of the disease (median, yr)	5.6 (N=207)	2.2 (N=77)
Never smokers	75.1% (N=201)	80.2% (N=86)
HLA-B27 positive	73.7% (N=190)	59.7% (N=72)
Uveitis ever	30.2% (N=159)	11.7 (N=60)
Peripheral arthritis	25% (N=228)	37.9% (N=95)
Enthesitis	43.6% (N=133)	45.9% (N=74)
Biologics treatment previous	(N=165)	(N=65)
0	23.0%	32.3%
1	40.0%	35.4%
>1	36.9%	32.3%
BASDAI mean±SD 0-10 NRS	6.3±1.6 (N=190)	5.9±1.4 (N=73)
BASFI mean±SD	5.9±2.0 (N=164)	4.9±2.0 (N=61)
ASDAS mean	3.9±2.6 (N=227)	3.1±2.6 (N=95)
CRP mean (mg/L)	12.1 (N=227)	9.0 (N=95)
Treatment with NSAIDs	83.0% (N=206)	84.4% (N=77)
Treatment with DMARDs	35.9% (N=206)	35.0% (N=77)

No statistically significant differences were observed in BASDAI and ASDAS between both subpopulation (AS and nr-axSpA) (Table 2). In the last visit of the patients, BASDAI50 was observed in 39.7% of AS patients and 44.6% of nr-axSpA. 29.1% and 45.7% of the patients presented ASDAS remission within the AS and nr-axSpA population, respectively.

Table 2. Evolution of clinical variables of activity

	AS		nr-axSpA	
	Baseline	Last visit	Baseline	Last visit
BASDAI evolution	6.3±1.6 (N=190)	3.9±2.2 (N=190)	5.9±1.4 (N=73)	3.6±2.1 (N=70)
ASDAS evolution	3.9±2.6 (N=227)	2.6±2.4 (N=227)	3.1±2.6 (N=95)	1.9±1.6 (N=94)
CRP mean	12.1 (N=227)	6,8 (N=334)	9.0 (N=95)	4,0 (N=94)

## Conclusion:

In this nationwide real-life study, effectiveness of CZP was demonstrated in both Radiographic and Non-Radiographic Axial Spondyloarthritis.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The efficacy of Golimumab (GLM) treatment in spondyloarthritis (SpA) has been widely documented. The aim of this study was to analyze the long-term retention of GLM and to identify independent predictors of retention in patients with SpA.

**Methods:** Prospective monocentric cohort of Spa patients treated with GLM according with clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analyzed with Cox proportional hazard regression model.

**Results:** 105 patients were included, 49 (46.7%) Ankylosing Spondylitis (AS), 40 (38.1%) non-radiographic axial SpA (nr-AxSpA) and 16 (15.2%) peripheral SpA. The baseline characteristics of the patients are shown in Table 1. Mean follow-up time 23.8 months (SD 20.9). Mean survival time was 47.2 months (95% CI: 39.4-54.9). Age, gender, HLA-B27, radiographic or nr-AxSpA and previous biological use were significant in the univariate analysis. Concomitant DMARD had no influence on GLM retention rate (HR: 1.2; 95% CI: 0.6-2.4; p: 0.6).

Table 1. Baseline demographic and clinical characteristics of the patients.

	All (axial and peripheral SpA)	AS	nr-AxSpA
Age -mean (SD)-years	45.1 (13.2)	51.1 (10.8)	39.8%
Male gender %	49.5%	61.2%	47.5%
Mean evolution time (SD) years	11.8 (12.3)	18.8 (10.1)	7.3 (10.3)
HLA-B27	69.6%	90.7%	52.6%
Uveitis	16.2%	24.5%	10.0%
Back pain -mean (SD)	7.5 (7.0)	6.5 (2.4)	9.1 (10.7)
BASDAI -mean (SD)	6.2 (1.6)	6.3 (2.1)	6.2 (1.2)
BASFI -mean (SD)	5.8 (2.3)	6.0 (2.4)	5.4 (2.1)
CRP mg/dl Mean (SD)	1.1 (1.7)	1.5 (2.1)	0.65 (1.4)
Concomitant DMARD %	29.8%	31.3%	7.5%
Biological Therapy naïve %	45.7%	30.6%	60%

Upon Cox regression analysis, patients with AS had significant better retention rate compared to nr-AxSpA (HR: 2.1; 95% CI: 1.1-4.2;  $p < 0.035$ ). There was a numerically better GLM retention rate in patients treated previously with less number of biologicals, but did not reach statistical significance. 39/105 (37%) withdraw GLM treatment. 26/39 (66,7%) due to lack of efficacy, 6/39 (15,4%) due to adverse events and 7/39 (17,5%) due to other reasons.

**Conclusion:** Real-world Golimumab retention rate in patients with Spondyloarthritis was good and did not depend on concomitant treatment with DMARD. Patients with Ankylosing Spondylitis had a better Golimumab retention rate than patients with non-radiological Axial Spondyloarthritis. A better retention rate was expected in patients who had previously used less biological, but was not found due probably to the low effectiveness of Golimumab in patients with non-radiological Axial Spondyloarthritis.

## **Impact of Time Since Diagnosis, Age, and Number of Prior Non-Steroidal Anti-Inflammatory Drugs on 52-Week Clinical Response to Adalimumab in Patients with Ankylosing Spondylitis**

Joachim Sieper<sup>1</sup>, Atul A. Deodhar<sup>2</sup>, **Maja Hojnik**<sup>3</sup>, Ying Zhang<sup>4</sup> and Maxime Dougados<sup>5</sup>, <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Oregon Health & Science University, Portland, OR, <sup>3</sup>AbbVie, Ljubljana, Slovenia, <sup>4</sup>AbbVie Inc., North Chicago, IL, <sup>5</sup>René Descartes University and Hôpital Cochin, Paris, France

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** Ankylosing spondylitis (AS) patients (pts) were found to respond better to TNF inhibitors (TNFi) if treated early in the disease course.<sup>1</sup> The actual disease onset and hence disease duration is not always known. Previously, younger age was found to have the largest positive impact on clinical outcomes following 12 weeks (wks) of adalimumab (ADA) treatment.<sup>2</sup> The objective of this analysis was to examine the impact of time since diagnosis, age, and number of prior NSAIDs as surrogates for disease duration on clinical outcomes in AS pts from ATLAS trial treated with ADA for 52 wks.

**Methods :** ATLAS<sup>3,4</sup> was a phase 3 randomized double-blind placebo(PBO)-controlled trial evaluating the safety and efficacy of originator ADA in pts with active AS who failed NSAID therapy. In this post hoc analysis, pts who received at least one dose of ADA during the PBO-controlled period or open label extension and received prior NSAID(s) at baseline (BL) were categorized by BL: (1) time since diagnosis (<2 vs ≥2; <5 vs ≥5; <10 vs ≥10 years [y]), (2) age (<35, 35–45, and >45 y), and (3) number of prior NSAIDs (≤2 vs >2). The effect of time since diagnosis, age, and number of prior NSAIDs on AS outcome measures following 52 wks of ADA treatment was examined.

**Results :** At wk 52, 274 pts had received at least one dose of ADA and had at least one prior NSAID at BL. A majority of pts were ≥5 y since AS diagnosis (188 [68.6%]), ≤45 y of age (163 [59.5%]), HLA-B27+ (213 [77.7%]), and had ≤2 prior NSAIDs (158 [57.7%]). Pts with shorter time since diagnosis were generally younger (late thirties). Across all subcategories, >70% of pts were male. The BL disease activity measures were numerically similar across

most categories. Following 52 wks of ADA treatment, the proportions of pts achieving ASAS20 and ASAS40 responses were numerically higher and mean decreases in BASDAI and BASFI scores from BL larger in subcategories with shorter time since diagnosis, younger age, and fewer prior NSAIDs (**Table**). There were significant differences in ASAS40, BASDAI, and BASFI scores between time since diagnosis (<2 vs ≥2 and <5 vs ≥5 y) and age (<35 vs ≥45 y) subcategories.

**Conclusion :** Following 52 wks of ADA treatment, shorter time since diagnosis and younger age were associated with greater clinical responses and improvements in disease activity and functionality. Although younger age (<35 vs ≥45 y) had significant positive impact on the clinical outcomes similar to wk 12 results, shorter time since diagnosis (<2 vs ≥2 and <5 vs ≥5 y) was also associated with better 52-wk clinical outcomes. These results suggest that early effective treatment intervention may improve long-term clinical outcomes in AS pts.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Patients with ankylosing spondylitis had better adalimumab survival than patients with non-radiographic axial spondyloarthritis

**Background/Purpose:** Drug survival rate is generally accepted as a reliable indicator of both efficacy and safety profile of a biological DMARD. We aimed to evaluate survival rates of adalimumab (ADA) in ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nrAxSpA) patients registered in HUR-BIO (Hacettepe University Rheumatology Biologic Registry) and potential predictors of drug continuation.

**Methods:** HUR-BIO is a monocentric database of biologics including 1938 SpA patients by January 2017. All AS and nrAxSpA patients in HUR-BIO prescribed ADA at least once were enrolled in the study. Patients who were prescribed ADA within 6 months period before analysis defined as drug continuing. Reasons for ADA discontinuation were categorized as adverse events (AEs), inefficacy (primary and secondary) and others. Kaplan-Meier analysis was used to estimate ADA survival rates. Potential predictors of ADA continuation were evaluated using Cox proportional regression model in only AS patients due to small number of patients in nrAxSpA group.

**Results:** In total, 421 AS and 103 nrAxSpA patients were analyzed. Median duration of ADA usage was 14.5 (0-139.2) months in AS and 8.7 (0-84.2) months in nrAxSpA group. Baseline characteristics of patients were shown in Table 1. Among AS patients, ADA was discontinued due to inefficacy in 70 (30.4%) and adverse events in 39 (17.0%). The reason for ADA discontinuation was inefficacy in 28 (48.3%) and adverse events in 5 (8.6%) nrAxSpA patients. Figure 1 represents the Kaplan-Meier plots of ADA survival. Log-rank between AS and nrAxSpA patients was found as  $p=0.044$ . Cox proportional regression model failed to demonstrate any predictor of ADA discontinuation in AS patients.

**Conclusion:** In this single center biological SpA cohort, ADA had better drug survival in AS patients compared with nrAxSpA consistent with literature<sup>1</sup>. Although certain factors such as uveitis, baseline increased acute phase reactants, and being biological naïve were associated with better ADA survival in univariate analysis, we could not demonstrate any predictors in Cox regression analysis.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Inhibition of IL-17A with secukinumab is an approved therapy for patients (pts) with AS.<sup>1</sup> It has been previously reported that response rates with TNF $\alpha$  inhibitors (TNFi) are higher in AS pts with elevated baseline (BL) CRP levels;<sup>2-4</sup> however, this relationship is unclear for IL-17A-inhibition. This *post-hoc* analysis assessed the response to secukinumab treatment in AS pts with normal or elevated BL CRP from the phase 3 MEASURE 1 and MEASURE 2 studies over 3 years.

**Methods:** The study designs of MEASURE 1 and 2 have been reported elsewhere.<sup>1</sup> This analysis pooled data from all pts with available BL CRP levels in the 2 studies who received subcutaneous (s.c.) secukinumab 150 mg (approved dose; N = 197) or placebo (PBO; N = 195). Efficacy endpoints included ASAS20/40, BASDAI, BASDAI50, AS disease activity score (ASDAS) inactive disease, and ASAS partial remission (ASAS PR) in pts stratified by BL CRP as defined by the central lab: normal (<5 mg/L) or elevated ( $\geq$ 5 mg/L). Data are presented using non-responder imputation through Week (Wk) 16 and multiple imputation from Wk 20–156 for binary variables, and mixed-effect model repeated measure for all time points through Wk 156 for continuous variables.

**Results:** Overall, 36.5% (143/392) of pts with normal CRP and 63.5% (249/392) of pts with elevated CRP at BL were included in this pooled analysis. The proportion (36% and 64%) of pts with normal and elevated BL CRP was similar in the secukinumab 150 mg and PBO groups. BL demographic/clinical characteristics were balanced across the normal and elevated BL CRP groups (mean age  $\pm$  SD: 43.8  $\pm$  12.0 and 41.0  $\pm$  12.5 years, mean time since diagnosis  $\pm$  SD: 7.0  $\pm$  8.7 and 7.2  $\pm$  7.9 years, mean BASDAI  $\pm$  SD: 6.7  $\pm$  1.5 and 6.4  $\pm$  1.5, respectively). At Wk 16, the ASAS20 and ASAS40 response rates were improved with secukinumab 150 mg vs PBO in pts with normal or elevated BL CRP (Figure and Table). The treatment effect of secukinumab 150 mg vs PBO at Wk 16 was significant in pts with a normal or elevated BL CRP for all other outcomes, except for ASAS PR in the normal BL CRP group ( $P$  = 0.07; Table). Results were sustained or further improved through 156 wks of secukinumab treatment in both groups.

**Conclusion:** Secukinumab 150 mg demonstrated efficacy in AS pts with either normal or elevated BL CRP, with greater magnitude of response in pts with elevated BL CRP.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Secukinumab is a fully human anti-interleukin-17A monoclonal antibody approved for the treatment of patients with moderate to severe ankylosing spondylitis (AS). A limited number of studies have evaluated the use of secukinumab in a real-world setting since its approval in the United States on January 15, 2016. The objective of this analysis was to describe the demographic and clinical characteristics of patients with AS who were treated with secukinumab in routine clinical practice, stratified by previous biologic experience.

**Methods:** Retrospective data from the Symphony Health Solutions Lx commercial claims database were used to identify patients with AS who had  $\geq 1$  secukinumab treatment between January 15, 2016 and December 31, 2016. Patients eligible for inclusion were  $\geq 18$  years of age who had the diagnosis of AS (ICD-10-CM Code M45 or M08.1; ICD-9-CM Code 720.0) and  $\geq 1$  pharmacy or medical claim in the 12 months prior to their first secukinumab treatment (index date), and any pharmacy or medical claim  $> 30$  days after the index date. Patient demographics and secukinumab dosage were examined at the index date. Clinical characteristics, comorbidities and treatment history in the 12 months prior to the index date were identified and presented for biologic-naïve and biologic-experienced patients with AS.

**Results:** A total of 543 patients who initiated secukinumab were included in this study; the mean (SD) age of included patients was 46.4 (12.3) years and 51.6% were female. Of the 543 patients, 358 patients (65.9%) had received another biologic in the previous 12 months, and 185 patients (34.1%) were biologic naïve. Patient demographics, clinical characteristics and treatment history were mostly similar between the two cohorts (**Table 1**). Most patients (59.1%) initiated secukinumab with the 150-mg dose (biologic experienced, 62.3%; biologic naïve, 53.0%); nearly two-thirds of all patients (64.5%) received a full loading regimen. A higher proportion of biologic-naïve patients had prior tsDMARD use compared with biologic-experienced patients (9.2% vs 2.8%); however, both cohorts were similar in prior NSAID, oral corticosteroid and csDMARD use. Among biologic-experienced patients, the most common biologics previously used were adalimumab (41.3%) and etanercept (31.3%). Overall, the most prevalent comorbidities were hypertension (25.4%), cancer (20.4%), rheumatoid arthritis (19.7%) and hyperlipidemia (19.5%).

**Conclusion:** In this retrospective, administrative claims-based study, approximately two-thirds of patients with AS who initiated secukinumab used biologics in the previous 12-month period. While most patients initiated secukinumab at the approved dose of 150 mg, nearly 40% of patients initiated secukinumab at a dose of 300 mg. These results provide early insights into real-world use of secukinumab among biologic-naïve and biologic-experienced patients with AS in the United States.

**Table 1.** Demographics, clinical characteristics and treatment history of patients with AS treated with secukinumab stratified by previous biologic experience

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To better understand the real-world efficacy of biologics for the treatment of psoriatic arthritis (PsA), there is a need to evaluate the persistence and adherence with biologics among patients with PsA seen in routine clinical practice. This study described the patient demographics, disease characteristics and treatment patterns of patients with PsA who initiated a subcutaneously administered (SC) biologic in a US claims database.

**Methods:** Patients with  $\geq 1$  pharmacy claim for an FDA-approved SC biologic between 01/15/2016 and 01/31/2017 were identified from the Truven Health Analytics MarketScan Commercial and Medicare Supplemental Databases. Eligible patients were aged  $\geq 18$  years at the time of biologic initiation (index date) and were continuously enrolled with medical and pharmacy claims  $\geq 12$  months prior to (baseline period) and  $\geq 6$  months after the index date. Patients had  $\geq 1$  PsA diagnosis (ICD-9-CM 696.0 or ICD-10-CM L40.5x) and no pharmacy claims for the index biologic during the baseline period. Patient demographics were assessed at the index date; clinical characteristics and treatment history were examined during the baseline period. Biologic discontinuation, number of days persistent and adherence (proportion of days covered) with the index biologic were evaluated over the 6-month follow-up period.

**Results:** A total of 2208 eligible SC biologic initiations were identified in patients with PsA, including adalimumab (n = 946), certolizumab pegol (n = 171), etanercept (n = 589), golimumab (n = 94) and secukinumab (n = 408), with mean follow-up of 253 to 275 days. Demographics and clinical characteristics were similar across biologic groups (**Table 1**). A lower proportion of patients initiating adalimumab or etanercept had prior biologic use (28% and 37%, respectively) compared with certolizumab pegol (72%), golimumab (68%) and secukinumab (76%). The 6-month discontinuation rate was lowest with secukinumab (12%), followed by adalimumab (16%), golimumab (18%), certolizumab pegol (20%) and etanercept (22%). Mean days persistent on the index biologic ranged from 153 days (etanercept) to 164 days (secukinumab). The mean proportion of days covered was similar among secukinumab, adalimumab, etanercept and golimumab (0.73-0.76) and lowest for certolizumab pegol (0.63) (**Table 2**).

**Conclusion:** Patients who initiated secukinumab had the lowest discontinuation rate and highest number of days persistent over 6 months compared with the other SC biologics assessed.

**Table 1.** Baseline Demographics, Clinical Characteristics and Treatment History in Patients With PsA Who Initiated a Biologic (N = 2208 Initiations)

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** An overall low rate of spinal radiographic progression with the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) was reported with secukinumab (SEC), a fully human interleukin 17A (IL-17A) inhibitor in the 2-year (2y) uncontrolled ankylosing spondylitis (AS) MEASURE 1 study (1). The objective of this analysis was to investigate those patients whose mSASSS either increased or decreased at 2 yr (Wk 104) in more detail.

**Methods:** In the MEASURE 1 trial patients received subcutaneous SEC 75mg or 150mg or placebo (PBO) every 4 weeks up to 2 years. Analysis of radiographic progression of the cervical and lumbar spine was performed in X-ray completers using mean mSASSS of two experienced readers blinded to time sequence of the images. To supplement the established published analysis we now performed an analysis using only vertebral edges (VE) scores where both readers were in agreement, and the scores of the initial PBO group were merged and included in the analysis. Progression in mSASSS at 2y vs. baseline (BL) was defined by a change of >1.838 (smallest detectable change, SDC), while ‘improvement’ was defined by < -1.838 and no change by -1.838 to 1.838. Furthermore, a shift analysis was performed to explore the course of radiographic progression based on the occurrence of syndesmophytes, evaluating an increase of an mSASSS of 0 or 1 to 2 or 3 vs. a decrease in mSASSS from 2 or 3 to 1 or 0 on single VE from BL to 2y.

**Results:** A total of 257 patients were X-ray completers at Wk104. Overall, 13.2% patients showed an increase and 6.2% patients showed a decrease of mSASSS as defined. BL demographics and clinical characteristics of patients with mSASSS progression, ‘improvement’ and stable scores were similar.

A total of 4947 VE could be analyzed. No mSASSS change to Wk104 was seen in 4891/4947 (98.9%) VEs, mSASSS increase in 46/4947 (0.9%) VEs and mSASSS decreased in 10/4947 (0.2%) VEs. Of interest, in 9 out of 10 VEs with an mSASSS decrease at Wk104, a change of -2 or -3 was recorded.

Overall, 4291 VEs had no syndesmophytes (86.7%) and 656 VEs (13.3%) had syndesmophytes at BL. Development of a new syndesmophyte was seen in 32/4291 (0.7%) VEs whereas 9/656 VEs syndesmophytes at BL (1.4%) were no longer detected at Wk104. An increase of mSASSS to 2 or 3 was found in 13 out of 173 VEs (0.08%) with an mSASSS score 1 or 2 at BL.

**Conclusion:** This detailed exploratory analysis at the vertebral unit level complements the previous analysis (1) based on adjudicated scores from blinded readers. This analysis shows that the radiographic status remained stable in almost 99% of VEs in secukinumab-treated patients. The previously reported proportion of patients showing a decrease in mSASSS change is confirmed by the scores at the VE level. Since this is most probably due to background noise it requires further investigation which may include a reevaluation of images. Only the mSASSS at BL was predictive of radiographic progression. These findings may influence future radiographic studies and analyses.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Treatment with TNF inhibitors (TNFi) has led to a reduction in signs and symptoms, and improvement in physical function and quality of life in patients with ankylosing spondylitis (AS). Whether TNFi impact the incidence of AS-related comorbidities and extra-articular manifestations (EAMs) is not known.

**Methods:** We conducted a retrospective cohort study using three commercial insurance claims databases (Multi-Payer Claims Database [MPCD; 2007–2010], Truven MarketScan<sup>®</sup> [2010–2014], and the US Medicare Fee-for-Service Claims data [2006–2014]) to evaluate EAMs (uveitis, psoriasis, inflammatory bowel disease) and comorbidities (cardiac, renal, pulmonary, neurologic) in AS patients diagnosed by a rheumatologist (index date), having 6 months baseline data prior to index date, and drug-specific exposures after AS diagnosis. Three mutually-exclusive hierarchical exposure groups were examined: (1) no therapy or prescription of non-steroidal anti-inflammatory drugs (NSAIDs), (2) conventional disease-modifying antirheumatic drugs (DMARDs), and (3) TNFi. Prevalence of comorbidities were ascertained in 12-month periods (6 months pre- and post-index date). Incidence of comorbidities and EAMs were ascertained during the period following treatment initiation and the earliest of death, loss of medical coverage, end of study, first outcome occurrence, treatment discontinuation, or initiation of therapy at a higher level in exposure hierarchy. Comparisons were made using the mid-p exact test ( $\alpha=0.05$ ).

**Results:** Out of nearly 40 million beneficiaries, 63,052 patients were included. Table 1 shows the prevalence of comorbidities and EAMs of AS by treatment exposures, stratified by data source. Comorbidities were more common in Medicare AS patients compared to MPCD or MarketScan<sup>®</sup>. Table 2 shows the incidence rates of outcomes by

treatment exposures, stratified by data source. Despite the possibility of patients with more severe disease receiving TNFi treatment, their crude incidence of certain cardiac, pulmonary and neurologic comorbidities was lower compared to those treated with NSAIDs or DMARDs alone, although they had higher incidence of some EAMs.

**Conclusion:** This was the largest investigation of the prevalence and incidence of comorbidities and EAMs of AS within the US, and suggests TNFi to be disease-modifying. In the absence of control for confounding, these findings should be considered preliminary.

**Table 1:** Prevalence of comorbidities and EAMs during 12 months (per 100 patient-years), stratified by data source

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Secukinumab has demonstrated sustained efficacy in patients (pts) with active AS.<sup>1,2</sup> We investigated improvement in pain and fatigue scores from baseline (BL) through Week (Wk) 104 in AS pts stratified by BL CRP status and prior use of TNF inhibitor (TNFi) therapy from the MEASURE 2 trial.

**Methods:** The MEASURE 2 study design has been reported previously.<sup>1</sup> This *post-hoc* analysis assessed the mean change from BL in total spinal and nocturnal pain scores (by visual analog scale) using mixed-effect model repeated measure analysis through Wk 16 (least squares mean change) and observed data from Wk 20–104 (mean change). The results are reported for the overall population, pts stratified by BL CRP level (normal [ $<5$  mg/L] or elevated [ $\geq 5$  mg/L]), and by prior use of TNFi (TNFi-naïve vs TNFi-inadequate responder/intolerant [TNFi-IR]) for the approved secukinumab 150 mg subcutaneous dose. The proportion of pts reporting clinically meaningful improvements ( $\geq 20\%$  mean change from BL) in spinal pain scores was also assessed. The correlations between pain (spinal or nocturnal) and functional assessment of chronic illness therapy–fatigue (FACIT–Fatigue) score and response (improvement  $\geq 4$  points) were also evaluated.

**Results:** In the overall population (N = 219), secukinumab 150 mg-treated pts (n = 72) reported rapid reductions across pain scores by Wk 1, which were sustained or further improved through Wk 104: mean change (secukinumab vs placebo [PBO]) in spinal pain: Wk 1 (–10.6 vs –3.6,  $P < 0.05$ ), Wk 16 (–29.0 vs –11.4,  $P < 0.0001$ ), and Wk 104 (secukinumab: –36.4); mean change in nocturnal pain: Wk 1 (–12.7 vs –1.7,  $P < 0.001$ ), Wk 16 (–30.3 vs –10.1,  $P < 0.0001$ ), and Wk 104 (secukinumab: –38.6). Furthermore, 63% of pts on secukinumab reported clinically meaningful improvements vs PBO in spinal pain as early as Wk 3 (36%,  $P < 0.01$ ), increasing to 78% at Wk 104. Secukinumab improved pain scores to a similar extent, irrespective of BL CRP status (Table). At Wk 16, moderate correlations were observed between spinal or nocturnal pain and fatigue (FACIT–Fatigue score: –0.49/–0.48 [ $P < 0.05$  for both correlations]; FACIT–Fatigue response: –0.48/–0.51 [ $P < 0.05$  for both correlations]). Improvements in pain scores and correlations between pain and fatigue showed similar trends among TNFi-naïve and TNFi-IR pts, with a greater magnitude of improvement observed in the TNFi-naïve group (Table).

**Conclusion:** Secukinumab provides rapid and sustained pain relief through 104 wks of therapy in AS pts with normal or elevated BL CRP levels and in TNFi-naïve and TNFi-IR pts. Pain relief showed a positive correlation with improvement in fatigue.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Secukinumab has demonstrated a consistent and reliable safety profile in three Phase 3 studies in ankylosing spondylitis (AS): MEASURE 1 (NCT01358175), MEASURE 2 (NCT01649375), and MEASURE 3 (NCT02008916).<sup>1-4</sup> Here, we report long-term (up to 3 years) pooled safety and tolerability data for secukinumab from these three studies (data cut-off: June 25, 2016).

**Methods:** Overall, 371, 219, and 226 patients with active AS were randomized in MEASURE 1, MEASURE 2, and MEASURE 3, respectively. Study design, efficacy, and safety results of these studies have been reported elsewhere.<sup>4,5</sup> Secukinumab doses differed in the studies and included intravenous 10 mg/kg or subcutaneous (s.c.; 75–300 mg) multi-dose loading, followed by s.c. maintenance dosing (75, 150, or 300 mg). Data collected up to the last patient performing the Week (Wk) 156 visit in MEASURE 1, the Wk 104 visit in MEASURE 2, and the Wk 52 visit in MEASURE 3 were pooled at the individual patient level. Exposure-adjusted incidence rates were calculated to account for differences in treatment exposure, and safety analyses included all patients who received  $\geq 1$  dose of secukinumab.

**Results:** A total of 794 patients were included in the analysis (representing 1706.3 patient-years of exposure). The exposure-adjusted incidence rates of adverse events (AEs) and serious AEs with secukinumab across the entire safety period were 146.8 and 6.2 per 100 patient-years, respectively. Nasopharyngitis, diarrhea, headache and upper respiratory tract infections were the most frequently reported AEs (Table). The incidences of serious infections, *Candida* infections, uveitis, and inflammatory bowel disease were low and consistent with previous reports over shorter exposure periods<sup>1</sup> (Table). No cases of suicidal ideation or depression were reported.

**Conclusion:** Secukinumab was well tolerated during long term treatment (representing 1706.3 patient-years of exposure) in patients with AS, with a favorable safety profile consistent with previous reports, with no new safety signals.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To investigate the effect of intravenously administered (IV) golimumab (GLM, 2 mg/kg), an anti-TNF $\alpha$  monoclonal antibody, on sleep problems, total back pain (TBP), and night back pain (NBP) in adult patients with active AS.

**Methods:** GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled trial. Patients ( $\geq 18$  years) had a diagnosis of definite AS (modified New York criteria) and BASDAI  $\geq 4$ , TBP visual analog scale (VAS)  $\geq 4$ , and CRP  $\geq 0.3$ mg/dL. At baseline, 208 patients were randomized to IV GLM 2mg/kg (N=105) at Wk0, 4, and every 8 weeks or placebo (N=103) at Wk0, 4, and 12, with crossover to IV GLM at Wk16 and through Wk52. Sleep problems were assessed using the Medical Outcomes Study Sleep Scale (MOS-SS, range 0-100), a generic instrument designed to assess six dimensions of sleep: Sleep disturbance, Somnolence, Sleep adequacy, Snoring, Awaken short of breath or headache, and Quantity of sleep/optimal sleep during the past 4 weeks. The six dimensions are also used to generate the composite Sleep Problems Index (SPI). An increase in score from baseline represents improvement. TBP and NBP over the past week were assessed using VAS (0-10 cm; 0=no pain, 10=most severe pain). Wk28 results are presented here. Unadjusted p-values of least square mean differences between treatment groups were based on analysis of covariance controlling for prior anti-TNF therapy.

## Results:

Mean changes in MOS-SS Sleep Index and 6 subscales are presented in Table 1. Greater mean improvement ( $p < 0.05$ ) in the MOS-SS sleep index and 4 subscales at Wk8 was observed in GLM compared to PBO, and in the sleep index and 4 subscales at Week 16. Mean improvements from baseline to Weeks 8 and 16 in patient's assessment of TBP (cm) were greater ( $p < 0.001$ ) in GLM than PBO (-2.70 vs -0.86 and -3.15 vs -1.15, respectively), and after PBO crossed over to GLM, the differences diminished at Wk28 (-3.14 vs -3.34, respectively). Mean improvements at Wk8 and 16 from baseline in patient's assessment of NBP (cm) were also greater ( $p < 0.001$ ) in GLM than PBO (-3.03 vs -0.87 and -3.44 vs -0.85, respectively), and differences diminished at Wk28 (-3.47 vs -3.42, respectively). Changes from baseline in all subscales of MOS-SS were correlated (Spearman correlations ranging between -0.10 and -0.45) with TBP and NBP at Wk8, 16, and 28 ( $p$  values  $< 0.05$ ), with the exception of Snoring and both TBP and NBP at Wk16. Change in NBP was associated with change in Sleep Problem Index at all 3 time points ( $p = 0.002$ ,  $p = 0.001$ , and  $p = 0.031$ , respectively). In the general linear model, most of the association between change in TBP and change in Sleep Problem Index was explained by the association between change in NBP and change in Sleep Problem Index.

## Conclusion:

Adult patients with active AS treated with IV GLM showed improvements in sleep problems, TBP, and NBP. NBP

improvement was associated with improvement in sleep problems.

Table 1. Summary of mean (standard deviation) changes in MOS-SS and its subscales.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To evaluate patient-reported outcomes (PRO) of physical functioning, mental health functioning, health state, and health-related quality of life (HRQoL) in patients (pts) with active AS treated with intravenous (IV) golimumab (GLM), an anti-TNF $\alpha$  monoclonal antibody.

**Methods:** GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo(PBO)-controlled trial. Pts ( $\geq 18$  years) had a diagnosis of definite AS (modified New York criteria) and BASDAI  $\geq 4$ , total back pain visual analog scale (VAS)  $\geq 4$ , and CRP  $\geq 0.3$ mg/dL. At baseline, 208 pts were randomized to IV GLM 2mg/kg (N=105) at Wks0, 4, and every 8 wks or PBO (N=103) at Wks0, 4, and 12, with crossover to IV GLM at Wk16. PRO instruments included: SF-36, a generic instrument designed to measure physical & mental health functioning; EQ-5D VAS, a generic measure of current health state; and AS Quality of Life (ASQoL), a disease-specific instrument designed to measure impact of AS on HRQoL. SF-36 scores range from 0-100; higher scores indicate better functioning. It has Physical (PCS) and Mental Component Summary (MCS) and 8 subscales (physical functioning, role-physical, body pain, general health, vitality, social functioning, role-emotional, & mental health). EQ-5D has a scale of 0-100 (0=worst health you can imagine; 100=best health you can imagine). ASQoL assesses sleep, mood, motivation, ability to cope, activities of daily living, independence, relationships, & social life in pts with AS; range: 0-18, higher scores indicating worse HRQoL. Unadjusted p-values of least square mean differences between treatment groups were based on analysis of covariance controlling for prior anti-TNF therapy.

**Results:** Table summarizes mean changes from baseline at Wks8, 16, and 28. Mean improvements in SF-36 PCS/MCS were greater in the IV GLM group than PBO at Wk8 (6.83 vs 2.07,  $p < 0.001$ ; 5.56 vs 1.67,  $p = 0.006$ , respectively) and maintained through Wk16 (8.52 vs 2.87,  $p < 0.001$ ; 6.47 vs 0.84,  $p < 0.001$ , respectively). Greater mean improvements in all SF-36 subscales were observed in the IV GLM group at Wks8 & 16 compared to PBO ( $p < 0.01$ , with the exception of the role-emotional subscale [ $p = 0.058$ ]). Proportion of pts achieving clinically meaningful change ( $\geq 5$ ) in SF-36 PCS/MCS was higher in IV GLM than PBO at Wks8 & 16 (PCS: 58.1 vs 27.2, 67.6 vs 35.9, respectively; MCS: 48.6 vs 34.0, 54.3 vs 29.1, respectively;  $p < 0.05$  for all). Mean EQ-5D VAS improvements were greater ( $p < 0.001$ ) in IV GLM than PBO at Wks8 & 16 (17.61 vs 6.63, 20.32 vs 4.79, respectively). Greater mean improvements in ASQoL observed in IV GLM compared to PBO at Wks8 & 16 (-4.5 vs -1.5,  $p < 0.001$ , -5.4 vs -1.8,  $p < 0.001$ , respectively). By Wk28, after PBO crossover to IV GLM, mean improvement in PCS, MCS, EQ-5D VAS, and ASQoL was similar between the two treatment arms.

**Conclusion:** Adult pts with active AS treated with IV GLM showed marked improvements in physical functioning, mental health functioning, health state, and HRQoL.

Table Summary of mean (standard deviation) changes in SF-36, EQ-5D, and ASQoL			
		IV GOLIMUMAB 2mg/kg	PLACEBO
Patients		105	103
Mean (SD) change from baseline in SF-36 PCS:	Week 8	6.83 (6.90) (p<0.001)	2.07 (5.66)
	Week 16	8.52 (7.54) (p<0.001)	2.87 (6.11)
	Week 28	9.08 (8.02)	9.29 (7.09)
Mean (SD) change from baseline in SF-36 MCS:	Week 8	5.56 (9.26) (p=0.006)	1.67 (8.80)
	Week 16	6.47 (9.12) (p<0.001)	0.84 (9.82)
	Week 28	6.16 (10.91)	5.60 (9.70)
Mean (SD) change from baseline in EQ-5D VAS:	Week 8	17.61 (24.02) (p<0.001)	6.63 (19.88)
	Week 16	20.32 (24.59) (p<0.001)	4.79 (23.47)
	Week 28	20.52 (27.86)	22.45 (23.08)
Mean (SD) change from baseline in ASQoL:	Week 8	-4.5 (4.71) (p<0.001)	-1.5 (3.90)
	Week 16	-5.4 (5.01) (p<0.001)	-1.8 (4.50)
	Week 28	-5.3 (5.24)	-5.3 (4.84)

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Subcutaneous (SC) golimumab (GLM) is currently approved for adult patients (pts) with RA, PsA, and AS. The GO-ALIVE study was designed to evaluate the safety and efficacy of IV GLM in adult pts with active AS.

**Methods:** GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled trial. Pts ( $\geq 18$  yrs) had a diagnosis of definite AS (per modified New York criteria) and BASDAI  $\geq 4$ , total back pain visual analogue scale  $\geq 4$ , and CRP  $\geq 0.3$ mg/dL. Pts were randomized (1:1) to IV GLM 2mg/kg at weeks (wks) 0, 4, and every 8 wks or PBO at wks 0, 4, and 12, with crossover to GLM at wk16 through wk52. Up to 20% of pts could have had a prior anti-TNF agent (other than GLM), and up to 10% of pts could have complete ankylosis of the spine. The primary endpoint was ASAS20 at wk16. Other assessments included BASDAI, BASFI, and enthesitis (UCSF index). Missing data were imputed using LOCF. Pts were monitored for adverse events (AEs). Efficacy and safety data through wk52/wk60 are reported here.

**Results:** 208 pts were randomized and received study agent (PBO: 103; GLM: 105); 5.8% had complete ankylosis of the spine. 17 pts (PBO, n=4; PBO to GLM, n=5; GLM, n=8) discontinued study agent through week 60. At wk 16, greater proportions of pts in the GLM group as compared to PBO had ASAS20 (73% vs 26%), ASAS40 (48% vs 9%), ASAS partial remission (16% vs 4%), and BASDAI50 (41% vs 15%) and GLM pts had greater mean improvements in BASFI (-2.4 vs. -0.5). After crossover to GLM at wk16, clinical efficacy in the PBO group approached that in the GLM group as early as wk20. Efficacy was maintained through week 52 with comparable response levels in the two treatment groups. At wk52, 69.5% of GLM pts and 65.0% of PBO  $\rightarrow$  GLM pts had an ASAS20 response; 56.2% and 51.5%, respectively, had an ASAS40 response, and 24.8% and 24.3%, respectively, achieved ASAS partial remission. BASDAI 50/70 was achieved by 56.2%/33.3% of GLM pts and 55.3%/35.0% of PBO  $\rightarrow$  GLM pts at wk52. Mean changes in BASFI and BASMI at wk52 were similar to wk16 and comparable between the treatment groups. Among pts with enthesitis at baseline, mean decreases in enthesitis score were similar for GLM (n=87; -3.8) and PBO  $\rightarrow$  GLM (n=85; -3.6) pts at wk52. Through wk60, 204 pts received  $\geq 1$  administration

of GLM. Of these, 55.4% had  $\geq 1$  adverse event (AE), including 3.4% who had a serious AE (SAE). Infections were the most common type of AE (32.8%). One pt who screened negative for tuberculosis was diagnosed with pulmonary TB. There were no deaths, malignancies, or opportunistic infections.

**Conclusion:** Response to IV GLM 2mg/kg was maintained through wk52 and comparable between patients who were randomized to GLM versus those who switched to GLM at wk 16. Through wk60, the safety profile was consistent with other anti-TNFs, including SC GLM.

Table. Efficacy at week 52

	Placebo → Golimumab 2 mg/kg	Golimumab 2 mg/kg
Patients randomized, n	103	105
<b>Clinical efficacy</b>		
ASAS20, n (%)	67 (65.0%)	79 (75.2%)
ASAS40, n (%)	53 (51.5%)	59 (56.2%)
BASDAI 50, n (%)	57 (55.3%)	59 (56.2%)
BASDAI 70, n (%)	36 (35.0%)	35 (33.3%)
Change from baseline in BASFI		
n	102	105
mean (SD)	-2.6 (2.5)	-2.7 (2.5)
ASAS partial remission, n (%)	25 (24.3%)	26 (24.8%)
Change from baseline in BASMI (linear)		
n	101	100
mean (SD)	-0.4 (0.7)	-0.4 (0.6)
Change from baseline in enthesitis*		
n	85	87
mean (SD)	-3.6 (4.0)	-3.8 (5.0)

\* Among pts with enthesitis at baseline (PBO→GLM: n=85; GLM: n=87).

ASAS20/40,  $\geq 20\%/40\%$  improvement in ASsessment in Ankylosing Spondylitis (ASAS) International Working Group criteria; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BASMI, Bath Ankylosing Spondylitis Metrology Index; SD, standard deviation

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Approximately 30-50% of patients with axial SpA (axSpA) who receive a first bDMARD do not respond well. Current practice in these patients is switching to another bDMARD but the scientific evidence for this attitude is sparse. The aims of this study were: First, to investigate if switching biological DMARDs (bDMARDs) after the failure to prior bDMARD is efficacious in patients with axSpA. Secondly, to evaluate the influence on this efficacy of: i) the reason to discontinue prior TNF inhibitor (TNFi), ii) changing the type of TNFi and iii) changing the target.

**Methods:** A systematic literature review until January 2017 was performed using Medline, EMBASE and Cochrane databases. The research question was formulated according to the PICOS method: Population (axSpA patients with failure to at least one bDMARD); Intervention (second or consecutive bDMARD); Outcome (clinical response according to ASAS, BASDAI or ASDAS criteria); and Study design (longitudinal studies with at least 50 patients and 12 weeks of follow-up). Data were extracted by two independent reviewers using a specific form. **Results** are shown as relative frequencies (%).

**Results:** In total, 9 studies out of 1,862 citations were included. Most of them were observational studies reporting data from national registries and only two used data from clinical trials. In these studies, 1,956 patients (91% AS and 9% nr-axSpA) switched to a second bDMARD (97% TNFi and 3% IL-17i) and 170 to a third bDMARD (all TNFi). The most common reason was inefficacy, followed by intolerance or adverse events related to the administered drug. Baseline characteristics (median -range-) of patients who switched bDMARDs were: age 43 (38-46) years old, 67% (54-80) males, 77% (62-84) HLA-B27+, and BASDAI before switching drugs 6.2 (5.2-7.1). As a control group, data from 4,191 patients after receiving the first bDMARD were analysed.

Time to assess response after switching was 6 (3-12) months. The criteria to define clinical response were heterogeneous. Clinical response (BASDAI50) after a second TNFi was achieved by 25-56% of patients compared to 50-72% after the first TNFi. Also, 47% of patients switching to IL-17i after a TNFi responded (ASAS40) compared to 66% in those who received IL-17i as first line (Figure). The response after switching was not influenced by the reason to discontinue, type of prior TNFi or changing the target.

**Conclusion:** In patients with axSpA, switching to a second bDMARD (a TNFi or IL-17i) after prior TNFi is efficacious. Nevertheless, the clinical response is lower than the observed in patients naive to bDMARD. So far, the reason to discontinue prior bDMARD or the type of bDMARD have not been identified as predictors of response. Published evidence for switching to a third bDMARD is lacking.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Limited data are available on anti-TNF survival in non-radiographic axial spondyloarthritis (nr-axSpA) patients and their long-term survival in ankylosing spondylitis (AS). The aim of the study was to evaluate long term survival of the first anti-TNF drug treatment among patients with AS and nr-axSpA enrolled in the TURKBIO database and to compare the discontinuation rates for infliximab (INF), etanercept (ETN), and adalimumab (ADA) in each of the two groups.

**Methods:** All AS and nr-axSpA patients receiving biological therapies registered in the TURKBIO database between the dates of october 2011 and april 2017 were included in the study. AS diagnosis was made according to modified New York classification criteria and nr-axSpA according to ASAS AxSpA classification criteria. Demographic and clinical data, the date of starting to use biological drug, using frequency and dose of biological drugs, BASFI, BASDAI, BASMI, ASDAS scores, date and reason for discontinuing to use drug were collected. Baseline characteristics and drug survival rates were compared between AS and nr-axSpA patients. Drug survival was calculated by the Kaplan-Meier method and risk for discontinuation among treatment groups compared by Long Rank test.

**Results:** A total of 924 patients were included in the study (AS, n = 871 and nr-axSpA, n = 53). More than half of the patients with AS were male (60.7% in AS vs 34.0% in nr-axSpA group,  $p < 0.001$ ). AS patients had longer symptom duration ( $104.90 \pm 79.06$  vs  $75.11 \pm 45.29$  months,  $p < 0.036$ ) compared to nr-axSpA. Median levels of CRP and ESR were similar for nr-axSpA (CRP:  $27.03 \pm 34.71$ , ESR:  $30.50 \pm 25.77$ ) and AS (CRP:  $22.32 \pm 29.95$ , ESR:  $35.40 \pm 22.91$ ). The scores of BASFI, BASMI and ASDAS were found to be similar in both groups. Median BASDAI scores at first TNFi initiation were higher in patients with nr-axSpA than in patients with AS ( $58.65 \pm 18.21$ ,  $51.06 \pm 18.91$ ,  $p = 0.030$ ). Cumulative drug survival rates did not show significant difference among INF (at 59. months: 18,5%), ADA (at 71. months: 39,5%) and ETN (at 51. months: 24,2%) in nr-axSpA group ( $p = 0,699$ ) (Figure 1). Similarly, drug survival rates at 78, 77, 78. months for 3 anti-TNF drugs had shown no difference in AS patients (INF (at 78. months: 38,1%), ADA (at 77. months: 52,4%), ETN (at 78. months: 39,0%)) ( $p = 0,151$ ) (Figure 2). Cumulative survival rates in AS patients (at 78. months: 42,2%) were found to be significantly higher than that (at 71. months: 28,2%) in nr-axSpA patients ( $p < 0,001$ ) (Figure 3).

**Conclusion:** In contrast to the literature that revealed similar short term survival rates for anti-TNF drugs in patients with AS and nr-axSPA, we found higher survival rates in patients with AS compared to patients with nr-axSpa in this long-term observational study. A limitation of the study may be the low number of nr-axSpa patients using anti-TNF, related to the requirements of social insurance system.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

## **Background/Purpose:**

Some clinical guidance recommends empirical TNFi dose reductions in AS patients despite lack of robust supportive evidence. Recently, we communicated that a strategy of dose reduction in patients with persistent clinical remission is not inferior to full doses. While it has been suggested that drug level monitoring may guide optimization and prevent overtreatment in rheumatoid arthritis patients on TNFi therapy, there is no conclusive data on biomarkers that may help the monitoring of TNFi treatment in AS. The objective of the present study was to explore potential clinical and biologic predictors of poor clinical response, defined as not meeting low disease activity (LDA) defined as: BASDAI, physician global assessment and patient and nocturnal axial pain, all <4, after 1 year of follow-up.

## **Methods:**

This is a nested study on a prospective multicenter, parallel controlled and randomized open-label clinical trial testing non-inferiority of dose reduction vs maintenance of full doses in patients with remission while treated with any antiTNF drug (REDES-TNF, NCT01604629 / EudraCT 2011-005871-18). The study included and analyzed a total of 113 AS patients (55 full dose arm and 58 reduced dose arm) with persistent clinical remission under TNFi.

Clinical variables analyzed included ASDAS-CRP, ASAS response criteria, BASDAI, BASFi and quality of life (ASQoL). Blood samples for measurement of TNFi levels, antibodies anti-drug and inflammatory mediators were collected whenever possible within the 24 hours before TNFi Injection. Plasma levels of TNF alpha, IL-6, esclerostin (SOST) and dickkopf-related protein 1 (DKK-1), high sensitivity CRP (hs-CRP). All TNF inhibitor concentrations were measured by capture ELISA with available commercial kits, and antibodies against drugs were analysed by a homemade two-site (bridging) ELISA.

**Results:** BASFI, ASQoL and the type of TNFi used were all significantly associated with the probability of LDA after 1 year in univariate models, but only the type of TNFi (Infliximab) and BASFI continued to be significant in multivariate models. Since type of TNFi was not randomized, no conclusions can be derived on whether infliximab is having poor outcomes or used differentially. The treatment effect (dose group assigned) did not show significant heterogeneity according to either BASFI ( $p=0.5244$ ) nor type of TNFi ( $p=0.887$ ) suggesting that dose reduction is not predictive of poor outcome. Plasma levels for inflammatory biomarkers and drug levels were available for 55 subjects (29 in full dose group and 26 in experimental group); of all of biomarkers analyzed, only values for hs-CRP were higher in subjects not meeting LDA at 1 year. Univariate methods for clinical and analytical biomarkers showed poor predictive value, with lower bounds of 95% CI for ROC AUC values always below 0.62; multivariate methods were unfeasible since no combination of factors improved the univariate models

**Conclusion:** Baseline BASFI and high hs-CRP serum levels have been identified as potential markers of poor prognosis of LDA at 1 year, regardless of dose reduction or not. Further studies may include these markers and explore additional factors in order to build a predictive model for persistent LDA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Medications used in the treatment of spondyloarthritis (SpA) include nonsteroidal anti-inflammatory drugs (NSAIDs) and biologics, with each class having distinct characteristics that patients may consider. Qualitative research in rheumatoid arthritis (RA) and psoriasis has shown that patients place highest value on medications that improve pain and function, have low risk of adverse events, and can be administered at home. Little data exist on SpA patient preferences regarding medications characteristics.

**Methods:** Through a review of records from an urban academic arthritis clinic, adult patients with ankylosing spondylitis or psoriatic arthritis were invited to participate in one of four focus group sessions. Participants were required to have been prescribed either an NSAID or biologic medication within the past year and to speak English fluently. Literature in RA/psoriasis and a SpA expert informed development of a facilitator script with questions to address SpA symptoms, medication efficacy and side effects, cost/availability and other concerns. During each 2-hour session, a trained facilitator guided patients through a semi-structured interview with the following four questions: (1) “What made you decide to start treatment for your arthritis condition?”, (2) “What about your medication made you hesitant to take it?”, (3) “Do you wish you were taking another type of medication for your condition, and if so, why?”, and (4) “Are you glad to be taking your current medication, and if so, why?” Audio recordings were transcribed and coded by two coders using an inductive reasoning approach to identify themes (NVIVO11 software).

**Results:** Sixteen SpA patients participated in one of the focus group sessions. The median age was 52 (range 23-65), 50% were female, 63% had psoriatic arthritis and 75% used a TNF inhibitor. Themes are detailed in the **Table**, and included: control of pain and stiffness, durability of medication efficacy, preventing irreversible damage, maintenance of mobility and ability to work or fulfill social roles, avoidance of side effects, avoidance of needles, alternative treatments, and long-term affordability/access.

**Conclusion:** SpA patient focus groups identified some factors influencing medication preferences that were similar to RA or psoriasis patients. SpA patients expressed concern for a treatment’s ability to maintain or restore one’s occupational or social role, to avoid surgeries and prevent damage, and for long-term affordability/access to medications. This study provides insights into SpA patients’ medication preferences to guide future quantitative analyses and shared decision making in clinical care.

**Table.** Selected themes and quotations from SpA focus groups on medication preferences

1: Reducing pain/stiffness

“It hurts so bad, seems like it’s pulling my spine out of my back and I can’t walk when that happens because I be in so much pain in trying to get in bed – it’s horrible.”

2: Maintaining/restoring independence

“I gotta live – I gotta move around, I gotta walk, I gotta go to the store, I gotta go to the bathroom, I gotta come back to the hospital...I just gotta. I need the job. I need to be able to get up, to function. It don’t have to be 90%, just let me function 70% of the day. Where I can fix something to eat, can get up and wash, go to the bathroom.”

3. Preventing disease progression

“Well for me, I’m thinking about getting worse. You know. Because I thought that these drugs that’s what it’s supposed to do is make it so that it doesn’t get worse. But it is getting worse. I can feel it.”

4: Medication durability and maintained affordability/access

“The [medication name], now that I’m taking it, and if it’s taken away from me, the withdrawal. After 90 days and it’s out your system, then what? You get a flare-up. What do you do then? You just run to the emergency room. You get a \$500 bill. \$300 for the ambulance. To drive the ambulance because you can’t get up, walk. Or take yourself to the hospital...The withdrawal of the medication already being in your system and then it’s out. Then...you go back to that pain like it never left. But it gets worse. It’s worse than it was the day that you picked up that medication.

5: Avoiding injections

When my doctor prescribed [medication name] to me, I’m frightened of needles too, it’s my first time ever shooting myself in a needle, you know? I mean, I did heroin but I never shot up. And to inject myself every Thursday and I have to wait until the last minute and I know I gotta do it before midnight– I’ll go all the way till that last second”

6. Long term affordability/access

“It’s something that gave me my life back four months ago- I might not be able to afford it. I get something that helps and I feel it was gonna be taken away from me...I don’t make that much money. I live by myself and I gotta do everything by myself. I don’t get welfare, I don’t get food stamps, get nothing. My job, they – you know, give you health benefits – I can’t get all those benefits! I won’t be able to eat. And before I take my medicine, I gotta eat...I just wish I didn’t have to take it ‘cause I can’t afford it.”

7. Concern about side effects

“I had a fear when I first started taking [medication name], of the side effects. My immune system, all of those. I was afraid that I’m going to be the one person that’s going to come down with everything that could possibly go wrong. I was afraid of lymphoma. But I realized my pain and I had to do what I had to do and it all turned out well in the long run but that was my biggest fear, of the side effects”

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Efficacy of biological treatment in patients with axial spondyloarthritis (SpA) varies and is dependent on both disease-related and patient-related factors. The goal of this study was to examine variables correlating with patient-reported performance of biologic agents in an Israeli cohort of patients with axial SpA.

**Methods:** Patients with a clinical diagnosis of axial SpA, either followed in the Rheumatology Unit of Bnai Zion Medical Center (BZMC) or members of the Mifrakim Tz'eirim, the Israeli Association of Young Patients with Rheumatic Diseases (MT), were requested to fill out questionnaires concerning the efficacy of their current treatment, clinical symptoms, dietary habits, mood status, physical activity, working status and basic demographic and disease-related data. Efficacy of treatment was estimated as percentage of global improvement in the disease status. Improvement of 70% or more was considered as clinically significant. Variables of interest were compared between groups of patients, those who achieved or failed to achieve clinically significant improvement. *t*-test or chi square test were used for group comparisons, as appropriate. Values of  $p < 0.05$  were considered significant.

**Results:** A total of 197 patients with axial SpA filled out the questionnaires by phone or via e-mail. Of 107 patients followed in BZMC, 73 were diagnosed with ankylosing spondylitis and 34 with non-radiographic axial SpA. Details of the diagnosis of axial SpA in the 90 patients enrolled from MT were not available, but these patients did not differ from BZMC patients by reported disease-related features, except from the prevalence of uveitis (15% vs 28%,  $p = 0.02$ ). Ninety-one patients (85%) from the BZMC cohort and 63 patients (70%) from the MT cohort had received biological therapy. Of these, treatment-induced global improvement in the disease status of 70% was reported by 100 patients: 64 patients from BZMC and 36 from MT cohorts, respectively ( $p = 0.14$ ). These 100 patients were compared to the second group of 54 patients who failed to achieve 70% improvement. The groups did not differ significantly in age, gender ratio, body mass index, presence of family history of SpA, symptom duration, diagnostic delay, prevalence of peripheral joint involvement, diarrhea, uveitis, psoriasis, self-reported stress or depression, dietary preferences, smoking, insomnia or physical activity ( $p > 0.05$  for all comparisons). Patients from the group with limited response to biological therapy were older at the time of diagnosis ( $37.4 \pm 10.6$  vs  $32.3 \pm 10.0$  years old,

p=0.004), had lower education level ( $13.1 \pm 3.4$  vs  $14.9 \pm 3.2$  years schooling, p=0.001), reported more heel pain (p<0.001), widespread pain (p<0.001), unexplained fatigue (p=0.002), consumed less alcohol (p=0.016) and were less employed during the study period (p=0.009).

**Conclusion:** Improvement after administration of biological treatment in patients with axial SpA correlates with some well-defined disease and patient-related factors. Awareness of these factors may enable refinement of treatment when matched for treatment expectations.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Anti-TNF- $\alpha$  agents are the mainstay of pharmacotherapy for patients with axial spondyloarthritis (AxSpA) who failed treatment with NSAIDs. A little is known about the influence of early versus delayed treatment initiation on their clinical efficacy.

**Methods:** Baseline demographic data and efficacy parameters of patients starting their first anti-TNF- $\alpha$  treatment  $\leq 3$  years (EARLY) or  $> 3$  years (DEALYED) after diagnosis of AxSpA from the Czech national registry ATTRA were compared. ATTRA is a centralized prospective computerized registry of patients receiving bDMARD therapy for rheumatic diseases collecting data on efficacy, safety and quality of life of all patients treated in the Czech Republic. Anti-TNF- $\alpha$  therapy was indicated for patients with AxSpA who have failed treatment with NSAIDs with CRP  $\geq 1$ mg/dl and BASDAI score  $\geq 4$ .

**Results:** Data from 1899 axSpA patients were available for analysis. 689 patients started treatment  $\leq 3$  years and 1210  $> 3$  years after the diagnosis of AxSpA. There was no difference in gender distribution (72% males) or mean CRP level (2.5 mg/dl) at the time of treatment initiation between EARLY and DELAYED groups. Patients in the EARLY group were significantly younger (mean age  $36.4 \pm 10.4$  vs  $42.2 \pm 10.9$  years;  $P < 0.001$ ) with shorter symptom duration ( $8.1 \pm 7.4$  vs  $15.1 \pm 9.0$  years;  $P < 0.001$ ). EARLY patients were less likely to be HLA B27

positive (87.9% vs 93.2%;  $P < 0.001$ ). Disease activity was assessed using BASDAI at months 0, 3, 6, 12, 18 and 24. Activity was higher in the DELAYED group at all timepoints with statistically significant differences at baseline ( $6.4 \pm 1.7$  vs  $6.2 \pm 1.7$ ;  $P = 0.003$ ), 6 ( $2.5 \pm 1.9$  vs  $2.3 \pm 1.8$ ;  $P = 0.038$ ), 18 ( $2.3 \pm 1.8$  vs  $1.9 \pm 1.7$ ;  $P = 0.001$ ) and 24 months ( $2.3 \pm 1.8$  vs  $2.0 \pm 1.8$ ;  $P = 0.049$ ). There was no difference in survival on therapy between the groups with 85% patients remaining on the initial treatment at 1 year and 77% at 2 years. Radiographic progression was not assessed.

**Conclusion:** AxSpA patients starting anti-TNF- $\alpha$  therapy later than 3 years after diagnosis had slightly higher activity before and during treatment, however the differences were small and survival on therapy was not different compared to patients with earlier treatment initiation.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Secukinumab provided sustained improvement in the signs and symptoms of ankylosing spondylitis (AS) over 2 years in the MEASURE 2 study (NCT01649375).<sup>1,2</sup> Here we report the efficacy and safety of secukinumab over 3 years from the study.

**Methods:** 219 patients (pts) with active AS were randomized to subcutaneous secukinumab 150 mg (72 pts), 75 mg (73 pts) or placebo (PBO, 74 pts) at baseline. At Week (Wk) 16, PBO treated pts were re-randomized 1:1 to secukinumab 150 or 75 mg, irrespective of clinical response. Pts initially randomized to secukinumab and those who

switched from PBO to secukinumab at Wk 16 were included in the analysis (secukinumab 150 mg, N = 106 and secukinumab 75 mg, N = 105). Outcome measures at Wk 156 included ASAS20 and 40, ASDAS-CRP inactive disease, ASAS5/6, BASDAI, SF-36 PCS and ASAS partial remission. Analyses stratified by anti-TNF $\alpha$  status (anti-TNF $\alpha$ -naïve and anti-TNF $\alpha$  inadequate response [IR]) were pre-specified. Data are reported as observed. Safety analyses included all pts who received  $\geq 1$  dose of secukinumab.

**Results:** At Wk 156, the completion rate for secukinumab 150 mg was 81.1% (86/106), compared to 72.4% (76/105) for 75 mg. The higher discontinuation rate for 75 mg was in part due to lack of efficacy or patient/guardian decision. Efficacy observed across endpoints from Wks 52 to 156 is summarized in the Table. Higher responses were observed in the 150 mg group. Improvements in ASAS20 and ASAS40 responses were sustained in anti-TNF $\alpha$ -naïve and anti-TNF $\alpha$ -IR pts (Table). Over the entire study period, the mean exposure [ $\pm$  SD] to secukinumab was 914.3  $\pm$  315.5 days. The safety and tolerability profile of secukinumab was consistent with previous reports; nasopharyngitis, upper respiratory tract infection, diarrhoea and bronchitis were the most frequently reported adverse events (AEs). The exposure-adjusted incidence rates with secukinumab for AEs of interest were serious infections/infestations (1.5), Crohn's disease (0.6), malignant/unspecified tumours (0.6) and major adverse cardiovascular events (0.6) per 100 pt-years.

**Conclusion:** Secukinumab 150 mg provided sustained response in the signs and symptoms along with physical function through 3 years in pts with AS, with over 80% retention rate. The safety profile remained favourable and was consistent with previous reports.<sup>1,2</sup>

## **Comparison of Radiologic Parameters of Ankylosing Spondylitis Treated with Anti-TNF- $\alpha$ Versus Non-Steroidal Anti-Inflammatory Drugs and Sulfasalazine**

**Seung Min Son**, Orthopaedic surgery, Pusan National University Yangsan Hospital, Yangsan, Korea, Republic of (South)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

There are many studies about impact of TNF-inhibitors on radiographic progression but little data are available on the relationship between treatment agents and sagittal balance in AS. We focus on radiological aspects related to treatment agents and compare sagittal balance treated with anti-TNF- $\alpha$  to non-steroidal anti-inflammatory drugs and sulfasalazine.

### **Methods:**

One hundred thirty three consecutive AS patients were enrolled prospectively. AS patients were eligible to participate in the trial if they were in medical treatment with same treatment agents at least from 1 year. All patients were treated with NSAIDs and sulfasalazine first. 69 patients were showed excellent outcome of pain control with same agents (Group A). But 64 patients complained of intractable low back pain even though treated with same agents. After at least 3 months, we changed treatment agents for these patients to anti-TNF- $\alpha$  therapy (Group B). Radiographic parameters, that is, sacral slope (SS), pelvic tilt (PT), pelvic incidence (PI), thoracic kyphosis (TK), lumbar lordosis (LL), horizontal distance between C7 plumb line and the posterosuperior corner of the sacrum (C7PL), sacrofemoral distance (SFD), C7PL/SFD ratio (C7/SFD), spinosacral angle (SSA), spinopelvic angle (SPA), C2-C7 lordosis (CL), C2-C7 sagittal vertical axis (C2-C7 SVA) were measured. For the assessment of

clinical outcome, the Bath AS Disease Activity Index (BASDAI) score and erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) level were checked. Radiologic and clinical parameters were checked at enrolment, when changing treatment agents and every 6 months during the follow-up period.

### Results:

Significant differences were observed at baseline between two groups. Mean ESR, CRP, and BASDAI were significantly higher in group B. Patients in group B had significantly higher TK compared with group A. In comparison between both groups after treatment, patients in group B had significantly higher lumbar lordosis after treatment. And clinical outcomes including ESR, CRP, BASDAI were significantly lower in group B. At the comparisons between before and after treatment in both groups, there was no significant difference among radiologic parameters in group A. Only BASDAI score had lower after treatment in group A. But in group B, lumbar lordosis and cervical lordosis were significantly increased after treatment. And ESR, CRP, and BASDAI were significantly lower than before treatment. Correlation analysis revealed significant relationships between radiologic parameters and BASDAI. Under multiple regression analysis, lumbar lordosis was the significant predictor for BASDAI.

### Conclusion:

This study shows a clear association between treatment agents and radiologic parameters in AS. Furthermore, patients in group B and patients in group A were found to be significantly different in terms of sagittal radiologic parameters like thoracic kyphosis and lumbar lordosis. In addition, correlation analysis revealed significant relationships between radiologic parameters and clinical outcomes. Anti-TNF- $\alpha$  treatment improved lumbar lordosis and made slow thoracic kyphotic progression with improvement of clinical outcomes in AS.

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Large-scale observational cohorts identified in national biological registries may be used to study effectiveness of biological disease modifying drugs (bDMARDs) in ankylosing spondylitis (AS). However, aggregation of data and generalizability of results depends on whether baseline characteristics and disease activity are comparable across countries.

The aims of this interim report, which is part of an ongoing collaborative project between the five Nordic countries, were to explore the following in AS patients who started first line treatment with a bDMARD during 2010-2016 A) baseline characteristics and disease activity per country, B) prescription rate of first line bDMARD per capita per country in 2016.

### **Methods:**

An observational, prospective cohort study conducted in parallel in the 5 Nordic countries. Data regarding the numbers of AS patients (ICD10 code M45) who initiated bDMARD treatment during 2010-2016 were collected from the Nordic rheumatologic biological registries SRQ (Sweden), NOR-DMARD (6 Norwegian treatment centres), DANBIO (Denmark), ROB-FIN (Finland) and ICEBIO (Iceland).

For the calculation of prescription rate, background population numbers (year 2016) were retrieved from each country.

No statistical comparisons were conducted for the current interim analysis.

### **Results:**

In total, 4392 bDMARD treatment initiations were identified in AS patients 2010-2016 (Sweden 1986, Norway 663, Denmark 970, Finland 623, Iceland 150). Demographics and baseline characteristics are presented in Table. The age at start of bDMARD and the proportion of HLA-B27-positivity appeared similar across the countries whereas there seemed to be differences in baseline disease activity, use of conventional synthetic (cs)DMARDS and rate of smoking.

The crude incidence rate of first line bDMARD start in 2016 ranged from 1.3 (Finland) to 10.7 (Iceland), per 100000 capita.

### **Conclusion:**

The biological registries of the Nordic countries can be used to conduct large scale observational studies in AS. However, despite the relatively homogenous populations and health-care systems in the region, variations in the incidence of bDMARD use and in the patient baseline characteristics were observed. National differences in disease classification and in treatment strategies need to be explored further and taken into account when interpreting merged data from several countries.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The value of biologic DMARDs (bDMARDs) in SpA is well recognized but global access to these treatments can be limited due to high cost and other factors. This study explores variation in the use of bDMARDs in SpA across countries and to what extent socio-economic (SE) factors may explain variation.

**Methods:** Patients fulfilling the ASAS SpA criteria in the multi-national, cross-sectional ASAS COMOSPA study were studied. Multi-level logistic regression models with random intercept for country were constructed with current use of bDMARDs as the dependent variable. Contribution of socio-economic factors using country health expenditures and gross domestic product (GDP) (all low vs medium/high tertiles) as independent country-level factors, was explored in models adjusted for socio-demographic as well as clinical variables known to determine bDMARD-use in SpA.

**Results:** In total, 3370 patients from 22 countries were included (mean [SD] age 43 [14] years; 66% male; 88% axial disease). Across countries, 1275 (38%) were bDMARD users. Crude mean bDMARD-use varied between 5% (China) to 74% (Belgium). After adjustment for relevant socio-demographic and clinical variables, important variation in bDMARD-use across countries remained (Figure,  $p < 0.001$ ). Country-level socio-economic factors, specifically higher health expenditures were related to higher bDMARD uptake (Table), though not meeting

statistical significance (OR 1.96;95%CI 0.94,4.10). Similar findings were found with country GDP (OR 1.93;95%CI 0.91,4.06).

**Conclusion:** There remains important residual variation across countries in bDMARD uptake of patients with SpA followed in specialized SpA centers. This is despite adjustment of well-known factors for bDMARD use such as clinical and country-level socio-economic factors.

## **Real-World Effectiveness of TNF Inhibition in Spondyloarthritis. Data from a Large Nationwide Prospective Cohort – the British Society for Rheumatology Biologics Register for Ankylosing Spondylitis**

**Gareth T. Jones**<sup>1</sup>, Andrew Keat<sup>2</sup>, Ejaz Pathan<sup>3</sup> and Gary J. Macfarlane<sup>1</sup>, <sup>1</sup>Epidemiology Group, School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, United Kingdom, <sup>2</sup>Rheumatology., Northwick Park Hospital, London, United Kingdom, <sup>3</sup>Department of Rheumatology, Aberdeen Royal Infirmary, Aberdeen, United Kingdom

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

TNF inhibition has revolutionised the treatment of axial spondyloarthritis (AxSpA). Much of what we know about the use of these drugs comes from randomised controlled trials (RCTs). However, RCT populations are highly selected, often from specialist centres, and there are potential threats to external validity – i.e. that the treatment effect in this sub-group of patients is not representative of the wider eligible patient population.

The aim of the current study, using a large, nationally representative patient registry, was to (a) determine the effectiveness of TNF inhibition in a large ‘real-world’ patient population; and (b) examine predictors of treatment failure.

## **Methods:**

The British Society for Rheumatology (BSR) Biologics Register for Ankylosing Spondylitis recruits patients with AxSpA newly starting TNF inhibition. At baseline, clinical and patient-reported data is collected from the medical notes and patient questionnaires. Patients are followed up at 3, 6 and 12 months, and treatment failure was defined as failure to achieve an ASAS20 response by 1yr – a composite outcome comprising patient global assessment, pain, function, and inflammation.

Logistic regression was used to determine the relationship between baseline clinical and patient-reported characteristics and treatment failure.

## **Results:**

Data were available on 354 patients recruited between Apr-2013 and Sep-2016, of whom 127 (36%) had failed to achieve an ASAS20 response by 1yr. There was no difference in age between those who did / did not achieve an ASAS20 response, nor by gender.

Patients with peripheral joint disease were significantly less likely to achieve ASAS20 response than other patients (OR: 1.90; 95%CI: 1.13-3.19). There was some evidence that patients with non-radiographic disease and those who were HLA-B27 negative were less likely to respond than other patients, although this did not reach statistical significance (see Table). Similarly, no clear or significant association was observed with disease activity or function.

## **Conclusion:**

We have shown, in this real-world AxSpA patient population receiving their first TNF inhibitor, around two-thirds achieve satisfactory treatment response within 1yr. This is reassuringly comparable to the proportion of responders in randomised clinical trial populations. There are few strong predictors of treatment response and it may be that some patients have other conditions (e.g. fibromyalgia) that may be less likely to respond to biologic therapy. Early identification of patients who fail to respond within 1yr remains a clinical challenge, emphasising the importance of early monitoring after commencing these therapies.

Table: Factors associated with failure to achieve ASAS20 response by 1yr

Baseline exposure		OR (95%CI) for failure to achieve ASAS20 response by 1yr
Age (quartiles)	18-34yrs	1.00
	34-44yrs	0.86 (0.43-1.69)
	44-54yrs	1.11 (0.58-2.13)
	54-82yrs	1.27 (0.68-2.36)
Sex	Male	1.00
	Female	1.19 (0.74-1.90)
Extra-spinal features (Yes versus No)	Peripheral joint involvement	1.90 (1.13-3.19)
	Uveitis	0.72 (0.42-1.22)
	Psoriasis	1.11 (0.56-2.20)
	Inflammatory bowel disease	1.29 (0.69-2.41)
Modified New York criteria	Positive	1.00
	Negative	1.22 (0.78-1.91)
HLA-B27	Positive	1.00
	Negative	1.67 (0.95-2.94)
Disease activity (BASDAI)	<4.0	1.93 (0.81-4.56)
	4.0-4.9	1.00
	5.0-5.9	1.01 (0.44-2.32)
	6.0-6.9	0.66 (0.29-1.52)
	7.0-7.9	0.98 (0.45-2.10)
	8.0-8.9	0.66 (0.28-1.58)
	>=9.0	1.46 (0.52-4.13)
Function (BASFI)	<4.0	1.94 (0.79-4.79)
	4.0-4.9	1.00
	5.0-5.9	1.34 (0.50-3.58)
	6.0-6.9	0.66 (0.24-1.85)
	7.0-7.9	1.68 (0.66-4.32)
	8.0-8.9	2.08 (0.82-5.27)
	>=9.0	2.43 (0.93-6.35)

## **The Effect of Extraarticular Manifestations on Tumor Necrotic Factor $\alpha$ Inhibitor Drug Survival in Patients with Ankylosing Spondylitis: Nationwide Data from the Korean College of Rheumatology Biologics (KOBIO) Registry**

**Yunsuek Kim**, Internal medicine, Soonchunhyang university Seoul hospital, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The tumor necrosis factor  $\alpha$  inhibitor (TNFi) therapy has been shown to be remarkably effective in ankylosing spondylitis (AS). However, almost 30% of AS patients stop TNFi or switch to another TNFi because of inefficacy or adverse effects, annually. The objective of our study was to assess the predictors of TNFi drug survival including extraarticular manifestations, using nationwide registry in Korea.

**Methods:** Data were obtained from the Korean College of Rheumatology BIOlogics (KOBIO) registry which is multi-center based national wide data from 53 tertiary care hospitals in Korea. Demographics, clinical features, laboratory findings, disease activity indices (BASDAI, ASDAS-ESR, ASDAS-CRP), and extraarticular manifestations (uveitis, enthesitis, dactylitis, psoriasis, inflammatory bowel disease) were studied in patients with AS during the TNFi therapy. We analyzed the drug survival of 5 TNFi agents (etanercept, infliximab, infliximab biosimilar, adalimumab, and golimumab) and the factors affect drug survival especially in terms of extraarticular manifestations. To verify affecting factors, univariable and multivariable cox regression analysis were performed.

**Results:** Of 1482 AS patients starting TNFi drugs from Dec 2012 to Jan 2017 were included. In baseline, there was no difference of demographics, disease activity and extraarticular manifestations between continued and discontinued TNFi group except gender distribution, CRP, platelet counts, and HLA-B27 positivity. The effect of extraarticular manifestations including uveitis (unadjusted HR: 0.92, 95% CI 0.57 to 1.48  $p$  value 0.74), enthesitis, dactylitis, psoriasis, and inflammatory bowel disease on TNFi drug survival was not statistically significant. But peripheral arthritis was statistically significantly associated with TNFi drug survival (unadjusted HR: 2.21 95% CI 1.66 to 2.95, adjusted HR 1.38 95% CI 1.01 to 1.88). Of disease activity indices, higher level of ASDAS-ESR showed statistical significance in TNFi drug survival (unadjusted HR: 1.87 95% CI 1.73 to 2.03, adjusted HR: 2.23 95% CI 2.00 to 2.63). Golimumab had higher retention rate to TNFi therapy than etanercept during 3 years of follow-up period (unadjusted HR: 0.46 95% CI 0.31 to 0.68, adjusted HR: 0.65 95% CI 0.43 to 0.99).

**Conclusion:** In national wide KOBIO registry, extraarticular manifestations including uveitis could not affect TNFi drug survival. But the development of peripheral arthritis during TNFi therapy had higher risk of discontinuance of its treatment in AS patients.

---

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Several recommendations have been published for the use of TNF $\alpha$  blockers (TNFb) in patients with axial Spondyloarthritis (axSpA). However, there is only sparse data on the adherence to these recommendations in daily clinical practice and the long-term impact of adhering to them. In this study, we aimed: a) to describe the adherence to the 2006 and 2016 ASAS/EULAR recommendations for TNFb initiation and continuation; b) to evaluate the impact of the adherence to these recommendations over 5 years of follow-up.

**Methods:** Data from the early axSpA patients from the DESIR cohort (first 5 years of follow-up) were analysed. We evaluated the adherence to 2006 and 2016 ASAS/EULAR recommendation for: a) TNFb initiation (patients were considered adherent if they initiated a TNFb when they met the conditions to do so according to recommendations or did not initiate a TNFb when conditions were not met) and; b) TNFb continuation (considering only those patients who initiated TNFb). Predictive factors and the impact of the adherence to these recommendations over 5 years were explored by multivariate logistic regression and mixed models with random effects, respectively.

**Results:** Out of the 708 patients included in the analysis, 440 (62.15%) and 389 (54.94%) were adherent to 2006 and 2016 recommendations for TNFb initiation, respectively. Patients adhering to 2006 recommendations for TNFb initiation were more frequently male [49.5% vs. 40.7%, OR 1.45 (95%CI 1.07-1.98)] and had more frequently a high level of education (university studies) [62.0%, vs. 53.7%, OR 1.43 (95%CI 1.05-1.95)] against patients not adhering. Patients adherent to 2006 and/or 2016 recommendations for TNFb initiation showed significantly lower levels in BASFI, SF-36 (mental and physical components) and in the number of days of sick leave over the 5 years of follow-up [ $10.7 \pm 44.1$  vs.  $19.4 \pm 58.4$  days,  $p < 0.001$ , in adherent vs. non-adherent patients for 2016 recommendations, respectively].

Among the 258 patients who initiated TNFb over follow-up, 232 (93.93%) continued the treatment. Among these, adherence to TNFb continuation recommendations was observed in 47.37% and 49.39% of patients, for 2006 and 2016 recommendations, respectively. Better outcomes over 5 years of follow-up were found in the group of patients adhering to recommendations for TNFb continuation (Table 1).

**Conclusion:** This study suggests that adherence to recommendations in the initiation and continuation of TNFb leads to better long-term outcomes in terms of quality of life and sick leave.

**Table 1. Impact of the adherence to recommendations for TNFb continuation over 5 years of follow-up.**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

No data are available from head-to-head randomized controlled trials (RCTs) between secukinumab 150mg (SEC; an anti-IL-17A) and golimumab 50mg (GOL; a TNF inhibitor [TNFi]) in patients with active AS. Matching-Adjusted Indirect Comparison (MAIC) is a method supported and used in decision-making by UK National Institute for Health and Care Excellence (NICE). It ensures comparisons across effectively balanced trial populations. This study assessed the comparative effectiveness of SEC and GOL up to week 24 using MAIC with pooled individual patient data (IPD) from the RCTs MEASURE 1 (M1) and MEASURE 2 (M2) and published aggregate data from GO-RAISE.

**Methods:**

IPD from the pooled SEC arms of M1 and M2 (n=197) were weighted to match the baseline characteristics of the GOL arm from GO-RAISE (n=138). Pooled data were used to maximize the effective sample size (ESS) for SEC. Placebo arms were also matched; placebo-adjusted comparisons were possible only until week 16 because patients could receive active treatment from this time onwards. Logistic regression determined weights for age, sex, BASFI, disease duration, CRP and previous TNFi therapy. Variables were selected by expert opinion and regression analyses. Recalculated outcomes from M1, M2 (SEC, ESS=102; placebo, ESS=81) were compared with GO-RAISE (GOL, n=138; placebo, n=78). Pairwise comparisons – reported as odds ratios (ORs [95% CIs]) – were performed for Assessment of SpondyloArthritis international Society (ASAS) 20, 40 and partial remission (PR) responses at nearest-equivalent time points across trials: weeks 12 (SEC)/14 (GOL), 14 (GOL)/16 (SEC) and 24 (SEC and GOL). Strict thresholds were avoided when interpreting *p* values in line with American Statistical Association 2016 guidance.

**Results:**

There was no evidence of differences in ASAS 20 and 40 responses between SEC and GOL at weeks 12/14 and 14/16 (both placebo-adjusted). At week 24, non-placebo-adjusted ASAS 20 and 40 responses were higher with SEC than GOL (OR [95% CI]: 1.58 [0.93–2.69] *p*=0.089 and 1.58 [0.94–2.64] *p*=0.084, respectively). There was no evidence of differences in ASAS PR responses between SEC and GOL at weeks 12/14, 14/16 and 24. A sensitivity analysis that also matched for BASDAI score yielded similar results.

**Conclusion:**

There was no evidence of differences in ASAS responses between SEC and GOL in placebo-adjusted analyses. In non-placebo-adjusted analyses, SEC showed higher ASAS 20 and 40 responses than GOL at week 24.

ASAS 20/40 and PR responses are the absolute mean response rate (GO-RAISE) and the predicted mean response rates (MEASURE 1 and MEASURE 2). Error bars shown are 95% CIs. ASAS, Assessment of SpondyloArthritis International Society; ASAS 20/40, at least a 20%/40% improvement according to ASAS response criteria; ASAS PR, ASAS partial remission; CI, confidence interval; ESS, effective sample size; GOL, golimumab; OR, odds ratio; SEC, secukinumab.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To compare the clinical efficacy of dose-tapering strategy of tumor-necrosis factor inhibitor (TNFi) with that of standard-dose TNFi treatment in patients with spondyloarthritis (SpA)

**Methods:** This observational cohort study was based on prospectively registered data of nationwide KOBIO registry. A total of 776 SpA patients with available data and more than one year of TNFi adherence were included. Quantification of TNFi dosage were expressed using dose-quotient (DQ), which was calculated as  $\frac{\text{actual prescribed dose}}{\text{standard dose}} \times \frac{\text{standard dosing interval}}{\text{actual dosing interval}}$  annually. We used linear mixed model to estimate the change in disease activity (ASDAS-CRP, BASDAI and BASFI) over 3 years between the two strategies. Classifying as dose-tapering was based on both mean DQ of patients (individual level) and DQs of all 1-year observations from all patients (time level). Incidence of discontinuation of TNFi due to inefficacy and adverse event were also compared.

**Results:** At the individual level, patients with mean DQ<1.0 (tapering group, n=322) were more likely to have obesity (33.5% vs. 29.4%, p<0.001) and be first TNFi users (82.9% vs. 75.1%, p=0.009) and showed higher CRP level (2.6 $\pm$ 4.1 vs. 2.1 $\pm$ 4.2 mg/dL, p=0.039) than those with standard-dose TNFi (standard-dose group, n=454). Other baseline clinical factors including age, gender, smoking status, HLA-B27 positivity, and disease activity were comparable. Change in ASDAS-CRP over time in the tapering group was not significantly different from that in the standard-dose group (p value for time\*group=0.872). This result was consistent after adjustment for baseline factors (age, obesity, HLA-B27 and definite sacroiliitis) which showed relevant interaction with ASDAS-CRP changes (figure 1). At the time level, 186 (24.0%), 204 (35.6%) and 95 (41.9%) patients received reduced dose of TNFi during 0~1, 1~2 and 2~3-year period, respectively. There was no significant interaction between yearly DQ and relevant ASDAS-CRP change (p value for time\*DQ=0.435) (figure 2). In the multivariable model, difference in ASDAS-CRP between the standard-dose TNFi and tapering TNFi over the entire follow-up was 0.10 (95% CI=-0.01 to 0.21). Two treatment strategies showed comparable efficacy regarding BASDAI and BASFI. Incidences of drug discontinuation due to inefficacy and adverse events between the two groups were also comparable (figure 2).

**Conclusion:** In SpA patients with at least one year of TNFi adherence, dose-tapering of TNFi showed a comparable clinical efficacy to standard-dose TNFi treatment.

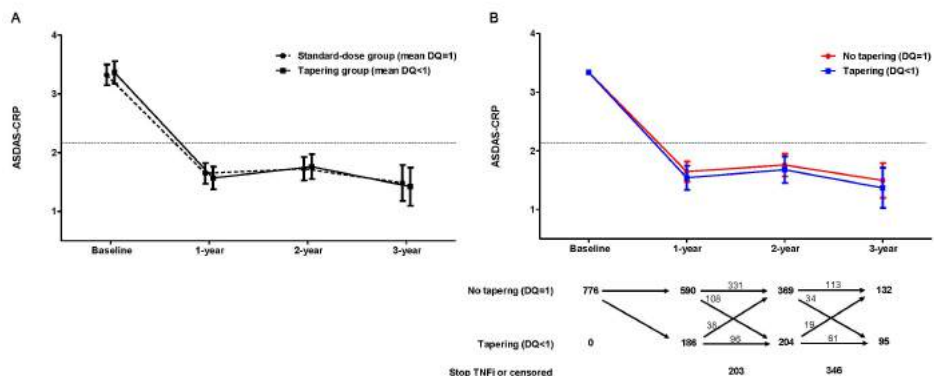

Figure 1. Change in ASDAS-CRP in patients with standard-dose TNFi versus tapered TNFi at individual level (A) and time level (B)

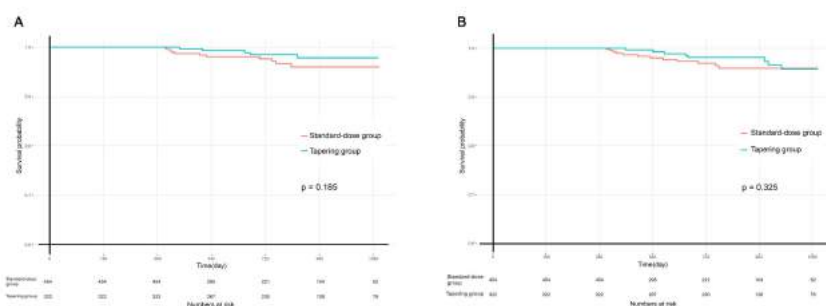

Figure 2. Incidence of TNFi discontinuation due to adverse event (A) and inefficacy (B) between the two groups

## Opioid Use in Patients with Ankylosing Spondylitis

**Victor S. Sloan**<sup>1</sup>, Anna Sheahan<sup>1</sup>, Jeffrey Stark<sup>2</sup> and Robert Y. Suruki<sup>1</sup>, <sup>1</sup>UCB Pharma, Raleigh, NC, <sup>2</sup>UCB Pharma, Smyrna, GA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Background/Purpose:** The use or misuse of opioids has become a major public health issue in the USA. It is estimated that the economic burden of misuse of prescription opioids is approximately \$78 billion/year,<sup>1</sup> and by 2009, opioid deaths outnumbered deaths from motor vehicle accidents.<sup>2</sup> In the 2000s, new standards from The Joint Commission led to increased prescribing of opioids for non-cancer pain.<sup>3</sup>

Ankylosing spondylitis (AS) is a serious, chronic inflammatory condition primarily involving the axial skeleton; progressive spinal pain is a hallmark of the disease. Recent treatment guidelines recommend use of non-steroidal anti-inflammatory drugs (NSAIDs) as initial pharmacotherapy, and TNF inhibitors (TNFi) in patients with insufficient response to NSAIDs; anti-IL17 therapies are not mentioned due to paucity of data and timing, and the use of opioids is not addressed.<sup>4</sup> We performed an initial analysis to attempt to assess the use of opioids in patients with AS.

**Methods:** Patients aged  $\geq 18$  years with AS (ICD9 720.0, ICD10 M45.X) were identified in the Truven MarketScan<sup>®</sup> database during the period 2011 to 2016. The period following the first AS medical code (i.e. index date) was then examined for claims for opioid medication dispensing. The concomitant use of TNFi and/or NSAIDs during the same follow-up period was also ascertained. Anti-IL17 therapies were not included in this analysis due to insufficient exposure data.

**Results:** Of the 56,236 patients with AS in the database, 27,347 (48.6%) had  $\geq 1$  opioid claim during the follow-up period. Among this subset of opioid-exposed AS patients, 9,808 (35.9%) also had a claim for a TNFi, 17,539 (64.1%) had a claim for an NSAID, and 20,449 (74.8%) received an NSAID and/or a TNFi during the follow-up period. The exposure rates were similar when the analysis was restricted to AS patients with  $\geq 2$  opioid claims during the follow-up period.

**Conclusion:** Opioid use is common among patients with AS. Of the AS patients using opioids in this analysis, approximately one-quarter were using only opioids and no medications recommended in treatment guidelines.<sup>4</sup> In addition to the well-recognized public health and societal issues around opioid treatment, lack of therapies directed at inflammation almost certainly results in suboptimal treatment of this serious inflammatory condition. Further analyses are warranted to better assess the reasons for the lack of appropriate therapies and to understand which practitioners are prescribing the opioids; this methodology is unable to identify alternating use of medication types. Given the high usage of opioids in AS, appropriate circumstances for their use should be defined, and educational efforts should be made to help guide practitioners and patients to more appropriate therapies.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A non-medical switch from originator (INX, Remicade) to biosimilar infliximab (CT-P13, Remsima) was conducted in 36 patients with ankylosing spondylitis (AS) in one clinical center. The aim of the study was to compare measures of disease activity 3 months before and 3 months after the switch, and to monitor effectiveness and safety of treatment within 6 months after the switch.

**Methods:** Measures of disease activity (BASDAI, CRP) 3 months before and 3 months after switch were compared. Measures of disease activity (BASDAI, ASDAS, CRP, ESR), quality of life (HAQ, RAPID 3, EUROQOL) and patient satisfaction with treatment assessed by Treatment Satisfaction Questionnaire for Medication (TSQM) questionnaire were evaluated in month 0, 3 and 6 after the switch. Mean  $\pm$ SD and absolute/relative frequencies were used to describe continuous and categorical variables. P-value of Wilcoxon pair test was used when assessing significance of 3 and 6 months change.

**Results:** 36 patients with AS were switched from Remicade to Remsima. Prior INX treatment duration was  $86.2 \pm 34.7$  months. The baseline characteristics are shown in table 1. Comparison of change in BASDAI and CRP 3 months before and after the switch is shown in table 2. The evolution of disease activity measures and patient reported outcomes (PROMs) and TSQM over 6 months after the switch is shown in table 3. There was no serious adverse event. One patient had a reverse switch to INX because of his request.

*\*Wilcoxon pair test. difference between values at the start of the treatment and after 3 months.*

*\*\*Wilcoxon pair test. difference between values at the start of the treatment and after 6 months.*

**Conclusion:** We have observed no consistent trend of change in disease activity measures and PROMs that would suggest a decrease in efficacy in the limited time frame of our study. The mild decrease in patients' satisfaction assessed by TSQM that was not correlated with other PROMs may have been caused by a placebo effect. Our study supports the results of other real life studies indicating no decrease of efficacy after a non-medical switch from originator to biosimilar infliximab.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

According to Danish national guidelines issued in April 2016, a non-medical switch from originator (ETA, Enbrel) to biosimilar Etanercept (SB4, Benepali) (50 mg s.c.) was conducted for economic reasons in patients with inflammatory rheumatic diseases treated in routine care. Changes in disease activity 3-months pre-switch and 0-3 months after the switch were comparable.<sup>1)</sup>

We aimed to investigate the 1-year retention rates and reasons for withdrawal in ETA-treated patients (pts) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (SpA) who switched to SB4 (*“switchers”*) and to characterize ETA treated patients, who did not switch to SB4 (*“non-switchers”*).

## **Methods:**

Patients were monitored prospectively in the DANBIO registry. Reasons for SB4 withdrawal were categorized as adverse events (AE), lack of effect (LOE) or other. Baseline characteristics associated with SB4 withdrawal were explored by multivariable Cox regression analyses stratified by diagnosis(RA/PsA/SpA) and included gender/age/concomitant methotrexate(MTX)/SB4 dose/patient's global score(PGS). Comparisons of switchers (at baseline = first SB4 treatment) versus non-switchers (per April 1<sup>st</sup> 2016) were by Chi-square/Mann-Whitney.

## **Results:**

A total of 2.030 ETA treated patients were identified, of which 1623(80%) were switched to SB4.

In switchers, 276 patients (18%) stopped SB4 treatment during follow-up, mainly due to LOE (54%) or AE (28%) (Table). In RA, characteristics associated with withdrawal were no concomitant MTX and higher PGS (all  $p < 0.05$ ) whereas gender, age and SB4 dose were insignificant. In PsA, associated factors were female gender, higher PGS and lower SB4 doses, whereas no significant factors were found in SpA.

Compared to non-switchers, switchers more frequently had PsA (22%/12%), received co-medication with methotrexate (48%/42%), were men (40%/35%), were rarely treated with 25 mg ETA (1%/43%) doses and had lower PGS (29(13-54)mm /33(14-62)mm) (median(IQR)), (all  $p < 0.05$ ) whereas age was similar.

## **Conclusion:**

Of 2030 ETA treated patients, 80% conducted a nationwide, non-medical switch from originator ETA to biosimilar SB4. 18% of switchers withdrew during 1-year follow-up. Comparison of the withdrawal rate with a historic ETA treated patient cohort is ongoing and will be presented at the ACR. In RA and PsA withdrawal was associated with higher patient's global scores. Some channeling to non-medical switching was observed, since non-switchers differed in baseline characteristics and often received 25 mg ETA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Enthesitis is one of the manifestations of psoriatic arthritis (PsA), but no clear definition for the diagnosis exists. To further evaluate the added value of sonographic evaluation of entheses in diagnosing enthesitis, more knowledge on factors associated with sonographic enthesitis is needed. We aim to evaluate which clinical characteristics are associated with sonographic enthesitis changes in a cross-sectional PsA population.

**Methods:** established PsA patients were asked to participate, irrespective of enthesitis complaints. Patients were interviewed on history of musculoskeletal complaints (MSC), more specifically if they had complaints during activities and whether they avoided physical activities (during exercise, work, household tasks, hobbies, chores). Tenderness was determined in the MASEI entheses and those in the Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES). Previously we showed that a modified Madrid Sonographic Enthesitis Index (MASEI, i.e. excluding knee entheses thickness and scoring PD-signal semi-quantitatively) distinguishes entheses of PsA patients from those of healthy volunteers. A sonographer unaware of clinical findings scored the modified MASEI. Multivariable linear regressions of structural (erosions, calcifications, structure) and inflammatory (thickness, bursitis and PD) modified MASEI scores were performed (transformed for a better distribution). Variables included age, gender, PsA duration, medication use (non/NSAIDs vs. sDMARDs vs. bDMARDs), LEI + MASES and avoidance (no vs. yes).

**Results:** 84 PsA patients participated (45 males, mean age 55, median disease duration 8 years). Median modified MASEI was 12 (IQR 7.25-17), with a structural component score of 7 (3-10) and inflammatory component score of 6 (3.5-8.5). 8 patients used no medication or NSAIDs only, 36 used sDMARDs and 40 used bDMARDs. 45 patients reported avoiding activities. In a multivariable analysis, inflammatory modified MASEI was negatively associated with avoidance (i.e. fewer inflammatory changes in patients reporting avoidance) and positively associated with age, BMI and use of biologics. Structural MASEI was positively associated with age only.

**Conclusion:** Avoiding physical activities is associated with fewer inflammatory changes of the entheses. More inflammatory changes are seen in older or overweight patients and patients on biologics, in the latter possibly due to more active disease.

**Table 1. Univariable and multivariable linear regression analysis of inflammatory and structural summary scores of MASEI**

	inflammatory modified MASEI				structural modified MASEI			
	Univariable		Multivariable		Univariable		Multivariable	
age	<b>0.018</b>	[0.005;0.031]	<b>0.015</b>	[0.002;0.029]	<b>0.034</b>	[0.017;0.051]	<b>0.032</b>	[0.013;0.051]

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** There are limited data regarding persistency of TNF inhibitor (TNFi) therapies in patients with ankylosing spondylitis (AS) treated in real-world clinical practice. The objective of this analysis was to evaluate time to discontinuation of a TNFi therapy in patients with AS in the US-based Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) Registry.

**Methods:** This analysis included all patients with AS aged  $\geq 18$  years enrolled in the Corrona PsA/SpA registry between April 2013 and January 2015 who were receiving or initiated a TNFi therapy at the time of registry enrollment (index visit) and had  $\geq 1$  follow-up visit. Patient demographics, clinical characteristics, patient-reported outcomes (PROs) and treatment history at baseline were summarized descriptively. Median (95% CI) time from enrollment to discontinuation of the index TNFi therapy was estimated using Kaplan-Meier analysis.

**Results:** Of the 179 patients included in the analysis, 30.3% were female, 91.8% were white, mean (SD) age was 47.8 (14.0) years and mean (SD) body mass index was 29.3 (6.9) kg/m<sup>2</sup> (**Table 1**). The mean (SD) disease duration was 18.3 (12.7) years, and 89.9% of patients had received prior biologic therapy. At baseline, the mean (SD) Bath Ankylosing Spondylitis Disease Activity Index and Bath Ankylosing Spondylitis Functional Index scores were 3.9 (2.5) and 3.2 (2.8), respectively, and patients reported mean (SD) pain and fatigue scores of 38.1 (30.2) and 45.5 (29.4), respectively; additional disease activity measures and PROs are described in **Table 1**. A total of 57 patients (31.8%) discontinued their index TNFi therapy during follow-up. The median (95% CI) time from enrollment to TNFi discontinuation was 41 (34 to not estimable) months (**Figure 1**).

**Conclusion:** Approximately 30% of patients with AS who received a TNFi therapy at time of enrollment in the Corrona PsA/SpA registry and had ≥ 1 follow-up visit discontinued their index TNFi therapy, with a median time to discontinuation of 41 months. These results provide insight into the persistency of TNFi therapy in US patients with AS in a real-world setting.

**Table 1.** Patient Demographics, Clinical Characteristics and Treatment History at the Index Visit Among Patients With AS With ≥ 1 Follow-Up Visit in the Corrona PsA/SpA Registry

Characteristic*	Patients With AS With ≥ 1 Follow-Up Visit N = 179
Age	47.8 (14.0)
Female, n (%)	54 (30.3)
White, n (%)	157 (91.8)
BMI, kg/m <sup>2</sup>	29.3 (6.9)
BMI (in kg/m <sup>2</sup> ) classifications, n (%)	
Normal/underweight (< 25.0)	47 (26.9)
Overweight (25.0 to < 30.0)	61 (34.9)
Obese (≥ 30.0)	67 (38.3)
Disease duration, years	18.3 (12.7)
History of prior biologic use, n (%)	161 (89.9)
≥ 2 prior biologics	48 (26.8)
History of prior csDMARD use, n (%)	66 (36.9)
History of prior prednisone use, n (%)	18 (10.1)
Current prednisone use, n (%)	10 (5.6)
BASDAI (0-10)	3.9 (2.5)
BASFI (0-10)	3.2 (2.8)
ASDAS-CRP	1.9 (0.8)
Patient pain (VAS, 0-100)	38.1 (30.2)
Patient fatigue (VAS, 0-100)	45.5 (29.4)
HAQ (0-3)	0.5 (0.6)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Background/Purpose:** There is a need to better characterize patients with ankylosing spondylitis (AS) who discontinue vs continue TNF inhibitor (TNFi) therapies in real-world clinical settings. The objective of this study was to compare patient characteristics and disease outcomes in patients with AS who continued vs discontinued a TNFi therapy by their second follow-up visit in the US-based Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) Registry.

**Methods:** All patients with AS aged  $\geq 18$  years enrolled in the Corrona PsA/SpA Registry between April 2013 and January 2015 who were receiving or initiated a TNFi agent at the time of registry enrollment (index visit) and had  $\geq 2$  follow-up visits were included. Patients were assigned to a cohort based on continued or discontinued use of their TNFi at the second follow-up visit (mean [SD] follow-up, 17.8 [7.1] months). Patient demographics, clinical characteristics, patient-reported outcomes (PROs) and treatment history at baseline were compared between cohorts using *t*-tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. Reasons for discontinuation of the index TNFi were summarized descriptively. Mean changes from baseline in clinical disease activity measures and PROs were assessed at second follow-up and compared between cohorts using unadjusted mean differences.

**Results:** Of the 155 included patients, 37 (23.9%) discontinued their index TNFi therapy by the second follow-up visit, including 24 patients who switched to another biologic. Patients who discontinued their index TNFi were significantly older (52.1 vs 46.6 years), more likely to be obese (59.5% vs 34.2%) and had significantly worse mean BASDAI (4.8 vs 3.5) and BASFI (4.2 vs 2.8) scores at the index visit compared with those who continued their TNFi. Of the 37 patients who discontinued their index TNFi, 18 provided reasons for discontinuation; the most common provider-reported reasons for discontinuation were lack of effect ( $n = 6$ ), side effects ( $n = 4$ ) and other reasons ( $n = 5$ ). Patients who discontinued their index TNFi had worse outcomes with respect to disease activity and PROs at the second follow-up visit compared with those who continued their TNFi; however, differences between the groups did not reach statistical significance (Table 1).

**Conclusion:** Patients with AS in the Corrona PsA/SpA Registry who discontinued their index TNFi therapy by the second follow-up visit were older, more likely to be obese and had higher disease activity at baseline compared with patients who continued their TNFi. Differences in clinical disease activity measures and PROs at the second follow-up visit between those who discontinued vs continued their TNFi did not reach statistical significance, possibly due to small sample size. These results provide insight into patient characteristics and disease outcomes in patients with AS who discontinue vs continue TNFi therapy.

**Table 1.** Change From Baseline in Clinical and Patient-Reported Outcomes at the Second Follow-Up Visit in Patients With AS Who Continued vs Discontinued a TNFi Therapy

Outcome Measure	Mean (SD) Change From Baseline		Unadjusted Difference, $\beta$ (95% CI)	P Value
	Continued TNFi $n = 118$	Discontinued TNFi $n = 37$		
ASDAS	-0.09 (0.69)	0.36 (0.82)	0.45 (-0.03 to 0.92)	0.06
BASDAI (0-10)	-0.15 (1.82)	-0.82 (1.97)	-0.67 (-1.41 to 0.06)	0.07
BASFI (0-10)	-0.10 (1.48)	-0.24 (1.94)	-0.14 (-0.77 to 0.48)	0.65

Greenberg<sup>5</sup>, <sup>1</sup>Swedish Medical Center and University of Washington, Seattle, WA, <sup>2</sup>Corrona, LLC, Southborough, MA, <sup>3</sup>University of Massachusetts Medical School, Worcester, MA, <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, <sup>5</sup>New York University School of Medicine, New York, NY

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Few real-world studies have characterized the use of first- vs second-line tumor necrosis factor inhibitors (TNFis) in US patients with psoriatic arthritis (PsA). This study examined disease characteristics and described patterns of TNFi use through the first follow-up visit ( $\approx$  6 months) in patients with PsA who initiated a first- vs second-line TNFi in the US Corrona PsA/SpA Registry.

**Methods:** This study included adult patients with PsA enrolled in the Corrona PsA/SpA Registry who initiated first- or second-line TNFi therapy between March 2013 and September 2016 with  $\geq 1$  follow-up visit. Patient demographics, disease characteristics and patient-reported outcomes were assessed at the time of TNFi initiation (baseline) and compared between cohorts using two-sample *t*-tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. The proportions of patients who continued their index TNFi, discontinued without switching, or switched to another biologic at the time of the first follow-up visit was examined and compared between cohorts.

**Results:** Of the 230 patients with PsA who had  $\geq 1$  follow-up visit (median [IQR] time to first follow-up, 6.8 [6.0, 9.7] months), 139 patients initiated a first-line TNFi and 91 patients initiated a second-line TNFi. At baseline, patients who initiated a second-line TNFi had higher enthesitis and dactylitis counts, were less likely to be in minimal disease activity and had worse pain and fatigue compared with patients who initiated a first-line TNFi; however, these differences were not statistically significant (**Table 1**). A higher proportion of patients initiating a first-line TNFi continued their TNFi at the first follow-up visit than those initiating a second-line TNFi (76.3% vs 59.3%;  $P = 0.001$ ). Among first-line initiators, 19.4% and 4.3% discontinued their index TNFi without switching, or

switched to another biologic, respectively, compared with 22.0% and 18.7% of patients initiating a second-line TNFi (**Figure 1**; both  $P = 0.001$ ). Of the 17 first- and 19 second-line TNFi initiators with provider-reported reasons for discontinuing or switching TNFis, the most common reasons were lack of effect (44.4% and 60.0%, respectively) and adverse effects (27.8% and 10.0%, respectively).

**Conclusion:** Patients with PsA initiating a second-line TNFi were more likely to discontinue or switch therapies compared with patients initiating a first-line TNFi, with the most common reason for discontinuation/switch due to lack of effect. These findings from a US registry suggest potential unmet needs for patients with PsA when using TNFis as a second-line therapy in a real-world setting.

**Table 1.** Baseline Demographic, Disease and Patient-Reported Characteristics of Patients With PsA at the Time of Initiation of First- or Second-Line TNFi

Characteristic*	First-Line TNFi n = 139	Second-Line TNFi n = 91
Age, years	51.8 (13.9)	53.3 (11.8)

## Treatment Changes By Joint Activity and Skin Severity in Patients with Comorbid PsA and PsO

**Philip J Mease**<sup>1</sup>, Carol J. Etzel<sup>2</sup>, Jeffrey Lisse<sup>3</sup>, April W Armstrong<sup>4</sup>, William J Huster<sup>3</sup>, Sabrina Rebello<sup>2</sup>, Rhiannon Dodge<sup>2</sup>, Talia M Muram<sup>3</sup>, Sarah Al Sawah<sup>3</sup>, Mwangi J Murage<sup>3</sup>, Jeffrey D Greenberg<sup>2</sup> and William Malatestinic<sup>3</sup>, <sup>1</sup>Swedish Medical Center and University of Washington, Seattle, WA, <sup>2</sup>Corrona, LLC, Southborough, MA, <sup>3</sup>Eli Lilly and Company, Indianapolis, IN, <sup>4</sup>Keck School of Medicine, University of Southern California, Los Angeles, CA

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Background/Purpose:** Treatment of both joint and skin symptoms is important for overall disease management of patients with psoriatic arthritis and comorbid psoriasis<sup>1,2</sup>. The objective of this study was to characterize treatment changes and the reasons in patients with comorbid PsA and PsO through 12 months of follow-up after enrollment into Corrona registry. Changes in joint/skin severity at the 12 month visit vs at enrollment were also evaluated.

**Methods:** Enrollment visit data from the Corrona PsA/SpA registry were obtained from 3/21/2013-9/30/2016 on patients with PsA diagnosed by a rheumatologist with a history of PsO. Patients were categorized into the following drug status groups: no change in therapy or change (reduction, addition or switch) in therapy. Reasons for discontinuation were categorized as: efficacy, safety, other, or unreported. Change in joint activity and skin severity from enrollment to 12 month visit were classified by change in category of CDAI, BSA or both. CDAI categories were as Low:  $\leq 10$ , Moderate:  $10 < \text{CDAI} \leq 22$ , and High:  $> 22$ . BSA was categorized as Low:  $\leq 3\%$ , Moderate:  $> 3$  to  $10\%$ , and High:  $> 10\%$ .

**Results:** 647 patients had CDAI, BSA, and known drug status. Majority (n=369, 57%) of patients had no changes in therapy. 278 patients had a change in therapy. Reasons for change were: no reason (70.9%, n=197), efficacy (10.4%; n=29); safety (5.8%; n=16), and other (12.9%; n=36). For patients whose joint or skin severity improved or worsened, the median change in BSA and CDAI scores was  $\geq 4$ . Improvement in either joint or skin severity were seen in 135 (21%) and 138 (21%) patients, respectively. Worsening of either joint or skin severity were seen in 113 (18%) and 52 (8%) patients, respectively. No change in both joint and skin severity was seen in 281 (43%) patients. Patients with improvement in both joint and skin severity saw the greatest median reduction in CDAI and had the second largest median decrease in BSA, while those who worsened in both had the greatest median increase in CDAI and BSA scores (Table 1).

**Conclusion:** The majority of patients had no change in therapy and no change in either joint or skin severity after 12 months of follow-up. Patients with improvement in both joint and skin severity saw a large median reduction in CDAI and BSA while those who worsened had the greatest median increase in CDAI and BSA. Further study of the real-world impact of therapy changes on subsequent joint activity and skin severity is needed.

Table 1: Changes in Joint Activity and Skin Severity at 12 month FU visit

	n	%	$\Delta$ in CDAI median (IQR)	$\Delta$ in BSA median (IQR)
Improve on both	39	6.0	-9.2 (-13.7, -3.1)	-7.0 (-14.0, -3.0)
Improve in Skin, no change in Joints	89	13.8	0.0 (-2.5, 2.4)	-8.0 (-12.0, -4.0)
Improve in Joints, no change in Skin	85	13.1	-7.3 (-12.5, -3.5)	0.0 (-1.0, 0.0)
No Change in both	281	43.4	-0.1 (-2.4, 1.2)	0.0 (-1.0, 0.0)
Worsen in Skin, Improve in Joints	11	1.7	-5.5 (-8.0, -2.2)	4.0 (2.0, 8.0)
Worsen in Joints, Improve in Skin	10	1.5	6.6 (4.0, 11.1)	-4.5 (-12.0, -4.0)
Worsen in Skin, No change in Joints	29	4.5	-0.5 (-0.8, 1.0)	4.0 (3.0, 9.0)
Worsen in Joints, No change in Skin	91	14.1	6.5 (2.6, 10.5)	0.0 (-1.0, 0.0)
Worsen in Both	12	1.9	10.0 (6.5, 18.8)	6.0 (3.5, 8.0)
TOTAL	647	100.0	-0.3 (-4.0, 2.5)	0.0 (-2.0, 0.0)

## **Efficacy of Biologics and New Anti-Inflammatory Agents Used in the Treatment of Active Psoriatic Arthritis: Systematic Literature Review and Network Meta-Analysis of the Evidence.**

**Mahdi Gharaibeh**<sup>1</sup>, Yingxin Xu<sup>2</sup>, Joseph Lee<sup>3</sup>, Madhura Chitnis<sup>2</sup> and David Collier<sup>4</sup>, <sup>1</sup>Amgen Inc., Thousand Oaks, CA, <sup>2</sup>Evidera, Bethesda, MD, <sup>3</sup>videra, Bethesda, MD, <sup>4</sup>Amgen, Inc, Terni, Italy

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Psoriatic arthritis (PsA) is an inflammatory arthritis associated with psoriasis. Biologics are usually the first-line FDA-approved disease-modifying anti-rheumatic drug (DMARD) treatment; however, no published network meta-analysis (NMA) has presented efficacy results by prior biologic experience. The aim of this study is to compare the efficacy of treatments in moderate-to-severe PsA in biologic-naïve and biologic-exposed patients (pts).

### **Methods:**

MEDLINE, Embase, Cochrane Central Register of Controlled Trials, and conference databases for the European League Against Rheumatism, American College of Rheumatology (ACR), and British Society for Rheumatology in 2015 and 2016 were searched for randomized controlled trials published from 1/2009 to 4/2017. Treatments included were tumor necrosis factor inhibitors (TNFis; etanercept ETN, adalimumab ADA, infliximab IFX, certolizumab pegol CZP, and golimumab GOL), IL-17 inhibitors (secukinumab SEC, ixekizumab, and brodalumab BRO), phosphodiesterase 4 inhibitor (apremilast APR) and IL-12/23 blocker (ustekinumab UST). Outcomes of interest were the proportion of pts achieving  $\geq 20\%$  improvement in ACR response criteria (ACR20) and proportion achieving Psoriatic Arthritis Response Criteria (PsARC) at 12 and 24 weeks; these were the most commonly used outcomes in RCTs. A Bayesian NMA estimated the comparative efficacy of these regimens via the best fitting random- or fixed-effects model.

### **Results:**

Among 34 trials identified, 16 PsA trials for biologic-naïve therapy were included, of which 5 trials also reported data for biologic-exposed pts. Pts in placebo arms received best standard of care (BSC), including non-steroidal anti-inflammatory drugs with concomitant conventional non-biologic DMARDs; BSC served as the common comparator in the NMA. Full results are shown in Table 1. For ACR20 at 12 weeks in a biologic-naïve population, the odds ratio (OR) of response for TNFis vs. BSC ranged from 3.36 for CZP to 19.49 for ETN and from 2.33 for BRO280 to 2.54 for APR in other biologics. At 24 weeks, the OR of response for TNFis vs. BSC ranged from 4.28 for CZP to 11.26 for GOL and from 2.64 for UST45 to 6.77 for SEC150 in other biologics. For ACR20 at 24 weeks in a biologic-exposed population, the OR of response for the TNFi CZP was 12.38 and ranged from 2.97 for SEC150 to 5.65 for SEC300 in other biologics. For PsARC at 12 weeks in a biologic-naïve population, the OR of response for TNFis ranged from 4.22 for ADA to 24.75 for ETN while it ranged from 5.02 for IFX to 13.8 for GOL100 at 24 weeks in other biologics.

## Conclusion:

Response rates vary greatly with DMARD treatment. There was a trend for higher odds of response with TNFis vs. other treatments in biologic-naïve PsA pts. There were too few biologic-exposed outcomes to draw any conclusions. The results of this NMA suggest that TNFis show improved response for joint outcomes in PsA pts.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Both EULAR (European League Against Rheumatism) and GRAPPA (Group for Research and Assessment of Psoriasis and Psoriatic Arthritis) recently published treatment guidelines for Psoriatic Arthritis (PsA). Despite them, it remains unclear how physicians approach the management of PsA since there are few studies in the real world.

The purpose of the study was to describe treatment patterns (treatment discontinuation, switches, and therapy additions) for PsA patients in a real-world setting.

### **Methods:**

A Retrospective descriptive study was performed in a university hospital with its own health insurance and captive population. All patients fulfilling Classification Criteria for Psoriatic Arthritis (CASPAR) with at least 3 visits of follow-up were included. Electronic medical records were reviewed between 01/01/2000 and 05/31/2017.

### **Results:**

A total of 275 patients with PsA were included, with a median follow-up of 5.3 years (IQR: 2.1-10.2). Demographical data can be found in Table 1.

First line treatment were NSAIDs in 9.45% of the patients, traditional DMARD (tDMARD) in 88%, being methotrexate the most frequent one (76%), and biologic DMARDs (bDMARD) in 2.18%. None received

combination of tDMARDs. Reasons for switching or discontinuation were: lack of response 41%, adverse events 35%, remission 12% and suspension by the patient 12%.

bDMARD were used in 29.5% of the patients. As monotherapy in 55.4 % of the cases, and combined with methotrexate and leflunomide in 38.5 % and 6% respectively.

Survival rate of DMARDs at the end of follow up was 40% for tDMARD and 72% for bDMARD.

Additional information on both tDMARD and bDMARD can be found in Table 2.

At end of follow up mean DAS28 was 3.1 (SD: 1.4), mean HAQ: 0.42 (SD: 0.6), and 51% of patients fulfilled Minimal Disease Activity (MDA) criteria.

### **Conclusion:**

In this real-world data, 40% of the patients continued with the first tDMARD after 5 years of follow up and only one third of patients required bDMARD. Drug survival was very good both for tDMARDs and bDMARDs.

Table 1

Total PsA patients	275
Males, n (%)	162 (58.91)
Axial involvement, n (%)	40 (14.5%)
Median follow up time, years (IQR)	5.3 (2.1-10.2)
Mean age at diagnosis of Psoriasis, years (SD)	35.1 (16.9)
Mean age at diagnosis of PsA, years (SD)	48.3 (15.1)
Median time between diagnosis of Psoriasis and PsA, years (IQR)	13.1 (5.3-22.9)
Median time between first musculoskeletal symptom and diagnosis of PsA, years (IQR)	0.6 (0.2-2.1)

Table 2

NSAIDs as first line, n (%)	26 (9.45)
tDMARD as first line, n (%)	243 (88%)
bDMARD as first line, n (%)	6 (2.18)
tDMARD ever, n (%)	249 (90.54)
Methotrexate, n (%)	218 (87.55)
Sulfasalazine, n (%)	15 (6.02)
Leflunomide, n (%)	15 (6.02)
Cyclosporine, n (%)	1 (0.4)
Median time from diagnosis to start of tDMARD, years (IQR)	0.3 (0.07-3.1)
Survival of first tDMARD at 3rd year, % (CI 95%)	52 (44-59)
Survival of first tDMARD at 5th year, % (CI 95%)	40 (32-48)
Combination of tDMARD ever, n (%)	13 (4.73)
bDMARD ever, n (%)	81 (29.5)
TNFi, n (%)	77 (95)
Anti-IL 17, n (%)	2 (2.47)
Anti-IL 12-23, n (%)	2 (2.47)
bDMARD in combination with tDMARD, n (%)	36 (44,6)
Median time from first tDMARD to first bDMARD, years (IQR)	3.4 (0.9-8)
Survival of first bDMARD at 3rd year, % (CI 95%)	81 (66-90)
Survival of first bDMARD at 5th year, % (CI 95%)	72 (54-85)

Curtis<sup>3</sup>, Sathya Velkuru<sup>4</sup> and Joel Kremer<sup>5</sup>, <sup>1</sup>Medicine, div-of Rheumatology, Albany Medical College, Albany, NY, <sup>2</sup>Corrona Research Foundation, Albany, NY, <sup>3</sup>Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL, <sup>4</sup>Medicine, Albany Medical College, Albany, NY, <sup>5</sup>Albany Medical College and the Center for Rheumatology, Albany, NY

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Psoriasis is a complex disorder with cutaneous and rheumatological manifestations affecting 2-3% of the population of the Western world. The prevalence of hypertension (HTN) in patients with psoriasis has been well documented; about 30% of all psoriatic arthritis (PsA) patients have HTN. Treatment of PsA has also been shown to improve certain cardiovascular risks. We hypothesized that blood pressure was related to PsA disease activity. We also evaluated the relationship between PsA and blood pressure as it relates to initiation of TNF inhibitors (TNFi).

## Methods:

We utilized the CORRONA database and examined patients with PsA from March 2013 to January 2017. Descriptive statistics were used to summarize patient demographic and clinical data at baseline (first visit in CORRONA database). An analysis of variance was made to determine associations between 3 categories of MD-defined psoriatic body surface area (BSA) and systolic blood pressure (SBP) and diastolic blood pressure (DBP). Spearman correlations were made between continuous values of systolic or diastolic blood pressure and BSA and clinical disease activity index (CDAI) using all visits. We also looked at changes in SBP or DBP between visits correlated with changes in CDAI in those who were initiated on TNFi while they were in the registry. LOESS curves were generated to visualize relationships between variables.

## Results:

1481 patients with PsA were identified, who had a total of 6109 registry visits. When body surface area (BSA) of psoriasis was categorized into <sup>2</sup> 2%, 3-10% and >10% in analysis of variance, SBP was higher with increased BSA ( $p=0.0048$ ,  $F=7.26$ ,  $r^2=0.025$ ). DBP was also higher with an increased BSA ( $p<0.0001$ ,  $F=15.28$ ,  $r^2=0.005$ ). SBP was positively correlated with CDAI ( $p=0.0057$ ,  $r=0.037$ ), as was DBP ( $p=0.0012$ ,  $r=0.044$ ). The association between SBP change and CDAI change in those who were initiated with a TNFi showed an overall decrease in SBP that was not statistically significant ( $p=0.26$ ,  $r=-0.041$ ). In addition, DBP change and CDAI change in those who initiated a TNFi also showed a non-statistically significant decrease ( $p=0.13$ ,  $r=-0.054$ ).

## Conclusion:

In patients with PsA, there was a significant positive relationship between blood pressure and both psoriasis BSA and joint disease activity, measured by CDAI. We also conclude that clinically, the initiation of TNFi did decrease blood pressure, but the decrease was not significant. We believe that this is the first study to look at relationships between the initiation of TNFi treatment and blood pressure in PsA patients.

## Residual Disease Activity in Psoriatic Arthritis Triggers Treatment Adjustment in Only a Quarter of Patients in Daily Clinical Practice

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** With expanding therapeutic possibilities for the treatment of psoriatic arthritis (PsA) it will be increasingly important to determine residual disease and define when to adjust treatment. The rationale behind treatment decisions in current daily clinical practice and the relation with residual disease activity has not been investigated.

The aim of this study was to assess the current clinical practice on defining residual disease and the subsequent treatment decisions made in PsA patients.

**Methods:** This cross sectional study included 142 consecutive PsA patients who visited the outpatient clinic. The treating rheumatologist scored disease activity and her/his opinion on the presence of residual disease and the subsequent treatment decisions made. Patients scored patient disease activity scores.

**Results:** Two thirds (90/142) of the patients had musculoskeletal residual disease activity, with half of those having even moderate to high disease activity according to CDAI. There were no differences between the groups with or without residual disease activity in gender, disease duration, comorbidity, current treatment duration or number of previously used cDMARDS. Residual disease activity was more frequently reported in patients treated with a cDMARD only or a 2nd TNFi. 74% of the patients with residual disease activity were currently treated with either a cDMARD only or a first TNFi, suggesting that treatment modification could be an option. Of the 90 patients with residual disease, in 21(23%) treatment adjustment was initiated. Treatment changes were considered less frequent in those patients treated with a 2nd TNFi. No differences were seen in disease activity and demographics between those with or without a treatment adjustment. Judgment by the physician and/or patient rather than objective hurdles to treatment intensification (absence of additional treatment options, lack of compliance, intolerance) drove the decision not to modify treatment.

**Conclusion:** In almost 2/3 of the patients there was a presence of residual disease activity but only resulted in treatment adjustment in only a minority. As the adjustment could not be explained by comorbidities or a lack of treatment options there is clearly a further need for research to understand why disease activity does not lead to treatment adjustment in these cases.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose :** There is a lack of validated outcome measures in non-psoriatic peripheral spondyloarthritis (pSpA). Therefore, a modified version of the minimal disease activity (mMDA)<sup>1</sup> was developed and validated. Identification of factors that predict long-term mMDA response in pSpA patients (pts) can facilitate decisions

regarding treatment initiation and maintenance. The purpose of this analysis was to determine predictors of long-term mMDA response following adalimumab (ADA) treatment in pSpA pts from the ABILITY-2 study.

**Methods :** ABILITY-2<sup>2</sup> was a phase 3 randomized, double-blind trial evaluating the efficacy and safety of 40 mg ADA every other week versus placebo (PBO) over 12 weeks (wks) followed by open-label (OL) ADA for 144 wks in pts with pSpA. This post-hoc analysis included pts who received at least one dose of ADA during the PBO-controlled period or OL extension. The mMDA for pSpA was defined as achieving at least 5 out of the following 6 criteria: 1) TJC78  $\leq$  1; 2) SJC76  $\leq$  1; 3) pt pain visual analog scale (VAS)  $\leq$  15 of 100 mm; 4) pt global activity (PtGA) VAS  $\leq$  20 of 100 mm; 5) HAQ-DI  $\leq$  0.5; and 6) tender entheses points  $\leq$  1 (Leeds Enthesitis Index [LEI] or Spondyloarthritis Research Consortium of Canada [SPARCC] Enthesitis Index). In this post hoc analysis, multiple logistic regression with stepwise variable selection was used to determine predictors of long-term (yrs 1-3) and sustained (defined as mMDA for at least 24 consecutive wks) mMDA responses. Variable selection of baseline (BL) pt demographics and disease characteristics were performed with and without mMDA response at after 12 wks of ADA exposure (mMDA12) as a candidate.

**Results :** In pSpA pts treated with ADA, mMDA (5/6 LEI or SPARCC) was achieved by almost 41%, 49%, and 50% of pts at yrs 1, 2, and 3, respectively and sustained mMDA response was achieved by 42% of pts. Regardless of mMDA definition, achieving mMDA response after 12 wks of ADA exposure was a robust positive predictor of attaining both long-term mMDA at yrs 1-3 and sustained mMDA (**Figure**). In the model examining the BL predictors (model without mMDA12), age, BL enthesitis and BL BASDAI scores were most commonly selected as negative predictors for achieving long-term and sustained mMDA. Other selected predictors included BL dactylitis, physician's global assessment, hsCRP, and male sex; however, these predictors were not consistently selected for all time points or sustained mMDA.

**Conclusion :** Early mMDA response is a stronger and more consistent predictor of long-term mMDA, whether at 1, 2, or 3 yrs or sustained over time, than BL characteristics. The 5/6 versions of mMDA could be an appropriate treatment target in pSpA pts.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Psoriatic arthritis (PsA) is an inflammatory condition characterized by peripheral arthritis and psoriatic skin lesions requiring therapies that control both skin and joint symptoms. In the absence of head-to-head trials, indirect comparison provides informative evidence for decision makers. This study compared the clinical (ACR 20/50/70; PASI 75/90) and cost-effectiveness outcomes of targeted immunomodulators (TIMs) among PsA patients without prior biologic treatment via a network meta-analysis (NMA).

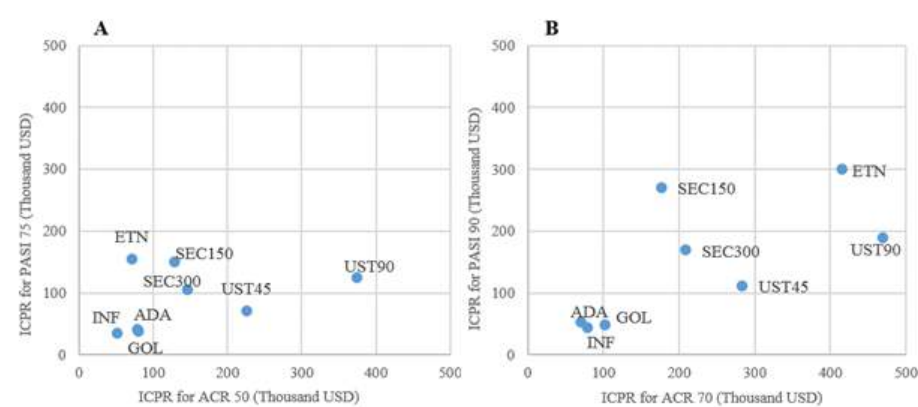

**Methods:** A systematic literature review was conducted to identify Phase 3 randomized controlled trials (RCTs) for tumor necrosis factor- $\alpha$  inhibitors (TNFi's: adalimumab [ADA], certolizumab pegol [CZP], etanercept [ETN], golimumab [GOL], and infliximab [INF]), an interleukin-17A inhibitor (secukinumab [SEC]), an interleukin-12/23 inhibitor (ustekinumab [UST]), and a phosphodiesterase-4 inhibitor (apremilast [APR]) in active PsA. Joint (ACR 20/50/70) and skin (PASI 75/90) responses at Week 24 were estimated via Bayesian NMA among biologic-naïve patients. Treatment costs were based on Wholesale Acquisition Cost as of May 8, 2017 and included drug acquisition and administration costs. Incremental costs per responder relative to placebo were calculated as incremental treatment costs during 24 weeks divided by response rate difference vs. placebo.

**Results:** Eleven RCTs that reported ACR and/or PASI responses at Week 24 among biologic-naïve PsA patients were included. GOL, ADA, and SEC 150 had higher ACR 20 response than other TIMs. In terms of ACR 50, INF, ETN, and ADA had higher efficacy compared with other TIMs (**Table 1**). With respect to ACR 70 and PASI responses, ADA, INF, and GOL had higher efficacy than other TIMs. In terms of cost-effectiveness, INF (\$50,812 for ACR 50/\$35,227 for PASI 75), ADA (\$78,608/\$41,093), and GOL (\$80,533/\$37,443) were associated with lower incremental costs per additional ACR 50 responder and per additional PASI 75 responder than other TIMs (**Figure 1A**). A similar ranking of these drugs was observed in ICPR for ACR 70 and PASI 90 (**Figure 1B**).

**Conclusion:** At Week 24, INF, GOL, and ADA had the lowest incremental cost per responder for joint and skin outcomes in PsA patients without prior biologic treatments.

Table 1. ACR 20/50/70 and PASI 75/90 response rates at Week 24 <sup>1</sup>					
	ACR response rates			PASI response rates	
	ACR 20	ACR 50	ACR 70	PASI 75	PASI 90
<b>PBO</b>	17.5% (15.5%, 19.6%)	6.3% (5.0%, 7.8%)	2.4% (1.7%, 3.5%)	6.6% (4.3%, 9.8%)	2.2% (1.2%, 3.7%)

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

We are currently witnessing a diversification of the available biotherapies (bDMARDs) for psoriatic arthritis (PsA), with the arrival of new classes of medication. Those treatment options are new, and there is no consensual hierarchy in the use of those medications, and no head-to-head comparative study. The present meta-analysis aims to evaluate the respective efficacy of TNF inhibitors, IL-17 inhibitor (ustekinumab), IL-12/23 inhibitor (secukinumab), and CTLA4-Ig (abatacept), on ACR response criteria, PASI response criteria, HAQ-DI, enthesitis and dactylitis outcomes in PsA.

### **Methods:**

Randomised controlled trials assessing TNF inhibitors, ustekinumab, secukinumab or abatacept in psoriatic arthritis were selected through the MedLine database, ACR and EULAR scientific meeting archives. ACR20, ACR50, ACR70, PASI75 and PASI90 response rates and the proportion of patients with residual dactylitis or enthesitis were collected at the time of evaluation of the primary endpoint. The pooled response risk ratios (RRs) and 95% confidence intervals (95%CI) were quantified for the standard dose of anti-TNF (golimumab 50 mg), ustekinumab (45 mg), secukinumab (150 mg) or abatacept (125 mg) in comparison with placebo. A meta-analysis was performed using the inverse variance approach and statistical heterogeneity was assessed with the Cochran Q-test and I<sup>2</sup> values.

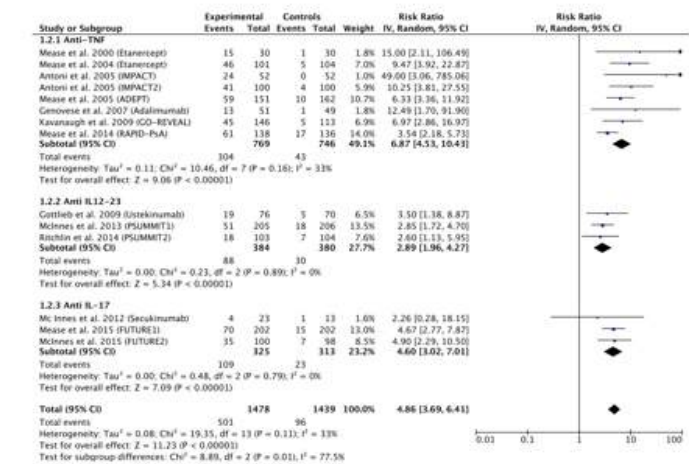

### **Results:**

15 RCTs were selected for the meta-analysis. Anti-TNF, secukinumab, ustekinumab and abatacept showed higher ACR20 response rates, with RRs (95%CI) ranging from 3.51 (2.92, 4.22) to 1.77 (1.31, 2.39), in comparison with placebo. Anti-TNF, secukinumab and ustekinumab showed higher ACR50 (see table) and ACR70 response rates, with RRs (95%CI) ranging from 6.87 (4.53, 10.43) to 2.89 (1.96, 4.27) and 10.80 (6.25, 18.66) to 4.29 (2.04, 8.99), respectively, in comparison with placebo. Anti-TNF, secukinumab and ustekinumab showed higher PASI75

response rates, with RRs (95% CIs) ranging from 16.61 (6.38, 43.26) to 5.54 (3.01, 10.21), in comparison with placebo. Anti-TNF, secukinumab and ustekinumab showed a lower proportion of residual enthesitis, with RRs (95% CIs) ranging from 0.65 (0.50, 0.84) to 0.83 (0.71, 0.97), while only anti-TNF and secukinumab showed a lower proportion of residual dactylitis, with RRs (95%CI) ranging from 0.48 (0.31, 0.74) to 0.53 (0.43, 0.65), in comparison with placebo.

### Conclusion:

In this meta-analysis, bDMARDs showed higher ACR20/50/70 and PASI75 response rates and a lower proportion of residual enthesitis and dactylitis, in comparison with placebo. However, the respective efficacy of bDMARDs, quantified using ORs or NNTs (data not shown), is variable among the different outcomes measures, in particular for enthesitis and dactylitis. Head-to-head studies are needed to draw definitive conclusions on potential efficacy differences between bDMARDs in PsA patients.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Ankylosing Spondylitis (AS) is not only characterized by pathological bone formation leading to ankylosis, but also by bone loss which may lead to vertebral fractures (VFX). TNF-alpha inhibitors (TNFi) have proven to be effective in blocking the inflammation process. A few studies also showed an increase of Bone Mineral Density (BMD) in AS patients treated with TNFi but the incidence of VFX after two years of treatment was increased.

## Methods:

Consecutive TNFi naive patients diagnosed with AS according to the Modified New York criteria were included. Patients were recruited from the VUmc and the Amsterdam Outpatient clinic Reade and were treated with TNFi for 4 years. BMD at hip and lumbar spine (LS) were measured at baseline, after 2 and 4 years. T-scores were categorized as 'normal BMD', 'osteopenia' and 'osteoporosis', based on the WHO osteoporosis criteria. The incidence of VFX was determined by two observers using the Genant method.

## Results:

In total, 70 AS patients with complete datasets (67.1% male) were included. The mean age was 41.6 years and the disease duration (time since diagnosis) was 9.8 years. At baseline 42% of the patients had a decreased BMD of the hip and 34% of the spine, of whom 19 patients (27%) had both a decreased hip BMD as well as a decreased lumbar BMD. The BMD of spine and hip improved after 2 and 4 years of TNFi treatment (Table 1). In 7 patients (10%), 8 VFX were observed both at baseline and after 2 years. After 4 years of TNFi-treatment 11 VFX were observed in 9 patients.

After 4 years, 2 out of 9 patients with >1 VFX had a decreased BMD at hip and lumbar spine whereas the other 7 patients had a normal BMD. The majority of VFX was localized in the mid or lower thoracic spine.

*Table 1:* BMD measurement in spine and hip of 70 AS patients treated with TNFi.

	Baseline	After 2 years of TNFi	After 4 years of TNFi
Osteopenia LS*	23(32.9)	19 (27.1)	21(30.0)
Osteoporosis LS	6 (8.6)	3(4.3)	2(2.9)
Abnormal BMD LS	29 (41.5)	21(31.4)	23(32.9)
Osteopenia total hip	22 (31.4)	19(27.1)	16(22.9)
Osteoporosis total hip	2 (2.9)	2 (2.9)	3(4.3)
Abnormal BMD total hip**	24(34.3)	21(30.0)	19(27.2)
Patients with VFx	7 (10.0)	7(10.0)	9(12.9)
Total number of VFx	8	8	11

\*Lumbar Spine

\*\*N=68, because 2 patients had a total hip replacement

Abnormal BMD = osteopenia and/or osteoporosis according to WHO guideline

Vertebral fractures (VFx) are presented in number of patients with a VFx and the actual prevalence of VFx. Outcomes are presented in n (%)

## Conclusion:

The percentage of relatively young AS patients with a decreased BMD at baseline of the hip and lumbar spine was high (34-41%). After 4 years of TNFi-treatment the BMD of the lumbar spine improved in 8.6% of the patients and of the hip in 7.2% of the patients. At baseline, several vertebral fractures were found and a few additional vertebral fractures were observed after 4 years of treatment.

**Session Time:** 9:00AM-11:00AM

\_\_\_\_\_

**Background/Purpose:** The incorporation of biological disease modifying drugs (b-

DMARD) has substantially improved the outcome of patients with Psoriatic Arthritis (PsA). Our aim was to evaluate b-DMARD's patterns, their accumulated survival and long-term efficacy in patients with PsA using the Lund Efficacy Index (LUNDEX).

**Methods:** A retrospective multicentric study was carried out through the collection of medical records data. Patients aged  $\geq 18$  years with PsA by CASPAR criteria who had started therapy with b-DMARD were included. Socio-demographic and clinical data were collected. We consigned beginning date of b-DMARD, concomitant treatment, suspension or change of b-DMARD, reasons of the suspensions. A therapeutic response was defined according to minimal disease activity (MDA) at 6 and 12 months and then annually since the beginning of biological treatment. Statistical analysis: Student T test and Chi2 test for univariate analysis. Cumulative survival was assessed using Kaplan Meier curves and comparisons using Log Rank. Multivariate Cox regression analysis was performed.

**Results:** Seventy-two patients with PsA were included, 39 (54.2%) were men. The median of age was 54.5 years (IQR 45-61) and median disease duration was 11 years (IQR 6-15). 71.2% (n=42) of patients had comorbidities. Regarding the first biological agent, 45.8% received Adalimumab (ADA), 36.1% Etanercept (ETN), 5.6% Certolizumab, 4.2% Infliximab and Ustekinumab, 1.4% Golimumab. 25.4% (n=15) received them as monotherapy. 79.7% received NSAIDs, 61% Methotrexate, 25.9% Prednisone ( $\leq 10$  mg/day), 12.1% Leflunomide and 1.7% Sulfasalazine as concomitant treatment. 35.8% (n=19) of patients stopped taking the first biologic. The mean survival of b-DMARD was 82 months (SD $\pm 7.4$ ). Causes of suspension were inefficacy (43%), lack of provision (28.6%), side effects (14.3%), and others. The LUNDEX for the first biologic was 24.7% at 6 months and 44.3% at 1 year. The mean survival of ADA was 90 months (SD $\pm 10.4$ ) and for ETN 79 months (SD $\pm 12$ ). Older patients ( $>55$  years old) and obese patients (BMI  $\geq 30$ ) had less drug survival. In the Cox's regression analysis, after adjusting for different confounders, older age was the main variable associated with less drug survival: HR=1.064 (CI=1.01-1.11) (figure 1). LUNDEX was lower in obese vs non-obese patients, 16% vs 66% at 1 year, 10.5 vs 74.9% at 2 years and 5.9 vs 81.8% at 3 years.

**Conclusion:** The mean survival of the first biologic was 82 months. Older age and obesity were associated with lower survival of biologic therapy.

Figure 1: Drug survival of patients less than 55 years older and older than 55 years old.

## Depression and Fatigue in Patients with Ankylosing Spondylitis

Ji Hui Shin<sup>1</sup>, Sun Ju Ahn<sup>2</sup> and Tae-Hwan Kim<sup>3</sup>, <sup>1</sup>rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of (South), <sup>2</sup>Medical Research Coordinator, Hanyang University Hospital for Rheumatic Disease Research Center, Seoul, Korea, Republic of (South), <sup>3</sup>Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of (South)

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** ARHP Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment Poster

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Ankylosing spondylitis (AS) is a chronic inflammatory disease that leads to bony ankyloses. The disease occurs in early adulthood, a critical stage in life, causing physical and mental problems. There are many researches on the degrees of ankyloses and activity of the disease, but studies correlating AS with psychological effects—such as depression and fatigue—are rarer. Therefore, we sought to identify depression status in patients with AS and to find correlations among depression, fatigue, and disease activity.

**Methods:** The subjects of the study were 300 patients with AS, whose data were collected in the hospital from March 2017 to April 2017. All subjects agreed to participate in the research. The data were collected based on the self-reported survey that inquires general features (sex, age, and disease period) and the level of depression measured by CES-D. Based on the CES-D score, the patients were grouped depending on depression level (0-15: normal, 16-21: moderate, 22 : severe). Depression levels were compared to the disease activity measured by BASDAI, BASFI, ESR, CRP and fatigue level, measured by FACIT-F. The collected data were statistically analyzed utilizing SPSS statistics 24.0.

**Results:** 82.7 % of the patients were male, and average age and disease duration were 37.9 years old and 7.21 years. 21 percent of the patients reported smoking, and 55 % drinking. 3.3 % were diagnosed with depression, with a BASDAI of 3.35 and BASFI of 1.72. ESR and CRP were 19.02 mm/hr and 1.25 mg/dl each. The average of CES-D, or level of depression, was 11.12, which is normal, but 22.1 % of the patients had a moderate depression level. The degree of depression correlated with BASDAI, BASFI, and FACIT-F, but it was unrelated with disease duration. The fatigue level was 15.5, which is normal, and was less than the degree of depression. Fatigue showed a correlation with depression and disease activity. Depression was shown to be correlated with diseases activity (BASDAI, BASFI), but fatigue was not.

### Conclusion:

22 % of the patients with AS showed a moderate level of depression, which need intensive treatment. Depression levels correlated with disease activity, but it was unrelated with disease period. It seems that the aftereffects of AS continue after the onset of the disease. This study may contribute to reducing disease activity and improving AS patients' quality of life by regulating depression and fatigue.

## Elevated IL-1 Expression Levels in Mesenchymal Stem Cells Derived from Spondyloarthritis Patients Might be Linked to Increased Osteoblast Mineralization

**Gerlinde Layh-Schmitt**<sup>1</sup>, Breanna Nguyen<sup>1</sup>, Emily Lazowick<sup>1</sup>, Stephen R. Brooks<sup>2</sup> and Robert Colbert<sup>1</sup>, <sup>1</sup>National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD,

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Axial spondyloarthritis (AxSpA) is an immune-mediated inflammatory disease involving the spine and sacroiliac joint. AxSpA is characterized by vertebral trabecular bone loss and progressive bone formation in the spine. To date, the root cause of osteoproliferation and aberrant bone formation is unknown. Therefore, we evaluated, (i) whether bone progenitor cells (mesenchymal cells (MSCs) and osteoblasts (OBs)) derived from AxSpA patients (P) exhibit differences in their capacity to form mineralizing osteoblasts in comparison to healthy controls (HC), and (ii) whether inflammatory cytokines alter osteoblastogenesis and gene expression patterns in MSCs.

**Methods:** We used MSCs derived from induced pluripotent stem cells (iPSCs) generated from P and HC skin fibroblasts. MSCs from 3 HC and 5 P were differentiated into mineralizing osteoblasts. The influence of cytokines (combination of IFN $\gamma$ /TNF $\alpha$  and IL-1 $\beta$ ) and the IL-1 receptor antagonist (IL-1ra) on MSCs and osteoblastogenesis was examined. The degree of osteoblast calcification was measured by alizarin red stain. Cell numbers were determined by DAPI staining. Whole transcriptome expression profiles were established for MSCs with and without cytokine treatments by using RNA-seq and Nanostring. (3 HC and 4P). Standard approaches and statistical methods were used to analyze the data.

**Results:** On average, OBs derived from P (n=5) exhibited a 1.4 fold higher mineralization capacity compared to OBs from HC (n=3) (p<0.05; Mann Whitney test). Interestingly, in all tested P IL-1 $\alpha$  (n= 4) or IL-1 $\beta$  (n=3) mRNA levels were enriched compared to HC up to 5 fold (p<0.05). Stimulation with IFN $\gamma$  & TNF $\alpha$  induced IL-1 $\alpha$  and IL-1 $\beta$  up to 20-fold and COX2 up to 15-fold. Incubation of P and HC MSC lines with IL-1 $\beta$  for 24h induced IL-1 $\beta$ , IL-1 $\alpha$  and COX2 expression 5,10-20, and 3-5 fold (p<0.05), respectively. Treatment of MSCs for 48h with IL-1 $\beta$  before differentiation, led to a 25% increase of OB numbers and the degree of mineralization was up 2.5 fold (p<0.05). This effect was prevented by IL-1ra, which inhibited base line mineralization by 15%.

**Conclusion:** The results suggest that, under certain conditions, IL-1 can enhance proliferation of bone progenitors and osteoblast mineralization by auto- or paracrine mechanisms. Interestingly, exogenous IL-1 $\beta$  induced IL-1 $\alpha$ , IL1 $\beta$ , and COX2 in MSCs correlated with increased proliferation and mineralization of OB. Since COX2 is crucial for the synthesis of prostaglandin E2 (PGE2) which can mediate aberrant ossification through  $\beta$ -catenin stabilization, we will evaluate whether PGE2 and  $\beta$ -catenin are increased in patient cell lines in future studies.

# A Mitogen-Associated Protein Kinase (MAPK) Associated Kinase 2 Inhibitor Decreases *In Vitro* Th17 and Monocyte Inflammatory Responses in Spondyloarthritis

**Davide Simone**, Hui Shi, Nuha Ansar, Alison Davies, Karen Doig and Paul Bowness, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

**First publication:** September 18, 2017

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The current biologic treatment for Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA) are limited to TNF- $\alpha$  inhibitors (TNFi) and, more recently, IL-17A monoclonal antibodies. These treatments work in a percentage of patients and are not effective against all the disease manifestations. Targeting cellular pathways leading to the production of inflammatory cytokines is a new and appealing therapeutic approach for inflammatory conditions. The inhibition of the mitogen-activated protein kinase (MAPK), attempted in the past in Rheumatoid Arthritis (RA), yielded undesirable effects, including toxicity and tachyphylaxis. We aimed to assess the *in vitro* efficacy of a small molecule inhibiting the MAPK-associated protein kinase 2 (MK2) in limiting the cytokine response in T-cells (including Th17), and in monocytes derived from patients with inflammatory arthritis.

**Methods:** CD4<sup>+</sup> T cells and monocytes were isolated from peripheral blood mononuclear cells (PBMCs) of AS (n=16), PsA (n=12), RA patients (n=11) and healthy controls (HC, n=7) and stimulated for six days under either neutral (Th0) or Th17-promoting conditions in the presence of MK2 inhibitor (CC0786512, Celgene) or control (DMSO). The level of IL-17A, IFN- $\gamma$ , GM-CSF, IL-17F in the culture was measured using Cytokine Bead Array (CBA). Cells were also stained for intracellular cytokines and Foxp3 and analysed by flow cytometry. Cytotoxicity and proliferation were also assessed with Annexin V/7-AAD staining and CFSE dilution. Monocytes were stimulated with lipopolysaccharide (LPS) for 18 hours and treated with CC0786512 and the secretion of TNF- $\alpha$ , IL-6, MIP-1 $\alpha$ , MCP-1, GM-CSF measured with ELISA or CBA.

**Results:** CC0786512 effectively inhibited secretion of IL-17A, GM-CSF and IL-17F in CD4<sup>+</sup> T cells from AS and PsA (Figure), with negligible effects on viability or cell proliferation. The compound worked on T cells cultured both in neutral (Th0) and *in vitro* Th17 polarising conditions, with effects in samples derived from TNFi-treated and TNFi-naïve patients. The inhibition of MK2 reduced the number of Th17 cells generated under Th17 driving conditions, and in particular of Th17 cells co-expressing IFN- $\gamma$ . In monocytes, the MK2 inhibition resulted in reduced TNF- $\alpha$ , MIP-1 $\alpha$  and MCP-1 secretion.

**Conclusion:** Our results indicate that the MK2 inhibitor significantly inhibits both Th17 T cell and monocyte immune responses in cells derived from patients with AS and PsA. Our results encourage further investigation and make MK2 a promising novel therapeutic target in the treatment of Spondyloarthritis.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** F759 mice with a single amino-acid substitution in signal transducer subunit of IL-6 receptor gp130 (Y759F) develops arthritis spontaneously due to IL-17A and IL-6 mediated synergistic activation of positive-feedback loop of NF- $\kappa$ B signaling (inflammation amplifier). We sought to see whether this mechanism is operational in Reactive arthritis.

**Methods:** Arthritis was induced with oral feeding of *salmonella enterica* followed by ankle microbleeding in the ankle joints of F759 mice. Sera IL-6 along with IL-6 mRNA and STAT3 phosphorylation in synovium were measured. Further,exosomes isolated from sera of salmonella infected and control mice and were injected into the joints of mice, and measured the expression of proinflammatory cytokine, chemokines and growth factor. On the other hand, sera and synovial fluid of patients with ReA multiple cytokines, chemokines and growth factors were also measured. Finally, synovial fibroblasts (FLS) were cultured to purity and stimulated with IL-6, IL-17, IL-6 plus IL-17 and IL-6 were measured to see synergistic activation.

**Results:** IL-6 in sera of arthritic mice were significantly higher ( $p<0.05$ ) than control mice along with increase STAT3 phosphorylation in the synovium. Though, oral infection itself not sufficient to induce arthritis but if infection is followed by microbleeding then it significantly induces the arthritis in these mice (Fig-1). Further, exosomes from salmonella infected mice induced arthritis in ankle joint and significantly increased IL-6 expression ( $p<0.05$ ). Similarly, in comparison to IL-6 and IL-17 alone these cytokines synergistically induced more IL-6 production from FLS isolated from ReA patients (Fig-2). Finally, we found that SF concentrations of effectors of inflammation amplifiers like IL-6, CCL-20, PLGF and FGF-basic were significantly higher in patients with ReA/uSpA as compared to osteoarthritis patients. Further, levels of these factors were also high in SF compared to sera in ReA patients.

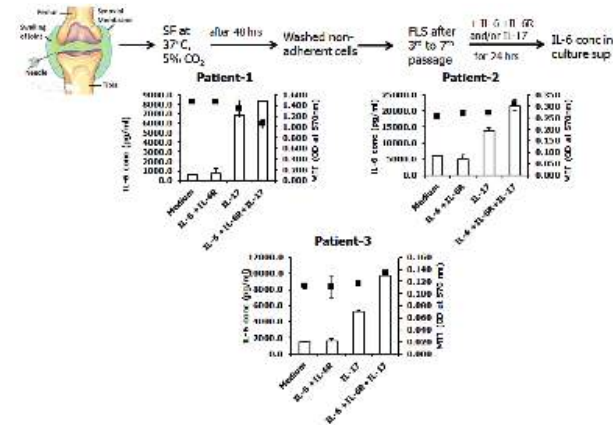

**Conclusion:** Data of mice and patients support that synovitis in ReA is perpetuated by inflammation amplifier or synergistic induction of IL-6 and IL-17.

**Figure 1:** Oral infection of *Salmonella* followed by microbleeding

into the ankle joint induces clinical symptoms of arthritis.

**Figure 2:** Activation of FLS isolated from ReA patients with IL-6 and IL-17 alone and synergistically with both cytokines and measurement of IL-6 level in culture supernatant.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Recent data has revealed occurrence of musculoskeletal manifestations in particular sacroiliitis and inflammatory back pain (IBP) secondary to isotretinoin therapy for acne vulgaris, accordingly our study conducted to detect the prevalence of isotretinoin triggered rheumatic side-effects, with close clinical and radiological follow up to assess the drug impact on musculoskeletal system.

### **Methods:**

513 acne patients on isotretinoin therapy were enrolled from dermatology out patients' clinic, screened for musculoskeletal manifestations related features resulting from isotretinoin therapy, all patients were HLA B27 negative. At baseline C-reactive protein (CRP), Magnetic resonance imaging (MRI) sacroiliac joint, onset of IBP and pain score were reported. MRI proven sacroiliitis, has been scored with semi-quantitative score. Clinical and radiological follow up of our patients were done, patients who met ASAS classification criteria for spondyloarthropathy (SpA) were assessed for disease activity by Ankylosing Spondylitis Disease Activity Score (ASDAS) (3). MRI for sacroiliac joints and CRP were repeated three weeks after being symptomless, with isotretinoin discontinuation.

## Results:

513 acne patients were enrolled, 123 (23.9%) developed IBP, and 88 (17.1%) developed arthralgia and arthritis. The mean onset of IBP was  $(2.1 \pm 0.85)$  months, with mean baseline pain score of  $(4.34 \pm 3.09)$ . MRI proven sacroiliitis was found in (0.13%) of total number of acne patients, and (42.27%) of symptomatic patients, baseline CRP was  $(32.05 \pm 17.23 \text{ mg/L})$  and  $(3.4 \pm 2.7 \text{ mg/L})$  after being symptomless. 51.9% of the symptomatic patients had fulfilled the ASAS criteria for axial SpA, 97.6% of patients were treated with NSAID, however 2.4% were treated with anti TNF biologic. all cases normalized within 9 months, the mean time of normalization was  $(6.27 \pm 1.7)$  months. There was significant positive correlation for MRI scores, with pain, ASAS scores, baseline CRP. Unilateral sacroiliitis patients had significant rapid improvement than bilateral sacroiliitis ( $P < 0.05$ ).

**Conclusion:** Isotretinoin induced SpA is quite common side effect. Early rheumatologic assessment, and intervention is recommended. MRI is the modality of choice in early detection, and follow up of isotretinoin induced sacroiliitis.

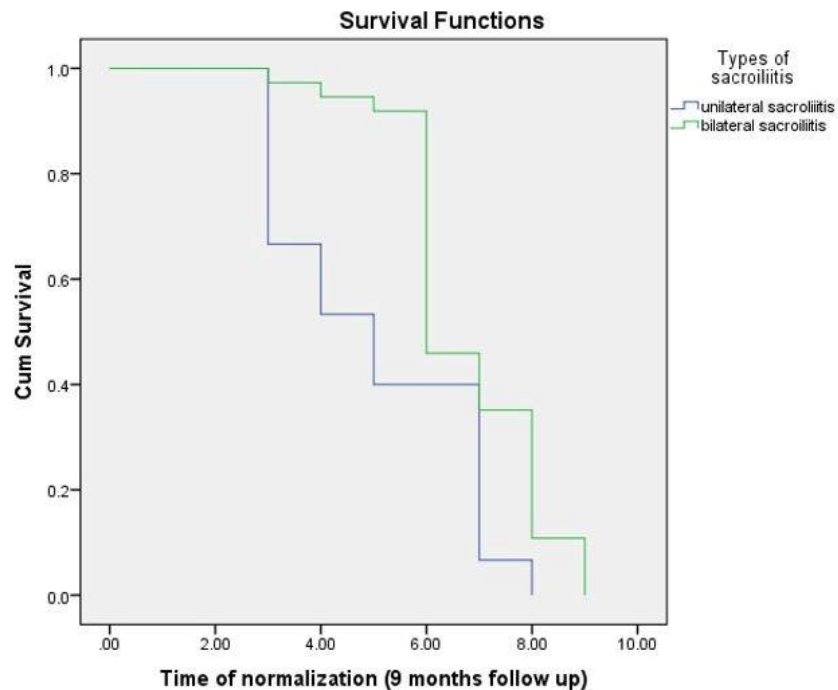

MRI (a) axial T1WI, (b) axial STIR, showing early bilateral acute sacroiliitis evidenced by edema signal (dark signal in T1WI and bright in STIR) of both sacral and iliac sides. Follow up MRI in (c) coronal and (d) axial STIR images revealed marked resolution of the previously reported bilateral sacroiliitis

**Table 1. Correlation between MRI scores, and different study variables**

Variable	MRI score	
	r	p-value
GAGS score	0.396	0.004
Pain score	0.465	0.001
ASAS score	0.416	0.002
CRP level at diagnosis	0.693	<0.001
Dose of isotretinoin/kg	0.21	0.135

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Ankylosing Spondylitis (AS) is a chronic inflammatory disease characterized by new bone growth that leads to syndesmophyte formation and subsequent vertebral ankyloses, although AS patients frequently present with low bone mineral density and fractures that can be associated with systemic inflammation and decreased mobility. In fact, acute stages of inflammation in these patients showed mononuclear cell infiltrates, including increased number of osteoclasts (OCs). However, studies that evaluated osteoclastogenesis in AS patients presented different results, and some of them have demonstrated a decrease in osteoclast differentiation in AS patients. There is no data regarding the influence of clinical disease parameters, inflammatory markers and therapy in AS osteoclastogenesis. Thus, the main objective of this study is to determine if the osteoclastogenic capacity of peripheral blood mononuclear cells (PBMCs) is different in male patients with AS compared to healthy controls and to investigate the relationship between osteoclastogenesis and clinical parameters.

**Methods:** Eight-five male AS patients had mean of age  $42.6 \pm 9.0$  yrs and a mean of disease duration  $17.4 \pm 9.7$  yrs. PBMCs from AS patients and 59 healthy controls were tested for CD16+ cells and induced to differentiation. After 21 days, the cells were tested to TRAP (tartrate-resistant acid phosphatase) and the apoptosis was detected using TACs TdT blue *in situ*. Serum levels of nuclear factor- $\kappa$ B ligand (RANKL) and osteoprotegerin (OPG) were evaluated in both groups.

**Results:** PBMCs from male AS patients had fewer CD16+ cells ( $25.06 \pm 8.59$  vs  $28.59 \pm 10.20$ ,  $p=0.026$ ) and produced fewer osteoclasts ( $647.66 \pm 669.4$  vs  $764.43 \pm 561.9$ ,  $p=0.014$ ) compared to controls. Apoptosis occurred less frequently in osteoclasts obtained from AS patients than in osteoclasts from the control group. A lower RANKL/OPG was observed in AS patients compared to controls ( $0.046 \pm 0.035$  vs  $0.068 \pm 0.071$ ,  $p=0.046$ ). AS patients taking NSAID (non-steroidal anti-inflammatory drugs) presented no difference regarding the number of OCs produced and the percentage of CD16+ cells compared to controls ( $p>0.05$ ). However, patients taking TNF inhibitors (TNFi) presented with lower OC numbers than the control group. A generalized linear model with gamma distribution analysis (including disease duration, NSAID and TNFi use) demonstrated that disease duration was negatively associated with osteoclastogenesis: for each year of disease duration, a decrease of 16.6% in the mean osteoclast number was found ( $p<0.001$ ).

**Conclusion:** Monocytes from male AS patients display a lower capacity to generate osteoclasts *in vitro* compared to cells from controls. This difference was not observed in AS patients taking NSAIDs, differently osteoclastogenesis in AS patients using TNFi. Osteoclastogenesis was negatively correlated with disease duration. These finding supports the idea that osteoclasts play a role in the physiopathology of bone disease in AS patients.

## **Bimekizumab Dual Inhibition of IL-17A and IL-17F Provides Evidence of IL-17F Contribution to Chronic Inflammation in Disease-Relevant Cells**

**Ash Maroof**<sup>1</sup>, Remi Okoye<sup>1</sup>, Tim Smallie<sup>1</sup>, Dominique Baeten<sup>2,3</sup>, Sophie Archer<sup>1</sup>, Catherine Simpson<sup>1</sup>, Meryn Griffiths<sup>1</sup> and Stevan Shaw<sup>1</sup>, <sup>1</sup>UCB Pharma, Slough, United Kingdom, <sup>2</sup>UCB Pharma, Brussels, Belgium, <sup>3</sup>University of Amsterdam, Amsterdam, Netherlands

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IL-17A and IL-17F share structural homology and have similar biologic function.<sup>1</sup> Although the contribution of IL-17A to immune-mediated inflammatory diseases has been widely reported,<sup>1,2</sup> the role of IL-17F is less well characterized. Bimekizumab, a humanized monoclonal IgG1 antibody, developed to neutralize both IL-17A and IL-17F potently and selectively, is under clinical development as a treatment for immune-mediated diseases such as PsA and psoriasis. This study aimed to assess the involvement of IL-17F in chronic inflammation in tissue from patients with PsA and disease-relevant cells, and to determine the effect of dual neutralization of IL-17A and IL-17F in suppressing inflammation, compared with blockade of IL-17A alone.

**Methods:** Synovial and lesional skin tissue from patients with PsA was probed by immunostaining for expression of IL-17F protein. Primary normal human dermal fibroblasts (NHDFs) and synoviocytes from patients with PsA, in the presence of TNF, were stimulated with recombinant IL-17A and IL-17F. Using cytokine-specific blocking antibodies, the individual and combined effects of IL-17A and IL-17F were explored using a complex *in vitro* model (synoviocytes from patients with PsA and primary NHDFs were treated with proinflammatory mediators from supernatant [SN] of sorted Th17 cells) and transcriptional as well as migratory studies were performed.

**Results:** IL-17F expression was observed in tissue biopsies from patients with PsA. In primary NHDFs and synoviocytes from patients with PsA, stimulation with recombinant IL-17F promoted production of proinflammatory mediators, such as IL-6 and IL-8, though to a lesser extent than with recombinant IL-17A. Treatment of Th17 SN-stimulated synoviocytes from patients with PsA with bimekizumab led to greater reductions of IL-6 (42% lower,  $p < 0.05$ ) and IL-8 (35% lower,  $p < 0.05$ ) production than IL-17A inhibition. Bimekizumab treatment of Th17 SN-stimulated primary NHDFs also reduced production of IL-6 (35% lower,  $p < 0.0001$ ) and IL-8 (57% lower,  $p < 0.0001$ ) more than IL-17A alone. Combining IL-17A + IL-17F monoclonal antibodies produced similar results to bimekizumab. Levels of expression of 27 inflammation-linked genes, including *CXCL1*, *CXCL2*, *CXCL3*, and *IL-15RA*, were lower with dual neutralization of IL-17A and IL-17F by bimekizumab versus IL-17A inhibition. Suppression of neutrophil and monocyte (Fig.) migration was substantially greater with bimekizumab than with blockade of IL-17A alone.

**Conclusion:** Dual neutralization of IL-17A and IL-17F provides evidence for the contribution of IL-17F to inflammation in joints and skin beyond IL-17A alone. Dual inhibition of IL-17A and IL-17F by bimekizumab may provide an effective treatment for immune-mediated inflammatory diseases such as PsA.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Whilst HLA-B\*27 is the MHC allele associated with AS, there is strong evidence indicating that other HLA-B alleles and MHC genes are involved in the disease. Large studies in European case-control cohorts have demonstrated risk associations with HLA-B\*40 and multiple other HLA-B, -A and class II alleles, and demonstrated that in that ethnic group the amino-acid sequence at position 97 in HLA-B is the key determinant of HLA associations with AS (Cortes et al, Nat Com, 2015). A recent study in Korean AS cases and controls additionally identified association at HLA-C\*15:02 (Kim et al, Arthritis Res Ther, 2015). In the current study, we examined in an expanded East Asian cohort the MHC associations of AS.

**Methods:** 1637 Chinese, Taiwanese and Korean AS cases meeting the modified New York Criteria for AS, and 1589 ethnically matched controls, were genotyped with the Illumina ImmunoChip, including a dense coverage of the MHC region. HLA genotypes and amino-acid composition was imputed using the SNP2HLA program using the Korean HLA reference panel (n=413) and association tested using logistic regression using 10 principal components to control for population stratification effects. Only HLA types with imputation information scores >0.8 were considered.

**Results:** Strong association was seen with HLA-B\*27 (odds ratio (OR) 158, P=10<sup>-127</sup>). Controlling for this association, risk association is seen with HLA-B\*40 (OR=8.22, P=7.66x10<sup>-83</sup>). Controlling for both HLA-B\*27 and -B\*40, no other HLA-B associations are seen (P>0.05). At amino-acid level the strongest association seen in uncontrolled analysis was with histidine or tyrosine at position 9 in HLA-B (p=10<sup>-155</sup>), but association at P<10<sup>-100</sup> was seen with multiple HLA-B amino acids at P<10<sup>-100</sup> including asparagine (found on HLA-B\*27 alleles) at position 97, previously reported to be the main amino-acid determining HLA-B associations with AS. Controlling for HLA-B\*27 alone, or with -B\*27 and -B\*40, the strongest HLA amino-acid association remains with HLA-B position 97 (serine, found on HLA-B\*7, \*8, \*15, \*2707, \*40, \*41, \*48; P=10<sup>-115</sup> and 10<sup>-71</sup> respectively)

**Conclusion:** This study confirms in East Asians that the primary amino-acid driver of HLA associations in AS is amino-acid position 97, which remains associated with AS independently of both HLA-B\*27 and -B\*40, the two key driver alleles in this ethnicity.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Host response to microbes is considered to contribute to the pathogenesis to axSpA and other HLA-B27 associated diseases. The p38 MAP kinase pathway plays an important role in the resistance of bacterial replication in HLA-B27 expressing human monocytic U937 cells (Sahlberg AS et al: Arthritis Rheum 2007;56:2652). This prompted us to study the phosphorylation of the MAP kinases p38, extracellular signal-regulated kinase (ERK)1/2 and c-Jun-N-terminal kinase (JNK) in patients with axSpA.

**Methods:** The study comprised 20 patients [10 men, 10 women, mean age 31.1 years (range 22-48), 19/20 patients HLA-B27 positive, time from first period of back pain mean 5.9 years (range 0.3-16), mean BASDAI 4.4 (SD 1.7)] referred to rheumatology unit for diagnostic workup due to back pain. Radiological sacroiliitis was observed in 1/18 patients, and inflammation in sacroiliac joints by MRI was observed in 17/20 patients. The patients were diagnosed to have axSpA fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria. We included 26 patients [7 men, 19 women, mean age 49 years, range 19-79, mean DAS28 4.0 (SD 1.3)] with early untreated RA fulfilling the 2010 ACR/EULAR classification criteria as a disease control group, and 18 adult volunteers (9 men, 9 women, mean age 39 years, range 25-70) as healthy controls. Whole blood phosphospecific flow cytometry was used to reveal phosphorylation of p38, ERK1/2 and JNK in nonstimulated monocytes, and in monocytes stimulated by *E. coli*-derived lipopolysaccharides (LPS), whole cells of *E. coli* or lipoteichoic acid (LTA). Fluorescence histograms for monocyte pERK1/2-PE-CF594, pJNK-AlexaFluor647 and pp38-PE-Cy7 were created and fluorescence intensities were expressed as relative fluorescence units (RFU). Phosphorylation capability of MAP kinases was determined by fold-increase, i.e. the ratio of RFU of the stimulated sample to the nonstimulated one. Significance of difference between axSpA and RA patients and healthy subjects was tested by ANCOVA, adjusted for high sensitivity (hs)CRP levels.

**Results:** Basal phosphorylation level of p38 in axSpA monocytes was significantly higher than that in healthy subjects' monocytes (P=0.009), while the difference between RA and healthy subjects was not statistically significant. The respective phosphorylation levels of ERK1/2 and JNK did not differ significantly between the 3 subject groups. The fold-increases of p38 phosphorylation in axSpA monocytes upon LPS or *E.coli* stimulation were significantly lower than those in healthy subjects' monocytes (P=0.004 and 0.002, respectively), while the respective differences between RA and healthy subjects were not statistically significant. The p38 RFU values of the stimulated monocytes did not differ significantly between the 3 subject groups. The fold-increases of ERK1/2 and JNK phosphorylation did not differ significantly between the 3 subject groups.

**Conclusion:** Enhanced monocyte baseline phosphorylation of p38 suggests *in vivo* preactivation of monocytes in patients at the time of diagnosis of axSpA.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Reactive arthritis (ReA) is an inflammatory condition occurring several weeks after gastrointestinal (GI) or genitourinary (GU) infections. HLA-B27 positivity is considered a risk factor, though not necessarily predictive of disease incidence. Among non-genetic factors, the intestinal microbiome may play a role in disease susceptibility. The objective of this study was to characterize the gut microbiota and host gene interactions in ReA.

**Methods:** Adult ReA (n=32) and control (n=32) subjects with preceding GI and/or GU infections that did not develop arthritis were prospectively recruited in Guatemala, a highly prevalent geographic region for this disease. Clinical variables, HLA status, and fecal samples were collected. Fecal DNA was extracted and high-throughput sequencing of the V4 hypervariable region of bacterial 16S rRNA was performed using the MiSeq Illumina platform (150 bp read length, paired-end protocol) to determine intestinal microbiota composition. Data was analyzed with Quantitative Insights into Microbial Ecology (QIIME), R, Linear discriminant analysis Effect Size (LEfSe), and co-occurrence networks.

**Results:** ReA subjects showed no significant differences from controls in gut bacterial alpha or beta diversity. Furthermore, there were no differences when subjects were grouped by prior exposure to antibiotics or sulfasalazine. However, there was a higher abundance of *Erwinia* and *Pseudomonas*, and increased prevalence of typical enteropathogens associated with ReA. In fact, at least one enteropathogen was present in 71.9% of ReA subjects vs 46.8% of controls ( $p < 0.05$ ). LEfSe analysis showed that subjects with ultrasound evidence of enthesitis were enriched in *Campylobacter*, while subjects with uveitis and radiographic sacroiliitis were respectively enriched in *Erwinia* and *unclassified Ruminococcaceae*, and both enriched in *Dialister* (log LDA  $> 2$ ). Host genetics, particularly HLA-A24, were associated with differences in gut microbiota diversity irrespective of disease status. We determined several co-occurring taxa that were also predictive of HLA-A24 status, including *Ruminococcaceae-Rikenellaceae-Coriobacteriaceae* and *Prevotellaceae-unclassified Sphingobacteriales-Elusimicrobiaceae*.

**Conclusion:** This is the first culture-independent study characterizing the gut microbial community of ReA. Although bacterial factors correlated with disease presence and clinical features of ReA, host genetics also appeared to be a major independent driver of intestinal community composition. Understanding of these gut microbiota host-genetic relationships may further clarify the pathogenesis of ReA and related spondyloarthropathies.

JMJD3 epigenetically regulate ankylosing spondylitis inflammation through Th17 differentiation

**Background/Purpose:** Inflammation is the initial stage of ankylosing spondylitis (AS), looking for possible inflammatory regulator will have a great significance in AS treatment. Jumonji domain-containing protein D3 (JMJD3) could specifically demethylate the 27<sup>th</sup> lysine of histones H3(H3K27), which was found in inflammation and many autoimmune diseases. The most important functions of JMJD3 are regulating the differentiation of T cell subsets. JMJD3 specifically de-methylated H3K27 trimethylation in the promoter sequence of the retinoid-acid

receptor-related orphan receptor c (RORc) gene, which is considered to be the beginning of Th17 differentiations. As we known, Th17 has been determined its important role in AS inflammation. So this research aims to explore the epigenetic regulation of JMJD3 in AS inflammation through Th17 differentiations.

**Methods:** A total of 40 AS patients in active stage and 20 healthy controls (25.2±4.1 years) participated in the experiments. All patients were met with the modified New York criteria. 20 of them whose BASDAI≤4 were classified into AS-Stable group(25.8±7.1years), others were classified into AS-Active group(31.2±8.4years). The serum level of IL-17 was detected by ELISA. The proteins were all detected by Western blotting. The mRNA were detected by quantitative PCR .

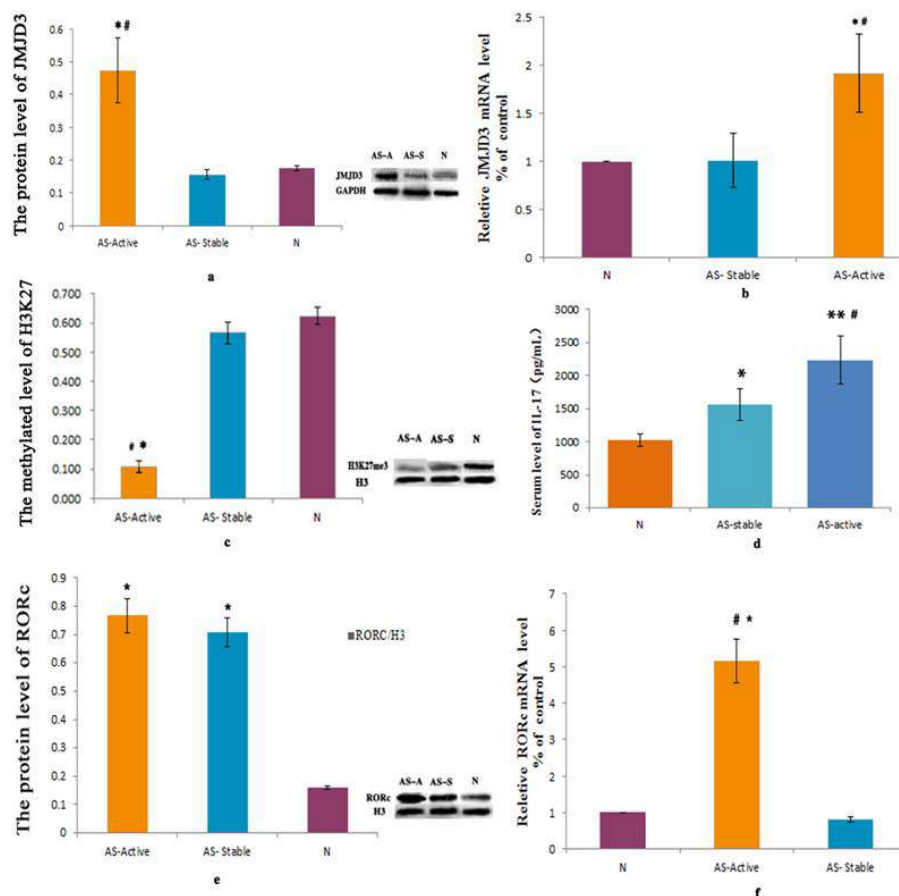

Figure 1 The serum level of IL-17(d), the expression level of JMJD3(a,b), the methylation level of H3K27(c) in AS patients and the expression level of RORc(e,f)

with normal controls: \*p<0.05 \*\*p<0.01; with AS-stable: #p<0.01

**Results:** As in Figure1. The serum IL-17 levels were significantly higher in AS- active patients. The level of JMJD3 is significant higher in AS-active. The methylation level of H3K27 was reduced in AS-active than in others. The protein level of RORc is higher in AS-active and AS-stable, but in transcriptional level the AS-active group was higher than other two groups.

In Figure 2. The protein level and phosphorylated level of JAK2 and STAT3 were higher in AS-active. The transcriptional level were higher too.

**Figure 2 The expression level of JAK2/STAT3 signal pathway in AS**  
with normal controls: \* $p < 0.05$ , \*\*  $p < 0.01$

**Conclusion:** Our study found that JMJD3 catalyzes the demethylation of H3K27 might be an important epigenetic mechanisms in AS inflammatory. The highly expression of JMJD3 in active AS patients may leading to the higher expression of RORc, and could activation the signal transduction through JAK2/STAT3 pathway, inducing a large number of IL-17 secretions. That could be the beginning of the differentiation and function of Th17, and JMJD3 maybe the core epigenetic regulator in this inflammation process. These exciting findings have broad implications for finding possible biomarkers in the inflammatory of AS, and may give us a new possible point of view from the epigenetic regulation mechanism of Th17 in the inflammation stage of AS.

**First publication:** September 18, 2017

**SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Identification of disease-associated or protective bacteria may elucidate new biomarkers or probiotic supplements for people suffering from SpA, or for people at-risk of disease development. The colitogenic *Prevotella copri* was associated with new-onset rheumatoid arthritis, and *Prevotella* spp. were increased in the cecum of HLA-B27 transgenic rats. In ankylosing spondylitis patients, several bacterial families, including *Porphyromonadaceae*, were increased. *Lactobacillus murinus* protects against murine colitis, and ileitis does not occur in germ-free BALB/c ZAP-70<sup>W163C</sup>-mutant (SKG) mice. Thus, microbes are associated with SpA disease progression and regulation but it is unclear how the microbial community structure differs as a result of genetic susceptibility to SpA, or the impact of additional pro-inflammatory triggers. Since SpA is IL-23- and microbe-dependent in SKG mice, we examined the relationship between IL-23, gut dysbiosis and SpA development in response to microbial  $\beta$ -1,3-glucan (curdlan).

### **Methods:**

Altered Schaedler flora (ASF)-colonized SKG and BALB/c mice were treated one day prior to curdlan, and then weekly, with anti-IL-23 p19-specific mAb or isotype control mAb, or with curdlan or vehicle control. SPF-SKG mice were treated weekly with anti-IL-23 or isotype mAb for 3 weeks, then with curdlan or vehicle control. Fecal samples were collected longitudinally and the microbiota community profiles were analyzed by RT-PCR and sequencing of the 16S rRNA gene using Illumina MiSeq technology. Sequence data was analyzed using QIIME and mixOmics platforms. Arthritis, spondylitis and ileitis were assessed histologically.

### **Results:**

After colonizing germ-free mice with ASF, 4/8 bacterial strains were detected in ASF-SKG and ASF-BALB/c mice: *Clostridium* sp., *Lactobacillus murinus*, *Mucispirillum schaedleri* and *Parabacteroides* sp. The relative abundance of *L. murinus* increased in mice treated with curdlan and anti-IL-23 mAb compared with curdlan alone or with isotype mAb. Treatment of naïve SPF-SKG mice with anti-IL-23 mAb significantly altered the fecal microbiota composition relative to isotype mAb treatment for prolonged periods. These shifts persisted after washing out anti-IL-23. The microbiota composition of mice treated with isotype mAb and curdlan was distinct to that of mice treated with anti-IL-23 mAb with curdlan or saline, both of which clustered together regardless of curdlan or saline treatment.

### **Conclusion:**

Interaction of the microbiota with the immune system of SKG mice alters the composition of both a simplified consortium and an unrestricted bacterial community. Curdlan triggers the decline of a gut-protective *Lactobacillus* species within a simplified consortium. Moreover, IL-23 modifies the host's support for this gut-protective species. Treatment of SPF-SKG mice with anti-IL-23 mAb not only suppresses SpA development but shifts the fecal microbiota composition and prevents the usual outgrowth of bacteria associated with arthritis and inflammatory bowel disease in response to curdlan. Our results suggest that positive feedback between host IL-23 and dysbiosis predisposes to a host gut environment hostile to gut-protective species and SpA development.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## Background/Purpose:

Psoriatic arthritis (PsA) occurs in a third of patients with psoriasis (Ps) and up to 30% of patients with PsA do not have an adequate response to any treatment. The precise pathogenesis of PsA/Ps remains unknown and its understanding is crucial for the development of new therapies. We hypothesize that the microenvironment plays a crucial role in shaping the pathogenic immune response. To address this, we utilize a dual approach to decipher the transcriptome of the skin microenvironment and the immunomes of PsA patients with active disease. This multi-dimensional strategy will enable the distillation of immune cell subsets in the periphery that can potentiate pathogenic responses in the microenvironment.

## Methods:

Skin punch biopsies of psoriatic and morphologically normal sites and paired whole blood were obtained from patients (n=3) with active PsA requiring intensification of treatment. Total RNA extracted from the skin punch biopsies and gene expression analysis was performed with Nanostring. Peripheral Blood Mononuclear Cells (PBMCs) from PsA patients (n=3) and sex-matched healthy donors (n=3) were stimulated with PMA-Ionomycin, stained with 37 phenotypic T cells markers and interrogated with the CyTOF platform. Dimensional reduction and unsupervised clustering analyses were performed with Multi-dimensional Automated Reduction and Visualization (MARVis), an in-house customised machine learning software.

## Results:

Nanostring results revealed that gene signatures enriched in psoriatic skin (like *GZMA*, *GZMB*, *ARG1*, *NOS2*) are suggestive of inflammation mediated by subsets of immune cells such as neutrophils, CD8<sup>+</sup> T cells and macrophages. Moreover, several immunoattractant chemokines like *CCL20*, *CXCL13* and *CXCL2* were expressed at higher levels in psoriatic skin compared to morphologically-normal skin. Given the enrichment of chemokines in the microenvironment, we next examined the immune cell subsets in the peripheral blood which may be responding to these chemical signals. We studied the systemic immune profiles of these patients with CyTOF and noticed significant differences in the immunomes of PsA patients compared to healthy donors. Specifically, in PsA patients, we observed a decline in the Mucosal Associated Invariant T (MAIT) population displaying an immune-modulatory phenotype (TCRVa7.2+CD8+CD161+CCR6+IFN $\gamma$ +) and an enrichment in activated CD8<sup>+</sup> T effector cells (CD8+CCR6+CXCR3+Tbet+GranB+). The expression of CCR6 is indicative of the migratory potential of these pro-inflammatory T cells in response to CCL20 to sites such as the skin and joints.

## Conclusion:

Our approach of analysing the psoriatic skin transcriptome and immunome exemplifies the role of microenvironment in shaping the systemic immune response. We observed at the skin level, that the microenvironment secretes a cocktail of chemokines that may serve to shape the composition of the peripheral immunome and affect the relative proportion of cells infiltrating the lesions. These preliminary findings warrant further analysis on a larger PsA patient cohort and will improve the understanding of the pathogenesis of Ps and PsA and facilitate the identification of novel immune therapeutic targets.

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** IL-17A is a central driver of spondyloarthritis (SpA) pathology. IL-17A production was originally proposed to be IL-23 dependent. Emerging preclinical and clinical evidence from SpA-related diseases such as Crohn's disease suggest, however, that IL-17A and IL-23 have a partially overlapping but distinct biology. We aimed to assess to what extent IL-17A is dependent on IL-23 in SpA by selectively targeting the IL-23R in HLA-B27/Huβ2m transgenic rat model of SpA, which we showed previously to be IL-17A-dependent.

**Methods:** HLA-B27/Huβ2m tg rats were immunized with low dose heat-inactivated *M. tuberculosis* to induce experimental SpA. Rats were treated with anti-mouse/rat chimeric IL-23R antibody or vehicle in a prophylactic (treatment initiation before onset of symptoms) or therapeutic (treatment initiation after onset of clinical symptoms) experiment. Spondylitis and arthritis were clinically scored, hind limb swelling was measured. Ex vivo cytokine expression was measured in lymph nodes and spleen. Serum samples were analyzed for anti-IL23R exposure.

**Results:** During prophylactic treatment, 58% and 67% of the rats in the control group developed spondylitis and arthritis, respectively. The average arthritis score at the end of the study was  $3.9 \pm 1.1$  and the average hind paw swelling was  $0.35 \pm 0.09 \text{ cm}^3$ . Prophylactic treatment completely protected against the development of spondylitis and arthritis (figure 1). In the therapeutic treatment strategy, however, anti-IL23R treatment failed to reduce incidence or decrease the severity of experimental SpA (figure 1). The differential effect of IL-23R targeting in the initiation phase versus established disease could not be explained by pharmacokinetic differences, serum analyses revealed similar exposure levels. Mechanistically, the expression of downstream effector cytokines such as IL-17A ( $p < 0.05$ ) and IL-22 ( $p < 0.01$ ) was reduced in the popliteal lymph nodes of rats treated prophylactically with anti-IL23R versus controls, with a similar trend in spleen. Accordingly, IL-17A production upon ex vivo re-stimulation was reduced in samples from prophylactically treated rats. In contrast, similar popliteal lymph node expression data in samples from the therapeutic experiment indicate no difference in IL-17A and IL-22 expression in the anti-IL23R treated rats compared to controls.

**Conclusion:** IL-17A expression and production is dependent on the IL-23 axis in the initiation phase of experimental SpA but not in established disease. Accordingly, targeting of this axis with an anti-IL23R antibody completely prevented the onset of arthritis and spondylitis in HLA-B27/Hu $\beta$ 2m transgenic rats, but failed to reduce axial and peripheral joint inflammation in established disease. The cellular origin of IL-23-independent IL-17A production and the relevance to human SpA remains to be investigated.

Figure 1: Swelling of the hind paws during follow up in prophylactic versus therapeutic treatment with anti-IL-23R or vehicle control (data are means  $\pm$  SEM)

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### Background/Purpose:

Gene expression studies are useful to investigate the pathogenesis of complex diseases. The critical role of antigen-presenting cells such as dendritic cells (DCs) being suspected in SpA, we wished to study their particular biology, starting from unbiased transcriptomic experiment.

### Methods:

MDDCs were obtained from circulating CD14<sup>+</sup> monocytes after 7 days of culture with GMCSF + IL-4. Transcriptomes were profiled using Affymetrix microarrays (HuGene 1.0 ST) and further confirmed by RNA-seq (78 million paired-end reads (2x100 nt) per sample). Differentially expressed (DE) genes between SpA (ASAS criteria) and healthy controls (HC) were listed with LIMMA. Functional annotation was performed with DAVID and InnateDB. RT-qPCR was used to test the reproducibility of the signature over time. Intra-cellular lipid droplets (LD) volume and number were quantified by Bodipy® labeling and confocal microscopy. Cellular content of chol pathway metabolites was quantified by mass spectrometry (MS).

### Results:

For transcriptomic analysis, we generated 3 lists of DE genes (nominal  $p < 0.01$ ) comparing (A) HLA-B27<sup>+</sup> SpA (n=40) to B27-neg HC (n=30), (B) B27<sup>+</sup> HC (n=44) to B27-neg HC and (C) B27<sup>+</sup> SpA to B27<sup>+</sup> HC. Subtraction A–B and intersection with C yielded a robust list of 68 genes affected by SpA controlling for unrelated HLA-B27 effect. Analysis of functional pathways revealed a significant overrepresentation of genes involved in chol

biosynthesis and its regulation ( $p < 1 \times 10^{-4}$ ). Five of the 6 genes in this pathway (SQLE, MSMO1, LDLR, INSIG1, SREBF2) were downregulated in SpA. These findings were confirmed by RNA-seq on the same samples and by qPCR on a new series of samples drawn from the same group of individuals (11 SpA vs. 10 HC). Using MS, we evidenced a significant increase of chol and 27-OH-chol content in MDDC from another panel of SpA ( $n = 14$ ) compared to HC ( $n = 8$ ) ( $p < 0.05$ ), suggesting that downregulation of cholesterol synthesis might be secondary to chol overload. Consistently, there was a highly significant increase in the size ( $p = 5 \times 10^{-4}$ ) and overall volume ( $p < 2 \times 10^{-4}$ ) of LD in SpA ( $n=12$ ) compared to HC ( $n=11$ ) MDDCs (Figure). Importantly, there was no difference of total nor fractionated chol plasma levels between SpA and controls.

## Conclusion:

Our study identified a downregulation of the chol synthesis pathway in MDDCs from SpA patients that seems to be secondary to lipid overload in those cells. Our findings are consistent with a state of pre-activation of those cells that could lead to a strong inflammatory response to endogenous or environmental stimuli.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The association between HLA-B27 and spondyloarthritis (SpA) remains unexplained more than 40 years after its discovery. To further explore the pathogenic role of HLA-B27, we produced transgenic *Drosophila* for several human HLA-B alleles, associated (B\*2705, B\*2704) or not (B\*0702) with SpA, and for the b2m invariant chain partner.

**Methods:** Transgenes were expressed with different drivers in the wing or eye imaginal discs (*i.e.* the precursor tissues of the adult fly wing or eye). Their expression was examined by PCR and Western-blot. Cell surface or intra-cellular levels of unfolded (HC10 antibody) and well-folded (ME1 and W6/32 antibodies) HLA-B were examined by FACS and by immunofluorescence (IF). Genetic interactions with candidate genes controlling several signaling pathways were addressed.

**Results:** IF experiments revealed high levels of well-folded HLA-B27 alleles on the cell surface, but less of the HLA-B\*0702. FACS analysis confirmed that HLA-B\*2705/b2m and HLA-B\*2704/b2m better fold than HLA-B\*0702/b2m, in *Drosophila*. Co-expression of HLA-B27 (B2705 or B2704) alleles and b2m in the wing tissue specifically induced the loss of posterior and anterior cross-veins leading to a CVL phenotype. Furthermore, the eye size was reduced when HLA-B27 alleles (but not HLA-B\*0702) were expressed in this tissue with b2m. Genetic interaction tests for candidate signaling pathways involved in the eye and wing development showed a selective decrease of the Bone Morphogenetic Protein (BMP) signaling when HLA-B\*2705/b2m was expressed with no evidence for ER stress induction. Those results were confirmed by the decreased phosphorylation of the transcription factor MAD. Altogether, our results allow us to hypothesize that HLA-B\*2705 could act downstream of the BMP receptor. Moreover, overexpression of the *Drosophila* SMAD7 homolog *Dad*, a negative regulator of the BMP pathway, was observed. Interestingly, transcriptomic study showed that SpA-prone HLA-B27/b2m transgenic rat lines also exhibit a specific increase of SMAD7 in their dendritic cells.

**Conclusion:** HLA-B27 seems to have a better capacity to fold and reach the cell surface than HLA-B\*0702, in the presence of b2m in *Drosophila*, even in the absence of the class-I MHC peptide-loading complex machinery. CVL and small-eye phenotypes resulting from the expression of both SpA-associated HLA-B27 subtypes (*i.e.* B\*2705 and B\*2704) but not of HLA-B\*0702 was induced by disrupting MAD phosphorylation. Those results highlight the effectors (rSMADs) and inhibitor (SMAD7) of the BMP/TGF $\beta$  pathway as candidate targets for the pathogenic role of HLA-B27 in SpA.

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Although accumulating evidence continues to point toward a critical role for IL23 signaling in spondyloarthritis (SpA), the cellular and molecular events involved, as well as the respective contributions of enthesial and synovial inflammation, remain incompletely understood. In this study we have combined ex vivo organ culture of enthesial and synovial explants from SpA patients and controls with in-situ hybridization (ISH) and gene expression analysis of synovial tissue to further delineate the molecular and cellular pathogenesis underlying SpA.

**Methods:** Under an HSS IRB approved protocol, patients undergoing total hip replacement (THR) were recruited into 3 groups: **SpA** (either psoriatic arthritis or ankylosing spondylitis, meeting ASAS or CASPAR criteria or were being treated with DMARDS/biologics); **HO** (OA patients a previous contralateral THR who had history of post-THR heterotopic ossification) and **OA** (OA patients a previous contralateral THR with no history of HO. For Phase 1 of this study (n=15/group), synovial tissue was collected intra-operatively and immediately aliquoted into RNA later for RNA isolation and subsequent sequencing, or OCT for ISH analysis. For Phase 2 (n=10/group), enthesal tissue (ligamentum teres) and synovial tissue were cultured +/- RORγT inhibitor (2 hours) followed by +/- cytokine stimulation (hTNF/hIL23) for 24 and 48 hours. These cultures were analyzed via MSD for secreted cytokines and via TaqMan RT-PCR.

### **Results:**

RNA sequencing identified the presence of a macrophage signature with elevation of MMPs and MARCO in SpA tissue. Additionally preliminary ISH analysis has shown a potential enrichment of CD163 positive macrophages in areas of synovial inflammation. Expression analysis of ALI cultured explants also identified a remarkable enrichment of MARCO-positive macrophages in synovium (cf enthesis) and, consistent with the RNA sequencing of whole tissue, induction of MMP production in synovium following cytokine stimulation. In contrast enthesal tissue that had a lower MMP and MARCO signature, responded to cytokine stimulation with induction of IL17A/F and IFNγ. Importantly, this latter effect was most pronounced in SpA patients and inhibited by an ROR inhibitor.

### **Conclusion:**

Our results suggest that the synovial and enthesal tissues in SpA patients have distinct cellular phenotypes and differential responses to cytokines and involvement of ROR $\gamma$ t signaling. In line with previous observations (refs) a prominent macrophage signature is seen in the synovium, and this is associated with elevation of MMP induction in SpA. Whereas enthesal tissue produced IL17 and IFN $\gamma$  in response to TNF and IL23, consistent with the presence of a resident population of IL23R positive T cells at this site in SpA.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

Dysregulated IL-23/IL-17 responses have been linked to a myriad of inflammatory diseases including psoriasis, psoriatic arthritis and other forms of spondyloarthritis (SpA). IL-23/IL-17 inflammation is controlled by ROR $\gamma$ t, the key Thelper17 (Th17) cell transcriptional regulator. ROR $\gamma$ t is also expressed by subsets of innate-like T cells, including invariant natural killer T (iNKT) and  $\gamma\delta$ -T cells, but how this contributes to inflammatory disorders such as SpA is still unclear.

## Methods:

Blood samples were obtained from 27 healthy control subjects and 33 patients with newly diagnosed SpA (following ASAS 2010 criteria). Synovial fluid (SF) was obtained from patients with an active knee synovitis and an indication for aspiration. Patients were treatment naïve or under treatment with a NSAID and/or DMARD (Methotrexate, Sulfasalazine), but naïve for treatment with biologicals at the time of sampling. PBMC and SFMC were isolated from patient samples and were directly analyzed by multi-color flow cytometry for analysis of iNKT cells (CD3+6B11+ TCRV $\beta$ 11+),  $\gamma\delta$ -T cells (CD3+TCR $\gamma\delta$ +) and CD161+ and CD161- conventional Tconv (T cells excluded from innate-like T cells). Rorc and Il-23r mRNA expression on specific T cell subsets was measured by means of PrimeFlow RNA Assays. Flow cytometric data were analysed by standard gating procedures using FlowJo software and further explored by FlowSOM, a novel method for computational multi-color flow cytometry. Furthermore, sorted  $\gamma\delta$ -T cells and iNKT cells were cultured in the presence of  $\alpha$ GalCer (for iNKT) or aCD3/aCD28Ab ( $\gamma\delta$ -T cells) with addition of IL-23, IL-1 $\beta$ , TGFB1 and IL-2 (IL-23 cocktail) in the presence or absence of a ROR $\gamma$ t inhibitor. Cytokine production of cells was determined by intracellular flow cytometric staining or in supernatants by multiplex protein assays (MSD). In addition, phenotypical analyses were done by qPCR with specific primers for *IL-23R*, *IL-17A* and *F*, *IL-22* and *RORC*.

## Results:

Here, we describe a unique population of ROR $\gamma$ t<sup>+</sup>T-bet<sup>lo</sup>PLZF<sup>-</sup> iNKT and TCR $\gamma\delta$ -hi T cells ( $\gamma\delta$ -T cells with a high expression of the  $\gamma\delta$ TCR), present in healthy peripheral blood. iNKT and  $\gamma\delta$ -hi T cells showed marked IL-23 mediated Th17-like immune responses and are clearly enriched within inflamed joints. Interestingly, in depth metacluster analyses by FlowSOM iterations showed skewing of novel iNKT cell subsets, already detectable in the blood of SpA patients. ROR $\gamma$ t blocked Th17 cell function and inhibited IL-17 production while surprisingly preserved IL-22 production by iNKT and  $\gamma\delta$ -T cells. Further FlowSOM analyses showed that ROR $\gamma$ t inhibition impacts distinctive IL-17+ iNKT cell subsets while preserving IL-22 subsets.

## Conclusion:

Overall, these findings highlight a unique diversity of human ROR $\gamma$ t<sup>+</sup> innate-like T cells and underscore the potential of ROR $\gamma$ t antagonism to modulate aberrant Type 17 responses.

# Increase in Arginase Activity and Related Arginine Metabolites in Patients with Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA): Potential Mechanisms for Endothelial Dysfunction

**M. Elaine Husni**<sup>1</sup>, Vandana Rai<sup>2</sup>, Marcia Leon Rabanal<sup>3</sup> and Unnikrishnan Chandrasekharan<sup>4</sup>, <sup>1</sup>Cleveland Clinic, Cleveland, OH, <sup>2</sup>Cellular and Molecular Medicine, Cleveland Clinic Foundation, Cleveland, OH, <sup>3</sup>Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, <sup>4</sup>Department of Cellular and Molecular Medicine, Cleveland Clinic, Cleveland, OH

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

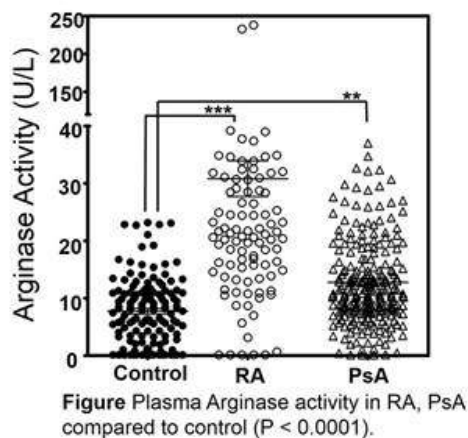

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A high prevalence of CVD exists among patients with PsA and RA. The cardiovascular morbidity and mortality are hypothesized to be due in part to persistent systemic inflammation. Chronic inflammation promotes endothelial dysfunction with reduced vascular reactivity, leading to CVD. L-arginine metabolism is critical for maintaining normal endothelial homeostasis, and arginases are the central enzymes in the urea cycle that catalyze L-arginine to L-ornithine and urea. L-arginine is also the sole source of nitric oxide (NO), an enhancer of endothelial function as well as modulator of insulin sensitivity, whose production is catalyzed by NO synthases (NOS). Elevated arginase activity diminishes L-arginine bioavailability, thus decreasing NO production, which may lead to CVD by promoting endothelial dysfunction. Furthermore, elevated arginase activity leads to excessive production of ornithine leading to vascular problems. The aim of this study is to identify specific pathways leading to aberrant L-arginine metabolism as a potential cause of the increased CVD risk observed in RA and PsA patients.

**Methods:** Liquid chromatography-mass spectrometry was used to measure plasma levels of L-arginine and its metabolites [L-ornithine, L-citrulline, asymmetric dimethylarginine (ADMA) and symmetric dimethylarginine (SDMA)]. Global arginine bioavailability ratio (GABR, ratio of L-arginine to L-ornithine + L-citrulline) and arginine methylation index (ArgMI, ADMA + SDMA/MMA) values in RA and PsA were compared to those in control subjects. Plasma arginase activity was measured using Quantichrom Arginase Assay kit, according to the manufacturer's instructions. Correlations between L-arginine metabolites and cardiovascular risk factors are analyzed using Spearman correlation.

**Results:** There was a 400% and 160% increased level of plasma arginase activity in RA (n=119) and PsA (n=233) subjects, respectively, as compared to controls (n=148). Also, RA patients with existing CVD had higher arginase activity than RA patients without CVD. In addition, we found increased abundance of methylated arginines in RA and PsA. Compared to controls, the RA patients showed significantly lower levels of plasma L-arginine, and GABR and elevated levels of ADMA, SDMA and ArgMI. Arginase activity and L-ornithine were elevated in RA, while the level of L-citrulline was diminished. In comparison to controls, the PsA patients also showed lower levels of plasma L-arginine as well as elevated levels of plasma ADMA and SDMA.

**Conclusion:** Elevated plasma arginase activity and dimethylarginine in RA and PsA subjects may contribute to impair NO generation, which may lead to accelerated atherosclerosis. Future studies should explore potential therapeutic interventions targeting dysregulation of arginine metabolism.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Spondyloarthropathies and Psoriatic Arthritis – Pathogenesis, Etiology Poster II

**Session Type:** ACR Poster Session B

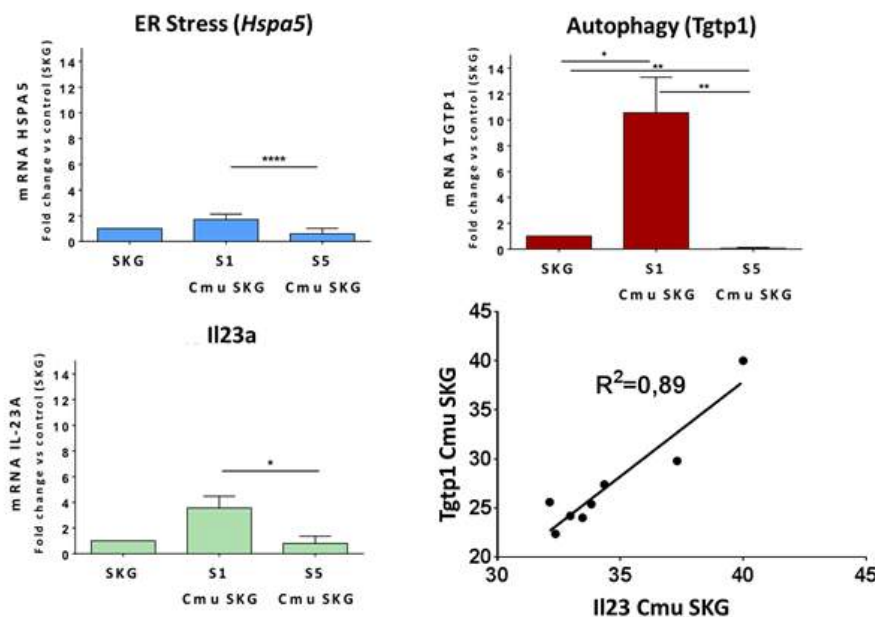

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** The sterile inflammatory arthritis associated with spondylitis, uveitis and rash, known as reactive arthritis, commences a few weeks after certain gastrointestinal or genitourinary infections, including Salmonella and Chlamydia in genetically-susceptible patients. ZAP-70<sup>W163C</sup> mutant BALB/c mice (known as SKG) develop a syndrome highly similar to human reactive arthritis after vaginal infection with *C. muridarum*. In that model, Chlamydial DNA was found in splenic and lymph node CD11b+ cells distant from the site of infection. We hypothesized that monocytes and macrophages disseminate pro-inflammatory *C. muridarum* pathogen-associated inflammatory molecules (PAMPs) to distant sites in susceptible SKG mice to induce inflammatory cytokine-mediated pathology.

**Methods:** Female SKG and BALB/c mice were genitally infected with *C. muridarum*. Arthritis was assessed weekly for 12 weeks post-infection. Joint sections were scored after sacrifice and genital tracts were analyzed 1 week post-infection. We compared *Hspa5*, *Tgtp1*, *IL-23* expression by RT-qPCR in genital tract from SKG mice before or 1 week after infection. Anti-TNF or isotype were delivered either immediately after infection or after arthritis developed. We engineered *C. muridarum* expressing luciferase and GFP (pGFP-Luc-CM) to monitor *in vivo* uptake and dissemination. We depleted macrophages from Chlamydia-infected SKG mice with clodronate liposomes.

**Results:** SKG but not BALB/c mice developed typical histological features of chronic reactive arthritis but remained autoantibody-negative, from 5 weeks after genital infection. When applied at infection, anti-TNF blocked *C. muridarum*-induced reactive arthritis in SKG mice. Seven weeks post-infection, SKG but not BALB/c mice developed inflammatory salpingitis. One week post-infection, we observed *C. muridarum* dissemination in the upper genital tract of SKG but not BALB/c mice. After infection with pGFP-Luc-CM, *C. muridarum* GFP signal was exclusively found in CD11b+Ly6g-Lyc6c+F4/80+MHC class II+ macrophages in both strains. Expression of macrophage *Tgtp1* and *IL23a* but not *Hspa5* expression was upregulated one week after *C. muridarum* infection and returned to baseline levels 5 weeks after infection. *Tgtp1* and *IL23a* mRNA expression were highly correlated (Figure) in genital tract one week upon infection. Depletion of macrophages using clodronate liposomes just prior to infection prevented arthritis.

**Conclusion:** These data indicate that macrophages, IL-23 and TNF are required for the development of Chlamydia-induced reactive arthritis in SKG mice. Macrophages exclusively take up Chlamydia from the site of infection and, in susceptible mice/individuals, upregulate autophagy and IL-23 production and transport persistent bacteria to distant sites such as upper genital tract and joints to trigger TNF-mediated inflammatory pathology.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

Atherosclerosis in SLE results from a complex interplay between traditional risk factors, SLE-specific factors, chronic inflammation and multifaceted effects of SLE therapeutics. In particular, corticosteroids may exert a double-edged effect by increasing traditional risk factors on one hand and inhibiting the inflammatory process on the other. In this meta-analysis, we aim to determine the association between corticosteroids and subclinical atherosclerosis in SLE patients and investigate the influence of strength, duration and cumulative dose of steroids.

### **Methods:**

A comprehensive literature search was conducted in Cochrane Library, Scopus, MEDLINE, PubMed and EMBASE for articles published in English from January 1985 through June 2016 in adult age group. Studies were eligible if they presented the dose of steroid administered to the SLE group and used mean CIMT as evaluated by high-resolution ultrasound (surrogate marker of subclinical atherosclerosis). Two independent reviewers performed study selection and data extraction. All articles with multiple publications were considered for data extraction but only one was used for final analysis. The required data to estimate the effect-sizes associated with each study was extracted. Using Hedges' random-effect model, the estimated effect-sizes were pooled together. Heterogeneity was explored using subgroup analysis and meta-regression technique. Publication bias was tested using funnel plot and Eggers test.

### **Results:**

Out of 254 citations, 24 studies were eligible. Disease characteristics and quality score of the studies are shown in Table 1. The pooled effect size showed statistically significant increase in subclinical atherosclerosis in SLE patients (SMD=0.821, P=0.000; 95% CI, 0.512 to 1.22). In a univariate meta-regression model, corticosteroid consumption significantly increased the risk of subclinical atherosclerosis in SLE patients (B=0.018, P= 0.027; 95% CI, 0.002 to

0.035). Result also showed, there was insignificant relationship between the duration as well as cumulative dose and the risk of subclinical atherosclerosis in SLE patient. Subgroup analysis showed that the above association of corticosteroid and subclinical atherosclerosis in SLE patients is not affected by the dose of the steroid.

## Conclusion:

Our findings concluded that corticosteroids increase the risk of early atherosclerosis in SLE patients. We also found that subclinical atherosclerosis is not influenced by the strength, duration or cumulative dose of steroids. The biggest challenge to this analysis is the heterogeneity of the studies included. Further research is needed to better understand the adjusted effect of SLE disease activity in the role of steroids in subclinical atherosclerosis.

**First publication:** September 18, 2017

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Resistant hypertension (RHTN) is defined as blood pressure that remains >140/90 mm Hg despite concurrent use of three different antihypertensive drugs. RHTN has an incidence of 0.7 cases per 100 person-years among patients with hypertension and is associated with a 47% increased risk of cardiovascular events. However, there is no information about RHTN in SLE. Therefore, we estimated the incidence of RHTN in patients with SLE and compared demographic characteristics, immunologic markers, renal function, and mortality in patients who did and did not develop RHTN.

**Methods:** Patients with SLE were identified from the electronic health records at an academic medical center using a validated algorithm that has a positive predictive value of 94%. The diagnosis of RHTN required the use of 3 antihypertensive drugs concurrently and a mean blood pressure >140/90 mm Hg during the following six months, or the use of  $\geq 4$  antihypertensive drugs simultaneously. Age, sex, race, immunologic laboratory results, creatinine concentrations at the time of first visit for SLE were compared among patients who developed RHTN and those who did not. Mortality was estimated and compared among patients with and without RHTN during subsequent follow-up.

**Results:** Of 1,135 patients with SLE identified, 27 were excluded due to pre-existing RHTN present before the first ICD9 code for SLE. Ninety-one patients (8.9%) developed RHTN and 1,017 did not over a follow-up of 7,689 person-years, with an incidence rate of 1.2 cases/100 person-years. Age and sex distribution were similar in patients

who developed RHTN and those who did not (Table 1), but patients with RHTN were more likely to be African American ( $p<0.001$ ), and had lower C3 ( $p=0.01$ ), higher CRP ( $p<0.001$ ), higher erythrocyte sedimentation rate ( $p<0.001$ ), and higher creatinine ( $p<0.001$ ) at baseline (Table 1). Twenty one patients with resistant hypertension and 111 patients without resistant hypertension died. A logistic regression model indicated higher mortality associated with RHTN [odds ratio: 2.45, (95% CI 1.45-4.14),  $p<0.001$ ].

**Conclusion:** Patients with SLE have an incidence rate of RHTN of 1.2 cases/100 person-years, which is higher than that reported in a population of patients with hypertension. RHTN is more frequent in African-American than Caucasian lupus patients and those with low C3 levels, higher inflammatory markers, and increased creatinine. RHTN is associated with increased mortality in patients with SLE.

**Table: Patient Characteristics at the time of first ICD9 Code for SLE**

	<b>RHTN</b> n=91	<b>No RHTN</b> n=1017	<b>P-value</b>
<b>Demographics</b>			
Age, years	42 [22-56]	39 [27-51]	0.59
Female, n (%)	82 (90.1%)	914 (89.9%)	0.94
Caucasian, n (%)	43 (47.3%)	702 (69.0%)	<0.001
African American, n (%)	43 (47.3%)	231 (22.7%)	
Race other or unknown, n (%)	5 (5.5%)	84 (8.3%)	
<b>Immunologic markers</b>			
C3, mg/dl**	96 [69-123]	111 [82-132]	0.01
C4, mg/dl**	19 [14-28]	20 [12-28]	0.62
CRP, mg/L**	10.4 [2.8-41.7]	3.5 [1.0-12.2]	<0.001
ESR, mm/hr**	40 [18-78]	25 [10-49]	<0.001

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

The aim of this work is to study the prevalence of mycobacterial infection (M.I.), the associated factors and their clinical significance in patients included in a large SLE cohort.

### **Methods:**

Retrospective descriptive study of RELESSER patients with a history of M.I. and analysis of the factors associated with the infection of this etiology.

### **Results:**

In RELESSER 3,658 SLE patients were included. 90% are women with a mean age of 32.9 years. 93% are Caucasians. The mean follow-up time ( $\pm$  S.D.) was 120.2 ( $\pm$  87.6) months. 705 (19.3%) patients had at least a serious infection, 1,227 serious infections occurred. M.I. were diagnosed in 42 patients (1.2% of all RELESSER patients, 3.4% of all serious infections), 85.7% women. The incidence rate of mycobacterial infection was 1 per 1,000 patients/year (95%CI:0.7-1.4).

M.I. presentation was pulmonary in 18 (42.9%) patients and extrapulmonary in 24 (57.1%) patients [joints in 8 (19.0%) patients, soft tissue in 6 (14.3%) and other sites in 10 (23.8%)]. The extrapulmonary form was associated with the use of immunosuppressants: 84.6% of the 13 patients treated with immunosuppressive drugs versus 44.4% of the 27 patients without ( $p=0.01$ ). We did not observe this association with the use of corticosteroids.

To study the factors associated with mycobacterial infection, we performed a bivariate analysis including the variables associated with severe infection identified in RELESSER (age, sex, ethnicity, use of corticosteroids, immunosuppressants, antimalarials, previous admission by SLE activity, use of rituximab, use of anti-TNF, Katz severity index, SDI damage index, SLEDAI activity index and Charlson comorbidity index). There is a statistically significant association with previous admission by SLE activity (RR:2.9, 95-95%:1.3-6.2,  $p=0.007$ ), renal impairment (RR:2.0, CI 95%:1,1-3,7,  $p=0,04$ ), the Katz score (RR:2.1, 95% CI:1.1- 4.0,  $p=0.04$ ) and the Charlson index (RR: 2.5; 95% CI: 1.3-4.8,  $p=0.009$ ). The accumulated damage ( $SDI > 0$ ) was closely associated with significance:RR: 2.0; 95% CI: 1.0-4.0,  $p=0.07$ . The use of immunosuppressants was associated with a significant increase in the risk of mycobacterial infection: RR:4.3; 95% CI:2.2-8.3,  $p=0.31$ .

Two patients (4.8%) died (1 respiratory and 1 extrapulmonary). The mean survival after diagnosis in these cases was 21 days.

### **Conclusion:**

M.I. in RELESSER affects 1.15% of patients. Its incidence rate is 1 per 1,000 patients/year (95%CI:0.7-1.4). Extrapulmonary localization affects more than half of the patients and is associated with the use of immunosuppressants. Previous admission by SLE activity, renal involvement, severity of SLE, and increased number of associated comorbidities are factors associated with the existence of mycobacterial infection.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

### **Background/Purpose:**

There is limited evidence on the risk of neoplasia in autoimmune diseases such as systemic lupus erythematosus. The objective of this study is to analyze the incidence of cancer in the Spanish population with SLE and the factors associated in its development: RelesSER Registry Data.

### **Methods:**

We calculated the incidence density of malignant neoplasms, the standardized incidence ratio and the average time to develop the first neoplasm after diagnosis of SLE in patients of the SLE registry of the Spanish Rheumatology Society (RelesSER) fulfilling ACR97 criteria. We carried out a bivariate analysis of the associated factors to neoplasms and multivariate by logistic regression.

### **Results:**

A total of 3607 patients (90.4% female) were included. We registered 140 neoplasms in women (4.3%) and 14 in men (4%) ( $p < 0.821$ ). Incidence density 7.3 / 1000 patient-years (95%CI:4.85-10.98) (7.39 in patient-years women and 6.93 in men) without significant differences. After stratification by gender and age, cancer appeared in 3.2% of the women aged under 45 versus 3.8% of the men; 4.1 % of women aged 45-65 years versus 5.9% of men and a

5.3% of women 65 and older versus 2.5% of men the same age. The standardized incidence ratio (SIR) was 2.16; 1.51 in men and 2.38 in women, highest for women under 65 years old. The SIR for > 65 years was 0.98; 0.59 in men and 1.55 in women.

The average time until development of the first malignant neoplasm was 10 years (RI:5.75-17.00), being lower in women [9.5(RI:5.00-17.0) years] than in men [12.5(8.75-17.5)] and in patients under 45 years versus over 45 years [8.0(RI:5.00-16.00)].

Malignant neoplasms were the cause of death in 10% of the patients (15/154), predominantly hematological and breast cancers, both at 19% followed by lung cancer in 14.3%.

Factors associated to malignant neoplasms in the bivariate analysis are shown in (table 1). No immunosuppressive therapy was associated with the development of neoplasms. In the multivariate model, adjusted for age and time of disease duration, age was the only significant variable (OR:1.030; 95%CI: 1.003-1.059; p=0.029) with a trend for ACE inhibitors use (OR:1.866; 95%CI: 0.808-4.306; p= 0.144), SLEDAI (last visit) (OR :0.904; 95%CI: 0.806-1.015; p= 0.089, SLICC/ACR DI) (without neoplasias) (OR: 1.160; 95%CI: 0.961- 1.401; p= 0.123), and duration of the disease in months (OR: 1.003; 95% CI: 1.000–1.006; p= 0.068).

### Conclusion:

The incidence of neoplasia in Spanish women with SLE is higher than expected for age and gender. Malignant neoplasms were the cause of death in 10 % of the patients, predominating hematological and breast cancers followed by lung cancer.

Acknowledgements:"The RelesSER registry has been supported by the FIS (ISCIII) - European Regional Development Fund (FEDER), fellowship PI11 / 02857." It has also been partially funded by: GSK, UCB, Roche and Novartis."

Table1- Factors associated to malignant neoplasms in the bivariate analysis

	Cáncer	Control	Value of p
Gender, men %	4	96	0.821
Gender, women %	4.3	95.7	0.821

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

EULAR and ACR are supporting multi-phase development of SLE classification criteria based on weighted criteria and a continuous probability scale. Prior steps included criteria generation, criteria reduction through Delphi and Nominal Group Technique exercises, literature review for sensitivity/specificity of candidate criteria, and organization of candidate criteria into seven clinical and three immunologic domains. Our next goals were to refine definitions of candidate criteria, determine relative weights using multicriteria decision analysis (MCDA), and identify a threshold score on a continuous scale for SLE classification.

## **Methods:**

An SLE Expert Panel (9 North American, 8 European) submitted 167 unique cases, with range of SLE probability. Experts scored 20 representative cases using the candidate criteria and rank-ordered them. In a two day meeting, experts reviewed inter-rater reliability of scoring, refined criteria definitions, and participated in a MCDA exercise using 1000Minds<sup>TM</sup> software. Experts were presented with a series of decisions between two cases, each with different criteria from two domains (e.g. oral ulcers [cutaneous] and acute pericarditis [serositis] vs. alopecia [cutaneous] and pleural effusion [serositis]). Experts anonymously voted for the case more likely to be classified as SLE. Votes were discussed until consensus was reached for each decision. Using the consensus decisions, 1000Minds<sup>TM</sup> calculated criteria weights, assigned a total score to each of remaining 147 cases and rank-ordered the cases. Experts voted on whether each case should be classified as SLE. The score of the last case for which consensus was achieved was the threshold score. Experts repeated the MCDA for criteria whose calculated weights were inconsistent with expert opinion until group consensus was achieved.

## Results:

Inter-rater reliability was good; human data entry error, not following instructions, and differing interpretations of criteria definitions accounted for discrepancies. Arthritis and pericarditis definitions were modified through group discussion. The MCDA involved 74 pairwise decisions. Cranial neuropathy and Class VI lupus nephritis were removed as they added little to SLE classification. MCDA was repeated for the arthritis and cutaneous domains as initial weights did not match expert opinion. Criteria weights and scores were re-calculated. Experts reached consensus for SLE classification for case scores >83.

## Conclusion:

Using an iterative process, the expert panel refined and weighted candidate criteria definitions and determined a threshold score of >83 for SLE classification. Validation is the next step.

## Prolonged Antimalarial Treatment Increases the Risk for Severe Brady-Arrhythmias in Systemic Lupus Erythematosus

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Severe brady-arrhythmias [complete atrioventricular block (cAVB) and sick sinus syndrome (SSS)] have a prevalence of 0.04% and 0.8% in the general population respectively and are sparsely reported in systemic lupus erythematosus (SLE). Immune-mediated damage to the conduction system and atherosclerosis represent the most important risk factors. However, several case reports raised the possibility that antimalarials (AM) may play a role. The aim of the present study is to analyze the characteristics and associated factors of such arrhythmias in a defined lupus cohort.

**Methods:** The database of a large lupus clinic was searched for patients who received a permanent pacemaker (PPM) from 2000 to December 2016. Demographic, clinical, immunological and therapeutic data along with electrocardiographic (ECG) and echocardiographic (ECHO) variables were analyzed (based on the last available ECG and ECHO, respectively). Patients with a PPM due to brady-arrhythmias (cases) were compared with age-, sex- and disease duration-matched ( $\pm 5$  years) patients without a PPM (controls, 1:2 ratio). Statistical analysis was performed with SAS 9.0;  $p < 0.05$  was considered significant.

**Results:** Out of 1366 patients, 18 (14 females) received a PPM, 13 with cAVB (prevalence 0.95%) and 5 with SSS (0.37%). Six patients (33.3%) had coronary artery disease (CAD) whereas four (22.2%) had cardiac surgery shortly before PPM implantation. Seven patients (38.9%) did not have any risk factors (coronary angiography at the time of PPM implantation was normal in all of them, no prior structural heart disease). Six of these 7 patients developed ocular toxicity due to chronic AM treatment (all were taking AM for 22.6 years on average) shortly before or after PPM. One patient received a PPM two years after renal transplantation. A comparison between cases and controls for associated factors is shown in Table 1.

<b>Table 1. Comparison between patients with severe brady-arrhythmia and controls for demographic variables, prior heart disease, atherosclerotic risk factors and disease-related variables.</b>			
<b>Variable (at PPM implantation)</b>	<b>Cases (n=18)</b>	<b>Controls (n=34)</b>	<b>P</b>
Age (y)	55.14 $\pm$ 17.42	58.9 $\pm$ 13.06	0.158

Endocarditis ever	4 (22.2%)	4 (11.8%)	0.248
Valvular surgery ever	2 (11.1%)	0 (0%)	N/A
Pulmonary arterial hypertension ever	2 (11.1%)	4 (11.8%)	0.414
Body Mass Index	27.35 $\pm$ 5.98	25.92 $\pm$ 5.47	0.569
Hypertension ever	16 (88.9%)	22 (64.7%)	<b>0.013</b>
Hyperlipidemia ever	12 (66.7%)	13 (38.2%)	<b>0.05</b>
Diabetes ever	4 (22.2%)	3 (8.8%)	0.206
Smoking ever	8 (44.4%)	13 (38.2%)	0.08
SLEDAI-2K	2.11 $\pm$ 3.38	3.62 $\pm$ 4.09	0.136
AMS up to 2 years before PPM	2.06 $\pm$ 3.17	3.11 $\pm$ 3.46	0.199
SLICC/DI	3.83 $\pm$ 2.23	2.74 $\pm$ 2.88	0.1
End-stage renal disease	2 (11.1%)	2 (5.9%)	0.317
eGFR	63.27 $\pm$ 23.85	78.24 $\pm$ 32.16	<b>0.025</b>
Cumulative steroid dose	58.17 $\pm$ 49.86	42.44 $\pm$ 46.23	0.313
Years on antimalarials	15.44 $\pm$ 6.83	11.62 $\pm$ 9.95	<b>0.013</b>
CAD: coronary artery disease, MI: myocardial infarction, PTCA: percutaneous transluminal coronary angioplasty), AMS: Adjusted Mean SLEDAI-2K, eGFR: estimated Glomerular Filtration Rate			

Significant differences in ECG variables included 1<sup>st</sup> degree AVB [16.7% vs. 0%,  $p=0.02$ ], right bundle branch block [55.6% vs. 3.3%,  $p<0.001$ ] and left anterior fascicular block [44.4% vs. 0%,  $p<0.001$ ]. ECHO variables revealed a significant difference in the prevalence of septal hypertrophy [46.7% vs. 25%,  $p=0.014$ ]. Multi-variate analysis revealed that prolonged AM treatment was the only independent factor associated with the development of such arrhythmias [OR=1.15, 95%CI=1.01-1.31,  $p=0.035$ ].

**Conclusion:** The prevalence of cAVB in SLE was approximately 24-fold that of the general population. Prolonged AM treatment increases the risk for severe brady-arrhythmias and may be considered as their cause in the absence of

other risk factors. Certain ECG characteristics (RBBB, LAFB) may represent indicators of an ongoing damage in the conduction system and should be monitored in such patients.

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Disease course in systemic lupus erythematosus (SLE) is believed to follow three distinct patterns over time, namely relapsing-remitting, persistently active and prolonged quiescent. We recently showed that a small subgroup of patients might follow a course characterized by an initial active clinical presentation, followed by complete clinical remission, occasionally with no medications. The aim of the present study was to assess the prevalence, demographic, clinical and immunological characteristics of such patients.

**Methods:** The inception cohort a large lupus clinic (patients enrolled within 18 months from diagnosis) was investigated. Selected patients had a minimum follow-up of 10 years and no interval greater than 18 months between consecutive visits. Prolonged clinical remission was defined as clinical SLEDAI-2K=0 (serology excluded), achieved within the first five years since diagnosis and maintained for  $\geq 10$  years. Descriptive statistics were used.

**Results:** Of 883 inception patients, 382 met inclusion criteria. Twenty-seven (24 females, 21 Caucasians) achieved prolonged clinical remission (prevalence 7.1%) in  $1.6 \pm 1.3$  years (median 1.2) since diagnosis. Mean age at diagnosis was  $39 \pm 14.1$  years. Clinical manifestations at diagnosis included mucocutaneous involvement in 19 (70.4%), arthritis in 16 (59.3%), serositis in 5 (18.5%), nephritis in 7 (25.9%), central nervous system in 2 (7.4%) and cytopenias in 15 (55.6%). Immunological and therapeutic characteristics are shown in Table 1.

Table 1. Clinical, immunological and therapeutic characteristics at enrollment and at 10 years		
Variable	At enrollment	At 10 years
SLEDAI-2K (mean±SD)	10.7±11.6	1.19±1.59
Low C3/C4	9 (33.3%)	8 (29.6%)
Anti-dsDNA (+)	13 (48.1%)	6 (22.2%)
Anti-SSA/Ro (+)	8 (29.6%)	8 (29.6%)
Anti-SSB/La (+)	1 (3.7%)	2 (7.4%)
Anti-Sm (+)	1 (3.7%)	3 (11.1%)
Anti-RNP (+)	3 (11.1%)	5 (18.5%)
Antimalarials (n, %)	16 (59.3%)	11 (40.7%)
Glucocorticosteroids (n, %)	17 (63%)	6 (22.2%)
Mean prednisone dose (mg/day)	16.8±9.5	5.3±3.2
Immunosuppressives (n, %)	9 (33.3%)	3 (11.1%)
SLICC/DI (mean±SD)	0.26±0.53 *	0.96±1.06
* At one year after diagnosis, SLICC/DI: Systemic Lupus International Collaborating Clinics/Damage Index		

Cumulative glucocorticosteroid dose over 10 years was 18.1±12.4grams. Beyond 10 years, 7 patients (25.9%) relapsed at a mean of 15.2±3.8 years since diagnosis (four with musculoskeletal and/or skin involvement). In the remaining three patients (two with nephritis and one with catastrophic antiphospholipid syndrome), the flare occurred during or shortly after pregnancy. Twenty of the 27 patients (5.2% of the entire cohort) sustained remission for the entire length of follow-up (17.8±6.7 years) and thus had pure monophasic disease. Twelve patients (44.4%) were not taking any medications after 10 years. Three patients died (11.1%), one from lung cancer and two from unknown cause.

**Conclusion:** A monophasic disease course was observed in 5.2% of our inception SLE patients, while approximately half of them maintained remission without any medications after 10 years from diagnosis.

## Antimalarial-Induced Cardiomyopathy in Systemic Lupus Erythematosus

**Konstantinos Tselios**<sup>1</sup>, Mery Deeb<sup>2</sup>, Dafna D Gladman<sup>3</sup>, Paula Harvey<sup>4</sup>, Shadi Akhtari<sup>4</sup>, Susanna Mak<sup>5</sup>, Jagdish Butany<sup>6</sup> and Murray Urowitz<sup>7</sup>, <sup>1</sup>Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>2</sup>Division of Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, <sup>3</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, <sup>4</sup>Cardiology, Women's College Hospital, University of Toronto, Toronto, ON, Canada, <sup>5</sup>Mecklinger Family and Posluns Family <sup>[1]</sup>Cardiac Catheterization Research Laboratory, University of Toronto, Mount Sinai Hospital, Toronto, ON, Canada, <sup>6</sup>Department of Pathology and Laboratory Medicine, University Health Network, Toronto, ON, Canada, <sup>7</sup>Centre for Prognosis Studies in the Rheumatic Diseases, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Antimalarials (AM) are currently recommended for the management of all patients with systemic lupus erythematosus (SLE) without specific contra-indications. Their main adverse effect is retinal damage, however heart disease has been described in isolated cases. The aim of this study is to describe a series of patients with AM-induced cardiomyopathy (AMIC) in a defined lupus cohort.

**Methods:** Patients attending the Lupus Clinic and diagnosed with definite [based on endomyocardial biopsy (EMB)] and possible [based on cardiac magnetic resonance (CMR) and other investigations] AMIC were included.

**Results:** Eight female patients (age 62.5 years, disease duration 35 years, AM use duration 22 years, all medians) were diagnosed with AMIC in the past two years during evaluation for cardiovascular disease. Diagnosis was based on EMB in three, showing extensive vacuolation of the cardiomyocytes and intracytoplasmic myelinoid and curvilinear bodies. CMR was highly suggestive of AMIC in another four patients with features including ventricular hypertrophy and/or atrial enlargement and late gadolinium enhancement in a non-vascular pattern. Another patient was diagnosed based on complete atrioventricular block, left ventricular and septal hypertrophy along with AM-related ocular toxicity. Clinical presentation was that of congestive heart failure in two patients and syncope in one; investigations in the remaining patients were initiated based on abnormal cardiac troponin I (cTnI) and brain natriuretic peptide (BNP). All patients had abnormal cTnI and BNP whereas 7/8 also had chronically elevated creatine phosphokinase (CPK). Right bundle branch block (RBBB) was present in 4 patients, while two of them also had left anterior fascicular block (LAFB). Apart from atrial and/or ventricular hypertrophy, all patients had interventricular septum (IVS) hypertrophy and moderate diastolic dysfunction. During follow-up, one patient died due to refractory heart failure; she was complicated with septic shock during ICU hospitalization. In 5/7 patients, hypertrophy regression and a steady decrease of heart biomarkers was observed. Coronary angiography was performed in 6/8 patients and was normal. Daily hydroxychloroquine dose exceeded 6.5mg/kg in three patients. Details are shown in Table 1.

**Conclusion:** AMIC is a rare, probably under-recognized, complication of prolonged AM treatment. It usually presents as a hypertrophic, restrictive cardiomyopathy particularly affecting IVS with or without conduction abnormalities. Heart-specific biomarkers and serum CPK may be of value for early diagnosis.

Table 1. Demographics, AM duration, ECG, heart imaging, biomarkers and outcome of AMIC patients							
	Age	SLE/AM duration (y)/AM type	ECG	TTE	CMR	Biomarkers	Outcome
1	74	44/13/HCQ	RBBB, LAFB	LVH, RVH, LA, RA, IVSH, low LVEF, DD	LVH, RVH, LA, RA, IVSH	BNP, cTnI, CPK	Regression of hypertrophy, steady decrease of biomarkers over 2 years, conduction abnormalities deteriorated with 1 <sup>st</sup> degree AVB and atrial fibrillation
2	68	22/22/CQ	RBBB, LAFB	LVH, RVH, LA, RA, IVSH, DD	LVH, RVH, LA, RA, IVSH, LGE	BNP, cTnI, CPK	Regression of hypertrophy, steady decrease of biomarkers over 2 years, conduction abnormalities
3	65	53/45/HCQ	Normal	LVH, IVSH	LVH, LA, IVSH, LGE	BNP, cTnI, CPK	No significant regression of hypertrophy after 6 months, no decrease of heart biomarkers
4	59	38/19/HCQ	Normal	LVH, IVSH, LA, RA	LVH, IVSH	BNP, cTnI	Regression of hypertrophy after 6 months, decrease of heart biomarkers

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** A QI set for systemic lupus erythematosus (SLE) was developed in the United States. However, this does not necessarily conform to the Japanese medical condition. Instead, they could be a burden to the estimators because they need to look up the medical chart records. The aim of this study was to develop a QI set systematically for Japanese SLE patients that we can evaluate easily using electronic health data.

**Methods:** We used a validated process that combined available scientific evidence and expert consensus to develop a QI set for SLE. First, we performed a literature review to retrieve all clinical practice guidelines (CPGs) and QI development studies that are relevant to SLE by using the Ovid MEDLINE and Elsevier EMBASE databases. The CPGs were defined as follows: ① organizing the panel committee, ② implementation of the literature review, and ③ implementation of the grading quality of evidence and strength of recommendations. Second, we extracted the candidate QI items that can be evaluated by using electronic health data (administrative and laboratory data) from the final selected literature. Third, we used a modification of the RAND/UCLA Appropriateness Method. An interdisciplinary expert panel that comprised seven rheumatologists, one primary care physician, one dermatologist, and one obstetrician convened to discuss the evidence and provide final ratings on the appropriateness. Before the face-to-face meeting, we shared via e-mail the rating sheet and documents that summarized the scientific evidence to panelists and asked them to rate the appropriateness of each QI (the first round of rating). At the face-to-face meeting, each panelist received an anonymous summary of the rankings by the other members of the group. The discussion was aimed at determining whether different ratings resulted from real clinical disagreement. After several

minor revisions, the panelists re-rated the appropriateness of each item by using the same scale (the second round of rating).

**Results:** We found 3621 articles through the initial search. After the title and abstract screening, 224 articles were further analyzed. Finally, four literatures on CPGs and 30 studies on QI development were identified. Seventeen potential indicators were extracted as candidate QI items from these literatures. Ten expert panel members evaluated the 17 potential indicators in the first round of rating and face-to-face meeting among the panelists and then excluded three indicators. At the second round of rating, the panelists re-rated the appropriateness of the 14 items and removed two items. Accordingly, we selected the remaining 12 indicators as the final QI set. The median appropriateness of these 12 indicators was at least 7.5, and the percentage of agreement of all the items exceeded 80%. The areas covered included assessment of disease activity, treatment, and drug toxicity monitoring. All the indicators can be measured by using existing electronic health data alone, without medical record review, and all are process indicators.

**Conclusion:** We identified 12 QIs for assessment of SLE patients based on administrative data. This study may contribute to the spread of QIs in the area of rheumatology in Japan.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is a systemic inflammatory disease which has an increased risk for comorbid osteoporosis, related to the disease and long term corticosteroid therapy. Bone turnover markers (BTMs) reflect the process of bone formation and resorption; imbalances in this process are associated with

bone loss and osteoporosis. Changes in BTMs have been observed in SLE patients with conflicting results. This study examined the association between BTMs and their relationship to disease activity.

**Methods:** SLE patients were identified from a university research registry and biorepository of patients with rheumatic disease. Demographics, disease activity, medication use and laboratory data were collected. Serum was assayed for C-terminal telopeptide of type 1 collagen (CTX), a bone resorption marker, and osteocalcin (OC), a bone formation marker. Serum CTX index, expressed as a ratio of measured CTX value to upper limit of normal value for age and gender, was used for analysis. The patients were stratified by SLE disease activity index (SLEDAI): a score of <3 (low disease activity) and ≥3 (higher disease activity). We analyzed correlations between BTMs and variables that have known associations.

**Results:** Serum levels of BTMs were measured in 42 subjects of which 88% were white females with a median age of 36 years, and 19% had lupus nephritis or chronic kidney disease. Most were on ongoing corticosteroid treatment (68%) and 47% were on vitamin D supplementation. Only 36% had a serum vitamin D level >30 ng/mL and 32% were insufficient (20-30 ng/mL) and 32% were deficient (<20 ng/mL). The median OC value was 13.5 ng/mL (normal 9-42), and the median CTX index was 0.54. Subjects with a higher SLEDAI score had lower median OC level compared to those with low SLEDAI score (median [IQR] of 11 [10, 16] vs. 18 [13, 22],  $p=0.02$ ). There were no significant differences in CTX between these two groups. There was a positive correlation between the CTX index and OC ( $r = 0.537$ ,  $p<0.01$ ).

**Conclusion:** SLE patients with higher disease activity had lower OC levels than in those with low disease activity, suggesting that inflammation may suppress bone formation. There was no difference in CTX index between patients with higher and low disease activity. Bone formation and resorption markers were positively correlated in our SLE cohort, suggesting a coupled bone turnover state. The next step is to determine if corticosteroid dosage plays a role in the decreased bone formation observed in this cohort.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Depression is more common in patients with systemic lupus erythematosus (SLE) than in the general population. However, few studies have investigated predictors of depression in SLE patients and those studies have shown inconsistent results. This study evaluated the prevalence of, and risk factors for, depression in ethnically homogeneous Korean SLE patients.

**Methods:** In this study, 505 consecutive SLE patients were enrolled from KORNET registry. Demographic variables, SLE manifestations, laboratory findings, PGA, SLEDAI-2000, and SLICC damage index were recorded at enrollment. Based on the previous study, SLE Patients were identified as having depressive symptoms using the Beck Depression Inventory (BDI)  $\geq 16$ , and we categorized the SLE patients, according to the BDI total score, into four groups: Group I (BDI 0–9), Group II (BDI 10–15), Group III (BDI 16–23) and Group IV (BDI 24–63). Multivariate logistic regression analyses were performed to identify independent risk factors for depression in SLE patients.

**Results:** Of the 505 patients, SLE patients were categorized as follows: Group I (n = 320), Group II (n = 88), Group III (n = 65), and Group IV (n = 32). In our cohort, total 97 (19.2%) patients were diagnosed as having depression (Group III and Group IV). The SLE patients with higher BDI score were older, and had higher proportions of current smokers and SLICC score  $>1$ , and on the other hands, lower levels of income and education. In the serologic findings, patients with higher BDI score had lower anti-dsDNA positivity and conversely higher aCL positivity. In the multivariate analysis, the following variables were remained as significant predictors of depression in SLE patients: current smokers, lower education and income levels, aCL positivity, and SLICC score  $>1$ .

**Conclusion:** Our results found that depression was prevalent in patients with SLE and multifactorial factors were associated with depression in SLE. Our study helps to guide target programs for those at high risk for depression in SLE.

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:**

To study the effect of the metabolic syndrome (MetS) on organ damage, renal function and mortality in patients with SLE.

## Methods:

Consecutive patients who fulfilled  $\geq 4$  ACR criteria for SLE and were assessed for the presence of MetS between 2010 and 2011 were included. The MetS was defined by the updated joint consensus criteria, using the Asian criteria for central obesity, when  $\geq 3$  of the following were present: (1) Increased waist circumference to  $\geq 90$ cm in men or 80cm in women; (2) Elevated blood pressure to  $\geq 130/85$ mmHg or requiring drug therapy; (3) Elevated serum triglyceride level to  $\geq 1.7$ mmol/L; (4) Reduced serum HDL-cholesterol to  $\leq 1.0$ mmol/L in men and  $\leq 1.3$ mmol/L in women; and (5) Elevated fasting glucose level to  $\geq 5.6$ mmol/L. Longitudinal data regarding change in renal function (4-variable eGFR), new organ damage, vascular events and mortality were retrieved from our cohort database. The association of the MetS with new organ damage and mortality was studied by logistic regression.

## Results:

577 SLE patients were studied (93% women; age  $41.2 \pm 13.4$  years; SLE duration  $9.3 \pm 7.2$  years). All were ethnic Chinese and the mean follow-up was  $66.3 \pm 1.8$  months. The mean body mass index of the patients was  $22.3 \pm 3.9$ kg/m<sup>2</sup> (11%  $> 27$ kg/m<sup>2</sup>). A total of 85 (14.7%) patients qualified the MetS (28% fulfilling waist; 20% fulfilling blood pressure; 25% fulfilling triglyceride; 33% fulfilling HDL and 9.2% fulfilling glucose criteria). New organ damage and vascular (coronary, cerebrovascular and peripheral vascular) events developed in 128 (22%) and 23 (4.0%) patients, respectively. The commonest new arterial events were stroke (50%), acute coronary syndrome (33%) and peripheral vascular disease (17%). Thirty-nine (6.8%) patients died (infection 36%; vascular causes 18%; cancer 15%; lung fibrosis 8%; suicide 3%). Patients with the MetS (N=85), when compared to those without (N=492), had significantly higher SDI accrual at last visits ( $0.70 \pm 1.0$  vs  $0.26 \pm 0.6$ ;  $p < 0.001$ ). Regarding individual systems, the increase in SDI scores in the ocular, renal, cardiovascular, musculoskeletal and endocrine (new diabetes mellitus) systems were significantly higher in the MetS group of patients. Patients with the MetS had a significantly greater decline in eGFR over time ( $-18.2 \pm 27\%$  vs  $-7.80 \pm 19\%$ ;  $p = 0.002$ ). New vascular events (11% vs 2.8%;  $p = 0.001$ ), all-cause mortality (14% vs 5.5%;  $p = 0.003$ ), vascular mortality (7.1% vs 0.2%;  $p < 0.001$ ) were significantly more common in patients with MetS. Logistic regression revealed that the MetS was significantly associated with new damage in the ocular (OR 2.77[1.05-7.34];  $p = 0.04$ , renal (OR 4.72[1.86-12.0];  $p = 0.001$ ), cardiovascular (OR 3.66[1.03-12.9];  $p = 0.04$ ) and endocrine system (OR 41.9[4.93-357];  $p = 0.001$ ), adjusted for age, sex, SLE duration and the antiphospholipid antibodies. The MetS increased the risk of new vascular events (OR 2.94[1.18-7.31];  $p = 0.02$ ), all-cause mortality (OR 1.60[0.73-3.47];  $p = 0.24$ ) and vascular mortality (OR 30.3[3.42-268];  $p = 0.002$ ) after adjustment for the same covariates.

## Conclusion:

In this 5-year longitudinal study, the MetS is significantly associated with new organ damage, more renal function decline, vascular events and mortality in patients with SLE.

## Arthritis and Hydroxychloroquine Are Associated with Decreased Risk of Macrophage Activation Syndrome Among Adults Hospitalized with SLE

**Kristin D'Silva**<sup>1</sup>, Ezra Cohen<sup>2</sup>, David J. Kreps<sup>3</sup>, Mary Beth Son<sup>2</sup> and Karen H. Costenbader<sup>3</sup>, <sup>1</sup>Internal Medicine, Brigham and Women's Hospital, Boston, MA, <sup>2</sup>Boston Children's Hospital, Boston, MA, <sup>3</sup>Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

**First publication:** September 18, 2017

## **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

## **Background/Purpose:**

Macrophage activation syndrome (MAS) is an uncommon but potentially fatal complication of SLE. We conducted a case-control study comparing hospitalized adults with SLE with and without MAS to better understand risk factors associated with development of MAS.

## **Methods:**

Within our large academic hospital lupus registry (n= 2094 SLE patients with  $\geq 4$  ACR criteria, 1970-2016), we identified patients  $\geq$  age 18 with a hospital admission. We identified SLE patients with MAS among them by screening for a ferritin  $> 5,000$  ng/ml during a hospital admission, excluding patients with end stage renal disease, iron overload and cirrhosis, and confirming MAS diagnosis by medical record review. For each case, we chose 4 hospitalized SLE patients without MAS, matched on dates of SLE diagnosis ( $\pm 1$  year) and hospital admission ( $\pm 1$  year). We collected demographic and clinical factors from the medical records. We employed conditional logistic regression models to identify factors associated with MAS.

## **Results:**

We identified 21 SLE patients hospitalized with MAS and matched them to 84 adults hospitalized with SLE but without MAS. The most common causes of admission among SLE controls were lupus flare (48%; 30% with nephritis) and infection (30%). Cases and controls had similar age at SLE diagnosis (29 vs. 30 years), proportion of females (76 vs. 85%), median area-level income (\$52,122 vs. \$64,178), racial distribution, and length of time between SLE diagnosis and hospitalization (2,010 vs. 1,849 days) (all p-values  $>0.05$ ). Among cases, mean SLE Disease Activity Index (SLEDAI) scores at admission (31 vs. 21,  $p=0.002$ ) and length of stay (17 vs. 3 days,  $p<0.0001$ ) were higher than among controls. Mortality was 19% among cases and 1% among controls ( $p=0.01$ ). In multivariable models, the presence of prior arthritis (OR 0.09, 95%CI 0.01-0.62) and hydroxychloroquine use on admission (OR 0.21, 95%CI 0.05-0.94) were associated with decreased MAS risk, while higher SLEDAI scores were associated with increased MAS risk (OR 1.11, 95% CI 1.03-1.19) (**Table**). There were no differences in other ACR criteria or medication use at time of admission.

## **Conclusion:**

The finding that hydroxychloroquine was associated with a reduced risk of MAS among hospitalized SLE patients is novel. Hydroxychloroquine is a SLE-stabilizing medication associated with reducing SLE flares and organ complications. In addition, the presence of arthritis may signify a distinct SLE phenotype with a decreased risk of hematologic manifestations, or reflect that patients with arthritis are more likely to receive hydroxychloroquine. Although the comparison group in this study was seriously ill SLE patients admitted to the hospital with mean SLEDAI score of 21, the association of highly elevated SLEDAI on admission with increased MAS risk is important for clinicians, as SLE patients with extremely active disease may be at highest MAS risk.

## Shrinking Lung Syndrome in Systemic Lupus Erythematosus Patients: A Diagnosis We Should Suspect More Often

**Didem Saygin**<sup>1</sup>, Chris Lau<sup>2</sup>, Marco Lopez-Velazquez<sup>3</sup> and Kristin B. Highland<sup>4</sup>, <sup>1</sup>Internal Medicine, Department of Internal Medicine, Cleveland Clinic, Cleveland, OH, <sup>2</sup>Pulmonary and Critical Care, Cleveland Clinic, Cleveland, OH, <sup>3</sup>Internal Medicine, Cleveland Clinic, Cleveland, OH, <sup>4</sup>Rheumatology.org, Cleveland Clinic, Cleveland, OH

**First publication:** September 18, 2017

### SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** Shrinking lung syndrome (SLS) is a rare pulmonary manifestation of systemic lupus erythematosus (SLE) characterized by dyspnea, pleuritic chest pain, restriction on pulmonary function test (PFT), and signs of diaphragm dysfunction without evidence of significant pleuroparenchymal disease. We believe that lack of diagnostic criteria leads to misdiagnosis of SLS. Diagnosis of SLS requires careful evaluation of respiratory mechanics which includes spirometry, lung volumes, diffusion capacity, change in FEV1 (forced expiratory volume in one second) from sitting to supine, and consideration for specific diaphragm testing such as Sniff test, ultrasonography or electromyography (EMG). Careful consideration for mimickers of SLS such as obesity, pleural and central nervous system diseases should be considered since each has different management strategies. We report clinical, imaging and PFT characteristics of SLS in order to better understand the physiology seen in SLS and to increase awareness on this unsuspected entity.

**Methods:** We performed an electronic search of patients seen at the Cleveland Clinic between January 2005 – February 2017 with ICD-10 codes for SLE, restrictive lung disease, diaphragm dysfunction, or pleurisy. Clinical data were retrieved from the electronic medical records.

**Results:** Our search revealed 462 patients with SLE who had PFT results and a diagnostic code for restrictive lung disease, diaphragm dysfunction, or pleurisy. 38 of them were initially suspected to have SLS based on the opinion of their treating physician. Yet, only 27 patients had lung volumes (71%), and 20 had sitting/supine spirometry (53%). 35 had a chest X ray and/or computed tomography (92%). Sniff testing was performed in 7 cases, and showed abnormality in 70% of cases. EMG was done in 11 cases, and showed paresis/paralysis in 50% of cases. None had ultrasound of the diaphragm.

Ultimately, 8 out of 38 patients had a SLS diagnosis (Table). 30 patients had an alternative diagnosis including obesity (n=9), pleurisy (n=7), interstitial lung disease (n=4), severe pleural disease (n=4), asthma (n=2), emphysema (n=1), pneumonia (n=1) and rib fracture (n=1). 18 patients had a BMI >30 (47%), 5 had BMI >40 (13%). When present, lung volumes were useful to differentiate a restrictive pattern between diaphragm dysfunction and obesity related restriction. Diaphragmatic eventration and bibasilar infiltrates were the most common radiographic findings in SLS patients.

**Conclusion:** Our study showed that the majority of patients suspected with SLS had an alternative diagnosis. Almost one third of patients with suspected SLS did not have lung volumes or diaphragmatic function analysis done and almost half-of these patients did not have sitting/supine spirometry performed. SLS is a diagnosis of exclusion and a comprehensive evaluation to exclude other reasons for a restrictive ventilatory defect is essential.

## SESSION INFORMATION

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Session Type:** ACR Poster Session B

**Session Time:** 9:00AM-11:00AM

**Background/Purpose:** To develop GRADE-based recommendations for the diagnosis and monitoring of systemic lupus erythematosus patients in Canada.

**Methods:** Recommendations were developed using the GRADE (Grading of Recommendations, Assessment, Development and Evaluation) approach. The Canadian SLE Working Group (panel of Canadian rheumatologists and patient representative from CAPA (Canadian Arthritis Patient Alliance)) was created. Questions for recommendation development were identified based on a survey of SLE practice patterns of Canadian Rheumatology Association members. Systematic literature reviews of randomized controlled trials and observational studies were conducted. Evidence to Recommendation Tables were prepared and presented to the panel at two face-to-face meetings for discussion and voting during and post-meeting online.

**Results:** There are fourteen recommendations for diagnosing and monitoring lupus patients (Table 1). Three recommendations focused on diagnosis, disease activity and damage assessment and suggested a validated disease activity score per visit and annual damage score. One strong recommendation was made for cardiovascular risk assessment and conditional recommendations for osteoporosis (2) and osteonecrosis (1). Three conditional recommendations were made for peripartum assessments, one on cervical cancer screening, and two on hepatitis B and C screening. A strong recommendation was made for annual influenza vaccination.

**Conclusion:** These are the first GRADE-based recommendations for the diagnosis and monitoring of SLE internationally. Evidence is moderate to low quality resulting in more conditional versus strong recommendations. Additional studies and special attention to pediatric lupus populations and patient preferences are needed.

**Table 1. Summary of Recommendations With Strength of Evidence for the Diagnosis and Monitoring of SLE in Canada**

<b>Recommendation</b>	<b>Strength of Recommendation</b>	<b>Quality of Evidence</b>
1. We recommend that all adult and pediatric patients suspected of SLE be referred to a lupus specialist, most often a rheumatologist, to confirm diagnosis and be involved in ongoing care	Strong	Moderate
2. For adult and pediatric patients with SLE, we suggest assessing disease activity with a validated instrument of disease activity during baseline and follow up visits.	Conditional	Low
3. For adult and pediatric patients with SLE, we suggest assessing disease damage annually with a validated measure.	Conditional	Low
4. For adult lupus patients, we recommend that indicators of obesity, smoking status, diabetes, blood pressure and a basic lipid profile be measured upon diagnosis of SLE and be reassessed periodically according to current recommendations in the general population and be used to inform the cardiovascular risk assessment.	Strong	Moderate
5. For adult patients with SLE, we suggest assessing the risk of osteoporosis and fractures every 1 to 3 years using a detailed history and focused physical examination, and measuring bone mineral density in patients with other risk factors according to recommendations in the general population.	Conditional	Low
6. For all adults with SLE, we suggest screening 25-hydroxyvitamin D as part of the assessment for risk of osteoporosis and fractures	Conditional	Low
7. For adult patients with SLE who do not have	Conditional	Low

clinical symptoms suggestive of osteonecrosis, we suggest not screening for or performing investigations for osteonecrosis. For patients who have suspected clinical symptoms of osteonecrosis, we suggest radiographs as the initial imaging modality rather than MRI or bone scan with SPECT according to recommendations in the general population.		
8. For women with SLE, we suggest that anti-Ro and anti-La antibodies be measured immediately prior to pregnancy or during the first trimester.	Conditional	Low
9. For pregnant women with SLE, we suggest that uterine and umbilical Doppler studies be performed in the second or third trimester, or at the time of a suspected flare.	Conditional	Low
10. For women with prior or active lupus nephritis who are pregnant, we suggest measuring serum creatinine and urine protein to creatinine ratio every 4-6 weeks, or more frequently if clinically indicated. We suggest blood pressure and urinalysis be measured prior to pregnancy and every 4-6 weeks until 28 weeks, every 1-2 weeks until 36 weeks and then weekly until delivery.	Conditional	Low
11. All female adult patients with SLE who are or have been sexually active, regardless of sexual orientation, we suggest annual cervical cancer screening rather than screening every 3 years at least up to the age of 69.	Conditional	Low
12. We recommend that adults and children with SLE receive an annual	Strong	Moderate

inactivated influenza vaccination in a single dose.		
13/14. For adults and pediatric patients with a diagnosis of SLE and high-risk behaviours for HBV and/or HCV acquisition, we recommend screening for Hepatitis B surface antigen and/or Hepatitis C and repeating according to recommendations for the general population. For patients being considered for immunomodulatory therapy, we suggest screening for HBV before starting treatment	Conditional	Low

### **SESSION INFORMATION**

**Session Date:** Monday, November 6, 2017

**Session Title:** Systemic Lupus Erythematosus – Clinical Aspects and Treatment Poster II: Damage and Comorbidities

**Background/Purpose:** Systemic lupus erythematosus (SLE) is heterogeneous in its clinical prognosis and lupus nephritis (LN) is a major cause of morbidity and mortality among children and adults with SLE. LN patients typically receive higher doses of corticosteroids (CS) than do non-renal SLE patients. The excess burden of disease and treatment on hospitalization and in-hospital death associated with SLE and LN remains incompletely understood. This study characterized rates of hospitalizations, CS-related reasons for hospitalization, and in-hospital mortality of SLE and LN pts compared to: 1) each other; 2) matched controls.

**Methods:** Retrospective cohort study using the Truven Healthcare MarketScan® Commercial Claims and Encounters and Medicare Supplemental and Coordination of Benefits database from 1999 to 2014. LN and SLE cohorts were based on validated algorithms using claims data.<sup>1,2</sup> Controls with claims for non-autoimmune conditions were matched on age and gender at index date. All pts had  $\geq 365$  days of enrollment  $\pm$  index date. End of study was the first of end of enrollment or database, or date of death. Potentially CS-related reasons for hospitalization were evaluated on a claims-based modification of adverse events (AEs) on a CS toxicity index.<sup>3</sup>

**Results:** 54,813 SLE pts w/o renal involvement and 8,839 LN pts were identified. LN adults had the longest hospitalizations (Table 1); Incidence rate ratios (IRRs) confirm statistically significantly higher rates of hospitalization and in-hospital mortality for LN compared to SLE and for both disease groups compared to controls (Figure 1). LN was associated with increased incidence of several potentially CS-related AEs (e.g. diabetes, aseptic necrosis of bone, depression) as the primary reason for hospitalization compared with the non-renal SLE group (Table 2).

**Conclusion:** The medical need for safe and effective treatments of LN and SLE remains unmet. The retrospective, claims-based results do not permit pt-level assessment of the relative contributions of disease severity, treatment, and other potential confounders of these findings. Ongoing analyses are examining the role of steroid exposure on CS-related hospitalizations.
